SPOLY

---------------------------------- OLE Automation Sample Program: SPoly ----------------------------------

SPoly is a program which draws polygons. The only way to make spoly draw a polygon is to use its programmability interface.

One OLE Automation object is exposed by Spoly:

* spoly.application

Spoly.Application is the object associated with spoly's main window. It controls drawing polygons and clearing the display.

---------------- Program Structure ---------------- SPoly implements IDispatch by hand for spoly.application.

---------------------------------- Methods defined on spoly.application ----------------------------------

Name Description --- Draw() Draw the polygon.

Reset() Delete all points from the polygon.

AddPoint(X, Y) Add a point with coordinates (x,y) to the polygon

EnumPoints() as VT_ENUM Return a collection of the polygon's points

GetXOrigin() as short Get the X origin of the polygon. SetXOrigin(x as short) Set the X origin of the polygon. GetYOrigin() as short Get the Y origin of the polygon. SetYOrigin(y as short) Set the Y origin of the polygon. GetWidth() as short Get and the line width of the polygon.

SetWidth(width as short) Set the line width of the polygon.

-------------------------- Shortcomings of this sample -------------------------- 1. Many items in this sample should be properties. Instead, they are implemented as methods. Anything which behaves like an attribute of the object should be a property.

2. This is not a good example of how to implement a collection.

MAKEFILE   (SPOLY Sample)

```

*HRESULT CPoly::Invoke(...)
*Purpose:
*  Dispatch a method or property request for objects of type CPoly.
*
*  see the IDispatch document for more information, and a general
*  description of this method.
*
*Entry:
*  dispidMember = the DISPID of the member being requested
*
*  riid = reference to the interface ID of the interface on this object
*    that the requested member belongs to. IID_NULL means to interpret
*    the member as belonging to the implementation defined "default"
*    or "primary" interface.
*
```

```
*  lcid = the caller's locale ID
*
*  wFlags = flags indicating the type of access being requested
*
*  pdispparams = pointer to the DISPPARAMS struct containing the
*    requested members arguments (if any) and its named parameter
*    DISPIDs (if any).
*
*Exit:
*  return value = HRESULT
*   see the IDispatch spec for a description of possible success codes.
*
*  pvarResult = pointer to a caller allocated VARIANT containing
*    the members return value (if any).
*
*  pexcepinfo = caller allocated exception info structure, this will
*    be filled in only if an exception was raised that must be passed
*    up through Invoke to an enclosing handler.
*
*  puArgErr = pointer to a caller allocated UINT, that will contain the
*    index of the offending argument if a DISP_E_TYPEMISMATCH error
*    was returned indicating that one of the arguments was of an
*    incorrect type and/or could not be reasonably coerced to a proper
*    type.

SPOLY2

----------------------------------- OLE Automation Sample Program: SPoly2 -----------------------------------

SPoly2 is a program which draws polygons. The only way to make spoly2 draw a polygon is to use its programmability interface.

One OLE Automation object is exposed by spoly2:

- spoly2.application

Spoly2.Application is the object associated with spoly2's main window. It controls drawing polygons and clearing the display.

---------------- Program Structure ---------------- SPoly2 implements IDispatch by using INTERFACEDATA, DispGetIDsOfNames and DispInvoke.

----------------------------------- Methods defined on spoly2.application -----------------------------------

Name Description --- Draw() Draw the polygon.

Reset() Delete all points from the polygon.

AddPoint(X, Y) Add a point with coordinates (x,y) to the polygon

EnumPoints() as VT_ENUM Return a collection of the polygon's points

GetXOrigin() as short Get the X origin of the polygon. SetXOrigin(x as short) Set the X origin of the polygon. GetYOrigin() as short Get the Y origin of the polygon. SetYOrigin(y as short) Set the Y origin of the polygon. GetWidth() as short Get and the line width of the polygon.

SetWidth(width as short) Set the line width of the polygon.

-------------------------- Shortcomings of this sample -------------------------- 1. Many items in this sample should be properties. Instead, they are implemented as methods. Anything which behaves like an attribute of the object should be a property.

2. This is not a good example of how to implement a collection.

MAKEFILE   (SPOLY2 Sample)

```

TIBROWSE

-------------------------------------- OLE Automation Sample Program: TiBrowse --------------------------------------

Tibrowse is a sample OLE Automation browser. When started, it asks the user to selected a type library (.tlb) file. The browser then displays the contents of this file.

-------------------------- Shortcomings of this sample -------------------------- 1. This browser is not suitable for use by end users. It is deficient in many ways. A few of them: - Users should never have to know that uuid's exist. Thus,
they should not be displayed in a browser. - Items that are restricted or that start with underscore should not be displayed in a browser. - Duplicates for propery get/set pairs should be removed since users think about properties, not about get/set pairs.

MAKEFILE (TIBROWSE Sample)

```
####
#makefile - makefile for tibrowse.exe
#
#       Copyright (C) 1992, Microsoft Corporation
#
#Purpose:
#  Builds the OLE 2.0 sample IDispatch server, tibrowse.exe.
#
#
#  Usage: NMAKE                  ; build with defaults
#     or: NMAKE option           ; build with the given option(s)
#     or: NMAKE clean            ; erase all compiled files
#
#     option:
#         dev = [win16 | win32] ; dev=win32 is the default
#         DEBUG=[0|1]           ; DEBUG=1 is the default
#
#Notes:
#  This makefile assumes that the PATH, INCLUDE and LIB environment
#  variables are setup properly.
#

--

#include <windows.h>
#include "cdialog.h"

//
+---------------------------------------------------------------------------
//
//  Member:     CHlprDialog::ShowDialog
//
//  Synopsis:   Creates the dialog so that it's DialogProc member function
can
//              be invoked.
//
//  Arguments:  [hinst]        - handle of the application instance
//              [lpszTemplate] - identifies the dialog box template
//              [hwndOwner]    - handle of the owner window
//
//  Returns:    return value from the dialog box
//
//  History:    4-12-94   stevebl   Created
//
//  Notes:      The dialog box object exists until deleted by the caller.
//              It can be shown any number of times.
//
//              This function is analgous to Windows' DialogBox function.
The
//              main difference being that you don't specify a DialogProc;
//              you override the pure virtal function
CHlprDialog::DialogProc.
//
//--------------------------------------------------------------------------
--
```

```
int CHlprDialog::ShowDialog(HINSTANCE hinst, LPCTSTR lpszTemplate, HWND
hwndOwner)
{
    _hInstance = hinst;
    return(DialogBoxParam(hinst, lpszTemplate, hwndOwner,
(DLGPROC)::DialogProc, (long)this));
}

//
+---------------------------------------------------------------------------
//
//  Function:   DialogProc
//
//  Synopsis:   Common DialogProc used by all CHlprDialog class objects.
//
//  Arguments:  [hwndDlg] - handle of dialog box
//              [uMsg]    - message
//              [wParam]  - first message parameter
//              [lParam]  - second message parameter
//
//  Returns:    response from the CHlprDialog::DialogProc method
//
//  History:    4-12-94   stevebl   Created
//
//  Notes:      This procedure is the DialogProc registered for all dialogs
//              created with the CHlprDialog class.  It uses the parameter
//              passed with the WM_INITDIALOG message to identify the dialog
//              classes' "this" pointer which it then stores in the window
//              structure's GWL_USERDATA field.  All subsequent messages
//              can then be forwarded on to the correct dialog class's
//              DialogProc method by using the pointer stored in the
//              GWL_USERDATA field.
//
//---------------------------------------------------------------------------
--

/*
 * FillClassList
 *
 * Purpose:
 *  Enumerates available OLE object classes from the registration
 *  database that we can convert or activate the specified clsid from.
 *
 *  Note that this function removes any prior contents of the listbox.
 *
 * Parameters:
 *  clsid           Class ID for class to find convert classes for
 *  hList           HWND to the listbox to fill.
 *  hListInvisible  HWND to invisible listbox that stores "activate as"
list.
 *  lpszCurrentClass LPSTR to put the (hr) class name of the clsid; we
 *                   do it here since we've already got the reg db open.
 *  fIsLinkedObject BOOL is the original object a linked object
 *  wFormat         WORD specifying the format of the original class.
 *  cClsidExclude   UINT number of entries in exclude list
 *  lpClsidExclude  LPCLSID array classes to exclude for list
 *
 * Return Value:
 *  UINT            Number of strings added to the listbox, -1 on failure.

DBALLOC.CPP   (WRAPUI Sample)

```
/***
*dballoc.cpp
*
*  Copyright (C) 1992-93, Microsoft Corporation.  All Rights Reserved.
*
*Purpose:
*  This file contains a debug implementation of the IMalloc interface.
*
*  This implementation is basically a simple wrapping of the C runtime,
*  with additional work to detect memory leakage, and memory overwrite.
*
*  Leakage is detected by tracking each allocation in an address
*  instance table, and then checking to see if the table is empty
*  when the last reference to the allocator is released.
*
*  Memory overwrite is detected by placing a signature at the end
*  of every allocated block, and checking to make sure the signature
*  is unchanged when the block is freed.
*
*  This implementation also has additional param validation code, as
*  well as additional check make sure that instances that are passed
*  to Free() were actually allocated by the corresponding instance
*  of the allocator.
*
*
*  Creating an instance of this debug allocator that uses the default
*  output interface would look like the following,
*
*
*  BOOL init_application_instance()
*  {
*    HRESULT hresult;
*    IMalloc FAR* pmalloc;
*
*    pmalloc = NULL;
*
*    if((hresult = OleStdCreateDbAlloc(0,&pmalloc))!=NOERROR)
*      goto LReturn;
*
*    hresult = OleInitialize(pmalloc);
*
*    // release pmalloc to let OLE hold the only ref to the it. later
*    // when OleUnitialize is called, memory leaks will be reported.
*    if(pmalloc != NULL)
*      pmalloc->Release();
*
*  LReturn:
*
*    return (hresult == NOERROR) ? TRUE : FALSE;
*  }
*
*
```

```
*  CONSIDER: could add an option to force error generation, something
*   like DBALLOC_ERRORGEN
*
*  CONSIDER: add support for heap-checking. say for example,
*   DBALLOC_HEAPCHECK would do a heapcheck every free? every 'n'
*   calls to free? ...
*
*
*Implementation Notes:
*
*  The method IMalloc::DidAlloc() is allowed to always return
*  "Dont Know" (-1).  This method is called by Ole, and they take
*  some appropriate action when they get this answer.
*

/*
 * OleUILockLibrary
 *
 *
 * Purpose:
 *   Increments & decrements a lock count to force this library to stay
 *   alive, all OLE 2.x DLL objects servers (ie. INPROC server DLL) which
 *   use the OLE2UI library in a DLL form must call this function passing
TRUE
 *   in their InitInstance() routine and balance with a call, passing FALSE
 *   in their ExitInstance(). This is done so as to keep DllCanUnloadNow()
 *   from returning NOERROR until the OLE 2.x DLL server goes away.
 *   While the INPROC server DLL is loaded, it wants to force the OLE2UI
 *   DLL to remain loaded (ie. force it to return S_FALSE from the OLE2UI's
 *   DllCanUnloadNow function). It is possible that the INROC server DLL
 *   gets unloaded from a call to CoFreeUnusedLibraries, but it is still
 *   necessary for the OLE2UI library to remain in use (eg. because an
 *   enumerator returned from OleStdEnumFmtEtc_Create still exists). only
 *   after all explicit "OleUILockLibrary" locks and instances of objects
 *   created have been release will the DllCanUnloadNow function for the
 *   OLE2UI library DLL return NOERROR.
 *
 *   If the INPROC server DLL links to the OLE2UI library as a static
 *   library, then this OleUILockLibrary function should NOT be used.
 *   instead the INPROC server DLL should call OleUICanUnloadNow API from
 *   within its own DllCanUnloadNow function. The idea here is, that if
there
 *   are any existing instance of objects created by the OLE2UI library
 *   functions (eg. EnumFORMATETC objects created by
OleStdEnumFmtEtc_Create)
 *   then, the INPROC server DLL must NOT let itself be unloaded.
 *
 *   An EXE based object using the OLE2UI libray need NOT use either the
 *   OleUILockLibrary or OleUICanUnloadNow functions. All objects created
 *   by the OLE2UI library will have LRPC proxies and stubs created to
 *   manage remoting method calls. the worst that can happen when the EXE
 *   exits is that any outstanding proxies for unreleased objects will get
 *   RPC_E_SERVERDIED errors; they will not GPFault.
 *
 * Return Value:
 *   HRESULT    NOERROR it is safe to go away, S_FALSE this code must stay
 *              loaded.

/*
 * OleStdIconLabelTextOut
 *
 * Purpose:
 *  Replacement for DrawText to be used in the "Display as Icon" metafile.
 *  Uses ExtTextOut to output a string center on (at most) two lines.
 *  Uses a very simple word wrap algorithm to split the lines.
 *
 * Parameters:  (same as for ExtTextOut, except for hFont)
 *  hDC           device context to draw into; if this is NULL, then we
don't
 *                ETO the text, we just return the index of the beginning
 *                of the second line
 *  hFont         font to use
 *  nXStart       x-coordinate of starting position
 *  nYStart       y-coordinate of starting position
 *  fuOptions     rectangle type
 *  lpRect        rect far * containing rectangle to draw text in.
 *  lpszString    string to draw
 *  cchString     length of string (truncated if over OLEUI_CCHLABELMAX)
 *  lpDX          spacing between character cells
 *
 * Return Value:
 *  UINT          Index of beginning of last line (0 if there's only one
 *                line of text).
 *
 */

/* SetHatchWindowSize
 *
 *
 *  Purpose:
 *      Move/size the HatchWindow correctly given the rect required by the
 *      in-place server object window and the lprcClipRect imposed by the
 *      in-place container. both rect's are expressed in the client coord.
 *      of the in-place container's window (which is the parent of the
 *      HatchWindow).
 *
 *      OLE2NOTE: the in-place server must honor the lprcClipRect specified
 *      by its in-place container. it must NOT draw outside of the ClipRect.
 *      in order to achieve this, the hatch window is sized to be
 *      exactly the size that should be visible (rcVisRect). the
 *      rcVisRect is defined as the intersection of the full size of
 *      the HatchRect window and the lprcClipRect.
 *      the ClipRect could infact clip the HatchRect on the
 *      right/bottom and/or on the top/left. if it is clipped on the
 *      right/bottom then it is sufficient to simply resize the hatch
 *      window. but if the HatchRect is clipped on the top/left then
 *      in-place server document window (child of HatchWindow) must be moved
 *      by the delta that was clipped. the window origin of the
 *      in-place server window will then have negative coordinates relative
 *      to its parent HatchWindow.
 *
 *  Parameters:
 *      hWndHatch       hatch window handle
 *      lprcIPObjRect   full size of in-place server object window
 *      lprcClipRect    clipping rect imposed by in-place container
 *      lpptOffset      offset required to position in-place server object
 *                      window properly. caller should call:
```

```
 *                          OffsetRect(&rcObjRect,lpptOffset->x,lpptOffset-
>y)
 *
 *  Return Value:
 *      none

 * OleUIInitialize
 *
 * NOTE: This function should only be called by your application IF it is
 * using the static-link version of this library.  If the DLL version is
 * being used, this function is automatically called from the OLE2UI DLL's
 * LibMain.
 *
 * Purpose:
 *   Initializes the OLE UI Library.
 *
 * Parameters:
```

```
 *
 *  hInstance       HINSTANCE of the module where the UI library resources
 *                  and Dialog Procedures are contained.  If you are calling
 *                  this function yourself, this should be the instance
handle
 *                  of your application.
 *
 *  hPrevInst       HINSTANCE of the previous application instance.
 *                  This is the parameter passed in to your WinMain.  For
 *                  the DLL version, this should always be set to zero (for
 *                  WIN16 DLLs).
 *
 * Return Value:
 *  BOOL            TRUE if initialization was successful.
 *                  FALSE if either the "Magic Number" did not verify, or
one of
 *                  the window classes could not be registered.  If the
 *                  "Magic Number" did not verify, then the resources
 *                  in your module are of a different version than the
 *                  ones you compiled with.

/*
 * OleUICanUnloadNow
 *
 * NOTE: if you statically link to this library and you implement
 *       DllCanUnloadNow, then you must call this routine in your
 *       implementation of DllCanUnloadNow to determine if you can be
 *       unloaded or not.
 *       this function should NOT be used if the OLE2UI library is used
 *       in DLL form.
 *
 * Purpose:
 *   Determines when it is safe to go away
 *   (ie. there are no existing object instances).
 *
 * Return Value:
 *   HRESULT    NOERROR it is safe to go away, S_FALSE this code must stay
 *              loaded.
 *
 * Comments:
 *
 *   If an INPROC server DLL links to the OLE2UI library as a static
 *   library, then the OleUILockLibrary function should NOT be used.
 *   instead the INPROC server DLL should call OleUICanUnloadNow API from
 *   within its own DllCanUnloadNow function. The idea here is, that if
there
 *   are any existing instance of objects created by the OLE2UI library
 *   functions (eg. EnumFORMATETC objects created by
OleStdEnumFmtEtc_Create)
 *   then, the INPROC server DLL must NOT let itself be unloaded.
 *
 *   An EXE based object using the OLE2UI libray need NOT use either the
 *   OleUILockLibrary or OleUICanUnloadNow functions. All objects created
 *   by the OLE2UI library will have LRPC proxies and stubs created to
 *   manage remoting method calls. the worst that can happen when the EXE
 *   exits is that any outstanding proxies for unreleased objects will get
 *   RPC_E_SERVERDIED errors; they will not GPFault.
 */

 * OleUIAddVerbMenu
 *
 * Purpose:
 *  Add the Verb menu for the specified object to the given menu.  If the
 *  object has one verb, we directly add the verb to the given menu.  If
 *  the object has multiple verbs we create a cascading sub-menu.
 *
 * Parameters:
 *  lpObj           LPOLEOBJECT pointing to the selected object.  If this
 *                  is NULL, then we create a default disabled menu item.
 *
 *  lpszShortType   LPSTR with short type name (AuxName==2) corresponding
 *                  to the lpOleObj. if the string is NOT known, then NULL
 *                  may be passed. if NULL is passed, then
 *                  IOleObject::GetUserType will be called to retrieve it.
 *                  if the caller has the string handy, then it is faster
 *                  to pass it in.
 *
 *  hMenu           HMENU in which to make modifications.
 *
 *  uPos            Position of the menu item
 *
 *  uIDVerbMin      UINT ID value at which to start the verbs.
 *                      verb_0 = wIDMVerbMin + verb_0
 *                      verb_1 = wIDMVerbMin + verb_1
 *                      verb_2 = wIDMVerbMin + verb_2
 *                      etc.
 *  uIDVerbMax      UINT maximum ID value allowed for object verbs.
 *                     if uIDVerbMax==0 then any ID value is allowed
 *
 *  bAddConvert     BOOL specifying whether or not to add a "Convert" item
 *                  to the bottom of the menu (with a separator).
 *
 *  idConvert       UINT ID value to use for the Convert menu item, if
 *                  bAddConvert is TRUE.
 *
 *  lphMenu         HMENU FAR * of the cascading verb menu if it's created.
 *                  If there is only one verb, this will be filled with
NULL.
 *
 *
 * Return Value:
 *  BOOL            TRUE if lpObj was valid and we added at least one verb
 *                  to the menu.  FALSE if lpObj was NULL and we created

/* OleStdGetDropEffect
** -------------------
**
** Convert a keyboard state into a DROPEFFECT.
**
** returns the DROPEFFECT value derived from the key state.
**    the following is the standard interpretation:
**          no modifier -- Default Drop     (NULL is returned)
**          CTRL        -- DROPEFFECT_COPY
**          SHIFT       -- DROPEFFECT_MOVE
**          CTRL-SHIFT  -- DROPEFFECT_LINK
**
**    Default Drop: this depends on the type of the target application.
**    this is re-interpretable by each target application. a typical
**    interpretation is if the drag is local to the same document
**    (which is source of the drag) then a MOVE operation is
**    performed. if the drag is not local, then a COPY operation is
**    performed.
*/

/* OleStdSetupAdvises
** ------------------
**    Setup the standard View advise required by a standard,
**    compound document-oriented container. Such a container relies on
**    Ole to manage the presentation of the Ole object. The container
**    call IViewObject::Draw to render (display) the object.
**
**    This helper routine performs the following tasks:
**                        setup View advise
**                        Call IOleObject::SetHostNames
**                        Call OleSetContainedObject
**
**    fCreate should be set to TRUE if the object is being created. if
**    an existing object is being loaded, then fCreate should be FALSE.
**    if it is a creation situation, then the ADVF_PRIMEFIRST flag is
**    used when settinp up the IViewObject::Advise. This will result in
**    the immediate sending of the initial picture.
**
**    OLE2NOTE: the standard container does NOT need to set up an OLE
**    Advise (IOleObject::Advise). this routine does NOT set up an OLE
**    Advise (a previous version of this function used to setup this
**    advise, but it was not useful).
*/

 * OleStdCreateStorageOnHGlobal()
 *
 * Purpose:
 *  Create a memory based IStorage*.
 *
 *  OLE2NOTE: if fDeleteOnRelease==TRUE, then the ILockBytes is created
 *            such that it will delete them memory on its last release.
 *            the IStorage on created on top of the ILockBytes in NOT
 *            created with STGM_DELETEONRELEASE. when the IStorage receives
 *             its last release, it will release the ILockBytes which will
 *             in turn free the memory. it is in fact an error to specify
 *             STGM_DELETEONRELEASE in this situation.
 *
 * Parameters:
 *  hGlobal --  handle to MEM_SHARE allocated memory. may be NULL and
 *               memory will be automatically allocated.
 *  fDeleteOnRelease -- controls if the memory is freed on the last release.
 *  grfMode --  flags passed to StgCreateDocfileOnILockBytes
 *
 *  NOTE: if hGlobal is NULL, then a new IStorage is created and
 *               STGM_CREATE flag is passed to StgCreateDocfileOnILockBytes.
 *        if hGlobal is non-NULL, then it is assumed that the hGlobal
already
 *               has an IStorage inside it and STGM_CONVERT flag is passed
 *               to StgCreateDocfileOnILockBytes.
 *
 * Return Value:
 *    SCODE  -  S_OK if successful

/*
 * XformSizeInPixelsToHimetric
 * XformSizeInHimetricToPixels
 *
 * Functions to convert a SIZEL structure (Size functions) or
 * an int (Width functions) between a device coordinate system and
 * logical HiMetric units.
 *
 * Parameters:
 *  hDC             HDC providing reference to the pixel mapping.  If
 *                  NULL, a screen DC is used.
 *
 *  Size Functions:
 *  lpSizeSrc       LPSIZEL providing the structure to convert.  This
 *                  contains pixels in XformSizeInPixelsToHimetric and
 *                  logical HiMetric units in the complement function.
 *  lpSizeDst       LPSIZEL providing the structure to receive converted
 *                  units.  This contains pixels in
 *                  XformSizeInPixelsToHimetric and logical HiMetric
 *                  units in the complement function.
 *
 *  Width Functions:
 *  iWidth          int containing the value to convert.
 *
 * Return Value:
 *  Size Functions:     None
 *  Width Functions:    Converted value of the input parameters.
 *
 * NOTE:
 *  When displaying on the screen, Window apps display everything enlarged
 *  from its actual size so that it is easier to read. For example, if an
 *  app wants to display a 1in. horizontal line, that when printed is
 *  actually a 1in. line on the printed page, then it will display the line
 *  on the screen physically larger than 1in. This is described as a line
 *  that is "logically" 1in. along the display width. Windows maintains as
 *  part of the device-specific information about a given display device:
 *      LOGPIXELSX -- no. of pixels per logical in along the display width
 *      LOGPIXELSY -- no. of pixels per logical in along the display height
 *
 *  The following formula converts a distance in pixels into its equivalent
 *  logical HIMETRIC units:
```

```
 *
 *      DistInHiMetric = (HIMETRIC_PER_INCH * DistInPix)
 *                       -------------------------------
 *                           PIXELS_PER_LOGICAL_IN
 *

SUMINFO.H (WRAPUI Sample)

```
/*************************************************************************
**
**    OLE 2.0 Property Set Utilities
**
**    suminfo.h
**
**    This file contains file contains data structure defintions,
**    function prototypes, constants, etc. for OLE 2.0 Property Set
**    utilities used to manage the Summary Info property set.
**
**    (c) Copyright Microsoft Corp. 1990 - 1992 All Rights Reserved
**
*************************************************************************/

#ifndef SUMINFO_H
#define SUMINFO_H

#include <ole2.h>
#include <objbase.h>
#include <oleauto.h>

/* A SUMINFO variable is an instance of an abstract data type.  Thus,
**    there can be an arbitrary number of SummaryInfo streams open
**    simultaneously (subject to available memory).  Each variable must
**    be initialized prior to use by calling Init and freed after its
**    last use by calling Free.  The param argument to Init is reserved
**    for future expansion and should be zero initially. Once a SUMINFO
**    variable is allocated (by Init), the user can call the Set
**    procedures to initialize fields.  A copy of the arguments is made
**    in every case except SetThumbnail where control of the storage
**    occupied by the METAFILEPICT is merely transferred.  When the
**    Free routine is called, all storage will be deallocated including
**    that of the thumbnail.  The arguments to SetThumbNail and the
**    return values from GetThumbNail correspond to the OLE2.0 spec.
**    Note that on input, the thumbnail is read on demand but all the
**    other properties are pre-loaded.  The thumbnail is manipulated as
**    a windows handle to a METAFILEPICT structure, which in turn
**    contains a handle to the METAFILE.  The transferClip argument on
**    GetThumbNail, when set to true, transfers responsibility for
**    storage management of the thumbnail to the caller; that is, after
**    Free has been called, the handle is still valid. Clear can be
**    used to free storage for all the properties but then you must
**    call Read to load them again.  All the code is based on FAR
**    pointers.
**    CoInitialize MUST be called PRIOR to calling OleStdInitSummaryInfo.
**    Memory is allocated using the currently active IMalloc*
**    allocator (as is returned by call CoGetMalloc(MEMCTX_TASK) ).
**
** Common scenarios:
**    Read SummaryInfo
**    ----------------
**      OleStdInitSummaryInfo()
**      OleStdReadSummaryInfo()
**      . . . . .
**      call different Get routines
**      . . . . .
**      OleStdFreeSummaryInfo()
**
**    Create SummaryInfo
**    ------------------
**      OleStdInitSummaryInfo()
**      call different Set routines
**      OleStdWriteSummaryInfo()
**      OleStdFreeSummaryInfo()
**
**    Update SummaryInfo
**    ------------------
**      OleStdInitSummaryInfo()
**      OleStdReadSummaryInfo()
**      OleStdGetThumbNailProperty(necessary only if no SetThumb)
**      call different Set routines
**      OleStdWriteSummaryInfo()
**      OleStdFreeSummaryInfo()
*/

// Note: this file is designed to be stand-alone; it includes a
// carefully chosen, minimal set of headers.
//
// For conditional compilation we use the ole2 conventions,
//    _MAC      = mac
//    WIN32     = Win32 (NT really)
//    <nothing> = defaults to Win16

// REVIEW: the following needs to modified to handle _MAC
#define STRICT
#include <windows.h>
#include <string.h>
#include <ole2.h>
#include "ole2ui.h"

/* A LPSUMINFO variable is a pointer to an instance of an abstract data
**    type.  There can be an arbitrary number of SummaryInfo streams open
**    simultaneously (subject to available memory); each must have its
**    own LPSUMINFO instance. Each LPSUMINFO instance must
**    be initialized prior to use by calling Init and freed after its
**    last use by calling Free.  The param argument to Init is reserved
**    for future expansion and should be zero initially. Once a LPSUMINFO
**    instance is allocated (by Init), the user can call the Set
**    procedures to initialize fields.  A copy of the arguments is made
**    in every case except SetThumbnail where control of the storage
**    occupied by the METAFILEPICT is merely transferred.  When the
**    Free routine is called, all storage will be deallocated including
**    that of the thumbnail.  The arguments to SetThumbNail and the
**    return values from GetThumbNail correspond to the OLE2.0 spec.
**    Note that on input, the thumbnail is read on demand but all the
**    other properties are pre-loaded.  The thumbnail is manipulated as
**    a windows handle to a METAFILEPICT structure, which in turn
**    contains a handle to the METAFILE.  The transferClip argument on
**    GetThumbNail, when set to true, transfers responsibility for
**    storage management of the thumbnail to the caller; that is, after
**    Free has been called, the handle is still valid. Clear can be
**    used to free storage for all the properties but then you must
**    call Read to load them again.  All the code is based on FAR
**    pointers.
**    CoInitialize MUST be called PRIOR to calling OleStdInitSummaryInfo.
**    Memory is allocated using the currently active IMalloc*
**    allocator (as is returned by call CoGetMalloc(MEMCTX_TASK) ).
**
** Common scenarios:
**    Read SummaryInfo
**    ----------------
**      OleStdInitSummaryInfo()
**      OleStdReadSummaryInfo()
**      . . . . .
**      call different Get routines
**      . . . . .
**      OleStdFreeSummaryInfo()
**
**    Create SummaryInfo
**    ------------------
**      OleStdInitSummaryInfo()
**      call different Set routines
**      OleStdWriteSummaryInfo()
**      OleStdFreeSummaryInfo()
**
**    Update SummaryInfo
**    ------------------
**      OleStdInitSummaryInfo()
**      OleStdReadSummaryInfo()
**      OleStdGetThumbNailProperty(necessary only if no SetThumb)
**      call different Set routines
**      OleStdWriteSummaryInfo()
**      OleStdFreeSummaryInfo()

**    DWORD FAR* byteCount          - size of thumbnail stream
**                                      for VT_CF_WIN case this should
**                                      be combined size of both the
**                                      Metafile as well as the
**                                      MetafilePict structure.
**    BOOL transferClip             - transfer ownership of thumbnail
**                                      to caller. (see comment)
**
** Return Value:
**    int vtcfNo                    - OLE thumbnail selector value
**      VT_CF_WIN                   - Windows thumbnail
**                                      (interpret clipFormatNo as
**                                      Windows clipboard format)
**      VT_CF_FMTID                 - (NOT IMPLEMENTED)
**                                      thumbnail format is specified
**                                      by ID. use clipFormatNo.
**                                      (but NOT a Windows format ID)
**
**      VT_CF_NAME                  - (NOT IMPLEMENTED)
**                                      thumbnail format is specified
**                                      by name. use lpszName.
**      VT_CF_EMPTY                 - blank thumbnail
**                                      (clip will be NULL)
**      VT_CF_OOM                   - Memory allocation failure
**
** Comments:
**    NOTE: Currently there is only proper support for VT_CF_WIN.
**    OleStdSetThumbNailProperty does implement VT_CF_FMTID and VT_CF_NAME,
**    however, OleStdGetThumbNailProperty, OleStdReadSummaryInfo and
**    OleStdWriteSummaryInfo only support VT_CF_WIN.
**
**    Note that on input, the thumbnail is read on demand while all the
**    other properties are pre-loaded.  The thumbnail is manipulated as
**    a windows handle to a METAFILEPICT structure, which in turn
**    contains a handle to the METAFILE.  The transferClip argument on
**    GetThumbNail, when set to true, transfers responsibility for
**    storage management of the thumbnail to the caller; that is, after
**    OleStdFreeSummaryInfo has been called, the handle is still valid.

/
*----------------------------------------------------------------------------
 * ParseFile
 * Purpose:  Determine if the filename is a legal DOS name
 * Input:    Long pointer to a SINGLE file name
 *           Circumstance checked:
 *           1) Valid as directory name, but not as file name
 *           2) Empty String
 *           3) Illegal Drive label
 *           4) Period in invalid location (in extention, 1st in file name)
 *           5) Missing directory character
 *           6) Illegal character
 *           7) Wildcard in directory name
 *           8) Double slash beyond 1st 2 characters
 *           9) Space character in the middle of the name (trailing spaces
OK)
 *          10) Filename greater than 8 characters
 *          11) Extention greater than 3 characters
 * Notes:
 *   Filename length is NOT checked.
 *   Valid filenames will have leading spaces, trailing spaces and
 *     terminating period stripped in place.
 *
 * Returns:  If valid, LOWORD is byte offset to filename
 *                     HIWORD is byte offset to extention
 *                           if string ends with period, 0
 *                           if no extention is given, string length
 *           If invalid, LOWORD is error code suggesting problem (< 0)
 *                       HIWORD is approximate offset where problem found
 *                       Note that this may be beyond the offending
character

ADVF

The **ADVF** enumeration values are flags used by a container object to specify the requested behavior when setting up an advise sink or a caching connection with an object. These values have different meanings depending on the type of connection in which they are used, and each interface uses its own subset of the flags.

```
typedef enum tagADVF
{
     ADVF_NODATA              = 1,
     ADVF_PRIMEFIRST          = 4,
     ADVF_ONLYONCE            = 2,
     ADVF_DATAONSTOP          = 64,
     ADVFCACHE_NOHANDLER      = 8,
     ADVFCACHE_FORCEBUILTIN = 16,
     ADVFCACHE_ONSAVE         = 32
} ADVF;
```

Elements

ADVF_NODATA

For data advisory connections (**IDataObject::DAdvise** or **IDataAdviseHolder::Advise**), this flag requests the data object not to send data when it calls **IAdviseSink::OnDataChange**. The recipient of the change notification can later request the data by calling **IDataObject::GetData**. The data object can honor the request by passing TYMED_NULL in the **STGMEDIUM** parameter, or it can provide the data anyway. For example, the data object might have multiple advisory connections, not all of which specified ADVF_NODATA, in which case the object might send the same notification to all connections. Regardless of the container's request, its **IAdviseSink** implementation must check the **STGMEDIUM** parameter because it is responsible for releasing the medium if it is not TYMED_NULL.

For cache connections (**IOleCache::Cache**), this flag requests that the cache not be updated by changes made to the running object. Instead, the container will update the cache by explicitly calling **IOleCache::SetData**. This situation typically occurs when the iconic aspect of an object is being cached.

ADVF_NODATA is not a valid flag for view advisory connections (**IViewObject::SetAdvise**) and it returns E_INVALIDARG.

ADVF_PRIMEFIRST

Requests that the object not wait for the data or view to change before making an initial call to **IAdviseSink::OnDataChange** (for data or view advisory connections) or updating the cache (for cache connections). Used with ADVF_ONLYONCE, this parameter provides an asynchronous **GetData** call.

ADVF_ONLYONCE

Requests that the object make only one change notification or cache update before deleting the connection.

ADVF_ONLYONCE automatically deletes the advisory connection after sending one data or view notification. The advisory sink receives only one **IAdviseSink** call. A nonzero connection ID is returned if the connection is established so the caller can use it to delete the connection prior to the first change notification.

For data change notifications, the combination of ADVF_ONLYONCE and ADVF_PRIMEFIRST provides, in effect, an asynchronous **IDataObject::GetData** call.

When used with caching, ADVF_ONLYONCE updates the cache one time only, on receipt of the first OnDataChange notification. After the update is complete, the advisory connection between the object and the cache is disconnected. The source object for the advisory connection calls the

IAdviseSink::Release method.

ADVF_DATAONSTOP

For data advisory connections, assures accessibility to data. This flag indicates that when the data object is closing, it should call **IAdviseSink::OnDataChange** providing data with the call. Typically, this value is used in combination with ADVF_NODATA. Without this value, by the time an **OnDataChange** call without data reaches the sink, the source might have completed its shutdown and the data might not be accessible. Sinks that specify this value should accept data provided in **OnDataChange** if it is being passed, because they may not get another chance to retrieve it.

For cache connections, this flag indicates that the object should update the cache as part of object closure.

ADVF_DATAONSTOP is not a valid flag for view advisory connections.

ADVFCACHE_NOHANDLER

Synonym for ADVFCACHE_FORCEBUILTIN, which is used more often.

ADVFCACHE_FORCEBUILTIN

This value is used by DLL object applications and object handlers that perform the drawing of their objects. ADVFCACHE_FORCEBUILTIN instructs OLE to cache presentation data to ensure that there is a presentation in the cache. This value is not a valid flag for data or view advisory connections. For cache connections, this flag caches data that requires only code shipped with OLE (or the underlying operating system) to be present in order to produce it with **IDataObject::GetData** or **IViewObject::Draw**. By specifying this value, the container can ensure that the data can be retrieved even when the object or handler code is not available.

ADVFCACHE_ONSAVE

For cache connections, this flag updates the cached representation only when the object containing the cache is saved. The cache is also updated when the OLE object transitions from the running state back to the loaded state (because a subsequent save operation would require rerunning the object). This value is not a valid flag for data or view advisory connections.

Comments

For a data or view advisory connection, the container uses the **ADVF** constants when setting up a connection between an **IAdviseSink** instance and and either an **IDataObject** or **IViewObject** instance. These connections are set up using the **IDataObject::DAdvise**, **IDataAdviseHolder::Advise**, or **IViewObject::SetAdvise** methods.

For a caching connection, the constants are specified in the **IOleCache::Cache** method to indicate the container's requests on how the object should update its cache.

These constants are also used in the *advf* member of the **STATDATA** structure. This structure is used by **IEnumSTATDATA** to describe the enumerated connections, and the *advf* member indicates the flags that were specified when the advisory or cache connection was established. When **STATDATA** is used for an **IOleObject::EnumAdvise** enumerator, the *advf* member is indeterminate.

BIND_FLAGS

The **BIND_FLAGS** enumeration values are used to control aspects of moniker binding operations. The values are used in the **BIND_OPTS** structure . Callers of **IMoniker** methods can specify values from this enumeration, and implementors of **IMoniker** methods can use these values in determining what they should do.

The **BIND_FLAGS** enumeration is defined in OBJIDL.IDL.

```
typedef enum tagBIND_FLAGS
{
     BIND_MAYBOTHERUSER     = 1,
     BIND_JUSTTESTEXISTENCE = 2,
} BIND_FLAGS;
```

Elements

BIND_MAYBOTHERUSER

If this flag is specified, the moniker implementation can interact with the end user. If not present, the moniker implementation should not interact with the user in any way, such as by asking for a password for a network volume that needs mounting. If prohibited from interacting with the user when it otherwise would, a moniker implementation can use a different algorithm that does not require user interaction, or it can fail with the error MK_MUSTBOTHERUSER.

BIND_JUSTTESTEXISTENCE

If this flag is specified, the caller is not interested in having the operation carried out, but only in learning whether the operation could have been carried out had this flag not been specified. For example, this flag lets the caller indicate only an interest in finding out whether an object actually exists by using this flag in a **IMoniker::BindToObject** call. Moniker implementations can, however, ignore this possible optimization and carry out the operation in full. Callers must be able to deal with both cases.

See Also

BIND_OPTS, **IBindCtx**

BINDSPEED

The **BINDSPEED** enumeration values indicate approximately how long the caller will wait to bind to an object. Callers of the **IOleItemContainer::GetObject** method specify values from this enumeration, and implementors of that method use these values as a guideline for how quickly they must complete their operation.

The **BINDSPEED** enumeration is defined in OLEIDL.IDL.

```
typedef enum tagBINDSPEED
{
     BINDSPEED_INDEFINITE   = 1,
     BINDSPEED_MODERATE     = 2,
     BINDSPEED_IMMEDIATE    = 3
} BINDSPEED;
```

Elements

BINDSPEED_INDEFINITE
Indicates that there is no time limit on the binding operation.

BINDSPEED_MODERATE
Indicates that the **IOleItemContainer::GetObject** operation must be completed in a moderate amount of time. If this flag is specified, the implementation of **IOleItemContainer::GetObject** should return MK_E_EXCEEEDEDDEADLINE unless the object is one of the following:

- Already in the running state
- A pseudo-object (i.e., an object internal to the item container, such as a cell-range in a spreadsheet or a character-range in a word processor).
- An object supported by an in-process server (so it is always in the running state when it is loaded). In this case, **IOleItemContainer::GetObject** should load the designated object, and, if the **OleIsRunning** API function indicates that the object is running, return successfully.

BINDSPEED_IMMEDIATE
Indicates that the caller will wait only a short time. In this case, **IOleItemContainer::GetObject** should return MK_E_EXCEEEDEDDEADLINE unless the object is already in the running state or is a pseudo-object.

Comments

The system-supplied item moniker implementation is the primary caller of **IOleItemContainer::GetObject**. The **BINDSPEED** value that it specifies depends on the deadline specified by the caller of the moniker operation.

The deadline is stored in the *dwTickCountDeadline* field of the **BIND_OPTS** structure in the bind context passed to the moniker operation. This value is based on the return value of the **GetTickCount** API function. If *dwTickCountDeadline* is zero, indicating no deadline, the item moniker implementation specifies BINDSPEED_INDEFINITE. (This is the default *dwTickCountDeadline* value for a bind context returned by the **CreateBindCtx** API function.) If the difference between *dwTickCountDeadline* and the value returned by the **GetTickCount** API function is greater than 2500, the item moniker implementation specifies BINDSPEED_MODERATE. If the difference is less than 2500, the item moniker implementation specifies BINDSPEED_IMMEDIATE.

Implementations of **IOleItemContainer::GetObject** can use the **BINDSPEED** value as a shortcut approximation of the binding deadline, or they can use the **IBindCtx** instance parameter to determine the exact deadline.

See Also

BIND_OPTS, **IBindCtx::GetBindOptions**, **IOleItemContainer::GetObject**

CALLTYPE

The **CALLTYPE** enumeration constants are the call type used by **IMessageFilter::HandleInComingCall**.

Defined in the **IMessageFilter** interface (*msgflt.idl*).

```
typedef enum tagCALLTYPE
{
     CALLTYPE_TOPLEVEL             = 1,
     CALLTYPE_NESTED               = 2,
     CALLTYPE_ASYNC                = 3,
     CALLTYPE_TOPLEVEL_CALLPENDING = 4,
     CALLTYPE_ASYNC_CALLPENDING    = 5
} CALLTYPE;
```

Elements

CALLTYPE_TOPLEVEL
toplevel call - no outgoing call

CALLTYPE_NESTED
callback on behalf of previous outgoing call - should always handle

CALLTYPE_ASYNC
aysnchronous call - can NOT be rejected

CALLTYPE_TOPLEVEL_CALLPENDING
new toplevel call with new LID

CALLTYPE_ASYNC_CALLPENDING
async call - can NOT be rejected

See Also

IMessageFilter::HandleInComingCall, **IMessageFilter**

CLSCTX

The **CLSCTX** enumeration constants specify the execution context for a class object. Different pieces of code can be associated with one CLSID for use in different execution contexts.

```
typedef enum tagCLSCTX
{
     CLSCTX_INPROC_SERVER   = 1,
     CLSCTX_INPROC_HANDLER  = 2,
     CLSCTX_LOCAL_SERVER    = 4
} CLSCTX;
```

Elements

CLSCTX_INPROC_SERVER
The code that creates and manages objects of this class runs in the same process as the caller of the function specifying the class context.

CLSCTX_INPROC_HANDLER
The code that manages objects of this class is an in-process handler. This is a DLL that runs in the client process and implements client-side structures of this class when instances of the class are accessed remotely.

CLSCTX_LOCAL_SERVER
The EXE code that creates and manages objects of this class is loaded in a separate process space (runs on same machine but in a different process).

To indicate that multiple contexts are acceptable, you can string multiple values together with boolean ORs. The contexts are tried in the order in which they are listed.

The following table shows the use and reasons for CLSCTX values in calls to **CoGetClassObject**, which is used in the implementation of other OLE functions:

Function Called	**Context Flag Used**
OleLoad	CLSCTX_INPROC_HANDLER | CLSCTX_INPROC_SERVER Putting an OLE object into the loaded state requires in-process access; but, it doesn't matter if all of the object's function is presently available.
IRunnableObject::Run	CLSCTX_INPROC_SERVER | CLSCTX_LOCAL_SERVER Running an OLE object requires connecting to the full code of the object wherever it is located.
CoUnMarshalInterface	CLSCTX_INPROC_HANDLER Unmarshalling needs the form of the class designed for remote access.

DATADIR

The **DATADIR** enumeration values specify the formats for which the **IDataObject::EnumFormatEtc** method supplies an enumerator. The values are used in the *dwDirection* parameter used in a call to the **IDataObject::EnumFormatEtc** method.

```
typedef enum tagDATADIR
{
     DATADIR_GET = 1,
     DATADIR_SET = 2
} DATADIR;
```

Elements

DATADIR_GET
: Requests that **IDataObject::EnumFormatEtc** supply an enumerator for the formats that can be specified in **IDataObject::GetData**.

DATADIR_SET
: Requests that **IDataObject::EnumFormatEtc** supply an enumerator for the formats that can be specified in **IDataObject::SetData**.

IDataObject

DISCARDCACHE

The **DISCARDCACHE** enumeration values are used in the **IOleCache2::DiscardCache** method to specify what to do with caches that are to be discarded from memory if their dirty bit has been set. The *dwDiscardOptions* parameter specifies whether or not to save these caches.

Defined in the

```
typedef enum tagDISCARDCACHE
{
     DISCARDCACHE_SAVEIFDIRTY    = 0,
     DISCARDCACHE_NOSAVE         = 1
} DISCARDCACHE;
```

Elements

DISCARDCACHE_SAVEIFDIRTY
  Indicates that the cache is to be saved to disk.

DISCARDCACHE_NOSAVE
  Indicates that the cache can be discarded without saving it.

See Also

IOleCache2::DiscardCache

DROPEFFECT

The **DoDragDrop** function and many of the methods in the **IDropSource** and **IDropTarget** interfaces pass information about the effects of a drag-and-drop operation in a **DROPEFFECT** enumeration.

Valid drop effect values are the result of applying the OR operation to the values contained in the **DROPEFFECT** enumeration:

```
typedef enum tagDROPEFFECT
{
     DROPEFFECT_NONE   = 0,
     DROPEFFECT_COPY   = 1,
     DROPEFFECT_MOVE   = 2,
     DROPEFFECT_LINK   = 4,
     DROPEFFECT_SCROLL = 0x80000000,
     }DROPEFFECT;
```

These values have the following meaning:

DROPEFFECT name	**Value**	**Description**
DROPEFFECT_NONE	0	Drop target cannot accept the data.
DROPEFFECT_COPY	1	Drop results in a copy. The original data is untouched by the drag source.
DROPEFFECT_MOVE	2	Drag source should remove the data.
DROPEFFECT_LINK	4	Drag source should create a link to the original data.
DROPEFFECT_SCROLL	0x80000000	Scrolling is about to start or is currently occurring in the target. This value is used in addition to the other values.

Note Your application should always mask values from the **DROPEFFECT** enumeration to ensure compatibility with future implementations. Presently, only four of the 32 bit positions in a **DROPEFFECT** have meaning. In the future, more interpretations for the bits will be added. Drag sources and drop targets should carefully mask these values appropriately before comparing. They should never compare a **DROPEFFECT** against, say, DROPEFFECT_COPY by

```
if (dwDropEffect == DROPEFFECT_COPY)...
```

Instead, the application should always mask for the value or values being sought:

```
if (dwDropEffect & DROPEFFECT_COPY) == DROPEFFECT_COPY)...
```

or

```
if (dwDropEffect & DROPEFFECT_COPY)...
```

This allows for the definition of new drop effects, while preserving backwards compatibility with existing code.

See Also

DoDragDrop, **IDropSource**, **IDropTarget**

DVASPECT

The **DVASPECT** enumeration values specify the desired data or view aspect of the object when drawing or getting data.

```
typedef enum tagDVASPECT
{
     DVASPECT_CONTENT    = 1,
     DVASPECT_THUMBNAIL  = 2,
     DVASPECT_ICON       = 4,
     DVASPECT_DOCPRINT   = 8
} DVASPECT;
```

Elements

DVASPECT_CONTENT
: Provide a representation of an object so it can be displayed as an embedded object inside of a container. This value is typically specified for compound document objects. The presentation can be provided for the screen or printer.

DVASPECT_THUMBNAIL
: Provide a thumbnail representation of an object so it can be displayed in a browsing tool. The thumbnail is approximately a 120 by 120 pixel, 16-color (recommended) device-independent bitmap potentially wrapped in a metafile.

DVASPECT_ICON
: Provide an iconic representation of an object.

DVASPECT_DOCPRINT
: Provide a representation of the object on the screen as though it were printed to a printer using the Print command from the File menu. The described data may represent a sequence of pages.

Comments

This enumeration is used in the *dwAspect* field of the **FORMATETC** structure. Only one **DVASPECT** value can be used to specify a single presentation aspect in a **FORMATETC** structure. The **FORMATETC** structure is used in **IDataObject**, **IAdviseSink**, and **IOleCache** methods. The **DVASPECT** enumeration values are also used in **IViewObject** methods.

See Also

IAdviseSink, **IDataObject**, **IOleObject**, **IViewObject**, **IViewObject2**, **OleDraw**, **FORMATETC**, **OBJECTDESCRIPTOR**

EXTCONN

The **EXTCONN** enumeration specifies the type of external connection existing on an embedded object. Currently, the only supported type is EXTCONN_STRONG, meaning that the external connection is a link. This E**XTCONN** constant is used in the **IExternalConnection::AddConnection** and **IExternalConnection::ReleaseConnection** methods.

```
typedef enum tagEXTCONN
{
     EXTCONN_STRONG    = 0X0001,
     EXTCONN_WEAK            = 0X0002,
     EXTCONN_CALLABLE  = 0X0004
} EXTCONN;
```

Elements

EXTCONN_STRONG
If this value is specified, the external connection must keep the object alive until all strong external connections are cleared through **IExternalConnection::ReleaseConnection**.

EXTCONN_WEAK
This value is currently not used.

EXTCONN_CALLABLE
This value is currently not used.

LOCKTYPE

The **LOCKTYPE** enumeration values indicate the type of locking requested for the specified range of bytes. The values are used in the **ILockBytes::LockRegion** and **IStream::LockRegion** methods.

Defined in the **IStream** interface (*stream.idl*).

```
typedef enum tagLOCKTYPE
{
     LOCK_WRITE       = 1,
     LOCK_EXCLUSIVE   = 2,
     LOCK_ONLYONCE    = 4
} LOCKTYPE;
```

Elements

LOCK_WRITE
: If this lock is granted, the specified range of bytes can be opened and read any number of times, but writing to the locked range is prohibited except for the owner that was granted this lock.

LOCK_EXCLUSIVE
: If this lock is granted, writing to the specified range of bytes is prohibited except for the owner that was granted this lock.

LOCK_ONLYONCE
: If this lock is granted, no other LOCK_ONLYONCE lock can be obtained on the range. Usually this lock type is an alias for some other lock type. Thus, specific implementations can have additional behavior associated with this lock type.

MKRREDUCE

The **MKRREDUCE** enumeration constants are used to specify how far the moniker should be reduced. They are used in the **IMoniker::Reduce** method. **MKRREDUCE** is defined in OBJIDL.IDL.

```
typedef enum tagMKRREDUCE
{
     MKRREDUCE_ONE           = 3<<16,
     MKRREDUCE_TOUSER        = 2<<16,
     MKRREDUCE_THROUGHUSER   = 1<<16,
     MKRREDUCE_ALL           = 0
} MKRREDUCE;
```

Elements

MKRREDUCE_ONE
Performs only one step of reducing the moniker. In general, the caller must have specific knowledge about the particular kind of moniker to take advantage of this option.

MKRREDUCE_TOUSER
Reduce the moniker to a form that the user identifies as a persistent object. If no such point exists, then this option should be treated as MKRREDUCE_ALL.

MKRREDUCE_THROUGHUSER
Reduce the moniker to where any further reduction would reduce it to a form that the user does not identify as a persistent object. Often, this is the same stage as MKRREDUCE_TOUSER.

MKRREDUCE_ALL
Reduce the moniker until it is in simplest form, that is, reduce it to itself.

See Also

IMoniker::Reduce

MKSYS

The **MKSYS** enumeration constants indicate the moniker's class. They are returned from the **IMoniker::IsSystemMoniker** method. **MKSYS** is defined in OBJIDL.IDL.

```
typedef enum tagMKSYS
{
     MKSYS_NONE                  = 0,
     MKSYS_GENERICCOMPOSITE        = 1,
     MKSYS_FILEMONIKER           = 2,
     MKSYS_ANTIMONIKER           = 3,
     MKSYS_ITEMMONIKER           = 4,
     MKSYS_POINTERMONIKER        = 5
} MKSYS;
```

Elements

MKSYS_NONE
  Indicates a custom moniker implementation.

MKSYS_GENERICCOMPOSITE
  Indicates the system's generic composite moniker class.

MKSYS_FILEMONIKER
  Indicates the system's file moniker class.

MKSYS_ANTIMONIKER
  Indicates the system's anti-moniker class.

MKSYS_ITEMMONIKER
  Indicates the system's item moniker class.

MKSYS_POINTERMONIKER
  Indicates the system's pointer moniker class.

See Also

IMoniker::IsSystemMoniker

MSHCTX

The **MSHCTX** enumeration constants specify the destination context, that is, the process in which the unmarshaling is to be done. These flags are used in the **IMarshal** and **IStdMarshalInfo** interfaces and in the **CoMarshalInterface** and **CoGetStandardMarshal** API functions.

MSHCTX is defined in WTYPES.IDL.

```
typedef enum tagMSHCTX
{
     MSHCTX_LOCAL                = 0,
     MSHCTX_NOSHAREDMEM          = 1,
     MSHCTX_DIFFERENTMACHINE     = 2,
     MSHCTX_INPROC               = 3
} MSHCTX;
```

Elements

MSHCTX_LOCAL
The unmarshaling process is local and has shared memory access with the marshaling process.

MSHCTX_NOSHAREDMEM
The unmarshaling process does not have shared memory access with the marshaling process.

MSHCTX_DIFFERENTMACHINE
The unmarshaling process is on a different machine. The marshaling code cannot assume that a particular piece of application code is installed on that machine.

MSHCTX_INPROC
The unmarshaling will be done in another apartment in the same process. If your object supports multiple threads, your custom marshaler can pass a direct pointer instead of creating a proxy object.

See Also

CoGetStandardMarshal, **CoMarshalInterface**, **IMarshal**, **IStdMarshalInfo**

MSHLFLAGS

The **MSHLFLAGS** enumeration constants determine why the marshaling is to be done. These flags are used in the **IMarshal** interface and the **CoMarshalInterface** and **CoGetStandardMarshal** API functions.

MSHFLAGS is defined in WTYPES.IDL.

```
typedef enum tagMSHLFLAGS
{
     MSHLFLAGS_NORMAL           = 0,
     MSHLFLAGS_TABLESTRONG      = 1,
     MSHLFLAGS_TABLEWEAK        = 2
} MSHLFLAGS;
```

Elements

MSHLFLAGS_NORMAL
: The marshaling is occurring because an interface pointer is being passed from one process to another. This is the normal case. The data packet produced by the marshaling process will be unmarshaled in the destination process. The marshaled data packet can be unmarshaled just once, or not at all. If the receiver unmarshals the data packet successfully, the **CoReleaseMarshalData** API function is automatically called on the data packet as part of the unmarshaling process. If the receiver does not or cannot unmarshal the data packet, the sender must call the **CoReleaseMarshalData** API function on the data packet.

MSHLFLAGS_TABLESTRONG
: The marshaling is occurring because the data packet is to be stored in a globally-accessible table from which it can be unmarshaled one or more times, or not at all. The presence of the data packet in the table counts as a strong reference to the interface being marshaled, meaning that it is sufficient to keep the object alive. When the data packet is removed from the table, the table implementor must call the **CoReleaseMarshalData** API function on the data packet.

MSHLFLAGS_TABLESTRONG is used by the **RegisterDragDrop** API function when registering a window as a drop target. This keeps the window registered as a drop target no matter how many times the end-user drags across the window. The **RevokeDragDrop** API function calls **CoReleaseMarshalData**.

MSHLFLAGS_TABLEWEAK
: The marshaling is occurring because the data packet is to be stored in a globally-accessible table from which it can be unmarshaled one or more times, or not at all. However, the presence of the data packet in the table acts as a weak reference to the interface being marshaled, meaning that it is not sufficient to keep the object alive. When the data packet is removed from the table, the table implementor must call the **CoReleaseMarshalData** API function on the data packet.

MSHLFLAGS_TABLEWEAK is typically used when registering an object in the Running Object Table (ROT). This prevents the object's entry in the ROT from keeping the object alive in the absence of any other connections. See **IRunningObjectTable::Register** for more information.

See Also

CoGetStandardMarshal, **CoMarshalInterface**, **IMarshal**

OLECLOSE

The **OLECLOSE** enumeration constants are used in the **IOleObject::Close** method to determine whether the object should be saved before closing. These are defined *ole2.h* and in the **IOleObject** interface (*oleobj.idl*).

```
typedef enum tagOLECLOSE
{
     OLECLOSE_SAVEIFDIRTY  = 0,
     OLECLOSE_NOSAVE       = 1,
     OLECLOSE_PROMPTSAVE   = 2
} OLECLOSE;
```

Elements

OLECLOSE_SAVEIFDIRTY
: Indicates that the object should be saved if it is dirty.

OLECLOSE_NOSAVE
: Indicates that the object should not be saved, even if it is dirty. This flag is typically used when an object is being deleted.

OLECLOSE_PROMPTSAVE
: Indicates that if the object is dirty, the **IOleObject::Close** implementation should display a dialog to let the end user determine whether to save the object. However, if the object is in the running state but its user interface is invisible, the the end user should not be prompted, and the close should be handled as if OLECLOSE_SAVEIFDIRTY had been specified.

See Also

IOleObject::Close

OLECONTF

The **OLECONTF** enumeration indicate the kind of objects to be enumerated by the returned **IEnumUnknown** interface. **OLECONTF** contains a set of bitwise constants used in the **IOleContainer::EnumObjects** method.

```
typedef enum tagOLECONTF
{
     OLECONTF_EMBEDDINGS    = 1;
     OLECONTF_LINKS         = 2;
     OLECONTF_OTHERS        = 4;
     OLECONTF_ONLYUSER      = 8;
     OLECONTF_ONLYIFRUNNING = 16
} OLECONTF;
```

Elements

OLECONTF_EMBEDDINGS
Enumerate the embedded objects in the container.

OLECONTF_LINKS
Enumerate the linked objects in the container.

OLECONTF_OTHERS
Enumerate all objects in the container that are not OLE compound document objects (i.e.; objects other than linked or embedded objects). Use this flag to enumerate the container's pseudo-objects.

OLECONTF_ONLYUSER
Enumerate only those objects the user is aware of. For example; hidden named-ranges in Microsoft Excel would not be enumerated using this value.

OLECONTF_ONLYIFRUNNING
Enumerate only those linked or embedded objects that are currently in the running state for this container.

See Also

IEnumUnknown, **IOleContainer::EnumObjects**

OLEGETMONIKER

The **OLEGETMONIKER** enumeration constants indicate the requested behavior of the **IOleObject::GetMoniker** and **IOleClientSite::GetMoniker** methods. These constants are defined in *ole2.h* and in the **IOleObject** interface (*oleobj.idl*).

```
typedef enum tagOLEGETMONIKER
{
     OLEGETMONIKER_ONLYIFTHERE = 1,
     OLEGETMONIKER_FORCEASSIGN = 2,
     OLEGETMONIKER_UNASSIGN    = 3,
     OLEGETMONIKER_TEMPFORUSER = 4
} OLEGETMONIKER;
```

Elements

OLEGETMONIKER_ONLYIFTHERE
: Indicates that if a moniker for the object or container does not exist, **GetMoniker** should return E_FAIL and not assign a moniker.

OLEGETMONIKER_FORCEASSIGN
: Indicates that if a moniker for the object or container does not exist, **GetMoniker** should create one.

OLEGETMONIKER_UNASSIGN
: Indicates that **IOleClientSite::GetMoniker** can release the object's moniker (although it is not required to do so). This constant is not valid in **IOleObject::GetMoniker**.

OLEGETMONIKER_TEMPFORUSER
: Indicates that if a moniker for the object does not exist, **IOleObject::GetMoniker** can create a temporary moniker that can be used for display purposes (**IMoniker::GetDisplayName**) but not for binding. This is enables the object server to return a descriptive name for the object without incurring the overhead of creating and maintaining a moniker until a link is actually created.

Comments

If the OLEGETMONIKER_FORCEASSIGN flag causes a container to create a moniker for the object, the container should notify the object by calling the **IOleObject::SetMoniker** method.

See Also

IMoniker, **IOleClientSite::GetMoniker**, **IOleObject::GetMoniker**

OLELINKBIND

The **OLELINKBIND** enumeration constants control binding operations to a link source. They are used in the **IOleLink::BindToSource** method, and **OLELINKBIND** is defined in OLEIDL.IDL.

```
typedef enum tagOLELINKBIND
{
    OLELINKBIND_EVENIFCLASSDIFF = 1,
} OLELINKBIND;
```

Element

OLELINKBIND_EVENIFCLASSDIFF
Indicates that the binding operation should proceed even if the current class of the link source is different from the last time the link was bound. For example, the link source could be a Lotus spreadsheet that was converted to an Excel spreadsheet.

See Also

IOleLink::BindToSource

OLEMISC

The **OLEMISC** enumeration is a set of bitwise constants that can be combined to describe miscellaneous characteristics of an object or class of objects. A container can call the **IOleObject::GetMiscStatus** method to determine the **OLEMISC** bits set for an object. The values specified in an object server's CLSID\MiscStatus entry in the registration database are based on the **OLEMISC** enumeration. These constants are also used in the *dwStatus* member of the **OBJECTDESCRIPTOR** structure. **OLEMISC** is defined in *ole2.h* and in the **IOleObject** interface (*oleobj.idl*).

```
typedef enum tagOLEMISC // bitwise
{
     OLEMISC_RECOMPOSEONRESIZE            = 1,
     OLEMISC_ONLYICONIC                   = 2,
     OLEMISC_INSERTNOTREPLACE             = 4,
     OLEMISC_STATIC                       = 8,
     OLEMISC_CANTLINKINSIDE               = 16,
     OLEMISC_CANLINKBYOLE1                = 32,
     OLEMISC_ISLINKOBJECT                 = 64,
     OLEMISC_INSIDEOUT                    = 128,
     OLEMISC_ACTIVATEWHENVISIBLE          = 256
     OLEMISC_RENDERINGISDEVICEINDEPENDENT = 512
} OLEMISC;
```

Elements

OLEMISC_RECOMPOSEONRESIZE

Indicates that when the container resizes the space allocated to displaying one of the object's presentations, the object wants to recompose the presentation. This means that on resize, the object wants to do more than scale its picture. If this bit is set, the container should force the object to the running state and call **IOleObject::SetExtent** with the new size.

OLEMISC_ONLYICONIC

Indicates that the object has no useful content view other than its icon. From the user's perspective, the Display As Icon checkbox (in the Paste Special dialog box) for this object should always be checked, and should not be uncheckable. Note that such an object should still have a drawable content aspect; it will look the same as its icon view.

OLEMISC_INSERTNOTREPLACE

Indicates that the object has initialized itself from the data in the container's current selection. Containers should examine this bit after calling **IOleObject::InitFromData** to initialize an object from the current selection. If set, the container should insert the object beside the current selection rather than replacing the current selection. If this bit is not set, the object being inserted replaces the current selection.

OLEMISC_STATIC

Indicates that this object is a static object, which is an object that contains only a presentation; it contains no native data. See **OleCreateStaticFromData**.

OLEMISC_CANTLINKINSIDE

Indicates that this object cannot be the link source that when bound to activates (runs) the object. If the object is selected and copied to the clipboard, the object's container can offer a link in a clipboard data transfer that, when bound, must connect to the outside of the object. The user would see the object selected in its container, not open for editing. Rather than doing this, the container can simply refuse to offer a link source when transferring objects with this bit set. Examples of objects that have this bit set include OLE1 objects, static objects, and links.

OLEMISC_CANLINKBYOLE1
: Indicates that this object can be linked to by OLE 1 containers. This bit is used in the *dwStatus* member of the **OBJECTDESCRIPTOR** structure transferred with the Object and Link Source Descriptor formats. An object can be linked to by OLE 1 containers if it is an untitled document, a file, or a selection of data within a file. Embedded objects or pseudo-objects that are contained within an embedded object cannot be linked to by OLE 1 containers (i.e., OLE 1 containers cannot link to link sources that, when bound, require more than one object server to be run.

OLEMISC_ISLINKOBJECT
: This object is a link object. This bit is significant to OLE 1 and is set by the OLE 2 link object; object applications have no need to set this bit.

OLEMISC_INSIDEOUT
: This object is capable of activating in-place, without requiring installation of menus and toolbars to run. Several such objects can be active concurrently. Some containers, such as forms, may choose to activate such objects automatically.

OLEMISC_ACTIVATEWHENVISIBLE
: This bit is set only when OLEMISC_INSIDEOUT is set, and indicates that this object prefers to be activated whenever it is visible. Some containers may always ignore this hint.

OLEMISC_RENDERINGISDEVICEINDEPENDENT
: This object does not pay any attention to target devices. Its presention data will be the same in all cases.

See Also

IOleObject::GetMiscStatus, **OBJECTDESCRIPTOR**

OLERENDER

The **OLERENDER** enumeration constants are used in the various object creation API functions to indicate the type of caching requested for the newly created object.

```
typedef enum tagOLERENDER
{
     OLERENDER_NONE   = 0;
     OLERENDER_DRAW   = 1;
     OLERENDER_FORMAT = 2;
     OLERENDER_ASIS   = 3
} OLERENDER;
```

Elements

OLERENDER_NONE
The client is not requesting any locally cached drawing or data retrieval capabilities in the object. *pFormatEtc* is ignored for this option.

OLERENDER_DRAW
The client will draw the content of the object on the screen (a NULL target device) using **IViewObject:Draw**. The object itself determines the data formats that need to be cached. With this render option, only the *ptd* and *dwAspect* members of *pFormatEtc* are significant, since the object may cache things differently depending on the parameter values. However, *pFormatEtc* can legally be NULL here, in which case the object is to assume the display target device and the DVASPECT_CONTENT aspect.

OLERENDER_FORMAT
The client will pull one format from the object using **IDataObject::GetData()**. The format of the data to be cached is passed in *pFormatEtc*, which may not in this case be NULL.

OLERENDER_ASIS
The client is not requesting any locally cached drawing or data retrieval capabilities in the object. *pFormatEtc* is ignored for this option. The difference between this and the OLERENDER_FORMAT value is important in such functions as **OleCreateFromData()** and **OleCreateLinkFromData()**.

See Also

OleCreate, **OleCreateFromData**, **OleCreateFromFile**, **OleCreateLink**, **OleCreateLinkFromData**, **OleCreateLinkToFile**, **OleCreateStaticFromData**

OLEUIPASTEFLAG

This enumeration is used to indicate the user options that are available to the user when pasting this format, and within which group or list of choices (Paste, Paste Link, etc) this entry is to be available. OLEUIPASTEFLAG is used by the **OLEUIPASTEENTRY** structure. It

```
typedef enum tagOLEUIPASTEFLAG
{
     OLEUIPASTE_ENABLEICON    = 2048,
     OLEUIPASTE_PASTEONLY     = 0,
     OLEUIPASTE_PASTE         = 512,
     OLEUIPASTE_LINKANYTYPE   = 1024,
     OLEUIPASTE_LINKTYPE1     = 1,
     OLEUIPASTE_LINKTYPE2     = 2,
     OLEUIPASTE_LINKTYPE3     = 4,
     OLEUIPASTE_LINKTYPE4     = 8,
     OLEUIPASTE_LINKTYPE5     = 16,
     OLEUIPASTE_LINKTYPE6     = 32,
     OLEUIPASTE_LINKTYPE7     = 64,
     OLEUIPASTE_LINKTYPE8     = 128
} OLEUIPASTEFLAG;
```

OLEUIPASTE_ENABLEICON

If the container does not specify this flag for the entry in the **OLEUIPASTEENTRY**array passed as input to **OleUIPasteSpecial**, the DisplayAsIcon button will be unchecked and disabled when the user selects the format that corresponds to the entry.

OLEUIPASTE_PASTEONLY

Indicates that the entry in the OLEUIPASTEENTRY array is valid for pasting only.

OLEUIPASTE_PASTE

Indicates that the entry in the **OLEUIPASTEENTRY**array is valid for pasting. It may also be valid for linking if any of the following linking flags are specified. If it is valid for linking, then the following flags indicate which link types are acceptable by OR'ing together the appropriate OLEUIPASTE_LINKTYPE<#> values. These values correspond as follows to the array of link types passed to **OleUIPasteSpecial**:

OLEUIPASTE_LINKTYPE1=arrLinkTypes[0]
OLEUIPASTE_LINKTYPE2=arrLinkTypes[1]
OLEUIPASTE_LINKTYPE3=arrLinkTypes[2]
OLEUIPASTE_LINKTYPE4=arrLinkTypes[3]
OLEUIPASTE_LINKTYPE5=arrLinkTypes[4]
OLEUIPASTE_LINKTYPE6=arrLinkTypes[5]
OLEUIPASTE_LINKTYPE7=arrLinkTypes[6]
OLEUIPASTE_LINKTYPE8=arrLinkTypes[7]

where,

UINT arrLinkTypes[8] is an array of registered clipboard formats for linking. A maximum of 8 link types is allowed.

OLEUPDATE

The **OLEUPDATE** enumeration constants are used to indicate whether the linked object updates the cached data for the linked object automatically or only when the container calls either the **IOleObject::Update** or **IOleLink::Update** methods. The constants are used in the **IOleLink** interface.

The **OLEUPDATE** enumeration is defined in OLEIDL.IDL..

```
typedef enum tagOLEUPDATE
{
     OLEUPDATE_ALWAYS = 1;
     OLEUPDATE_ONCALL = 3
} OLEUPDATE;
typedef OLEUPDATE *LPOLEUPDATE;
```

Elements

OLEUPDATE_ALWAYS
Update the link object whenever possible, this option corresponds to the Automatic update option in the Links dialog box.

OLEUPDATE_ONCALL
Update the link object only when **IOleObject::Update** or **IOleLink::Update** is called, this option corresponds to the Manual update option in the Links dialog box.

See Also

IOleLink::SetUpdateOptions, **IOleLink::GetUpdateOptions**

OLEVERBATTRIB

The **OLEVERBATTRIB** enumeration constants are used in the **OLEVERB** structure to describe the attributes of a specified verb for an object. Defined in the **IEnumOLEVERB** interface (*eoverb.idl*).

```
typedef enum tagOLEVERBATTRIB
{
     OLEVERBATTRIB_NEVERDIRTIES    = 1,
     OLEVERBATTRIB_ONCONTAINERMENU = 2
} OLEVERBATTRIB;
```

Elements

OLEVERBATTRIB_NEVERDIRTIES
OLEVERBATTRIB_ONCONTAINERMENU
Indicates a verb that should appear in the container's menu of verbs for this object.

See Also

IEnumOLEVERB, **OLEVERB**

OLEWHICHMK

The **OLEWHICHMK** enumeration constants indicate which part of an object's moniker is being set or retrieved. These constants are used in the **IOleObject** and **IOleClientSite** interfaces, and are defined in *ole2.h* and in the **IOleObject** interface (*oleobj.idl*).

```
typedef enum tagOLEWHICHMK
{
     OLEWHICHMK_CONTAINER = 1,
     OLEWHICHMK_OBJREL    = 2,
     OLEWHICHMK_OBJFULL   = 3
} OLEWHICHMK;
```

Elements

OLEWHICHMK_CONTAINER
: Indicates the moniker of the object's container, Typically this is a file moniker. This moniker is not persistently stored inside the object, since the container can be renamed even while the object is not loaded.

OLEWHICHMK_OBJREL
: Indicates the moniker of the object relative to its container. Typically this is an item moniker, and it is part of the persistent state of the object. If this moniker is composed on to the end of the container's moniker, the resulting moniker is the full moniker of the object.

OLEWHICHMK_OBJFULL
: Indicates the full moniker of the object. Binding to this moniker results in a connection to the object. This moniker is not persistently stored inside the object, since the container can be renamed even while the object is not loaded.

IOleClientSite::GetMoniker, **IOleObject::GetMoniker**, **IOleObject::SetMoniker**

PENDINGMSG

The **PENDINGMSG** enumeration constants are return values of **IMessageFilter::MessagePending**.

Defined in the **IMessageFilter** interface (*msgflt.idl*).

```
typedef enum tagPENDINGMSG
{
     PENDINGMSG_CANCELCALL      = 0,
     PENDINGMSG_WAITNOPROCESS   = 1,
     PENDINGMSG_WAITDEFPROCESS  = 2
} PENDINGMSG;
```

Elements

PENDINGMSG_CANCELCALL
  cancel the outgoing call

PENDINGMSG_WAITNOPROCESS
  wait for the return and don't dispatch the message

PENDINGMSG_WAITDEFPROCESS
  wait and dispatch the message

See Also

IMessageFilter::MessagePending

PENDINGTYPE

The **PENDINGTYPE** enumeration constants indicate the level of nesting in the **IMessageFilter::MessagePending** method.

Defined in the **IMessageFilter** interface (*msgflt.idl*).

```
typedef enum tagPENDINGTYPE
{
     PENDINGTYPE_TOPLEVEL = 1,
     PENDINGTYPE_NESTED   = 2
} PENDINGTYPE;
```

Elements

PENDINGTYPE_TOPLEVEL
toplevel call

PENDINGTYPE_NESTED
nested call

See Also

IMessageFilter::MessagePending

REGCLS

The **REGCLS** enumeration defines flags used in **CoRegisterClassObject** to control the type of connections to the class object. It is defined as follows:

```
typedef enum tagREGCLS
{
     REGCLS_SINGLEUSE        = 0,
     REGCLS_MULTIPLEUSE      = 1,
     REGCLS_MULTI_SEPARATE   = 2,
     } REGCLS;
```

Elements

REGCLS_SINGLEUSE
: Specifies that once an application has connected to the class object with **CoGetClassObject**, the class object is removed from public view so that no other applications can connect to it. This flag is commonly used for single document interface (SDI) applications. Specifying this flag does not affect the responsibility of the object application to call **CoRevokeClassObject**; it must always call **CoRevokeClassObject** when it is finished with an object class.

REGCLS_MULTIPLEUSE
: Specifies that multiple applications can connect to the class object through calls to **CoGetClassObject**.

REGCLS_MULTI_SEPARATE
: Similar to REGCLS_MULTIPLEUSE, except that REGCLS_MULTI_SEPARATE does not automatically register the class object as CLSCTX_INPROC_SERVER for a local server. Instead, it provides separate control over each context. When a class is registered this way, if that server tries to bind to an object with its own class id, it will start another copy of the server.

Comments

In **CoRegisterClassObject**, members of both the **REGCLS** and the **CLSCTX** enumerations, taken together, determine how the class object is registered.

The following table summarizes the allowable flag combinations and the object registrations affected by the combinations:

	REGCLS_ SINGLEUSE	**REGCLS_ MULTIPLEUSE**	**REGCLS_ MULTI_ SEPARATE**	**Other**
CLSCTX_ INPROC_ SERVER	Error	Inproc	Inproc	Error
CLSCTX_ LOCAL_ SERVER	Local	Inproc/local	Local	Error
Both of the above	Error	Inproc/local	Inproc/local	Error
Other	Error	Error	Error	Error

REGCLS_MULTIPLEUSE in combination with CLSCTX_LOCAL_SERVER automatically registers the class object as an in-process server (CLSCTX_INPROC_SERVER). In contrast, registering a class object as a local server and specifying REGCLS_MULTIPLE_SEPARATE does not register the class object as an in-process server (registers the object with the CLSCTX_LOCAL_SERVER flag, but does not automatically add the CLSCTX_INPROC_SERVER flag as is the case when you specify the REGCLS_MULTIPLEUSE flag. This distinction is important in applications that are both OLE containers and OLE embeddings, allowing a container/server to be inserted into itself.

In general, the following two registrations have the same effect -- they register class objects as both multiple-use and as in-process servers:

```
CLSCTX_LOCAL_SERVER, REGCLS_MULTIPLEUSE
```

```
(CLSCTX_INPROC_SERVER|CLSCTX_LOCAL_SERVER), REGCLS_MULTI_SEPARATE
```

The following registers the class object only as a multiple-use local server:

```
CLSCTX_LOCAL_SERVER, REGCLS_MULTI_SEPARATE
```

See Also

CoGetClassObject, **CoRegisterClassObject**, **CoRevokeClassObject**, **DllGetClassObject**

SERVERCALL

The **SERVERCALL** enumeration constants indicate the status of server call - returned by **IMessageFilter::HandleInComingCall** and passed to **IMessageFilter::RetryRejectedCall**.

Defined in the **IMessageFilter** interface (*msgflt.idl*).

```
typedef enum tagSERVERCALL
{
     SERVERCALL_ISHANDLED  = 0,
     SERVERCALL_REJECTED   = 1,
     SERVERCALL_RETRYLATER = 2
} SERVERCALL;
```

Elements

SERVERCALL_ISHANDLED
SERVERCALL_REJECTED
SERVERCALL_RETRYLATER

See Also

IMessageFilter::HandleInComingCall, **IMessageFilter::RetryRejectedCall**

STATFLAG

The **STATFLAG** enumeration values indicate whether the method should try to return a name in the *pwcsName* member of the **STATSTG** structure. The values are used in the **ILockBytes::Stat**, **IStorage::Stat**, and **IStream::Stat** methods to save memory when the *pwcsName* member is not needed.

Defined in the **IOLETypes** pseudo-interface (*oletyp.idl*).

```
typedef enum tagSTATFLAG
{
     STATFLAG_DEFAULT = 0,
     STATFLAG_NONAME  = 1
} STATFLAG;
```

Elements

STATFLAG_DEFAULT
Requests that the statistics include the *pwcsName* member of the **STATSTG** structure.

STATFLAG_NONAME
Requests that the statistics not include the *pwcsName* member of the **STATSTG** structure. If the name is omitted, there is no need for the **Stat** methods to allocate and free memory for the string value for the name and the method can save an **Alloc** and **Free** operation.

See Also

ILockBytes::Stat, **IStorage::Stat**, **IStream::Stat**

STATSTATE

The **STATSTATE** enumeration values indicate state information about the storage object and are used as a mask. The values are used in the **IStorage::SetStateBits** method.

Defined in the ().

```
typedef enum tagSTATSTATE
{
     STATSTATE_DOC = 1,
     STATSTATE_CONVERT  = 2,
     STATSTATE_FILESTGSAME  = 4
} STATSTATE;
```

Elements

STATSTATE_DOC
.

Indicates that the storage object is a document file. This bit is set on the root storage object as part of a normal File/Save sequence. With nested storage objects, the application manages the storage objects and sets or clears this bit as appropriate. If the nested object is an embedded object, this bit can be ignored. It is cleared in a newly created storage object. However, some applications might use this bit to enable editing an embedded storage object without first copying the object to the file system. For example, a mail application might set this bit for attachments so the attachments can be edited without copying them first to a file.

STATSTATE_CONVERT

Indicates that a convert operation was done on this storage object while it was in a passive state.

STATSTATE_FILESTGSAME

Indicates that the embedded object and document representations for the storage object are the same. Thus, the storage object can be saved in a document file simply by copying the storage object bits.

See Also

IStorage::SetStateBits.

STGC

The **STGC** enumeration constants specify the conditions for performing the commit operation in the **IStorage::Commit** and **IStream::Commit** methods.

Defined in the **IOLETypes** pseudo-interface (*oletyp.idl*).

```
typedef enum tagSTGC
{
     STGC_DEFAULT                           = 0,
     STGC_OVERWRITE                         = 1,
     STGC_ONLYIFCURRENT                     = 2,
     STGC_DANGEROUSLYCOMMITMERELYTODISKCACHE = 4
} STGC;
```

Elements

STGC_DEFAULT

Indicates that none of the other values apply. You can specify this condition or some combination of the other three. You would use this value mainly to make your code more readable.

STGC_OVERWRITE

Indicates that the commit operation can overwrite existing data to reduce overall space requirements. This value is not recommended for typical usage because it is not as robust as the default case. In this case, it is possible for the commit to fail after the old data is overwritten but before the new data is completely committed. Then, neither the old version nor the new version of the storage object will be intact.

You can use this value in cases where:

- the user has indicated a willingness to risk losing the data
- the low memory save sequence will be used to safely save the storage object to a smaller file
- a previous commit returned STG_E_MEDIUMFULL but overwriting the existing data would provide enough space to commit changes to the storage object

Note that the commit operation checks for adequate space before any overwriting occurs. Thus, even with this value specified, if the commit operation fails due to space requirements, the old data will remain safe. The case where data loss can occur is when the commit operation fails due to some reason other than lack of space and the STGC_OVERWRITE value was specified.

STGC_ONLYIFCURRENT

Prevents multiple users of a storage object from overwriting one another's changes. The commit operation occurs only if there have been no changes to the saved storage object since the user most recently opened the storage object. Thus, the saved version of the storage object is the same version that the user has been editing. If other users have changed the storage object, the commit operation fails and returns the STG_E_NOTCURRENT value. You can override this behavior by calling the **Commit** method again using the STGC_DEFAULT value.

STGC_DANGEROUSLYCOMMITMERELYTODISKCACHE

Commits the changes to a write-behind disk cache, but does not save the cache to the disk. In a write-behind disk cache, the operation that writes to disk actually writes to a disk cache thus increasing performance. The cache is eventually written to the disk but usually not until after the write operation has already returned. The performance increase comes at the expense of an increased risk of losing data if a problem occurs before the cache is saved and the data in the cache is lost.

If you do not specify this value, then committing changes to root level storage objects is robust even if a disk cache is used. The two-phase commit process ensures that data is stored on the disk and not just to the disk cache.

Comments

You can specify STGC_DEFAULT or some combination of the other three values. Typically, you would use STGC_ONLYIFCURRENT to protect the storage object in cases where more than one user can edit the object simultaneously.

See Also

IStorage, **IStream**

STGFMT

The **STGFMT** enumeration values indicate the format of a storage object and are used in the **STATSTG** structure and in the **StgCreateDocFile** and **StgIsStorageFile** API functions.

Defined in the **IOLETypes** pseudo-interface (*oletyp.idl*).

```
typedef enum tagSTGFMT
{
     STGFMT_DOCUMENT  = 0,
     STGFMT_DIRECTORY = 1,
     STGFMT_CATALOG   = 2,
     STGFMT_FILE      = 3
} STGFMT;
```

Elements

STGFMT_DOCUMENT
Indicates a document format.

STGFMT_DIRECTORY
Indicates a directory format.

STGFMT_CATALOG
Indicates a catalog format.

STGFMT_FILE
Indicates a file format.

See Also

STATSTG, **StgCreateDocFile**, **StgIsStorageFile**

STGM

The **STGM** enumeration values are used in the storage and stream interfaces to indicate the conditions for creating and deleting the object and access modes for the object.

Defined in the ().

```
typedef enum tagSTGM
{
     STGM_READ = OF_READ,            // 0x0000
     STGM_WRITE = OF_WRITE,          // 0x0001
     STGM_READWRITE = OF_READWRITE,  // 0x0002

     STGM_SHARE_DENY_NONE = OF_SHARE_DENY_NONE,    // 0x0040
     STGM_SHARE_DENY_READ = OF_SHARE_DENY_READ,    // 0x0030
     STGM_SHARE_DENY_WRITE = OF_SHARE_DENY_WRITE,  // 0x0020
     STGM_SHARE_EXCLUSIVE = OF_SHARE_EXCLUSIVE,    // 0x0010

     STGM_DIRECT = 0x00000000,
     STGM_TRANSACTED = 0x00010000,

     STGM_CREATE = OF_CREATE       // 0x1000,
     STGM_CONVERT = 0x00020000,
     STGM_FAILIFTHERE = 0x00000000,

     STGM_PRIORITY = 0x00040000,

     STGM_DELETEONRELEASE = 0x04000000,

} STGM;
```

Elements

STGM_READ, STGM_WRITE, STGM_READWRITE

For stream objects, STGM_READ allows you to call the **IStream::Read** method. For storage objects, you can enumerate the storage elements and open them for reading.

STGM_WRITE lets you save changes to the object.

STGM_READWRITE is the combination of STGM_READ and STGM_WRITE.

STGM_SHARE_DENY_NONE, STGM_SHARE_DENY_READ, STGM_SHARE_DENY_WRITE, STGM_SHARE_EXCLUSIVE

STGM_SHARE_DENY_NONE specifies that subsequent openings of the object are not denied read or write access.

STGM_SHARE_DENY_READ prevents others from subsequently opening the object in STGM_READ mode. It is typically used on a root storage object.

STGM_SHARE_DENY_WRITE prevents others from subsequently opening the object in STGM_WRITE mode. This value is typically used to prevent unnecessary copies made of an object opened by multiple users. If this value is not specified, a snapshot copy must be made for each subsequent opening. Thus, you can improve performance by specifying this value.

STGM_SHARE_EXCLUSIVE is the combination of STGM_SHARE_DENY_READ and STGM_SHARE_DENY_WRITE.

STGM_DIRECT, STGM_TRANSACTED

In direct mode, each change to a storage element is written as it occurs. This is the default.

In transacted mode, changes are buffered and are written only if an explicit commit operation is called. The changes can be ignored by calling the **Revert** method in the **IStream** or **IStorage** interfaces. Transacted mode is not supported in the OLE-provided implementation of compound files.

STGM_CREATE, STGM_CONVERT, STGM_FAILIFTHERE

STGM_CREATE indicates that an existing storage object or stream should be removed before the new one replaces it. A new object is created when this flag is specified only if the existing object has been successfully removed.

STGM_CONVERT flag is used in three situations:

- when you are trying to create a storage object on disk but a file of that name already exists
- when you are trying to create a stream inside a storage object but a stream with the specified name already exists
- when you are creating a byte array object but one with the specified name already exists

STGM_CONVERT creates the new object while preserving existing data in a stream named **CONTENTS**. In the case of a storage object or a byte array, the old data is flattened to a stream regardless of whether the existing file or byte array currently contains a layered storage object.

STGM_FAILIFTHERE causes the create operation to fail if an existing object with the specified name exists. In this case, STG_E_FILEALREADYEXISTS is returned. STGM_FAILIFTHERE applies to both storage objects and streams.

STGM_PRIORITY

Opens the storage object with exclusive access to the most recently committed version. Thus, other users cannot commit changes to the object while you have it open in priority mode. You gain performance benefits for copy operations but you prevent others from committing changes. So you should limit the time you keep objects open in priority mode. You must specify STGM_DIRECT and STGM_READ with priority mode.

STGM_DELETEONRELEASE

Indicates that the underlying file is to be automatically destroyed when the root storage object is released. This capability is most useful for creating temporary files.

Comments

You can combine these flags but you can only choose one flag from each group of related flags.

See Also

IStream::Read.

STGMOVE

The **STGMOVE** enumeration values indicate whether a storage element is to be moved or copied. They are used in the **IStorage::MoveElementTo** method.

Defined in the **IOLETypes** pseudo-interface (*oletyp.idl*).

```
typedef enum tagSTGMOVE
{
     STGMOVE_MOVE = 0,
     STGMOVE_COPY = 1
} STGMOVE;
```

Elements

STGMOVE_MOVE
Indicates the method should move the data from the source to the destination.

STGMOVE_COPY
Indicates the method should copy the data from the source to the destination. A copy is the same as a move except the source element is not removed after copying the element to the destination. Copying an element on top of itself is undefined.

See Also

IStorage::MoveElementTo

STGTY

The **STGTY** enumeration values are used in the *type* member of the **STATSTG** structure to indicate the type of the storage element. A storage element is a storage object, a stream object, or a byte array object (LOCKBYTES).

Defined in the **IStream** interface (*stream.idl*).

```
typedef enum tagSTGTY
{
     STGTY_STORAGE    = 1,
     STGTY_STREAM     = 2,
     STGTY_LOCKBYTES  = 3,
     STGTY_PROPERTY   = 4
} STGTY;
```

Elements

STGTY_STORAGE
  Indicates that the storage element is a storage object.

STGTY_STREAM
  Indicates that the storage element is a stream object.

STGTY_LOCKBYTES
  Indicates that the storage element is a byte array object.

STGTY_PROPERTY
  Indicates that the storage element is a property storage object.

See Also

IStream, **STATSTG**

STREAM_SEEK

The **STREAM_SEEK** enumeration values specify the origin from which to calculate the new seek pointer location. They are used for the *dworigin* parameter in the **IStream::Seek** method. The new seek position is calculated using this value and the *dlibMove* parameter.

Defined in the **IStream** interface (*stream.idl*).

```
typedef enum tagSTREAM_SEEK
{
     STREAM_SEEK_SET = 0,
     STREAM_SEEK_CUR = 1,
     STREAM_SEEK_END = 2
} STREAM_SEEK;
```

Elements

STREAM_SEEK_SET
Indicates that the new seek pointer is an offset relative to the beginning of the stream. In this case, the *dlibMove* parameter is the new seek position relative to the beginning of the stream.

STREAM_SEEK_CUR
Indicates that the new seek pointer is an offset relative to the current seek pointer location. In this case, the *dlibMove* parameter is the signed displacement from the current seek position.

STREAM_SEEK_END
Indicates that the new seek pointer is an offset relative to the end of the stream. In this case, the *dlibMove* parameter is the new seek position relative to the end of the stream.

See Also

IStream::Seek

TYMED

The **TYMED** enumeration values indicate the type of storage medium being used in a data transfer. They are used in the **STGMEDIUM** or **FORMATETC** structures.

```
typedef [transmit_as(long)] enum tagTYMED
{
     TYMED_HGLOBAL   = 1;
     TYMED_FILE      = 2;
     TYMED_ISTREAM   = 4;
     TYMED_ISTORAGE  = 8;
     TYMED_GDI       = 16;
     TYMED_MFPICT    = 32;
     TYMED_ENHMF     = 64;
     TYMED_NULL      = 0
} TYMED;
```

Elements

TYMED_HGLOBAL
: The storage medium is a global memory handle (HGLOBAL). Allocate the global handle with the GMEM_SHARE flag. If the **STGMEDIUM** *punkForRelease* member is NULL, the destination process should use **GlobalFree** to release the memory.

TYMED_FILE
: The storage medium is a disk file identified by a path. If the **STGMEDIUM** *punkForRelease* member is NULL, the destination process should use **OpenFile** to delete the file.

TYMED_ISTREAM
: The storage medium is a stream object identified by an **IStream** pointer. Use **IStream::Read** to read the data. If the **STGMEDIUM** *punkForRelease* member is NULL, the destination process should use **IStream::Release** to release the stream component.

TYMED_ISTORAGE
: The storage medium is a storage component identified by an **IStorage** pointer. The data is in the streams and storages contained by this **IStorage** instance. If the **STGMEDIUM** *punkForRelease* member is NULL, the destination process should use **IStorage::Release** to release the storage component.

TYMED_GDI
: The storage medium is a GDI component (HBITMAP). If the **STGMEDIUM** *punkForRelease* member is NULL, the destination process should use **DeleteObject** to delete the bitmap.

TYMED_MFPICT
: The storage medium is a metafile (HMETAFILE). Use the Windows or WIN32 API functions to access the metafile's data. If the **STGMEDIUM** *punkForRelease* member is NULL, the destination process should use **DeleteMetaFile** to delete the bitmap.

TYMED_ENHMF
: The storage medium is an enhanced metafile. If the **STGMEDIUM** *punkForRelease* member is NULL, the destination process should use **DeleteEnhMetaFile** to delete the bitmap.

TYMED_NULL
: Indicates that no data is being passed.

Comments

During data transfer operations, a storage medium is specified. This medium must be released after the data transfer operation. The provider of the medium indicates its choice of ownership scenarios in the value it provides in the **STGMEDIUM** structure. A NULL value for the **IUNKNOWN** field indicates that the receiving body of code owns and can free the medium. A non-NULL pointer specifies that

ReleaseStgMedium can always be called to free the medium.

See Also

FORMATETC, **IAdviseSink**, **IDataObject**, **IOleCache**, **ReleaseStgMedium**, **STGMEDIUM**

USERCLASSTYPE

The **USERCLASSTYPE** enumeration constants indicate the different variants of the display name associated with a class of objects. They are used in the **IOleObject::GetUserType** method and the **OleRegGetUserType** function. These constants are defined in *ole2.h* and in the **IOleObject** interface (*oleobj.idl*).

```
typedef enum tagUSERCLASSTYPE
{
     USERCLASSTYPE_FULL    = 1,
     USERCLASSTYPE_SHORT   = 2,
     USERCLASSTYPE_APPNAME = 3,
} USERCLASSTYPE;
```

Elements

USERCLASSTYPE_FULL
Indicates the full type name of the class.

USERCLASSTYPE_SHORT
Indicates a short name (maximum of 15 characters) that is used for popup menus and the Links dialog box.

USERCLASSTYPE_APPNAME
Indicates the name of the application servicing the class and is used in the Result text in dialogs.

See Also

IOleObject::GetUserType, **OleRegGetUserType**

BindMoniker QuickInfo

Binds the specified moniker, that is, locates the object identified by the moniker, which activates the object if it isn't active already, and retrieves the specified interface pointer to that object.

```
HRESULT BindMoniker(
  LPMONIKER pmk,             //Pointer to the moniker to be bound
  DWORD grfOpt,              //Reserved
  REFIID iidResult,          //IID of interface pointer desired
  LPVOID FAR *ppvResult      //Receives interface pointer
 );
```

Parameters

pmk
Points to the moniker that is to be bound.

grfOpt
Reserved for future use; must be zero.

iidResult
Specifies the IID of the interface pointer desired.

ppvResult
Receives a pointer to the requested interface. If an error occurs, *ppvResult* is NULL; otherwise, the caller is responsible for calling **IUnknown::Release**.

Return Values

S_OK
Indicates that the moniker was successfully bound.

MK_E_NOOBJECT
Indicates that the object identifed by *pmk* could not be found. If *pmk* is a composite moniker, the object indicated is some intermediate object identified in the composite.

E_OUTOFMEMORY
Indicates insufficient memory.

E_INVALIDARG
Indicates one or more invalid arguments.

The return value can also be any of the error values returned by **IMoniker::BindToObject**.

Comments

The **BindMoniker** helper function packages the following functionality:

```
IBindCtx *pbc;
CreateBindCtx(0, &pbc);
pmk->BindToObject(pbc, NULL, riid, ppvObj);
pbc->Release();
```

BindMoniker is a helper function that is convenient for a moniker client to call to bind one moniker. A moniker client uses a moniker to acquire an interface pointer to the object that the moniker identifies. If you have several monikers to bind in quick succession, and if you know that those monikers will activate the same objects, it may be more efficient to call the **IMoniker::BindToObject** method directly so you can use the same bind context for all the monikers. See the **IBindCtx** interface for more information.

The most common examples of moniker clients are applications that act as link containers; that is, container applications that allow their documents to contain linked objects. However, link containers are a special case in that they generally do not need to make direct calls to **IMoniker** methods. Instead, they manipulate linked objects through the **IOleLink** interface; the default handler implements this interface and calls the appropriate **IMoniker** methods as needed.

See Also

CreateBindCtx, **IMoniker::BindToObject**

CLSIDFromProgID QuickInfo

Looks up a CLSID from a ProgID in the registry.

```
HRESULT CLSIDFromProgID(
    LPCOLESTR lpszProgID,        //Points to the ProgID whose CLSID is requested
    LPCLSID pclsid               //Receives a pointer to the created CLSID
  );
```

Parameters

lpszProgID
Points to the ProgID whose CLSID is requested.

pclsid
Receives a pointer to the location of the created CLSID on return.

Return Values

S_OK
Indicates the CLSID was created successfully.

CO_E_CLASSSTRING
Indicates the registered CLSID for the ProgID is invalid.

REGDB_E_WRITEREGDB
Indicates an error occurred writing to the registry.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

Given a ProgID, **CLSIDFromProgID** looks up its associated CLSID from a ProgID in the registry. If the ProgID cannot be found in the registry, **CLSIDFromProgID** creates an OLE 1 CLSID for it. Because of the restrictions placed on OLE 1 CLSID values, **CLSIDFromProgID** and **CLSIDFromString** are the *only* two functions that can be used to generate a CLSID for an OLE 1 object.

See Also

ProgIDFromCLSID

CLSIDFromString QuickInfo

Converts a string generated by the **StringFromCLSID** function back into the original CLSID.

```
HRESULT CLSIDFromString(
    LPOLESTR lpsz,        //Points to the string representation of the CLSID
    LPCLSID pclsid        //Receives a pointer to the CLSID on return
  );
```

Parameters

lpsz
Points to the string representation of the CLSID.

pclsid
Receives a pointer to the CLSID on return.

Return Values

S_OK
Indicates the CLSID was returned successfully.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

Because of the restrictions placed on OLE 1 CLSID values, **CLSIDFromProgID** and **CLSIDFromString** are the *only* two functions that can be used to generate a CLSID for an OLE 1 object.

See Also

CLSIDFromProgID, **StringFromCLSID**

CoBuildVersion QuickInfo

This function is obsolete.

CoCreateFreeThreadedMarshaler

Creates an object that implements special marshalling behavior. This is a helpler function that makes it easier to define objects with VTBLs that different apartment model threads can access directly.

```
HRESULT CoCreateFreeThreadedMarshaler(
   LPUNKNOWN punkOuter,          //Points to the stream from which the object is to be marshaled
   LPUNKNOWN                     //The interface requested from the unmarshaled object
punkMarshaler
  );
```

Parameters

punkOuter

Specifies a pointer to the controlling IUnknown of the object that is going to have the special marshaling behavior specified by the object this function creates.

punkMarshaler

[out] On return, contains a pointer to the private IUnknown of an object that implements this special marshaling behavior.

Return Values

S_OK

Indicates the marshaler was created successfully.

E_OUTOFMEMORY

Indicates that the marshaler object could not be created.

Comments

CoCreateFreeThreadedMarshaler is a helper API that makes it easier to define an object that allows direct access to its VTBL from multiple apartment-model threads of execution, and uses standard marshaling if a reference to the object is sent to another process.

When there is a request for a pointer to an object, the marshal context of the request is determined by the specified member of the MSHCTX enumeration. When the marshal context is MSHCTX_INPROC, meaning that the pointer to the object need only be marshaled across different threads in the same process, the marshal code only has to copy the pointer to the interface being marshaled into the marshaling stream. For any other marshaling context, use standard marshaling to complete the operation.

CoCreateFreeThreadedMarshaler implements code that defines this context-dependent behavior, and, on return, writes to its *punkMarshaler* parameter a pointer to the private unknown for a object that does this standard type of marshaling. The function then aggregates this marshaler object with the object that should have this marshaling behavior.

See Also

CoMarshalInterThreadInterfaceInStream, **CoGetInterfaceAndReleaseStream**

CoCreateGuid [QuickInfo]

Creates a GUID, a unique 128-bit integer used for CLSIDs and interface identifiers.

```
HRESULT CoCreateGuid(
   GUID   *pguid        //Receives a pointer to the GUID on return
  );
```

Parameter

pguid
Receives a pointer to the requested GUID on return.

Return Value

S_OK
Indicates the GUID was successfully created.

Win32 errors are returned by **UuidCreate** but wrapped as an HRESULT.

Comments

The **CoCreateGuid** function calls **UuidCreate** (documented in the *RPC Programmer's Guide and Reference*), which creates a GUID, a globally unique 128-bit integer used for CLSIDs and interface IDs. To a very high degree of certainty, this function returns a unique value - no other invocation, on the same or any other system (networked or not) should return the same value.

CoCreateInstance QuickInfo

Creates a single uninitialized object of the kind associated with the specified CLSID and returns any requested interface pointer. Call **CoCreateInstance** when you want to create a single object based on a CLSID. If you want to create multiple objects from a single class object, refer to the CoGetClassObject function.

STDAPI CoCreateInstance(
  REFCLSID *rclsid*,   //Class identifier
  LPUNKNOWN *pUnkOuter*,   //Object is or isn't part of an aggregate
  DWORD *dwClsContext*,   //Context for running executable code
  REFIID *riid*,   //Interface identifier
  LPVOID * *ppv*   //Pointer to storage of interface pointer
 );

Parameters

rclsid
Specifies the CLSID that will associate the correct data and code.

pUnkOuter
If **NULL**, indicates that the object is not being created as part of an aggregate. If non-**NULL**, points to the controlling unknown of the aggregate that will use the newly created object.

dwClsContext
Specifies the context in which the executable is to be run. The values are taken from the enumeration CLSCTX.

riid
Specifies the interface to be used to communicate with the object.

ppv
Points to where to return the pointer to the requested interface.

Return Values

S_OK
Indicates that an instance of the specified object class was successfully created.

REGDB_E_CLASSNOTREG
Indicates that a specified class is not registered in the registration database.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

CLASS_E_NOAGGREGATION
Indicates this class cannot be created as part of an aggregate.

Comments

The **CoCreateInstance** helper function connects to the class object associated with the specified CLSID, creates an uninitialized instance, and releases the class object. It encapsulates the following functionality:

```
CoGetClassObject(rclsid, dwClsContext, NULL, IID_IClassFactory,
      &pCF);
hresult = pCF->CreateInstance(pUnkOuter, riid, ppvObj)
pCF->Release();
```

It is convenient to use this function when you need to create only a single instance through a class object, and do not need to keep the class object around to create other instances. If you do, see the **CoGetClassObject** function.

See Also

CoGetClassObject, **IClassFactory::CreateInstance**

CoCreateStandardMalloc

This function is obsolete. The system-provided implementation is the only one available.

CoDisconnectObject QuickInfo

Disconnects all remote process connections being maintained on behalf of all the interface pointers on a specified object. Only the process that actually manages the object should call **CoDisconnectObject**.

```
STDAPI CoDisconnectObject(
    IUnknown * pUnk,          //Points to the object
    DWORD dwReserved          //Reserved for future use
  );
```

Parameters

pUnk
Points to the object to be disconnected. This does not necessarily have to be an **IUnknown** pointer. It can be a pointer to any interface supported by the object, as long as the interface is derived from **IUnknown**.

dwReserved
Reserved for future use; must be zero.

Return Values

S_OK
Indicates all connections to remote processes were successfully deleted.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

E_FAIL
Indicates an unspecified error occurred.

Comments

The **CoDisconnectObject** function is not used in the typical course of processing (clients of interfaces should use **IUnknown::Release**). The primary purpose of **CoDisconnectObject** is to give an application control over connections from other processes that were made to objects managed by the application. For example, suppose an OLE container loads an embedded object and then links are established between the embedded object and outside containers. If the container application wants to exit, it is not appropriate for these remote connections to keep the object active beyond the lifetime of its container. When the object's container closes, such links should be disconnected. To forcefully close any existing connection(s), the object's container can call **CoDisconnectObject**.

Before calling **CoDisconnectObject**, the container should first call **IOleObject::Close** for all OLE objects. The objects will send **OnClose** notifications to inform all clients of the impending closure.

Calling this function is a privileged operation, to be invoked only by the process in which the object is actually managed.

See Also

IOleObject::Close

CoDosDateTimeToFileTime QuickInfo

Converts the MS-DOS representation of the time and date to a **FILETIME** structure, which Win32 uses to determine the date and time.

```
BOOL CoDosDateTimeToFileTime(
    WORD nDosDate,              //The 16-bit MS-DOS date
    WORD nDosTime,              //The 16-bit MS-DOS time
    FILETIME * lpFileTime       //Pointer to the FILETIME structure
  );
```

Parameters

nDosDate
Specifies the 16-bit MS-DOS date.

nDosTime
Specifies the 16-bit MS-DOS time.

lpFileTime
Points to the **FILETIME** structure.

Return Values

TRUE
Indicates the **FILETIME** structure was created successfully.

FALSE
Indicates the **FILETIME** structure was not created successfully, probably because of invalid arguments.

Comments

The **FILETIME** structure and the **CoDosDateTimeToFileTime** and **CoFileTimeToDosDateTime** functions are part of the Win32 API definition. They are provided for compatibility in all OLE implementations, but are redundant on Win32 platforms.

MS-DOS records file dates and times as packed 16-bit values. An MS-DOS date has the following format:

Bits	**Contents**
0-4	Days of the month (1-31).
5-8	Months (1 = January, 2 = February, and so forth).
9-15	Year offset from 1980 (add 1980 to get actual year).

An MS-DOS time has the following format:

Bits	**Contents**
0-4	Seconds divided by 2.
5-10	Minutes (0-59).
11-15	Hours (0-23 on a 24-hour clock).

See Also

CoFileTimeToDosDateTime, **CoFileTimeNow**

CoFileTimeNow QuickInfo

Returns the current time as a **FILETIME** structure.

```
HRESULT CoFileTimeNow(
   FILETIME   * lpFileTime        //Points to where to return the FILETIME structure
  );
```

Parameter

lpFileTime
  Points to where to return the **FILETIME** structure.

Return Values

S_OK
  Indicates the current time was converted to a **FILETIME** structure.

E_OUTOFMEMORY
  Out of memory.

E_INVALIDARG
  Indicates *lpFileTime* is invalid.

E_UNEXPECTED
  Indicates an unexpected error occurred.

E_FAIL
  Indicates the current time was not converted to a **FILETIME** structure.

See Also

CoDosDateTimeToFileTime, **CoFileTimeToDosDateTime**

CoFileTimeToDosDateTime

Converts a **FILETIME** into MS-DOS date and time values.

```
BOOL CoFileTimeToDosDateTime(
   FILETIME   * lpFileTime,       //Points to the FILETIME structure to be converted
   LPWORD lpDosDate,              //Points to the 16-bit MS-DOS date
   LPWORD lpDosTime               //Points to the 16-bit MS-DOS time
  );
```

Parameters

lpFileTime
Points to the **FILETIME** structure to be converted.

lpDosDate
Points to the 16-bit MS-DOS date.

lpDosTime
Points to the 16-bit MS-DOS time.

Return Values

TRUE
Indicates the **FILETIME** structure was converted successfully.

FALSE
Indicates the **FILETIME** structure was not converted successfully.

Comments

This is the inverse of the operation provided by the **CoDosDateTimeToFileTime** function.

See Also

CoDosDateTimeToFileTime, **CoFileTimeNow**

CoFreeAllLibraries QuickInfo

Frees all the DLLs that have been loaded with the **CoLoadLibrary** function, regardless of whether they are currently in use.

void CoFreeAllLibraries();

Comments

The OLE Component Object Model(COM) library maintains a list of loaded DLLs for each process that **CoFreeAllLibraries** uses to unload the libraries. The **CoUninitialize** function calls **CoFreeAllLibraries** internally, so OLE applications usually have no need to call this function directly.

See Also

CoLoadLibrary, **CoFreeLibrary**, **CoFreeUnusedLibraries**, **CoUninitialize**

CoFreeLibrary QuickInfo

Frees a library that was previously loaded with the *bAutoFree* parameter of the **CoLoadLibrary** function set to FALSE.

```
void CoFreeLibrary(
    HINSTANCE  hInst      //The handle of the library module to be freed
  );
```

Parameter

hInst

Specifies the handle to the library module to be freed, as returned by **CoLoadLibrary**.

Comments

The **CoFreeLibrary** function should be called to free a library that is to be freed explicitly. This is established when the library is loaded with the *bAutoFree* parameter of **CoLoadLibrary** set to FALSE. It is illegal to free a library explicitly when the corresponding **CoLoadLibrary** call specifies that it be freed automatically (the *bAutoFree* parameter is set to TRUE).

See Also

CoFreeAllLibraries, **CoFreeUnusedLibraries**, **CoLoadLibrary**

CoFreeUnusedLibraries QuickInfo

Unloads any DLLs that have been loaded with the *bAutoFree* parameter of the **CoLoadLibrary** function set to TRUE, but are no longer in use.

void CoFreeUnusedLibraries();

Comments

Applications can call **CoFreeUnusedLibraries** periodically to free resources. It is most efficient to call it either at the top of a message loop or in some idle-time task. **CoFreeUnusedLibraries** internally calls **DllCanUnloadNow** for DLLs that implement and export that function.

See Also

CoFreeLibrary, **CoFreeUnusedLibraries**, **CoLoadLibrary**, **DLLCanUnloadNow**

CoGetClassObject QuickInfo

Provides the caller with a pointer to an interface on a class object associated with a specified CLSID. The **CoGetClassObject** function transparently locates, and if necessary, dynamically loads the executable code required to do this.

Call **CoGetClassObject** when you want to create multiple objects through a class object for which there is a CLSID in the system registry. You would then call **IClassFactory::CreateInstance** to create an uninitialized object. It is not always necessary to go through this process. To create a single object, call instead the **CoCreateInstance** function, which encapsulates connecting to the class object, creating the instance, and releasing the class object. OLE also provides many other ways to create an object in the form of numerous helper functions and interface member functions whose function is to create objects of a single type and provide a pointer to an interface on that object.

```
STDAPI CoGetClassObject(
  REFCLSID rclsid,              //CLSID associated with the class object
  DWORD dwClsContext,           //Context for running executable code
  LPVOID pvReserved,            //Must be NULL
  REFIID riid,                  //Interface identifier
  LPVOID * ppv                  //On return, pointer to location of interface pointer
 );
```

Parameters

rclsid
Specifies the CLSID that will associate the correct data and code.

dwClsContext
Specifies the context in which the executable code is to be run. For information on the context values and their use, see the **CLSCTX** enumeration.

pvReserved
Reserved for future use. Must be NULL.

riid
Specifies the interface to be used to communicate with the class object. This interface is almost always **IClassFactory** (represented by the *riid* **IID_IClassFactory**).

ppv
Points to where the resulting interface pointer is to be stored.

Return Values

S_OK
Location and connection to the specified class object was successful.

REGDB_E_CLASSNOTREG
CLSID is not properly registered.

E_NOINTERFACE
The object pointed to by *ppv* does not support the interface identified by *riid*.

REGDB_E_READREGDB
Error reading the registration database.

CO_E_DLLNOTFOUND
In process DLL or handler DLL not found (depends on context).

CO_E_APPNOTFOUND
EXE not found (CLSCTX_LOCAL_SERVER only).

E_ACCESSDENIED
General access failure (returned from **LoadLib/CreateProcess**).

CO_E_ERRORINDLL

EXE has error in image.

CO_E_APPDIDNTREG
EXE was launched, but it didn't register class object (may or may not have shutdown).

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

E_NOINTERFACE
The **QueryInterface** on the class object returned E_NOINTERFACE.

Comments

A class object in OLE is an intermediate object that supports an interface that permits operations common to a group of objects. The objects in this group are instances derived from the same object definition represented by a single CLSID. Usually, the interface on a class object is **IClassFactory**, through which you can create object instances of a given definition (class).

A call to **CoGetClassObject** creates, initializes, and gives the caller access (through an interface specified with the *riid* parameter) to the class object. The class object is the one associated with the CLSID that you specify in the *rclsid* parameter. Details of how code and data are located and associated are transparent to the caller, as is the dynamic loading of associated code not already loaded. There are two places to find a CLSID for a given object definition:

- The registry holds an association between CLSIDs and file suffixes, and between CLSIDs and file signatures for determining the class of an object.
- When an object is saved to persistent storage, its CLSID is stored with its data.

To create and initialize embedded or linked OLE document objects, it is not necessary to call **CoGetClassObject** directly. Instead, call one of the **OleCreate** or **OleCreate***Xxx* helper functions. These functions encapsulate the entire object instantiation and initialization process, and call, among other functions, **CoGetClassObject**.

The *riid* parameter specifies the interface the client will use to communicate with the class object. In most cases, this interface is **IClassFactory**. This provides access to the **IClassFactory::CreateInstance** member function, through which the caller can then create an uninitialized object of the kind specified in its implementation. All object definitions registered in the system with a CLSID must implement **IClassFactory**.

In rare cases, however, you may want to specify some other interface that defines operations common to a set of objects. For example, in the way OLE implements monikers, the interface on the class object is **IParseDisplayName**, used to transform the display name of an object into a moniker.

The *dwClsContext* parameter specifies the execution context, allowing one CLSID to be associated with different pieces of code in different execution contexts. The **CLSCTX** enumeration , defined in COMPOBJ.H, specifies the available context flags. **CoGetClassObject** consults (as appropriate for the context indicated) both the registration database and the class objects that are currently registered by calling the **CoRegisterClassObject** function.

See Also

CoRegisterClassObject, **CoRevokeClassObject**, **OleLoad**, **CLSCTX**

CoGetCurrentProcess QuickInfo

Returns a value that is unique to the current thread. It can be used to avoid PROCESSID reuse problems.

DWORD CoGetCurrentProcess();

Return Value

DWORD value
    Indicates a unique value for the current thread that can be used to avoid PROCESSID reuse problems.

Comments

The **CoGetCurrentProcess** function returns a value that is effectively unique, because it is not used again until 2 (32) more threads have been created on the current workstation or until the workstation is rebooted.

Using the value returned from a call to **CoGetCurrentProcess** can help you maintain tables that are keyed by threads or in uniquely identifying a thread to other threads or processes.

Using the value returned by **CoGetCurrentProcess** is more robust than using the HTASK task handle value returned by the Win32 function **GetCurrentTask**, because Windows task handles can be reused relatively quickly when a window's task dies.

CoGetInterfaceAndReleaseStream

Unmarshals a buffer containing an interface pointer and releases the stream when an interface pointer has been marshalled from another thread to the calling thread.

```
HRESULT CoGetInterfaceAndReleaseStream(
   LPSTREAM * ppStm,              //Points to the stream from which the object is to be marshalled
   REFIID riid,                   //The interface requested from the unmarshalled object
   LPVOID * ppv                   //On return, location of the interface pointer
  );
```

Parameters

pstm
   Points to the stream containing the interface to be unmarshaled.

riid
   Specifies the interface requested from the unmarshaled object.

ppv
   [Out] On return, points to the location of the unmarshaled interface pointer.

Return Values

S_OK
   Indicates the output interface was unmarshaled and the stream was released.

E_INVALIDARG
   Indicates that input arguments are invalid.

Other results from **CoUnmarshalInterface**

Comments

CoGetInterfaceAndReleaseStream is a companion helper API to **CoMarshalInterThreadInterfaceInStream**, reversing the result of the latter.   It unmarshals the buffer and releases the stream that contained the interface. If the unmarshaling fails, the stream is still released because there is no effective way to recover from a failure of this kind.

See Also

CoMarshalInterThreadInterfaceInStream

CoGetMalloc QuickInfo

Retrieves the default OLE task memory allocator (a pointer to the system implementation of the **IMalloc** interface) so applications can use it to manage memory.

```
HRESULT CoGetMalloc(
   DWORD dwMemContext,        //Indicates if memory is private or shared
   LPMALLOC * ppMalloc        //Receives pointer to memory allocator on return
  );
```

Parameters

dwMemContext
Indicates this is reserved; the value must be 1.

ppMalloc
Receives a pointer to the memory allocator on return.

Return Values

S_OK
Indicates the allocator was retrieved successfully.

E_INVALIDARG
Indicates either *dwMemContext* is not equal to 1, or *ppMalloc* is an invalid out pointer.

E_OUTOFMEMORY
Inidcates pointer wasn't returned because the system is out of memory.

Comments

The pointer to the **IMalloc** interface pointer received through the *ppMalloc* parameter cannot be called from a remote process—each process must have its own allocator.

See Also

IMalloc, **CoTaskMemAlloc**

CoGetMarshalSizeMax QuickInfo

Retrieves an upper bound on the number of bytes needed to marshal the specified interface pointer on the specified object.

```
STDAPI CoGetMarshalSizeMax(
    ULONG *pulSize,              //Receives maximum size
    REFIID riid,                 //Identifies interface to be marshalled
    IUnknown * pUnk,             //Interface pointer to be marshaled
    DWORD dwDestContext,         //Specifies destination process
    LPVOID pvDestContext,        //Reserved for future use
    DWORD mshlflags              //Specifies reason for marshalling
  );
```

Parameters

pulSize
Receives the maximum marshal size; a value of zero means that the size of the data is unknown.

riid
Specifies the IID of the interface pointer to be marshalled. This interface must be derived from the **IUnknown** interface.

pUnk
Indicates the interface pointer to be marshalled; can be NULL.

dwDestContext
Specifies the destination context, that is, the process in which the unmarshaling will be done. The legal values for *dwDestContext* are taken from the enumeration **MSHCTX**.

pvDestContext
Indicates reserved for use with future **MSHCTX** values. This must be set to NULL.

mshlflags
Specifies why marshalling is taking place. The legal values for *mshlflags* are taken from the enumeration **MSHLFLAGS**.

Return Values

S_OK
Indicates the upper bound was returned successfully.

CO_E_NOTINITIALIZED
Indicates the **CoInitialize** or **OleInitialize** function was not called on the current thread before this function was called.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

You typically call this function before calling the **CoMarshalInterface** function. See the description of that function for information on calling these functions.

See Also

CoMarshalInterface, **IMarshal::GetMarshalSizeMax**

CoGetStandardMarshal QuickInfo

Returns an **IMarshal** pointer to the system's default marshalling implementation. Use this implementation to create a proxy for the specified interface pointer in another process.

```
STDAPI CoGetStandardMarshal(
    REFIID riid,                  //Identifies interface being marshalled
    IUnknown * pUnk,              //Interface pointer being marshalled
    DWORD dwDestContext,          //Specifies destination process
    LPVOID pvDestContext,         //Reserved for future use
    DWORD mshlflags,              //Specifies reason for marshalling
    LPMARSHAL * ppMarshal         //Receives pointer to standard marshaller
  );
```

Parameters

riid
: Specifies the IID of the interface pointer to be marshalled. This interface must be derived from the **IUnknown** interface.

pUnk
: Indicates interface pointer to be marshalled. This interface pointer does not have to have the same IID specified by the *riid* parameter; it can be a pointer to any **IUnknown**-derived interface on the object. The standard marshaller will call the **QueryInterface** function on this pointer requesting the interface specified by *riid*.

dwDestContext
: Specifies the destination context, that is, the process in which the unmarshalling will be done. The legal values for *dwDestContext* are taken from the enumeration **MSHCTX**.

pvDestContext
: Reserved for use with future **MSHCTX** values.

mshlflags
: Specifies why marshalling is taking place. The legal values for *mshlflags* are taken from the enumeration **MSHLFLAGS**.

ppMarshal
: Receives the standard marshaller.

Return Values

S_OK
: Indicates that the **IMarshal** instance was returned successfully.

CO_E_NOTINITIALIZED
: Indicates that the **CoInitialize** or **OleInitialize** function was not called on the current thread before this function was called.

E_OUTOFMEMORY
: Out of memory.

E_INVALIDARG
: Indicates one or more arguments are invalid.

E_UNEXPECTED
: Indicates an unexpected error occurred.

E_FAIL
: Indicates an unspecified error.

Comments

You typically do not need to call this function. If you are performing custom marshalling (that is, writing your own implementation of **IMarshal**), you can delegate certain destination contexts to the standard marshaller. You should delegate any destination contexts that you don't fully understand or don't want to handle. The standard marshaller returned by this function is the one used by OLE when an object does not support the **IMarshal** interface.

See Also

IMarshal

CoGetTreatAsClass [QuickInfo]

Returns the CLSID of an object that can emulate the specified object.

```
HRESULT CoGetTreatAsClass(
    REFCLSID clsidOld,        //CLSID of object that is being emulated
    LPCLSID pclsidNew         //Points to location of CLSID for object that can emulate clsidOld
  );
```

Parameters

clsidOld
Specifies the CLSID of the object that can be emulated or treated as an object with a different CLSID.

pclsidNew
Points to the location where the CLSID that can emulate *clsidOld* objects is retrieved. This parameter cannot be NULL. If there is no emulation information for *clsidOld* objects, then the *clsidOld* parameter is returned.

Return Values

S_OK
Indicates that a new CLSID was successfully returned.

S_FALSE
Indicates that there is no emulation information for the *clsidOld* parameter and that the **pclsidNew* parameter is set to *clsidOld*.

REGDB_E_READREGDB
Indicates an error reading the registration database.

See the **CLSIDFromString** function for other possible errors.

Comments

This function returns the **TreatAs** entry in the registration database for the specified object. If there is no **TreatAs** entry for the specfied object, this function returns the CLSID of the original object (*clsidOld*).

Use this function to obtain the CLSID of an object application that can emulate the specified object. The end-user can request that a specified object be treated as an object of a different class, or a setup program can register one class of objects to be treated as objects of a different class. For example, a spreadsheet application may be able to read and write spreadsheets from a different application. The first application can then emulate the objects of the second by treating them as its own.

In the first case, the end-user makes the request through the Convert To dialog box. For example, the end-user might wish to edit a spreadsheet created by one application using a different application that can read and write the spreadsheet format of the original application. In the second case, an application's setup program can specify to activate objects of one class as objects of a different class. For example, when the application is updated, the objects created with the earlier version can be activated and treated as objects of the new version.

In either case, the object application or the setup program calls the **CoTreatAsClass** function to set the **TreatAs** entry in the registration database. Subsequently, all objects of the original CLSID are activated and treated as objects of the second CLSID.

See Also

CoTreatAsClass

CoInitialize QuickInfo

The **CoInitialize** function initializes the Component Object Model(COM) library. You must initialize the library before you can call its functions. Applications must call **CoInitialize** before they make any other COM library calls with two exceptions: the **CoGetMalloc** function, and memory allocation calls.

```
HRESULT CoInitialize(
  LPVOID pvReserved        //Reserved, must be NULL
 );
```

Parameter

pvReserved
In 32-bit OLE, this parameter must be NULL. The 32-bit version of OLE does not support applications replacing OLE's allocator and if the parameter is not NULL, **CoInitialize** returns E_INVALIDARG.

Return Values

S_OK
Indicates the library was initialized successfully.

S_FALSE
Indicates that the library is already initialized or that it could not release default allocator.

E_OUTOFMEMORY
Indicates that it was unable to initialize because the system is out of memory.

E_INVALIDARG
Indicates the argument is invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

You need to call this before you call any of the OLE library functions unless you call the **OleInitialize** function, which calls **CoInitialize** internally.

Typically, **CoInitialize** is called only once in the process that uses the OLE library. There can be multiple calls, but subsequent calls return S_FALSE. To close the library gracefully, each successful call to **CoInitialize**, including those that return S_FALSE, *must* be balanced by a corresponding call to the **CoUninitialize** function.

See Also

CoInitialize, **OleInitialize**

CoIsHandlerConnected QuickInfo

Determines if a remote object is connected to its corresponding object.

```
BOOL CoIsHandlerConnected(
    LPUNKNOWN pUnk          //Points to the remoted object
  );
```

Parameter

pUnk
Specifies the object in question.

Return Values

TRUE
Indicates the object either is not remote or is remote and is still valid (it is still connected to its remote handler).

FALSE
Indicates the object is remote and is invalid (no longer connected to its remote handler).

Comments

The **CoIsHandlerConnected** function determines the validity of a remote object specified by a pointer to its controlling unknown interface (the *pUnk* parameter). If the specified remote object is remote and is still connected to its remote handler, or is not a remote object, the function returns TRUE. If the specified object is still remote but is not connected to its remote handler, the function returns FALSE, and the caller should respond by releasing the object.

CoIsOle1Class QuickInfo

Determines if a given CLSID represents an OLE 1 object. This is one of several OLE compatibility functions. You can use these functions to determine if an object class is from OLE 1 and to convert objects between OLE 1 and OLE 2 storage formats.

```
BOOL CoIsOle1Class(
   REFCLSID rclsid,          //CLSID to check
  );
```

Parameter

rclsid
Indicates the reference to the CLSID to check.

Return Values

S_TRUE
Indicates that the CLSID refers to an OLE 1 object.

S_FALSE
Indicates that the CLSID does not refer to an OLE 1 object.

Comments

The **CoIsOle1Class** function is useful for preventing linking to embedded OLE 1 objects within a container. Once a container has determined that copied data represents an embedded object, **CoIsOle1Class** can be called to determine whether the embedded object is an OLE 1 object. If **CoIsOle1Class** returns S_TRUE, the container does not offer Link Source.

See Also

OleConvertIStorageToOLESTREAM, **OleConvertIStorageToOLESTREAMEx**, **OleConvertOLESTREAMToIStorage**, **OleConvertOLESTREAMToIStorageEx**

CoLoadLibrary QuickInfo

Loads a specific DLL into the caller's process. The **CoGetClassObject** function calls **CoLoadLibrary** internally; applications should not call it directly.

```
HINSTANCE CoLoadLibrary(
   LPOLESTR lpszLibName,          //Points to the name of the library to be loaded
   BOOL bAutoFree                 //Indicates whether library is automatically freed
  );
```

Parameters

lpszLibName
Points to the name of the library to be loaded. The use of this name is the same as in the Win32 function **LoadLibrary**.

bAutoFree
If TRUE, indicates that this library is freed when it is no longer needed, through a call to either the **CoFreeUnusedLibraries** or **CoUninitialize** functions. If FALSE, the library should be explicitly freed with the **CoFreeLibrary** function.

Return Values

Module Handle
Indicates handle of the loaded library.

NULL
Indicates library could not be loaded.

Comments

The **CoLoadLibrary** function is called internally by the **CoGetClassObject** function when the class context (CLSCTX) indicates a DLL. **CoLoadLibrary** loads a DLL specified by the *lpszLibName* parameter into the process that called **CoGetClassObject**. Containers should not call **CoLoadLibrary** directly.

Internally, a reference count is kept on the loaded DLL, by using **CoLoadLibrary** to increment the count and the **CoFreeLibrary** function to decrement it.

CoFreeAllLibraries, **CoFreeLibrary**, **CoFreeUnusedLibraries**, **CoGetClassObject**

CoLockObjectExternal QuickInfo

Called either to lock an object to ensure that it stays in memory, or to release such a lock. Call **CoLockObjectExternal** to place a strong lock on an object to ensure that it stays in memory.

```
STDAPI CoLockObjectExternal(
  IUnknown * pUnk,              //Pointer to object to be locked or unlocked
  BOOL fLock,                   //TRUE = lock, FALSE = unlock
  BOOL fLastUnlockReleases      //TRUE = release all pointers to object
 );
```

Parameters

pUnk
Points to the object (through its **IUnknown** interface) to be locked or unlocked.

fLock
Specifies whether the object is to be locked or released. Specifying TRUE holds a reference to the object (keeping it in memory), locking it independently of external or internal **AddRef/Release** operations, registrations, or revocations. If *fLock* is TRUE, *fLastLockReleases* is ignored. FALSE releases a lock previously set with a call to this function.

fLastUnlockReleases
Specifies whether a given lock is the last reference that is supposed to keep an object alive. If it is, TRUE releases all pointers to the object (there may be other references that are not supposed to keep it alive).

Return Values

S_OK
Indicates the object was locked successfully.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

The **CoLockObjectExternal** function prevents the reference count of an object from going to zero, thereby "locking" it into existence until the lock is released. The same function (with different parameters) releases the lock. The lock is implemented by having the system call **IUnknown::AddRef** on the object. The system then waits to call **IUnknown::Release** on the object until a later call to **CoLockObjectExternal** with *fLock* set to FALSE. This function can be used to maintain a reference count on the object on behalf of the end-user, because it acts outside of the object, as does the user.

The **CoLockObjectExternal** function *must* be called in the process in which the object actually resides (the EXE process, not the process in which handlers may be loaded).

Calling **CoLockObjectExternal** sets a strong lock on an object. A strong lock keeps an object in memory, while a weak lock does not. Strong locks are required, for example, during a silent update to an OLE embedding. The embedded object's container must remain in memory until the update process is complete. There must also be a strong lock on an application object to ensure that the application stays alive until it has finished providing services to its clients. All external references place a strong reference lock on an object.

The **CoLockObjectExternal** function is typically called in the following situations:

- Object applications should call **CoLockObjectExternal** with both *fLock* and *fLastLockReleases* set to TRUE when they become visible. This call creates a strong lock on behalf of the user. When the application is closing, free the lock with a call to **CoLockObjectExternal**, setting *fLock* to FALSE and *fLastLockReleases* to TRUE.

- A call to **CoLockObjectExternal** on the application object can also be used in the implementation of **IOleContainer::LockContainer**.

There are several things to be aware of when you use **CoLockObjectExternal** in the implementation of **IOleContainer::LockContainer**. An embedded object would call **IOleContainer::LockContainer** on its container to keep it running (to lock it) in the absence of other reasons to keep it running. When the embedded object becomes visible, the container must weaken its connection to the embedded object with a call to the **OleSetContainedObject** function, so other connections can affect the object.

Unless an application manages all aspects of its application and document shutdown completely with calls to **CoLockObjectExternal**, the container must keep a private lock count in **IOleContainer::LockContainer** so that it exits when the lock count reaches zero and the container is invisible. Maintaining all aspects of shutdown, and thereby avoiding keeping a private lock count, means that **CoLockObjectExternal** should be called whenever one of the following conditions occur:

- A document is created and destroyed or made visible or invisible.
- An application is started and shut down by the user.
- A pseudo-object is created and destroyed.

For debugging purposes, it may be useful to keep a count of the number of external locks (and unlocks) set on the application.

Note The end-user has explicit control over the lifetime of an application, even if there are external locks on it. That is, if a user decides to close the application (File, Exit), it *must* shut down. In the presence of external locks (such as the lock set by **CoLockObjectExternal**), the application can call the **CoDisconnectObject** function to force these connections to close prior to shutdown.

See Also

IOleContainer::LockContainer, **OleSetContainedObject**

CoMarshalHresult QuickInfo

Marshals an HRESULT to the specified stream so it can be unmarshaled using the **CoUnmarshalHresult** function.

```
STDAPI CoMarshalHresult(
    IStream * pStm,           //Stream to be used for marshalling
    HRESULT hresult           //HRESULT to be marshalled
  );
```

Parameters

pStm
Points to the stream used for marshalling.

hresult
Specifies the HRESULT in the originating process.

Return Values

S_OK
Indicates the HRESULT was marshalled successfully.

STG_E_INVALIDPOINTER
Indicates bad pointer passed in for *pStm*.

STG_E_MEDIUMFULL
Indicates the medium is full.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

You typically do not need to call this function. If you are performing custom marshalling (that is, writing your own implementation of **IMarshal**) and you need to marshal an HRESULT from one process to another, either as a parameter or a return code, you must call this function. An HRESULT is process-specific, so an HRESULT valid in one process might not be valid in another.

Note that the HRESULT returned by **CoMarshalHresult** indicates the success or failure of the marshalling process and is unrelated to the HRESULT parameter.

See Also

CoUnmarshalHresult

CoMarshalInterface QuickInfo

Marshals an interface pointer into the specified stream. Marshalling consists of writing the appropriate data into the stream so the **CoUnmarshalInterface** function can use that data to initialize a proxy object in another process. **CoMarshalInterface** can marshal only interfaces derived from **IUnknown**.

```
STDAPI CoMarshalInterface(
    IStream *pStm,              //Stream used for marshalling
    REFIID riid,                //Identifies interface being marshalled
    IUnknown *pUnk,             //Interface pointer being marshalled
    DWORD dwDestContext,        //Specifies destination process
    void *pvDestContext,        //Reserved for future use
    DWORD mshlflags             //Specifies reason for marshalling
  );
```

Parameters

pStm
Points to the stream to be used during marshalling.

riid
Specifies the IID of the interface pointer being marshaled. This interface must be derived from the **IUnknown** interface.

pUnk
Points to the interface pointer to be marshalled.

dwDestContext
Specifies the destination context, which is the process in which the unmarshalling will be done. The legal values for *dwDestContext* are taken from the enumeration **MSHCTX**.

pvDestContext
Indicates reserved for future use; must be set to zero by the caller.

mshlflags
Specifies why marshalling is taking place. The legal values for *mshlflags* are taken from the **MSHLFLAGS** enumeration.

Return Values

S_OK
Indicates the interface pointer was marshalled successfully.

CO_E_NOTINITIALIZED
Indicates the **CoInitialize** or **OleInitialize** function was not called on the current thread before this function was called.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

E_FAIL
Indicates an unspecified error.

IStream errors
See the **IStream** interface for information on possible stream access errors.

Comments

The main steps that **CoMarshalInterface** performs are the following:

1. The function checks whether custom marshaling is supported by calling the **QueryInterface** function on *pUnk* and asking for an **IMarshal** interface pointer. If the object does not support custom marshalling, the function gets an **IMarshal** interface pointer to the system's standard marshalling implementation.
2. Using whichever **IMarshal** interface pointer it has acquired, the function calls **IMarshal::GetUnmarshalClass** to get the CLSID of the unmarshaller (the proxy to be created). Then it writes the CLSID to the stream.
3. The function calls **IMarshal::MarshalInterface** to marshal the interface pointer.

You typically do not need to call this function. OLE calls it from within interface proxies or stubs that marshal an interface pointer.

The only situation in which you might need to call this function is if you are performing custom marshalling (that is, writing your own implementation of **IMarshal**). Your implementation of **IMarshal::MarshalInterface** writes to a stream the data needed to initialize a custom proxy in the destination context. If your custom proxy will need access to a private object, you can include an interface pointer to that object as part of the data you write to the stream. In such situations, if you want to use standard marshalling when passing the interface pointer, you can call **CoMarshalInterface** to do so; this is an example of using standard marshaling within your implementation of custom marshaling.

See Also

CoUnmarshalInterface, **IMarshal::MarshalInterface**

CoMarshalInterThreadInterfaceInStream

Passes streams containing interfaces between different threads, and is a helper that allows you to pass interface pointers easily and correctly between threads.

```
HRESULT CoMarshalInterThreadInterfaceInStream(
   REFIID riid,                    //Interface exposed by the object to be marshaled
   LPUNKNOWN pUnk,                 //Points to the object to be marshaled
   LPSTREAM * ppStm                //Output pointer to the stream interface
  );
```

Parameters

riid
Specifies the interface that is to be marshalled.

pUnk
Points to the **IUnknown** of the object to be marshalled, thus specifying the object.

ppStm
[Out] On return, points to the stream containing the interface .

Return Values

S_OK
Output stream contains marshalled interface.

E_OUTOFMEMORY
There was not enough memory to complete the call.

E_INVALIDARG
One or more arguments are invalid.

Comments

CoMarshalInterThreadInterfaceInStream is a helper function that facilitates passing streams containing interfaces between threads, although you could implement it yourself from existing APIs if desired. It creates a stream and passes it to **CoMarshalInterface**, then passes the pointer to that stream back to the caller. The stream it returns is guaranteed to behave correctly when different threads access it. The receiving thread can then call the corresponding helper function **CoGetInterfaceAndReleaseStream** to get the interface pointer and release the stream object.

See Also

CoGetInterfaceAndReleaseStream

CoRegisterClassObject QuickInfo

Registers an EXE class object with OLE so that other applications can connect to it. EXE object applications should call **CoRegisterClassObject** on startup. It can also be used to register internal objects for use by the same EXE or other code (such as DLLs) that the EXE uses.

```
STDAPI CoRegisterClassObject(
    REFCLSID rclsid,              //Class identifier to be registered
    IUnknown * pUnk,              //Pointer to the class object
    DWORD dwClsContext,           //Context for running executable code
    DWORD flags,                  //How to connect to the class object
    LPDWORD * lpdwRegister        //Pointer to the value returned
  );
```

Parameters

rclsid
Specifies the CLSID registered.

pUnk
Points to the class object whose availability is being published.

dwClsContext
Specifies the context in which the executable code is to be run. For information on these context values, see the **CLSCTX** enumeration.

flags
Determines how connections are made to the class object. For information on these flags, see the **REGCLS** enumeration.

lpdwRegister
Points to the value returned by **CoRegisterClassObject** that identifies the class object; later used by the **CoRevokeClassObject** function to revoke the registration.

Return Values

S_OK
Indicates the class object was registered successfully.

CO_E_OBJISREG
Indicates already registered in the class object table.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

Only EXE object applications call **CoRegisterClassObject**. Servers that can create and support more than one kind of object (such as multiple types of embeddable objects) must also register each of class of object it supports. Object handlers or DLL object applications do not call this function; instead, they must implement and export the **DllGetClassObject** function.

When a multiple-use EXE object application is started, it must create a class object with the **IClassFactory** interface on it and register it with a call to **CoRegisterClassObject**. Object applications that support several different object definitions must allocate a different class object for each.

Multiple registrations of the same class object are independent and do not produce an error. Each subsequent registration yields a unique key in *lpdwRegister*.

Multiple document interface (MDI) applications must register their class objects. Single document interface (SDI) applications must register their class objects only if they can be started by means of the **/Embedding** switch.

The server for a class object should call **CoRevokeClassObject** to revoke the class object when all of the following are true:

- There are no existing instances of the object definition
- There are no locks on the class object
- The application providing services to the class object is not under user control (not visible to the user on the display).

After the class object is revoked, when its reference count reaches zero, the class object can be destroyed, allowing the application to exit.

For information on the *flags* parameter, refer to the **REGCLS** enumeration.

CoGetClassObject, **CoRevokeClassObject**, **DllGetClassObject**, **REGCLS**, **CLSCTX**

CoRegisterMallocSpy

Registers an implementation of the **IMallocSpy** interface in OLE, thereafter requiring OLE to call its wrapper methods around every call to the corresponding **IMalloc** method. **IMallocSpy** is defined in OLE to allow debugging of memory allocations.

```
HRESULT CoRegisterMallocSpy(
  LPMALLOCSPY pMallocSpy        //Pointer to an instance of IMallocSpy
 );
```

Parameter

pMallocSpy
Points to an instance of the **IMallocSpy** implementation.

Return Values

S_OK
Indicates the **IMallocSpy** object is successfully registered.

CO_E_OBJISREG
Indicates there is already a registered spy.

E_INVALIDARG
Indicates the call to the **QueryInterface** function in *pMallocSpy* for **IID_IMallocSpy** is unsuccessful, or *pMallocSpy* is NULL.

Comments

The **CoRegisterMallocSpy** function registers the **IMallocSpy** object, which is used to debug calls to **IMalloc** methods. The function calls **QueryInterface** on the pointer **pMallocSpy** for the interface **IID_IMallocSpy**. This is to ensure that *pMallocSpy* really supports an implementation of *IMallocSpy*. By the rules of OLE, it is expected that a successful call to **QueryInterface** has added a reference (through the **AddRef** function) to the **IMallocSpy** object. That is, **CoRegisterMallocSpy** does not directly call **AddRef** on *pMallocSpy*, but fully expects that the **QueryInterface** call will.

When the **IMallocSpy** object is registered, whenever there is a call to one of the **IMalloc** methods, OLE first calls the corresponding **IMallocSpy** pre-method. Then, after executing the **IMalloc** method, OLE calls the corresponding **IMallocSpy** post-method. For example, whenever there is a call to **IMalloc::Alloc**, from whatever source, OLE calls **IMallocSpy::PreAlloc**, calls **IMalloc::Alloc**, and after that allocation is completed, calls **IMallocSpy::PostAlloc**.

See Also

IMallocSpy, **CoRevokeMallocSpy**, **CoGetMalloc**

CoRegisterMessageFilter QuickInfo

Registers with OLE the instance of an EXE application's **IMessageFilter** interface, which is to be used for handling concurrency issues. DLL object applications cannot register a message filter.

```
HRESULT CoRegisterMessageFilter(
   LPMESSAGEFILTER lpMessageFilter,          //IMessageFilter interface supplied by app
   LPMESSAGEFILTER * lplpMessageFilter       //Prior IMessageFilter instance if non-NULL
  );
```

Parameters

lpMessageFilter
Points to an **IMessageFilter** interface supplied by the application. Can be NULL, indicating that the current **IMessageFilter** registration should be revoked.

lplpMessageFilter
If this parameter is non-NULL, returns a pointer to the previously registered **IMessageFilter** instance. If NULL, indicates no previous **IMessageFilter** instance was registered.

Return Values

S_OK
Indicates the **IMessageFilter** instance registered or revoked successfully.

S_FALSE
Indicates an error registering or revoking **IMessageFilter** instance.

CoReleaseMarshalData QuickInfo

Destroys a previously marshalled data packet.

```
STDAPI CoReleaseMarshalData(
    IStream * pStm          //Stream containing data packet
  );
```

Parameter

pStm
Points to the stream that contains the data packet which is to be destroyed.

Return Values

S_OK
Indicates the data packet was successfully destroyed.

STG_E_INVALIDPOINTER
Indicates an **IStream** error dealing with the *pStm* parameter.

CO_E_NOTINITIALIZED
Indicates that the **CoInitialize** or **OleInitialize** function was not called on the current thread before this function was called.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates *pStm* is invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

E_FAIL
Indicates an unspecified error.

Comments

The main steps that **CoReleaseMarshalData** performs are the following:

1. The function reads a CLSID from the stream.
2. If standard marshalling is being used, the function gets an **IMarshal** pointer to an instance of the standard unmarshaller. If custom marshalling is being used, the function creates a proxy by calling the **CoCreateInstance** function, passing the CLSID it read from the stream, and requests an **IMarshal** interface pointer to the newly created proxy.
3. Using whichever **IMarshal** interface pointer it has acquired, the function calls **IMarshal::ReleaseMarshalData**.

You typically do not call this function. The only situation in which you might need to call this function is if you use custom marshalling (write and use your own implementation of **IMarshal**). Examples of when **CoReleaseMarshalData** should be called include the following situations:

- An attempt was made to unmarshal the data packet, but it failed.
- A marshalled data packet was removed from a global table.

As an analogy, the data packet can be thought of as a reference to the original object, just as if it were another interface pointer being held on the object. Like a real interface pointer, that data packet must be released at some point. The use of **IMarshal::ReleaseMarshalData** to release data packets is analogous to the use of **IUnknown::Release** to release interface pointers.

Note that you do not need to call **CoReleaseMarshalData** after a successful call of the **CoUnmarshalInterface** function; that function releases the marshal data as part of the processing that it does.

See Also

IMarshal::ReleaseMarshalData

CoRevokeClassObject QuickInfo

Informs OLE that a class object, previously registered with the **CoRegisterClassObject** function, is no longer available for use.

```
HRESULT CoRevokeClassObject(
  DWORD dwRegister        //Token on class object returned from call to CoRegisterClassObject
 );
```

Parameter

dwRegister
Specifies the token previously returned from the **CoRegisterClassObject** function.

Return Values

S_OK
Indicates the class object was successfully revoked.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates the *dwRegister* parameter does not map to a registered class object.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

If a call to **CoRevokeClassObject** is successful, it means that the class object has been removed from the global class object table. However, if other clients still have pointers to the class object and have caused the reference count to be incremented by calls to **IUnknown::AddRef**, the reference count will not be zero. When this occurs, applications may benefit if subsequent calls (with the obvious exceptions of **IUnknown::AddRef** and **IUnknown::Release**) to the class object fail.

The object application *must* call **CoRevokeClassObject** to revoke registered class objects before exiting the program. Class object implementors should call **CoRevokeClassObject** as part of the release sequence. You must specifically revoke the class object even when you have specified the *flags* value REGCLS_SINGLEUSE in a call to **CoRegisterClassObject**, indicating that only one application can connect to the class object.

See Also

CoGetClassObject, **CoRegisterClassObject**

CoRevokeMallocSpy

Revokes a registered **IMallocSpy** object.

HRESULT CoRevokeMallocSpy();

Return Values

S_OK
: Indicates the **IMallocSpy** object is successfully revoked.

CO_E_OBJNOTREG
: Indicates no spy is currently registered.

E_ACCESSDENIED
: Indicates a spy is registered but there are outstanding allocations (not yet freed) made while this spy was active.

Comments

The **IMallocSpy** object is released when it is revoked. This release corresponds to the call to **IUnknown::AddRef** in the implementation of the **QueryInterface** function by the **CoRegisterMallocSpy** function. The implementation of the **IMallocSpy** interface should then do any appropriate clean-up.

If the return code is E_ACCESSDENIED, there are still outstanding allocations that were done while the spy was active. The registered spy cannot be revoked at this time because it may have attached arbitrary headers and/or trailers to these allocations which only the spy knows about. Only the spy's **PreFree** (or **PreRealloc**) method knows how to account for these headers and trailers. Before returning E_ACCESSDENIED, **CoRevokeMallocSpy** notes internally that a revoke is pending. When the outstanding allocations have been freed, the revoke proceeds automatically, releasing the **IMallocSpy** object. This means that it is necessary to call **CoRevokeMallocSpy** only once for each call to **CoRegisterMallocSpy**, even if E_ACCESSDENIED is returned.

See Also

IMallocSpy, **CoRegisterMallocSpy**, **CoGetMalloc**

CoTaskMemAlloc [QuickInfo]

Allocates a block of task memory in the same way that **IMalloc::Alloc** does.

```
LPVOID CoTaskMemAlloc(
  ULONG cb        //Size in bytes of memory block to be allocated
 );
```

Parameter

cb
Specifies the size (in bytes) of the memory block to be allocated.

Return Values

Allocated memory block
Indicates memory block allocated successfully.

NULL
Indicates insufficient memory available.

Comments

The **CoTaskMemAlloc** function uses the default allocator to allocate a memory block in the same way that **IMalloc::Alloc** does. It is not necessary to call the **CoGetMalloc** function before calling **CoTaskMemAlloc**.

The initial contents of the returned memory block are undefined - there is no guarantee that the block has been initialized. The allocated block may be larger than *cb* bytes because of the space required for alignment and for maintenance information.

If *cb* is zero, **CoTaskMemAlloc** allocates a zero-length item and returns a valid pointer to that item. If there is insufficient memory available, **CoTaskMemAlloc** returns NULL.

Note Applications should always check the return value from this method, even when requesting small amounts of memory, because there is no guarantee the memory will be allocated.

See Also

IMalloc::Alloc, **CoGetMalloc**, **CoTaskMemFree**, **CoTaskMemRealloc**

CoTaskMemFree   QuickInfo

Frees a block of task memory previously allocated through a call to the CoTaskMemAlloc or CoTaskMemRealloc function.

```
void CoTaskMemFree(
    void pv          //Points to memory block to be freed
  );
```

Parameter

pv
Points to the memory block to be freed.

Comments

The **CoTaskMemFree** function, using the default OLE allocator, frees a block of memory previously allocated through a call to the **CoTaskMemAlloc** or **CoTaskMemRealloc** function.

The number of bytes freed equals the number of bytes that were originally allocated or reallocated. After the call, the memory block pointed to by *pv* is invalid and can no longer be used.

Note The *pv* parameter can be NULL, in which case this method has no effect.

See Also

CoTaskMemAlloc, **CoTaskMemRealloc**, **CoGetMalloc**, **IMalloc::Free**

CoTaskMemRealloc QuickInfo

Changes the size of a previously allocated block of task memory.

```
LPVOID CoTaskMemRealloc(
   LPVOID pv,          //Points to memory block to be reallocated
   ULONG cb            //Size in bytes of block to be reallocated
  );
```

Parameters

pv
Points to the memory block to be reallocated. It can be a NULL pointer, as discussed in the Comments.

cb
Specifies the size in bytes of the memory block to be reallocated. It can be zero, as discussed in the following remarks.

Return Values

Reallocated memory block
Indicates memory block successfully reallocated.

NULL
Indicates insufficient memory or *cb* is zero and *pv* is not NULL.

Comments

The **CoTaskMemRealloc** function changes the size of a previously allocated memory block in the same way that **IMalloc::Realloc** does. It is not necessary to call the **CoGetMalloc** function to get a pointer to the OLE allocator before calling **CoTaskMemRealloc**.

The *pv* argument points to the beginning of the memory block. If *pv* is NULL, **CoTaskMemRealloc** allocates a new memory block in the same way as the **CoTaskMemAlloc** function. If *pv* is not NULL, it should be a pointer returned by a prior call to **CoTaskMemAlloc**.

The *cb* argument specifies the size (in bytes) of the new block. The contents of the block are unchanged up to the shorter of the new and old sizes, although the new block can be in a different location. Because the new block can be in a different memory location, the pointer returned by **CoTaskMemRealloc** is not guaranteed to be the pointer passed through the *pv* argument. If *pv* is not NULL and *cb* is zero, then the memory pointed to by *pv* is freed.

CoTaskMemRealloc returns a void pointer to the reallocated (and possibly moved) memory block. The return value is NULL if the size is zero and the buffer argument is not NULL, or if there is not enough memory available to expand the block to the given size. In the first case, the original block is freed; in the second, the original block is unchanged.

The storage space pointed to by the return value is guaranteed to be suitably aligned for storage of any type of object. To get a pointer to a type other than **void**, use a type cast on the return value.

See Also

CoTaskMemAlloc, **CoTaskMemFree**, **CoGetMalloc**, **IMalloc::Realloc**

CoTreatAsClass QuickInfo

Establishes or removes an emulation so objects of one class are treated as objects of a different class.

```
STDAPI CoTreatAsClass(
   REFCLSID clsidOld,        //CLSID for the original object to be emulated
   REFCLSID clsidNew         //CLSID for the new object that emulates the original
  );
```

Parameters

clsidOld
Specifies the CLSID of the object to be emulated.

clsidNew
Specifies the CLSID of the object that should emulate the original object. This replaces any existing emulation for *clsidOld*. Can be CLSID_NULL, in which case any existing emulation for *clsidOld* is removed.

Return Values

S_OK
Indicates the emulation was successfully established or removed.

REGDB_E_CLASSNOTREG
Indicates the *clsidOld* parameter is not properly registered in the registration database.

REGDB_E_READREGDB
Indicates error reading from registration database.

REGDB_E_WRITEREGDB
Indicates error writing to registration database.

E_INVALIDARG
Indicates the *clsidOld* parameter specifies an OLE 1 class.

Comments

This function sets the **TreatAs** entry in the registration database for the specified object. After this entry is set, the **CoGetClassObject** function and object handlers (including the default handler) are transparently forwarded to the new CLSID when they consult the registration database for the old CLSID. For example, launching the object application for *clsidOld* would actually launch the object application for *clsidNew* instead. The **IOleObject::EnumVerbs** method in the default handler enumerates the verbs from *clsidNew* instead of *clsidOld*.

During installation, setup programs should call **CoTreatAsClass**, setting the *clsidNew* parameter to CLSID_NULL to remove any existing emulation for the classes they install.

If you set a class to emulate itself, that is, the values for *clsidNew* and *clsidOld* are the same, this function has two possible results depending on the **AutoTreatAs** key in the registration database. If there is a CLSID assigned to the **AutoTreatAs** key, then the **AutoTreatAs** CLSID is assigned to the **TreatAs** key. If there is no value assigned to the **AutoTreatAs** key, then the **TreatAs** entry is removed.

The **CoTreatAsClass** function does not validate whether an appropriate registration database entry for *clsidNew* currently exists.

See Also

CoGetTreatAsClass

CoUninitialize QuickInfo

Closes the OLE Component Object Model(COM) library, freeing any resources that it maintains and forcing all RPC connections to close.

void CoUninitialize();

Comments

The **CoInitialize** and **CoUninitialize** calls must be balanced - if there are multiple calls to the **CoInitialize** function, there must be the same number of calls to **CoUninitialize**: Only the **CoUninitialize** call corresponding to the **CoInitialize** call that initialized the library can close it.

The **OleUninitialize** function calls **CoUninitialize** internally, so applications that call **OleUninitialize** do not also need to call **CoUninitialize**.

The **CoUninitialize** function should be called on application shutdown, as the last call made to the COM library after the application hides its main windows and falls through its main message loop. If there are open conversations remaining, **CoUninitialize** starts a modal message loop and dispatches any pending messages from the containers or server for this OLE application. By dispatching the messages, **CoUninitialize** ensures that the application does not quit before receiving all of its pending messages. Non-OLE messages are discarded.

See Also

CoInitialize, **OleUninitialize**

CoUnmarshalHresult QuickInfo

Unmarshals an **HRESULT** type from the specified stream.

```
STDAPI CoUnmarshalHresult(
    LPSTREAM pStm,          //Stream used for unmarshalling
    HRESULT * phresult      //Receives the HRESULT
  );
```

Parameters

pStm
Points to the stream from which the **HRESULT** is to be unmarshalled.

phresult
Receives the unmarshalled **HRESULT**.

Return Values

S_OK
Indicates the **HRESULT** was unmarshalled successfully.

STG_E_INVALIDPOINTER
Indicates *pStm* is an invalid pointer.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

You typically do not need to call this function. The only situation in which you would need to call this function is if you are performing custom marshalling (that is, writing your own implementation of **IMarshal**). You must use **CoUnmarshalHresult** to unmarshal **HRESULT**s previously marshalled by a call to the **CoMarshalHresult** function.

See Also

CoMarshalHresult

CoUnmarshalInterface QuickInfo

Initializes a proxy object using data written into the stream by a previous call to the **CoMarshalInterface** function, and returns an interface pointer to that proxy object.

```
STDAPI CoUnmarshalInterface(
    IStream * pStm,         //Stream used for unmarshalling
    REFIID riid,            //IID of interface pointer desired
    void ** ppv             //Receives the interface pointer
  );
```

Parameters

pStm
Points to the stream from which the interface pointer is to be unmarshalled.

riid
Specifies the IID of the interface pointer desired.

ppv
Receives the interface pointer.

Return Values

S_OK
Indicates the interface was unmarshalled successfully.

STG_E_INVALIDPOINTER
Indicates *pStm* is an invalid pointer.

CO_E_NOTINITIALIZED
Indicates the **CoInitialize** or **OleInitialize** function was not called on the current thread before this function was called.

CO_E_OBJNOTCONNECTED
Indicates the object application has been disconnected from the remoting system (for example, as a result of a call to the **CoDisconnectObject** function).

REGDB_E_CLASSNOTREG
Indicates an error occurred reading the registration database.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

E_NOINTERFACE
Indicates the final **QueryInterface** of this function for the requested interface returned E_NOINTERFACE.

E_FAIL
Indicates an unspecified error.

CoCreateInstance errors
Indicates an error occurred when creating the handler (standard or custom marshaling).

Comments

The main steps that **CoUnmarshalInterface** performs are the following:

1. The function reads a CLSID from the stream.
2. If standard marshalling is being used, the function gets an **IMarshal** pointer to an instance of the standard unmarshaller. If custom marshalling is being used, the function creates a proxy by calling

the **CoCreateInstance** function, passing the CLSID it read from the stream, and requests an **IMarshal** interface pointer to the newly created proxy.

3. Using whichever **IMarshal** interface pointer it has acquired, the function then calls **IMarshal::UnmarshalInterface** and, if appropriate, **IMarshal::ReleaseMarshalData**.

You typically do not need to call this function. The primary caller of this function is OLE, from within interface proxies or stubs that unmarshal an interface pointer.

The only place where you might need to call this function is from your implementation of **IMarshal::UnmarshalInterface**, if you are performing custom marshaling. If your implementation of **IMarshal::MarshalInterface** called the **CoMarshalInterface** function to marshal an interface pointer to the stream, you must call **CoUnmarshalInterface** to retrieve that interface pointer. The retrieved interface pointer is typically a pointer to a private object in the originating process.

See Also

CoMarshalInterface, **IMarshal::UnmarshalInterface**

CreateAntiMoniker **QuickInfo**

Creates and returns a new anti-moniker.

WINOLEAPI CreateAntiMoniker(
**LPMONIKER FAR ****ppmk* //Receives the anti-moniker
);

Parameter

ppmk
Receives an **IMoniker** interface pointer to the new anti-moniker. The returned pointer is NULL if an error occurs; if non-NULL, the function has called **IUnknown::AddRef** on the parameter and the caller is responsible for calling **IUnknown::Release**.

Return Values

S_OK
Indicates the anti-moniker was created successfully.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

You would call this function only if you are writing your own moniker class (implementing the **IMoniker** interface). If you want an anti-moniker to act as the inverse for your moniker class, you can call **CreateAntiMoniker** from your implementation of **IMoniker::Inverse**.

The inverse of a moniker is analogous to the ".." directory in MS-DOS file systems; the ".." directory acts as the inverse to any other directory name, because appending ".." to a directory name results in an empty path. In the same way, the inverse of a moniker typically is also the inverse of all monikers in the same class. However, it is not necessarily the inverse of a moniker of a different class.

An anti-moniker can be used as the inverse for certain classes of monikers. For example, the system-provided implementations of file monikers, item monikers, and pointer monikers all use anti-monikers as their inverse; consequently, an anti-moniker composed to the right of a file, item, or pointer moniker composes to nothing.

If you're a moniker client, you typically do not know the class of the moniker you're using. If you need to get the inverse of a moniker, you should always call **IMoniker::Inverse** rather that the **CreateAntiMoniker** function, because you cannot be certain that the moniker you're using considers an anti-moniker to be its inverse. For example, if you need to remove the last piece of a composite moniker, call **IMoniker::Enum** on the composite, specifying FALSE as the first parameter; this call creates an enumerator that returns the component monikers in reverse order. Use the enumerator to retrieve the last piece of the composite, and call **IMoniker::Inverse** on that moniker. The moniker returned by **IMoniker::Inverse** will remove the last piece of the composite.

If you are writing a new moniker class and you have no special requirements for its inverse, you can use **CreateAntiMoniker** in your implementation of the **IMoniker::Inverse** method, and then check for an anti-moniker in your implementation of **IMoniker::ComposeWith**.

IMoniker::Inverse, **IMoniker::ComposeWith**, **IMoniker - Anti-Moniker Implementation**

CreateBindCtx QuickInfo

Creates a bind context. A bind context is an object that stores information about a particular moniker-binding operation. A bind context is required as a parameter in many methods of the **IMoniker** interface and in certain functions related to monikers.

```
STDAPI CreateBindCtx(
    DWORD reserved,         //Reserved for future use
    LPBC FAR* ppbc          //Receives the pointer to the bind context
  );
```

Parameters

reserved
Indicates reserved for future use; must be zero.

ppbc
Receives an **IBindCtx** interface pointer to the new bind context. The returned pointer is NULL if an error occurs; if non-NULL, the caller is responsible for calling **IUnknown::Release** on the parameter.

Return Values

S_OK
Indicates the bind context was allocated and initialized successfully.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

The most common use of **CreateBindCtx** is in binding a moniker (getting a pointer to an interface by ideintifying it through a moniker). This X typically takes the following steps:

1. Create a bind context by calling the **CreateBindCtx** function.
2. Call the **IMoniker::BindToObject** method on the moniker, retrieving an interface pointer.
3. Release the bind context.
4. Use the interface pointer.
5. Release the interface pointer.

Here's a code fragment that illustrates these steps:

```
// pMnk is an IMoniker * that points to a previously-acquired moniker
IFoo *pFoo;
IBindCtx *pbc;

CreateBindCtx( 0, &pbc );
pMnk->BindToObject( pbc, NULL, IID_IFoo, &pFoo );
pbc->Release();
// pFoo now points to the object; safe to use pFoo
pFoo->Release();
```

Bind contexts are also used in other methods of the **IMoniker** interface besides **IMoniker::BindToObject** and in the **MkParseDisplayName** function.

A bind context retains references to the objects that are bound during the binding operation. This causes the bound objects to remain active until the bind context is released. This can improve performance in subsequent binding operations if they are trying to bind to the same objects. However, this potential performance enhancement should be balanced against the costs of keeping the objects activated unnecessarily (i.e., keeping the object's server running).

In general, you can benefit from reusing a bind context for a few sequential bind operations if those operations are likely to require the same objects, but you should release the bind context rather than holding onto it for a long period. If you don't release the bind context, objects registered with the bind context will remain active unnecessarily.

A bind context contains a **BIND_OPTS** structure, which contains parameters that apply to all steps in a binding operations. When you create a bind context using **CreateBindCtx**, the fields of the **BIND_OPTS** structure are initialized to the following values:

```
cbStruct = sizeof(BIND_OPTS)
grfFlags = 0
grfMode = STGM_READWRITE
dwTickCountDeadline = 0.
```

You can call the **IBindCtx::SetBindOptions** method to modify these values, if you want values other from the defaults.

See Also

BIND_OPTS, **IBindCtx**, **IMoniker**, **MkParseDisplayName**

CreateDataAdviseHolder QuickInfo

Returns a new instance of an OLE-provided implementation of the **IDataAdviseHolder** interface.

STDAPI CreateDataAdviseHolder(
  IDataAdviseHolder ***ppDAHolder* //Pointer to the new instance of IDataAdviseHolder
 );

Parameter

ppDAHolder
 Points to the location where the pointer to the new advise holder object should be returned.

Return Values

S_OK
 The **IDataAdviseHolder** interface was instantiated and the pointer returned.

E_OUTOFMEMORY
 Indicates that OLE ran out of memory and **IDataAdviseHolder** could not be instantiated.

Comments

The **IDataAdviseHolder** interface is called by your implementation of the **IDataObject**::DAdvise interface to keep track of connections to advise sinks and to send notifications when necessary.

See Also

IDataAdviseHolder

CreateDataCache QuickInfo

Returns a new instance of an OLE-provided implementation of a cache.

```
HRESULT CreateDataCache(
   LPUNKNOWN pUnkOuter,        //Pointer to controlling unknown of aggregate
   REFCLSID rclsid,            //CLSID used to generate icon labels
   REFIID riid,                //Interface used to communicate with cache
   LPVOID FAR *ppvObj          //Pointer to returned cache object
  );
```

Parameters

pUnkOuter
: Points to the controlling unknown if the cache is to be created as part of an aggregate. This parameter may be NULL, indicating that there is no aggregate.

rclsid
: Specifies the CLSID used to generate icon labels. This value is typically CLSID_NULL.

riid
: Specifies the interface that will be used by the caller to communicate with the cache. This value is typically **IID_IOleCache.**

ppvObj
: Points to the location of the returned cache object.

Return Values

S_OK
: Indicates the OLE-provided cache was instantiated and the pointer returned.

E_INVALIDARG
: Indicates one or more arguments are invalid.

E_OUTOFMEMORY
: Indicates the interface could not be instantiated due to a lack of memory.

E_NOINTERFACE
: Indicates the interface represented by *riid* is not supported by the object. The parameter *ppvObj* is set to NULL.

Comments

The cache created by **CreateDataCache** supports the **IOleCache**, **IOleCache2**, and **IOleCacheControl** interfaces for controlling the cache. It also supports the **IPersistStorage**, **IDataObject** (without advise sinks), **IViewObject**, and **IViewObject2** interfaces.

See Also

IOleCache, **IOleCache2**, **IOleCacheControl**

CreateFileMoniker QuickInfo

Creates a file moniker based on the specified path.

```
WINOLEAPI CreateFileMoniker(
   LPCOLESTR lpszPathName,       //Pathname to be used
   LPMONIKER FAR *ppmk           //Receives the file moniker
  );
```

Parameters

lpszPathName

Points to a zero-terminated string containing the path on which this moniker is based. For Win32 applications, the **LPCOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

ppmk

Receives an **IMoniker** interface pointer to the new file moniker. The returned pointer is NULL if an error occurs; if non-NULL, the function has called **IUnknown::AddRef** on the parameter and the caller is responsible for calling **IUnknown::Release**.

Return Values

S_OK

Indicates the moniker was created successfully.

MK_E_SYNTAX

Indicates an error in the syntax of a path was encountered while creating a moniker.

E_OUTOFMEMORY

Indicates insufficient memory.

Comments

CreateFileMoniker should be called by moniker providers, to create a file moniker when that is suitable for identifying its objects. Moniker providers hand out monikers to identify their objects so they are accessible to other parties. You must use file monikers if the objects being identified are stored in files. If each object resides in its own file, file monikers are the only type you need. For objects smaller than a file, you need to use another type of moniker (for example, item monikers) in addition to file monikers. Your objects must also implement the **IPersistFile** interface for them to be loaded when a file moniker is bound.

The most common example of moniker providers are OLE server applications that support linking. For OLE server applications that support linking only to file-based documents in their entirety, file monikers are the only type of moniker needed. OLE server applications that support linking to objects smaller than a document (such as sections of a document or embedded objects), must use item monikers as well as file monikers.

The *lpszPathName* can be a relative path, a UNC path (e.g., \\*server**share**path*), or a drive letter based path (e.g., c:\). If based on a relative path, the resulting moniker will need to be composed onto another file moniker before it can be bound.

A file moniker cannot be composed to the right of any other kind of moniker. It is possible to compose two file monikers together if the first moniker is based on an absolute path and the other is a relative path, resulting in a single file moniker based on the combination of the two paths. To identify objects stored within a file, it is necessary to compose other types of monikers (usually item monikers) to the right of a file moniker.

See Also

IMoniker - File Moniker Implementation

CreateGenericComposite QuickInfo

Performs a generic composition of *pmkFirst* and *pmkRest* and returns the resulting moniker.

```
WINOLEAPI CreateGenericComposite(
   LPMONIKER pmkFirst,                  //First moniker
   LPMONIKER pmkRest,                   //Second moniker
   LPMONIKER FAR *ppmkComposite         //Receives the composite
  );
```

Parameters

pmkFirst
Points to the moniker to be composed to the left of the *pmkRest* moniker. Can point to any kind of moniker, including a generic composite.

pmkRest
Points to the moniker to be composed to the right of the *pmkFirst* moniker. Can point to any kind of moniker, including a generic composite.

ppmkComposite
Receives an **IMoniker** pointer to the moniker that is the result of composing *pmkFirst* and *pmkRest*. If either *pmkFirst* or *pmkRest* are NULL, the returned pointer is the one that is non-NULL. If both *pmkFirst* and *pmkRest* are NULL, or if an error occurs, the returned pointer is NULL. If the returned pointer is non-NULL, the function has called **IUnknown::AddRef** on the parameter and the caller is responsible for calling **IUnknown::Release**.

Return Values

S_OK
Indicates the two input monikers were successfully composed.

MK_E_SYNTAX
Indicates the two monikers could not be composed due to an error in the syntax of a path (for example, if both *pmkFirst* and *pmkRest* are file monikers based on absolute paths).

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

You would call this function only if you are writing your own moniker class (implementing the **IMoniker** interface). If you want to perform a generic composition in your implementation of the **IMoniker::ComposeWith** method, call this function from there.

Composition is the process of joining two monikers together. Sometimes two monikers of specific classes can be combined; for example, a file moniker representing an incomplete path and another file moniker representing a relative path can be combined to form a single file moniker representing the complete path. This is an example of "non-generic" composition. "Generic" composition, on the other hand, can connect any two monikers, no matter what their classes. Because a non-generic composition depends on the class of the monikers involved, it can be done only in the implementation of the **IMoniker::ComposeWith** method for a particular class. You can define new types of non-generic compositions if you write a new moniker class. In contrast, it is only necessary to call the CreateGenericComposite for generic compositions.

If you are a moniker client and you need to compose two monikers together, you should call the **IMoniker::ComposeWith** method. This gives the first moniker a chance to perform a non-generic composition. The only time you should call **CreateGenericComposite** is if you are writing a new moniker class. In the implementation of **IMoniker::ComposeWith**, you should call **CreateGenericComposite** once you have determined that your implementation cannot do a non-generic composition.

During the process of composing the two monikers, **CreateGenericComposite** makes all possible simplifications. Consider the example where *pmkFirst* is the generic composite moniker, *A* (°) *B* (°) *C*, and *pmkRest* is the generic composite moniker, $C_{(-1)}$ (°) $B_{(-1)}$ (°) *Z* (where $C_{(-1)}$ is the inverse of *C*). The function first composes *C* to $C_{(-1)}$, which composes to nothing. Then it composes *B* and $B_{(-1)}$ to nothing. Finally, it composes *A* to *Z*, and returns a pointer to the generic composite moniker, *A* (°) *Z*.

See Also

IMoniker::ComposeWith, **IMoniker - Generic Composite Moniker Implementation**

CreateILockBytesOnHGlobal [QuickInfo]

Returns an OLE-provided implementation of the **ILockBytes** interface which allows you to build a storage object in memory.

```
HRESULT CreateILockBytesOnHGlobal(
    HGLOBAL hGlobal,             //Memory handle for the byte array object
    BOOL fDeleteOnRelease,       //Indicates whether to free memory when the object is released
    ILockBytes ** ppLkbyt        //Points to location for pointer to the new byte array object
  );
```

Parameters

hGlobal

Contains the memory handle allocated by the **GlobalAlloc** function. The handle must be allocated as moveable and nondiscardable. If the handle is to be shared between processes, it must also be allocated as shared. New handles should be allocated with a size of zero. If *hGlobal* is NULL, the **CreateILockBytesOnHGlobal** function internally allocates a new shared memory block of size zero.

fDeleteOnRelease

Indicates whether the underlying handle for this byte array object should be automatically freed when the object is released.

ppLkbyt

Points to the location where this method places the pointer for the new byte array object, that is, the new instance of the **ILockBytes** interface.

Return Values

S_OK

Indicates the **ILockBytes** instance was created successfully.

E_INVALIDARG

Indicates an invalid value was specified for the *hGlobal* parameter.

E_OUTOFMEMORY

Indicates not enough memory to create an **ILockBytes** instance.

Comments

This function creates a byte array object in memory using the OLE-provided implementation of the **ILockBytes** interface. The returned byte array object can be the basis for a compound file. You can call the **StgCreateDocfileOnILockBytes** function to build a compound file on top of this byte array object. The **ILockBytes** instance calls the **GlobalReAlloc** function to grow the memory block as needed.

The current contents of the memory block are undisturbed by the creation of the new byte array object. After creating the **ILockBytes** instance, you can use the **StgOpenStorageOnILockBytes** function to reopen a previously existing storage object already contained in the memory block.

Note If you free the *hGlobal* memory handle, the byte array object is no longer valid. You must call the **ILockBytes::Release** method before freeing the memory handle.

The value of the *hGlobal* parameter can be changed by a subsequent call to the **GlobalReAlloc** function; thus, you cannot rely on this value after the byte array object is created.

See Also

StgOpenStorageOnILockBytes

CreateItemMoniker [QuickInfo]

Creates an item moniker based on a string that identifies an object within a container, typically a compound document.

WINOLEAPI CreateItemMoniker(
   LPCOLESTR *lpszDelim*,   //Delimiter string
   LPCOLESTR *lpszItem*,   //Item name
   LPMONIKER FAR **ppmk*   //Receives the item moniker
 );

Parameters

lpszDelim
  Points to a zero-terminated string containing the delimiter (typically "!") used to separate this item's display name from the display name of its container. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

lpszItem
  Points to a zero-terminated string containing the container's name for the object being identified. This name can later be used to retrieve a pointer to the object in a call to **IOleItemContainer::GetObject**.

ppmk
  Receives an **IMoniker** pointer to the new item moniker. The returned pointer is NULL if an error occurs; if non-NULL, the function has called **IUnknown::AddRef** on the parameter and the caller is responsible for calling **IUnknown::Release**.

Return Values

S_OK
  Indicates the moniker was created successfully.

E_OUTOFMEMORY
  Indicates insufficient memory.

Comments

A moniker providerthat can identify its objects with an item moniker would call CreateItemMoniker. A moniker provider hands out monikers to identify its objects so they are accessible to other parties. Item monikers identify objects that are contained within another object and can be individually identified using a string. The container of the object must also implement the **IOleContainer** interface so the objects can be loaded when a item moniker is bound.

The most common example of moniker providers are OLE applications that support linking. If your OLE application supports OLE linking to objects smaller than a file-based documents, you need to use item monikers. A server application that allows linking to a selection within a document, uses item monikers to identify those objects. Container applications that allow linking to embedded objects use item monikers to identify the embedded objects.

The *lpszItem* parameter is the name used by the document to uniquely identify the object. For example, if the object being identified is a cell range in a spreadsheet, an appropriate name might be something like "A1:E7." If the object being identified is an embedded object, an appropriate name might be something like "embedobj1." The document containing the object must provide an implementation of the **IOleItemContainer** interface that can interpret the name and locate the corresponding object. This allows the item moniker to be bound to the object it identifies.

Item monikers are typically not used in isolation; they must be composed with a moniker that identifies the document that contains the object. For example, if the object being identified is a cell range contained in a file-based document, the item moniker identifying that object must be composed with the file moniker identifying that document; this results in a composite moniker like "C:\work\sales.xls!A1:E7." It's also possible to have nested containers, for example, if an object is contained within an embedded object inside another document. The complete moniker of such an object would look like "C:\work\report.doc!embedobj1!A1:E7." In such a situation, each container object must call **CreateItemMoniker** and provide its own implementation of the **IOleItemContainer** interface.

See Also

IMoniker::ComposeWith, **IOleItemContainer**, **IMoniker - Item Moniker Implementation**

CreateOleAdviseHolder QuickInfo

Creates an advise holder for managing compound document notifications. It returns an instance of the OLE implementation of the **IOleAdviseHolder** interface.

HRESULT CreateOleAdviseHolder(
  ppOAHolder   //Pointer to a pointer
 );

Parameter

ppOAHolder
  Points to where to return the new **IOleAdviseHolder** instance.

Return Values

S_OK
  Indicates that the new OLE advise holder returned successfully.

E_OUTOFMEMORY
  Indicates insufficient memory to create new advise holder.

Comments

The helper function **CreateOleAdviseHolder** is an OLE implementation of the **IOleAdviseHolder** interface. Anyone who wants to write their own implementation of this interface may do so; but the advise holder returned by **CreateOleAdviseHolder** will suffice for the great majority of applications. If your application has a need to implement **IOleAdviseHolder::EnumAdvise**; you will need to implement your own advise holder because the one provided by OLE does not support this method.

See Also

IOleAdviseHolder

CreatePointerMoniker QuickInfo

Creates a pointer moniker based on a specified interface pointer.

```
WINOLEAPI CreatePointerMoniker(
   LPUNKNOWN punk,              //Interface pointer to be used
   LPMONIKER FAR *ppmk          //Receives the pointer moniker
  );
```

Parameters

punk
Points to an interface pointer to the object to be identified by the resulting moniker.

ppmk
Receives an **IMoniker** interface pointer to the new pointer moniker. The returned pointer is NULL if an error occurs; if non-NULL, the function has called **IUnknown::AddRef** on the parameter and the caller is responsible for calling **IUnknown::Release**.

Return Values

S_OK
Indicates the pointer moniker was created successfully.

E_UNEXPECTED
Indicates an unexpected error occurred.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

You rarely need to call this function.

A pointer moniker is essentially a wrapping of an interface pointer that allows it to be passed to those interfaces that require monikers. Pointer monikers allow an object that has no persistent representation to participate in a moniker binding operation. Binding a pointer moniker is done by calling the pointer's **IUnknown::QueryInterface** method.

See Also

IMoniker - Pointer Moniker Implementation

CreateStreamOnHGlobal QuickInfo

Returns an OLE-provided implementation of the **IStream** interface with the stream object stored in global memory.

```
HRESULT CreateStreamOnHGlobal(
    HGLOBAL hGlobal,              //Memory handle for the stream object
    BOOL fDeleteOnRelease,        //Indicates whether to free memory when the object is released
    LPSTREAM * ppstm              //Points to location for pointer to the new stream object
  );
```

Parameters

hGlobal
Contains the memory handle allocated by the **GlobalAlloc** function. The handle must be allocated as moveable and nondiscardable. If the handle is to be shared between processes, it must also be allocated as shared. New handles should be allocated with a size of zero. If *hGlobal* is NULL, the **CreateStreamOnHGlobal** function internally allocates a new shared memory block of size zero.

fDeleteOnRelease
Indicates whether the underlying handle for this stream object should be automatically freed when the stream object is released.

ppstm
Points to the location where this method places a pointer to the new stream object, that is, the new **IStream** instance. It cannot be NULL.

Return Values

S_OK
Indicates the stream object was created successfully.

E_OUTOFMEMORY
Indicates the stream could not be created due to lack of memory.

E_INVALIDARG
Indicates invalid value for one of the parameters.

Comments

This function creates a stream object in memory using the OLE-provided implementation of the **IStream** interface. The returned stream object supports both reading and writing, is not transacted, and does not support locking.

The initial contents of the stream are the current contents of the memory block provided in the *hGlobal* parameter. If the *hGlobal* paramter is NULL, this function internally allocates memory.

The current contents of the memory block are undisturbed by the creation of the new stream object. Thus, you can use this function to open an existing stream in memory.

The initial size of the stream is the size of the memory handle returned by the Win32 **GlobalSize** function. Because of rounding, this is not necessarily the same size that was originally allocated for the handle. If the logical size of the stream is important, you should follow the call to this function with a call to the **IStream::SetSize** method.

See Also

CreateStreamOnHGlobal, **IStream::SetSize**

GlobalSize in Win32

DllCanUnloadNow

Determines whether the DLL that implements it is in use. It is called by OLE, not by the application. If the DLL is not in use, the calling function can safely unload it from memory.

Note OLE does not provide this function. DLLs that support the OLE Component Object Model(COM) should implement and export **DllCanUnloadNow**.

HRESULT DllCanUnloadNow();

Return Values

S_OK
 Indicates that the DLL can be unloaded.

S_FALSE
 Indicates that the DLL cannot be unloaded now.

Comments

A call to **DllCanUnloadNow** determines whether the DLL from which it is exported is still in use. A DLL is no longer in use when it is not managing any existing objects (the reference count on all of its objects is 0).

Notes to Callers

You should not have to call **DllCanUnloadNow** directly. OLE calls it only through a call to the **CoFreeUnusedLibraries** function. When it returns S_OK, **CoFreeUnusedLibraries** safely frees the DLL.

Notes to Implementors

You need to implement **DllCanUnloadNow** in, and export it from, DLLs that are to be dynamically loaded through a call to the **CoGetClassObject** function. (You also need to implement and export the **DllGetClassObject** function in the same DLL).

If a DLL loaded by **CoGetClassObject** fails to export **DllCanUnloadNow**, the DLL will not be unloaded until the application calls the **CoUninitialize** function to release the OLE libraries.

If the DLL links to another DLL, returning S_OK from **DllCanUnloadNow** will also cause the second, dependent DLL to be unloaded. To eliminate the possibility of a crash, the DLL should call the **CoLoadLibrary** function(*path_to_second DLL*, TRUE), which forces the COM library to reload the second DLL and set it up for a call to **CoFreeUnusedLibraries** to free it separately when appropriate.

DllCanUnloadNow should return S_FALSE if there are any existing references to objects that the DLL manages.

See Also

DllGetClassObject

DllGetClassObject QuickInfo

Retrieves the class object from a DLL object handler or object application. It is called from within the **CoGetClassObject** function when the class context is a DLL.

Note OLE does not provide this function. DLLs that support the OLE Component Object Model must implement **DllGetClassObject** in OLE object handlers or DLL applications.

```
HRESULT DllGetClassObject(
  REFCLSID rclsid,     //CLSID for the class object
  REFIID riid,         //Identifier that identifies the interface that communicates with the
                       class object
  LPVOID  * ppv        //Points to the pointer of the communicating interface
   );
```

Parameters

rclsid
Specifies the CLSID that will associate the correct data and code.

riid
Specifies the interface that the caller is to use to communicate with the class object. Usually, this is **IID_IClassFactory**.

ppv
Points either to the pointer of the requested interface or, if an error occurs, to NULL.

Return Values

S_OK
Indicates that the object was retrieved successfully.

CLASS_E_CLASSNOTAVAILABLE
Indicates that the DLL does not support the class (object definition).

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates that one or more arguments are invalid.

E_UNEXPECTED
Indicates that an unexpected error occurred.

Comments

If a call to the **CoGetClassObject** function finds the class object that is to be loaded in a DLL, **CoGetClassObject** uses the DLL's exported **DllGetClassObject** function.

Notes to Callers

You should not call **DllGetClassObject** directly. When an object is defined in a DLL, **CoGetClassObject** calls the **CoLoadLibrary** function to load the DLL, which, in turn, calls **DllGetClassObject**.

Notes to Implementors

You need to implement **DllGetClassObject** in (and export it from) DLLs that support the OLE Component Object Model.

Example

Following is an example (in C++) of an implementation of **DllGetClassObject**. In this example, **DllGetClassObject** creates a class factory object and calls its **QueryInterface** method to retrieve a pointer to the interface requested in *riid*. The implementation safely releases the reference it holds to the **IClassFactory** interface because it returns a reference-counted pointer to **IClassFactory** to the caller.

```
HRESULT_export  PASCAL DllGetClassObject
        (REFCLSID rclsid, REFIID riid, LPVOID * ppvObj)
{
     HRESULT hres = E_OUTOFMEMORY;
     *ppvObj = NULL;

     CClassFactory *pClassFactory = new CClassFactory(rclsid);
     if (pClassFactory != NULL)   {
       hRes = pClassFactory->QueryInterface(riid, ppvObj);
       pClassFactory->Release();
     }
     return hRes;
}
```

CoGetClassObject, **DllCanUnloadNow**

DoDragDrop QuickInfo

Carries out an OLE drag and drop operation.

```
HRESULT DoDragDrop(
  IDataObject * pDataObject,          //Data object being dragged
  IDropSource * pDropSource,          //Instance of IDropSource for source application
  DWORD dwOKEffect,                   //Specifies the effects allowed by the source
  DWORD * pdwEffect                   //Points to effects of the OLE drag and drop on the source
 );
```

Parameters

pDataObject
Points to an instance of the **IDataObject** interface, which provides the data being dragged.

pDropSource
Points to an instance of the **IDropSource** interface, which is used to communicate with the source during the drag operation.

dwOKEffect
Specifies the effects the source allows in the OLE drag and drop operation. Most significant is whether it permits a move. The *dwOKEffect* and *pdwEffect* parameters obtain values from the **DROPEFFECT** enumeration. For a list of values, see **DROPEFFECT**.

pdwEffect
Points to a value that indicates how the OLE drag and drop operation affected the source data. The *pdwEffect* parameter is set only if the operation is not canceled.

Return Values

DRAGDROP_S_DROP
Indicates the OLE drag and drop operation was successful.

DRAGDROP_S_CANCEL
Indicates the OLE drag and drop operation was canceled.

E_OUTOFMEMORY
Out of memory.

E_UNSPEC
Indicates an unexpected error occurred.

Comments

If you are developing an application that can act as a data source for an OLE drag and drop operation, you must call **DoDragDrop** when you detect that the user has started an OLE drag and drop operation.

The **DoDragDrop** function enters a loop in which it calls various methods in the **IDropSource** and **IDropTarget** interfaces.

1. The **DoDragDrop** function determines the window under the current cursor location. It then checks to see if this window is a valid drop target.
2. If the window is a valid drop target, **DoDragDrop** calls **IDropTarget::DragEnter**. This method returns an effect code indicating what would happen if the drop actually occurred. For a list of valid drop effects, see the **DROPEFFECT** enumeration.
3. **DoDragDrop** calls **IDropSource::GiveFeedback** with the effect code so that the drop source interface can provide appropriate visual feedback to the user. The *pDropSource* pointer passed into **DoDragDrop** specifies the appropriate **IDropSource** interface.
4. **DoDragDrop** tracks mouse cursor movements and changes in the keyboard or mouse button state.
    - If the user moves out of a window, **DoDragDrop** calls **IDropTarget::DragLeave**.
    - If the mouse enters another window, **DoDragDrop** determines if that window is a valid drop target

and then calls **IDropTarget::DragEnter** for that window.

- If the mouse moves but stays within the same window, **DoDragDrop** calls **IDropTarget::DragOver**.

5. If there is a change in the keyboard or mouse button state, **DoDragDrop** calls **IDropSource::QueryContinueDrag** and determines whether to continue the drag, to drop the data, or to cancel the operation based on the return value.
    - If the return value is S_OK, **DoDragDrop** first calls **IDropTarget::DragOver** to continue the operation. This method returns a new effect value and **DoDragDrop** then calls **IDropSource::GiveFeedback** with the new effect so appropriate visual feedback can be set. For a list of valid drop effects, see the **DROPEFFECT** enumeration. **IDropTarget::DragOver** and **IDropSource::GiveFeedback** are paired so that as the mouse moves across the drop target, the user is given the most up-to-date feedback on the mouse's position.
    - If the return value is DRAGDROP_S_DROP, **DoDragDrop** calls **IDropTarget::Drop**. The **DoDragDrop** function returns the last effect code to the source, so the source application can perform the appropriate operation on the source data, for example, cut the data if the operation was a move.
    - If the return value is DRAGDROP_S_CANCEL, the **DoDragDrop** function calls **IDropTarget::DragLeave**.

IDropSource::GiveFeedback

FACILITY_NT_BIT

```
#define FACILITY_NT_BIT 0x10000000
```

Defines bits so macros are guaranteed to work.

FAILED

```
#define FAILED(Status) ((HRESULT)(Status)<0)
```

Provides a generic test for failure on any status value. Negative numbers indicate failure.

GetClassFile QuickInfo

Returns the CLSID associated with the given filename.

HRESULT GetClassFile(
  LPCWSTR *szFileName*, //Pointer to filename for which you are requesting a CLSID
  CLSID * *pclsid* //Pointer to location for returning the CLSID
 );

Parameters

szFileName
Points to the filename for which you are requesting the associated CLSID.

pclsid
Points to the location where the the associated CLSID is returned.

Return Values

S_OK
Indicates the CLSID was successfully returned.

MK_E_CANTOPENFILE
Indicates unable to open the specified filename.

MK_E_INVALIDEXTENSION
Indicates the specified extension in the registry is invalid.

Note This function can also return any file system errors.

Comments

The CLSID returned by this function is used, for example, by File Monikers to locate the object application that can open the file. For example, when a link to a file-based document is activated, the file moniker uses the returned CLSID to locate the application for the link source.

The following strategies are used to determine an appropriate CLSID:

1. If the file contains a storage object, as determined by a call to the **StgIsStorageFile** function, the **GetClassFile** function returns the CLSID that was written with the **IStorage::SetClass** method.
2. If the file is not a storage object, the **GetClassFile** function attempts to match various bits in the file against a pattern in the registry. A pattern in the registry can contain a series of entries of the form:

   ```
   regdb key = offset, cb, mask, value
   ```

   The value of the *offset* item is an offset from the beginning or end of the file and the *cb* item is a length in bytes. These two values represent a particular byte range in the file. (A negative value for the *offset* item is interpreted from the end of the file). The *mask* value is a bit mask that is used to perform a logical AND operation with the byte range specifed by *offset* and *cb*. The result of the logical AND operation is compared with the *value* item. If the *mask* is omitted, it is assumed to be all ones.

   Each pattern in the registry is compared to the file in the order of the patterns in the database. The first pattern where each of the *value* items matches the result of the AND operation determines the CLSID of the file. For example, the pattern contained in the following entries of the registry requires that the first four bytes be AB CD 12 34 and that the last four bytes be FE FE FE FE:

   ```
   HKEY_CLASSES_ROOT
      FileType
        {12345678-0000-0001-C000-000000000095}
          0 = 0, 4, FFFFFFFF, ABCD1234
          1 = -4, 4, , FEFEFEFE
   ```

If a file contains such a pattern, the CLSID {12345678-0000-0001-C000-000000000095} will be associated with this file.

3. If the above strategies fail, the **GetClassFile** function searches for the File Extension key in the registry that corresponds to the *.ext* portion of the filename. If the database entry contains a valid CLSID, this function returns that CLSID.
4. Otherwise, MK_E_INVALIDEXTENSION is returned.

See Also

WriteClassStg

GetConvertStg QuickInfo

Returns the current value of the convert bit for the specifed storage object.

```
HRESULT GetConvertStg(
   IStorage * pStg          //Points to the storage object
  );
```

Parameter

pStg
Points to the storage object from which to retrieve the convert bit.

Return Values

S_OK
Indicates the convert bit is set to TRUE.

S_FALSE
Indicates the convert bit is cleared (FALSE).

STG_E_ACCESSDENIED
Indicates cannot access the storage object.

IStorage::OpenStream, **IStorage::OpenStorage**, and **IStream::Read** storage and stream access errors.

Comments

This function is used by object applications that support converting the object from one format to another. The object application must be able to read the storage object using the format of its previous CLSID and write the object using the format of its new CLSID to support converting the object. For example, a spreadsheet created by one application can be converted to the format used by a different application.

The convert bit is set by a call to the **SetConvertStg** function. A container application can call this function on the request of an end user, or a setup program can call it when installing a new version of an application. An end user requests converting an object through the Convert To dialog box. When an object is converted, the new CLSID is permanently assigned to the object, so the object is subsequently associated with the new CLSID.

Then, when the object is activated, the object application calls the **GetConvertStg** function to retrieve the value of the convert bit from the storage object. If the bit is set, the object's CLSID has been changed, and the object application must read the old format and write the new format for the storage object.

After retrieving the bit value, the object application should clear the convert bit by calling the **SetConvertStg** function with its *fConvert* parameter set to FALSE.

See Also

SetConvertStg

GetHGlobalFromILockBytes QuickInfo

Returns a global memory handle to a byte array object created using the **CreateILockBytesOnHGlobal** function.

```
HRESULT GetHGlobalFromILockBytes(
   ILockBytes * pLkbyt,          //Points to the byte array object
   HGLOBAL * phglobal            //Points to the current memory handle for the specified byte array
  );
```

Parameters

pLkbyt
Points to the byte array object previously created by a call to the **CreateILockBytesOnHGlobal** function.

phglobal
Points to the current memory handle used by the specified byte array object.

Return Values

S_OK
Indicates the handle was returned successfully.

E_INVALIDARG
Indicates invalid value specified for the *pLkbyt* parameter. It can also indicate that the byte array object passed in is not one created by the **CreateILockBytesOnHGlobal** function.

Comments

The handle this function returns might be different from the original handle due to intervening calls to the **GlobalRealloc** function.

The contents of the returned memory handle can be written to a clean disk file, and then opened as a storage object using the **StgOpenStorage** function.

This function only works within the same process from which the byte array was created.

See Also

StgOpenStorage

GetHGlobalFromStream QuickInfo

Returns the global memory handle to a stream that was created using the **CreateStreamOnHGlobal** function.

```
HRESULT GetHGlobalFromStream(
    IStream * pstm,           //Points to the stream object
    HGLOBAL * phglobal        //Points to the current memory handle for the specified stream
  );
```

Parameters

pstm
  Points to the stream object previously created by a call to the **CreateStreamOnHGlobal** function.

phglobal
  Points to the current memory handle used by the specified stream object.

Return Values

S_OK
  Indicates the handle was successfully returned.

E_INVALIDARG
  Indicates invalid value specified for the *pstm* parameter. It can also indicate that the stream object passed in is not one created by a call to the **CreateStreamOnHGlobal** function.

Comments

The handle this function returns may be different from the original handle due to intervening **GlobalRealloc** calls.

This function only works within the same process from which the byte array was created.

See Also

CreateStreamOnHGlobal

GlobalRealloc in Win32

GetRunningObjectTable QuickInfo

Returns an **IRunningObjectTable** pointer to the local Running Object Table (ROT).

```
HRESULT GetRunningObjectTable(
   DWORD reserved,                    //Reserved
   LPRUNNINGOBJECTTABLE *pprot        //Receives an IRunningObjectTable pointer
  );
```

Parameters

reserved
Indicates reserved for future use.

pprot
Receives an **IRunningObjectTable** interface pointer to the local ROT. If an error occurs, **pprot* is undefined; otherwise, the caller is responsible for calling **IUnknown::Release** on the parameter.

Return Values

S_OK
Indicates that an **IRunningObjectTable** pointer was successfully returned.

E_UNEXPECTED
Indicates an unexpected error.

Comments

Each workstation has a local ROT that maintains a table of the objects that have been registered as running on that machine. This function returns an **IRunningObjectTable** interface pointer, which provides access to that table.

Moniker providers, which hand out monikers identifying objects to make them accessible to others, should call **GetRunningObjectTable**. Use the interface pointer returned by this function to register your objects when they begin running, to record the times that those objects are modified, and to revoke their registrations when they stop running. See the **IRunningObjectTable** interface for more information.

The most common types of moniker provider are compound-document link sources. This includes server applications that support linking to their documents (or portions of a document) and container applications that support linking to embeddings within their documents. Server applications that do not support linking can also use the ROT to cooperate with container applications that support linking to embeddings.

If you're writing your own moniker class (implementing the **IMoniker** interface) and you need an interface pointer to the ROT, use the **IBindCtx::GetRunningObjectTable** method rather than the **GetRunningObjectTable** function. This allows future implementations of the **IBindCtx** interface to modify binding behavior.

See Also

IBindCtx::GetRunningObjectTable, **IMoniker**, **IRunningObjectTable**

GetScode

```
#define GetScode(hr) ((SCODE) (hr))
```

Extracts the **SCODE** from an **HRESULT**

This macro is obsolete and should not be used.

HRESULT_CODE

```
#define HRESULT_CODE(hr) ((hr) & 0xFFFF)
```

Returns the error code part of the **HRESULT**.

HRESULT_FACILITY

```
#define HRESULT_FACILITY(hr) (((hr) >> 16) & 0x1fff)
```

Returns the facility from the **HRESULT**.

HRESULT_FROM_NT

```
#define HRESULT_FROM_NT(x) ((HRESULT) ((x) | FACILITY_NT_BIT))
```

Maps an NT status value into an **HRESULT**.

HRESULT_FROM_WIN32

```
#define HRESULT_FROM_WIN32(x) (x ? ((HRESULT) (((x) & 0x0000FFFF) | (FACILITY_WIN32 <<
    16) | 0x80000000)) : 0 )
```

Maps a WIN32 error value into an **HRESULT**. Note that this assumes WIN32 errors fall in the range of -32k to 32k.

HRESULT_SEVERITY

```
#define HRESULT_SEVERITY(hr) (((hr) >> 31) & 0x1)
```

Returns the severity bit from the **HRESULT**.

IIDFromString [QuickInfo]

Converts a string generated by the **StringFromIID** function back into the original interface identifier.

```
HRESULT IIDFromString(
    LPOLESTR lpsz,          //Points to the string representation of the IID
    LPIID lpiid             //Receives a pointer to the requested IID on return
  );
```

Parameters

lpsz
Points to the string representation of the IID.

lpiid
Receives a pointer to the requested IID on return.

Return Values

S_OK
Indicates that the string was successfully converted.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates that one or more arguments are invalid.

Comments

The function converts the interface ID in a way that guarantees different interface IDs will always be converted to different strings.

See Also

StringFromIID

IsAccelerator QuickInfo

Determines whether the keystroke maps to an accelerator in the given accelerator table.

```
BOOL IsAccelerator(
    HACCEL hAccel,           //Handle to accelerator table
    INT cAccelEntries,       //Number of entries in the accelerator table
    LPMSG lpMsg,             //Points to the keystroke message to be translated
    WORD * lpwCmd            //Where to return the corresponding command ID
  );
```

Parameters

hAccel
Specifies the handle to the accelerator table.

cAccelEntries
Specifies the number of entries in the accelerator table.

lpMsg
Points to the keystroke message to be translated.

lpwCmd
Points to where to return the corresponding command ID if there is an accelerator for the keystroke. It may be NULL.

Return Values

TRUE
Indicates the message is for the object application.

FALSE
Indicates the message is not for the object and should be forwarded to the container.

Comments

While active in-place, the object *always* has first chance to translate the keystrokes into accelerators. If the keystroke corresponds to one of its accelerators, the object must *not* call the OleTranslateAccelerator function – even if its call to the Windows **TranslateAccelerator** function fails. Failure to process keystrokes in this manner can lead to inconsistent behavior.

If the keystroke is not one of the object's accelerators, then the object must call **OleTranslateAccelerator** to let the container try its accelerator translation.

The object application can call **IsAccelerator** to determine if the accelerator message belongs to it. Some object applications do accelerator translation on their own and do not call **TranslateAccelerator**. Those applications will not call **IsAccelerator**, because they already have the information.

See Also

OleTranslateAccelerator

TranslateAccelerator in Win32

IS_ERROR

```
#define IS_ERROR(Status) ((unsigned long)(Status) >> 31 == SEVERITY_ERROR)
```

Provides a generic test for errors on any status value.

IsEqualGUID   QuickInfo

Determines whether two GUIDs are equal.

```
BOOL IsEqualGUID(
   REFGUID rguid1,        //The GUID to compare to rguid2
   REFGUID rguid2         //The GUID to compare to rguid1
  );
```

Parameters

rguid1
Specifies the GUID to compare to *rguid2*.

rguid2
Specifies the GUID to compare to *rguid1*.

Return Values

TRUE
Indicates the GUIDs are equal.

FALSE
Indicates the GUIDs are not equal.

Comments

IsEqualGUID is used by the **IsEqualCLSID** and **IsEqualIID** functions.

See Also

IsEqualCLSID, **IsEqualIID**

IsEqualCLSID

Determines whether two CLSIDs are equal.

```
BOOL IsEqualCLSID(
    REFCLSID rclsid1,          //The CLSID to compare to rclsid2
    REFCLSID rclsid2           //The CLSID to compare to rclsid1
  );
```

Parameters

rclsid1
    Specifies the CLSID to compare to *rclsid2*.

rclsid2
    Specifies the CLSID to compare to *rclsid1*.

Return Values

TRUE
    Indicates that the CLSIDs are equal.

FALSE
    Indicates that the CLSIDs are not equal.

See Also

IsEqualGUID, **IsEqualIID**

IsEqualIID

Determines whether two interface IDs are equal.

```
BOOL IsEqualIID(
    REFGUID riid1,          //The interface ID to compare to riid2
    REFGUID riid2           //The interface ID to compare to riid1
  );
```

Parameters

riid1
Specifies the interface ID to compare with *riid2*.

riid2
Specifies the interface IID to compare with *riid1*.

Return Values

TRUE
Indicates that the interface IDs are equal.

FALSE
Indicates that the interface IDs are not equal.

See Also

IsEqualGUID, **IsEqualCLSID**

IsValidIid

This function is obsolete.

IsValidInterface

This function is obsolete.

IsValidPtrIn

This function is obsolete.

IsValidPtrOut

This function is obsolete.

MAKE_HRESULT

```
#define MAKE_HRESULT(sev,fac,code) \HRESULT) (((unsigned long)(sev)<<31) | ((unsigned long)(fac)<<16) | ((unsigned long)(code))) )
```

Creates an **HRESULT** value from component pieces of the 32-bit value.

MAKE_SCODE

```
#define MAKE_SCODE(sev,fac,code) \((SCODE) (((unsigned long)(sev)<<31) | ((unsigned long)
    (fac)<<16) | ((unsigned long)(code))) )
```

Returns an **SCODE** given an **HRESULT**.

MkParseDisplayName QuickInfo

Converts a string into a moniker that identifies the object named by the string. This is the inverse of the **IMoniker::GetDisplayName** operation, which retrieves the display name associated with a moniker.

```
WINOLEAPI MkParseDisplayName(
    LPBC pbc,                   //Bind context to be used
    LPCOLESTR szUserName,       //Display name
    ULONG FAR *pchEaten,        //Receives number of characters consumed
    LPMONIKER FAR *ppmk         //Receives moniker built from display name
  );
```

Parameters

pbc
Points to the binding context to be used in this binding operation.

szUserName
Points to a zero-terminated string containing the display name to be parsed. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

pchEaten
Receives the number of characters of *szUserName* that were consumed. If the function is successful, **pchEaten* is the length of *szUserName*; otherwise, it is the number of characters successfully parsed.

ppmk
Receives a pointer to the moniker that was built from *szUserName*. The returned pointer is NULL if an error occurs; if non-NULL, the function has called **IUnknown::AddRef** on the parameter and the caller is responsible for calling **IUnknown::Release**.

Return Values

S_OK
Indicates the parse operation was successful and the moniker was created.

MK_E_SYNTAX
Indicates an error in the syntax of a filename or an error in the syntax of the resulting composite moniker.

E_OUTOFMEMORY
Indicates insufficient memory.

In addition, the return value can be any of the error return values from **IMoniker::BindToObject**, **IOleItemContainer::GetObject**, or **IParseDisplayName::ParseDisplayName**.

Comments

The **MkParseDisplayName** function parses a human-readable name into a moniker that can be used to identify a link source. The resulting moniker can be a simple moniker (such as a file moniker), or it can be a generic composite made up of the component moniker pieces. For example, the following display name:

```
"c:\mydir\somefile!item 1"
```

could be parsed into the following generic composite moniker:

```
(FileMoniker based on "c:\mydir\somefile")  (°)  (ItemMoniker based on "item 1")
```

The most common situation in which you need to call **MkParseDisplayName** is in the implementation of the standard Links dialog, which allows an end-user to specify the source of a linked object by typing in a string. You may also need to call **MkParseDisplayName** if your application supports a macro language that permits remote references (reference to elements outside of the document).

Note that parsing a display name often requires activating the same objects that would be activated during a binding operation. Therefore, parsing a display name can be as expensive as binding to the object that it refers. Objects that are bound during the parsing operation are cached in the passed-in bind context. If you plan to bind the moniker returned by **MkParseDisplayName**, the best time to do so is immediately after the function returns, using the same bind context; this removes the need to activate objects a second time.

The **MkParseDisplayName** function parses as much of the display name as it understands into a moniker. The function then calls **IMoniker::ParseDisplayName** on the newly created moniker, passing the remainder of the display name. The moniker returned by **IMoniker::ParseDisplayName** is composed onto the end of the existing moniker and, if any of the display name remains unparsed, **IMoniker::ParseDisplayName** is called on the result of the composition. This process is repeated until the entire display name has been parsed.

The **MkParseDisplayName** function attempts the following strategies to parse the beginning of the display name, using the first one that succeeds:

1. The function looks in the Running Object Table for file monikers corresponding to all prefixes of *szDisplayName* that consist solely of valid filename characters. This strategy can identify documents that are as yet unsaved.
2. The function checks the maximal prefix of *szDisplayName*, which consists solely of valid filename characters, to see if an OLE 1 document is registered by that name (this may require some DDE broadcasts). In this case, the returned moniker is an internal moniker provided by the OLE 1 compatibility layer of OLE 2.
3. The function consults the file system to check whether a prefix of *szDisplayName* matches an existing file. The filename can be drive absolute, drive relative, working-directory relative, or begin with an explicit network share name. This is the common case.
4. If the initial character of *szDisplayName* is an '@', the function finds the longest string immediately following it that conforms to the legal ProgID syntax. The function converts this string to a CLSID using the **CLSIDFromProgID** function. If the CLSID represents an OLE 2 class, the function loads the corresponding class object and asks for an **IParseDisplayName** interface pointer. The resulting **IParseDisplayName** interface is then given the whole string to parse, starting with the '@'. If the CLSID represents an OLE 1 class, then the function treats the string following the ProgID as an OLE1/DDE link designator having <*filename*>!<*item*> syntax.

See Also

IMoniker::ParseDisplayName, **IMoniker::GetDisplayName**, **IParseDisplayName**

MonikerCommonPrefixWith QuickInfo

Returns a moniker based on the common prefix that the two monikers share. This function is intended for use only in **IMoniker::CommonPrefixWith** implementations.

```
WINOLEAPI MonikerCommonPrefixWith(
    LPMONIKER pmkThis,                //First moniker being compared
    LPMONIKER pmkOther,               //Second moniker being compared
    LPMONIKER FAR *ppmkCommon         //Receives common prefix
  );
```

Parameters

pmkThis
Points to one of the monikers to compare.

pmkOther
Points to the other moniker to compare.

ppmkCommon
Receives a pointer to a moniker based on the common prefix of *pmkThis* and *pmkOther*. The returned pointer is NULL if an error occurs; if non-NULL, the function has called **IUnknown::AddRef** on the parameter and the caller is responsible for calling **IUnknown::Release**.

Return Values

S_OK
Indicates a common prefix exists that is neither *pmkThis* nor *pmkOther*.

MK_S_HIM
Indicates the entire *pmkOther* moniker is a prefix of the *pmkThis* moniker.

MK_S_ME
Indicates the entire *pmkThis* moniker is a prefix of the *pmkOther* moniker.

MK_S_US
Indicates the *pmkThis* and *pmkOther* monikers are equal.

MK_E_NOPREFIX
Indicates the monikers have no common prefix.

MK_E_NOTBINDABLE
Indicates this function was called on a relative moniker. It is not meaningful to take the common prefix of relative monikers.

E_UNEXPECTED
Indicates an unexpected error occurred.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

Call **MonikerCommonPrefixWith** only if you are writing your own moniker class (implementing the **IMoniker** interface). Call this function from your implementation of the **IMoniker::CommonPrefixWith** method.

Your implementation of **IMoniker::CommonPrefixWith** should first check whether the other moniker is of a type you recognize and handle in a special way. If not, you should call **MonikerCommonPrefixWith**, passing itself as *pmkThis* and the other moniker as *pmkOther*. **MonikerCommonPrefixWith** correctly handles the cases where either moniker is a generic composite.

You should call this function only if *pmkSrc* and *pmkDest* are both absolute monikers (where an absolute moniker is either a file moniker or a generic composite whose left-most component is a file moniker, and where the file moniker represents an absolute path). Do not call this function on relative monikers.

See Also

IMoniker::CommonPrefixWith

MonikerRelativePathTo QuickInfo

Returns a moniker that, when composed onto the end of the first specified moniker (or one with a similar structure), yields the second specified moniker. This function is intended for use only by **IMoniker::RelativePathTo** implementations.

```
WINOLEAPI MonikerRelativePathTo(
   LPMONIKER pmkSrc,                 //Moniker identifying source
   LPMONIKER pmkDest,                //Moniker identifying destination
   LPMONIKER FAR * ppmkRelPath,      //Receives relative moniker
   BOOL dwReserved                   //Reserved; must be non-zero
  );
```

Parameters

pmkSrc
Points to the moniker that, when composed with the relative moniker to be created, produces *pmkDest*. This moniker identifies the "source" of the relative moniker to be created.

pmkDest
Points to the moniker to be expressed relative to *pmkSrc*. This moniker identifies the "destination" of the relative moniker to be created.

ppmkRelPath
Receives a pointer to the relative moniker. The returned pointer is NULL if an error occurs; if non-NULL, the function has called **IUnknown::AddRef** on the parameter and the caller is responsible for calling **IUnknown::Release**.

dwReserved
Reserved; must be non-zero.

Return Values

S_OK
Indicates a meaningful relative path has been returned.

MK_S_HIM
Indicates the only form of the relative path is the other moniker.

MK_E_NOTBINDABLE
Indicates that *pmkSrc* is a relative moniker, such as an item moniker. *pmkSrc* must be composed with the moniker of its container before a relative path can be determined.

E_INVALIDARG
Specifies the parameter *dwReserved* was set to zero.

E_UNEXPECTED
Indicates an unexpected error occurred.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

Call **MonikerRelativePathTo** only if you are writing your own moniker class (implementing the **IMoniker** interface). Call this function from your implementation of the **IMoniker::RelativePathTo** method.

Your implementation of **IMoniker::RelativePathTo** should first check whether the other moniker is of a type you recognize and handle in a special way. If not, you should call **MonikerRelativePathTo**, passing itself as *pmkThis* and the other moniker as *pmkOther*. **MonikerRelativePathTo** correctly handles the cases where either moniker is a generic composite.

You should call this function only if *pmkSrc* and *pmkDest* are both absolute monikers, where an absolute moniker is either a file moniker or a generic composite whose left-most component is a file moniker, and where the file moniker represents an absolute path. Do not call this function on relative monikers.

IMoniker::RelativePathTo

OleBuildVersion QuickInfo

This function is obsolete.

OleConvertIStorageToOLESTREAM QuickInfo

Converts the specified storage object from OLE 2 structured storage to the OLE 1 storage model but does not include the presentation data. This is one of several compatibility functions. You can use these functions to determine if an object class is from OLE 1 and to convert objects between OLE 1 and OLE 2 storage formats.

```
HRESULT OleConvertIStorageToOLESTREAM(
  IStorage * pStg,            //Points to the OLE 2 storage object to be converted
  LPOLESTREAM lpolestm        //Points to the stream where the OLE1 storage is written
 );
```

Parameters

pStg
Points to the storage object to be converted to an OLE 1 storage.

lpolestm
Points to a stream where the persistent representation of the object is saved using the OLE 1 storage model.

Return Values

S_OK
Indicates the storage object was successfully converted and the **OLESTREAM** structure contains the persistent representation of an OLE 1 object.

CONVERT10_E_STG_NO_STD_STREAM
Indicates object cannot be converted because its storage is missing a stream.

CONVERT10_S_NO_PRESENTATION
Indicates the specified storage object contains a Paintbrush object in DIB format and there is no presentation data in the **OLESTREAM**.

E_INVALIDARG
Indicates invalid value for the *pstg* or *lpolestm* parameters.

Comments

This function converts an OLE 2 storage object to OLE 1 format. The **OLESTREAM** code implemented for OLE 1 must be available.

On entry, the stream pointed to by *lpolestm* should be created and positioned just as it would be for an **OleSaveToStream** call. On exit, the stream contains the persistent representation of the object using OLE 1 storage.

Note Paintbrush objects are dealt with differently from other objects because their native data is in DIB format. When Paintbrush objects are converted using **OleConvertIStorageToOLESTREAM**, no presentation data is added to the **OLESTREAM**. To include presentation data, use the **OleConvertIStorageToOLESTREAMEx** function instead.

OleConvertIStorageToOLESTREAMEx   QuickInfo

Converts the specified storage object from OLE 2 structured storage to the OLE 1 storage model, including the presentation data. This is one of several compatibility functions. You can use these functions to determine if an object class is from OLE 1 and to convert objects between OLE 1 and OLE 2 storage formats.

```
HRESULT OleConvertIStorageToOLESTREAMEx(
    IStorage   * pStg,           //Points to the OLE 2 storage object to be converted
    CLIPFORMAT  cfFormat,        //Presentation data format
    LONG   lWidth,               //Width in HIMETRIC
    LONG   lHeight,              //Height in HIMETRIC
    DWORD   dwSize,              //Size of data in bytes
    STGMEDIUM   pmedium,         //Points to STGMEDIUM of data
    LPOLESTREAM   lpolestm       //Points to the stream where the OLE1 storage is written
  );
```

Parameters

pStg
Points to the storage object to be converted to an OLE 1 storage.

cfFormat
Specifies the format of the presentation data. May be NULL, in which case the *lWidth, lHeight, dwSize,* and *pmedium* parameters are ignored. *lWidth*
Specifies the width of the object presentation data in HIMETRIC units.

lHeight
Specifies the height of the object presentation data in HIMETRIC units.

dwSize
Specifies the size of the data to be converted, in bytes.

pmedium
Points to the **STGMEDIUM** structure for the serialized data to be converted. See **STGMEDIUM** for more information.

lpolestm
Points to a stream where the persistent representation of the object is saved using the OLE 1 storage model.

Return Values

S_OK
Indicates the conversion was completed successfully.

DV_E_STGMEDIUM
Specifies the *hGlobal* member of **STGMEDIUM** is NULL.

E_INVALIDARG
Specifies the *dwSize* parameter is NULL; or the *pstg* parameter is invalid; or the *lpolestm* parameter is invalid.

DV_E_TYMED
Specifies the *tymed* member of the **STGMEDIUM** structure is not TYMED_HGOLBAL or TYMED_ISTREAM.

Comments

This function converts an OLE 2 storage object to OLE 1 format. It differs from the **OleConvertIStorageToOLESTREAM** function in that the presentation data to be written to the OLE 1 storage is passed in.

Because **OleConvertIStorageToOLESTREAMEx** can specify which presentation data to convert, it can be used by applications that do not use OLE default caching resources but do use OLE's conversion resources.

The value of the tymed member of **STGMEDIUM** must be either TYMED_HGLOBAL or TYMED_ISTREAM. The medium is not released by **OleConvertIStorageToOLESTREAMEx**.

See Also

CoIsOle1Class, **OleConvertIStorageToOLESTREAM**, **OleConvertOLESTREAMToIStorage**, **OleConvertOLESTREAMToIStorageEx**

OleConvertOLESTREAMToIStorage QuickInfo

Converts the specified object from the OLE 1 storage model to an OLE 2 structured storage object without specifying presentation data. This is one of several compatibility functions. You can use these functions to determine if an object class is from OLE 1 and to convert objects between OLE 1 and OLE 2 storage formats.

```
HRESULT OleConvertOLESTREAMToIStorage(
  LPOLESTREAM lpolestm,             //Points to the stream where the OLE 1 storage is written
  IStorage * pstg,                  //Points to OLE 2 storage object
  const DVTARGETDEVICE * ptd        //Points to target device
 );
```

Parameters

lpolestm
Points to a stream that contains the persistent representation of the object in the OLE 1 storage format.

pstg
Points to the OLE 2 structured storage object.

ptd
Points to the target device for which the OLE 1 object is rendered.

Return Values

S_OK
Indicates the object was successfully converted.

CONVERT10_S_NO_PRESENTATION
Indicates object either has no presentation data or uses native data for its presentation.

DV_E_DVTARGETDEVICE or DV_E_DVTARGETDEVICE_SIZE
Indicates invalid value for *ptd*.

E_INVALIDARG
Indicates invalid value for *lpolestm*.

Comments

This function converts an OLE 1 object to an OLE 2 structured storage object. You can use this function to update OLE 1 objects to OLE 2 objects when a new version of the object application supports OLE 2.

On entry, the *lpolestm* parameter should be created and positioned just as it would be for an **OleLoadFromStream** function call. On exit, the *lpolestm* parameter is positioned just as it would be on exit from an **OleLoadFromStream** function, and the *pstg* parameter contains the uncommitted persistent representation of the OLE 2 storage object.

For OLE 1 objects that use native data for their presentation, the **OleConvertOLESTREAMToIStorage** function returns CONVERT10_S_NO_PRESENTATION. On receiving this return value, callers should call **IOleObject::Update** to get the presentation data so that it can be written to storage.

The following steps describe the conversion process:

1. Create a root **IStorage** object by calling the **StgCreateDocfile** function(..., &*pstg*).
2. Open the OLE 1 file (using **OpenFile** or another OLE 1 technique).
3. Using the OLE 1 procedure for reading files, read from the file until an OLE object is encountered.
4. Allocate an **IStorage** object from the root **IStorage** created in step 1:

```
pstg->lpVtbl->CreateStorage(...&pStgChild);
hRes = OleConvertIStorageToOLESTREAM(polestm, pStgChild);
```

```
  hRes = OleLoad(pStgChild, &IID_IOleObject, pClientSite, ppvObj);
```

5. Repeat step 3 until the file is completely read.

OleConvertOLESTREAMToIStorageEx QuickInfo

Converts the specified object from the OLE 1 storage model to an OLE 2 structured storage object including presentation data. This is one of several compatibility functions. You can use these functions to determine if an object class is from OLE 1 and to convert objects between OLE 1 and OLE 2 storage formats.

```
HRESULT OleConvertOLESTREAMToIStorageEx(
    LPOLESTREAM lpolestm,        //Points to the a stream where the OLE1 storage is written
    IStorage * pstg,             //Points to OLE 2 storage object
    CLIPFORMAT * pcfFormat,      //Points to location where presentation data is returned
    LONG * plWidth,              //Points to location where width value is returned
    LONG * plHeight,             //Points to location where height value is returned
    DWORD * pdwSize,             //Points to location where size is returned
    STGMEDIUM pmedium            //Points to location where the STGMEDIUM structure is returned
   );
```

Parameters

lpolestm
Points to a stream that contains the persistent representation of the object in the OLE 1 storage format.

pstg
Points to the OLE 2 structured storage object.

pcfFormat
Points to the location where the format of the presentation data is returned. May be NULL, indicating the absence of presentation data.

plWidth
Points to the location where the width value (in HIMETRIC) of the presentation data is returned.

plHeight
Points to the location where the height value (in HIMETRIC) of the presentation data is returned.

pdwSize
Points to the location where the size in bytes of the converted data is returned.

pmedium
Points to the location where the **STGMEDIUM** structure for the converted serialized data is returned.

Return Values

S_OK
Indicates the conversion was completed successfully.

DV_E_TYMED|
Specifies the value of the *tymed* member of **STGMEDIUM** is not TYMED_ISTREAM or TYMED_NULL.

Comments

This function converts an OLE 1 object to an OLE 2 structured storage object. You can use this function to update OLE 1 objects to OLE 2 objects when a new version of the object application supports OLE 2.

This function differs from the **OleConvertOLESTREAMToIStorage** function in that the presentation data read from the **OLESTREAM** structure is passed out and the newly created OLE 2 storage object does not contain a presentation stream.

Since this function can specify which presentation data to convert, it can be used by applications that do not use OLE's default caching resources but do use the conversion resources.

The *tymed* member of **STGMEDIUM** can only be TYMED_NULL or TYMED_ISTREAM. If TYMED_NULL, then the data will be returned in a global handle through the *hGlobal* member of **STGMEDIUM**, otherwise data will be written into the *pstm* member of this structure.

CoIsOle1Class, **OleConvertIStorageToOLESTREAM**, **OleConvertIStorageToOLESTREAMEx**, **OleConvertOLESTREAMToIStorage**

OleCreate QuickInfo

Creates an embedded object identified by a CLSID. You use it typically to implement the menu item that allows the end user to insert a new object.

```
STDAPI OleCreate(
  REFCLSID rclsid,              //CLSID of embedded object to be created
  REFIID riid,                  //Interface used to communicate with new object
  DWORD renderopt,              //RENDEROPT value indicating cached capabilities
  FORMATETC * pFormatEtc,       //FORMATETC value, depending upon RENDEROPT value
  IOleClientSite * pClientSite, //Client site pointer to request services from the container
  IStorage * pStg,              //IStorage instance to be used as storage for the object
  void ** ppvObject             //On return, pointer to new object
 );
```

Parameters

rclsid
Specifies the CLSID of the embedded object that is to be created.

riid
Identifies the interface, usually **IID_IOleObject**, through which the caller will communicate with the new object.

renderopt
A value from the enumeration **OLERENDER**, indicating the locally cached drawing capabilities the newly created object is to have. The **OLERENDER** value chosen affects the possible values for the *pFormatEtc* parameter.

pFormatEtc
Depending on which of the **OLERENDER** flags is used as the value of *renderopt*, may be one of the **FORMATETC** enumeration values. Refer to the **OLERENDER** enumeration for restrictions. This parameter, along with the *renderopt* parameter, specifies what the new object can cache initially.

pClientSite
Points to an instance of **IOleClientSite**, the primary interface through which the object will request services from its container. Value may be NULL.

pStg
Points to an instance of the **IStorage** interface to be used as the storage for the object. This parameter may not be NULL.

ppvObject
Upon successful return, receives a pointer to the interface requested in *riid* on the newly created object.

Return Values

S_OK
Indicates embedded object created successfully.

E_OUTOFMEMORY
Indicates embedded object cannot be created due to lack of memory.

Comments

The **OleCreate** function creates a new embedded object, and is typically called to implement the menu item Insert New Object**.** When **OleCreate** returns, the object it has created is blank (contains no data), unless *renderopt* is OLERENDER_DRAW or OLERENDER_FORMAT, and is loaded. Containers typically then call the **OleRun** function or **IOleObject::DoVerb** to show the object for initial editing.

The *rclsid* parameter specifies the CLSID of the requested object. CLSIDs of registered objects are stored in the registry. When an application user selects Insert Object, a selection box allows the user to select the type of object desired from those in the system registry. When **OleCreate** is used to implement the Insert Object menu item, the CLSID associated with the selected item is assigned to the *rclsid* parameter of **OleCreate**.

The *riid* parameter specifies the interface the client will use to communicate with the new object. Upon successful return, the *ppvObject* parameter holds a pointer to the requested interface.

The created object's cache contains information that allows a presentation of a contained object when the container is opened. Information about what should be cached is passed in the *renderopt* and *pFormatetc* values. When **OleCreate** returns, the created object's cache is not necessarily filled. Instead, the cache is filled the first time the object enters the running state. The caller can add additional cache control with a call to **IOleCache::Cache** after the return of **OleCreate** and before the object is run. If *renderopt* is OLERENDER_DRAW or OLERENDER_FORMAT, **OleCreate** requires that the object support the **IOleCache** interface. There is no such requirement for any other value of *renderopt*.

If *pClientSite* is non-NULL, **OleCreate** calls **IOleObject::SetClientSite** with the *pClientSite* parameter. **IOleClientSite** is the primary interface by which an object requests services from its container.

If *pClientSite* is NULL, you must make a specific call to **IOleObject::SetClientSite** before attempting any operations.

See Also

OLERENDER, **FORMATETC**, **IOleClientSite**, **IOleObject**

OleCreateDefaultHandler QuickInfo

Creates a new instance of the default embedding handler. This instance is initialized so it creates a local server when the embedded object enters the running state.

```
HRESULT OleCreateDefaultHandler(
    REFCLSID clsid,               //Identifies OLE server to be loaded
    LPUNKNOWN pUnkOuter,          //Controlling unknown if aggregated; else NULL
    REFIID riid,                  //Interface for communicating with handler
    LPVOID FAR *lplpvObj          //Receives pointer to interface on handler
  );
```

Parameters

clsid
  Specifies CLSID identifying the OLE server to be loaded when the embedded object enters the running state.

pUnkOuter
  Points to the controlling **IUnknown** interface if the handler is to be aggregated; NULL if it is not to be aggregated.

riid
  Specifies the interface, usually **IID_IOleObject**, through which the caller will communicate with the handler.

lplpObj
  On return, receives a pointer to the interface requested in *riid* on the newly created handler.

Return Values

E_OUTOFMEMORY
  Indicates a handler cannot be created because the system is out of memory

NOERROR
  Indicates the creation operation was successful.

Comments

OleCreateDefaultHandler creates a new instance of the default embedding handler, initialized so it creates a local server identified by the *clsid* parameter when the embedded object enters the running state.

If the given object definition does not have a special handler, a call to **OleCreateDefaultHandler** produces the same results as a call to the **CoCreateInstance** function with the class context parameter assigned the value CLSCTX_INPROC_HANDLER.

When to Use

If you are writing a handler and want to use the services of the default handler, call **OleCreateDefaultHandler**. OLE also calls it internally when the CLSID specified in an object creation call is not registered.

See Also

CoCreateInstance, **CLSCTX**

OleCreateEmbeddingHelper QuickInfo

Creates an OLE embedding helper object using application-supplied code aggregated with pieces of the OLE default object handler. This helper object can be created and used in a specific context and role, as determined by the caller.

```
HRESULT OleCreateEmbeddingHelper(
    REFCLSID clsid,                 //The ID of the class to be helped
    LPUNKNOWN pUnkOuter,            //Points to controlling IUnknown
    DWORD flags,                    //Specifies the purpose for the helper
    LPCLASSFACTORY pCF,             //Points to IClassFactory instance
    REFIID riid,                    //The ID of the interface sought by caller
    LPVOID * lplpvObj               //Points to return point for helper
  );
```

Parameters

clsid
Specifies the CLSID of the class to be helped.

pUnkOuter
Points to the controlling **IUnknown** interface if the handler is to be aggregated; NULL if it is not to be aggregated.

flags
Specifies the role and creation context for the embedding helper; see the following comments for legal values.

pCF
Points to the application's **IClassFactory** instance; can be NULL.

riid
Specifies the interface ID desired by the caller.

lplpvObj
Points to where to return the newly created embedding helper.

Return Values

S_OK
Indicates that the OLE embedding helper was created successfully.

E_NOINTERFACE
Indicates that the interface is not supported by the object.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates that one or more arguments are invalid.

E_UNEXPECTED
Indicates that an unexpected error occurred.

Comments

The **OleCreateEmbeddingHelper** function is used to create a new instance of the OLE default handler, which can be used to support objects in various roles. The caller passes a pointer to its **IClassFactory** implementation to **OleCreateEmbeddingHelper**. This object and the default handler are then aggregated to create the new embedding helper object.

The **OleCreateEmbeddingHelper** function is usually used to support one of the following implementations:

- An object application that is being used as both a container and a server, and which supports inserting objects into itself. In this case, the application registers its CLSID for different contexts by calling the **CoRegisterClassObject** function and specifying CLSCTX_LOCAL_SERVER | CLSCTX_INPROC_SERVER as the *dwClsctx* parameter, and REGCLS_MULTI_SEPARATE as the *flags* parameter. The local class is used to create the object and the in-process class creates the embedding helper, passing in the pointer to the first object's class factory in *pCF*.

- An in-process object handler, in which case, the DLL creates the embedding helper by passing in a pointer to a private implementation of **IClassFactory** in *pCF.*

The *flags* parameter indicates how the embedding helper is to be used and how and when the embedding helper is initialized. The values for *flags* are obtained by OR-ing together values from the following table:

Values for *flags* Parameter	**Purpose**
EMBDHLP_INPROC_HANDLER	Creates an embedding helper that can be used with DLL object applications; specifically, the helper exposes the caching features of the default object handler.
EMBDHLP_INPROC_SERVER	Creates an embedding helper that can be used with in-process servers.
EMBDHLP_CREATENOW	EMBDHLP_CREATENOW creates the application-supplied piece of the object immediately.
EMBDHLP_DELAYCREATE	EMBDHLP_DELAYCREATE delays creating the application-supplied piece of the object until the object is put into its running state.

Calling

```
OleCreateEmbeddingHelper
     (clsid, pUnkOuter, EMBDHLP_INPROC_HANDLER | EMBDHLP_CREATENOW,
     NULL, riid, ppvObj)
```

is the same as calling

```
OleCreateDefaultHandler(clsid, pUnkOuter, riid, ppvObj)
```

See Also

OleCreateDefaultHandler

OleCreateFromData QuickInfo

Creates an embedded object from a data transfer object retrieved either from the clipboard or as part of an OLE drag and drop operation. It is intended to be used to implement a paste from an OLE drag and drop operation.

```
HRESULT OleCreateFromData(
  LPDATAOBJECT pSrcDataObj,      //Data transfer object holding data used to create new object
  REFIID riid,                   //Interface to be used to communicate with the new object
  DWORD renderopt,               //Value from OLERENDER
  LPFORMATETC pFormatEtc,        //Depending on renderopt, pointer to value from FORMATETC
  LPOLECLIENTSITE pClientSite,   //Points to instance of IOleClientSite
  LPSTORAGE pStg,                //Points to instance of IStorage used to store object
  LPVOID FAR* ppvObj             //Receives a pointer to the interface requested in riid
 );
```

Parameters

pSrcDataObj
Points to the data transfer object that holds the data from which the object is created.

riid
Identifies the interface the caller later uses to communicate with the new object (usually **IID_IOleObject)**.

renderopt
A value from the enumeration **OLERENDER** that indicates the locally cached drawing or data retrieval capabilities the newly created object is to have. Additional considerations are described in the Comments section below.

pFormatEtc
A value from the enumeration **OLERENDER** that indicates the locally cached drawing or data retrieval capabilities the newly created object is to have. The **OLERENDER** value chosen affects the possible values for the *pFormatEtc* parameter.

pClientSite
Points to an instance of **IOleClientSite**, the primary interface through which the object will request services from its container. May be NULL.

pStg
Points to an instance of the **IStorage** interface to be used as the storage for the object. This parameter may not be NULL.

ppvObj
Receives a pointer to the interface requested in *riid* on the newly created object on return.

Return Values

S_OK
Indicates that the embedded object was created successfully.

OLE_E_STATIC
Indicates OLE can create only a static object.

DV_E_FORMATETC
Indicates no acceptable formats are available for object creation.

Comments

The **OleCreateFromData** function creates an embedded object from an instance of the **IDataObject** interface. The data object in this case is either the type retrieved from the clipboard with a call to the **OleGetClipboard** function or is part of an OLE drag and drop operation (the data object is passed to a call to **IDropTarget::Drop**).

If either the FileName or FileNameW clipboard format (CF_FILENAME) is present in the data transfer object, and CF_EMBEDDEDOBJECT or CF_EMBEDSOURCE do not exist, **OleCreateFromData** creates a package containing the indicated file. (Generally, it takes the first available format.) The Microsoft Windows NT File Manager places these formats on the clipboard when the user selects the File / Copy To Clipboard menu command.

If **OleCreateFromData** cannot create a package, it tries to create an object using the CF_EMBEDDEDOBJECT format. If that format is not available, **OleCreateFromData** tries to create it with the CF_EMBEDSOURCE format. If neither of these formats is available and the data transfer object supports the **IPersistStorage** interface, **OleCreateFromData** calls **IPersistStorage::Save** to have the object save itself.

If an existing linked object is selected, then copied, it appears on the clipboard as just another embeddable object. Consequently, a paste operation that invokes **OleCreateFromData** may create a linked object. After the paste operation, the container should call the **QueryInterface** function, requesting IID_IOleLink, to determine if a linked object was created.

Use the *renderopt* and *pFormatetc* parameters to control the caching capability of the newly created object. For information on how to determine what is to be cached, refer to the **OLERENDER** enumeration for a description of the interaction between *renderopt* and *pFormatetc*. However, values of *renderopt* also specifically affect the way **OleCreateFromData** initializes the cache.

When **OleCreateFromData** uses either the CF_EMBEDDEDOBJECT or the CF_EMBEDSOURCE clipboard format to create the embedded object, the main difference between the two is where the cache-initialization data is stored:

- CF_EMBEDDEDOBJECT indicates that the source is an existing embedded object. It already has in its cache the appropriate data, and OLE uses this data to initialize the cache of the new object.
- CF_EMBEDSOURCE indicates that the source data object contains the cache initialization information in formats other than CF_EMBEDSOURCE. **OleCreateFromData** uses these to initialize the cache of the newly embedded object.

The *renderopt* values affect cache initialization as follows:

Value	Description
OLERENDER_DRAW & OLERENDER_FORMAT	If the presentation information to be cached is currently present in the appropriate cache initialization pool, it is used. (Appropriate locations are in the source data object cache for CF_EMBEDDEDOBJECT, and in the other formats in the source data object for CF_EMBEDSOURCE.) If the information is not present, the cache is initially empty, but will be filled the first time the object is run. No other formats are cached in the newly created object.
OLERENDER_NONE	Nothing is to be cached in the newly created object. If the source has the CF_EMBEDDEDOBJECT format, any existing cached data that has been copied is removed.
OLERENDER_ASIS	If the source has the CF_EMBEDDEDOBJECT format, the cache of the new object is to contain the same cache data as the source

object. For CF_EMBEDSOURCE, nothing is to be cached in the newly created object.

This option should be used by more sophisticated containers. After this call, such containers would call **IOleCache::Cache** and **IOleCache::Uncache** to set up exactly what is to be cached. For CF_EMBEDSOURCE, they would then also call **IOleCache::InitCache**.

See Also

OleCreate

OleCreateFromFile QuickInfo

Creates an embedded object from the contents of a named file.

```
OleCreateFromFile(
    REFCLSID rclsid,                    //Reserved. Must be CLSID_NULL
    LPCOLESTR lpszFileName,             //Points to full path name of file used ot create object
    REFIID riid,                        //Interface to be used to communicate with new object
    DWORD renderopt,                    //Value from OLERENDER
    LPFORMATETC pFormatEtc,             //FORMATETC value depending on OLERENDER value
    LPOLECLIENTSITE pClientSite,        //Pointer to an instance of IOleClientSite
    LPSTORAGE pStg,                     //Pointer to IStorage instance to be used as object storage
    LPVOID FAR* ppvObj                  //Receives a pointer to the interface requested in riid
  );
```

Parameters

rclsid
Reserved. Must be CLSID_NULL.

lpszFileName
Points to the full path name specifying the file from which the object should be initialized.

riid
Identifies the interface the caller later uses to communicate with the new object (usually **IID_IOleObject**).

renderopt
A value from the enumeration **OLERENDER** that indicates the locally cached drawing or data-retrieval capabilities the newly created object is to have. The **OLERENDER** value chosen affects the possible values for the *pFormatEtc* parameter.

pFormatEtc
Depending on which of the **OLERENDER** flags is used as the value of *renderopt*, can be one of the **FORMATETC** enumeration values. Refer also to the **OLERENDER** enumeration for restrictions.

pClientSite
Points to an instance of **IOleClientSite**, the primary interface through which the object will request services from its container. May be NULL.

pStg
Points to an instance of the **IStorage** interface to be used as the storage for the object. This parameter may not be NULL.

ppvObj
Receives a pointer to the interface requested in *riid* on the newly created object on return.

Return Values

S_OK
Indicates embedded object successfully created.

STG_E_FILENOTFOUND
Indicates file not bound.

OLE_E_CANT_BINDTOSOURCE
Indicates not able to bind to source.

STG_E_MEDIUMFULL
Indicates the medium is full.

DV_E_TYMED
Indicates invalid TYMED.

DV_E_LINDEX
Indicates invalid LINDEX.

DV_E_FORMATETC
Indicates invalid **FORMATETC** structure.

E_OUTOFMEMORY
Indicates OLE libraries have not been properly initialized.

Comments

The **OleCreateFromFile** function creates a new embedded object from the contents of a named file. If the ProgID in the registration database contains the PackageOnFileDrop key, it creates a package. If not, the function calls the **GetClassFile** function to get the CLSID associated with the *lpszFileName* parameter, and then creates an OLE 2-embedded object associated with that CLSID. The *rclsid* parameter of **OleCreateFromFile** will always be ignored, and should be set to CLSID_NULL.

As for other **OleCreate***Xxx* functions, the newly created object is not shown to the user for editing, which requires a **DoVerb** operation. It is used in to implement insert file operations, such as the Create from File command in Word for Windows.

GetClassFile

OleCreateLink [QuickInfo]

Creates an OLE compound-document linked object.

```
HRESULT OleCreateLink(
   LPMONIKER pmkLinkSrc,          //Points to IMoniker instance indicating source of linked object
   REFIID riid,                   //Interface to be used to communicate with the new object
   DWORD renderopt,               //Value from OLERENDER
   LPFORMATETC pFormatEtc,        //FORMATETC value depending on renderopt value
   LPOLECLIENTSITE pClientSite,   //Pointer to an instance of IOleClientSite
   LPSTORAGE pStg,                //Pointer to an IStorage instance used as the object storage
   LPVOID FAR* ppvObj             //Receives a pointer to the interface requested in riid
  );
```

Parameters

pmkLinkSrc
Points to an **IMoniker** interface instance that indicates the source of the linked object.

riid
Identifies the interface the caller later uses to communicate with the new object (usually **IID_IOleObject**).

renderopt
Specifies a value from the enumeration **OLERENDER** that indicates the locally cached drawing or data-retrieval capabilities the newly created object is to have. Additional considerations are described in the Comments section below.

lpFormatEtc
Specifies a value from the enumeration **OLERENDER** that indicates the locally cached drawing or data retrieval capabilities the newly created object is to have. The **OLERENDER** value chosen affects the possible values for the *pFormatEtc* parameter.

pClientSite
Points to an instance of **IOleClientSite**, the primary interface through which the object will request services from its container. May be NULL.

pStg
Points to an instance of the **IStorage** interface to be used as the storage for the object. This parameter may not be NULL.

ppvObj
Receives a pointer to the interface requested in *riid* on the newly created object on return.

Return Values

S_OK
Indicates the compound-document linked object was created successfully.

OLE_E_CANT_BINDTOSOURCE
Indicates not able to bind to source. Binding is necessary to get the cache's initialization data.

Comments

Call **OleCreateLink** whenever a container creates a linked object within itself.

See Also

IOleObject::SetMoniker, **IOleClientSite::GetMoniker**

OleCreateLinkFromData **QuickInfo**

Creates a linked object from a data transfer object retrieved either from the clipboard or as part of an OLE drag and drop operation.

```
HRESULT OleCreateLinkFromData(
    LPDATAOBJECT pSrcDataObj,        //Points to data transfer object used to create linked object
    REFIID riid,                     //Interface to be used to communicate with the new object
    DWORD renderopt,                 //OLERENDER value
    LPFORMATETC pFormatEtc,          //FORMATETC value, depends on OLERENDER value
    LPOLECLIENTSITE pClientSite,     //Points to IOleClientSite instance
    LPSTORAGE pStg,                  //Pointer to an IStorage instance used as the object storage
    LPVOID FAR* ppvObj               //On return, points to requested object
  );
```

Parameters

pSrcDataObj
Points to the data transfer object from which the linked object is to be created.

riid
Identifies the interface the caller later uses to communicate with the new object (usually **IID_IOleObject**).

renderopt
Specifies a value from the enumeration **OLERENDER** that indicates the locally cached drawing or data-retrieval capabilities the newly created object is to have. Additional considerations are described in the Comments section below.

pFormatEtc
Specifies a value from the enumeration **OLERENDER** that indicates the locally cached drawing or data-retrieval capabilities the newly created object is to have. The **OLERENDER** value chosen affects the possible values for the *pFormatEtc* parameter.

pClientSite
Points to an instance of **IOleClientSite**, the primary interface through which the object will request services from its container. May be NULL.

pStg
Points to an instance of the **IStorage** interface to be used as the storage for the object. This parameter may not be NULL.

ppvObj
Receives a pointer to the interface requested in *riid* on the newly created object on return.

Return Values

S_OK
Indicates the linked object was created successfully.

CLIPBRD_E_CANT_OPEN
Indicates not able to open the clipboard.

OLE_E_CANT_GETMONIKER
Indicates not able to extract the object's moniker.

OLE_E_CANT_BINDTOSOURCE
Indicates not able to bind to source. Binding is necessary to get the cache's initialization data.

Comments

The **OleCreateLinkFromData** function is used to implement either a paste-link or a drag-link operation.

Its operation is similar to that of the **OleCreateFromData** function, except that it creates a link, and looks for different data formats. If the CF_LINKSOURCE format is not present, and either the FileName or FileNameW clipboard format is present in the data transfer object, **OleCreateLinkFromData** creates a package containing the link to the indicated file.

You use the *renderopt* and *pFormatetc* parameters to control the caching capability of the newly created object. For information on how to determine what is to be cached, refer to the **OLERENDER** enumeration for a description of the interaction between *renderopt* and *pFormatetc*. However, values of *renderopt* also specifically affect the way **OleCreateLinkFromData** initializes the cache as follows:

Value	**Description**
OLERENDER_DRAW, OLERENDER_FORMAT	If the presentation information is in the other formats in the source data object,this information is used. If the information is not present, the cache is initially empty, but will be filled the first time the object is run. No other formats are cached in the newly created object.
OLERENDER_NONE, OLERENDER_ASIS	Nothing is to be cached in the newly created object.

See Also

OleCreateLink

OleCreateLinkToFile [QuickInfo]

Creates an object that is linked to a file.

```
STDAPI OleCreateLinkToFile(
    LPWSTR lpszFileName,            //Points to source of linked object
    REFIID riid,                    //Interface to be used to communicate with the new object
    DWORD renderopt,                //Value from OLERENDER
    LPFORMATETC pFormatEtc,         //FORMATETC value depending on renderopt value
    IOleClientSite * pClientSite,   //Pointer to an instance of IOleClientSite
    IStorage * pStg,                //Pointer to an IStorage instance used as the object storage
    void ** ppvObj                  //Receives a pointer to the interface requested in riid
  );
```

Parameters

lpszFileName
Points to the source file to be linked to.

riid
Identifies the interface the caller later uses to communicate with the new object (usually **IID_IOleObject**).

renderopt
Specifies a value from the enumeration **OLERENDER** that indicates the locally cached drawing or data-retrieval capabilities the newly created object is to have. Additional considerations are described in the Comments section below.

pFormatEtc
Specifies a value from the enumeration **OLERENDER** the indicates the locally cached drawing or data retrieval capabilities the newly created object is to have. The **OLERENDER** value chosen affects the possible values for the *pFormatEtc* parameter.

pClientSite
Points to an instance of **IOleClientSite**, the primary interface through which the object will request services from its container. May be NULL.

pStg
Points to an instance of the **IStorage** interface to be used as the storage for the object. This parameter may not be NULL.

ppvObj
Receives a pointer to the interface requested in *riid* on the newly created object on return.

Return Values

S_OK
Indicates the object was created successfully.

STG_E_FILENOTFOUND
Indicates file name is invalid.

OLE_E_CANT_BINDTOSOURCE
Indicates not able to bind to source.

Comments

The **OleCreateLinkToFile** function differs from the **OleCreateLink** function because it can create links to non-OLE aware files (as well as files that are OLE-aware) using the Windows Packager.

See Also

OleCreateLink

OleCreateMenuDescriptor QuickInfo

Creates and returns an OLE menu descriptor (that is, an OLE-provided data structure that describes the menus) for OLE to use when dispatching menu messages and commands.

```
HOLEMENU OleCreateMenuDescriptor(
    HMENU hmenuCombined,                    //Specifies a handle to the combined menu
    LPOLEMENUGROUPWIDTHS                    //Number of menus in each group
lpMenuWidths
   );
```

Parameters

hmenuCombined
Specifies a handle to the combined menu created by the object.

lpMenuWidths
Points to an array of six LONG values giving the number of menus in each group.

Return Value

Returns the handle to the descriptor, or NULL if insufficient memory is available.

Comments

The **OleCreateMenuDescriptor** function can be called by the object to create a descriptor for the composite menu. OLE then uses this descriptor to dispatch menu messages and commands.

See Also

OleDestroyMenuDescriptor

OleCreateStaticFromData QuickInfo

The **OleCreateStaticFromData** function creates a static object (containing only a representation, with no native data) from a data transfer object.

```
HRESULT OleCreateStaticFromData(
    LPDATAOBJECT pSrcDataObj,         //Data transfer object holding data used to create new object
    REFIID riid,                      //Interface to be used to communicate with the new object
    DWORD renderopt,                  //Value from OLERENDER
    LPFORMATETC pFormatEtc,           //Depending on renderopt, pointer to value from FORMATETC
    LPOLECLIENTSITE pClientSite,      //Points to instance of IOleClientSite
    LPSTORAGE pStg,                   //Points to instance of IStorage used to store object
    LPVOID FAR* ppvObj                //Receives a pointer to the interface requested in riid
  );
```

Parameters

pSrcDataObj
Points to the data transfer object that holds the data from which the object will be created.

riid
Identifies the interface with which the caller is to communicate with the new object (usually **IID_IOleObject**).

renderopt
A value from the enumeration **OLERENDER** indicating the locally cached drawing or data-retrieval capabilities that the container wants in the newly created component. It is an error to pass the render options OLERENDER_NONE or OLERENDER_ASIS to this function.

pFormatEtc
Depending on which of the **OLERENDER** flags is used as the value of *renderopt*, may be one of the **FORMATETC** enumeration values. Refer to the **OLERENDER** enumeration for restrictions.

pClientSite
Points to an instance of **IOleClientSite**, the primary interface through which the object will request services from its container. May be NULL.

pStg
Points to an instance of the **IStorage** interface to be used as the storage for the object. This parameter may not be NULL.

ppvObj
When the function returns successfully, contains a pointer to the interface requested in *riid* on the newly created object.

Return Value

S_OK
Indicates that the object was successfully created.

Comments

The **OleCreateStaticFromData** function can convert any object that provides an **IDataObject** interface to a static object. It is useful in implementing the Convert To Picture option for OLE linking or embedding.

Static objects can be created only if the source supports one of the OLE-rendered clipboard formats: CF_METAFILEPICT, CF_DIB, or CF_ BITMAP, and CF_ENHMF.

Static objects can be pasted from the clipboard using **OleCreateStaticFromData**. The **OleQueryCreateFromData** function will return OLE_S_STATIC if one of CF_METAFILEPICT, CF_DIB, or CF_BITMAP is present and an OLE format is not present. But, in that case, the **OleCreateFromData** function does not automatically create the static object – if the container will be pasting a static object it should call **OleCreateStaticFromData**.

The new static object is of class CLSID_StaticMetafile (in the case of CF_METAFILEPICT) and CLSID_StaticDib (in the case of CF_DIB or CF_BITMAP). The static object sets the OLEMISC_STATIC and OLE_CANTLINKINSIDE bits returned from **IOleObject::GetMiscStatus**. The static object will have the aspect DVASPECT_CONTENT and a LINDEX of -1.

The *pDataObject* is still valid after **OleCreateStaticFromData** returns. It is the caller's responsibility to free *pDataObject* – OLE does not release it.

There cannot be more than one presentation stream in a static object.

Note The **OLESTREAM**<->**IStorage** conversion functions also convert static objects.

See Also

OleCreateFromData

OleDestroyMenuDescriptor QuickInfo

Called by the container to free the shared menu descriptor allocated by the **OleCreateMenuDescriptor** function.

```
void OleDestroyMenuDescriptor(
    HOLEMENU holemenu        //Handle to the shared menu descriptor
  );
```

Parameter

holemenu

Specifies a handle to the shared menu descriptor that was returned by the **OleCreateMenuDescriptor** function.

Return Value

None. (This function does not indicate failure.)

See Also

OleCreateMenuDescriptor

OleDoAutoConvert QuickInfo

Automatically converts an object to a new class if conversion is needed.

```
HRESULT OleDoAutoConvert(
    IStorage * pStg,            //Pointer to storage object to be converted
    LPCLSID pClsidNew           //Points to new CLSID of converted object
  );
```

Parameters

pStg
Points to the persistent storage of the object to be converted.

pClsidNew
Points to the new CLSID for the object being converted. If there was no automatic conversion, this may be the same as the original class.

Return Values

S_OK
Indicates no conversion is needed or a conversion was successfully completed.

REGDB_E_KEYMISSING
Indicates cannot read a key from the registration database.

E_OUTOFMEMORY
Indicates the conversion was not successful due to a lack of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

See also the **OleGetAutoConvert** function for other error return values.

See the **IStorage::OpenStorage** and **IStorage::OpenStream** methods for possible errors when accessing storage and stream objects.

See also the **IStream** interface for other error return values when it is not possible to determine the existing CLSID or when it is not possible to update the storage object with new information.

Comments

This function automatically converts an object if automatic conversion has previously been specified in the registry by the **OleSetAutoConvert** function. Object conversion means that the object is permanently associated with a new CLSID. Automatic conversion is typically specified by the setup program for a new version of an object application so that objects created by its older versions can be automatically updated.

A container application that supports object conversion should call the **OleDoAutoConvert** function each time it loads an object. If the container uses the **OleLoad** helper function, it need not call **OleDoAutoConvert** explicitly because **OleLoad** calls it internally.

The **OleDoAutoConvert** function first determines whether any conversion is required by calling the **OleGetAutoConvert** function. If no conversion is required, the function returns S_OK. Otherwise, the storage object is modified and converted by activating the new object application. The new object application reads the existing data format but when the object is saved, the new native format for the object application is saved.

If the object to be automatically converted is an OLE 1 object, the ItemName string is stored in a stream called "\1Ole10ItemName." If this stream does not exist, the object's item name is NULL.

The storage object must be in the unloaded state when **OleDoAutoConvert** is called.

See Also

OleSetAutoConvert

OleDraw QuickInfo

The **OleDraw** helper function can be used to draw objects more easily. You can use it instead of calling **IViewObject::Draw** directly.

```
STDAPI OleDraw(
  IUnknown * pUnk,          //Points to the view object to be drawn
  DWORD dwAspect,           //Specifies how the object is to be represented
  HDC hdcDraw,              //Identifies the device context on which to draw
  LPCRECT lprcBounds        //Specifies the rectangle in which the object is drawn
 );
```

Parameters

pUnk
Points to the view object that is to be drawn.

dwAspect
Specifies how the object is to be represented. Representations include content, an icon, a thumbnail, or a printed document. Valid values are taken from the enumeration **DVASPECT**. See **DVASPECT** for more information.

hdcDraw
Specifies the device context on which to draw. Cannot be a metafile device context.

lprcBounds
Points to a **RECT** structure specifying the rectangle in which the object should be drawn. This parameter is converted to a **RECTL** structure and passed to **IViewObject::Draw**.

Return Values

S_OK
Indicates object was successfully drawn.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_OUTOFMEMORY
Indicates ran out of memory.

OLE_E_BLANK
Indicates there is no data to draw from.

E_ABORT
Indicates the draw operation was aborted.

VIEW_E_DRAW
Indicates an error occurred in drawing.

OLE_E_INVALIDRECT
Indicates the rectangle is invalid.

DV_E_NOIVIEWOBJECT
Indicates the object doesn't support the **IViewObject** interface.

Comments

The **OleDraw** helper function calls the **QueryInterface** method for the object specified (*pUnk*), asking for an **IViewObject** interface on that object. Then, **OleDraw** converts the **RECT** structure to a **RECTL** structure, and calls **IViewObject::Draw** as follows:

```
lpViewObj->Draw(dwAspect,-1,0,0,0,hdcDraw,&rectl,0,0,0);
```

Do not use **OleDraw** to draw into a metafile because it does not specify the *lprcWBounds* parameter required for drawing into metafiles.

See Also

IViewObject::Draw

OleDuplicateData QuickInfo

Duplicates the data found in the specified handle and returns a handle to the duplicated data. The source data is in a clipboard format. You use this function when implementing some of the data transfer interfaces such as **IDataObject**.

```
HANDLE OleDuplicateData(
    HANDLE hSrc,              //Handle of the source data
    CLIPFORMAT cfFormat,      //Clipboard format of the source data
    UINT uiFlags              //Flags used in global memory allocation
  );
```

Parameters

hSrc
Specifies the handle of the source data.

cfFormat
Specifies the clipboard format of the source data.

uiFlags
Specifies the flags to be used in allocate global memory for the copied data. These flags are passed to **GlobalAlloc**. If the value of *uiFlags* is NULL, GMEM_MOVEABLE is used as a default flag.

Return Values

HANDLE
Indicates data was successfully duplicated and the handle to the new data is the return value of the function.

NULL
Indicates error duplicating data.

Comments

The CF_METAFILEPICT, CF_PALETTE, or CF_BITMAP formats receive special handling. They are GDI handles and a new GDI object must be created instead of just copying the bytes. All other formats are duplicated byte-wise. For the formats that are duplicated byte-wise, *hSrc* must be a global memory handle.

OleFlushClipboard QuickInfo

Carries out the clipboard shutdown sequence. It also releases the instance of the **IDataObject** interface that was placed on the clipboard by the **OleSetClipboard** function.

HRESULT OleFlushClipboard();

Return Values

S_OK
  Indicates the clipboard has been flushed.

CLIPBRD_E_CANT_OPEN
  Indicates the Windows **OpenClipboard** function used within **OleFlushClipboard** failed.

CLIPBRD_E_CANT_CLOSE
  Indicates the Windows **CloseClipboard** function used within **OleFlushClipboard** failed.

Comments

If you are writing an application that can act as the source of a clipboard operation, you can call **OleFlushClipboard** to flush the clipboard and release the instance of **IDataObject** when your application is closed (e.g., if the user exits from your application). A call to the **OleSetClipboard** function using NULL will empty the clipboard.

The difference is that **OleFlushClipboard** leaves all formats offered by the data transfer object, including the OLE 1 compatibility formats, on the clipboard so they are available after application shutdown. In addition to OLE 1 compatibility formats, these include all formats offered on a global handle medium (all except for TYMED_FILE) and formatted with a NULL target device.

When your application closes, you should call **OleSetClipboard** using NULL if there is no need to leave data on the clipboard after shutdown or if data will be placed on the clipboard using the standard Windows clipboard functions. Applications should call **OleFlushClipboard** to enable pasting and paste-linking of OLE objects after shutdown.

Before calling **OleFlushClipboard**, it must be convenient to check the clipboard. You can call the **OleIsCurrentClipboard** function to determine if your data is still on the clipboard.

See Also

OleSetClipboard, **OleIsCurrentClipboard**, **IDataObject**,

OleGetAutoConvert QuickInfo

Returns the new CLSID to which the specified object can be automatically converted. This conversion CLSID is stored in the registration database.

```
HRESULT OleGetAutoConvert(
   REFCLSID clsidOld,         //CLSID of the object to be converted
   LPCLSID pClsidNew          //Pointer to new CLSID for object being converted
  );
```

Parameters

clsidOld
Specifies the CLSID for an object that can be automatically converted.

pClsidNew
Points to location where the new CLSID, if any, is returned. The original object, *clsidOld*, is automatically converted to this new CLSID when the object is opened. If there is no auto-conversion CLSID stored in the registration database, the value *clsidOld* is returned; the *pClsidNew* parameter cannot be NULL.

Return Values

S_OK
Indicates that a value was successfully returned through the *pclsidNew* parameter.

REGDB_E_CLASSNOTREG
Indicates the *clsidOld* CLSID is not properly registered in the registration database.

REGDB_E_READREGDB
Indicates error reading the registration database.

REGDB_E_KEYMISSING
Indicates auto convert is not active or there was no registration entry for the *clsidOld* parameter.

E_OUTOFMEMORY
Indicates the value was not returned due to a lack of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

This function returns the AutoConvertTo entry in the registration database for the specified object, which specifies whether objects of a given CLSID are to be automatically converted to a new CLSID. This is usually set up to convert files created by older versions of an application to the current version. If there is no AutoConvertTo entry, this function returns the value of *clsidOld*. This function is typically called by the **OleDoAutoConvert** function to determine if the object specified needs to be converted. If the object has an AutoConvertTo entry, then it will be converted.

Automatic conversion is typically set up during the installation of an object application. The setup program can take advantage of the AutoConvertTo subkey to tag a class of objects for automatic conversion to a different class of objects.

For example, a new version of a spreadsheet application may need to convert spreadsheets that were created with earlier versions of the application. These earlier version spreadsheet objects have a different CLSID than the new version. The setup program for the new version of the spreadsheet application tags objects in the registration database that have the old CLSID so they are automatically updated when they are loaded.

To tag the old spreadsheet objects, the setup program calls the **OleSetAutoConvert** function and passes it to the CLSIDs of the source and destination object classes. The **OleSetAutoConvert** function creates the required entry in the registration database. These entries appear in the registration database as subkeys of the CLSID key:

```
CLSID\{clsid}=MainUserTypeName\AutoConvertTo = clsid
```

See Also

OleSetAutoConvert, **OleDoAutoConvert**

OleGetClipboard QuickInfo

Retrieves a data object that you can use to access the clipboard contents.

```
HRESULT OleGetClipboard(
  IDataObject ** ppDataObj        //Points to location where a pointer to the data object is placed
 );
```

Parameter

ppDataObj
Points to the location where a pointer to the retrieved data object can be placed.

Return Values

S_OK
Indicates the data object was successfully retrieved.

E_OUTOFMEMORY
Indicates the data object was not returned due to a lack of memory.

CLIPBRD_E_CANT_CLOSE
Indicates the Windows **CloseClipboard** function used within **OleGetClipboard** failed.

CLIPBRD_E_CANT_OPEN
Indicates the Windows **OpenClipboard** function used with **OleGetClipboard** failed.

Comments

If you are writing an application that can accept data from the clipboard, you call **OleGetClipboard** to get a pointer to a data object that you can use to retrieve the contents of the clipboard.

There are three cases that the **OleGetClipboard** function handles:

1. The application that placed data on the clipboard with the **OleSetClipboard** function is still running.
2. The application that placed data on the clipboard with the **OleSetClipboard** function has subsequently called the **OleFlushClipboard** function.
3. There is data from a non-OLE application on the clipboard.

In the first case, the clipboard data object returned by the **OleGetClipboard** function may forward calls as necessary to the original data object placed on the clipboard and, thus, can potentially make RPC calls.

In the second case, OLE creates a default data object and returns it to the user. However, because the data on the Clipboard originated from an **OleSetClipboard** call, the OLE-provided data object contains more accurate information about the type of data on the Clipboard. In particular, the original medium (TYMED) on which the data was offered is known. Thus, if a data-source application offers a particular clipboard format, for example cfFOO, on an **IStorage** object and calls the **OleFlushClipboard** function, the storage object is copied into memory and the *hglobal* memory handle is put on the Clipboard. Then, when the **OleGetClipboard** function creates its default data object, the *hglobal* from the clipboard again becomes an **IStorage** object. Furthermore, the **FORMATETC** enumerator and the **IDataObject::QueryGetData** method would all correctly indicate that the original clipboard format (cfFOO) is again available on a TYMED_ISTORAGE.

In the third case, OLE still creates a default data object, but there is no special information about the data in the Clipboard formats (particularly for application-defined Clipboard formats). Thus, if an hGlobal-based storage medium were put on the Clipboard directly by a call to the **SetClipboardData** function, the **FORMATETC** enumerator and the **IDataObject::QueryGetData** method would not indicate that the data was available on a storage medium. A call to the **IDataObject::GetData** method for TYMED_ISTORAGE would succeed, however. Because of these limitations, it is strongly recommended that OLE-aware applications interact with the Clipboard using the OLE Clipboard functions.

The clipboard data object created by the **OleGetClipboard** function has a fairly extensive **IDataObject** implementation. The OLE-provided data object can convert OLE 1 clipboard format data into the representation expected by an OLE 2 caller. Also, any structured data is available on any structured or flat medium, and any flat data is available on any flat medium. However, GDI objects (such as metafiles and bitmaps) are only available on their respective mediums.

Note that the *tymed* member of the **FORMATETC** structure used in the **FORMATETC** enumerator contains the union of supported mediums. Applications looking for specific information (such as whether CF_TEXT is available on TYMED_HGLOBAL) should do the appropriate bit masking when checking this value.

If you call the **OleGetClipboard** function, you should only hold on to the returned **IDataObject** for a very short time. It consumes resources in the application that offered it.

See Also

OleSetClipboard

OleGetIconOfClass QuickInfo

Returns a handle to a metafile containing an icon and a string label for the specified CLSID.

```
HGLOBAL OleGetIconOfClass(
    REFCLSID rclsid,              //CLSID for which information is requested
    LPOLESTR lpszLabel,           //Points to string to use as label for icon
    BOOL fUseTypeAsLabel          //Indicates whether to use CLSID's user type name as icon label
  );
```

Parameters

rclsid
Specifies the CLSID for which the icon and string are requested.

lpszLabel
Points to a string to use as a label for the icon.

fUseTypeAsLabel
Indicates whether or not to use the user type string in the CLSID as the icon label.

Return Value

HGLOBAL
The *hGlobal* returned is a handle to a metafile that contains an icon and label for the specified CLSID. If the CLSID cannot be found in the registration database, NULL is returned.

See Also

OleGetIconOfFile, **OleMetafilePictFromIconAndLabel**

OleGetIconOfFile QuickInfo

Returns a handle to a metafile containing an icon and string label for the specified filename.

```
HGLOBAL OleGetIconOfFile(
   LPOLESTR lpszPath,          //Points to string that specifies the file for which info is requested
   BOOL fUseFileAsLabel        //Indicates whether to use the filename as the icon label
  );
```

Parameters

lpszPath
Points to a file for which the icon and string are requested.

fUseFileAsLabel
Indicates whether or not to use the filename as the icon label.

Return Value

HGLOBAL
The *hGlobal* returned is a handle to a metafile that contains an icon and label for the specified file. If there is no CLSID in the registration database for the file, then the string "Document" is used. If the value of *lpszPath* is NULL, then NULL is returned.

See Also

OleGetIconOfClass, **OleMetafilePictFromIconAndLabel**

OleInitialize QuickInfo

The **OleInitialize** function initializes the OLE library. You must initialize the library before you can call OLE functions.

```
HRESULT OleInitialize(
  LPVOID pvReserved      //Reserved, must be NULL
 );
```

Parameter

pvReserved
In 32-bit OLE, this parameter must be NULL. The 32-bit version of OLE does not support applications replacing OLE's allocator and if the parameter is not NULL, **OleInitialize** returns E_INVALIDARG.

Return Values

S_OK
Indicates the library was initialized successfully.

S_FALSE
Indicates OLE library is already initialized; a pointer to the IMalloc implementation was not used.

OLE_E_WRONGCOMPOBJ
Indicates COMPOBJ.DLL is the wrong version for OLE2.DLL.

E_OUTOFMEMORY
Indicates the library was not initialized because the system was out of memory.

E_INVALIDARG
Indicates an argument was invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

Applications *must* call **OleInitialize** before calling any other function in the OLE library.

Typically, **OleInitialize** is called only once in the process that uses the OLE library. There can be multiple calls, but subsequent calls return S_FALSE. To close the library gracefully, each successful call to **OleInitialize**, including those that return S_FALSE, *must* be balanced by a corresponding call to the **OleUninitialize** function.

See Also

OleUninitialize, **CoInitialize**

OleIsCurrentClipboard QuickInfo

Determines whether the **IDataObject** interface previously placed on the clipboard by the **OleSetClipboard** function is still on the clipboard.

```
HRESULT OleIsCurrentClipboard(
  IDataObject * pDataObj       //The data object previously copied or cut
 );
```

Parameter

pDataObject
Points to the instance of **IDataObject** that the caller previously placed on the clipboard.

Return Values

S_OK
Indicates that **IDataObject** is currently on the clipboard and the caller is the owner of the clipboard.

S_FALSE
Indicates that **IDataObject** is not on the clipboard.

Notes to Callers

OleIsCurrentClipboard only works for the data object used in the **OleSetClipboard** function. It cannot be called by the consumer of the data object to determine if the object that was on the clipboard at the previous **OleGetClipboard** call is still on the clipboard.

See Also

OleFlushClipboard, **OleSetClipboard**

OleIsRunning QuickInfo

Determines whether an object is currently in the running state.

```
BOOL OleIsRunning(
   LPOLEOBJECT pObject          //Pointer to IOleObject interface
  );
```

Parameter

pObject
  Points to an the object's **IOleObject** interface.

Return Value

The return value is TRUE if the object is running; otherwise, it is FALSE.

Comments

You can use **OleIsRunning** and **IRunnableObject::IsRunning** interchangeably. **OleIsRunning** queries the object for a pointer to the **IRunnableObject** interface. If successful, the function returns the results of calling the **IRunnableObject::IsRunning** method.

Note The implementation of **OleIsRunning** in earlier versions of OLE differs from that described here.

For more information on using this function, see **IRunnableObject::IsRunning**.

See Also

IRunnableObject::IsRunning

OleLoad [QuickInfo]

Loads into memory an object nested within a specified storage object.

```
HRESULT OleLoad(
    IStorage * pStg,                //Points to the storage object from which to load
    REFIID riid,                    //Interface to use for the object being loaded
    IOleClientSite * pClientSite,   //Points to the client site for the object
    LPVOID * ppvObj                 //Points to the newly loaded object
  );
```

Parameters

pStg
Points to the storage object from which to load the specified object.

riid
Specifies the interface that the caller wants to use when talking to the object once it is loaded.

pClientSite
Points to the client site for the object being loaded.

ppvObj
Points to the newly loaded object.

Return Values

S_OK
Indicates the object was loaded successfully.

E_OUTOFMEMORY
Indicates the object could not be loaded due to lack of memory.

E_NOINTERFACE
Indicates the object does not support the specified interface.

See also the **IPersistStorage::Load** method for other error return values.

Comments

OLE containers load objects into memory by calling this function. When calling the **OleLoad** function, the container application passes in a pointer to the open storage object in which the nested object is stored. Typically, the nested object to be loaded is a child storage object to the container's root storage object. Using the OLE information stored with the object, the object handler (usually, the default handler) attempts to load the object. On completion of the **OleLoad** function, the object is said to be in the loaded state with its object application not running.

Some applications load all of the object's native data. Containers often defer loading the contained objects until required to do so. For example, until an object is scrolled into view and needs to be drawn, it does not need to be loaded.

The **OleLoad** function performs the following steps:

1. If necessary, performs an automatic conversion of the object (see the **OleDoAutoConvert** function).
2. Gets the CLSID from the open storage object by calling the **IStorage::Stat** method.
3. Calls the **CoCreateInstance** function to create an instance of the handler. If the handler code is not available, the default handler is used (see the **OleCreateDefaultHandler** function).
4. Calls the **IOleObject::SetClientSite** method with the *pClientSite* parameter to inform the object of its client site.
5. Calls the **QueryInterface** method for the **IPersistStorage** interface. If successful, the **IPersistStorage::Load** method is invoked for the object.
6. Queries and returns the interface identified by the *riid* parameter.

See Also

ReadClassStg, **IClassFactory::CreateInstance**, **IPersistStorage::Load**

OleLoadFromStream QuickInfo

Loads an object from the stream.

```
HRESULT OleLoadFromStream(
   IStream * pStm,           //Points to stream from which object is to be loaded
   REFIID iidInterface,      //Interface to use for the object being loaded
    void ** ppvObj           //Points to the newly loaded object
  );
```

Parameters

pStm
Points to the stream from which the object is to be loaded.

iidInterface
Specifies the interface the caller wants to use to talk to the object once it is loaded.

ppvObj
Points to the newly loaded object.

Return Values

S_OK
Indicates the object was successfully loaded.

E_OUTOFMEMORY
Indicates the object could not be loaded due to a lack of memory.

E_NOINTERFACE
Indicates the specified interface is not supported.

See also the **ReadClassStm** function for other error return values.

See also the **CoCreateInstance** function for other error return values.

See also the **IPersistStorage::Load** method for other error return values.

Comments

This function can be used to load an object that supports the **IPersistStream** interface. The CLSID of the object must immediately precede the object's data in the stream.

If the CLSID for the stream is CLSID_NULL, the *ppvObj* parameter is set to NULL.

See Also

OleSaveToStream

OleLockRunning QuickInfo

Locks an already running object into its running state or unlocks it from its running state.

```
HRESULT OleLockRunning(
  LPUNKNOWN pUnknown,        //Pointer to IUnknown interface
  BOOL fLock,                //Flag indicating whether object is locked
  BOOL fLastUnlockCloses     //Flag indicating whether to close object
 );
```

Parameters

pUnknown
Points to an object's **IUnknown** interface in order to obtain a pointer to **IRunnableObject::LockRunning**.

fLock
TRUE locks the object into its running state. FALSE unlocks the object from its running state.

fLastUnlockCloses
TRUE specifies that if the connection being released is the last external lock on the object, the object should close. FALSE specifies that the object should remain open until closed by the user or another process.

Return Values

S_OK
Indicates that the object was successfully locked or unlocked.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Indicates one or more arguments are invalid .

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

The **OleLockRunning** function saves you the trouble of calling the **IRunnableObject::LockRunning** method. You can use **OleLockRunning** and **IRunnableObject::LockRunning** interchangeably. **OleLockRunning** queries for an **IRunnableObject** pointer. If successful, it returns the results of calling **IRunnableObject::LockRunning**.

Note The implementation of **OleLockRunning** in earlier versions of OLE differs from that described here.

For more information on using this function, see **IRunnableObject::LockRunning**.

See Also

CoLockObjectExternal, **IRunnableObject::LockRunning**, **OleNoteObjectVisible**

OleMetafilePictFromIconAndLabel QuickInfo

Creates a **METAFILEPICT** structure that contains a metafile in which the icon and label are drawn.

```
HGLOBAL OleMetafilePictFromIconAndLabel(
    HICON hIcon,                    //Handle to the icon to be drawn into the metafile
    LPOLESTR lpszLabel,             //Points to the string to be used as the icon label
    LPOLESTR lpszSourceFile,        //Points to the string that contains the path to the icon file
    UINT iIconIndex                 //Index of icon in lpszSourceFile
  );
```

Parameters

hIcon
Handle to the icon that is to be drawn into the metafile.

lpszLabel
Points to the string to be used as the icon label.

lpszSourceFile
Points to the string that contains the path and filename of the icon file. This string can be obtained from the user or from the registration database.

iIconIndex
Provides the index to the icon within the *lpszSourceFile* file.

Return Value

HGLOBAL
Indicates the *hGlobal* returned is the handle to a **METAFILEPICT** structure containing the icon and label. The metafile uses the MM_ANISOTROPIC mapping mode.

See Also

OleGetIconOfClass, **OleGetIconOfFile**

OleNoteObjectVisible QuickInfo

Increments or decrements an external reference that keeps the object in the running state.

```
STDAPI OleNoteObjectVisible(
   LPUNKNOWN pUnknown,       //Points to an IUnknown instance
   BOOL fVisible             //Indicates whether object is visible
  );
```

Parameters

pUnknown
Points to an **IUnknown** instance for the object that is to be locked or unlocked.

fVisible
Indicates whether the object is visible. If TRUE, OLE holds the object visible and alive regardless of external or internal **IUnknown::AddRef** and **IUnknown::Release** operations; registrations; or revokes. If FALSE, OLE releases its hold and the object can be closed.

Return Values

S_OK
Indicates the object was successfully locked or unlocked.

E_OUTOFMEMORY
Indicates insufficient memory to perform the operation.

E_INVALIDARG
Indicates an invalid argument.

E_UNEXPECTED
Indicates an unexpected error.

Comments

The **OleNoteObjectVisible** function calls the **CoLockObjectExternal** function. It is provided as a separate function to reinforce the need to lock an object when it becomes visible to the user and to release the object when it becomes invisible. This creates a strong lock on behalf of the user to ensure that the object cannot be closed by its container while it is visible.

See Also

CoLockObjectExternal

OleQueryCreateFromData **QuickInfo**

Checks whether a data object has one of the formats that would allow it to become an embedded object through a call to either the **OleCreateFromData** or **OleCreateStaticFromData** function.

```
STDAPI OleQueryCreateFromData(
   IDataObject * pSrcDataObject        //Points to the data transfer object to be queried
  );
```

Parameter

pSrcDataObject
   Points to the data transfer object to be queried.

Return Values

S_OK
   Indicates formats that support embedded-object creation are present.

S_FALSE
   Indicates no formats are present that support either embedded- or static-object creation.

OLE_S_STATIC
   Indicates formats that support static-object creation are present.

Comments

When an application retrieves a data transfer object through a call to the **OleGetClipboard** function, the application should call **OleQueryCreateFromData** as part of the process of deciding to enable or disable the **Edit/Paste** or **Edit/Paste Special...** commands. It tests for the presence of the following formats in the data object:

CF_EMBEDDEDOBJECT
CF_EMBEDSOURCE
cfFileName
CF_METAFILEPICT
CF_DIB
CF_BITMAP

Determining that the data object has one of these formats does not absolutely guarantee that the object creation will succeed, but is intended to help the process.

If **OleQueryCreateFromData** finds one of the CF_METAFILEPICT, CF_BITMAP, or CF_DIB formats and none of the other formats, it returns OLE_S_STATIC, indicating that you should call the **OleCreateStaticFromData** function to create the embedded object.

If **OleQueryCreateFromData** finds one of the other formats (CF_EMBEDDEDOBJECT, CF_EMBEDSOURCE, or cfFileName), even in combination with the static formats, it returns S_OK, indicating that you should call the **OleCreateFromData** function to create the embedded object.

See Also

OleCreateFromData, **OleCreateStaticFromData**, **OleQueryLinkFromData**

OleQueryLinkFromData   QuickInfo

The **OleQueryLinkFromData** function determines whether an OLE linked object (rather than an OLE embedded object) can be created from a clipboard data object.

```
STDAPI OleQueryLinkFromData(
   IDataObject * pSrcDataObject        //Points to the clipboard data object to be used to create the new object
  );
```

Parameter

pSrcDataObject
Points to the clipboard data object from which the object is to be created.

Return Value

Returns S_OK if the **OleCreateLinkFromData** function can be used to create the linked object; otherwise S_FALSE.

Comments

The **OleQueryLinkFromData** function is similar to the **OleQueryCreateFromData** function, but determines whether an OLE linked object (rather than an OLE embedded object) can be created from the clipboard data object. If the return value is S_OK, the application can then attempt to create the object with a call to **OleCreateLinkFromData**, although this is not guaranteed to create a link successfully.

OleRegGetUserType [QuickInfo]

Returns from the registry the user type of the specified class. Developers of custom DLL object applications use this function to emulate the behavior of the OLE default handler.

```
HRESULT OleRegGetUserType(
    REFCLSID clsid,              //Reference to the class identifier
    DWORD dwFormOfType,          //Specifies form of type name
    LPOLESTR * pszUserType       //Pointer to storage of string pointer
  );
```

Parameters

clsid
Specifies the class whose user type is requested.

dwFormOfType
Specifies a value that describes the form of the user-presentable string from the enumeration **USERCLASSTYPE**.

pszUserType
Points to storage of the returned user type.

Return Values

S_OK
Indicates the user type was returned successfully.

E_OUTOFMEMORY
Indicates there is insufficient memory to complete the operation.

REGDB_E_CLASSNOTREG
Indicates there is no CLSID registered for the class object.

REGDB_E_READREGDB
Indicates there was an error reading the registry.

OLE_E_REGDB_KEY
Indicates the *ProgID = MainUserTypeName* and *CLSID = MainUserTypeName* keys are missing from the registry.

Comments

Object applications can ask OLE to get the user type name of a specified class in one of two ways. One way is to call **OleRegGetUserType**. The other is to return OLE_S_USEREG in response to calls by the default object handler to **IOleObject::GetUserType**. OLE_S_USEREG instructs the default handler to call **OleRegGetUserType**. Because DLL object applications cannot return OLE_S_USEREG, they must call **OleRegGetUserType** rather than delegating the job to the object handler.

The **OleRegGetUserType** function and its sibling functions, **OleRegGetMiscStatus**, **OleRegEnumFormatEtc**, and **OleRegEnumVerbs**, provide a way for developers of custom DLL object applications to emulate the behavior of OLE's default object handler in getting information about objects from the registry. By using these functions, you avoid the considerable work of writing your own, and the pitfalls inherent in working directly in the registry. In addition, you get future enhancements and optimizations of these functions without having to code them yourself.

See Also

IOleObject::GetUserType, **OleRegGetMiscStatus**, **OleRegEnumFormatEtc**, **OleRegEnumVerbs**, **USERCLASSTYPE**

OleRegGetMiscStatus QuickInfo

Returns from the registry miscellaneous information about the presentation and behaviors supported by the specified class. Used by developers of custom DLL object applications to emulate the behavior of the OLE default handler.

```
HRESULT OleRegGetMiscStatus(
    REFCLSID clsid,           //Reference to class identifier
    DWORD dwAspect,           //Value specifying aspect of requested class
    DWORD * pdwStatus         //Pointer to returned status information
  );
```

Parameters

clsid
Specifies the class whose status information is requested.

dwAspect
Specifies the aspect of the class whose information is requested.

pdwStatus
Points to storage of the returned status information.

Return Values

S_OK
Indicates the status information was returned successfully.

E_OUTOFMEMORY
Indicates there is insufficient memory to complete the operation.

REGDB_E_CLASSNOTREG
Indicates no CLSID is registered for the class object.

REGDB_E_READREGDB
Indicates an error occurred reading the registry.

OLE_E_REGDB_KEY
Indicates the GetMiscStatus key is missing from the registry.

Comments

Object applications can ask OLE to get miscellaneous status information in one of two ways. One way is to call **OleRegGetMiscStatus.** The other is to return OLE_S_USEREG in response to calls by the default object handler to **IOleObject::GetMiscStatus**. OLE_S_USEREG instructs the default handler to call **OleRegGetMiscStatus**. Because DLL object applications cannot return OLE_S_USEREG, they must call **OleRegGetMiscStatus** rather than delegating the job to the object handler.

OleRegGetMiscStatus and its sibling functions, **OleRegGetUserType**, **OleRegEnumFormatEtc**, and **OleRegEnumVerbs**, provide a way for developers of custom DLL object applications to emulate the behavior of OLE's default object handler in getting information about objects from the registry. By using these functions, you avoid the considerable work of writing your own, and the pitfalls inherent in working directly in the registry. In addition, you get future enhancements and optimizations of these functions without having to code them yourself.

See Also

DVASPECT, **FORMATETC**, **OLEMISC**, **IOleObject::GetMiscStatus**, **OleRegEnumFormatEtc**, **OleRegEnumVerbs**, **OleRegGetUserType**

OleRegEnumFormatEtc QuickInfo

Enumerates data formats that an OLE object server has registered in the registration database. An object application or object handler calls this function to obtain an enumeration of those formats. Developers of custom DLL object applications use this function to emulate the behavior of the default object handler.

```
HRESULT OleRegEnumFormatEtc(
  REFCLSID clsid,                          //Reference to class identifier
  DWORD dwDirection,                       //Value specifying data formats
  LPENUMFORMATETC * ppenumFormatetc        //Pointer to returned format information
 );
```

Parameters

clsid
Specifies the class whose formats are being requested.

dwDirection
Specifies whether to enumerate formats that can be passed to **IDataObject::GetData** or formats that can be passed to **IDataObject::SetData**. Valid values are taken from the enumeration **DATADIR**.

ppenumFormatetc
Points to where to return the enumeration.

Return Values

S_OK
Indicates the enumerator was returned successfully.

E_OUTOFMEMORY
Indicates there is insufficient memory to complete the operation.

REGDB_E_CLASSNOTREG
Indicates there is no CLSID registered for the class object.

REGDB_E_READREGDB
Indicates there was an error reading the registry.

OLE_E_REGDB_KEY
Indicates the DataFormats/GetSet key is missing from the registry.

Comments

Object applications can ask OLE to enumerate supported data formats in one of two ways. One way is to call **OleRegEnumFormatEtc.** The other is to return OLE_S_USEREG in response to calls by the default object handler to **IDataObject::EnumFormatEtc**. OLE_S_USEREG instructs the default handler to call **OleRegEnumFormatEtc**. Because DLL object applications cannot return OLE_S_USEREG, they must call **OleRegEnumFormatEtc** rather than delegating the job to the object handler.

The **OleRegEnumFormatEtc** function and its sibling functions, **OleRegGetUserType**, **OleRegGetMiscStatus**, and **OleRegEnumVerbs**, provide a way for developers of custom DLL object applications to emulate the behavior of OLE's default object handler in getting information about objects from the registry. By using these functions, you avoid the considerable work of writing your own, and the pitfalls inherent in working directly in the registry. In addition, you get future enhancements and optimizations of these functions without having to code them yourself.

See Also

IDataObject::EnumFormatEtc

OleRegEnumVerbs QuickInfo

Returns an enumeration of the registered verbs for the specified class. Developers of custom DLL object applications use this function to emulate the behavior of the default object handler.

```
HRESULT OleRegEnumVerbs(
   REFCLSID clsid,                          //Reference to class identifier
   LPENUMOLEVERB * ppenumOleVerb            //Pointer to returned enumerator
  );
```

Parameters

clsid
Specifies the class whose verbs are being requested.

ppenumOleVerb
Points to where to return the enumeration.

Return Values

S_OK
Indicates the enumerator was returned successfully.

E_OUTOFMEMORY
Indicates there is insufficient memory to complete the operation.

OLEOBJ_E_NOVERBS
Indicates no verbs are registered for the class.

REGDB_E_CLASSNOTREG
Indicates no CLSID is registered for the class object.

REGDB_E_READREGDB
Indicates an error occurred reading the registry.

OLE_E_REGDB_KEY
Indicates the DataFormats/GetSet key is missing from the registry.

Comments

Object applications can ask OLE to enumerate supported verbs in one of two ways. One way is to call **OleRegEnumVerbs**. The other way is to return OLE_S_USEREG in response to calls by the default object handler to **IOleObject::EnumVerbs**. OLE_S_USEREG instructs the default handler to call **OleRegEnumVerbs**. Because DLL object applications cannot return OLE_S_USEREG, they must call **OleRegEnumVerbs** rather than delegating the job to the object handler.

The **OleRegEnumVerbs** function and its sibling functions, **OleRegGetUserType**, **OleRegGetMiscStatus**, and **OleRegEnumFormatEtc**, provide a way for developers of custom DLL object applications to emulate the behavior of OLE's default object handler in getting information about objects from the registry. By using these functions, you avoid the considerable work of writing your own, and the pitfalls inherent in working directly in the registry. In addition, you get future enhancements and optimizations of these functions without having to code them yourself.

See Also

IOleObject::EnumVerbs

OleRun QuickInfo

Runs an object.

```
HRESULT OleRun(
  LPUNKNOWN pUnknown        //Pointer to IUnknown interface
 );
```

Parameter

pUnknown
Points to an object's **IUnknown** interface in order to obtain a pointer from the **IRunnableObject** interface in order to call **Run**.

Return Values

S_OK
Indicates the object was successfully placed in the running state.

OLE_E_CLASSDIFF
Indicates the source of an OLE link has been converted to a different class.

E_INVALIDARG
Indicates an argument is invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

The implementation of **OleRun** was changed in OLE 2.01 to coincide with the publication of the **IRunnableObject** interface. You can use **OleRun** and **IRunnableObject::Run** interchangeably. **OleRun** queries the object for a pointer to **IRunnableObject**. If successful, the function returns the results of calling the **IRunnableObject::Run** method.

Note The implementation of **OleRun** in earlier versions of OLE differs from that described here.

For more information on using this function, see **IRunnableObject::Run**.

See Also

IOleLink::BindToSource, **IRunnableObject::Run**

OleSave QuickInfo

Saves an object opened in transacted mode into the specified storage object.

```
HRESULT OleSave(
   IPersistStorage * pPS,        //Points to the object to be saved
   IStorage * pStg,              //Points to the destination storage to which pPS is saved
   BOOL fSameAsLoad              //Indicates whether the object was loaded from pstg or not
  );
```

Parameters

pPS
Points to the object to be saved.

pStg
Points to the destination storage object to which *pPS* is to be saved.

fSameAsLoad
TRUE indicates that *pStg* is the same storage object from which the object was loaded or created; FALSE indicates that *pstg* was loaded or created from a different storage object.

Return Values

S_OK
Indicates the object was successfully saved.

STG_E_MEDIUMFULL
Indicates the object could not be saved due to lack of disk space.

See also the **IPersistStorage::Save** method for other error return values.

Comments

The **OleSave** helper function handles the common scenario in which an object is open in transacted mode and is to be saved into the specified storage object which uses the OLE-provided compound file implementation. Other scenarios can be handled with the **IPersistStorage** and **IStorage** interfaces directly.

The **OleSave** function does the following:

1. Calls the **IPersistStorage::GetClassID** method to get the CLSID.
2. Writes the CLSID to the storage object using the **WriteClassStg** function.
3. Calls the **IPersistStorage::Save** method to save the object.
4. If there were no errors on the save; calls the **IPersistStorage::Commit** method to commit the changes.

Note Static objects are saved into a stream called CONTENTS. Static metafile objects get saved in "placeable metafile format" and static DIB data gets saved in "DIB file format." These formats are defined to be the OLE standards for metafile and DIB. All data transferred using an **IStream** interface or a file (that is; via **IDataObject::GetDataHere**) must be in these formats. Also; all objects whose default file format is a metafile or DIB must write their data into a CONTENTS stream using these standard formats.

See Also

IStorage, **IPersistStorage**

OleSaveToStream QuickInfo

Saves an **IPersistStream** object to the specified stream.

```
HRESULT OleSaveToStream(
   IPersistStream * pPStm,        //Points to the object to be saved
   IStream * pStm                 //Points to the destination stream to which the object is saved
  );
```

Parameters

pPStm
Points to the **IPersistStorage** object to be saved to the stream. Can be NULL, which has the effect of writing CLSID_NULL to the stream.

pStm
Points to the stream in which the object is to be saved.

Return Values

S_OK
Indicates the object was successfully saved.

STG_E_MEDIUMFULL
Indicates there is no space left on device to save the object.

See also the **WriteClassStm** function for other error return values.

See also the **IPersistStream::Save** method for other error return values.

Comments

This function simplifies saving an **IPersistStream** object to a stream. The object is saved preceded by its CLSID. The **OleSaveToStream** function performs the following steps:

1. Calls the **IPersistStream::GetClassID** method to get the object's CLSID.
2. Writes the CLSID to the stream with the **WriteClassStm** function.
3. Calls the **IPersistStream::Save** method with *fClearDirty* set to TRUE. Note that this clears the dirty bit in the object.

OleLoadFromStream

OleSetAutoConvert [QuickInfo]

Tags an object for automatic conversion to a different class when the object is loaded.

HRESULT OleSetAutoConvert(
    REFCLSID *clsidOld*,   //CLSID to be converted
    REFCLSID *clsidNew*   //New CLSID after conversion
  );

Parameters

clsidOld
    Specifies the CLSID of the object class to be converted.

clsidNew
    Specifies the CLSID of the object class that should replace *clsidOld*. This new CLSID replaces any existing auto-conversion information in the registration database for *clsidOld*. If this value is CLSID_NULL, any existing auto-conversion information for *clsidOld* is removed from the registration database.

Return Values

S_OK
    Indicates the object was tagged successfully.

REGDB_E_CLASSNOTREG
    Indicates the CLSID is not properly registered in the registration database.

REGDB_E_READREGDB
    Indicates error reading from the registration database.

REGDB_E_WRITEREGDB
    Indicates error writing to the registration database.

REGDB_E_KEYMISSING
    Indicates cannot read a key from the registration database.

E_OUTOFMEMORY
    Indicates the auto-conversion cannot be completed due to a lack of memory.

E_INVALIDARG
    Indicates one or more arguments are invalid.

E_UNEXPECTED
    Indicates an unexpected error occurred.

Comments

The **OleSetAutoConvert** function sets the entry for AutoConvertTo entry for *clsidOld* in the registration database. This function does no validation of whether an appropriate registration database entry for *clsidNew* currently exists. When it is called, the **OleSetAutoConvert** function records the new CLSID for the object under the AutoConvertTo subkey in the registration database for *clsidOld*.

Object conversion means that the object is permanently associated with a new CLSID. Automatic conversion is typically specified by the setup program for a new version of an object application, so that objects created by its older versions can be automatically updated. You can write the setup program to tag a class of objects for automatic conversion to a different class of objects.

For example, a new version of a spreadsheet application may need to convert spreadsheets that were created with earlier versions of the application. These earlier version spreadsheet objects have a different CLSID than the new version. The setup program for the new version of the spreadsheet application tags objects in the registration database that have the old CLSID so they are automatically updated when they are loaded.

When installing a new CLSID, setup programs may call **OleSetAutoConvert** for various *clsidOld* values for older versions of their applications. They also should call **OleSetAutoConvert**, specifying the new class as the *clsidOld* parameter, and setting the *clsidNew* parameter to CLSID_NULL to remove any existing conversion for the new class.

The **OleSetAutoConvert** function creates the required entry in the registration database. These entries appear in the registration database as subkeys of the CLSID key:

```
CLSID\{clsid}=MainUserTypeName\AutoConvertTo = clsid
```

See Also

OleDoAutoConvert

OleSetClipboard QuickInfo

Places the specified **IDataObject** instance on the clipboard making it accessible to the **OleGetClipboard** function.

```
HRESULT OleSetClipboard(
    IDataObject * pDataObj        //The data object being copied or cut
  );
```

Parameter

pDataObj
Points to an **IDataObject** instance from which the data to be placed on the clipboard can be obtained. This parameter can be NULL; in which case the clipboard is emptied.

Return Values

S_OK
Indicates the **IDataObject** interface was placed on the clipboard.

CLIPBRD_E_CANT_OPEN
Indicates the Windows **OpenClipboard** function used within **OleSetClipboard** failed.

CLIPBRD_E_CANT_EMPTY
Indicates the Windows **EmptyClipboard** function used within **OleSetClipboard** failed.

CLIPBRD_E_CANT_CLOSE
Indicates the Windows **CloseClipboard** function used within **OleSetClipboard** failed.

Comments

If you are writing an application that can act as the source of a clipboard operation, you must:

1. Create an instance of the **IDataObject** interface for the data being copied or cut to the clipboard. This **IDataObject** should be the same as the **IDataObject** used in OLE drag and drop operations.
2. Call **OleSetClipboard** to place the **IDataObject** on the clipboard and make it accessible to the **OleGetClipboard** function. **OleSetClipboard** also calls the **IUnknown::AddRef** method on your data object.
3. If you wish, release the **IDataObject** once you have placed it on the clipboard to free the **IUnknown::AddRef** counter in your application.
4. If the user is cutting data to the clipboard, remove the data from the document.

All formats are offered on the clipboard using delayed rendering. The formats necessary for OLE 1 compatibility are synthesized from the OLE 2 formats that are present and are also put on the clipboard.

The **OleSetClipboard** function assigns ownership of the clipboard to an internal OLE window handle. The reference count of the data object is increased by 1. This is done so that delayed rendering can be used. The reference count is decreased by a call to the **OleFlushClipboard** function or by a subsequent call to **OleSetClipboard** using NULL.

The **OleSetClipboard** function empties the current clipboard before any new data is made available. When an application opens the clipboard (either directly or indirectly by calling the Windows **OpenClipboard** function), the clipboard cannot be used by any other application until it is closed. If the clipboard is currently open by another application, **OleSetClipboard** fails. The internal OLE window handle satisfies WM_RENDERFORMAT messages by delegating them to the instance of **IDataObject** that is on the clipboard.

Passing NULL for **IDataObject** is legal and it empties the clipboard. If the contents of the clipboard are the result of a previous **OleSetClipboard** call and the clipboard is released; the **IDataObject** that was passed to the previous call is released. The clipboard owner should use this as a signal that the data it previously offered is no longer on the clipboard.

If you need to leave the data on the clipboard after your application is closed, you can call **OleFlushClipboard** instead of **OleSetClipboard** using NULL.

See Also

OleGetClipboard, **OleIsCurrentClipboard**,

OleSetContainedObject QuickInfo

Notifies an object that it is embedded in an OLE container, which ensures that reference counting is done correctly for containers that support links to embedded objects.

```
STDAPI OleSetContainedObject(
    LPUNKNOWN pUnk               //Pointer to embedded object
    BOOL fContained              //Indicates if the object is embedded
  );
```

Parameters

pUnk
Specifies a pointer to the **IUnknown** interface of the object

fContained
Indicates TRUE if the object is an embedded object; FALSE otherwise.

Return Values

S_OK
Indicates object was notified successfully.

E_OUTOFMEMORY
Indicates insufficient memory to perform the operation.

E_INVALIDARG
Indicates an invalid argument.

E_UNEXPECTED
Indicates an unexpected error.

Comments

The implementation of **OleSetContainedObject** was changed in OLE 2.01 to coincide with the publication of the **IRunnableObject** interface. You can use **OleSetContainedObject** and the **IRunnableObject::SetContainedObject** method interchangeably. The **OleSetContainedObject** function queries the object for a pointer to the **IRunnableObject** interface. If successful, the function returns the results of calling **IRunnableObject::SetContainedObject**.

Note The implementation of **OleSetContainedObject** in earlier versions of OLE differs from that described here.

See Also

IRunnableObject::SetContainedObject

OleSetMenuDescriptor QuickInfo

Installs or removes OLE dispatching code from the container's frame window.

```
HRESULT OleCreateMenuDescriptor(
   HOLEMENU holemenu,                          //Handle to the composite menu descriptor
   HWND hwndFrame,                             //Handle to the container's frame window
   HWND hwndActiveObject,                      //Handle to the object's in-place activation window
   LPOLEINPLACEFRAME lpFrame,                  //Container's frame window
   LPOLEINPLACEACTIVEOBJECT lpActiveObj        //Active in-place object
 );
```

Parameters

holemenu
Specifies the handle to the composite menu descriptor returned by the **OleCreateMenuDescriptor** function. If NULL, the dispatching code is unhooked.

hwndFrame
Specifies the handle to the container's frame window where the in-place composite menu is to be installed.

hwndActiveObject
Specifies the handle to the object's in-place activation window. OLE dispatches menu messages and commands to this window.

lpFrame
Points to the container's frame window.

lpActiveObj
Points to the active in-place object.

Return Values

S_OK
Indicates the menu was installed correctly.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

E_FAIL
Indicates a Windows function call failed, indicating a resource allocation failure or improper arguments.

Comments

The container should call **OleSetMenuDescriptor** to install the dispatching code on *hwndFrame* when the object calls the **IOleInPlaceFrame::SetMenu** method, or to remove the dispatching code by passing NULL as the value for *holemenu* to **OleSetMenuDescriptor**.

OLE installs the context-sensitive help F1 message filter for the application if both the *lpFrame* and *lpActiveObj* parameters are non-NULL. Otherwise, the application must supply its own message filter.

See Also

OleCreateMenuDescriptor, **IOleInPlaceFrame::SetMenu**

OleTranslateAccelerator   QuickInfo

Called by the object application, allowing the container to translate its accelerators pointed to by *lpFrameInfo*.

```
HRESULT OleTranslateAccelertor(
  LPOLEINPLACEFRAME lpFrame,                //Possible location to send keystrokes
  LPOLEINPLACEFRAMEINFO lpFrameInfo,        //Accelerator table obtained from container
  LPMSG lpmsg                               //Structure containing the keystroke
 );
```

Parameters

lpFrame
Points to the **IOleInPlaceFrame** interface where the keystroke might be sent.

lpFrameInfo
Points to an **OLEINPLACEFRAMEINFO** structure containing the accelerator table obtained from the container.

lpmsg
Points to an **MSG** structure containing the keystroke.

Return Values

S_OK
Indicates the keystroke was processed.

S_FALSE
Indicates the object should continue processing this message.

E_INVALIDARG
Indicates one of the arguments is invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

Comments

While an object is UI active, it *always* has first chance at translating any messages received. If the object does not want to translate the message, it calls **OleTranslateAccelerator** to give the container a chance. If the keyboard input matches an accelerator found in the container-provided accelerator table, **OleTranslateAccelerator** passes the message and its command identifier on to the container through the **IOleInPlaceFrame::TranslateAccelerator** method. This method returns S_OK if the keystroke is consumed; otherwise it returns S_FALSE.

The **OleTranslateAccelerator** function is intended to be called only by local server object applications and not by in-process server objects. In the case of a local server object application, keyboard input goes directly to the object application's message pump. If the object does not translate the key, **OleTranslateAccelerator** gives the container application an opportunity to do it. In the case of an in-process server object, the keyboard input goes directly to the container's message pump.

Note   Accelerator tables for containers should be defined so they will work properly with object applications that do their own accelerator keystroke translations. These tables should take the form:

```
"char", wID, VIRTKEY, CONTROL
```

This is the most common way to describe keyboard accelerators. Failure to do so can result in keystrokes being lost or sent to the wrong object during an in-place session.

Objects can call the **IsAccelerator** function to see whether the accelerator keystroke belongs to the object or the container.

See Also

IsAccelerator, **IOleInPlaceFrame::TranslateAccelerator**

OleUIAddVerbMenu

Adds the Verb menu for the specified object to the given menu.

```
BOOL OleUIAddVerbMenu(
    LPOLEOBJECT *lpOleObj,      //Points to the selected object
    LPCTSTR lpszShortType,      //The short name corresponding to the object
    HMENU hMenu,                //The handle to the menu to modify
    UINT uPos,                  //The position of the menu item.
    UINT uIDVerbMin,            //The value at which to start the verbs
    UINT uIDVerbMax,            //The maximum ID value for object verbs
    BOOL bAddConvert,           //Specifies whether to add convert item
    UINT idConvert,             //The value to use for the convert item
    HMENU FAR * lphMenu         //Points to the cascading verb menu, if created
  );
```

Parameters

lpOleObj
The **LPOLEOBJECT** pointing to the selected object. If this is NULL, then a default disabled menu item is created.

lpszShortType
The **LPTSTR** with short type name (AuxName==2) corresponding to the *lpOleObj*. If the string is NOT known, then NULL may be passed. If NULL is passed, then **IOleObject::GetUserType** will be called to retrieve it. If the caller has easy access to the string, then it is faster to pass it in.

hMenu
The **HMENU** in which to make modifications.

uPos
The position of the menu item

iIDVerbMin
The **UINT** ID value at which to start the verbs.

uIDVerbMax
The **UINT** Maximum ID value to be used for object verbs. If *uIDVerbMax* is 0, then no maximum ID value is used.

bAddConvert
The BOOL specifying whether or not to add a Convert item to the bottom of the menu (preceded by a separator).

idConvert
The **UINT** ID value to use for the Convert menu item, if *bAddConvert* is TRUE.

lphMenu
The **HMENU FAR *** of the cascading verb menu if it's created. If there is only one verb, this will be filled with NULL.

Return Values

TRUE
Indicates *lpOleObj* was valid and at least one verb was added to the menu

FALSE
Indicates *lpOleObj* was NULL and a disabled default menu item was created.

Comments

If the object has one verb, the verb is added directly to the given menu. If the object has multiple verbs, a cascading sub-menu is created.

OleUIBusy

Invokes the standard Busy dialog box, allowing the user to manage concurrency.

```
UINT OleUIBusy(
   LPOLEUIBUSY   lpBZ    //Points to the initialization structure
  );
```

Parameter

lpBZ
Points to an **OLEUIBUSY** structure that contains information used to initialize the dialog box.

Return Values

Standard Success/Error Definitions

OLEUI_FALSE
Unknown failure (unused).

OLEUI_SUCCESS
No error, same as OLEUI_OK

OLEUI_OK
The user pressed theOK button.

OLEUI_CANCEL
Indicates that user has pressed the Cancel button and that the caller should cancel the operation.

OLEUI_BZ_SWITCHTOSELECTED
Indicates that the user has pressed Switch To and **OleUIBusy** was unable to determine how to switch to the blocking application. In this case, the caller should either take measures to attempt to resolve the conflict itself, if possible, or retry the operation. **OleUIBusy** will only return OLEUI_BZ_SWITCHTOSELECTED if the user has pressed the Switch To button, *hTask* is NULL and the BZ_NOTREESPONDING flag is set.

OLEUI_BZ_RETRYSELECTED
Indicates that the user has either pressed the Retry button or attempted to resolve the conflict (probably by switching to the blocking application). In this case, the caller should retry the operation.

OLEUI_BZ_CALLUNBLOCKED
Indicates that the dialog has been informed that the operation is no longer blocked.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID
The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE
Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_BZERR_HTASKINVALID
The *hTask* specified in the *hTask* member of the **OLEUIBUSY** structure is invalid.

Comments

The standard OLE Server Busy dialog box notifies the user that the server application is not receiving messages. The dialog then asks the user to either cancel the operation, switch to the task which is blocked, or continue waiting.

See Also

OLEUIBUSY

OleUICanConvertOrActivateAs

Determines if there are any OLE object classes in the registry that can be used to convert or activate the specified CLSID from.

```
BOOL OleUICanConvertOrActivateAs(
    REFCLSID rClsid,            //CLSID of the specified class
    BOOL fIsLinkedObject,       //Indicates whether the original object was a linked object
    WORD wFormat                //The format of the original class
  );
```

Parameters

rClsid
Points to the CLSID of the specified class.

fIsLinkedObject
TRUE if the original object is a linked object; FALSE otherwise.

wFormat
Specifies the format of the original class.

Return Values

TRUE
The specified class can be converted to or activated as another class.

FALSE
The specified class cannot be converted to or activated as another class.

Comments

Notes to Implementors

OleUICanConvertOrActivateAs searches the Registry for classes that include *wFormat* in their \Conversion\Readable\Main, \Conversion\ReadWriteable\Main, and \DataFormats\DefaultFile entries.

This function is useful for determining if a Convert... menu item should be disabled. If the CF_DISABLEDISPLAYASICON flag is specified in the call to **OleUIConvert**, then the Convert... menu item should be enabled only if **OleUICanConvertOrActivateAs** returns TRUE.

See Also

OleUIConvert

OleUIChangeIcon

Invokes the standard Change Icon dialog box, which allows the user to select an icon from an icon file, executable, or DLL.

```
UINT OleUIChangeIcon(
   LPOLEUICHANGEICON lpCI    //Points to the in-out structure for this dialog
  );
```

Parameter

lpCI
Points to the in-out structure for this dialog.

Return Values

Standard Success/Error Definitions

OLEUI_FALSE
Unknown failure (unused).

OLEUI_SUCCESS
No error, same as OLEUI_OK

OLEUI_OK
The user pressed the OK button.

OLEUI_CANCEL
The user pressed the Cancel button.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID
The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE
Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_CIERR_MUSTHAVECLSID
The *clsid* member was not the current CLSID.

OLEUI_CIERR_MUSTHAVECURRENTMETAFILE
The *hMetaPict* member was not the current metafile.

OLEUI_CIERR_SZICONEXEINVALID
The *szIconExe* value was invalid.

Comment

OleUIChangeIcon uses information contained in the **OLEUICHANGEICON** structure.

See Also

OLEUICHANGEICON

OleUIChangeSource

Invokes the Change Source dialog box, allowing the user to change the source of a link.

UINT OleUIChangeSource(
LPOLEUICHANGESOURCE *lpCS* //Points to the in-out structure
);

Parameter

lpCS
Points to the in-out structure for this dialog.

Return Values

Standard Success/Error Definitions

OLEUI_FALSE
Unknown failure (unused).

OLEUI_SUCCESS
No error, same as OLEUI_OK.

OLEUI_OK
The user pressed the OK button.

OLEUI_CANCEL
The user pressed the Cancel button.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID
The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE
Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_CSERR_LINKCNTRNULL
The *lpOleUILinkContainer* value is NULL.

OLEUI_CSERR_LINKCNTRINVALID
The *lpOleUILinkContainer* value is invalid.

OLEUI_CSERR_FROMNOTNULL
The *lpszFrom* value is not NULL.

OLEUI_CSERR_TONOTNULL
The *lpszTo* value is not NULL.

OLEUI_CSERR_SOURCEINVALID
The *lpszDisplayName* or *nFileLength* value is invalid, or cannot retrieve the link source.

OLEUI_CSERR_SOURCEPARSEERROR
The *nFilename* value is wrong.

Comments

The link source is not changed by the Change Source dialog itself. Instead, it is up to the caller to change the link source using the returned file and item strings. The Edit Links dialog typically does this for the caller.

See Also

OLEUICHANGESOURCE, **OleUIEditLinks**, **IOleUILinkContainer**

OleUIConvert

Invokes the standard Convert dialog box, allowing the user to change the type of a single specified object, or the type of all OLE objects of the specified object's class.

UINT OleUIConvert(
  LPOLEUICONVERT *lpCV* //Points to initialization structure
 );

Parameter

lpCV
 Points to an **OLEUICONVERT** structure that contains information used to initialize the dialog box.

Return Values

Standard Success/Error Definitions

OLEUI_FALSE
 Unknown failure (unused).

OLEUI_SUCCESS
 No error, same as OLEUI_OK

OLEUI_OK
 The user pressed the OK button.

OLEUI_CANCEL
 The user pressed the Cancel button.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
 Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
 The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
 Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
 The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
 The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
 The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
 The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
 The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
 The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID
 The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
 Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE
Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_CTERR_CLASSIDINVALID
A *clsid* value was invalid.

OLEUI_CTERR_DVASPECTINVALID
The *dvAspect* value was invalid. This member specifies the aspect of the object.

OLEUI_CTERR_CBFORMATINVALID
The *wFormat* value was invalid. This member specifies the data format of the object.

OLEUI_CTERR_STRINGINVALID
A string value (for example, *lpszUserType* or *lpszDefLabel*) was invalid.

Comments

OleUIConvert populates the Convert dialog's listbox with object classes by traversing the Registry and looking for entries in the Readable and ReadWritable keys. Every class that includes the original class' default file format in its Readable key is added to the Convert list, and every class that includes the original class' default file format in its ReadWritable key is added to the Activate As list. The Convert list is shown in the dialog's listbox when the Convert radio button is selected (the default selection), and the Activate As list is shown when Activate As is selected.

Note that you can change the type of all objects of a given class only when CF_CONVERTONLY is not specified.

The convert command, which invokes this function, should only be made available to the user if **OleUIConvertOrActivateAs** returns S_OK.

See Also

OLEUICONVERT, **OleUICanConvertOrActivateAs**

OleUIEditLinks

Invokes the standard Links dialog box, allowing the user to make modifications to a container's linked objects.

UINT OleUIEditLinks(
  LPOLEUIEDITLINKS *lpEL*   //Points to the initialization structure
 );

Parameter

lpEL
  Points to an **OLEUIEDITLINKS** structure that contains information used to initialize the dialog box.

Return Value

Standard Success/Error Definitions

OLEUI_FALSE
  Unknown failure (unused).

OLEUI_SUCCESS
  No error, same as OLEUI_OK.

OLEUI_OK
  The user pressed the OK button.

OLEUI_CANCEL
  The user pressed the Cancel button.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
  Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
  The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
  Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
  The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
  The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
  The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
  The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
  The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
  The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID
  The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
  Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE
Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

See Also

OLEUIEDITLINKS, **IOleUILinkContainer**

OleUIInsertObject

Invokes the standard Insert Object dialog box, which allows the user to select an object source and class name, as well as the option of displaying the object as itself or as an icon.

```
UINT OleUIInsertObject(
    LPOLEUIINSERTOBJECT lpIO    //Points to the in-out structure
  );
```

Parameter

lpIO
Points to the in-out structure for this dialog.

Return Values

Standard Success/Error Definitions

OLEUI_FALSE
Unknown failure (unused).

OLEUI_SUCCESS
No error, same as OLEUI_OK.

OLEUI_OK
The user pressed the OK button.

OLEUI_CANCEL
The user pressed the Cancel button.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID
The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE
Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_IOERR_LPSZFILEINVALID
The *lpszFile* value is invalid or user has insufficient write access permissions.. This *lpszFile* member points to the name of the file linked to or inserted.

OLEUI_IOERR_LPFORMATETCINVALID
The *lpFormatEtc* value is invalid. This member identifies the desired format.

OLEUI_IOERR_PPVOBJINVALID
The *ppvOjb* value is invalid. This member points to the location where the pointer for the object is returned.

OLEUI_IOERR_LPIOLECLIENTSITEINVALID
The *lpIOleClientSite* value is invalid. This member points to the client site for the object.

OLEUI_IOERR_LPISTORAGEINVALID
The *lpIStorage* value is invalid. This member points to the storage to be used for the object.

OLEUI_IOERR_SCODEHASERROR
The *sc* member of *lpIO* has additional error information.

OLEUI_IOERR_LPCLSIDEXCLUDEINVALID
The *lpClsidExclude* value is invalid. This member contains the list of CLSIDs to exclude.

OLEUI_IOERR_CCHFILEINVALID
The *cchFile* or *lpszFile* value is invalid. The *cchFile* member specifies the size of the *lpszFile* buffer. The *lpszFile* member points to the name of the file linked to or inserted.

Comments

OleUIInsertObject allows the user to select the type of object to be inserted from a listbox containing the object applications registered on the user's system. To populate that listbox, **OleUIInsertObject** traverses the registry, adding every object server it finds that meets the following criteria:

- The registry entry does not include the **NotInsertable** key.
- The registry entry includes a OLE 1.0 style **Protocol\\StdFileEditing\\Server** key.
- The registry entry includes the **Insertable** key.
- The object's CLSID is not included in the list of objects to exclude (the *lpClsidExclude* member of **OLEUIINSERTOBJECT**).

By default, **OleUIInsertObject** does not validate object servers; however, if the IOF_VERIFYSERVEREXIST flag is included in the *dwFlags* member of the **OLEUIINSERTOBJECT** structure, then **OleUIInsertObject** verifies that the server exists. If it does not exist, then the server's object is not added to the list of available objects. Server validation is a time-extensive operation and is a significant performance factor.

To free an HMETAFILEPICT returned from the Insert Object or Paste Special dialog box, delete the attached metafile on the handle, as follows:

```
void FreeHmetafilepict(HMETAFILEPICT hmfp)
{
    if (hmfp != NULL)
        {
        LPMETAFILEPICT pmfp = GlobalLock(hmfp);

        DeleteMetaFile(pmfp->hMF);
        GlobalUnlock(hmfp);
        GlobalFree(hmfp);
        }
}  // FreeHmetafilepict
```

See Also

OLEUIINSERTOBJECT

OpenFile **DeleteMetaFile**, **GlobalUnlock**, **GlobalFree** in Win32

OleUIObjectProperties

Invokes the Object Properties dialog, which displays General, View, Link information about an object.

```
UINT OleUIObjectProperties(
                                        //Points to the OLEUIOBJECTPROPS structure
LPOLEUIOBJECTPROPS
lpOP
   );
```

Parameter*lpOP*
Points to the **OLEUIOBJECTPROPS** structure.

Return Values

Standard Success/Error Definitions

OLEUI_FALSE
Unknown failure (unused).

OLEUI_SUCCESS
No error, same as OLEUI_OK.

OLEUI_OK
The user pressed the OK button.

OLEUI_CANCEL
The user pressed the Cancel button.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID
The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE

Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_OPERR_SUBPROPNULL
lpGP or *lpVP* is NULL, or *dwFlags* and OPF_OBJECTISLINK and *lpLP* are NULL.

OLEUI_OPERR_SUBPROPINVALID
Insufficient write-access permissions for the structures pointed to by *lpGP*, *lpVP*, or *lpLP*.

OLEUI_OPERR_PROPSHEETNULL
The *lpLP* value is NULL.

OLEUI_OPERR_PROPSHEETINVALID
Insufficient write-access for one or more of the structures used by OLEUIOBJECTPROPS.

OLEUI_OPERR_SUPPROP
The sub-link property pointer, *lpLP*, is NULL.

OLEUI_OPERR_PROPSINVALID
Insufficient write access for the sub-link property pointer, *lpLP*.

OLEUI_OPERR_PAGESINCORRECT
Some sub-link properties of the *lpPS* member are incorrect.

OLEUI_OPERR_INVALIDPAGES
Some sub-link properties of the *lpPS* member are incorrect.

OLEUI_OPERR_NOTSUPPORTED
A sub-link property of the *lpPS* member is incorrect.

OLEUI_OPERR_DLGPROCNOTNULL
A sub-link property of the *lpPS* member is incorrect.

OLEUI_OPERR_LPARAMNOTZERO
A sub-link property of the *lpPS* member is incorrect.

OLEUI_GPERR_STRINGINVALID
A string value (for example, *lplpszLabel* or *lplpszType*) is invalid.

OLEUI_GPERR_CLASSIDINVALID
The *clsid* value is invalid.

OLEUI_GPERR_LPCLSIDEXCLUDEINVALID
The *ClsidExcluded* value is invalid.

OLEUI_GPERR_CBFORMATINVALID
The *wFormat* value is invalid.

OLEUI_VPERR_METAPICTINVALID
The *hMetaPict* value is invalid.

OLEUI_VPERR_DVASPECTINVALID

The *dvAspect* value is invalid.

OLEUI_OPERR_PROPERTYSHEET
The *lpPS* value is incorrect.

OLEUI_OPERR_OBJINFOINVALID
The *lpObjInfo* value is NULL or the calling process doesn't have read access.

OLEUI_OPERR_LINKINFOINVALID
The *lpLinkInfo* value is NULL or the calling process doesn't have read access.

Comment

OleUIObjectProperties is passed an **OLEUIOBJECTPROPS** structure, which supplies the information needed to fill in the General, View, and Link tabs of the Object Properties dialog.

See Also

IOleUIObjInfo, **IOleUILinkInfo**, **OLEUIOBJECTPROPS**, **OLEUIGNRLPROPS**, **OLEUIVIEWPROPS**, **OLEUILINKPROPS**

OleUIPasteSpecial

Invokes the standard Paste Special dialog box, allowing the user to select the format of the clipboard object to be pasted or paste-linked.

```
UINT OleUIPasteSpecial(*
    LPOLEUIPASTESPECIAL lpPS     //In-out structure for this dialog
  );
```

Parameter

lpPS
LPOLEUIPASTESPECIAL pointing to the in-out structure for this dialog.

Return Values

Standard Success/Error Definitions

OLEUI_FALSE
Unknown failure (unused).

OLEUI_SUCCESS
No error, same as OLEUI_OK

OLEUI_OK
The user pressed the OK button.

OLEUI_CANCEL
The user pressed the Cancel button.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID
The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE
    Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
    Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
    A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
    A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
    Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
    A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
    Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_IOERR_SRCDATAOBJECTINVALID
    The *lpSrcDataObject* field of **OLEUIPASTESPECIAL** is invalid

OLEUI_IOERR_ARRPASTEENTRIESINVALID
    The *arrPasteEntries* field of **OLEUIPASTESPECIAL** is invalid.

OLEUI_IOERR_ARRLINKTYPESINVALID
    The *arrLinkTypes* field of **OLEUIPASTESPECIAL** is invalid

OLEUI_PSERR_CLIPBOARDCHANGED
    The clipboard contents changed while the dialog was displayed.

OLEUI_PSERR_GETCLIPBOAARDFAILED
    The *lpSrcDataObj* member is incorrect.

Comments

The design of the paste special dialog assumes the following: if you are willing to permit a user to link to an object, you are also willing to permit the user to embed that object. For this reason, if any of the OLEUIPASTE_LINKTYPE flags associated with the **OLEUIPASTEFLAG** enumeration are set, then the OLEUIPASTE_PASTE flag must also be set in order for the data formats to appear in the paste special box.

To free an HMETAFILEPICT returned from the Insert Object or Paste Special dialog box, delete the attached metafile on the handle, as follows:

```
void FreeHmetafilepict(HMETAFILEPICT hmfp)
{
    if (hmfp != NULL)
        {
        LPMETAFILEPICT pmfp = GlobalLock(hmfp);

        DeleteMetaFile(pmfp->hMF);
        GlobalUnlock(hmfp);
        GlobalFree(hmfp);
        }
}  // FreeHmetafilepict
```

See Also

OLEUIPASTESPECIAL, **OLEUIPASTEFLAG**

DeleteMetaFile, **GlobalUnlock**, **GlobalFree** in Win32

OleUIPromptUser

Displays a dialog box with the specified template and returns the response (button id) from the user. This function is used to display OLE warning messages, for example, Class Not Registered.

```
int __export FAR CDECLOleUIPromtUser(
    int nTemplate,            //Resource number of dialog
    HWND hwndParent       //Link identifier
  );
```

Parameters

nTemplate
Specifies the resource number of the dialog to display. See Comments.

hwndParent
The parent of the dialog box. Specifies zero or more optional arguments. These parameters are passed to **wsprintf** to format the message string.

Return Value

Returns the button id selected by the user (template dependent).

Standard Success/Error Definitions

OLEUI_FALSE
Unknown failure (unused).

OLEUI_SUCCESS
No error, same as OLEUI_OK

OLEUI_OK
The user pressed the OK button.

OLEUI_CANCEL
The user pressed the Cancel button.

Standard Field Validation Errors

OLEUI_ERR_STANDARDMIN
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

OLEUI_ERR_STRUCTURENULL
The pointer to an OLEUIXXX structure passed into the function was NULL.

OLEUI_ERR_STRUCTUREINVALID
Insufficient permissions for read or write access to an OLEUIXXX structure.

OLEUI_ERR_CBSTRUCTINCORRECT
The *cbstruct* value is incorrect.

OLEUI_ERR_HWNDOWNERINVALID
The *hWndOwner* value is invalid.

OLEUI_ERR_LPSZCAPTIONINVALID
The *lpszCaption* value is invalid.

OLEUI_ERR_LPFNHOOKINVALID
The *lpfnHook* value is invalid.

OLEUI_ERR_HINSTANCEINVALID
The *hInstance* value is invalid.

OLEUI_ERR_LPSZTEMPLATEINVALID
The *lpszTemplate* value is invalid.

OLEUI_ERR_HRESOURCEINVALID

The *hResource* value is invalid.

Initialization Errors

OLEUI_ERR_FINDTEMPLATEFAILURE
Unable to find the dialog template.

OLEUI_ERR_LOADTEMPLATEFAILURE
Unable to load the dialog template.

OLEUI_ERR_DIALOGFAILURE
Dialog initialization failed.

OLEUI_ERR_LOCALMEMALLOC
A call to **LocalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_GLOBALMEMALLOC
A call to **GlobalAlloc** or the standard *IMalloc* allocator failed.

OLEUI_ERR_LOADSTRING
Unable to **LoadString** localized resources from the library.

OLEUI_ERR_OLEMEMALLOC
A call to the standard *IMalloc* allocator failed.

Function Specific Errors

OLEUI_ERR_STANDARDMAX
Errors common to all dialogs lie in the range OLEUI_ERR_STANDARDMIN to OLEUI_ERR_STANDARDMAX. This value allows the application to test for standard messages in order to display error messages to the user.

Comments

The following dialog templates are defined in *Windows Interface Guidelines--A Guide for Designing Software*. The *nTemplate* parameter must be a currently defined resource; however, additional templates can be added to prompt.dlg.

```
IDD_LINKSOURCEUNAVAILABLE
IDD_CANNOTUPDATELINK
IDD_SERVERNOTREG
IDD_CANNOTRESPONDVERB
IDD_SERVERNOTFOUND
IDD_UPDATELINKS
```

See Also

wsprintf in Win32

OleUIUpdateLinks

Updates all links in the link container and displays a dialog box that shows the progress of the updating process. The process is stopped if the user presses the Stop button or when all links are processed.

```
BOOL OleUIUpdateLink(
    LPOLEUILINKCONTAINER                     //Points to the link container
lpOleUILinkCntr,
    HWND hwndParent,                         //Dialog box's parent window
    LPTSTR lpszTitle,                        //Dialog box title
    int cLinks                               //Number of links
  );
```

Parameters

lpOleUILinkCntr
The pointer to the Link Container.

hwndParent
The parent window of the dialog.

lpszTitle
The title of the dialog box.

cLinks
The total number of links.

Return Values

TRUE
The links were successfully updated.

FALSE
Unable to update the links.

See Also

IOleUILinkContainer::GetLinkUpdateOptions, **IOleUILinkContainer::UpdateLink**

OleUninitialize QuickInfo

Closes the OLE library, freeing any resources that it maintains.

void OleUninitialize();

Comments

You should call this function on application shutdown, as the last call made to the OLE library. **OleUninitialize** calls the **CoUninitialize** function internally to shut down the OLE Component Object(COM) Library.

The **OleInitialize** and **OleUninitialize** calls must be balanced – if there are multiple calls to the **OleInitialize** function, there must be the same number of calls to **OleUninitialize**: Only the **OleUninitialize** call corresponding to the **OleInitialize** call that actually initialized the COM library can close it.

See Also

OleInitialize, **CoUninitialize**

ProgIDFromCLSID

Retrieves the ProgID for a given CLSID.

```
HRESULT ProgIDFromCLSID(
   REFCLSID clsid,                //The CLSID for which the ProgID is requested
   LPOLESTR * lplpszProgID        //Receives a pointer to the requested ProgID on return
  );
```

Parameters

clsid
Specifies the CLSID for which the ProgID is requested.

lplpszProgID
Receives a pointer to the requested ProgID on return.

Return Values

S_OK
Indicates the ProgID was returned successfully.

REGDB_E_CLASSNOTREG
Indicates class not registered in the registry.

REGDB_E_READREGDB
Indicates error reading registry.

Comments

Every OLE 2 object class listed in the Insert Object dialog box must have a *programmatic identifier* (ProgID), a string that uniquely identifies a given class. In addition to determining the eligibility for the Insert Object dialog box, the ProgID can be used as an identifier in a macro programming language to identify a class. Finally, the ProgID is also the class name used for an OLE 2 class when placed in an OLE 1 container.

The **ProgIDFromCLSID** function uses entries in the registry to do the conversion. OLE 2 application authors are responsible for correctly configuring the registry at application installation time.

The ProgID string must be different than the class name of any OLE 1 application, including the OLE 1 version of the same application, if there is one. In addition, a ProgID string must not contain more than 39 characters or start with a digit. Except for a single period, it cannot contain any punctuation (including underscores).

The ProgID must *never* be shown to the user in the user interface. If you need a short human-readable string for an object, call **IOleObject::GetUserType**.

The **CLSIDFromProgID** function can be called to create a CLSID from a given ProgID. CLSIDs can be freed with the task allocator (refer to the **CoGetMalloc** function).

See Also

CLSIDFromProgID

PropagateResult

```
#define PropagateResult(hrPrevious, scBase) ((HRESULT) scBase)
```

PropagateResult is a no-op

This macro is obsolete and should not be used.

ReadClassStg QuickInfo

Reads the CLSID from the storage object.

```
HRESULT ReadClassStg(
    IStorage * pStg,          //Points to the storage containing the CLSID to be retrieved
    CLSID * pclsid            //Points to location for returning the CLSID
  );
```

Parameters

pStg
Points to the storage object containing the CLSID to be returned.

pclsid
Points to location where the CLSID is to be returned. May return CLSID_NULL.

Return Values

S_OK
Indicates the CLSID was returned successfully.

E_OUTOFMEMORY
Indicates the CLSID could not be returned due to lack of memory.

See also the **IStorage::Stat** method for other error return values.

See Also

This function is simply a helper function that calls the **IStorage::Stat** method and retrieves the CLSID from the resulting **STATSTG** structure.

See Also

OleLoad, **WriteClassStg**

ReadClassStm QuickInfo

Reads the CLSID previously written to a stream object with the **WriteClassStm** method.

```
HRESULT ReadClassStm(
   IStream * pStm,          //Points to the stream from which the CLSID is to be read
   CLSID * pclsid           //Points to the location where the CLSID is returned
  );
```

Parameters

pStm
Points to the stream object containing the CLSID to be read. This CLSID must have been previously written to the stream object using **WriteClassStm**.

pclsid
Points to the location where the CLSID is to be returned.

Return Values

S_OK
Indicates the CLSID was successfully returned.

STG_E_READFAULT
Indicates end of file was reached.

See also the **IStream::Read** method for other error return values.

Comments

Most applications do not call the **ReadClassStm** method. OLE calls it before making a call to an object's **IPersistStream::Load** implementation.

See Also

WriteClassStm, **ReadClassStg**, **WriteClassStg**

ReadFmtUserTypeStg QuickInfo

Returns the clipboard format and user type previously saved with the **WriteFmtUserTypeStg** function.

```
HRESULT ReadFmtUserTypeStg(
    IStorage * pStg,              //Points to storage object for which the values are to be retreived
    CLIPFORMAT * pcf,             //Points to location for returning the clipboard format
    LPWSTR * lplpszUserType       //Points to location for returning the user type string
  );
```

Parameters

pStg
Points to the storage object from which the information is to be read.

pcf
Points to the location where the clipboard format is to be returned. It can be NULL, indicating the format is of no interest to the caller.

lplpszUserType
Points to the location where the user type string is to be returned. It can be NULL, indicating the user type is of no interest to the caller.

Return Values

S_OK
Indicates the requested information was read successfully.

E_OUTOFMEMORY
Indicates the information could not be retrieved due to a lack of memory.

E_FAIL
Indicates the **WriteFmtUserTypeStg** function was never called on the object.

See also the **IStream::Read** method for other error return values.

Comments

This function returns the clipboard format and the user type string from the specified storage object. The **WriteClassStg** function must have been called before calling the **ReadFmtUserTypeStg** function.

See Also

WriteFmtUserTypeStg

RegisterDragDrop QuickInfo

Registers the specified window as a window that can be the target of an OLE drag and drop operation and specifies the **IDropTarget** instance to use for drop operations.

```
HRESULT RegisterDragDrop(
   HWND hwnd,                      //Window that can accept drops
   IDropTarget * pDropTarget       //Points to the IDropTarget interface
  );
```

Parameters

hwnd
Specifies the handle to a window that can be a target for an OLE drag and drop operation.

pDropTarget
Specifies the **IDropTarget** instance to use for communicating OLE drag and drop information for the specified window.

Return Values

S_OK
Indicates the application was registered successfully.

DRAGDROP_E_INVALIDHWND
Indicates invalid handle returned in the *hwnd* parameter.

DRAGDROP_E_ALREADYREGISTERED
Indicates the specified window has already been registered as a drop target.

E_OUTOFMEMORY
Indicates out of memory.

Comments

If your application can accept dropped objects during OLE drag and drop operations, you must call the **RegisterDragDrop** function. Do this whenever one of your application windows is available as a potential drop target, i.e., when the window appears unobscured on the screen.

The **RegisterDragDrop** function only registers one window at a time, so you must call it for each application window capable of accepting dropped objects.

As the mouse passes over unobscured portions of the target window during an OLE drag and drop operation, the **DoDragDrop** function calls the specified **IDropTarget::DragOver** method for the current window. When a drop operation actually occurs in a given window, the **DoDragDrop** function calls **IDropTarget::Drop**.

The **RegisterDragDrop** function also calls the **IUnknown::AddRef** method for your drop target interface.

See Also

RevokeDragDrop

ReleaseStgMedium [QuickInfo]

Frees the specified storage medium.

```
void ReleaseStgMedium(
   STGMEDIUM * pmedium        //Storage medium to be freed
  );
```

Parameter

pmedium
Points to the storage medium that is to be freed.

Return Value

None.

Comments

The **ReleaseStgMedium** function frees the specified storage medium. Use this function during data transfer operations where storage medium structures are parameters, such as **IDataObject::GetData** or **IDataObject::SetData**. This structure specifies the appropriate **IUnknown::Release** method for releasing the storage medium when it is no longer needed.

The **ReleaseStgMedium** function calls the appropriate method or function to release the specified storage medium. Either the original provider of the medium or the receiver of the medium can call **ReleaseStgMedium**.

In cases where the original provider of the medium is responsible for freeing the medium, the provider calls **ReleaseStgMedium**. The **ReleaseStgMedium** function first makes a call as described in the following table, depending on the type of storage medium being freed.

Medium	ReleaseStgMedium Action
TYMED_HGLOBAL	None.
TYMED_GDI	None.
TYMED_ENHMF	None.
TYMED_MFPICT	None.
TYMED_FILE	Frees the filename string using standard memory management mechanisms.
TYMED_ISTREAM	Calls **IStream::Release**.
TYMED_ISTORAGE	Calls **IStorage::Release**.

After making the call described in the preceding table, **ReleaseStgMedium** then calls the **IUnknown::Release** method for the specified storage medium. This method is specified in the storage medium structure.

In cases where the receiver of the medium is responsible for freeing the medium, the storage medium structure specifies NULL for the **IUnknown::Release** method. In this case, the receiver calls **ReleaseStgMedium,** which makes a call as described in the following table depending on the type of storage medium being freed.

Medium	ReleaseStgMedium Action
TYMED_HGLOBAL	Calls **GlobalFree** on the handle.
TYMED_GDI	Calls **DeleteObject** on the handle.
TYMED_ENHMF	Deletes the enhanced metafile.
TYMED_MFPICT	The *hMF* that it contains is deleted with **DeleteMetaFile**; then the handle itself is

	passed to **GlobalFree**.
TYMED_FILE	Frees the disk file by deleting it. Frees the file name string by using the standard memory management paradigm.
TYMED_ISTREAM	**Calls IStream::Release**.
TYMED_ISTORAGE	**Calls IStorage::Release**.

In either case after the call to **ReleaseStgMedium**, the specified storage medium is invalid and can no longer be used.

ResultFromScode

```
#define ResultFromScode(sc) ((HRESULT) (sc))
```

Converts an **SCODE** into an **HRESULT**.

This macro is obsolete and should not be used.

RevokeDragDrop [QuickInfo]

Revokes the registration of the specified application window as a potential target for OLE drag and drop operations.

```
HRESULT RevokeDragDrop(
   HWND hwnd         //Window that can accept drops
  );
```

Parameter

hwnd
Specifies the handle to a window previously registered as a target for an OLE drag and drop operation.

Return Values

S_OK
Indicates registration as a target window was revoked successfully.

DRAGDROP_E_INVALIDHWND
Indicates invalid handle returned in the *hwnd* parameter.

DRAGDROP_E_NOTREGISTERED
Indicates an attempt was made to revoke a drop target that has not been registered.

E_OUTOFMEMORY
Out of memory.

Comments

When your application window is no longer available as a potential target for an OLE drag and drop operation, you must call **RevokeDragDrop**.

This function calls the **IUnknown::Release** method for your drop target interface.

See Also

RegisterDragDrop

SCODE_CODE

```
#define SCODE_CODE(sc) ((sc) & 0xFFFF)
```

Extracts the code part of the **SCODE**.

SCODE_FACILITY

```
#define SCODE_FACILITY(sc) (((sc) >> 16) & 0x1fff)
```

Extracts the facility from the **SCODE**.

SCODE_SEVERITY

```
#define SCODE_SEVERITY(sc) (((sc) >> 31) & 0x1)
```

Extracts the severity field from the **SCODE**.

SetConvertStg QuickInfo

Indicates whether the object is to be automatically converted to a different CLSID. It does this by setting the conversion bit in a storage object. The setting can be retrieved with a call to the **GetConvertStg** function.

```
HRESULT SetConvertStg(
  IStorage * pStg,         //Storage object where the conversion bit is to be set
  BOOL fConvert            //Indicates whether an object is to be converted
 );
```

Parameters

pStg
Specifies the storage object in which to set the conversion bit.

fConvert
If TRUE, sets the conversion bit for the object. If FALSE, clears the conversion bit.

Return Values

S_OK
Indicates the object's conversion bit was set successfully.

STG_E_ACCESSDENIED
Indicates access to the storage object is not available.

E_OUTOFMEMORY
Indicates the conversion bit was not set due to a lack of memory.

E_INVALIDARG
Indicates one or more arguments are invalid.

E_UNEXPECTED
Indicates an unexpected error occurred.

See the **IStorage::CreateStream**, **IStorage::OpenStream**, **IStream::Read**, and **IStream::Write** methods for possible storage and stream access errors.

Comments

As part of converting an object from one class to another, container applications call **SetConvertStg** to set the conversion bit in the storage object. The bit is set to TRUE, indicating that the object has been tagged for conversion to a new class the next time it is loaded.

To retrieve the value of the conversion bit, an object application calls the **GetConvertStg** function when it is loading the object. If the bit is set, the object application converts the object to the new CLSID. To reset an object's conversion bit, the object application calls the **SetConvertStg** function with the *fConvert* parameter set to FALSE.

GetConvertStg

StgCreateDocfile **QuickInfo**

Creates a new storage object using the OLE-provided compound file implementation for the **IStorage** interface.

```
HRESULT StgCreateDocfile(
    const WCHAR * pwcsName,      //Points to pathname of compound file to create
    DWORD grfMode,               //Specifies the access mode for opening the storage object
    DWORD reserved,              //Reserved; must be zero
    IStorage ** ppstgOpen        //Points to location for returning the new storage object
  );
```

Parameters

pwcsName
Points to the pathname of the compound file to create. Passed uninterpreted to the file system. This can be a relative name or NULL. If NULL, a temporary compound file is allocated with a unique name.

grfMode
Specifies the access mode to use when opening the new storage object. For more information, see the **STGM** enumeration.

reserved
Reserved for future use; must be zero.

ppstgOpen
Points to the location where the new storage object is placed.

Return Values

S_OK
Indicates the compound file was successfully created.

STG_E_ACCESSDENIED
Indicates the calling process does not have sufficient access. Attempt to open file with conflicting permissions to a simultaneous open.

STG_E_FILEALREADYEXISTS
Indicates the compound file already exists and *grfMode* is set to STGM_FAILIFTHERE.

STG_S_CONVERTED
Indicates the specified file was successfully converted to Storage format.

STG_E_INSUFFICIENTMEMORY
Indicates the compound file was not created due to a lack of memory.

STG_E_INVALIDNAME
Indicates bad name in the *pwcsName* parameter.

STG_E_INVALIDPOINTER
Indicates bad pointer in the *pwcsName* parameter or the *ppStgOpen* parameter.

STG_E_INVALIDFLAG
Indicates bad flag combination in the *grfMode* pointer.

STG_E_TOOMANYOPENFILES
Indicates the compound file was not created due to a lack of file handles.

See also any file system errors for other error return values.

Comments

This function creates a new storage object using the OLE-provided, compound-file implementation for the **IStorage** interface. The name of the open compound file can be retrieved by calling the **IStorage::Stat** method.

The **StgCreateDocfile** function creates the file if it does not exist. If it does exist, the use of the STGM_CREATE, STGM_CONVERT, and STGM_FAILIFTHERE flags in the *grfMode* parameter indicate how to proceed. See the **STGM** enumeration for more information on these values.

If the compound file is opened in transacted mode (the *grfMode* parameter specifies STGM_TRANSACTED) and a file with this name already exists, the existing file is not altered until all outstanding changes are committed. If the calling process lacks write access to the existing file (because of access control in the file system), the *grfMode* parameter can only specify STGM_READ and *not* STGM_WRITE or STGM_READWRITE. The resulting new open compound file can still be written to, but a commit operation will fail (in transacted mode, write permissions are enforced at commit time).

If the *grfMode* parameter specifies STGM_TRANSACTED and no file yet exists with the name specified by the *pwcsName* parameter, the file is created immediately. In an access-controlled file system, the caller must have write permissions in the file system directory in which the compound file is created.

The absence of STGM_TRANSACTED in the *grfMode* parameter indicates the file is to be created and opened in direct access mode. Any existing file with the same name is destroyed before creating the new file.

The **StgCreateDocfile** function can be used to create a temporary compound file by passing a NULL value for the *pwcsName* parameter. However, these files are temporary only in the sense that they have a system-provided unique name - likely one that is meaningless to the user. The caller is responsible for deleting the temporary file when finished with it, unless STGM_DELETEONRELEASE was specified for the *grfMode* parameter.

Note By default, a Windows application can have 20 file handles open at one time. Each storage object opened in transacted mode uses three file handles. To increase the number of file handles the application has available, applications often call the Windows **SetHandleCount** function. However, the **SetHandleCount** function affects C run-time libraries (those statically linked to the application) that are hard-coded to expect only 20 file handles. There is no check on overflow, so if the application already has a few compound files open and it then uses a C run-time library (for example, **fopen** or **sopen**), the application corrupts memory past the end of the file-handle array (low in its data segment) if the library gets a file handle above 20.

To solve this problem, applications should reserve some number of file handles on start up, making them available to the components that might be based on C run-time libraries. If your application does not use any dynamic link libraries that use the C run-time libraries, there is no need for any special file-handle reservation code.

See Also

StgCreateDocFileOnILockBytes

StgCreateDocfileOnILockBytes QuickInfo

Creates and opens a new storage object on top of an **ILockBytes** instance provided by the caller. The storage object uses the OLE-provided, compound-file implementation for the **IStorage** interface.

```
HRESULT StgCreateDocfileOnILockBytes(
   ILockBytes * plkbyt,          //Specifies the byte array object
   DWORD grfMode,                //Specifies the access mode
   DWORD reserved,               //Reserved; must be zero
   IStorage ** ppstgOpen         //Points to location for returning the new storage object
  );
```

Parameters

plkbyt
Points to the underlying byte array object on which to create a compound file.

grfMode
Specifies the access mode to use when opening the new compound file. For more information, see the **STGM** enumeration.

reserved
Reserved for future use; must be zero.

ppstgOpen
Points to the location where the new storage object is placed.

Return Values

S_OK
Indicates the compound file was successfully created.

STG_E_ACCESSDENIED
Indicates the calling process does not have sufficient access. Attempt was made to open an **ILockBytes** object with permissions that conflict with another current opening of the same object.

STG_E_FILEALREADYEXISTS
Indicates the compound file already exists and the *grfMode* parameter is set to STGM_FAILIFTHERE.

STG_S_CONVERTED
Indicates the compound file was successfully converted. The original byte array object was successfully converted to **IStorage** format.

STG_E_INSUFFICIENTMEMORY
Indicates the storage object was not created due to a lack of memory.

STG_E_INVALIDPOINTER
Indicates a bad pointer was in the *pLkbyt* parameter or the *ppStgOpen* parameter.

STG_E_INVALIDFLAG
Indicates a bad flag combination was in the *grfMode* parameter.

STG_E_TOOMANYOPENFILES
Indicates the storage object was not created due to a lack of file handles.

See also any file system errors for other error return values.

See also the **ILockBytes** interface for other error return values.

Comments

This function creates a storage object on top of a byte array object using the OLE-provided, compound-file implementation for the **IStorage** interface. The **StgCreateDocfileOnILockBytes** function can be used to store a document in a relational database. The byte array indicated by the *pLkbyt* parameter is used for the underlying storage in place of a disk file.

The **StgCreateDocfileOnILockBytes** function has almost exactly the same semantics as the **StgCreateDocfile** function. For more information, see the discussion of **StgCreateDocfile**.

The newly created compound file is opened according to the access modes in the *grfMode* parameter. For conversion purposes, the file is always considered to already exist. As a result, it is not useful to use the STGM_FAILIFTHERE value, because it always causes an error to be returned. However, STGM_CREATE and STGM_CONVERT are both still useful.

The ability to build a compound file on top of a byte array object is provided to support having the data (underneath an **IStorage** and **IStream** tree structure) live in persistent space, space that does not ultimately reside in the file system. Given this capability, there is nothing preventing a document that *is* stored in a file from using this facility. For example, a container might do this to minimize the impact on its file format caused by adopting OLE. However, it is recommended that OLE documents adopt the **IStorage** interface for their own outer-level storage. This has the following advantages:

- The storage structure of the document is the same as its storage structure when it is an embedded object, reducing the number of cases the application needs to handle.
- One can write tools to access the OLE embeddings and links within the document without special knowledge of the document's file format. An example of such a tool is a copy utility that copies all the documents included in a container containing linked objects. A copy utility like this needs access to the contained links to determine the extent of files to be copied.
- The **IStorage** instance addresses the problem of how to commit the changes to the file. An application using the **ILockBytes** byte array must handle these issues itself.
- Future file systems will likely implement the **IStorage** and **IStream** interfaces as their native abstractions, rather than layer on top of a byte array as is done in compound files. Such a file system could be built so documents using the **IStorage** interface as their outer level containment structure would get an automatic efficiency gain by having the layering flattened when files are saved on the new file system.

See Also

StgCreateDocfile

StgIsStorageFile [QuickInfo]

Indicates whether a particular disk file contains a storage object.

HRESULT StgIsStorageFile(
  const WCHAR * *pwcsName*   //Points to a pathname of the file to check
 );

Parameter

pwcsName
  Points to the name of the disk file to be examined. The *pwcsName* parameter is passed uninterpreted to the underlying file system.

Return Values

S_OK
  Indicates the file contains a storage object.

S_FALSE
  Indicates the file does not contain a storage object.

STG_E_INVALIDFILENAME
  Indicates a bad filename was passed in the *pwcsName* parameter.

STG_E_FILENOTFOUND
  Indicates the *pwcsName* parameter could not be determined.

See also any file system errors for other error return values.

Comments

At the beginning of the disk file underlying a storage object is a signature distinguishing a storage object from other file formats. The **StgIsStorageFile** function is useful to applications whose documents use a disk file format that might or might not use storage objects.

See Also

StgIsStorageILockBytes

StgIsStorageILockBytes QuickInfo

Indicates whether the specified byte array contains a storage object.

```
HRESULT StgIsStorageILockBytes(
   ILockBytes * plkbyt          //Points to the byte array to be examined
  );
```

Parameter

plkbyt
Points to the byte array to be examined.

Return Values

S_OK
Indicates the specified byte array contains a storage object.

S_FALSE
Indicates the specified byte array does not contain a storage object.

File system errors.

ILockBytes interface error return values.

Comments

At the beginning of the **ILockBytes** byte array underlying a storage object is a signature distinguishing an **IStorage** object from other file formats. The **StgIsStorageILockBytes** function is useful to applications whose documents use an **ILockBytes** byte array format that might or might not use storage objects.

See Also

StgIsStorageFile

StgOpenStorage QuickInfo

Opens an existing root storage object in the file system. You can use this function to open directories, files, compound files, and summary catalogs. Nested storage objects can only be opened using their parent's **IStorage::OpenStorage** method.

```
HRESULT StgOpenStorage(
   const WCHAR * pwcsName,        //Points to the pathname of the file containing storage object
   IStorage * pstgPriority,       //Points to a previous opening of a root storage object
   DWORD grfMode,                 //Specifies the access mode for the object
   SNB snbExclude,                //Points to an SNB structure specifying elements to be excluded
   DWORD reserved,                //Reserved; must be zero
   IStorage ** ppstgOpen          //Points to location for returning the storage object
  );
```

Parameters

pwcsName

Points to the pathname of the storage object to open. This parameter is ignored if the *pStgPriority* parameter is not NULL.

pstgPriority

Most often NULL. If not NULL, this parameter is used instead of the *pwcsName* parameter to specify the storage object to open. It points to a previous opening of a root storage object, most often one that was opened in priority mode.

After the **StgOpenStorage** function returns, the storage object specified in the *pStgPriority* parameter on function entry is invalid, and can no longer be used. Use the one specified in the *ppStgOpen* parameter instead.

grfMode

Specifies the access mode to use to open the storage object.

snbExclude

If not NULL, this parameter points to a block of elements in this storage that are to be excluded as the storage object is opened. This exclusion occurs independent of whether a snapshot copy happens on the open. May be NULL.

reserved

Indicates reserved for future use; must be zero.

ppstgOpen

Points to the location where the opened storage is placed.

Return Values

S_OK

Indicates the storage object was successfully opened.

STG_E_FILENOTFOUND

Indicates the specified file does not exist.

STG_E_ACCESSDENIED

Indicates insufficient access to open file. Exclusions specified without read-write permissions or attempt to open file with conflicting permissions to a simultaneous open.

STG_E_FILEALREADYEXISTS

Indicates the file exists but is not a storage object.

STG_E_TOOMANYOPENFILES

Indicates the storage object was not opened because there are too many open files.

STG_E_INSUFFICIENTMEMORY

Indicates the storage object was not opened due to a lack of memory.

STG_E_INVALIDNAME

Indicates bad name in the *pwcsName* parameter or the *snbExclude* parameter.

STG_E_INVALIDPOINTER
: Indicates bad pointer in one of the parameters: *snbExclude*, *pwcsName*, *pstgPriority*, or *ppStgOpen*.

STG_E_INVALIDFLAG
: Indicates bad flag combination in the *grfMode* parameter.

STG_E_INVALIDFUNCTION
: Indicates STGM_DELETEONRELEASE specified in the *grfMode* parameter.

STG_E_OLDDLL
: Indicates the DLL being used to open this storage object is a version prior to the one used to create it.

STG_E_OLDFORMAT
: Indicates the storage object being opened was created by the Beta 1 storage provider. This format is no longer supported.

File system error return values.

Comments

This function opens the specified root storage object according to the access mode in the *grfMode* parameter. A pointer to the opened storage object is returned through the *ppstgOpen* parameter.

Note Opening a storage object in read and/or write mode without denying writer permission to others (the *grfMode* parameter specifies STGM_SHARE_DENY_WRITE) can be be a time consuming operation since the **StgOpenStorage** call must make a snapshot of the entire storage object.

Applications will often try to open storage objects with the following access permissions:

```
STGM_READ_WRITE | STGM_SHARE_DENY_WRITE
     // transacted vs. direct mode omitted for exposition
```

If the application succeeds, it will never need to do a snapshot copy. If it fails, the application can revert to using the permissions and make a snapshot copy:

```
STGM_READ_WRITE
     // transacted vs. direct mode omitted for exposition
```

In this case, the application should prompt the user before doing a time consuming copy. Alternatively, if the document sharing semantics implied by the access modes are appropriate, the application could try to open the storage as follows:

```
STGM_READ | STGM_SHARE_DENY_WRITE
     // transacted vs. direct mode omitted for exposition
```

In this case, if the application succeeds, a snapshot copy will not have been made (because STGM_SHARE_DENY_WRITE was specified, denying others write access).

To reduce the expense of making a snapshot copy, applications can open storage objects in priority mode (*grfMode* specifies STGM_PRIORITY).

The *snbExclude* parameter specifies a set of element names in this storage object that are to be emptied as the storage object is opened: streams are set to a length of zero; storage objects have all their elements removed. By excluding certain streams, the expense of making a snapshot copy can be significantly reduced. Almost always, this approach will be used after first opening the storage object in priority mode, then completely reading the now-excluded elements into memory. This earlier priority mode opening of the storage object should be passed through the *pstgPriority* parameter to remove the exclusion implied by priority mode. The calling application is responsible for rewriting the contents of excluded items before committing. Thus, this technique is most likely only useful to applications whose documents do not require constant access to their storage objects while they are active.

StgOpenStorageOnILockBytes QuickInfo

Opens an existing storage object that does not reside in a disk file, but instead has an underlying byte array provided by the caller.

```
HRESULT StgOpenStorageOnILockBytes(
    ILockBytes * plkbyt,           //Specifies the underlying byte array
    IStorage * pStgPriority,       //Points to a previous opening of a root storage object
    DWORD grfMode,                 //Specifies the access mode for the object
    SNB snbExclude,                //Points to an SNB structure specifying elements to be excluded
    DWORD reserved,                //Reserved, must be zero
    IStorage ** ppstgOpen          //Points to location for returning the storage object
  );
```

Parameters

plkbyt
Points to the underlying byte array that contains the storage object to be opened.

pStgPriority
Most often NULL. If not NULL, this parameter is used instead of the *plkbyt* parameter to specify the storage object to open. It points to a previous opening of a root storage object, most often one that was opened in priority mode.

After the **StgOpenStorageOnILockBytes** function returns, the storage object specified in the *pStgPriority* parameter on function entry is invalid, and can no longer be used; use the one specified in the *ppStgOpen* parameter instead.

grfMode
Specifies the access mode to use to open the storage object.

snbExclude
May be NULL. If not NULL, this parameter points to a block of elements in this storage that are to be excluded as the storage object is opened. This exclusion occurs independent of whether a snapshot copy happens on the open. .

reserved
Indicates reserved for future use; must be zero.

ppstgOpen
Points to the location where the opened storage is placed.

Return Values

S_OK
Indicates the storage object was successfully opened.

STG_E_FILENOTFOUND
Indicates the specified byte array does not exist.

STG_E_ACCESSDENIED
Indicates insufficient access to open the byte array. Exclusions specified without read-write permissions or attempt to open the byte array with conflicting permissions to a simultaneous open.

STG_E_FILEALREADYEXISTS
Indicates the byte array exists but is not a storage object.

STG_E_TOOMANYOPENFILES
Indicates the storage object was not opened because there are too many open files.

STG_E_INSUFFICIENTMEMORY
Indicates the storage object was not opened due to a lack of memory.

STG_E_INVALIDNAME
Indicates bad name in the *pwcsName* parameter or the *snbExclude* parameter.

STG_E_INVALIDPOINTER
: Indicates bad pointer in one of the parameters: *snbExclude*, *pwcsName*, *pstgPriority*, or *ppStgOpen*.

STG_E_INVALIDFLAG
: Indicates bad flag combination in the *grfMode* parameter.

STG_E_INVALIDFUNCTION
: Indicates STGM_DELETEONRELEASE specified in the *grfMode* parameter.

STG_E_OLDDLL
: Indicates the DLL being used to open this storage object is a version prior to the one used to create it.

STG_E_OLDFORMAT
: Indicates the storage object being opened was created by the Beta 1 storage provider. This format is no longer supported.

File system error return values.

ILockBytes interface error return values.

Comments

This function opens the specified root storage object. The storage object is opened according to the access mode in the *grfMode* parameter; a pointer to the opened storage object is returned through the *ppstgOpen* parameter.

The storage object must have been previously created by the **StgCreateDocfileOnILockBytes** function.

The semantics of the **StgOpenStorageOnILockBytes** function are almost exactly the same as those of the **StgOpenStorage** function. For more information, see the discussion of the **StgOpenStorage** function.

See Also

StgOpenStorage

StgSetTimes QuickInfo

Sets the creation, access, and modification times of the indicated file, if supported by the underlying file system.

```
HRESULT StgSetTimes(
    WCHAR const * lpszName,         //Points to the name of the file to be changed
    FILETIME const * pctime,        //Points to the new value for the creation time
    FILETIME const * patime,        //Points to the new value for the access time
    FILETIME const * pmtime         //Points to the new value for the modification time
  );
```

Parameters

lpszName
Points to the name of the file to be changed.

pctime
Points to the new value for the creation time.

patime
Points to the new value for the access time.

pmtime
Points to the new value for the modification time.

Return Values

S_OK
Indicates time values successfully set.

STG_E_FILENOTFOUND
Indicates element does not exist.

STG_E_INVALIDNAME
Indicates bad name passed in the *lpszName* parameter, or a file system error.

STG_E_ACCESSDENIED
Indicates insufficient permissions to access storage.

File system error return values.

Comments

This function sets the time values for the specified file. Each of the time value parameters can be NULL, indicating no modification should occur.

It is possible that one or more of these time values are not supported by the underlying file system. This function sets the times that can be set and ignores the rest.

StringFromCLSID QuickInfo

Converts the CLSID into a string of printable characters so different CLSIDs always convert to different strings.

```
HRESULT StringFromCLSID(
   REFCLSID rclsid,          //The CLSID to be converted
   LPOLESTR * lplpsz         //Receives the resulting string on return
  );
```

Parameters

rclsid
Specifies the CLSID to be converted.

lplpsz
Receives the resulting string on return.

Return Values

S_OK
Indicates the CLSID was successfully converted and returned.

E_OUTOFMEMORY
Out of memory.

Comments

The **StringFromCLSID** function calls the **StringFromGuid2** function to convert a globally unique identifier (GUID) into a string of printable characters.

See Also

CLSIDFromString, **StringFromGuid2**

StringFromGUID2 QuickInfo

Converts a globally unique identifier (GUID) into a string of printable characters.

```
int StringFromGUID2(
   REFGUID rguid,           //The interface ID to be converted
   LPOLESTR lpsz,           //Receives the resulting string on return
   int cbMax                //The maximum size the returned string is expected to be
  );
```

Parameters

rguid
Specifies the interface ID to be converted.

lpsz
Receives the resulting string on return.

cbMax
Specifies the maximum size the returned string is expected to be.

Return Values

0 (zero)
Indicates buffer is too small for returned string.

Non-zero value
Specifies the number of characters in the returned string, including the null terminator.

Comments

The string that the *lpsz* parameter receives has a format like the following sample:

```
[c200e360-38c5-11ce-ae62-08002b2b79ef]
```

where the successive fields break the GUID into the form DWORD-WORD-WORD-WORD-WORD.DWORD covering the 128-bit GUID. The string includes enclosing braces, which are an OLE convention.

See Also

StringFromCLSID

StringFromIID QuickInfo

Converts an interface ID into a string of printable characters.

```
HRESULT StringFromIID(
   REFIID rclsid               //The interface ID to be converted
   LPOLESTR * lplpsz           //Receives a pointer to the resulting string on return
  );
```

Parameters

rclsid
Specifies the interface ID to be converted.

lplpsz
Receives a pointer to the resulting string on return.

Return Values

S_OK
Indicates the character string was successfully returned.

E_OUTOFMEMORY
Out of memory.

Comments

The string returned by the function is freed in the standard way, using the task allocator (refer to the **CoGetMalloc**function).

See Also

IIDFromString, **CoGetMalloc**

SUCCEDDED

```
#define SUCCEEDED(Status) ((HRESULT)(Status) >= 0)
```

Provides a generic test for success on any status value. Non-negative numbers indicate success.

WriteClassStg QuickInfo

Stores the specified CLSID in a storage object.

```
HRESULT WriteClassStg(
   IStorage * pStg,        //Points to the storage object
   REFCLSID rclsid         //Specifies the CLSID to be stored in the storage object
  );
```

Parameters

pStg
Points to the storage object that will get a new CLSID.

rclsid
Points to the CLSID to be stored with the object.

Return Values

S_OK
Indicates the CLSID was successfully written to the file.

STG_E_MEDIUMFULL
Indicates the CLSID could not be written due to lack of memory.

IStorage::SetClass method error return values.

Comments

This function writes a CLSID to the specified storage object so it can be read by the **ReadClassStg** function. Container applications typically call this function before calling the **IPersistStorage::Save** method.

See Also

OleSave, **ReadClassStg**

WriteClassStm QuickInfo

Stores the specified CLSID in the stream.

```
HRESULT WriteClassStm(
  IStream * pStm,          //Points to the stream object
  REFCLSID rclsid          //Specifies the CLSID to be stored in the stream object
 );
```

Parameters

pStm
Points to the stream into which the CLSID is to be written.

rclsid
Specifies the CLSID to write to the stream.

Return Values

S_OK
Indicates the CLSID was successfully written.

STG_E_MEDIUMFULL
The CLSID could not be written because there is no space left on device.

IStorage::SetClass method error return values.

Comments

This function writes a CLSID to the specified stream object so it can be read by the **ReadClassStm** function. Most applications do not call the **WriteClassStm** function. OLE calls it before making a call to an object's **IPersistStream::Save** method.

See Also

ReadClassStm, **WriteClassStg**, **ReadClassStg**

WriteFmtUserTypeStg QuickInfo

Writes a clipboard format and user type to the storage object.

```
HRESULT WriteFmtUserTypeStg(
    IStorage * pStg,                    //Points to the storage object
    CLIPFORMAT cf,                     //Specifies the clipboard format
    LPWSTR * lpszUserType       //Points to the current user type
  );
```

Parameters

pStg

Points to the storage object where the information is to be written.

cf

Specifies the clipboard format that describes the structure of the native area of the storage object. The format tag includes the policy for the names of streams and substorages within this storage object and the rules for interpreting data within those streams.

lpszUserType

Points to the object's current user type. It cannot be NULL. This is the type returned by the **IOleObject::GetUserType** method. If this function is transported to a remote machine where the object class does not exist, this persistently stored user type can be shown to the user in dialog boxes.

Return Values

S_OK

Indicates the information was written successfully.

STG_E_MEDIUMFULL

Indicates information could not be written due to lack of space on the storage medium.

IStream::Write method error return values.

Comments

The **WriteFmtUserTypeStg** function must be called in an object's implementation of the **IPersistStorage::Save** method. It must also be called by document-level objects that use structured storage for their persistent representation in their save sequence.

To read the information saved, applications call the **ReadFmtUserTypeStg** function.

See Also

IPersistStorage::Save, **ReadFmtUserTypeStg**

Glossary

A

Activation

The process of binding an object in order to put it into its running state. Also refers to invoking a particular operation on an object. *See also* Binding.

Absolute moniker

A moniker that specifies the absolute location of an object. An absolute moniker is analogous to a full pathname. *See also* Moniker*.*

Advisory sink

An object that can receive notifications of changes in an embedded object or linked object because it implements the IAdviseSink interface (and possibly the IAdviseSink2 interface). Notifications originate in the object application, where they are cached in an advise holder, which passes them to advisory sinks implemented by object handlers. For an embedded object, the corresponding object handler forwards the notification to the object's container. For a linked object, the object handler forwards the notification to the link object, which in turn passes it on to the container. *See also* Object handler, Embedded object, Link object, Linked object, Container application.

Aggregate object

A component object that is made up of one or more other component objects. One object in the aggregate is designated the control object, which controls which interfaces in the aggregate are exposed and which are private. The control object has a special implementation of **IUnknown** called the controlling unknown. All non-controlling objects in the aggregate must pass calls to **IUnknown** methods through the controlling unknown.

Aggregation

A composition technique for implementing component objects. It allows you to build a new object with one or more existing objects that support some or all of the new object's required interfaces.

Anti-moniker

The inverse of a file, item, or pointer moniker. An anti-moniker is added to the end of a file-, item-, or pointer moniker to nullify it. This is analogous to the way that ".." nullifies a directory component of a pathname (that is, **\work\art\..** equals **\work**). Anti-monikers are used in the construction of relative monikers. *See also* Relative Moniker.

Artificial reference counting

A technique used to safeguard an object before making a call that could result in its premature destruction by ensuring it won't be de-allocated. A process calls the **AddRef** method of **IUnknown** to increment the count before making the call that could otherwise free the object prematurely, and after the function returns, calls the **IUnknown::Release** method to decrement the count.

Asynchronous call

A function that allows the next instruction in the process to be executed as soon as the call is made, without waiting for the function to return. Most OLE functions and interface methods are synchronous; that is, the function must return before the next instruction is executed. OLE defines six asynchronous methods, five within the **IAdviseSink** interface – **OnDataChange**, **OnViewChange**, **OnRename**, **OnSave**, and **OnClose** – and one within the **IAdviseSink2** interface – **OnLinkSourceChange**.

Automation
See OLE Automation

B

Bind context
An object that implements the **IBindCtx** interface. Bind contexts are used in moniker operations. A bind context holds references to the objects activated when a moniker is bound, contains parameters that apply to all operations during the binding of a generic composite moniker, and provides the means by which the moniker implementation should retrieve information about its environment. *See* Binding, Moniker.

Binding
Generically, binding is the process of associating a name to its referent. When referring to monikers specifically, binding is the process of locating the object named by the moniker, activating it (loading it in memory) if it isn't already, and returning an interface pointer to it. Binding puts an object into its running state, allowing the operations it supports to be invoked. Objects can be bound at run time (also called late binding or dynamic binding) or at compile time (also called static binding). In OLE Automation, vtable-based binding is referred to as "early binding" and IDispatch-based binding is referred to as "late binding."

C

Cache
Generally, a cache is a (usually temporary) local store of information. In OLE, the term cache is used in connection with linked or embedded objects, in which the cache contains information that defines the presentation of a contained object when the container is opened.

Cache initialization
The process of filling an embedded object's cache with data formats. The **IOleCache** interface provides methods that a container object can call to control the data that gets cached for embedded objects.. The **IOleCache::InitCache** method fills the cache using data provided by a transfer from the Clipboard or from a drag-and-drop operation. The **IOleCache::SetData** method fills the cache using data in a storage object.

Class
In object-oriented programming, a class is a set of objects whose behavior is defined by the same set of code (they share the same implementation).
A COM class is not necessarily the same as a class in an object-oriented language. A COM class can be identified by a CLSID, though for most COM operations, it is not necessary to know an object's class.

Class factory
A object that you use to create one or more instances of a an object identified by a given CLSID (class identifier). A class factory object implements the **IClassFactory** interface. A class factory is the most frequently used type of class object in OLE. *See also CLSID.*

Class identifier (CLSID)
A unique identification tag (UUID) associated with an OLE class object. A class object that is intended to create more than one object registers its CLSID in a task table in the registration database to enable clients to locate and load the executable code associated with the object(s). Every OLE object application (or container that allows linking to its embedded objects) must register a CLSID for each supported object definition.

Class object
In COM, class objects are called class factories, and typically have no behavior except to create new instances of the class. In object-oriented programming, an object whose state is shared by all the objects in a class, and whose behavior acts on that class-wide state data. *See also* Class factory.

Client
In referring to OLE objects, an object that requests services from another object. *See also* Container.

Client site
The display site for an embedded or linked object within a compound document. The client site is the principal means by which an object requests services from its container.

CLSID
See Class identifier

Component object
An object that conforms to the OLE component object model (COM). Clients deal with a component object only through a pointer to an interface (a related set of functions called methods). With the pointer, clients can call the methods that perform operations or manipulate the data associated with the object. Component objects are instances of an object definition, which specifies an implementation of the interfaces on the object.

Composite moniker
A moniker that consists of two or more monikers composed together. A composite moniker can be non-generic, meaning that its component monikers have special knowledge of each other, or generic, meaning that its component monikers know nothing about each other except that they are monikers. *See* Generic composite moniker.

Commit
The act of persistently saving any changes made to an object since its storage was opened or since the last time changes were saved. *See also Revert*.

Component object model (COM)
The OLE object-oriented programming model that defines how objects interact within a single application or between applications. In COM, clients have access to an OLE object through a pointer to an interface (a related set of functions called methods) on the object.

Composite menu
A shared menu bar composed of menu groups from both an in-place container and an in-place object application. The object application must install and remove the menu from the container's frame window.

Compound document
A document that contains data of different formats, created by different applications. Compound documents are created in a container application, such as Word, and information from other applications (such as spreadsheets, sound clips, and bitmaps) is either embedded in or linked to the container application. When the compound document is saved, the container application saves it.

Compound file

An OLE-provided implementation of structured storage which includes the **IStorage**, the **IStream**, and the **ILockBytes** interfaces. You use a set of **Stg*Xxx*** API functions to create and use a compound file.

Container

See Container application.

Container application

An application that supports compound documents. Container applications provide storage for the object, a site for display, access to the display site, and an advisory sink for receiving notifications of changes in the object. *See also* Compound document, Client site, and Advisory sink.

Container/Object

An application that has implemented OLE interfaces such that the application supports the features and capabilities of both a container and object application.

Container/Server

See Container/Object.

Control object

The object within an Aggregate object that controls which interfaces within the aggregate object are exposed and which are private.. The control object has a special implementation of **IUnknown** called the controlling unknown, and all other objects in the aggregate must pass calls to **IUnknown** methods through the controlling unknown. *See* Aggregate object.

D

Data transfer object

An object that supports the **IDataObject** interface and contains data to be transferred from one object to another either through the Clipboard or drag-and-drop operations.

Default object handler

A DLL provided with the OLE SDK that provides a partial implementation of basic interfaces. It is a surrogate in the processing space of the container application for the real object.

With the default object handler, it is possible to look at an object's stored data without actually activating the object. The default object handler performs other tasks on behalf of a loaded object, such as rendering an object from its cached state when the object is loaded into memory.

Direct access mode

One of two access modes in which a storage object can be opened. In direct mode, all changes are immediately committed to the root storage object. *See also* Transacted access mode.

Drag and drop

OLE specifies a set of data transfer and drag-and drop-interface-specific interfaces that allow applications to implement drag and drop, an operation in which the end-user uses the mouse or other pointing device to drag data from one window and drop it into another location in the same window or into another window.

E

Embedded object

A compound-document object that is stored with the container application, but when it is running, lives in the process space of the server application, which creates and subsequently edits it. The default handler provides a surrogate in the processing space of the container application for the real object.

Explicit caching

One of two ways an object can cache its presentation data. Explicit caching requires the physical creation of the cache nodes needed to save the data formats of the object. *See also* Implicit caching.

F

File moniker

A moniker based on a path in the file system. File monikers can be used to identify objects that are saved in their own files. A file moniker is an object that represents an implementation of the **IMoniker** interface for the file class. *See also* Item moniker and Generic composite moniker.

G

Global memory

See Shared application memory.

Generic composite moniker

The generic composite moniker is a sequenced collection of other types of monikers, starting with a file moniker to provide the document-level path and continuing with one or more item monikers. *See also* Item moniker and File moniker.

H

Handler

See Object handler.

Helper function

A function that encapsulates other functions and interface methods publicly available in the OLE SDK.

HRESULT

An opaque result handle defined to be zero for a successful return from a function and non-zero if error or status information is to be returned. To convert an HRESULT into the more detailed SCODE, applications call **GetScode**(). *See* SCODE.

I

Implicit caching

The "implied" caching of presentation data by an object that is capable of rendering itself using its native data. Cache nodes are not created with implicit caching. *See also* Explicit caching.

In parameter

A parameter that is allocated, set, and freed by the caller of a function.

In/Out parameter
A parameter that is initially allocated by the caller of a function and set, freed, and reallocated if necessary by that which is called.

In-process server
An object server or application implemented as a DLL that runs in the process space of the object's container. *See also* Local server, Remote server.

Instance
An object for which memory is allocated or which is persistent.

Instantiate
The process of creating an activating an obnect based on its definition.

Interface
A group of related functions that provide access to OLE objects. The set of OLE interfaces define a contract that allow objects to interact according to the Component Object Model (COM). While OLE provides many interface implementations, most interfaces can also be implemented by developers designing OLE applications.

Interface identifier (IID)
A unique identification tag associated with each interface. Some functions take IIDs as parameters to allow the callers to specify what type of interface pointer should be returned.

Item moniker
A moniker based on a string that identifies an object in a container. Item monikers can be used to identify objects smaller than a file, including embedded objects in a compound document, or a pseudo-object (like a range of cells in a spreadsheet). *See also* File moniker and Generic composite moniker.

L

Link object
A component object that is instantiated when a linked compound document object is created or loaded. The link object implements the IOleLink interface and is provided by OLE.

Linked object
A compound-document object whose source data physically resides where it was initially created. Only a moniker that represents the source data and the appropriate presentation data is kept with the compound document. Changes made to the link source are automatically reflected in the linked compound-document object in the container(s).

Link source
The data that is the source of a linked compound document object. A link source may be a file or a portion of a file, such as an embedded object or a selected range within a file (also called a pseudo object).

Loaded state
The state of a compound-document object after its data structures have been loaded into

container memory. The data structures are created by the object handler. *See also* Passive state and Running state.

Local server

An server application implemented as an EXE running on the same machine as the client application using it. Because the server application is an EXE, it runs in its own process. *See also* In-Process server and Remote server.

Lock

OLE defines two types of locks that can be held on an object: *strong* and *weak*. A strong lock will keep an object in memory, a weak lock will not.

LRPC (Lightweight remote procedure call)

OLE's RPC-based protocol for interprocess communication. LRPC is "lightweight" in that it handles communication between processes on one machine only.

M

Marshaling

The process of packaging and sending interface parameters across process boundaries.

Moniker

An object that implements the **IMoniker** interface. A moniker acts as a name that uniquely identifies a COM object. You can think of a moniker as a generalization of a pathname; in the same way that a pathname identifies a file in the file system, a moniker identifies a COM object. Monikers support an operation known as "binding," which is the process of locating the object named by the moniker, activating it (loading it in memory) if it isn't already, and returning an interface pointer to it.

Moniker class

An implementation of the IMoniker interface. System-supplied moniker classes include file monikers, item monikers, generic composite monikers, anti-monikers, and pointer monikers.

Moniker client

An application that uses monikers to acquire interface pointers to objects managed by another application.

Moniker provider

An application that hands out monikers that identify the objects it manages, so that they are accessible to other applications.

Multiple Document Interface (MDI) Application

An application that can support multiple documents from one application instance. MDI object applications can simultaneously serve a user and one or more embedding containers. *See also* Single Document Interface (SDI) application.

N

Native data

The data used by an OLE server application when editing an embedded object. *See also* Presentation data.

Nested object

An OLE object that is embedded within another OLE object through the use of a combination container/server application. OLE objects can be arbitrarily nested to any level.

O

Object

Generally, an instance of an entity that embodies both specific data and the functions that manipulate it.

Specifically in object-oriented programming, an object is an entity that has state, behavior and identity. An object's state consists of its attributes and and the attributes' current values. An object's behavior consists of the operations that can be performed on it and the accompanying state changes. An object's identity is what you use to distinguish it from other objects.

In contrast, COM objects' behavior is defined by the interfaces it supports. A COM object's state is not explicitly specified, but is implied by its interfaces. A COM object's identity is defined by the ability to use **IUnknown::QueryInterface** to move between interfaces.

A COM object follows a specific model in which clients (those using an object's services) gain access to the object's data only through a pointer to an interface consisting of a set of methods (related functions). The client can then call these methods to perform desired operations. There is no direct access to an OLE object's data.

Object application

An OLE-aware application that can create compound document objects. Containers can then embed or link to these objects.

Object handler

A piece of class-specific code that is dynamically loaded into the address space of its container. Object handlers process requests for specific classes of objects, so that much of the communication can be in-process. This is more efficient because it reduces the need for remote procedure calls.

Object state

One of three relationships between a compound document object in its container and the application responsible for the object's creation: *passive*, *loaded*, and *running*. Passive objects are stored (on disk or in a database), and the object is not selected or active. In the loaded state, its data structures have been loaded into memory, but is not yet available for operations such as editing. Running objects are both loaded and available for all operations.

Object type name

A unique identification string that is stored as part of the information available for an object in the registration database—for example, Acme Drawing.

OLE Automation

A way to manipulate an application's objects from outside the application. OLE automation is typically used to create applications that expose objects to programming tools and macro languages, create and manipulate one application's objects from another applications, or to create tools for accessing and manipulating objects. For information on OLE Automation, refer to the O*LE Programmer's Reference*, Volume 2.

Out parameter

A function parameter that is allocated and set by whatever a function calls, and must be freed by the caller.

P

Passive state

The state of an OLE object when it is stored (on disk or in a database). The object is not selected or active. *See also* Loaded state and Running state.

Persistent storage

Storage of a file or object in a medium such as a file system or database so that the file can be closed and then re-opened at a later time. Data can be retrieved from the file until the underlying file is deleted.

Pointer moniker

A moniker that wraps an interface pointer to an object in memory. Whereas most monikers identify objects that can be saved to persistent storage, pointer monikers identify objects that cannot. They allow such objects to participate in a moniker binding operation.

Presentation data

The data used by an OLE container applicationto display embedded or linked objects. *See also* Native data.

Primary verb

The action associated with the most common, preferred operation users perform on an object; the primary verb is always defined as verb zero in the system registration database. An object's primary verb is executed by double-clicking on the object.

Proxy

An interface-specific object that packages parameters for that interface in preparation for a remote method call. A proxy runs in the address space of the sender and communicates with a corresponding stub in the receiver's address space. *See also* Stub, Marshaling, and Unmarshaling.

Proxy manager

Manages all the proxies for a single object.

Pseudo object

A selection of data within a document or embedded object that can be the source for a compound-document object.

R

Reference counting

Keeping a count of each interface pointer instance to ensure that an object is not destroyed before all references to it are released.

Relative moniker

A moniker that specifies the location of an object relative to the location of another object. A relative moniker is analogous to a relative pathname (such as "..\backup\report.old").

Remote Server

A server application, implemented as an EXE, running on a different machine from the client application using it. *See also* In-process server, Local server.

Revert

The act of discarding any change(s) made to an object since the last time the changes were committed or the object's storage was opened. *See also* Commit, Transacted access mode.

Root IStorage object

The outermost **IStorage** instance in a document; also called the root storage object. Compound-document objects are always saved as children of a root **IStorage** object.

Running state

The state of an OLE object when the object application is running and it is possible to edit the object, access its interfaces, and receive notification of changes. *See also* Loaded state and Passive state.

Running object table (ROT)

A globally-accessible table on each machine that keeps track of all the OLE objects that can be identified by a moniker and are currently running on the machine. Monikers use the Running Object Table. Registering an object in the running object table increments the object's reference count. Before the object can be destroyed, its moniker must be released from the running object table.

S

SCODE

A DWORD value that is used to pass detailed information to the caller of an interface method or function. *See also* HRESULT.

Server

See Object application.

Shared application memory

Memory that is primarily used between processes to optimize the data copying that occurs in LPRC calls.

Single Document Interface (SDI) Application

An application that can support only one document at a time. Multiple instances of an SDI application must be started to service both an embedded object and a user. *See also* Multiple Document Interface (MDI) application.

Single object application

An application that is capable of creating and manipulating one class of object. *See also* Multiple object application.

Stand-alone object application

An object application implemented as an executable (EXE) program, rather than as a DLL object application.

State

See Loaded state, Passive state, and Running state.

Static object

An object that contains only a presentation, with no native data. A container application can treat a static object as though it were a linked or embedded object, except that it is not possible to edit a static object.

A static object can result, for example, from the breaking of a link on a linked object; you don't want the linked object to be updated anymore.

Storage object

An object that implements the **IStorage** interface. A storage object contains nested storage objects or stream objects, resulting in a directory/file system within a single file. It provides the underlying storage for compound documents. Container applications provide a nested storage object for each of their embedded objects. The embedded object stores its data nested storage and stream objects within the storage object provided by its container. *See also* Root IStorage object and Stream object.

Stream object

An object that implements the **IStream** interface. A stream object is analogous to a file in a directory/file system. *See also* Storage object.

Structured storage model

A specification that defines a hierarchical method of storing objects. OLE provides an implementation of the structured storage model called Compound Files. *See* Compound file.

Stub

When a function's or interface method's parameters are marshaled across a process boundary, the stub is an interface-specific object that unpackages the marshaled parameters and calls the required method. The stub runs in the receiver's address space and communicates with a corresponding proxy in the sender's address space. *See* Proxy, Marshaling, and Unmarshaling.

Stub manager

Manages all of the stubs for a single object.

Synchronous call

A function that does not allow further instructions in the process to be executed until the function returns. Most OLE interface methods, except some of the **IAdviseSink** methods, are synchronous calls. *See also* Asychronous call.

T

Transacted access mode

One of two access modes in which a storage object can be opened. When opened in transacted mode, changes are stored in temporary buffers until the root **IStorage** object commits its changes. *See also* Direct access mode, Commit, Revert.

U

Uniform data transfer

A model for transferring data via the Clipboard, drag and drop, or through automation. Objects conforming to the model implement the **IDataObject** interface. This model replaces DDE (dynamic data exchange). *See* Data transfer object.

Unmarshaling

The processing of unpackaging parameters that have been sent across process boundaries.

V

Virtual Table (VTBL)
An array of pointers that point to interface method implementations.

Visual Editing
A term in end-user documents that refers to the user's ability to interact with a compound-document object in the context of its container. The term most often used by developers is in-place activation. *See also* In-place activation.

Compatibility with OLE 1 and 16:32-Bit Interoperability

Note In moving from OLE 1 to OLE 2, the following changes in terminology were made:

- The OLE 1 term "server application" has been changed to "object application."
- The OLE 1 term "client application" has been changed to "container application."

Compatibility implies that an OLE 1 client application can contain OLE 2 embedded and linked objects and that an OLE 1 server application can create objects to be embedded in and linked to by OLE 2 containers. OLE provides these capabilities by means of a built-in compatibility layer in the core code, which includes a set of functions for conversion.

Interoperability is not the same as OLE 1 to OLE 2 compatibility. Interoperability implies that a 16-bit OLE application can interact with a 32-bit application running on the same system. Interoperability between 16- and 32-bit implementations means that 16-bit and 32-bit implementations can call each other.

Compatibility with OLE 1

The following figure illustrates how OLE 1 and OLE 2 applications communicate. OLE 1 applications make calls to other OLE 1 applications and to OLE 2 applications using DDE.

Compatibility between OLE 2 and OLE 1 applications is achieved through the implementation of two types of special remoting objects, called stubs and proxies. The stub is instantiated on the object, or server, application's side of the process; the proxy is instantiated on the container, or client, application's side. These special stubs and proxies use DDE to communicate rather than LRPC. When an OLE 2 object makes a call to a function in an OLE 1 client application, for example, the stub intercepts the call and responds appropriately. For the most part, this response simulates the response that an OLE 2 object or container would make. However, in a few cases the behavior is different or special **HRESULT** (SCODE) values are returned.

This chapter discusses the issues that affect applications that must be compatible with an earlier or more recent version of OLE and describes the functions that promote this compatibility.

Working with OLE 1 Clients

This section describes some of the idiosyncrasies of working with OLE 1 clients.

A successful call to the **IOleClientSite::GetContainer** method returns a pointer to the container's **IOleContainer** interface. If the container does not support the **IOleContainer** interface, OLE_E_NOT_SUPPORTED is returned. All OLE 1 clients fall in this category, as do OLE 2 containers that do not support linking to their embedded objects.

The **IOleClientSite::ShowObject** method, a request to make the embedded or linked object visible, always returns OLE_E_NOT_SUPPORTED when called on an OLE 1 client**.** The purpose of this method is to help make the user model work smoothly; its failure does not effect OLE functionality.

When an OLE 1 client contains an OLE 2 object and the object is activated or the **OleUpdate** function is called, the aspect of the data returned will always be DVASPECT_CONTENT. This is because OLE 1 clients have no concept of a **FORMATETC** data structure. This situation may occur when an iconic OLE 2 object is pasted from an OLE 2 container into an OLE 1 container. When the object is first pasted, its presentation remains iconic. With the next update, however, the object's content picture is returned.

OLE 1 clients can link to OLE 2 objects only if the link source:

- is represented by a file moniker or a generic composite moniker consisting of a file moniker and one item moniker.
- is not an embedded OLE 2 object.

An OLE 1 client can contain an incompatible link when a linked object is pasted from an OLE 2 container into the OLE 1 client or when an OLE 2 container saves the data to an OLE 1 file, to allow the OLE 1 version of the application access to its data. When the OLE 1 client loads the incompatible link, the link is converted to an embedded object and assigned the class name "Ole2Link." The OLE 1 client cannot connect to the link source. However, if the newly embedded object is then pasted into an OLE 2 container using the Clipboard, or converted to an OLE 2 object using the **OleConvertOLESTREAMToIStorage** function, it will be converted back to its original state as an OLE 2 linked object.

When the link source for an OLE 1 linked object changes its name, the link can remain intact only if the file moniker for the link source has changed. That is, if the link source is a range of cells within an OLE 2 spreadsheet application and the name of the file that contains the cell range changes, OLE will track the link. However, if the name of the cell range changes, the link will break.

Pasting an OLE 2 linked object into an OLE 1 client document and then calling the **OleCopyFromLink** function to convert it to an embedded object will fail if the data transfer object provided by the link source does not support the **IPersistStorage** interface. Creating an embedded object always requires native data, and the **IPersistStorage** interface provides access to native data.

Working with OLE 1 Servers

This section describes some of the known idiosyncrasies of embedding or linking OLE 1 objects.

As with OLE 2 objects, either the **IPersistStorage::InitNew** method or the **IPersistStorage::Load** method must be called to properly initialize a newly instantiated OLE 1 object before any other OLE calls are made. The **InitNew** method should be called to initialize a newly created object; the **Load** method should be called for existing objects. If one of the **OleCreate** helper functions or the **OleLoad** function is being used, these functions make the **IPersistStorage** call, eliminating the need to make the call directly. When an OLE 2 container with an OLE 1 embedded or linked object calls the **IDataObject::GetData** method or the **IDataObject::GetDataHere** method, the container can anticipate support for a smaller set of formats and storage mediums than would be supported for an OLE 2 object. The following table lists the combinations that can be supported.

Tymed Formats	Data Formats
TYMED_MFPICT	CF_METAFILEPICT
TYMED_GDI	CF_BITMAP
TYMED_HGLOBAL	cfNative, CF_DIB, and other OLE 1 server formats

For the aspect value of DVASPECT_ICON, only TYMED_MFPICT with CF_METAFILEPICT is supported. The icon returned from the **IDataObject::GetData** or **IDataObject::GetDataHere** call will always be the first icon (index 0) in the executable object application.

Several methods typically called by containers have unique implementations for OLE 1. The **IPersistStorage::IsDirty** method is defined to return S_OK if the object has changed since its last save to persistent storage; S_FALSE if it has not changed. When an OLE 2 container with an OLE 1 embedded object calls the **IPersistStorage::IsDirty** method, the compatibility code always returns S_OK when the server is running, because there is no way to determine if the object has in fact changed until the File Close or File Update command is selected. S_FALSE is returned when the server is not running.

An OLE 2 implementation of **IOleObject::IsUpToDate** can return either S_OK if the object is up-to-date, S_FALSE if it is not up-to-date, or OLE_E_UNAVAILABLE if the object cannot determine whether it is up-to-date. The OLE 1 implementation always returns either E_NOT_RUNNING, if the object is in the loaded state, or S_FALSE, if the server is running.

The OLE 1 implementation of the **IOleItemContainer::EnumObjects** method always returns OLE_E_NOTSUPPORTED because it is not possible for an OLE 1 server to enumerate its objects.

The **IOleObject::Close** method takes a save option as a parameter that indicates whether the object should be saved before the close occurs. For OLE 2 objects, there are three possible save options: OLECLOSE_SAVEIFDIRTY, OLECLOSE_NOSAVE, and OLECLOSE_PROMPTSAVE. The OLE 1 implementation of the **IOleObject::Close** method treats OLECLOSE_PROMPTSAVE as equivalent to OLECLOSE_SAVEIFDIRTY, because it is not possible to require an OLE 1 server to prompt the user.

OLE 2 containers cannot expect an OLE 1 object to activate in-place; all OLE 1 objects support activation in a separate, open window.

OLE 1 servers do not support linking to their embedded objects. It is up to OLE 2 containers with OLE 1 embedded objects to prevent a possible link from occurring. Containers can call the **CoIsOle1Class** function to determine at Clipboard copy time if a data selection being copied is an OLE 1 object. If the **CoIsOle1Class** function returns TRUE, indicating that the selection is an OLE 1 object, the container should not offer the Link Source format. Link Source must be available for a linked object to be created.

OLE 2 containers can store multiple presentations for an OLE 1 object. However, only the first presentation format is sent to the container when the OLE 1 server closes. After that, the server is in the process of closing down and cannot honor requests for any more formats. Therefore, only the first presentation cache will be updated. The rest will be out of date (perhaps blank) if the object has changed since the last update.

Because OLE 1 servers do not update the cache for every change to an embedded object until the user selects the File Update command, an OLE 2 container may not be obtaining the latest data from the server. By calling the **IOleObject::Update** method, the container can obtain the latest object data.

An OLE 1 embedded (not linked) object does not notify its container that its data has changed until the user chooses File Update or File Close. Therefore, if an OLE 2 container registers for a data-change notification on an OLE 2 object in a particular format, it should be aware that it will not be notified immediately when the data changes.

When an OLE 1 object is inserted into a container document and then closed without an update being invoked, the container document is not saved. Neither are the correct streams for the object written into storage. Any subsequent loading of the object by the container will fail. To protect against this, containers can keep data available after the object closes without updating by implementing the following:

```
OleCreate();                \\ to insert the object
OleRun();                   \\ if OLERENDER_NONE was specified
IOleObject::Update();       \\ to get snapshot of data
OleSave();
IOleObject::DoVerb();
```

Upgrading Applications

When an OLE 1 server is upgraded to an OLE 2 object application, several issues arise. A primary issue is whether the OLE 2 application will replace the OLE 1 application or both versions will coexist. If only the newer version will be available to the user, it is best to convert objects from the older version of the application automatically to the new version format. Objects can be converted on a global basis, where all objects of a specific class are converted, or on a more selective basis, where only some objects are converted. Conversion can be either automatic, under programmatic control, or under the control of a user.

The ability to detect whether an object is from an OLE 1 server is helpful for implementing conversion functionality. The OLE 2 implementation of the **IPersistStorage::Load** method can check for a stream named "\1Ole10Native." The "\1Ole10Native" stream contains a DWORD header whose value is the length of the native data that follows. The existence of this stream indicates that the data is coming from an OLE 1 server. Applications can check whether a storage object contains an object in an OLE 1 format by calling the **ReadFmtUserTypeStg** method and examining the contents of *pcfFormat.* This is where the OLE 1 class name would appear.

In the **IPersistStorage::Save** method, objects that are being permanently converted should be written back to storage in the new format and the "\1Ole10Native" stream should be deleted. The conversion bit in the storage should also be cleared once the conversion to the new format is complete.

To allow manual conversion of an old OLE 1 object to the new OLE 2 version, the OLE 2 object application must put the OLE 1 server's ProgID (OLE 1 server class name) into the registry under the **CLSID\{...}\Conversion\Readable\Main** entry. This entry indicates that the OLE 2 application can read its OLE 1 data format; the 'Clipboard format' of the OLE 1 data is the ProgID (that is, the class name) of the OLE 1 object.

To get a CLSID for an OLE 1 server, the **CLSIDFromProgId** function or the **CLSIDFromString** function must be called. That is, an OLE 1 application cannot be assigned a CLSID from an OLE 2 application with **uuidgen.exe**, **CoCreateGuid**, or by using a GUID from a range assigned by Microsoft. Because all OLE 1 CLSIDs are expected to fall in a specific range, OLE 1 CLSIDs are assigned with the **CLSIDFromProgId** function.

Refer to the appendix called "Registering Object Applications" for detailed information on the required registry entries for upgraded applications.

Functions to Support Compatibility

The following functions enable applications to determine whether an object class is from OLE 1, and to support conversion between OLE 1 and OLE 2 storage formats.

OLE 1 Compatibility Functions	Description
CoIsOle1Class	Determines if a given CLSID represents an OLE 1 object.
OleConvertIStorageToOLESTRAM	Converts the specified storage object from OLE 2 structured storage to the OLE 1 storage model.
OleConvertIStorageToOLESTREAMEx	Converts the specified storage object from OLE 2 structured storage to the OLE 1 storage model.
OleConvertOLESTREAMToIStorage	Converts the specified object from the OLE 1 storage model to an OLE 2 structured storage object.
OleConvertOLESTREAMToIStorageEx	Converts the specified object from the OLE 1 storage model to an OLE 2 structured storage object.

16:32 Bit Interoperability

The 32-bit implementation of OLE 2 is compatible with OLE 1 applications in the manner described above. Interoperability is achieved by converting calls made on objects in one model into calls suitable in another model. For example, if a call is made by a 16-bit application to an object that is a 32-bit implementation, the OLE 16:32 interoperability (thunk) layer takes care of marshalling and converting parameters between the two models.

Thunk Layer Operation

The thunk layer replaces the 16-bit implementations of OLE 2 with a new set of binaries that allow the 16-bit implementations to call the updated 32-bit implementation of OLE 2. These new binaries, collectively known as the thunk layer, forward all OLE 2 method and function calls to the 32-bit implementation of OLE. The OLE thunk layer inserts itself between implementations of different models. Whenever an interface is passed between implementation types, the system provides a thunk proxy and stub.

For example, a call to the **CreateFileMoniker** function returns a pointer to a moniker. When a 16-bit implementation calls the **CreateFileMoniker** function, the system thunks the call to the 32-bit OLE 2 implementation and creates a file moniker using a 32-bit implementation. When the call returns through the OLE thunk layer, the moniker pointer is translated into a 16/32 proxy.

A 16/32 proxy sets up an object in the 16-bit address space that, when called, converts each parameter for the specific method into the appropriate values for calling the 32-bit implementation. It then performs a model switch from 16-bit to 32-bit. The call is made on the 32-bit implementation, and then another model switch is made from the 32-bit to 16-bit implementation. In the process of switching back, any output parameters are converted into their 16-bit counterparts.

The system keeps track of the model of each pointer. For example, if a 16-bit application calls a 32-bit application, it passes a 16-bit pointer to an object. The thunk layer will create a 32/16 proxy to let the 32-bit application call the 16-bit application's object. In response, the 32-bit application calls back to the 16-bit application, passing the pointer it received. In this direction, the pointer being held by the 32-bit application holds is to a 32/16 proxy. The thunk layer also detects that the 32-bit pointer being passed in is a proxy, and passes the original pointer it started with to the 16-bit application. Thus, the 16-bit application sees the same pointer it passed in. This works when passing from 16 to 32 to 16, or from 32 to16 to 32. For more information about thunking, see the *Win32 SDK*.

Interoperability Using Standard Interfaces (OLE 2 Defined)

In its 32-bit implementation, OLE 2 is provided by the operating system and can translate OLE-defined interfaces and methods. Existing OLE 2 applications will continue to work as before. The following combinations of interoperability using the standard interfaces defined by OLE 2 are supported:

- 16 to 16 (in-process server)
- 16 to 16 (local server)
- 16 to 32 (local server)
- 32 to 32 (in-process server)
- 32 to 32 (local server)
- 32 to 16 (local server)

32- to16-bit (in-process server) interoperability using the standard interfaces is not supported.

Interoperability Using Custom Interfaces (either MIDL or Manually Written Marshalling)

Due to major architectural changes in the OLE communication layer, 16-bit applications that require remoting of custom interfaces are not supported at this time. However, 16-bit applications that use custom interfaces to an inprocess server should still function correctly. The following combinations of interoperability using custom interfaces are supported:

- 16 to 16 (inprocess server)
- 32 to 32 (inprocess server)
- 32 to 32 (local server using MIDL-generated stubs)

The following combinations of interoperability using custom interfaces are not supported:

- 16 to 16 (local server)
- 16 to 32 (all combinations)
- 32 to 16 (all combinations)

Programmers who have written applications that provide custom interfaces must rewrite the custom interface marshalling code to conform to the RPC-based communication layer. However, information about writing a 16-bit custom-marshalling library is not available at this time. For more information about RPC, see the *RPC Programmer's Guide and Reference*.

The Component Object Model

The Component Object Model (COM) is the base technology of OLE, a broad set of object-oriented technology standards. OLE includes, besides COM, object design standards at a higher level. Among these are standards for OLE Structured Storage, OLE Compound Documents, and OLE Controls. COM is the binary standard that defines the means for applications to interact within these technology standards.

To understand COM (and therefore all OLE technologies), it is crucial to bear in mind that it is not an object-oriented language, but a standard. Nor does COM specify how an application should be structured. Language, structure, and implementation details are left to the application programmer. COM does specify an object model and programming requirements that enable COM objects (also called OLE Components, or sometimes simply *objects*) to interact with other objects. These objects can be within a single process, in other processes, even on remote machines. They can have been written in other languages, and may be structurally quite dissimilar. That is why COM is referred to as a binary standard – it is a standard that applies after a program has been translated to binary machine code.

The only language requirement for COM is that code is generated in a language that can create structures of pointers and, either explicitly or implicitly, call functions through pointers. Object-oriented languages such as C++ and Smalltalk provide programming mechanisms that simplify the implementation of COM objects, but languages such as C, Pascal, Ada, and even BASIC programming environments can create and use OLE objects.

COM defines the essential nature of an OLE Component. In general, a software object is made up of a set of data and the functions that manipulate the data. An OLE Component is one in which access to an object's data is achieved exclusively through one or more sets of related functions. These function sets are called *interfaces*, and the functions of an interface are called *methods.* Further, COM requires that the only way to gain access to the methods of an interface is through a pointer to the interface.

Besides specifying the basic binary object standard, COM defines certain basic interfaces that provide function common to all COM-based technologies. It also provides a small number of API functions that all components require.

OLE Components and Interfaces

COM is a technology that allows objects to interact across process and machine boundaries as easily as objects within a single process interact. COM enables this by specifying that the only way to manipulate the data associated with an object is through what is called an *interface on the object.* When this term is used, it refers to an implementation in code of a COM binary-compliant interface that is associated with an object.

Talking about an object that *implements an interface* means that the object uses code that implements each method of the interface and provides COM binary-compliant pointers to those functions to the COM library. COM then makes those functions available to any client who asks for a pointer to the interface, whether the client is inside or outside of the process that implements those functions.

Interfaces and Interface Implementations

COM makes a fundamental distinction between interface definitions and their implementations. An *interface* is actually a contract that consists of a group of related function *prototypes* whose usage is defined but whose implementation is not. These function prototypes are equivalent to pure virtual base classes in C++ programming. An interface definition specifies the interface's member functions, called *methods,* their return types, the number and types of their parameters, and what they must do. There is no implementation associated with an interface.

An *interface implementation* is the code a programmer supplies to carry out the actions specified in an interface definition. Implementations of many of the interfaces a programmer could use in an object-based application are included in the OLE libraries. Programmers are, however, free to ignore these implementations and write their own. An interface implementation is to be associated with an object when an instance of that object is created, and provides the services that the object offers.

For example, a hypothetical interface named **IStack** (many interface names begin with the letter "I") might define two *methods,* named **Push** and **Pop**, specifying that successive calls to the **Pop** method return, in reverse order, values previously passed to the **Push** method. This interface definition, however, would not specify how the functions are to be implemented in code. In implementing the interface, however, one programmer might implement the stack as an array and implement the **Push** and **Pop** methods in such a way as to access that array; while another programmer might prefer to use a linked list and would implement the methods accordingly. Regardless of a particular implementation of the **Push** and **Pop** methods, however, the in-memory representation of a pointer to an **IStack** interface, and therefore its use by a client, is completely defined by the interface definition.

Simple objects may support only a single interface. More complicated objects, such as embeddable objects, typically support several interfaces. Clients have access to an OLE object only through a pointer to one of its interfaces, which, in turn, allows the client to call any of the methods that make up that interface. These methods determine how a client can use the object's data.

Interfaces, in fact, define a contract between an object and its clients. The contract specifies the methods that must be associated with each interface, and what the behavior of each of the methods must be in terms of input and output. The contract generally does not define *how* to implement the methods in an interface. Another important aspect of the contract is that if an object supports an interface, it must support all of its methods in some way. Not all of the methods in an implementation need to do something−if an object does not support the function implied by a method, its implementation may be a simple return, or perhaps the return of a meaningful error message−but the methods must *exist.*

COM uses the word "interface" in a sense different from that typically used in C++ programming. A C++ interface refers to *all* of the functions that a class supports and that clients of an object can call to interact with it. A COM interface refers to a predefined group of related functions that a COM class implements, but does not necessarily represent *all* the functions that the class supports.

Interface Pointers and Interfaces

An instance of an interface implementation is actually a pointer to an array of pointers to methods (a function table that refers to an implementation of all of the methods specified in the interface). Objects with multiple interfaces can provide pointers to more than one function table. Any code that has a pointer through which it can access the array can call the methods in that interface.

Speaking precisely about this multiple indirection is inconvenient, so instead, the pointer to the interface function table that another object must have to call its methods is called simply an *interface pointer*. You can manually create function tables in a C application or almost automatically with C++ (or other object-oriented languages that support COM).

With appropriate compiler support (which is inherent in C and C++), a client can call an interface method through its name, not its position in the array. Because an interface is a type, given the names of methods the compiler can check the types of parameters and return values of each interface method call. In contrast, such type-checking is not available even in C or C++ if a client uses a position-based calling scheme.

Each interface–the immutable contract of a functional group of methods–is referred to at runtime with a globally-unique interface identifier, an "IID". This IID, which is a specific instance of a GUID (a Globally Unique IDentifier supported by OLE) allows a client to ask an object precisely if it supports the semantics of the interface without unnecessary overhead and without the confusion that could arise in a system from having multiple versions of the same interface with the same name.

To summarize, it is important to understand what an interface is, and is not:

- An interface is not the same as a C++ class.
- An interface is not an object.
- Interfaces are strongly typed.
- Interfaces are immutable.

An interface is not a C++ class–the pure virtual definition carries no implementation. If you are a C++ programmer, you can, however, define your implementation of an interface as a class, but this falls under the heading of implementation details, which COM does not specify. An instance of an object that implements an interface must be created for the interface actually to exist. Furthermore, different object classes may implement an interface differently yet be used interchangeably in binary form, as long as the behavior conforms to the interface definition.

An interface is not an object – it is simply a related group of functions and is the binary standard through which clients and objects communicate. The object can be implemented in any language with any internal state representation, as long as it can provide pointers to interface methods.

Interfaces are strongly typed – every interface has its own interface identifier (a GUID), which eliminates the possibility of duplication that could occur with any other naming scheme.

Interfaces are immutable contracts – you cannot define a new version of an old interface and give it the same identifier. Adding or removing methods of an interface, or changing semantics creates a new interface, not a new version of an old interface. Therefore a new interface cannot conflict with an old interface. Objects can, of course, support multiple interfaces simultaneously, and can expose interfaces that are successive revisions of an interface, with different identifiers. Thus, each interface is a separate contract, so system-wide objects need not be concerned about whether the version of the interface they are calling is the one they expect. The interface ID (IID) defines the interface contract explicitly and uniquely.

IUnknown and Interface Definition Inheritance

Inheritance in COM does not mean code reuse. Because no implementations are associated with interfaces, interface inheritance does not mean code inheritance. It means only that the contract associated with an interface is inherited in a C++ pure-virtual base-class fashion and modified – either by adding new methods or by further qualifying the allowed usage of methods. There is no selective inheritance in COM: If one interface inherits from another, it includes all the methods that the other interface defines.

Inheritance is used sparingly in the predefined COM interfaces. All predefined interfaces inherit their definitions from the important interface **IUnknown**, which contains three vital methods: **QueryInterface**, **AddRef**, and **Release**. All COM objects must implement the **IUnknown** interface, because it provides the means to move freely between the different interfaces that an object supports with **QueryInterface**, and to manage its lifetime with **AddRef** and **Release**. More on these methods is discussed later in this chapter.

Any single object usually requires only a single implementation of the **IUnknown** methods. This means that by implementing any interface on an object you must completely implement the **IUnknown** functions. You do not generally need to explicitly inherit from nor implement **IUnknown** as its own interface. When a client of the object queries for it, it is usually necessary only to typecast another interface pointer into an **IUnknown**, as this interface makes up the first three entries in the function table already.

In some specific situations, notably in creating an object that supports aggregation, you may need to implement one set of **IUnknown** functions for all interfaces as well as a stand-alone **IUnknown** interface. This is described in the following section. In any case, any object implementor will implement **IUnknown** methods.

While there are a few interfaces that inherit their definitions from a second interface, in addition to **IUnknown**, the majority are simply the **IUnknown** interface methods plus the methods defined in the interface. This makes most interfaces relatively compact and easy to encapsulate.

Reusing Objects

An important goal of any object model is that object authors can reuse and extend objects provided by others as pieces of their own implementations. One way to do this in C++ and other languages is implementation inheritance, which allows an object to inherit ("subclass") some of its functions from another object while overriding other functions.

The problem for system-wide object interaction using traditional implementation inheritance is that the contract (the interface) between objects in an implementation hierarchy is not clearly defined. In fact, it is implicit and ambiguous. When the parent or child object changes its implementation, the behavior of related components may become undefined, or unstably implemented. In any single application, where the implementation can be managed by a single engineering team, who update all of the components at the same time, this is not always a major concern. In an environment where the components of one team are built through black-box reuse of other components built by other teams, this type of instability jeapordizes reuse. Additionally, implementation inheritance usually works only within process boundaries. This makes traditional implementation inheritance impractical for large, evolving systems composed of software components built by many engineering teams.

The key to building reusable components is to be able to treat the object as a black box. This means that the piece of code attempting to reuse another object knows nothing, and needs to know nothing, about the internal structure or implementation of the component being used. In other words, the code attempting to reuse a component depends upon the *behavior* of the object and not the exact *implementation*.

To achieve black-box reusability, COM adopts other established reusability mechanisms: *containment*/*delegation* and *aggregation*. For convenience in describing them, the object being reused is called the *inner object* and the object making use of that inner object is the *outer object*.

It is important to remember in both these mechanisms how the outer object appears to its clients. As far as the clients are concerned, both objects implement any interfaces to which the client can get a pointer. The client treats the outer object as a black box, and thus does not care, nor does it need to care, about the internal structure of the outer object – the client cares only about behavior.

Containment/Delegation

The first, and most common, mechanism is called containment/delegation. This type of reuse is a familiar concept found in most object-oriented languages and systems. The outer object acts as an object client to the inner object. The outer object "contains" the inner object and when the outer object requires the services of the inner object, the outer object explicitly delegates implementation to the inner object's methods. Thus, the outer object uses the inner object's services to implement itself.

It is not necessary for the outer and inner objects to support the same interfaces, although it certainly is reasonable to contain an object that implements an interface that the outer object does not, and implement the methods of the outer object simply as calls to the corresponding methods in the inner object. When the complexity of the outer and inner objects differs greatly, however, the outer object may implement some of the methods of its interfaces by delegating calls to interface methods implemented in the inner object.

It is simple to implement containment for an outer object. The outer object creates the inner objects it needs to use as any other client would. This is nothing new – the process is like a C++ object that itself contains a C++ string object that it uses to perform certain string functions, even if the outer object is not considered a "string" object in its own right. Then, using its pointer to the inner object, a call to a method in the outer object generates a call to an inner object method.

Aggregation

Aggregation is the other, richer, reuse mechanism, in which the outer object exposes interfaces from the inner object as if they were implemented on the outer object itself. This is useful when the outer object would always delegate every call to one of its interfaces to the same interface in the inner object. Aggregation is actually a specialized case of containment/delegation, and is available as a convenience to avoid extra implementation overhead in the outer object in these cases.

Aggregation is almost as simple to implement as containment is, except for the three **IUnknown** functions: **QueryInterface***,* **AddRef***,* and **Release**. The catch is that from the client's perspective, any **IUnknown** function on the outer object must affect the outer object. That is, **AddRef** and **Release** affect the outer object and **QueryInterface** exposes all the interfaces available on the outer object. However, if the outer object simply exposes an inner object's interface as its own, that inner object's **IUnknown** members called through that interface will behave differently than those **IUnknown** members on the outer object's interfaces, an absolute violation of the rules and properties governing **IUnknown**.

The solution is for the outer object to somehow pass the inner object some **IUnknown** pointer to which the inner object can re-route (that is, delegate) **IUnknown** calls in its own interfaces, and yet there must be a method through which the outer object can access the inner object's **IUnknown** functions that affect only the inner object. COM provides specific support for this solution. Briefly, aggregation requires an explicit implementation of **IUnknown** on the inner object and delegation of the **IUnknown** methods of any other interface to the outer object's **IUnknown** methods.

The COM Library

In addition to being a specification, COM also implements some important services in the COM Library. Provided as a DLL in Microsoft® Windows®, the COM Library includes:

- A small number of fundamental API functions that facilitate the creation of COM applications, both client and server. For clients, COM supplies basic functions for creating objects. For servers, COM supplies the means of exposing their objects.
- Implementation-locator services through which COM determines from a unique class identifier (CLSID) which server implements that class and where that server is located. This service includes support for a level of indirection, usually a system registry, between the identity of an object class and the packaging of the implementation such that clients are independent of the packaging, which can change in the future.
- Transparent remote procedure calls when an object is running in a local or remote server.
- A standard mechanism to allow an application to control how memory is allocated within its process, particularly memory that needs to be passed between cooperating objects such that it can be freed properly.

To use the basic services that COM supplies, all COM applications must call the **CoInitialize** function before calling any other COM function. This function initializes the COM library, allowing the application to use its services. OLE Compound Document applications call the **OleInitialize** function, which calls **CoInitialize** and also does some initialization required for compound documents.

It is also important to uninitialize the library. For each call to **CoInitialize** (or **OleInitialize**, there must be a corresponding call to **CoUninitialize** (or **OleUninitialize**).

OLE Class Objects and CLSIDs

A COM class is an implementation of a group of interfaces in code executed whenever you interact with a given object. It is important to make the distinction between a C++ class and a COM class. In C++, a class is a type. A COM class is simply a definition of the object, and carries no type, although a C++ programmer might implement it using a C++ class. COM is designed to allow a class (object definition) to be used by different applications, including applications written without knowledge of that particular class's existence. Therefore, class code for a given type of object exists either in a dynamic linked library (DLL) or in another application (EXE). COM specifies a mechanism by which the class code can be used by many different applications.

A COM class is identified by a unique 128-bit CLSID. This CLSID is used to associate an object class with the DLL or EXE in the file system whose code implements the class. A CLSID, like an interface identifier, is a GUID, so no other class, no matter who writes it, has a duplicate CLSID. Server implementors generally obtain CLSIDs through the **CoCreateGUID** function in COM. This function is guaranteed to produce unique CLSIDs, so server implementors across the world can independently develop and deploy their software without fear of accidental collision with software written by others.

Using unique CLSIDs avoids the possibility of name collisions among classes because CLSIDs are in no way connected to the names used in the underlying implementation. So, for example, two different vendors can write classes called "StackClass," but each would have a unique CLSID and therefore could not be confused.

On its host system, COM maintains a database (it makes use of the system registration database, or "registry" on Windows platforms) of all the CLSIDs for the servers installed on the system. This is a mapping between each CLSID and the location of the DLL or EXE that houses the code for that CLSID. COM consults this database whenever a client wants to create an instance of a COM class and use its services. The client, however, that needs to know only the CLSID, is independent of the specific installation location of the DLL or EXE on the particular machine.

When a COM application passes a CLSID to COM and asks for an object instance in return, it is a COM client. No matter where the server is located (in-process, local, or remote), a COM client always asks COM to create an object instance in exactly the same way.

The basic way to implement a class is through a COM *class object*. This is a simply an intermediate object that supports functions common to creating new instances of a given class. All class objects used to create objects from a CLSID support the **IClassFactory** interface, an interface that includes the important method **CreateInstance**. You implement an **IClassFactory** interface for each class of object that you offer to be instantiated.

When a client wants to create an instance of a class, it calls the COM function **CoGetClassObject**, supplying to it the CLSID of the desired class. This call instantiates the class object for the class and returns a pointer to the class object's **IClassFactory** interface implementation. The client would then call the returned interface's **CreateInstance** method, which creates an instance of the class and returns a pointer to a requested interface on the object.

At that point the client has interface pointers for *two separate objects*, the class object and an object of that class, each with their own reference counts. This is an important distinction.

The simplest way to create one instance is to call the COM function **CoCreateInstance.** It is a convenient helper function for clients that want to create a single instance of a class. The **CoCreateInstance** function internally calls **CoGetClassObject** itself, encapsulates the process just described, and additionally releases the class object for you.

In summary, a COM Client, in addition to its responsibilities as a COM application, must use COM to obtain a class object, ask the class object to create an object, initialize the object, and to call that object's (and the class object's) **Release** function when the client is finished with it.

Registering a COM Server

After you have defined a class in code and given it a CLSID and a class object, it is important to make OLE aware of the object by associating a DLL or EXE server with the CLSID.   By doing so, clients can create instances of it. There are two ways of doing this, depending on whether your class is available only dynamically (while some process or activity is running), or at any time (by running code that has been installed in the system).

In the former case, you can register a dynamic class with the system by using **CoRegisterClassObject**, passing to that function a CLSID and a pointer to an **IClassFactory** interface. Subsequent clients who call **CoCreateInstance** or **CoGetClassObject** with this CLSID will retrieve a reference to this **IClassFactory** pointer.

In the latter case, you can register information in the class database (within the registry) during installation of your component, telling COM what type of object you are defining and how it is to be instantiated. For example, classes implemented in dynamic-link libraries can specify that COM will load their DLL and call a well-known entry-point (**DllGetClassObject**) to retrieve an **IClassFactory** interface. Similarly, classes implemented in executables can specify that COM should execute their process and wait for the process to register their class object's **IClassFactory** through a call to the **CoRegisterClassObject** function.

Details about the information required in the registry can be found in Appendix A.

Getting a Pointer to an Object

Because OLE does not have a strict class model, there are several ways to instantiate or to get a pointer to an interface on an object. There are, in fact, four methods through which a client obtains its first interface pointer to a given object:

- Call a COM Library API function that creates an object of a pre-determined type – that is, the function will only return a pointer to one specific interface for a specific object class.
- Call a COM Library API function that can create an object based on a class identifier (CLSID) and that returns any type of interface pointer requested.
- Call a method of some interface that creates another object (or connects to an existing one) and returns an interface pointer on that separate object.
- Implement an object with an interface through which other objects pass their interface pointer to the client directly.

There are numerous OLE functions that return specific pointers to specific functions, such as **CoGetMalloc**, which returns a pointer to the standard OLE memory allocator.

The COM API functions **CoGetClassObject** and **CoCreateInstance**, described earlier, create a class object and return a pointer to a requested object. A special case of this kind of API is the OLE Compound Document helper API **OleCreate**, which creates an instance of an embeddable object based on a CLSID.

Among the many interface methods that return a pointer to a separate object are several that create and return a pointer to an enumerator object, which allows you to determine how many items of a given type an object maintains. OLE defines interfaces for enumerating a wide variety of items, such as strings, several structures important in various OLE technologies, monikers, and **IUnknown** interface pointers. The typical way to create an enumerator instance and get a pointer to its interface is to call a method from another interface. For example, the **IDataObject** interface defines two methods, **EnumDAdvise** and **EnumFormatEtc**, that return pointers to interfaces on two different enumeration objects. There are many other examples in OLE of methods that return pointers to objects, such as the OLE Compound Document interface **IOleObject::GetClientSite**, which, when called on the embedded or linked object, returns a pointer to the container object's implementation of **IOleClientSite**.

The fourth way to get a pointer to an object is used when two objects, such as an OLE Compound Document container and server need bi-directional communication. Each implements an object containing an interface method to which other objects can pass interface pointers. In the case of containers and servers, each object then passes its pointer to the other object. The implementing object, which is also the client of the created object, can then call the method and get the pointer that was passed.

QueryInterface: Navigating in an Object

Once you have an initial pointer to an interface on an object, OLE has a very simple mechanism to find out whether the object supports another specific interface, and, if so, to get a pointer to it. This mechanism is the **QueryInterface** method of the **IUnknown** interface. If the object supports the requested interface, the method must return a pointer to that interface. This permits an object to navigate freely through the interfaces that an object supports. **QueryInterface** separates the request "Do you support a given contract?" from the high-performance use of that contract once negotiations have been successful.

When a client initially gains access to an object, that client will receive, at a minimum, an **IUnknown** interface pointer (the most fundamental interface) through which it can control the lifetime of the object – tell the object when it is done using the object – and invoke **QueryInterface**. The client is programmed to ask each object it manages to perform some operations, but the **IUnknown** interface has no functions for those operations. Instead, those operations are expressed through other interfaces. The client is thus programmed to negotiate with objects for those interfaces. Specifically, the client will ask an object – by calling **QueryInterface** – for an interface through which the client may invoke the desired operations.

Since the object implements **QueryInterface**, it has the ability to accept or reject the request. If the object accepts the client's request, **QueryInterface** returns a new pointer to the requested interface to the client. Through that interface pointer, the client has access to the methods of that interface. If, on the other hand, the object rejects the client's request, **QueryInterface** returns a null pointer – an error – and the client has no pointer through which to call the desired functions. In this case, the client must deal gracefully with that possibility. For example, suppose a client has a pointer to interface A on an object, and asks for interfaces B and C. While the object supports interface B, it does not support interface C. The object returns a pointer to B, and reports that C is not supported.

A key point is that when an object rejects a call to **QueryInterface**, it is impossible for the client to ask the object to perform the operations expressed through the requested interface. A client *must* have an interface pointer to invoke methods in that interface. There is no alternative. If the object refuses to provide one, a client must be prepared to do without, simply not doing whatever it had intended to do with that object. Had the object supported that interface, the client might have done something useful with it. This works well in comparison with other object-oriented systems in which you cannot know whether a function will work until you call that function, and even then, handling failure is uncertain. **QueryInterface** provides a reliable and consistent way to know whether an object supports an interface before attempting to call its methods.

The **QueryInterface** method also provides a robust and reliable way for an object to indicate that it does *not* support a given contract. That is, if in a call to **QueryInterface** one asks an "old" object whether it supports a "new" interface (one, for example, that was invented after the old object had been shipped), the old object will reliably and , without causing a crash, answer "no." The technology that supports this is the algorithm by which IIDs are allocated. While this may seem like a small point, it is extremely important to the overall architecture of the system, and the ability to inquire of old things about new functionality is, surprisingly, a feature not present in most other object architectures.

Managing Object Lifetimes through Reference Counting

In traditional object systems, the life cycle of objects – the issues surrounding the creation and deletion of objects – is handled implicitly by the language (or the language runtime) –instances go explicitly out of scope as parameters or global variables, for example– or explicitly by application programmers.

In an evolving, decentrally constructed *system* made up of reused components, it is no longer true that any one or client, or even programmer, always "knows" how to deal with a component's lifetime. For a client with the right security privileges, it is still relatively easy to create objects through a simple request. But object deletion is another matter entirely. It is not necessarily clear when an object is no longer needed and should be deleted. Even when the original client is done with the object, it cannot simply shut the object down, because some other client (or clients) in the system may still have a reference to it.

One way to ensure that an object is no longer needed, so it can be deleted, is to depend entirely upon an underlying communication channel to inform the system when all connections to a cross-process or cross-channel object have disappeared. Schemes that use this method are unacceptable for several reasons. One problem is that it could require a major difference between the cross-process/cross-network programming model and the single-process programming model. In the cross-process/cross-network programming model, the communication system would provide the hooks necessary for component lifetime management, while in the single-process programming model, objects are directly connected without any intervening communications channel. Another problem is that this scheme could also result in a layer of system-provided software that would interfere with component performance in the in-process case. Furthermore, such a mechanism based on explicit monitoring would not tend to scale towards many thousands or millions of objects.

COM offers a scalable and distributed approach to this set of problems. Clients tell an object when they are using it and when they are done, and objects delete themselves when they are no longer needed. This approach mandates that all objects count references to themselves.

Just as an application must free memory it has allocated once that memory is no longer in use, a client of an object is responsible for freeing its references to the object when that object is no longer needed. In an object-oriented system, the client can only do this by giving the object an instruction to free itself.

It is important that an object be deallocated when it is no longer being used. The difficulty lies in determining when it is safe to deallocate an object. This is easy with automatic variables (those allocated on the stack) – they cannot be used outside the block in which they're declared, so the compiler deallocates them when the end of the block is reached. For COM objects, which are dynamically allocated, it is up to the clients of an object to decide when they no longer need to use the object – especially local or remote objects that may be in use by multiple clients at the same time. The object must wait until *all* clients are finished with it before freeing itself. Because COM objects are manipulated through interface pointers and can be used by objects in different processes or on other machines, the system cannot keep track of an object's clients.

COM's method of determining when it is safe to deallocate an object is manual reference counting. Each object maintains a 32-bit reference count that tracks how many clients are connected to it, that is, how many pointers exist to any of its interfaces in any client.

Implementing Reference Counting

Reference counting requires work on the part of both the implementor of a class and the clients who use objects of that class. When you implement a class, you must implement the **AddRef** and **Release** methods as part of the **IUnknown** interface. These two functions have simple implementations:

1. **AddRef** increments the object's internal reference count.
2. **Release** first decrements the object's internal reference count; then it checks whether the reference count has fallen to zero. If it has, that means no one is using the object any longer, so the **Release** function deallocates the object.

A common implementation approach for most objects is to have only one implementation of these functions (along with **QueryInterface**), which are shared between all interfaces, and therefore a reference count which applies to the entire object. Architecturally, however, from a client's perspective, reference counting is strictly and clearly a *per-interface-pointer* notion, and objects may be implemented which take advantage of this capability by dynamically constructing, destroying, loading, or unloading portions of their functionality based on the currently extant interface pointers

Whenever a client calls a method (or API function) that returns a new interface pointer, such as **QueryInterface**, the method being called is responsible for incrementing the reference count through the returned pointer. For example, when a client first creates an object, it receives an interface pointer to an object that, from the client's point of view, has a reference count of one. If the client then calls **AddRef** on the interface pointer, the reference count becomes two. The client must call **Release** twice on the interface pointer to drop all of its references to the object.

An illustration of how reference counts are strictly per-interface-pointer occurs when a client calls **QueryInterface** on the first pointer for either a new interface or the same interface. *In either of these cases* the client is required to call **Release** once for each pointer. COM does not require that an object return the same pointer when asked for the same interface multiple times. (The only exception to this is a query to **IUnknown**, which acts as an object's *identity* to COM.) This allows the object implementation to manage resources efficiently.

Rules for Managing Reference Counts

The elegance of using reference counting for object lifetime management is that independent objects can obtain and release access to a single object, and not have to coordinate with each other over lifetime management. In a sense, the object provides this management, so long as the client objects conform to the rules of use. Within a single object that is completely under the control of a single development organization, that organization can adopt whatever strategy it chooses. The following rules are about how to manage and communicate interface instances between objects, and are a reasonable starting point for a policy within an object.

The conceptual model is that interface pointers are thought of as living in pointer variables, which, for this discussion, include variables in memory locations and in internal processor registers, and both programmer- and compiler-generated variables. In short, it includes all internal computation state that holds an interface pointer. Assignment to or initialization of a pointer variable involves creating a *new copy* of an already existing pointer. Where there was one copy of the pointer in some variable (the value used in the assignment/initialization), there are now two. An assignment to a pointer variable *destroys* the pointer copy presently in the variable, as does the destruction of the variable itself (that is, the scope in which the variable is found, such as the stack frame, is destroyed).

Rule 1:

AddRef must be called for every new copy of an interface pointer, and **Release** called for every destruction of an interface pointer except where subsequent rules explicitly permit otherwise.

This is the default case. Unless special knowledge permits otherwise, the worst case must be assumed. The exceptions to Rule 1 all involve knowledge of the relationships of the lifetimes of two or more copies of an interface pointer. In general, they fall into two categories: 1) nested lifetimes and 2) overlapping lifetimes.

In a nested lifetime relationship, the first copy of the interface pointer is created, followed by the creation of the second copy. The second copy is destroyed before the end of the first copy's lifetime. The calls to **AddRef** and **Release** for the second copy can be omitted. The overlapping lifetime relationship begins like the nested lifetime relationship – the second interface pointer is created after the first. In overlapping lifetimes, however, the first pointer copy is destroyed before the second pointer copy. The calls to **AddRef** for the second copy and **Release** for the first copy can be omitted.

Rule 2:

If the piece of code has special knowledge of the relationships of the beginnings and the endings of the lifetimes of two or more copies of an interface pointer, it allows you to omit **AddRef**/**Release** pairs. The following rules call out specific common cases of Rule 2. The first two of these rules are particularly important, as they are especially common.

In-parameters to functions

The copy of an interface pointer which is passed as an actual parameter to a function has a lifetime which is nested in that of the pointer used to initialize the value. The actual parameter, therefore, need not be separately reference counted.

Out-parameters from functions, including return values

This situation falls under Rule 2. To set the out parameter, the function itself, by Rule 1, must have a stable copy of the interface pointer. On exit, the responsibility for releasing the pointer is transferred from the one called to the caller. Thus, the out-parameter need not be separately reference counted.

Local variables

A method implementation clearly has omniscient knowledge of the lifetimes of each of the pointer variables allocated on the stack frame. It can, therefore, use this knowledge to omit redundant **AddRef**/**Release** pairs.

Backpointers

Some data structures are contain two components, A and B, each with a pointer to the other. If the lifetime of one component (A) is known to contain the lifetime of the other (B), then the pointer from the second component back to the first (from B to A) need not be reference counted. Often, avoiding the cycle that would otherwise be created is important in maintaining the appropriate deallocation behavior. However, such non-reference counted pointers should be used *with extreme caution.* In particular, as the remoting infrastructure cannot know about the semantic relationship in use here, such backpointers cannot be remote references. In almost all cases, an alternative design of having the backpointer refer a second "friend" object of the first, rather than the object itself (thus avoiding the circularity), is a superior design.

The following rules call out common situations that follow from Rule 1.

In-Out parameters to functions

The caller must **AddRef** the actual parameter, since it will be released (with a call to **Release**) by the one called when the out-value is stored on top of it.

Fetching a global variable

The local copy of the interface pointer fetched from an existing copy of the pointer in a global variable must be independently reference counted since called functions might destroy the copy in the global while the local copy is still alive.

New pointers synthesized out of "thin air."

A function that synthesizes an interface pointer using special internal knowledge rather than obtaining it from some other source must do an initial **AddRef** on the newly synthesized pointer. Important examples of such routines include instance creation routines, implementations of **IUnknown::QueryInterface**, etc.

Returning a copy of an internally stored pointer

Once the pointer has been returned, the one called has no idea how its lifetime relates to that of the internally stored copy of the pointer. Thus, the one called must call **AddRef** on the pointer copy before returning it.

Finally, when implementing or using reference counted objects, a technique called *artificial reference counts* sometimes proves useful. In implementing a method of an interface, if you invoke functions that have even the remotest chance of decrementing your reference count, this may cause you to release before it returns to the method when it is called. The subsequent code in the method would crash.

A robust way to protect yourself from this is to insert an **AddRef** at the beginning of the method implementation which is paired with a **Release** just before the method returns.

These "artificial" reference counts guarantee object stability while processing is done.

Managing Memory Allocation

In COM, many, if not most, interface methods and APIs are called by code written by one programming organization and implemented by code written by another. Many of the parameters and return values of these functions are of types that can be passed around by value. Sometimes, however, it is necessary to pass data structures for which this is not the case, so it is necessary for both caller and called to have a compatible allocation and de-allocation policy. COM defines a universal convention for memory allocation, both because it is more reasonable than defining case-by-case rules, and so the COM remote procedure call implementation can correctly manage memory.

The methods of COM interface always provide memory management of pointers to the interface by calling the **AddRef** and **Release** functions found in the **IUnknown** interface, from which all other COM interfaces derive. This section describes only how to allocate memory for parameters that are not passed by value – *not* pointers to interfaces, but more mundane things like strings, pointers to structures, etc.

The OLE Memory Allocator

The COM Library provides an implementation of a memory allocator that is thread-safe (cannot cause problems in multi-threaded situations). A call to the API function **CoGetMalloc** provides a pointer to the OLE allocator, which is an implementation of the **IMalloc** interface. Whenever ownership of an allocated chunk of memory is passed through a COM interface or between a client and the COM library, you must use this allocator to allocate the memory. Allocation internal to an object can use any allocation scheme desired, but the COM memory allocator is a handy, efficient, and thread-safe allocator.

Allocation Rules for Non-by-value Parameters

Each parameter and the return value of a function can be classified into one of three groups: an **in** parameter, an **out** parameter (which includes return values), or an **in-out** parameter. In each class of parameter, the responsibility for allocating and freeing non-by-value parameters is the following:

- **in parameter** must be allocated and freed by the caller.
- **out parameter** must be allocated by the one called; freed by the caller.
- **in-out parameter** is initially allocated by the caller, then freed and re-allocated by the one called if necessary. As is true for out parameters, the caller is responsible for freeing the final returned value.

In the latter two cases, one piece of code allocates the memory and a different piece of code frees it. COM, again, requires the use of the COM allocator to ensure that the two pieces of code are using the same allocation methods.

Another area that needs special attention is the treatment of out and in-out parameters in failure conditions. If a function returns a status code which is a failure code, then, in general, the caller has no way to clean up the *out* or *in-out* parameters that are returned. This leads to a few additional rules:

out parameter

In error returns, the out parameters must *always* be reliably set to a value that will be cleaned up without any action by the caller. Further, it is the case that all out pointer parameters *must* explicitly be set to NULL. These are usually passed in a pointer-to-pointer parameter, but can also be passed as a member of a structure that the caller allocates and the called code fills. The most straightforward way to ensure this is (in part) to set these values to NULL on function entry. This rule is strong to promote more robust application interoperability.

in-out parameter

In error returns, all in-out parameters must either be left alone by the one called (and thus remaining at the value to which it was initialized by the caller; if the caller didn't initialize it, then it is an out-parameter, not an in-out-parameter) or be explicitly set as in the out-parameter error return case.

Remember that these memory management conventions for COM applications apply only across public interfaces and APIs – there is no requirement at all that memory allocation strictly internal to a COM application need be done using these mechanisms.

Debugging Memory Allocations

OLE provides an interface for developers to use to debug their memory allocations: the **IMallocSpy** interface. For each method in **IMalloc**, there are two methods in **IMallocSpy**, a "pre" method and a "post" method. Once a developer implements it and publishes it to the system, the system calls the **IMallocSpy** "pre" method just before the corresponding **IMalloc** method, effectively allowing the debug code to "spy" on the allocation operation, and calling the "post" method to release the spy.

For example, when OLE detects that the next call is a call to **IMalloc::Alloc**, it would call **IMallocSpy::PreAlloc**, executing whatever debug operations the developer wants during the **Alloc** execution, and then, when the **Alloc** call returns, call **IMallocSpy::PostAlloc** to release the spy and return control to the code.

Transparent Inter-object Communication

COM is designed to allow clients to communicate *transparently* with objects, regardless of where those objects are running – the same process, the same machine, or a different machine. This provides a *single programming model* for all types of objects, both object clients and object servers.

From a client's point of view, all objects are accessed through interface pointers. A pointer must be in-process. In fact, any call to an interface function always reaches *some* piece of in-process code first. If the object is in-process, the call reaches it directly, with no intervening system-infrastructure code. If the object is out-of-process, the call first reaches what is called a "proxy" object provided either by COM itself or by the object (if the implementor wishes). The proxy packages the interface pointer and generates the appropriate remote procedure call (or other communication mechanism in the case of custom generated proxies) to the other process or the other machine where the object implementation is located. This process of packaging pointers for transmission across process boundaries is called *marshaling*.

From a server's point of view, all calls to an object's interface functions are made through a pointer to that interface. Again, a pointer only has context in a single process, and so the caller must always be some piece of in-process code. If the object is in-process, the caller is the client itself. Otherwise, the caller is a "stub" object provided either by COM or by the object itself. The stub receives the remote procedure call (or other communication mechanism in the case of custom generated proxies) from the "proxy" in the client process, *unmarshals* the parameters, and calls the appropriate interface on the server object. From the points of view of both clients and servers, they always communicate directly with some other in-process code.

OLE provides an implementation of marshaling, referred to as *standard marshaling*. This implementation works very well for most objects, and greatly reduces programming requirements, making the marshaling process effectively transparent.

The clear separation of interface from implementation of OLE's process transparency can get, however, in the way for some situations when performance is of critical concern. The design of an interface that focuses on its function from the client's point of view can sometimes lead to design decisions that conflict with efficient implementation of that interface across a network. In cases like this, what is needed is not pure process transparency, but "process transparency, unless you need to care." COM provides this capability by allowing an object implementor to support *custom marshaling.* Standard marshaling is, in fact, an instance of custom marshaling–it is the default implementation used when an object does not require custom marshaling.

You can implement custom marshaling to allow an object to take different actions when used from across a network than it takes under local access – and it is completely transparent to the client. This architecture makes it possible to design client/object interfaces without regard to network performance issues, then, later, to address network performance issues without disrupting the established design.

COM does not specify how components are structured; it specifies how they interact. COM leaves the concern about the internal structure of a component to programming languages and development environments. Conversely, programming environments have no set standards for working with objects outside of the immediate application. C++, for example, works extremely well to manipulate objects inside an application, but has no support for working with objects outside the application. Generally, all other programming languages are the same in this regard. Therefore COM, through language-independent interfaces, picks up where programming languages leave off to provide the network-wide interoperability.

The double indirection of the *vtbl* structure means that the pointers in the table of function pointers do not need to point directly to the real implementation in the real object. This is the heart of process transparency.

For in-process servers, where the object is loaded directly into the client process, the function pointers in the table point directly to the actual implementation. In this case, a function call from the client to an interface method directly transfers execution control to the method. This cannot, however, work for local, let alone remote, objects because pointers to memory cannot be shared between processes. Nevertheless, the client must be able to call interface methods *as if it were calling the actual implementation*. Thus, the client uniformly transfers control to a method in some object by making the call.

A client always calls interface methods in some in-process object. If the actual object is local or remote, the call is made to a proxy object which then makes a remote procedure call to the actual object.

So what method is actually executed? The answer is that whenever there is a call to an out-of-process interface, each interface method is implemented by a proxy object. The proxy object is always an in-process object that acts on behalf of the object being called. This proxy object knows that the actual object is running in a local or remote server.

The proxy object packages up the function parameters in some data packets and generates an RPC call to the local or remote object. That packet is picked up by a stub object in the server's process on the local or a remote machine, which unpacks the parameters and makes the call to the real implementation of the method. When that function returns, the stub packages up any out-parameters and the return value, sends it back to the proxy, which unpacks them and returns them to the original client.

Thus, client and server always talk to each other as if everything was in-process. All calls from the client and all calls to the server are, at some point, in-process. But because the *vtbl* structure allows some agent, like COM, to intercept all function calls and all returns from functions, that agent can redirect those calls to an RPC call as necessary. Although in-process calls are, naturally, faster than out-of-process calls, the process differences are completely transparent to the client and server.

Concurrency and Synchronization Issues

Concurrency deals with things that can occur at the same time in the system. Whenever there is concurrency, synchronization is an issue. In OLE, there are two primary topics that raise issues in these categories: threading and calls that are not synchronous.

Processes and Threads

COM now permits you to create processes that contain more than one thread of execution, rather than the previous single-thread-per-process model, using a threading model called the *apartment model*. This multithreading model offers a message-based paradigm for dealing with multiple objects running concurrently. It allows you to write more efficient code by allowing a thread that is waiting for some time-consuming operation to allow another thread to be executed.

A thread of execution is the serial execution of code within a process. When there is only a single thread per process, each process is, effectively, a thread. Processes communicate through messages, using RPC to pass information between processes.

It is important to clarify what a COM object really is. Internal to any object server, a COM object is simply a pointer to data whose first piece of data is a pointer to a table of functions. Inside an object server there is really no difference between an **this** interface pointer and an instance of a C++ class derived from a pure-virtual base. Therefore, for a particular object server, there are really no OLE objects distinguishable from any other programming construct, as opposed to a window, which has operating-system-enforced behavior and existence. COM objects really only exist as the result of communication between two components.

A more exact way of stating this is that a COM object only appears as a result of a call to **CoCreateInstance**, being returned from another OLE interface, or as a programming construct being passed as an in-parameter to an interface. Thus, unless an application uses an OLE mechanism to create an instance of the interface, the only threading behavior is the Microsoft® Win32® base threading behavior. This provides a certain threading model with multiple threads of execution within a completely shared memory space, synchronized by various system implementations of semaphore primitives.

The big issue in programming with a multithreaded model is to ensure the code is *thread-safe*, so messages intended for a particular thread go only to that thread, and access to threads is protected somehow. The issues become more complicated when, for example, a single-threaded application loads a DLL server that creates multiple threads, and begins accessing an object of the single-threaded server from multiple threads at the same time. The apartment model addresses these issues.

The term *apartment* is used to indicate a logical grouping of related objects that all execute on the same thread, so must have synchronous execution. In addition, under the apartment model, while there can be multiple objects on a thread, an object cannot reside on more than one thread. This model means that calls to objects in other threads must be made on the thread that owns the object, in the same way that calls to objects in other processes must be made within the context of the owning process.

The inter-process and inter-thread models are similar. When it is necessary to pass an interface pointer to an object in another apartment (on another thread) within the same process, you use the same marshaling model that objects in different processes use to pass pointers across process boundaries. By getting a pointer to the standard marshaling object, you can marshal interface pointers across thread boundaries (between apartments) in the same way you do between processes.

Apartment threading rules are simple, but you must follow them carefully:

- Every object should live on only one thread (within a single apartment).
- You must call **OleInitialize** or **CoInitialize** to initialize each thread.
- All pointers to objects must be marshaled between apartments (ensuring that all calls to an object are made on its thread).
- Each apartment with objects in it must have a message queue to handle calls from other processes and apartments within the same process.
- Apartment-aware in-process objects must be registered as such in the system registry.
- Apartment-aware objects must write DLL entry points carefully.

While multiple objects can live on a single thread, no object can live on more than one thread. In addition, it is necessary to call **OleInitialize** or **CoInitialize** on each thread, because each thread requires the services of the OLE library

To facilitate marshaling interface pointers between apartments, OLE provides two helper functions. **CoMarshalInterThreadInterfaceInStream**, which marshals an interface into a stream object that is returned to the caller, and **CoGetInterfaceAndReleaseStream**, which unmarshals an interface pointer from a stream object and releases it. These functions are simply helpers that use **CoMarshalInterface** and **CoUnmarshalInterface**, which require the use of the flag MSHCTX_INPROC flag.

To set up a message queue for a thread, all that is necessary is that the thread's work function must have a **GetMessage**/**DispatchMessage** loop. If you use other synchronization primitives to communicate between threads, you can use the Win32 function **MsgWaitForMultipleObjects** to wait both for messages and for thread synchronization procedures (the Win32 SDK documentation for this function has an example of this sort of combination loop).

For thread-aware DLL-based or in-process objects, you need to set the threading model in the registry. The default model when you do not specify a threading model is single-thread-per-process. To specify a model, you add the **ThreadingModel** subkey to the **InprocServer32** key in the registration database.

To specify the apartment model, set **ThreadingModel=Apartment**. This permits in-process objects that can be created in multiple threads of a client application to interoperate correctly with older in-process objects that are not aware of multithreading. In-process objects not marked in this way are always created in the first initialized apartment (called the main apartment) in the process and other apartments automatically get proxied pointers to them.

You can also set **ThreadingModel=Both**. This subkey allows you to design a DLL that is thread-safe, but can run in both an apartment model server, and, when free-threading is supported in future releases of COM, a free-threading server.

DLLs that support instantiation of a class object must implement and export the functions **DllGetClassObject** and **DllCanUnloadNow**. When another object wants an instance of the class the DLL supports, a call to **CoGetClassObject** (either directly or through a call to **CoCreateInstance**) calls **DllGetClassObject** to get a pointer to its class object when the object is implemented in a DLL. As its name implies, **DllCanUnloadNow** is called to determine whether the DLL that implements it is in use, so the caller can safely unload it if it is not.

An apartment-aware object that calls **CoCreateInstance** on an apartment-aware object will call **DllGetClassObject** from its thread. **DllGetClassObject** should therefore be able to give away multiple class objects or a single thread-safe object (essentially just using **InterlockedIncrement**/**InterlockedDecrement** on their internal reference count). Calls to **CoFreeUnusedLibraries** from any thread always route through the main apartment's thread to call **DllCanUnloadNow**.

OLE also provides another helper function, **CoCreateFreeThreadedMarshaler**, which provides a pointer to an aggregatable object that implements code. This code allows direct access to an object's VTBL from multiple threads within the same process, but uses standard marshaling if a reference to the object is sent to another process.

Call Synchronization

OLE applications must be able to deal correctly with user input while processing one or more calls from OLE or the operating system. OLE calls between processes fall into three categories:

- Synchronous calls
- Asynchronous notifications
- Input-synchronized calls

Most of the communication that takes place within OLE is synchronous. When making *synchronous calls,* the caller waits for the reply before continuing and can receive incoming messages while waiting. OLE enters a modal loop to wait for the reply, receiving and dispatching other messages in a controlled manner.

When sending *asynchronous notifications,* the caller does not wait for the reply. OLE uses **PostMessage** or high-level events to send asynchronous notifications, depending on the platform. OLE defines five asynchronous methods:

- **IAdviseSink::OnDataChange**
- **IAdviseSink::OnViewChange**
- **IAdviseSink::OnRename**
- **IAdviseSink::OnSave**
- **IAdviseSink::OnClose**

While OLE is processing an asynchronous call, synchronous calls cannot be made. For example, a container application's implementation of **IAdviseSink::OnDataChange** cannot contain a call to **IPersistStorage::Save**.

When making *input-synchronized calls,* the object called must complete the call before yielding control. This ensures that focus management works correctly and that data entered by the user is processed appropriately. These calls are made by OLE through the Windows **SendMessage** function, without entering a modal loop. While processing an input-synchronized call, the object called must not call any function or method (including synchronous methods) that might yield control.

The following methods are input synchronized:

- **IOleWindow::GetWindow**
- **IOleInPlaceActiveObject::OnFrameWindowActivate**
- **IOleInPlaceActiveObject::OnDocWindowActivate**
- **IOleInPlaceActiveObject::ResizeBorder**
- **IOleInPlaceUIWindow::GetBorder**
- **IOleInPlaceUIWindow::RequestBorderSpace**
- **IOleInPlaceUIWindow::SetBorderSpace**
- **IOleInPlaceFrame::SetMenu**
- **IOleInPlaceFrame::SetStatusText**
- **IOleInPlaceObject::SetObjectRects**

To minimize problems that can arise from asynchronous message processing, the majority of OLE method calls are synchronous. With synchronous communication, there is no need for special code to dispatch and handle incoming messages. When an application makes a synchronous method call, OLE enters a modal wait loop that handles the required replies and dispatches incoming messages to applications capable of processing them.

OLE manages method calls by assigning an identifier called a *logical thread ID*. A new one is assigned when a user selects a menu command or when the application initiates a new OLE operation.

Subsequent calls that relate to the initial OLE call are assigned the same logical thread ID as the initial call.

Monikers

A moniker in COM is not only, as the name implies, a way to identify an object. A moniker is also implemented as an object. This object provides services allowing a component to obtain a pointer to the object identified by the moniker. This process is referred to as *binding*.

Monikers are objects that implement the **IMoniker** interface, and are generally implemented in DLLs as component objects. There are two ways of viewing the use of monikers: as a *moniker client*, a component that uses a moniker to get a pointer to another object, and as a *moniker provider*, a component that supplies monikers identifying its objects to moniker clients.

OLE uses monikers, for example, to identify, connect to, and run OLE Compound Document link objects. In this case, the link source acts as the moniker provider, and the container holding the link object acts as the moniker client.

Moniker Clients

Moniker clients must start by getting a moniker. There are several ways for a moniker client to get a moniker. For example, in OLE Compound Documents, when the end-user creates a linked item (either using Insert Object dialog, the clipboard, or drag-and drop), a moniker is embedded as part of the linked item. In that case, the programmer has minimal contact with monikers. Programmatically, if you have an interface pointer to an object that implements the **IMoniker** interface, you can use that to get a moniker, and there are methods on other interfaces that are defined to return monikers.

There are different kinds of monikers, which are used to identify different kinds of objects, but to a moniker client, all monikers look the same. A moniker client simply calls **IMoniker::BindToObject** on a moniker and gets an interface pointer to the object that the moniker identifies. No matter whether the moniker identifies an object as large as an entire spreadsheet or as small as a single cell within a spreadsheet, calling **IMoniker::BindToObject** will return a pointer to that object. If the object is already running, **IMoniker::BindToObject** will find it in memory. If the object is stored passively on disk, **IMoniker::BindToObject** will locate a server for that object, run the server, and have the server bring the object into the running state. All the details of the binding process are hidden from the moniker client. Thus, for a moniker client, using the moniker is very simple.

Moniker Providers

In general, a component should be a moniker provider when it allows access to one of its objects, while still controlling the object's storage. If a component is going to hand out monikers that identify its objects, it must be capable of performing the following tasks:

- On request, create a moniker that identifies an object.
- Enable the moniker to be bound when a client calls **IMoniker::BindToObject** on it.

A moniker provider must create a moniker of an appropriate *moniker class* to identify an object. The moniker class refers to a specific implementation of the **IMoniker** interface that defines the type of moniker created. While you can create a new moniker class through an implementation of the **IMoniker** interface, it is frequently unnecessary because OLE provides five different moniker classes, each with its own CLSID:

- File moniker
- Composite Moniker
- Item Moniker
- Anti-moniker
- Pointer moniker

The file, composite, and item monikers are the most frequently used monikers, as they can be used to make nearly any object in any location. Anti- and pointer monikers are primarily used inside OLE, but have some application in implementing custom monikers.

File Monikers

File monikers are the simplest moniker class. File monikers can be used to identify any object that is stored in its own file. A file moniker acts as a wrapper for the path name the native file system assigns to the file. Calling **IMoniker::BindToObject** for this moniker would cause this object to be activated and then would return an interface pointer to the object. The source of the object named by the moniker must provide an implementation of the **IPersistFile** interface to support binding a file moniker. File monikers can represent either a complete or a relative path.

For example, the file moniker for a spreadsheet object stored as the file C:\WORK\MYSHEET.XLS would contain information equivalent to that path name. The moniker would not necessarily consist of the same string, however. The string is just its *display name*, a representation of the moniker's contents that is meaningful to an end user. The display name, which is available through the **IMoniker::GetDisplayName** method, is used only when displaying a moniker to an end-user. This method gets the display name for any of the moniker classes. Internally, the moniker may store the same information in a format that is more efficient for performing moniker operations, but isn't meaningful to users. Then, when this same object is bound through a call to the **BindToObject** method. the object would be activated, probably by loading the file into the spreadsheet.

OLE offers moniker providers the helper API **CreateFileMoniker** that creates a file moniker object and returns its pointer to the provider.

Composite Monikers

One of the most useful features of monikers is that you can concatenate or *compose* monikers together. A composite moniker is a moniker that is a composition of other monikers, and can determine the relation between the parts. This lets you assemble the complete path to an object given two or more monikers that are the equivalent of partial paths. You can compose monikers of the same class (like two file monikers) or of different classes (like a file moniker and an item moniker). If you were to write your own moniker class, you could also compose your monikers with file or item monikers. The basic advantage of a composite is that it gives you one piece of code to implement every possible moniker that is a combination of simpler monikers.   That reduces tremendously the need for specific custom moniker classes.

Because monikers of different classes can be composed with one another, monikers provide the ability to join multiple namespaces. The file system defines a common namespace for objects stored as files because all applications understand a file-system path name. Similarly, a container object also defines a private namespace for the objects that it contains, because no container understands the names generated by another container. Monikers allow these name spaces to be joined because file monikers and item monikers can be composed. A moniker client can search the namespace for *all objects* using a single mechanism. The client simply calls **IMoniker::BindToObject** on the moniker, and the moniker code handles the rest. A call to **IMoniker::GetDisplayName** on a composite creates a name using the concatenation of all the individual monikers' display names.

Furthermore, because you can write your own moniker class, moniker composition allows you to add customized extensions to the namespace for objects.

Sometimes two monikers of specific classes can be combined in a special way. For example, a file moniker representing an incomplete path and another file moniker representing a relative path can be combined to form a single file moniker representing the complete path. For example, the file monikers **c:\work\art** could be composed with the relative file moniker **..\backup\myfile.doc** to equal **c:\work\backup\myfile.doc**. This is an example of "non-generic" composition.

"Generic" composition, on the other hand, permits the connection of any two monikers, no matter what their classes. For example, you could compose an item moniker onto a file moniker, though not, of course, the other way around.

Because a non-generic composition depends on the class of the monikers involved, its details are defined by a the implementation of a particular moniker class. You can define new types of non-generic compositions if you write a new moniker class. By contrast, generic compositions are defined by OLE. Monikers created as a result of generic composition are called generic composite monikers.

These three classes -- file monikers, item monikers, and generic composite monikers -- all work together, and they are the most commonly used classes of monikers.

Moniker clients should call **IMoniker::ComposeWith** to create a composite on moniker with another. The moniker it is called on internally decides whether it can do a generic or non-generic composition. If the moniker implementation determines that a generic composition is usable, OLE provides the **CreateGenericComposite** API function to facilitate this.

Item Monikers

Another OLE-implemented moniker class is the item moniker, which can be used to identify an object contained in another object. One type of contained object is an OLE object embedded in a compound document. A compound document could identify the embedded objects it contains by assigning each one an arbitrary name, such as "embedobj1," "embedobj2," and so forth. Another type of contained object is a user selection in a document, such as a range of cells in a spreadsheet or a range of characters in a text document. An object that consists of a selection is called a *pseudo-object* because it isn't treated as a distinct object until a user marks the selection. A spreadsheet might identify a cell range using a name such as "1A:7F", while a word processing document might identify a range of characters using the name of a bookmark.

An item moniker is useful primarily when concatenated -- or "composed" -- with another moniker, one that identifies the container. An item moniker is usually created, then composed onto (for example) a file moniker to create the equivalent of a complete path to the object. For example, you can compose the file moniker "C:\work\report.doc" (which identifies the container object) with the item moniker "embedobj1" (which identifies an object within the container) to form the moniker "C:\work\report.doc\embedobj1," which uniquely identifies a particular object within a particular file. You can also concatenate additional item monikers to identify deeply nested objects. For example, if "embedobj1" is the name of a spreadsheet object, then to identify a certain range of cells in that spreadsheet object you could append another item moniker to create a moniker that would be the equivalent of "C:\work\report.doc\embedobj1\1A:7F."

When combined with a file moniker, an item moniker forms a complete path. Item monikers thus extend the notion of path names beyond the file system, defining path names to identify individual objects, not just files.

There is a significant difference between an item moniker and a file moniker. The path contained in a file moniker is meaningful to anyone who understands the file system, while the partial path contained in an item moniker is meaningful only to *a particular container*. Everyone knows what "c:\work\report.doc" refers to, but only one particular container object knows what "1A:7F" refers to. One container cannot interpret an item moniker created by another application; the only container that knows which object is referred to by an item moniker is the container that assigned the item moniker to the object in the first place. For this reason, the source of the object named by the combination of a file and item moniker must not only implement **IPersistFile** to facilitate binding the file moniker, but also **IOleItemContainer** to facilitate resolving the name of the item moniker into the appropriate object, in the context of a file

The advantage of monikers is that someone using a moniker to locate an object doesn't need to understand the name contained within the item moniker, as long as the item moniker is part of a composite. Generally, it would not make sense for an item moniker to exist on its own. Instead, you would compose an item moniker onto a file moniker. You would then call **IMoniker::BindToObject** on the composite, which binds the individual monikers within it, interpreting the names.

To create an item moniker object and return its pointer to the moniker provider, OLE provides the helper API **CreateItemMoniker**. This function creates an item moniker object and returns its pointer to the provider.

Anti-monikers

OLE provides an implementation of a special type of moniker called an *anti-moniker*. You use this moniker in the creation of new moniker classes. You use it as the inverse of the moniker that it is composed onto, effectively canceling that moniker, in much the same way that the ".." operator moves up a directory level in a file system command.

It is necessary to have an anti-moniker available, because once a composite moniker is created, it is not possible to delete parts of the moniker if, for example, an object moves. Instead, you use an anti-moniker to remove one or more entries from a composite moniker.

Anti-monikers are a moniker class explicitly intended for use as an inverse. COM defines an API function named **CreateAntiMoniker**, which returns an anti-moniker. You generally use this function to implement the **IMoniker::Inverse** method.

An anti-moniker is *only* an inverse for those types of monikers that are implemented to treat anti-monikers as an inverse. For example, if you want to remove the last piece of a composite moniker, you should not create an anti-moniker and compose it to the end of the composite. You cannot be sure that the last piece of the composite considers an anti-moniker to be its inverse. Instead, you should call **IMoniker::Enum** on the composite moniker, specifying **FALSE** as the first parameter. This creates an enumerator that returns the component monikers in reverse order. Use the enumerator to retrieve the last piece of the composite, and call **IMoniker::Inverse** on that moniker. The moniker returned by **IMoniker::Inverse** is what you need to remove the last piece of the composite.

Pointer Monikers

A pointer moniker identifies an object that can exist only in the active or running state. This differs from other classes of monikers, which identify objects that can exist either in the passive or active state.

Suppose, for example, an application has an object that has no persistent representation. Normally, if a client of your application needs access to that object, you could simply pass the client a pointer to the object. However, suppose your client is expecting a moniker. The object cannot be identified with a file moniker, since it isn't stored in a file, nor with an item moniker, since it isn't contained in another object.

Instead, your application can create a pointer moniker, which is a moniker that simply contains a pointer internally, and pass that to the client. The client can treat this moniker like any other. However, when the client calls **IMoniker::BindToObject** on the pointer moniker, the moniker code does not check the Running Object Table (ROT) or load anything from storage. Instead, the moniker code simply calls **IUnknown::QueryInterface** on the pointer stored inside the moniker.

Pointer monikers allow objects that exist only in the active or running state to participate in moniker operations and be used by moniker clients. One important difference between pointer monikers and other classes of monikers is that pointer monikers cannot be saved to persistent storage. If you do, calling the **IMoniker::Save** method returns an error. This means that pointer monikers are useful only in specialized situations. You can use the **CreatePointerMoniker** API function if you need to use a pointer moniker.

Error Handling

At the source code level, all error values consist of three parts, separated by underscores. The first part is the prefix that identifies the facility associated with the error, the second part is E for error, and the third part is a string that describes the actual condition. For example, STG_E_MEDIUMFULL is returned when there is no space left on a hard disk. The STG prefix indicates the storage facility, the E indicates that the status code represents an error, and the MEDIUMFULL provides specific information about the error. Many of the values that you might want to return from an interface method or function are defined in winerror.h.

Success, warning, and error values are returned using a 32-bit number known as a result handle, or HRESULT. HRESULTs are really not handles to anything, but merely 32-bit values with several fields encoded in the value. A zero result indicates success and a non-zero result indicates failure.

HRESULTs work differently depending on the platform you are using. On 16-bit platforms, an HRESULT is generated from a 32-bit value known as a status code, or SCODE. On 32-bit platforms, an HRESULT is the same as an SCODE; they are synonymous. In fact, the SCODE is no longer used. 32-bit OLE uses only HRESULTs.

Structure of OLE Error Codes

SCODES on 16-bit platforms are divided into four fields: a severity code, a context field, a facility field, and an error code. The format of an SCODE on a 16-bit platform is shown below; the numbers indicate bit positions:

HRESULTs on 32-bit platforms have the following format:

The severity code in the 16-bit SCODE and the high order bit in the HRESULT indicates whether the return value represents success or failure. If set to zero, SEVERITY_SUCCESS, the value indicates success. If set to 1, SEVERITY_ERROR, it indicates failure.

In the 16-bit version of the SCODE, the context field is reserved; this field does not exist in the 32-bit version. The R, C, N, and r bits are reserved in both.

The facility field in both versions indicates the area of responsibility for the error. There are currently five facilities: FACILITY_NULL, FACILITY_ITF, FACILITY_DISPATCH, FACILITY_RPC, and FACILITY_STORAGE. If new facilities are necessary, Microsoft allocates them because they need to be unique. Most SCODEs and HRESULTs set the facility field to FACILITY_ITF, indicating an interface method error. The following table describes the various facility fields:

Facility	**Description**
FACILITY_NULL	For broadly applicable common status codes such as S_OK. This facility code has a value of zero.
FACILITY_ITF	For most status codes returned from interface methods, value is defined by the interface. That is, two SCODEs or HRESULTs with exactly the same 32-bit value returned from two different interfaces might have different meanings. This facility has a value of 4.
FACILITY_DISPATCH	For late binding **IDispatch** interface errors. This facility has a value of 2.
FACILITY_RPC	For status codes returned from remote procedure calls. This facility has a value of 1.
FACILITY_STORAGE	For status codes returned from **IStorage** or **IStream** method calls relating to structured storage. Status codes whose code (lower 16 bits) value is in the range of DOS error codes (that is, less than 256) have the same meaning as the corresponding DOS error. This facility has a value of 3.
FACILITY_WINDOWS	Used for additional error codes from Microsoft-defined interfaces.
FACILITY_WIN32	Used to provide a means of handling error codes from functions in the Win32 API as an HRESULT. Error codes in 16-bit OLE that duplicated Win32 error codes have also been changed to FACILITY_WIN32.

The code field is a unique number that is assigned to represent the error or warning.

By convention, **HRESULTs** generally have names in the following form:

```
<Facility>_<Severity>_<Reason>
```

where <*Facility*> is either the facility name or some other distinguishing identifier, <*Severity*> is a single letter, S or E, that indicates the severity of the error, and <*Reason*> is an identifier that describes the meaning of the code. For example, the status code STG_E_FILENOTFOUND indicates a storage-related error has occurred; specifically, a requested file does not exist. Status codes from FACILITY_NULL omit the <*Facility*>_ prefix.

Error codes are defined within the context of an interface implementation. Once defined, success codes cannot be changed or new success codes added. However, new failure codes can be written since they generally only provide hints at what might have gone wrong. Microsoft reserves the right to define new failure codes (but not success codes) for the interfaces described in this book in FACILITY_ITF or in new facilities.

Codes in FACILITY_ITF

These **HRESULTSs** with facilities such as FACILITY_NULL and FACILITY_RPC have universal meaning because they are defined at a single source: Microsoft. However, **HRESULTs** in FACILITY_ITF are determined by the interface method (or function) from which they are returned. That is, the same 32-bit value in FACILITY_ITF returned from two different interface methods might have different meanings.

The reason **HRESULTs** in FACILITY_ITF can have different meanings in different interfaces is that **HRESULTs** are kept to an efficient data type size of 32 bits. Unfortunately 32 bits is not large enough for the development of an allocation system for error codes that avoid conflict between codes allocated by different non-communicating programmers at different times in different places (unlike the handling of interface IDs and CLSIDs). As a result, the 32-bit **HRESULT** is structured in a way that Microsoft can define some universally-defined error codes, while allowing other programmers to define new error codes without fear of conflict. The status code convention is as follows:

1. Status codes in facilities *other than* FACILITY_ITF can only be defined by Microsoft.
2. Status codes in facility FACILITY_ITF are defined solely by the developer of the interface or API that returns the status code. To avoid conflicting error codes, whoever defines the interface is responsible for coordinating and publishing the FACILITY_ITF status codes associated with that interface.

All the OLE-defined FACILITY_ITF codes have a code value in the range of 0x0000 - 0x01FF. While it is legal to use any codes in FACILITY_ITF, it is recommended that only code values in the range of 0x0200 – 0xFFFF be used. This recommendation is made as a means of reducing confusion with any OLE-defined errors.

It is also recommended that developers define new functions and interfaces to return error codes as defined by OLE and in facilities other than FACILITY_ITF. In particular, interfaces that have any chance of being remoted using RPC in the future should define the FACILITY_RPC codes as legal. E_UNEXPECTED is a specific error code that most developers will want to make universally legal.

Using Macros for Error Handling

OLE defines a number of macros that make it easier to work with SCODEs on 16-bit platforms and HRESULTs on both platforms. Some of the macros and functions below provide conversion between the two data types and are quite useful in code that runs only on 16-bit platforms, code that runs on both 16-bit and 32-bit platforms, and 16-bit code that is being ported to a 32-bit platform. These same macros are meaningless in 32-bit environments and are available in order to provide compatibility and make porting easier. Newly written code should use the **HRESULT** macros and functions.

Error handling macros are listed below. Refer to *The OLE Programmer's Reference* for a complete description of each.

Macro	Description
GetScode	(Obsolete) Returns an SCODE given an HRESULT.
ResultFromScode	(Obsolete) Returns an HRESULT given an SCODE.
PropagateResult	(Obsolete) Generates an HRESULT to return to a function in cases where an error is being returned from an internally called function.
MAKE_HRESULT	Returns an HRESULT given an SCODE that represents an error.
MAKE_SCODE	Returns an SCODE given an HRESULT.
HRESULT_CODE	Extracts the error code part of the HRESULT.
HRESULT_FACILITY	Extracts the facility from the HRESULT.
HRESULT_SEVERITY	Extracts the severity bit from the SEVERITY.
SCODE_CODE	Extracts the error code part of the SCODE.
SCODE_FACILITY	Extracts the facility from the SCODE.
SCODE_SEVERITY	Extracts the severity field from the SCODE.
SUCCEEDED	Tests the severity of the SCODE or HRESULT - returns TRUE if the severity is zero and FALSE if it is one.
FAILED	Tests the severity of the SCODE or HRESULT - returns TRUE if the severity is one and FALSE if it is zero.
IS_ERROR	Provides a generic test for errors on any status value.
FACILITY_NT_BIT	Defines bits so macros are guaranteed to work.
RESULT_FROM_WIN32	Maps a Win32 error value into an HRESULT. This assumes that Win32 errors fall in the range -32k to 32k.
HRESULT_FORM_NT	Maps an NT status value into an HRESULT.

Note Calling **MAKE_HRESULT** for S_OK verification carries a performance penalty. You should not routinely use **MAKE_HRESULT** for successful results.

Error Handling Strategies

Because interface methods are virtual, it is not possible to know, as a caller, the full set of values that may be returned from any one call. One implementation of a method may return five values; another may return eight. The *OLE Programmer's Reference* lists common values that may be returned for each method; these are the values that you must check for and handle in your code because they have special meanings. Other values may be returned, but since they are not meaningful, you do not need to write special code to handle them. A simple check for zero or not zero is adequate.

HRESULTs

The values of some **HRESULT**s have been changed in 32-bit OLE to eliminate all duplication and overlapping with Win32 error codes. Those that duplicate Win32 error codes have been changed to FACILITY_WIN32 and those that overlap remain in FACILITY_NULL. Following is a list of their 32-bit values:

HRESULT	Value
E_UNEXPECTED	0x8000FFFF
E_NOTIMPL	0x80004001
E_OUTOFMEMORY	0x8007000E
E_INVALIDARG	0x80070057
E_NOINTERFACE	0x80004002
E_POINTER	0x80004003
E_HANDLE	0x80070006
E_ABORT	0x80004004
E_FAIL	0x80004005
E_ACCESSDENIED	0x80070005

Handling Error Information

Keep in mind that it is legal to return a status code only from the implementation of an interface method sanctioned as legally returnable. Failure to observe this rule invites the possibility of conflict between returned error code values and those sanctioned by the application. In particular, pay attention to this potential problem when propagating error codes from internally-Qcalled functions.

Applications that call interfaces should treat any unknown returned error code (as opposed to a success code) as synonymous with E_UNEXPECTED. This practice of handling unknown error codes is required by clients of the OLE-defined interfaces and APIs. Because typical programming practice is to handle a few specific error codes in detail and treat the rest generically, this requirement of handling unexpected or unknown error codes is easily met.

The following code sample shows the recommended way of handling unknown errors:

```
HRESULT hrErr;
hrErr = xxMethod();

switch (GetScode(hrErr))  {
     case NOERROR:
       //success
       break;

     case x1:
       .
       .
       break;

     case x2:
       .
       .
       break;

     case E_UNEXPECTED:
     default:
       //general failure
       break;
}
```

The following error check is often used with those routines that don't return anything special (other than S_OK or some unexpected error):

```
if (xxMethod() == NOERROR)
     //success
else
     //general failure;
```

Compound Documents

OLE compound documents enable users working within a single application to manipulate data written in various formats and derived from multiple sources. For example, a user might insert into a word processing document a graph created in a second application and a sound object created in a third application. Activating the graph causes the second application to load its user interface, or at least that part containing tools necessary to edit the object. Activating the sound object causes the third application to play it. In both cases, a user is able to manipulate data from external sources from within the context of a single document.

OLE compound document technology rests on a foundation consisting of COM, structured storage, and .uniform data transfer. As summarized below, each of these core technologies plays a critical role in OLE compound documents:

COM

A compound document object is essentially a COM object that can be embedded in, or linked to, an existing document. As a COM object, a compound document object exposes the **IUnknown** interface, through which clients can obtain pointers to its other interfaces, including several, such as **IOleObject**, **IOleLink**, **and** **IViewObject2**, that provide special features unique to compound document objects.

Structured Storage

A compound document object must implement the **IPersistStorage** or, optionally, **IPersistStream** interfaces to manage its own storage. A container used to create compound documents must supply the **IStorage** interface, through which objects store and retrieve data. Containers almost always provide instances of IStorage obtained from OLE's Compound Files implementation. Containers must also use an object's IPersistStorage and/or IPersistStream interfaces.

Uniform Data Transfer

Applications that support compound documents must implement **IDataObject** because embedded objects and linked objects begin as data that has been transferred using special OLE clipboard formats, rather than standard Microsoft® Windows® clipboard formats. In other words, formatting data as an embedded or linked object is simply one more option provided by OLE's uniform data transfer model.

OLE's compound document technology benefits both software developers and users alike. Instead of feeling obligated to cram every conceivable feature into a single application, software developers are now free, if they like, to develop smaller, more focused applications that rely on other applications to supply additional features. In cases where a software developer decides to provide an application with capabilities beyond its core features, the developer can implement these additional services as separate DLLs, which are loaded into memory only when their services are required. Users benefit from smaller, faster, more capable software that they can mix and match as needed, manipulating all required components from within a single master document.

Containers and Servers

Compound document applications are of two basic types: container applications and server applications. OLE container applications provide users with the ability to create, edit, save, and retrieve compound documents. OLE server applications provide users with the means to create documents and other data representations that can be contained as either links or embeddings in container applications. An OLE application can be a container application, a server application, or both.

OLE server applications also differ in whether they are implemented as *in-process servers* or *local servers*. An in-process server is a dynamic link library (DLL) that runs in the container application's process space. You can run an in-process server *only* from within the container application.

Note Future releases of OLE will enable linking and embedding across machine boundaries, so that a container application on one computer will be able to use a compound document object provided by a *remote server* running on another computer. From a container application's point of view, any OLE server application that runs in its own process space, whether on the same computer or a remote machine, is an *out-of-process server.*

Linking and Embedding

Users can create two types of compound-document objects: *linked* or *embedded*. The difference between the two types lies in how and where the object's source data is stored. Where the object resides affects, in turn, the object's portability and methods of activation, how data updates are performed, and the size and structure of its container.

Linked Objects

When a link to an object is inserted in a compound document, the source data, or *link source*, continues to reside wherever it was initially created, usually in another document. The compound document contains only a reference, or *link*, to the actual data stored at the link source, along with information about how to present that data to the user. Currently, moving a link source breaks the link unless both source and client maintain their relative positions in the directory tree. Eventually, link tracking by Windows will allow a link source to be moved independently of its client without breaking the link.

Activating a link runs the link source's server application, which the user requires in order to edit or otherwise manipulate the link data. Linking keeps the size of a compound document small. It is also useful when the data source is maintained by someone else and must be shared among many users. If the person maintaining the link source changes the data, the change is automatically updated in all documents containing a link to that data. In addition to creating simple links, users can nest links and combine linked and embedded objects to create complex documents.

Embedded Objects

An embedded object is physically stored in the compound document, along with all the information needed to manage the object. In other words, the embedded object is actually a part of the compound document in which it resides. This arrangement has a couple of disadvantages. First, a compound document containing embedded objects will be larger than one containing the same objects as links. Second, changes made to the source of an embedded object will not be automatically replicated in the embedded copy, and changes in the source will not be reflected in the source, as they are with a link.

Still, for certain purposes, embedding offers several advantages over links. First, users can transfer compound documents with embedded objects to other computers, or other locations on the same computer, without breaking a link. Second, users can edit embedded objects without changing the content of the original. Sometimes, this separation is precisely what is required. Third, embedded objects can be activated in place, meaning that the user can edit or otherwise manipulate the object without having to work in a separate window from that of the object's container. Instead, when the object is activated, the container application's user interface changes to expose those tools that are necessary to manage or modify the object.

Object Handlers

If an OLE server application is a local server, meaning that it runs in its own process space, communication between container and server must occur across process boundaries. Since this process is expensive, OLE relies on a surrogate object loaded into the container's process space to act on behalf of a local server application. This surrogate object, known as an *object handler* services container requests that do not require the attention of the server application, such as requests for drawing. When a container requests something that the object handler cannot provide, the handler communicates with the server application using COM's out-of-process communication mechanism.

An object handler is unique to an object class. When you create an instance of a handler for one class, you cannot use it for another. When used for a compound document, the object handler implements the container-side data structures when objects of a particular class are accessed remotely.

OLE provides a default object handler that local server applications can use. For applications that require special behaviors, developers can implement a custom handler that either replaces the default handler or uses it to provide certain default behaviors.

An object handler is a DLL containing several interacting components. These components include remoting pieces to manage communication between the handler and its server application, a cache for storing an object's data, along with information on how that data should be formatted and displayed, and a controlling object that coordinates the activities of the DLL's other components. In addition, if an object is a link, the DLL also includes a linking component, or *linked object,* which keeps track of the name and location of the link source.

The *cache* contains data and presentation information sufficient for the handler to display a loaded, but not running, object in its container. OLE provides an implementation of the cache used by OLE's default object handler and the link object. The cache stores data in formats needed by the object handler to satisfy container draw requests. When an object's data changes, the object sends a notification to the cache so that an update can occur. For more information on the cache, see "View Caching" later in this chapter.

The Default Handler and Custom Handlers

The default handler, an implementation provided by OLE, is used by most applications as the handler. An application implements a custom handler when the default handler's capabilities are insufficient. A custom handler can either completely replace the default handler or use parts of the functionality it provides where appropriate. In the latter case, the application handler is implemented as an aggregate object composed of a new control object and the default handler. Combination application/default handlers are also known as *in-process handlers*. The *remoting handler* is used for objects that are not assigned a CLSID in the system registry or that have no specified handler. All that is required from a handler for these types of objects is that they pass information across the process boundary.

In-Process Servers

If you implement an OLE server application as an in-process server – a DLL running in the process space of the container application – rather than as a local server – an EXE running in its own process space – communication between container and server is simplified because communication between the two can take the form of normal function calls. Remote procedure calls are not required because the two applications run in the same process space. As you would expect, the objects that manage the marshaling of parameters are also unnecessary , although they may be aggregated within the DLL without interfering with the communication between container and server.

When an OLE server application is implemented as an in-process server, a separate object handler is not required because the server itself lives in the client's process space. The main difference between an in-process server and object handler is that the server is able to manage the object in a running state while the handler cannot. One consequence of this difference is that a server must provide a user interface for manipulating the running object, while a handler delegates this requirement to the object's server. In creating an in-process server, you can aggregate on the OLE default handler, letting it handle basic chores, such as display, storage, and notifications while you implement only those services that the handler either does not provide or does not implement in the way you require

Advantages

The advantages of implementing your application as an in-process server are speed and combining some the advantages of an object handler and a local server. In-process servers are faster than local servers for several reasons. First, because they are smaller and run in the process space of the container application, they load more quickly. Second, they are optimized to perform certain tasks. Third, communication between container and server does not rely on remote procedure calls.

Disadvantages

In-process servers provide the speed and size advantage of an object handler with the editing capability of a local server. So why would you ever choose to implement your OLE application as a local server rather than an in-process server? There are several reasons:

- Security. Only a local server has its address space isolated from that of the client. An in-process server shares the address space and process context of the client and can therefore be less robust in the face of faults or malicious programming.
- Granularity. A local server can host multiple instances of its object across many different clients, sharing server state between objects in multiple clients in ways that would be difficult or impossible if implemented as an in-process server, which is simply a DLL loaded into each client.
- Compatibility. If you choose to implement an in-process server, you relinquish compatibility with OLE 1, which does not support such servers. This will not be a consideration for many developers, but if it is, then it is of critical concern.
- Inability to support links. An in-process server cannot serve as a link source. Since a DLL cannot run by itself, it cannot create a file object to be linked to.

Despite these disadvantages, an in-process server can be an excellent choice for its speed and size – if it fits all your other requirements.

Linked Objects

Linked objects, like embedded objects, rely on an object handler to communicate with server applications.The linked object itself, however, manages the naming and tracking of link sources.The linked object acts like an in-process server. For example, when activated, a linked object locates and launches the OLE server application that is the link source.

A linked object's handler is made up of two main components: the handler component and the linking component. The handler component contains the controlling and remoting pieces and functions much like a handler for an embedded object. The linking component has its own controller and cache and provides access to the object's structured storage. The linking component's controller supports source naming through the use of monikers, and binding, the process of locating and running the link source. (For more information on monikers and binding, see "The Component Object Model.")

When a user initially creates a linked object or loads an existing one from storage, the container loads an instance of the linking component into memory, along with the object handler. The linking component supplies interfaces – most notably **IOleLink** – that identify the object as a link and enable it to manage the naming, tracking, and updating of its link source.

By implementing the **IOleLink** interface, a linked object provides its container with functions that support linking. Only linked objects implement **IOleLink**, and by querying for this interface a container can determine whether a given object is embedded or linked. The most important function provided by **IOleLink** enables a container to binding to the source of the linked object, that is, to activate the connection to the document that stores the linked object's native data. **IOleLink** also defines functions for managing information about the linked object, such as cached presentation data and the location of the link source.

When a compound document containing a linked object is saved, the link's data is saved with the link source, not with the container. Only information about its name and location is saved along with the compound document. This behavior is in contrast to that of an embedded object, whose data is stored along with that of its container.

Container applications can provide information about their embedded objects such that the latter, or portions thereof, can act as link sources. By implementing support for linking to your container's embedded objects, you make nested embeddings possible, relieving the user of having to track down the originals of every embedding object to which a link is desired. For example, if a user wants to embed a Microsoft® Excel worksheet in Microsoft® Word, and the worksheet contains a bitmap created in Paintbrush™, the user can link to a copy of the bitmap contained in the worksheet rather than the original.

Notifications

Notifications are callbacks generated by an object when it detects a change in its name, state, data, or presentation. Containers and other clients require notifications to respond appropriately to these changes. A container registers to receive notifications by setting up an advisory connection to an object of interest. Other interested clients can do the same. The container also creates an advisory sink to receive the notifications. Using the connection established by the container, an object experiencing a change notifies the advisory sink. Upon receiving a notification, the container takes whatever action has been defined for the type of change that has occurred.

Types of Notifications

Notifications fall into three groups: compound document, data, and view. An object sends compound document notifications in response to being renamed, saved, closed or, in the case of a link, having its link source renamed. As you would expect, objects send data notifications in response to changes in their data and send view notifications in response to changes in their presentation. Container applications must register separately for each of these notification types, but all can be handled by a single advisory sink.

All containers, the object handler, and the linked object register for compound document notifications. The typical container also registers for view notifications. Data notifications are usually sent to both the linked object and object handler. A special purpose container, such as one that renders the data itself, might benefit from receiving data notifications instead of view notifications. For example, an embedded chart container with a link to a table can register for data notifications. Because a change to the table affects the chart, the receipt of a data notification would direct the container to get the new tabular data.

How Notifications Work

Notifications originate in the object application and flow to the container by way of the object handler. If the object is a linked object, the linked object intercepts the notifications from the object handler and notifies the container directly.

An object application must manage registration requests, keeping track of where to send which notifications and sending those notifications when appropriate. OLE provides two component objects to simplify this task: the OleAdviseHolder for compound document notifications and the DataAdviseHolder for data notifications.

Object applications determine the conditions that prompt the sending of each specific notification and the frequency with which each notification should be sent. When it is appropriate for multiple notifications to be sent, it does not matter which notification is sent first; they can be sent in any order.

The timing of notifications affects the performance and coordination between an object application and its containers. Whereas notifications sent too frequently slow processing, notifications sent too infrequently result in an out-of-sync container. Notification frequency can be compared with the rate at which an application repaints. Therefore, using similar logic for the timing of notifications (as is used for repainting) is wise.

Compound Document Interfaces

The following tables list the interfaces implemented by OLE containers, OLE servers, and compound document objects. The required interfaces *must* be implemented on the components for which they are listed. For example, containers must implement the **IOleClientSite** and **IAdviseSink** interfaces. All other features are optional. If you want to include a particular feature in your application, however, you must implement the interfaces shown for that feature in the table below. All other interfaces are required only if you are including a particular feature. For example, if you want your application to do message filtering (recommended), you must implement **IMessageFilter**.

The following table lists required and optional behaviors for OLE containers and which interfaces you must implement for each.

OLE Containers

Behavior	Interfaces
Required Behaviors	IOleClientSite
	IAdviseSink
Message Filtering	IMessageFilter
Linking	none
Linking to Embedded Objects	IOleItemContainer
	IPersistFile
	IClassFactory
In-Place Activation	IOleInPlaceSite
	IOleInPlaceActive-Frame
	IOleInPlaceUIObject
Drag and Drop	IDropSource
	IDropTarget
	IDataObject

The following table lists required and optional behaviors for OLE servers and their compound document objects and which interfaces you must implement for each. The table distinguishes OLE servers and their objects in order to clarify which component implements which interfaces. The table also notes the different requirements of objects provided by out-of-process versus in-process servers.

Feature	OLE Server	Compound Document Object	
		Out-of-Process	**In-Process**
Required Behaviors	IClassFactory	IOleObject	IOleObject
		IDataObject	IDataObject
		IPersistStorage	IPersistStorage
			IViewObject2
			IOleCache2
Message Filtering	IMessageFilter		
Linking	IOleItemContainer		IOleLink
	IPersistFile		IExternalConnection
In-Place-		IOleInPlaceObjec	IOleInPlaceObjec

Activation		t IOleInPlaceActiveObject	t IOleInPlaceActiveObject
Drag and Drop	IDropSource IDropTarget IDataObject		

Object States

A compound object exists in one of three states: passive, loaded, or running. A compound-document object's state describes the relationship between the object in its container and the application responsible for its creation. The following table summarizes these states:

Object State	Description
Passive	The compound-document object exists only in storage, either on disk or in a database. In this state, the object is unavailable for viewing or editing.
Loaded	The object's data structures created by the object handler are in the container's memory. The container has established communication with the object handler and there is cached presentation data available for rendering the object. Calls are processed by the object handler. This state, because of its low overhead, is used when a user is simply viewing or printing an object.
Running	The objects that control remoting have been created and the OLE server application is running. The object's interfaces are accessible, and the container can receive notification of changes. In this state, an end user can edit or otherwise manipulate the object.

Entering the Loaded State

When an object enters the loaded state, the in-memory structures representing the object are created so that operations can be invoked on it. The object's handler or in-process server is loaded. This process, referred to as *instantiation,* occurs when an object is loaded from persistent storage (a transition from the passive to the loaded state) or when an object is being created for the first time.

Internally, instantiation is a two-phase process. An object of the appropriate class is created, after which a method on that object is called to perform initialization and give access to the object's data. The initialization method is defined in one of the object's supported interfaces. The particular initialization method called depends on the context in which the object is being instantiated and the location of the initialization data.

Entering the Running State

When an embedded object makes the transition to the running state, the object handler must locate and run the server application in order to utilize the services that only the server provides. Embedded objects are placed in the running state either explicitly through a request by the container, such as a need to draw a format not currently cached, or implicitly by OLE in response to invoking some operation, such as when a user of the container double-clicks the object.

When a linked object makes the transition into the running state, the process is known as *binding*. In the process of binding, the object handler asks its stored moniker to locate the link's data, then runs the server application.

At first glance, binding a linked object appears to be no more complicated than running an embedded object. However, the following points complicate the process:

- A link can refer to an object, or a portion thereof, that is embedded in another container. This capability implies a potential for nested embeddings. Resolving references to such a hierarchy requires recursively traversing a *composite moniker*, beginning with the rightmost member.
- When the link source is running, OLE binds to the running instance of the object rather than running another instance. In the case of nested embedded objects, one of which is the link source, OLE must be able to bind to an already running object at any point.
- Running an object requires accessing the storage area for the object. When an embedded object is run, OLE receives a pointer to the storage during the load process, which it passes on to the OLE server application. For linked objects, however, there is no standard interface for accessing storage. The OLE server application may use the file system interface or some other mechanism.

Entering the Passive State

Object closure forces an embedded or linked object into the passive state. It is typically initiated from the OLE server application's user interface, such as when the user selects the File Close command. In this case, the OLE server application notifies the container, which releases its reference count on the object. When all references to the object have been released, the object can be freed. When all objects have been freed, the OLE server application can safely terminate.

A container application can also initiate object closure. To close an object, the container releases its reference count after completing an optional save operation. You can design containers to release objects when they are deactivating after an in-place activation session, allowing the user to click outside the object without losing the active editing session.

Implementing In-Place Activation

In-place activation enables a user to interact with an embedded object without leaving the container document. When a user activates the object, a *composite menu bar* comprising elements from both the container application's and server application's menu bars replaces the container's main menu bar. Commands and features from both applications are thus available to the user, including context sensitive help for the active object. When a user begins working with some non-object portion of the document, the object is deactivated, causing the container document's original menu to replace the composite menu.

This capability originally went by the name of *in-place editing.* The name was changed because editing is only one way for a user to interact with a running object. Sound clips, for example, can be listened to instead of editing. Video clips can be viewed instead of editing. In-place activation is particularly apt in the case of video clips because it allows them to run in place, without calling up a separate window. This could be critical if the video were to be viewed, say, in conjunction with adjacent text data in the container document.

Implementing in-place activation is strictly optional for both container and server applications. OLE still supports the model in which activating an object causes the server application to open a separate window. Linked objects always open in a separate window to emphasize that they reside in a separate document.

In-place activation begins with the object in response to an **IOleObject::DoVerb** call from its container. This call usually happens in response to a user double-clicking the object or selecting a command (verb) from the container application's Edit menu.

The in-place window receives keyboard and mouse input while the embedded object is active. When a user selects commands from the composite menu bar, the command and associated menu messages are sent to the container or object application, depending on which owns the particular drop-down menu selected. Input by means of an object's rulers, toolbars, or frame adornments go directly to the embedded object, which owns these windows.

An in-place-activated embedded object remains active until either the container deactivates it in response to user input or the object voluntarily gives up the active state, as a video clip might do, for example. A user can deactivate an object by clicking inside the container document but outside the object's in-place-activation window, or simply by clicking another object. An in-place-activated object remains active, however, if the user clicks the container's title bar, scroll bar or, in particular, menu bar.

You can implement an in-place-activation-object server either as an in-process server (DLL) or a local server (EXE). In both cases, the composite menu bar contains items (typically drop-down menus) from both the server and container processes. In the case of a in-process server, the in-place activation window is simply another child window in the container's window hierarchy, receiving its input through the container application's message pump.

In the case of a local server, the in-place activation window belongs to the embedded object's server application process, but its parent window belongs to the container. Input for the in-place-activation window appears in the server's message queue and is dispatched by the server's message loop. The OLE libraries are responsible for seeing to it that menu commands and messages are dispatched correctly.

Creating Linked and Embedded Objects from Existing Data

A user typically assembles a compound document by using either the clipboard or drag and drop to copy a data object from its server application to the user's container application. With applications that support OLE, the user can initiate the transfer from either the server or the container. For example, the server can copy data to the clipboard in the server application, then switch to the container application and choose Paste Special/Embedded Object or an equivalent menu command to create a new embedded object from the selected data. Or, the user can drag the data from one application to the other. The process is similar for creating a linked object.

Note An application that functions as both OLE server and container can use a selection of its own data to create an embedded or linked object at a new location within the same document.

Data transfer between OLE server and container applications is built on uniform data transfer, as described in Chapter 4, "Data Transfer." OLE servers and object handlers implement **IDataObject** in order to make their data available for transfers using either the clipboard or drag and drop. OLE objects support all the usual clipboard formats. In addition, they support six clipboard formats that support the creation of linked and embedded objects from a selected data object.

OLE clipboard formats describe data objects that, upon being dropped or pasted in OLE containers, are to become embedded or linked compound-document objects. The data object presents these formats to container applications in order of their fidelity as descriptions of the data. In other words, the object presents first the format that best represents it, followed by the next best format, and so on. This intentional ordering encourages a container application to use the best possible format.

View Caching

A container application must be able to obtain a presentation of an object for the purpose of displaying or printing it for users when the document is open but the object's server application is not running or is not installed on the user's machine. To assume, however, that the servers for all the objects that might conceivably be found in a document are installed on every user's machine and can always run on demand is unrealistic. The default object handler, which *is* available at all times, solves this dilemma by caching object presentations in the document's storage and manipulating these presentations on any platform regardless of the availablility of the object server on any particular installation of the container.

Containers can maintain drawing presentations for one or more specific target devices in addition to the one required to maintain the object on screen. Moreover, if you port the object from one platform to another, OLE automatically converts the object's data formats to ones supported on the new platform. For example, if you move an object from Windows to the Macintosh, OLE will convert its metafile presentations to PICT formats.

In order to present an accurate representation of an embedded object to the user, the object's container application initiates a dialog with the object handler, requesting data and drawing instructions. To be able to fulfill the container's requests, the handler must implement the **IDataObject**, **IViewObject2**, and **IOleCache** interfaces.

IDataObject enables an OLE container application to get data from and send data to its embedded or linked objects. When data changes in an object, this interface provides a way for the object to make its new data available to its container and provides the container with a way to update the data in its copy of the object. (For a discussion of data transfer in general, see Chapter 4, "Data Transfer.")

The **IViewObject2** interface is very much like the **IDataObject** interface except that it asks an object to draw itself on a device context, such as a screen, printer, or metafile, rather than move or copy its data to memory or some other transfer medium. The purpose of the interface is to enable an OLE container to obtain alternative pictorial representations of its embedded objects, whose data it already has, thereby avoiding the overhead of having to transfer entirely new instances of the same data objects simply to obtain new drawing instructions. Instead, the **IViewObject2** interface enables the container to ask an object to provide a pictorial representation of itself by drawing on a device context specified by the container.

When calling the **IViewObject2** interface, a container application can also specify that the object draw itself on a target device different than the one on which it will actually be rendered. This enables the container, as needed, to generate different renderings from a single object. For example, the caller could ask the object to compose itself for a printer even though the resulting drawing will be rendered on screen. The result, of course, would be a print-preview of the object.

The **IViewObject2** interface also provides methods that enable containers to register for view-change notifications. As with data and OLE advisories, a view advisory connection enables a container to update its renderings of an object at its own convenience rather than in response to a call from the object. For example, if a new version of an object's server application were to offer additional views of the same data, the object's default handler would call each container's implementation of **IAdviseSink::OnViewChange** to let them know that the new presentations were available. The container would retrieve this information from the advise sink only when needed.

Because Windows device contexts have meaning only within a single process, you cannot pass **IViewObject2** pointers across process boundaries. As a result, OLE local and remote servers have no need whatsoever to implement the interface, which wouldn't work properly even if they did. Only object handlers and in-process servers implement the **IViewObject2** interface. OLE provides a default implementation, which you can use in your own OLE in-process servers and object handlers simply by aggregating the OLE default handler. Or you can write your own implementation of **IViewObject**.

An object implements the **IOleCache** interface in order to let the handler know what capabilities it should cache. The object handler also owns the cache and ensures it is kept up to date. As the embedded object enters the running state, the handler sets up appropriate advisory connections on the server object, with itself acting as the sink. The **IDataObject** and **IViewObject2** interface implementations operate out of data cached on the client side. The handler's implementation of **IViewObject2** is responsible for determining what data formats to cache in order to satisfy client draw requests. The handler's implementation of **IDataObject** is responsible for getting data in various formats, etc., between memory and the underlying **IStorage** instance of the embedded object. Custom handlers can use these implementations by aggregating on the default handler.

Note The **IViewObject2** interface is a simple functional extension of **IViewObject** and should be implemented instead of the latter interface, which is now obsolete. In addition to providing the **IViewObject** methods, the **IViewObject2** interface provides a single additional member, **GetExtent**, which enables a container application to get the size of an object's presentation from the cache without first having to move the object into the running state with a call to **IOleObject::GetExtent**.

OLE Custom Interfaces

As an OLE developer, you implement and use objects that are based on the Component Object Model (COM). COM interfaces specify a contract between the interface implementor and its user. The contract applies to every COM object that supports that interface.

OLE provides a standard set of interfaces, but these OLE-provided interfaces may not be perfectly suited to your needs. Through custom interfaces, you can create new ones tailored to fulfill the specific needs of your application. Custom interfaces are extensions to the COM standard; they let you extend the standard behavior and still take advantage of the services provided by the base interface. Like all COM interfaces, custom interfaces derive from the **IUnknown** interface and must contain the three methods of **IUnknown**. Otherwise, they can support a wide range of methods and parameters. (Note that, currently, custom interfaces cannot include asynchronous methods. Asynchronous methods may be supported in future versions of OLE.)

Once the interface is written, anyone can use it. Calls to methods in COM interfaces can cross process boundaries as long as both processes are running on the same machine.

This appendix introduces custom interfaces and explains how to implement them. OLE experience is a prerequisite, as is a basic knowledge of RPC. For more information about OLE and COM technology, see the *OLE Reference Guide* and the other parts of this *OLE Programmer's Guide*. Refer to the *RPC Programmer's Guide and Reference* for information about the RPC programming environment.

How Do Client/Server Objects Work?

A client application, such as a compound document container, makes a call to methods in a COM interface. An object application (sometimes called the server) implements an object that provides the interface and methods that are called by the client. A reference to the object application is stored in the registry. OLE locates the object application through this reference and runs it.

The object application is a piece of code that implements one or more COM interfaces. It can be an in-process server in a DLL or a local executable that runs in another process. Making a call to an interface method in an object in another process involves the cooperation of several components. The standard proxy is a piece of interface-specific code that resides in the client's process space and prepares the interface parameters for transmittal. It packages, or marshals, them in such a way that they can be re-created and understood in the receiving process. The standard stub, also a piece of interface-specific code, resides in the server's process space and reverses the work of the proxy. The stub unpackages, or unmarshals, the sent parameters and forwards them to the object application. It also packages reply information to send back to the client.

Note Readers more familiar with RPC than OLE may be used to seeing the terms client stub and server stub. These terms are analogous to proxy and stub.

The following diagram shows the flow of communication between the components involved. On the client side of the process boundary, the client's method call goes through the proxy and then onto the channel. Note that the channel is part of the COM library. The channel sends the buffer containing the marshalled parameters to the RPC run-time library, which transmits it across the process boundary. The RPC run-time and the COM libraries exist on both sides of the process. Note also that the distinction between the channel and the RPC run-time is a characteristic of this implementation and is not part of the programming model or the conceptual model for OLE client/server objects. OLE object applications see only the proxy or stub and, indirectly, the channel. Future implementations may use different layers below the channel or no layers.

{ewc msdncd, EWGraphic, group10502 0 /a "SDK.wmf"}

The following sections discuss some of the issues involved in Custom Interface technology and describe these components in greater detail.

Connecting to the Object Application

An internal OLE component ensures that when a client request is made, the appropriate object is connected and ready to receive the request. OLE keeps a database of class information based on the system registry that the client caches locally through the COM library.

When the server is an in-process DLL, OLE simply passes the name of the DLL to the COM library. The COM library then loads the server and makes the method call. When the server is an executable in another process, OLE either creates the server process and starts the server or contacts it directly if it is already running.

Marshalling

Marshalling is the process of packaging and unpackaging parameters so a remote procedure call can take place. Different parameter types are marshalled in different ways. For example, marshalling an integer parameter involves simply copying the value into the message buffer (although even in this simple case, there are issues such as byte ordering to deal with with cross-machine calls). Marshalling an array, however, is a more complex process. Array members are copied in a specific order so that the other side can reconstruct the array exactly. When a pointer is marshalled, the data that the pointer is pointing to is copied following rules and conventions for dealing with nested pointers in structures. Unique functions exist to handle the marshalling of each parameter type.

There are two types of OLE marshalling: standard and custom.

With standard marshalling, the proxies and stubs are system-wide resources for the interface, and they interact with the channel through a standard protocol. Standard marshalling can be used by both standard OLE interfaces and custom interfaces:

- In the case of most OLE interfaces, the proxies and stubs for standard marshalling are themselves in-process component objects which are loaded from a system-wide DLL provided by OLE, OLE32.DLL.
- In the case of custom interfaces, the proxies and stubs for standard marshalling are generated by the interface designer, typically with MIDL. These proxies and stubs are statically configured in the registry, so any potential client can use the custom interface across process boundaries. These proxies and stubs are loaded from a DLL that is located via the system registry using the interface ID (IID) for the custom interface they marshal.

Standard marshalling is the default method for the provision of marshalling code when passing interface pointers. However, because multiple objects may implement a single interface any number of ways, standard marshalling may not be sufficient for a particular implementation. Therefore, any object may override the default and provide custom marshalling for its interfaces. Other implementations of the interface are not affected.

As an alternative to standard marshalling, an interface (standard or custom) can use custom marshalling. With custom marshalling, an object dynamically implements the proxies at run-time for each interface that it supports. For any given interface, the object can select OLE-provided standard marshalling or custom marshalling. This choice is made by the object on an interface by interface basis. Once the choice is made for a given interface, it remains in effect during the object's lifetime. However one interface on an object can use custom marshalling while another uses standard marshalling.

Custom marshalling is inherently unique to the object application that implements it. It uses proxies implemented by the object and provided to the system on request at run-time. Objects that custom-marshal must implement the **IMarshal** interface, whereas objects that support standard marshalling do not. For complete documentation of the **IMarshal** interface, see the *OLE Reference Guide*. Also, see the chapter "The Component Object Model" for more information on marshalling.

Marshalling support is provided by the system for all OLE-defined interfaces. This support is via component objects in the file OLE32.DLL. If you decide to write a custom interface, you must provide marshalling support for it. Typically, you will provide a standard marshalling DLL for the interface you design. You can use the tools contained in the *Win32 SDK* CD to create the proxy/stub code and the proxy/stub DLL.

Proxy

A proxy resides in the address space of the calling process and acts as a surrogate for the remote object. From the perspective of the calling object, the proxy is the object. Typically, the proxy's role is to package the interface parameters for calls to methods in its object interfaces. The proxy packages the parameters into a message buffer and passes the buffer onto the channel, which handles the transport between processes. The proxy is implemented as an aggregate, or composite, object. It contains a system-provided, manager piece called the proxy manager and one or more interface-specific components called interface proxies. The number of interface proxies equals the number of object interfaces that have been exposed to that particular client. To the client complying with the component object model, the proxy appears to be the real object.

Note With custom marshalling, the proxy can be implemented similarly or it can communicate directly to the object without using a stub.

Each interface proxy is a component object that implements the marshalling code for one of the object's interfaces. The proxy represents the object for which it provides marshalling code. Each proxy also implements the **IRpcProxyBuffer** interface. Although the object interface represented by the proxy is public, the **IRpcProxyBuffer** implementation is private and is used internally within the proxy. The proxy manager keeps track of the interface proxies and also contains the public implementation of the controlling **IUnknown** interface for the aggregate. Each interface proxy can exist in a separate DLL that is loaded when the interface it supports is materialized to the client.

The following diagram shows the structure of a proxy that supports the standard marshalling of parameters belonging to two interfaces: **IFoo1** and **IFoo2**. Each interface proxy implements **IRpcProxyBuffer** that is used for internal communication between the aggregate pieces. When the proxy is ready to pass its marshalled parameters across the process boundary, it calls methods in the **IRpcChannelBuffer** interface, which is implemented by the channel. The channel in turn forwards the call to the RPC run-time library so that it can reach its destination in the object.

{ewc msdncd, EWGraphic, group10502 1 /a "SDK.wmf"}

Stub

The stub, like the proxy, is made up of one or more interface pieces and a manager. Each interface stub provides code to unmarshal the parameters and code that calls one of the object's supported interfaces. Each stub also provides an interface for internal communication. The stub manager keeps track of the available interface stubs.

There are, however, some differences between the stub and the proxy:

- The most important difference is that the stub represents the client in the object's address space.
- The stub is not implemented as an aggregate object since there is no requirement that the client be viewed as a single unit; each piece in the stub is a separate component.
- The interface stubs are private, rather than public.
- The interface stubs implement **IRpcStubBuffer**, not **IRpcProxyBuffer**.
- Instead of packaging parameters to be marshalled, the stub unpackages them after they have been marshalled and then packages the reply.

The following diagram shows the structure of the stub. Each interface stub is connected to an interface on the object. The channel dispatches incoming messages to the appropriate interface stub. All the components talk to the channel through **IRpcChannelBuffer**, the interface that provides access to the RPC run-time library.

{ewc msdncd, EWGraphic, group10502 2 /a "SDK.wmf"}

Channel

The channel has the responsibility of transmitting all messages between client and object across the process boundary. The channel has been designed to work transparently with different channel types, is compatible with OSF DCE standard RPC, and supports single and multi-threaded applications.

Microsoft RPC

RPC is a model for programming in a distributed computing environment. The goal of RPC is to provide transparent communication so that the client appears to be directly communicating with the server. Microsoft's implementation of RPC is compatible with the Open Software Foundation (OSF) Distributed Computing Environment (DCE) RPC.

You can configure RPC to use one or more transports, one or more name services, and one or more security servers. The interface to those providers are handled by RPC. Because Microsoft RPC is designed to work with multiple providers, you can choose the providers that work best for your network. The transport is responsible for transmitting the data across the network. The name service takes an object name, such as a moniker, and finds its location on the network. The security server offers applications the option of denying access to specific users and/or groups. Refer to the next section "Writing a Custom Interface" for more detailed information about application security.

In addition to the RPC run-time libraries, Microsoft RPC includes the Interface Definition Language (IDL) and its compiler. Although the IDL file is a standard part of RPC, Microsoft has enhanced it to extend its functionality to support custom COM interfaces. The Microsoft Interface Definition Language (MIDL) compiler uses the IDL file that describes your custom interface to generate several files discussed in the section "Building a Proxy/Stub DLL".

Writing a Custom Interface

In order to perform the tasks discussed in the following section, you must obtain a Microsoft *Win32 Software Development Kit (SDK).* It contains a toolkit and all of the libraries you need for building a custom interface project. It provides more detailed information about how to write a custom interface using the MIDL compiler.

After installing the toolkit, you can design and write your custom interface using the MIDL compiler, and build the standard-marshalling proxy/stub DLL for your interface from the files generated by the compiler. You will then install the DLL in the system registry.

Designing Efficient Interfaces

There are some special considerations to keep in mind when designing a custom interface. If you follow these guidelines, your marshalling code can be used across the network when support for remotable objects is provided in a future release.

First of all, because data is shipped across address spaces, using architecture-dependent types such as **int** may prohibit the data from being re-created correctly in the object application's address space. The size of an integer varies from architecture to architecture. Thus, the data type **int** should not be used for structure data members or interface method parameters. Specifying data types unambiguously to the MIDL compiler will allow your interface to be more easily transferred to remote machines with different architectures and addressing schemes. The MIDL compiler requires all integer variables that may be remoted to be explicitly declared as short, long, or their unsigned equivalents.

A frequently used data type for pointers, the **void *** construct, allows the callee of a method to interpret the data pointed to according to the need. While local interfaces can use this construct, distributed applications cannot. This is because the MIDL compiler must know exactly what types of data are being transmitted so that the data can be accurately re-created on the receiving side. The **void *** construct is too vague.

Pointers to data must be used carefully. To re-create the data in the callee's address space, RPC must know the exact size of the data. If, for example, a **char *** parameter points to a buffer of characters rather than to a single character (as is implied), the data cannot be correctly re-created. Use the syntax available with MIDL to accurately describe the data structures represented by your type definitions.

Initialization is essential for pointers that are embedded in arrays and structures and passed across process boundaries. Uninitialized pointers may work when passed to a program in the same process space, but proxies and stubs assume that all pointers are initialized with valid addresses or are null.

Be careful when aliasing pointers (allowing pointers to point to the same piece of memory). If the aliasing is intentional, these pointers should be declared aliased in the IDL file. Pointers declared as non-aliased should never alias each other.

The MIDL has directional attributes that let you specify the data flow direction. The proxies and stubs use these attributes to determine whether to send the data from the client to the object or from the object to the client, respectively. Data labeled as *out* only is uninitialized on the way to the interface stub; data labeled as *in* only does not affect the data structures upon return. The *in, out* attribute indicates that data is sent to the object initialized and the object will change it before sending it back.

It is also imperative to realize the importance of defining status codes. This must be coordinated by the definer of the interface to avoid conflicting error codes.

Finally, the designer of an interface must develop an understanding of how the interface will be used by client applications. In particular, the frequency of method calls across the interface boundary and the amount of data to be transferred to complete a given method call together determine whether the interface will be efficient across process and machine boundaries. Although OLE makes cross-process and, eventually, cross-network calls transparent to programs, it cannot make high-frequency and high-bandwidth calls efficient across address spaces. In some cases, it is more appropriate to design interfaces that will normally be implemented only as in-process servers while other interfaces are more appropriate for remote use.

Creating a Custom Interface

Writing an application using a custom interface is similar to writing an OLE application using standard interfaces, with two important differences. First, in addition to registering the class identifier (CLSID) for your object, you also must register the unique interface identifier (IID) for your custom interface. Second, you must provide OLE with proxy and stub components capable of remoting the interface. In most cases, you will use the MIDL compiler to generate code to create the proxy/stub DLL for your custom interface.

As an OLE developer, you should already be familiar with the concept of using CLSIDs and interface identifiers (IIDs) to uniquely identify class objects and interfaces. The MIDL compiler refers to universally unique identifiers (UUIDs) and uses UUIDs to uniquely represent its interfaces. In this case, a UUID is the same as an IID. Every custom interface must have a IID; the UUIDGEN.EXE tool provided with the toolkit can create one for you.

MIDL is a rich, complex language that allows you to define interface parameters carefully in terms of their direction and type. Although the MIDL compiler offers much, you will need only a small subset of its attributes to define your interface.

The IDL file consists of two parts: the interface header and the interface body. The interface header, delimited by brackets, contains information about the interface as a whole, such as its IID. A prerequisite to completing the interface header is running the RPC utility UUIDGEN.EXE to create the IID. Because IIDs must be unique, never reuse one of them by copying it from one IDL file to another. The header also contains the keyword **object**, indicating that this interface is a COM-style interface (that is, derived from **IUnknown**). Whereas standard RPC interfaces have the version attribute in their interface headers, object interfaces do not.

The following excerpt is from an actual IDL file:

```
[
    object,
    uuid(7ACC12C3-C4BB-101A-BB6E-0000C09A6549),
    pointer_default(unique)
]
```

The **uuid** attribute precedes the unique identifier for the interface. The **pointer_default** attribute specifies the default IDL type for all pointers except for those included in parameter lists. Parameter list pointers must be explicitly declared with the pointer attribute. The default pointer type may either be **unique**, **ref**, or **ptr**. For more information on using IDL with pointers, see the *RPC Programmer's Guide and Reference*.

The interface body contains declarations for data members, prototypes for all methods, and other information such as directives to the preprocessor and include statements for other IDL files. The following example is the interface body for **ICustomInterface**:

```
interface ICustomInterface : IUnknown
{
    import "unknwn.idl";

    HRESULT CustomReport(void);
}
```

The **import** attribute allows an interface to reference constructs defined in other IDL files. Because **ICustomInterface** derives from **IUnknown**, the UNKNWN.IDL file must be included. **ICustomInterface** has only one method that takes no parameters; few interfaces will be this simple.

Building a Proxy/Stub DLL

Completed IDL files must be compiled with the IDL compiler, MIDL.EXE. The IDL compiler takes each IDL file and generates proxy/stub code (IDLNAME_P.C), an interface header file (IDLNAME.H), and an interface identifier file (IDLNAME_I.C). The header files contain both C and C++ class definitions.

By default, MIDL.EXE generates names based on your IDL file's name. However, you can use the following command line switches to override the default:

Command line switch	Description
-header	Specifies the name of the interface header file.
-proxy	Specifies the name of the proxy source file.
-iid	Specifies the name of the interface identifier file.

After a successful compile of the IDL file, the generated files are run through the standard C/C++ compile and link steps. These source files implement helper functions for marshalling and an implementation of **DllGetClassObject** for the proxy/stub libraries, among other things. Note that the RPC4RT.LIB library includes an implementation of the **DllGetClassObject** function. In this provided implementation, the CLSID of the proxy/stub has to be the same as the IID of your custom interface. If you want to use a CLSID that differs from the IID then you must provide your own implementation of the **DllGetClassObject** function.

The following diagram shows all the pieces involved in a build of a custom proxy/stub DLL. The IDL file, ITF.IDL, is fed into the IDL compiler. Three files are generated: ITF_P.C, ITF.H, and ITF_I.C. These three files are compiled and linked and the result is PROXSTUB.DLL.

{ewc msdncd, EWGraphic, group10502 3 /a "SDK.wmf"}

Registering a Proxy/Stub DLL

Before a client can use your custom interface, the proxy/stub DLL for the interface must be installed in the system registry. Registering the proxy/stub DLL involves creating a .REG file and running REGINI. In the following entries, notice that the IID for **ICustomInterface** is the same as the CLSID for the proxy/stub DLL.

```
 \Registry\MACHINE\SOFTWARE\Classes\Interface\
     {7ACC12C3-C4BB-101A-BB6E-0000C09A6549}
         = ICustomInterface
\Registry\MACHINE\SOFTWARE\Classes\Interface\
     {7ACC12C3-C4BB-101A-BB6E-0000C09A6549}\ProxyStubClsid32
         = {7ACC12C3-C4BB-101A-BB6E-0000C09A6549}
\Registry\MACHINE\SOFTWARE\Classes\CLSID\
     {7ACC12C3-C4BB-101A-BB6E-0000C09A6549}
         = ICustomInterface_PSFactory
\Registry\MACHINE\SOFTWARE\Classes\CLSID\
     {7ACC12C3-C4BB-101A-BB6E-0000C09A6549}\InprocServer32
         = proxstub.dll
```

Using a Custom Interface

The client code is the user of the custom interface. To use any interface, custom or standard, a client must know its IID. In the following function, **CustomRpt**, the driver that calls **CustomRpt** passes it the name of the object that is converted to a wide-character format. The object name is fed to **CreateFileMoniker** so that a file moniker can be created and the client can bind to the running object. Once the object is running, **CustomRpt** can access a pointer to either an interface in the standard proxy/stub, such as **IPersistFile**, or to the custom interface, **ICustomInterface**.

```
void CustomRpt(char *pszObject)
{
    HRESULT          hr;
    WCHAR                  szObject[128];
    WCHAR               wszMsg[128] = {L"Your Message Here...\n"};
    IMoniker                  *pmkObject = NULL;
    IUnknown            *pIUnk = NULL;
    IPersistFile        *pIPersistFile = NULL;
    ICustomInterface   *pICustomInterface = NULL;

    // Create a wide-character version of the object's file name.
    wsprintf(wszObject, L"%hs", pszObject);

    // Get a file moniker for the object (a *.smp file).
    hr = CreateFileMoniker(wszObject, &pmkObject);

    if(FAILED(hr))
    {
         printf("Client: CreateFileMoniker for Object failed");
         return;
    }

    // BindMoniker is equivalent to calling CreateBindCtx() followed by
    // a call to BindToObject(). It has the net result of binding the
    // interface (specified by the IID) to the moniker.

    hr = BindMoniker(pmkObject, 0, IID_IUnknown, (void **)&pIUnk);
    if (FAILED(hr))
    {
         printf("Client: BindMoniker failed (%x)\n", hr);
         return;
    }

    // Try a couple QueryInterface calls into the object code, first a
    // QueryInterface to IPersistFile...

    hr = pIUnk->QueryInterface(IID_IPersistFile,
       (void **)&pIPersistFile);

    if (FAILED(hr)) {
        printf("Client: QueryInterface IPersistFile failed (%x)\n", hr);
        pIUnk->Release();
        return;
    }

    // Followed by a QueryInterface to ICustomInterface.
    hr = pIUnk->QueryInterface(IID_ICustomInterface,
                    (void **)&pICustomInterface);

    if (FAILED(hr)) {
        printf("Client: QueryInterface failed (%x)\n", hr);
        pIUnk->Release();
        pIPersistFile->Release();
        return;
    }

    // CustomReport() is the object function that displays the time and
    // date information on the object.
    hr = pICustomInterface->CustomReport();

    if (FAILED(hr))
    {
        printf("Client: pICustomInterface->CustomReport failed (%x)\n",
             hr);
        pIUnk->Release();
        pIPersistFile->Release();
        return;
    }

    // Clean up resources by calling release on each of the interfaces.
    pIPersistFile->Release();
    pICustomInterface->Release();
    pIUnk->Release();
    return;
}
```

Data Transfer

The Component Object Model (COM) provides a standard mechanism for transferring data between applications. This mechanism is the *data object*, which is simply any COM object that implements the **IDataObject** interface. Some data objects, such as a piece of text copied to the clipboard, have **IDataObject** as their sole interface. Others, such as compound document objects, expose several interfaces, of which **IDataObject** is simply one. Data objects are fundamental to the working of compound documents, although they also have widespread application outside that OLE technology.

By exchanging pointers to a data object, providers and consumers of data can manage data transfers in a uniform manner, regardless of the format of the data, the type of medium used to transfer the data, or the target device on which it is to be rendered. You can include support in your application for basic clipboard transfers, drag and drop transfers, and OLE compound document transfers with a single implementation of **IDataObject**. Having done that, the amount of code required to accommodate the special semantics of each protocol is minimal.

Data Transfer Interfaces

The **IDataObject** interface provides consumers of data with methods for getting and setting an object's data, determining which formats the object supports, and registering for and receiving notifications when data in the object changes. When obtaining data, a caller can specify the format in which it wants to render the data. The source of the data, however, determines the storage medium, which it returns in an out parameter provided by the caller.

By itself, **IDataObject** supplies all the tools you need to implement Microsoft® Windows® clipboard transfers or compound document transfers in your applications. If you also want to support drag and drop transfers, you need to implement the **IDropSource** and **IDropTarget** **interfaces**along with **IDataObject**.

The **IDataObject** interface combined with OLE clipboard APIs provide all the capabilities of the Microsoft® Win32® clipboard APIs. Using both the platform's clipboard APIs and OLE's is usually redundant and unnecessary. Suppliers of data that support either drag and drop transfers or OLE compound documents *must* implement the **IDataObject** interface. If your application supports only clipboard transfers now, but you intend to add drag and drop or compound documents in later releases, you may want to implement **IDataObject** and the OLE clipboard APIs now in order to minimize the amount of time spent recoding and debugging later. You may also want to implement **IDataObject** in order to utilize transfer media other than global memory.

The following table summarizes which ones to use, depending on what types of data transfer you want to support:

If You Want to Support	You Must Use
Compound documents	**IDataObject**
Drag and drop transfers	**IDataObject**, **IDropSource**, **IDropTarget**, **DoDragDrop** (or the equivalent)
Windows clipboard transfers using global memory exclusively	Windows clipboard APIs
Windows clipboard transfers using exchange mediums other than global memory.	**IDataObject**
Clipboard transfers now but drag and drop or compound documents later	**IDataObject** and the interfaces and function listed above for "Drag and drop transfers"

When a user initiates a data transfer operation, the source application creates an instance of **IDataObject** and through it makes the data available in one or more formats. In a clipboard transfer, the application calls the **OleSetClipboard** function to pass a data-object pointer to OLE. (**OleSetClipboard** also offers standard clipboard data formats for both OLE version 1 and non-OLE applications.) In a drag and drop transfer, the application calls the **DoDragDrop** function instead.

On the receiving side of the transfer, the destination receives the **IDataObject** pointer either as an argument to an invocation of **IDropTarget::Drop** or by calling the **OleGetClipboard** function, depending on whether the transfer is by means of drag and drop or the clipboard. Having obtained this pointer, the destination calls **IDataObject::EnumFormatEtc** to learn what formats are available for retrieval and on what types of media they can be obtained. Armed with this information, the receiving application requests the data with a call to **IDataObject::GetData**.

Data Formats and Transfer Media

Most platforms, including Windows, define a standard protocol for transferring data between applications, based on a set of functions called the clipboard. Applications using these functions can share data even if their native data formats are wildly different. Generally, these clipboards have two significant shortcomings that COM has overcome.

First, data descriptions use only a format identifier, such as the single 16-bit clipboard format identifier on Windows, which means the clipboard can only describe the structure of its data, that is, the ordering of the bits. It can report, "I have a bitmap" or "I have some text," but it cannot specify the target devices for which the data is composed, which views or aspects of itself the data can provide, or which storage media are best suited for its transfer. For example, it cannot report, "I have a string of text that is stored in global memory and formatted for presentation either on screen or on a printer" or "I have a thumbnail sketch bitmap rendered for a 100 dpi dot-matrix printer and stored as a disk file."

Second, all data transfers using the clipboard generally occur through global memory. Using global memory is reasonably efficient for small amounts of data but horribly inefficient for large amounts, such as a 20 MB multimedia object. Global memory is slow for a large data object, whose size requires considerable swapping to virtual memory on disk. In cases where the data being exchanged is going to reside mostly on disk anyway, forcing it through this virtual-memory bottleneck is highly inefficient. A better way would skip global memory entirely and simply transfer the data directly to disk.

To alleviate these problems, COM introduces two new data structures: FORMATETC and STGMEDIUM.

The FORMATETC Structure

The FORMATETC structure is a generalized clipboard format, enhanced to encompass a target device, an *aspect* or view of the data, and a storage medium. A data consumer, such as an OLE container application, passes the FORMATETC structure as an argument in calls to **IDataObject** to indicate the type of data it wants from a data source, such as a compound document object. The source uses the FORMATETC structure to describe what formats it can provide. FORMATETC can describe virtually any data, including other objects such as monikers. A container can ask one of its embedded objects to list its data formats by calling **IDataObject::EnumFormatetc**, which returns an enumerator object that implements the **IEnumFormatEtc** interface. Instead of replying merely that it has "text and a bitmap," the object can provide a detailed description of the data, including the device (normally screen or printer) for which it is rendered, the aspect to be presented to the user (full contents, thumbnail, icon, or formatted for printing), and the storage medium containing the data (global memory, disk file, storage object, or stream). This ability to tightly describe data will, in time, result in higher quality printer and screen output as well as more efficiency in data browsing, where a thumbnail sketch is much faster to retrieve and display than a fully detailed rendering.

The following table lists fields of the FORMATETC data structure and the information they specify:

Field	**Specifies**
cfFormat	The format in which the data is to be rendered, which can be a standard clipboard format, a proprietary format, or an OLE format. For more information on OLE formats, see Chapter 5, "Compound Documents."
ptd	A DVTARGETDEVICE structure, which contains enough information about a Windows target device, such as a screen or printer, so that a handle to its device context (hDC) can be created using the Windows **CreateDC** function.
dwAspect	The aspect or view of the data to be rendered; can be the full contents, a thumbnail sketch, an icon, or formatted for printing.
lindex	The part of the aspect that is of interest; for the present, the value must be -1, indicating that the entire view is of interest.
tymed	The data's storage medium, which can be global memory, disk file, or an instance of one of COM's structured-storage interfaces.

The STGMEDIUM Structure

Just as the FORMATETC structure is an enhancement of the Windows clipboard format identifier, so the STGMEDIUM structure is an improvement of the global memory handle used to transfer the data. The STGMEDIUM structure includes a flag, *tymed,* which indicates the medium to be used, and a union comprising pointers and a handle for getting whichever medium is specified in *tymed.*

The STGMEDIUM structure enables both data sources and consumers to choose the most efficient exchange medium on a per-rendering basis. If the data is so big that it should be kept on disk, the data source can indicate a disk-based medium in its preferred format, only using global memory as a backup if that's the only medium the consumer understands. Being able to use the best medium for exchanges as the default improves overall performance of data exchange between applications. For example, if some of the data to be transferred is already on disk, the source application can move or copy it to a new destination, either in the same application or in some other, without having first to load the data into global memory. At the receiving end, the consumer of the data does not have to write it back to disk.

Drag and Drop

"Drag and drop" refers to data transfers in which a mouse or other pointing device is used to specify both the data source and its destination. In a typical drag and drop operation, a user selects the object to be transferred by moving the mouse pointer to it and holding down either the left button or some other button designated for this purpose. While continuing to hold down the button, the user initiates the transfer by dragging the object to its destination, which can be any OLE container. Drag and drop provides exactly the same functionality as the OLE Clipboard copy and paste but adds visual feedback and eliminates the need for menus. In fact, if an application supports Clipboard copy and paste, little extra is needed to support drag and drop.

During an OLE drag and drop operation, the following three separate pieces of code are used:

Drag-and-drop code source	**Implementation and use**
IDropSource interface	Implemented by the object containing the dragged data, referred to as the *drag source*.
IDropTarget interface	Implemented by the object that is intended to accept the drop, referred to as the *drop target*.
DoDragDrop function	Implemented by OLE and used to initiate a drag and drop operation. Once the operation is in progress, it facilitates communication between the drag source and the drop target.

The **IDropSource** and **IDropTarget** interfaces can be implemented in either a container or in an object application. The role of drag source or drop target is not limited to any one type of OLE application.

The OLE function **DoDragDrop** implements a loop that tracks mouse and keyboard movement until such time as the drag is canceled or a drop occurs. **DoDragDrop** is the key function in the drag and drop process, facilitating communication between the drag source and drop target.

During a drag and drop operation, three types of feedback can be displayed to the user:

Type of feedback	**Description**
Source feedback	Provided by the drag source, the source feedback indicates the data is being dragged and does not change during the course of the drag. Typically, the data is highlighted to signal it has been selected.
Pointer feedback	Provided by the drag source, the pointer feedback indicates what happens if the mouse is released at any given moment. Pointer feedback changes continually as the user moves the mouse and/or presses a modifier key. For example, if the pointer is moved into a window that cannot accept a drop, the pointer changes to the "not allowed" symbol.
Target feedback	Provided by the drop target, target feedback indicates where the drop is to occur.

Although the Windows 3.1 File Manager does not use OLE to implement drag and drop transfers, it is nevertheless an example of an application that acts as both a drag source and drop target and that provides all three types of feedback. When a user selects a file to copy, File Manager supplies source feedback by indicating the selection. As the selection is dragged and modifier keys are pressed, the mouse pointer changes. For example, if the user presses the CTRL key, a plus sign is added, indicating that the drop would result in a copy rather than moving the original. When the file is dragged over an area that is not a drop target, the pointer changes appropriately. Target feedback, a line drawn around a file or directory, is provided when the pointer is over an area that is a drop target.

Drag Source Responsibilities

The drag source is responsible for the following tasks:

- Providing a data-transfer object for the drop target that exposes the **IDataObject** and **IDropSource** interfaces.
- Generating pointer and source feedback.
- Determining when the drag operation has been canceled or a drop operation has occurred.
- Performing any action on the original data caused by the drop operation, such as deleting the data or creating a link to it.

The main task is creating a data-transfer object that exposes the **IDataObject** and **IDropSource** interfaces. The drag source might or might not include a copy of the selected data. Including it is not mandatory, but doing so safeguards against inadvertent changes and allows the Clipboard operations code to be identical to the drag and drop code.

While a drag operation is in progress, the drag source is responsible for setting the mouse pointer and, if appropriate, for providing additional source feedback to the user. The drag source cannot provide any feedback that tracks the mouse position other than by actually setting the real pointer (see the Windows **SetCursor** function). This rule must be enforced to avoid conflicts with the feedback provided by the drop target. (A drag source can also be a drop target. When dropping on itself, the source/target can, of course, provide target feedback to track the mouse position. In this case, however, it is the drop target tracking the mouse, not the source.) Based on the feedback offered by the drop target, the source sets an appropriate pointer.

Data Notification

Objects that consume data from an external source sometimes need to be informed when data in that source changes. For example, a stock ticker tape viewer that relies on data in some spreadsheet needs to be notified when that data changes so it can update its display. Similarly, a compound document needs information about data changes in its embedded objects so that it can update its data caches. In cases such as this, where dynamic updating of data is desirable, sources of data require some mechanism of notifying data consumers of changes as they occur without obligating the consumers to drop everything in order to update their data. Ideally, having been notified that a change has occurred in the data source, a consuming object can ask for an updated copy at its leisure.

COM's mechanism for handling asynchronous notifications of this type is an object called an advise sink, which is simply any COM object that implements an interface called **IAdviseSink**.   Consumers of data implement the **IAdviseSink**. They register to receive notifications by handing a pointer to the data object of interest.

The **IAdviseSink** interfaces exposes the following methods for receiving asynchronous notifications:

Method	**Notifies the Advise Sink that**
OnDataChange	Calling object's data has changed.
OnViewChange	Instructions for drawing the calling object have changed.
OnRename	Calling object's moniker has changed.
OnSave	Calling object has been saved to persistent storage.
OnClose	Calling object has been closed.

As the table indicates, the **IAdviseSink** interface exposes methods for notifying the advise sink of events other than changes in the calling object's data. The calling object can also notify the sink when the way in which it draws itself changes, or it is renamed, saved, or closed. These other notifications are used mainly or entirely in the context of compound documents, although the notification mechanism is identical. For more information on compound-document notifications, see "Compound Documents."

In order to take advantage of the advise sink, a data source must implement **IDataObject::DAdvise, IDataObject::DUnadvise,** and **IDataObject::EnumDAdvise.** A data consumer calls the **DAdvise** mothod to notify a data object that it wishes to be notified when the object's data changes. The consuming object calls the **DUnadvise** method to tear down this connection. Any interested party can call the **EnumAdvise** method to learn the number of objects having an advisory connection with a data object.

When data changes at the source, the data object calls **IAdviseSink::OnDataChange** on all data consumers that have registered to receive notifications. To keep track of advisory connections and manage the dispatch of notifications, data sources rely on an object called a *data advise holder*. You can create your own data advise holder by implementing the **IDataAdviseHolder** interface. Or, you can let COM do it for you by calling the helper function **CreateDataAdviseHolder**.

Overview

Today's software applications are more capable and easier to use than ever before. Yet as their feature sets have grown in complexity and size, they have become increasingly difficult and costly to engineer, maintain, and upgrade. Adding new features always runs the risk of introducing new, sometimes intractable bugs and endangers backward compatibility with earlier versions. In addition, most applications are monolithic, providing rich sets of features but no easy way to add missing features or remove unneeded ones. Applications that do support adding and removing features in the form of plug-in components may expose their services to sibling applications from the same vendor but rarely to those from entirely different vendors. As a result, applications from different vendors typically work together poorly or not at all.

Operating systems have a related set of problems. Because most operating systems are not sufficiently modular, upgrading, replacing, or overriding existing services in a clean, flexible way is difficult. Like application developers, systems vendors face the difficult choice of foregoing or compromising needed improvements in order to maintain backward compatibility, or disenfranchising existing users in order to move the technology forward. These are choices that serve no one.

Software developers have recognized for some time that object-oriented programming offers promising solutions to several of these problems. By encapsulating data and functions in a single entity, then providing access to this rich content through a single reference, or pointer, object-oriented programming makes it possible to break down monolithic applications into functional modules, or *components,* that can be added or removed as they are needed. Moreover, object-oriented programming can potentially reduce the expense of implementing new objects by enabling them, through mechanisms such as inheritance, polymorphism, and aggregation, to make use of the capabilities built into already-existing objects.

Even so, object-oriented programming has yet to reach its full potential because no standard framework has existed through which software objects created by different vendors could interact with one another within the same address space, much less across process, machine, and network boundaries. Once you have broken down software into manageable, interchangeable components, you need some way for those components to communicate. That's where OLE comes in.

OLE provides a standard conceptual framework for creating, managing, and accessing object-based components that provide services to other objects and applications. OLE components can exist as parts of an operating system or application, or as stand-alone entities, and the services they provide can be most anything that operating systems and applications currently supply. You can use OLE components to expose both data and services to programs created by other vendors and write your own applications in such a way as to take advantage of services provided by others. You can also extend or customize basic OLE services to suit the needs of your objects and applications while guaranteeing that they continue to work with other OLE components.

Explaining the Component Object Model

The bedrock on which OLE rests is the Component Object Model (COM), which provides both the programming model and binary standard for OLE components. COM defines and implements mechanisms that enable software components, such as applications, data objects, controls, and services, to interact as *objects*. A software object comprises some body of data, along with one or more functions for accessing and using that data. An OLE component is one in which access to an object's data is achieved exclusively through one or more sets of related functions called *interfaces.*

An object provider, or *server*, makes an OLE component available by implementing one or more interfaces. A prospective user, or *client,* of an OLE component gains access to the object by obtaining a pointer to one of its interfaces. With this pointer, the client can reliably use the object without understanding its implementation and with the assurances that the object will always behave the same way. In this sense, an object's interface is a contract defining its behavior for prospective clients. The object will honor that contract even if its client lives in a different process or on a different machine, runs under a different operating system, is written by a different software developer using a different computer language, or represents an earlier or later version than the client used before.

By defining interfaces as contracts between objects and their clients, COM effectively solves the versioning problem. Here's how. To create a new version of an object, you simply add new interfaces while leaving the older ones in place. You define the new interfaces in such a way that clients are permitted to query for either the new version of the interface, or the old version, but not for both. Because of this restriction, adding new interfaces, or new versions of older interfaces, in no way interferes with the way existing clients work with an object.

Because OLE components conform to a binary standard, you can implement them using nearly any programming language. Object-oriented languages such as C++ and Smalltalk are ideal for this purpose, but any procedural language, such as C or Pascal, that supports the notion of a reference, or pointer, to an object will do. OLE components implemented in one programming language will work, without modification, with applications or other objects implemented in another language. In addition, because OLE components are language-independent, they are not constrained by language-based requirements to operate in the same address space as the objects or applications using them. As a result, OLE components provide the basis for sharing information among separate objects in different processes on the same machine or on different networked computers.

OLE Information Management

Built on top of COM are core facilities for storing and naming objects and for transferring data between them. Together, these facilities form the core of system-wide information management. You can take advantage of these facilities by using OLE's supplied implementations, or you can extend or replace them with your own. These core facilities include structured storage, monikers, and uniform data transfer. Together they provide the infrastructure required for objects to interrelate across process, machine, and network boundaries.

OLE's structured storage model defines an architecture for storing and retrieving objects that reside inside files or other containers. The basic problem addressed by the structured storage model is how to write an object to and retrieve an object from any persistent storage when that object resides inside the flat file space of some container. OLE solves the problem by providing interfaces that support *storage* and *stream* objects. A storage object provides a hierarchical structure for mapping the location of storage and stream objects just as directories provide a way of locating files on disk. A stream object contains the object's data, or contents. Using structured storage is mandatory if you want to support compound documents or other forms of containment. OLE also provides a default implementation of structured storage called *compound files.*

OLE supports the persistent naming of objects through a mechanism called a *moniker.* A moniker provides a way for clients of an object to locate that object even when it resides in a different process or on a different computer. Objects have a file moniker, which is similar to their absolute pathnames, but their clients normally bind to them using a relative moniker*,* which indicates the object's location relative to the client. In this way, if client and object are both relocated, they can maintain their connection as long as their locations relative to each other remain the same. In general, a moniker also enables clients to locate and connect to some portion of an object−a certain range of cells in a spreadsheet, for example−by providing an *item moniker,* by which that *pseudo-object* is always known.

OLE's uniform data transfer model provides a single, standard mechanism for transferring objects and data between applications. Through a single interface, OLE supports standard Microsoft® Windows® clipboard transfers, as well as drag and drop, and embedded objects. Uniform data transfer greatly enhances the clipboard model by providing rich structures for describing the format of the data to be transferred and the storage medium in which a transfer is to occur. For example, instead of always having to pass data in a global memory handle, you can choose from among several storage media, including a disk-based file and pointers to OLE storage and stream interfaces.

Built on top of COM, structured storage, monikers, and uniform data transfer are the three technologies for which OLE is best known: compound documents, OLE automation, and OLE controls. For many software vendors, the desire to incorporate one or both of these technologies in their applications, or to make sure their applications work easily with operating systems and other applications that do, has been the prime motivation for turning to OLE.

Describing Compound Documents

A *compound document* is one that contains, along with its native data, one or more objects that were created in other applications and therefore have different data formats. Such objects are called *compound document objects.* An application used to create compound document objects is called an *OLE server application.* An application whose documents act as object clients is called a *container application* or, simply, a *container*. Any given application can be one, or the other, or both.

Compound document objects are essentially OLE components that also implement interfaces that support object linking and embedding. A linked object includes information about the location of its data and the formats necessary to present it on screen to the user, but the data itself is stored elsewhere. An embedded object is one whose data is stored along with that of its container. Applications that support linking and embedding can share data without having knowledge of one another's data structures and without having to implement separate protocols for every other application with which they communicate. Users of OLE compound document applications can embed data created in one application in a document created in another, and can view, edit, or otherwise manipulate that data without having to exit the application in which they are working. Users can also create links in one document to data in another so that changes to data in the source document are updated in the link.

Defining OLE Automation

OLE automation is the ability for one application or tool to manipulate programmatically objects exposed by another application. Using OLE automation, you can also create tools that access and manipulate objects. Such tools can include embedded macro languages, programming tools, object browsers, and compilers. Like compound documents, OLE automation is based on COM, but applications can implement OLE automation independently of compound documents or other OLE technologies.

Where to Find Additional Information

The current release of *OLE Programmer's Guide* examines the architecture and capabilities of OLE as a whole, as well as of each of its core facilities: COM, structured storage, and uniform data transfer. A separate chapter is devoted to compound documents, the technology that inspired the original development of OLE and laid the groundwork for its evolution into a systemwide, object-based service architecture. A subsequent release of the *OLE Programmer's Guide* will include detailed instructions for developing both OLE client and server applications for compound documents that work under both Microsoft® Windows NT™ and Microsoft® Windows® 95. For descriptions of specific interfaces, helper functions, data structures, and enumerations, refer to the *OLE Programmer's Reference,* Volume 1. For information on OLE automation and developing OLE controls, see the *OLE Programmer's Reference,* Volume 2 *Automation*.

Programming Considerations

While detailed application-specific information is beyond the scope of this appendix, this section contains some helpful guidelines for developing OLE applications.

Designing Component Objects

Component objects contain data specific to the object and one or more interface implementations. The data is private and inaccessible from outside the object, while the interface implementations are public and you can access them through pointers.

Because interfaces are a binary standard, interface implementation is language independent. However, C++ is the preferred language because it supports many of the object-oriented concepts inherent in OLE. Using a procedural language such as C involves extra work, as summarized below:

- You must explicitly initialize VTBLs either at compile-time or run-time and you should not change them later. Once initialized with function pointers, those pointers should remain unchanged until the application shuts down. VTBLs in C++ are declared as constants to prevent them from being modified inadvertently. However, in C there is no way to ensure that a VTBL will remain unchanged.

  To overcome this difference, OLE provides a mechanism that lets C developers declare VTBLs as constants. To do so, place the following statement before the *#include* statement for the "ole2.h" header file:

  ```
  #define CONST_VTABLE
  ```

- Each method requires a pointer to the object that owns the method. In C++, all members are implicitly dereferenced off the *this* pointer. In C, there must be an additional first parameter passed to each method that is a pointer to the interface in which the method is declared.
- Methods in C++ can have identical names because methods are actually known by a name that is the result of concatenating the method name to the class name. Methods in C must have a unique name to designate the object with which they are associated.

For example, the following C++ code sample defines an implementation of **IUnknown::QueryInterface**. The method name is **QueryInterface** and there are two parameters: a REFIID and a pointer to where to return the requested interface instance.

```
CUnknown::QueryInterface (REFIID riid, LPVOID * ppvObj);
```

A similar C implementation would require a more complex name and an additional first parameter to indicate the object owning the method:

```
IUnknown_Doc_QueryInterface (LPUNKNOWN pUnk, REFIID riid,
     LPVOID * ppvObj);
```

The following sections demonstrate how to declare a component object in a few typical ways: using C nested data structures, C++ nested classes, and C++ multiple inheritance. The demonstration object, called *CObj*, derives from **IUnknown** and supports two interfaces that also derive from **IUnknown**, **InterfaceA** and **InterfaceB**. *CObj's* private data includes a pointer to another component object in the application (*m_pCDoc*), a count of all the external references to the object (*m_ObjRefCount*), and pointers to two interfaces implemented by other component objects and used by *CObj (m_pOleObj* and *m_pStg)*. All object members use the *m_* prefix to make it easy to distinguish between member variables and other variables.

Component Objects: C Nested Structures

C interface implementations comprise data structures nested within the object's data structure. Each interface structure contains a VTBL pointer as its first member (*pVtbl*), a pointer to the object (*pCObj*), and a count of the external references to the interface (*m_RefCount*). The order of the members in the interface structures is identical, to facilitate code sharing.

```
typedef struct CObj {
  ULONG            m_ObjRefCount;
  LPSTORAGE        m_pStg;
  LPOLEOBJECT      m_pOleObj;
  struct CDOC    *  m_pCDoc;

  struct InterfaceA  {
    LPVTBL        pVtbl;
    struct CObj  *  pCObj;
    ULONG        m_RefCount;
  } m_InterfaceA;

  struct InterfaceB {
    LPVTBL       pVtbl;
    struct Obj  *   pCObj;
    ULONG        m_RefCount;
  } m_InterfaceB;

} COBJ;
```

Component Objects: C++ Nested Classes

The next example shows how the same object is declared and initialized using the C++ nested class approach. As in the C example, the nested class declaration includes one data structure for each interface and four private data members: an object-level reference count, two interface pointers, and a pointer to the enclosing object. The private implementations of the **IUnknown** methods are called by the implementations declared for the derived interfaces. For each interface implementation, there is a structure containing a public constructor and destructor, private declarations of the interface methods, a private pointer to *CObj*, and an interface-level reference counter for debugging purposes. To allow the nested interface classes to access the private members of the outer class, each interface class is made a friend of the outer class.

The benefits of implementing with C++ nested classes lie in the ability to include initialization code and method implementation inline. However, inline declaration is for the convenience of illustration and is not required.

```
class  CObj  {

private:
  ULONG          m_ObjRefCount;
  LPSTORAGE      m_pStg;
  LPOLEOBJECT    m_pOleObj;
  CDOC    *      m_pCDoc;

public:
  CObj();
  ~CObj();

  struct CUnknown : IUnknown
{
  private:
  ULONG          m_RefCount;
  CObj  *        m_pCObj;

  public:
  CUnknown(CObj (pCObj)
  { m_pCObj = pCObj; m_RefCount = 0; }
  HRESULT QueryInterface(REFIID riid, LPVOID  * ppvObj)
  ULONG AddRef(void) { return ++m_ObjRefCount; }
  ULONG Release(void);
}
friend CUnknown;
CUnknown m_Unknown;

struct InterfaceA : InterfaceA
{
  private:
  ULONG          m_RefCount;
  CObj  *        m_pCObj;

  public:
  CInterfaceA(CObj *pCObj)
  { m_pCObj = pCObj; m_RefCount = 0; }
  HRESULT QueryInterface(REFIID riid, LPVOID  * ppvObj)
  ULONG AddRef(void) { return ++m_ObjRefCount; }
  ULONG Release(void);
  HRESULT MethodA1(LPVOID  * ppvObj);
  HRESULT MethodA2(DWORD dwArg);
}
friend CInterfaceA;
CInterfaceA m_InterfaceA;

struct InterfaceB : InterfaceB
{
  private:
  ULONG         m_RefCount;
  CObj  *       m_pCObj;

  public:
  CInterfaceB(CObj *pCObj)
  { m_pCObj = pCObj; m_RefCount = 0; }
  HRESULT QueryInterface(REFIID riid, LPVOID  * ppvObj)
  ULONG AddRef(void) { return ++m_ObjRefCount; }
  ULONG Release(void);
  HRESULT MethodB1(void);
  HRESULT MethodB2(DWORD dwArg1, DWORD dwArg2);
}
friend CInterfaceB;
CInterfaceB m_InterfaceB;
```

Multiple Inheritance

The next example illustrates the use of C++ multiple inheritance. There are two disadvantages to using multiple inheritance with OLE. First, it is not possible to have an interface-level reference count. For more information about reference counting, see Chapter 2, "The Component Object Model." Second, there is the potential for confusion over the interpretation of the class statement. A standard C++ multiple inheritance declaration implies the "is a" relationship where an object inherits implementations. In OLE, however, interfaces are attributes of the object and implementations are not inherited.

The main advantage to using multiple inheritance lies in its simplicity. Only the prototypes for each of the interface methods are listed; no interface data structures or class definitions are necessary.

Because both InterfaceA and InterfaceB inherit from **IUnknown**, it is not necessary to list **IUnknown** explicitly in the class statement. A single implementation of the **IUnknown** methods (**QueryInterface**, **AddRef**, and **Release**) is sufficient.

```
class  CObj : public InterfaceA, public InterfaceB
{
private:
  ULONG          m_ObjRefCount;
  LPSTORAGE      m_pStg;
  LPOLEOBJECT    m_pOleObj;
  CDOC  *        m_pCDoc;

public:
  CObj();
  ~CObj();

  HRESULT QueryInterface(REFIID riid, LPVOID  * ppvObj)
  ULONG AddRef(void) { return ++m_ObjRefCount; }
  ULONG Release(void);

  HRESULT MethodA1(LPVOID  * ppvObj);
  HRESULT MethodA2(DWORD dwArg);

  HRESULT MethodB1(void);
  HRESULT MethodB2(DWORD dwArg1, DWORD dwArg2);
};
```

Aggregating Objects

An aggregate is an object like any other object in that it implements one or more interfaces. Internal to the aggregate, the implementation of certain interfaces is actually provided by one or more contained objects. Users of the object are unaware of this internal structure. They cannot tell and do not care that the object is an aggregate: aggregation is purely an implementation technique.

The figure below shows an aggregate object consisting of a control object that implements Interface A and Interface B, and a noncontrol object that implements Interface C. All these interface implementations are exposed publicly, as indicated by the line and circle extending to the outside of the aggregate.

{ewc msdncd, EWGraphic, group10505 0 /a "SDK.wmf"}

In the aggregation model, the *control object* determines how an aggregate behaves and operates, making decisions about which interfaces are exposed outside of the object and which interfaces remain private. The control object has a special instance of the **IUnknown** interface known as the *controlling unknown*. The controlling unknown must always be implemented as part of the new code written when the aggregate is put together from other objects. However, when the controlling unknown is passed in, it does not increment the reference count; instead it is a non-incrementing pointer.

The other objects can be implemented at any time. These noncontrol objects can be instantiated separately or as part of the aggregate. However, if these objects are to be capable of aggregation, they must be written to cooperate with the control object by forwarding their **QueryInterface**, **AddRef**, and **Release** calls to the controlling unknown. A reference count for the aggregate as a whole is maintained by the control object so that it is kept alive if there are one or more references to any of the interfaces supported by either the control or noncontrol objects.

It is possible for an object to call a method that may cause the object to be released. A technique known as "artificial reference counting" can be used to guard against this untimely release. The object calls **IUnknown::AddRef** before the potentially destructive method call and **IUnknown::Release** after it. If the object in question can be aggregated, it must call the controlling unknown's implementations of **AddRef** and **Release** (*pUnkOuter*->**AddRef** and *pUnkOuter*->**Release**) to artificially increment the reference count rather than its own implementations. For more information about reference counting, see Chapter 2, "The Component Object Model."

The next figure shows how the coordination between the control and noncontrol object works. The control object exposes the controlling unknown, Interface A and Interface B. The noncontrol object supports **IUnknown** and Interface C. All three interfaces derive from **IUnknown**.

The control object holds a pointer to the noncontrol object's **IUnknown** implementation so it can call the noncontrol methods when appropriate. The noncontrol object holds a pointer to the controlling unknown for the same reason. The pointer to the controlling unknown is supplied when the noncontrol object is instantiated. When the controlling unknown pointer is saved by the noncontrol object, **AddRef** is not called to increment the reference count as you might expect. This is because of the reference-counting cycle it would create. Instead, the noncontrol object just keeps a copy of the pointer and delegates calls to it as described in this section.

Referring again to the next figure, whereas the controlling unknown is available to the outside, as is indicated by the line and circle identifying it extending past the bounds of the aggregate, the noncontrol object's **IUnknown** implementation works locally and can't be obtained from outside the aggregate. It is called solely by the controlling unknown to obtain instances of the noncontrol interfaces, such as Interface C, to expose to the outside.

{ewc msdncd, EWGraphic, group10505 1 /a "SDK.wmf"}

Aggregation and Cached Interface Pointers

Interface-based reference counting has generally been a preferable way of keeping OLE objects stable, although 16-bit aggregates have proven troublesome. However, 32-bit OLE applications can overcome this difficulty with relative ease. For example, when a control object holds an interface pointer to a noncontrol object and the reference count has not been incremented, the pointer is said to be cached. In 16-bit OLE applications, this is achieved by calling **QueryInterface** to get the cached pointer and then releasing it in the following manner:

```
// 16-bit method for caching pointers to interfaces on noncontrol
// objects
IInterface1 *m_pi1;
m_pUnkInner->QueryInterface(IID_Interface1, &m_pi1);
m_pi1->Release();
```

To facilitate the use of per-interface reference counting in 32-bit OLE, the method for caching interface pointers has changed, as shown in the following:

```
// 32-bit method for caching pointers to interfaces on noncontrol
// objects.
IInterface1 *m_pi1;
m_pUnkInner->QueryInterface(IID_Interface1, &m_pi1);
m_pUnkOuter->Release();       \\ Uses the same m_pUnkOuter given to
                              \\ the aggregated object.
```

The difference is in the third line of code. Furthermore, when a cached pointer is released, include the following lines (no equivalent actions are done for 16-bit applications at the same point):

```
m_pUnkOuter->Addref();
m_pi1->Release();
```

Note These two approaches are not compatible; all 16-bit aggregate control objects must use the first method and all 32-bit aggregate control objects must use the second one.

Note that interface-based reference counting works best when control objects delay the acquisition of cached pointers and release them when there is no possible use for them.

During the destruction of any aggregate, even those in which the control object does not cache pointers, the control object must guard the destructor by means of artifical reference counting, as shown below:

```
ULONG Release_ObjectXXX(ObjectXXX *this)
{
     if(- -this->m_refs;
     {
           ++this->m_refs;
           ...destroy the instance..
     return 0;
     }
     return this->m_refs;
}
```

This code must be included because the sequence **m_pUnkOuter->AddRef()** followed by **m_pi1->Release** increments and decrements the reference count of the aggregate as a whole. Since this may occur in the destruction of the aggregate itself, the destructor must be guarded.

Note You cannot use this technique for noncontrol objects to hold cached pointers to objects higher up in the aggregate. The noncontrol object has no way of determining whether it has the same *pUnkOuter* as any other object in the aggregate. Although this is usually the case, it cannot be guaranteed.

Aggregation is entirely optional, and you should decide whether to use it as you design each object. However, providing support for aggregation costs little in time and complexity. The reward is larger than the cost in that aggregation enables the effective re-use of interface implementations. The key in implementing an aggregate object is making the correct delegation decision in both the aggregated and non-aggregated situations.

The following code example is an aggregate object implemented using C++ nested classes. The constructor takes as an argument the pointer to the control object's **IUnknown** implementation, or controlling unknown. If this pointer is NULL, indicating that the new object is not being aggregated, the *m_pUnkOuter* member is set to the address of *m_Unknown*, the local implementation of **IUnknown**. If *pUnkOuter* is not NULL, indicating that the new object is being aggregated, *m_pUnkOuter* is set to *pUnkOuter*. The Interface A implementations of the **IUnknown** methods forward their calls to the controlling unknown implementations. The controlling unknown **IUnknown** implementation manages queries for interfaces for the aggregate and maintains a master reference count.

```
class CAggregateObj
{
public:

Grouping Interfaces

Interface relationships are based on the ability to successfully obtain interface pointers by using **IUnknown::QueryInterface**. Although interface implementors are advised to design objects in such a way that interfaces are accessible from many other interfaces, there is generally no guarantee to a user that a specific interface is accessible from another interface. Implementations of **QueryInterface** are application-specific, so it usually cannot be assumed that it returns a pointer to another specific interface.

Two interfaces can be related in one of three possible ways. Each of these is set forth in the following list, using Interfaces named A and B as examples. Notice the importance of reference counting in managing the three types of relationships.

1. Given a pointer to Interface A, it **should** be possible to obtain a pointer to Interface B. Interface A and Interface B are managed by a single reference count. OLE defines the following interfaces that fall in this category:
   - **IOleObject**, **IDataObject**, **IViewObject**, **IOleCache**, **IOleInPlaceObject**, and **IPersistStorage**. If the object is a link, **IOleLink** should also be available.
   - **IPersistFile** and **IOleItemContainer**
   - **IOleClientSite** and **IOleInPlaceSite**
2. Given a pointer to Interface A, it **must not** be possible to obtain a pointer to Interface B. Interface A and Interface B can be managed by either a single reference count or separate reference counts. **IOleInPlaceActiveObject** and **IOleInPlaceObject** fall in this category. **IStorage** and **IStream**, typically implemented by OLE, also fall in this category, simply because they point to different objects.
3. Given a pointer to Interface A, it might be possible to obtain a pointer to Interface B, depending on the implementing application. Interface A and Interface B can be managed by a single reference count. Clients of the interfaces **cannot** assume it is always possible to obtain the same set of interfaces in this category from all implementing applications. The decision to group these interfaces is up to the implementor, and there is no guarantee they will be implemented in the same manner by all applications.

All OLE interfaces not specifically mentioned as belonging to the first or second groups belong to the third type. These interfaces can be grouped in a manner that works best for the application. It is wise to implement interfaces together whenever possible, because doing so leads to greater flexibility and interconnectivity. Implementing interfaces together implies they are within a single object supported by one piece of memory. The interfaces share one **IUnknown::QueryInterface** implementation that recognizes all related interfaces. Pointers to the interfaces are managed by a single reference count.

An object that has multiple groups of interfaces, each managed by its own reference count, is kept alive if there is at least one reference to any interface in one of the groups.

There are two possible approaches to interfaces that cannot be implemented together. They can be implemented either in separate objects, or in a single object that manages the interfaces independently. In the single object approach, there can be one **IUnknown::QueryInterface** implementation or several, depending on the number of interface groups in the object. In the single **QueryInterface** implementation, explicit steps must be taken to return pointers only to related interfaces.

Converting Mapping Modes

In Windows, mapping modes define how numbers relating to object sizes are to be passed and interpreted. The 32-bit version of OLE uses only one mapping mode, MM_HIMETRIC. The other Win32 mapping modes include MM_HIENGLISH, MM_LOENGLISH, MM_LOMETRIC, TWIPS, and PIXEL Modes (MM_ISOTROPIC and MM_ANISOTROPIC being PIXEL modes). When working with the visual presentation of OLE data, it is important to be aware of the mapping mode that OLE uses and how this mapping mode affects an application.

The mapping modes communicate physical sizes. For example, if an application using MM_HIMETRIC is to display a line ten centimeters long, the number of units would be 10,000. However, the line drawn on the screen would be ten centimeters long, regardless of the size of the video display area. The printed output would also be a line ten centimeters long.

Note For those applications that use a mapping mode other than MM_HIMETRIC, the sample user interface library provides some functions that can be used to convert objects to and from MM_HIMETRIC units.

Because people read display screens from a greater distance than they do printed copy, most applications written for Windows display text in a larger size than they print it, using what is commonly referred to as *logical resolution*. For example, a ten-point font is easy enough to read on the printed page, but generally appears too small on a screen for comfortable reading. To afford more comfortable viewing, applications typically expand the size of the displayed text to some logical size. Using this approach, a column of text that is physically six inches wide might be eight inches wide on the screen, yet still print as a six-inch column.

While this display-enlargement scheme works well from the user's point of view, a problem can occur when pasting objects into container documents. It is possible to lose the correct size ratio between the pasted object and the text owned and displayed by the container. The result is that the container's text is scaled up for readability but the pasted object might not be. Consequently, applications must preserve the relative size and position of text and objects, meaning that if text uses logical resolution, it should scale objects accordingly.

In the examples shown in the figure below, a chart object has been pasted from a source application that uses physical size into documents of two different containers that use logical resolution for display of the text. The container displaying the object on the left has scaled up the chart object to the logical size of the adjacent text to maintain the object/text size ratio. That is, it has been enlarged from its physical size by an amount that maintains its proportion to the text of the container document. In the document on the right, the application displays the chart object at its physical size, with no scaling to logical resolution for display. Both documents print with the correct object-to-text-size ratio.

{ewc msdncd, EWGraphic, group10505 2 /a "SDK.wmf"}

In OLE, the units for specifying the size of drawn objects is MM_HIMETRIC, which means object sizes are in physical units. However, containers need not use the MM_HIMETRIC mapping mode to draw pasted objects to the display. Rather, they should should map objects to the screen in the same manner as text. That is, if the container application displays text to the screen using a mapping mode that enlarges it, objects should be mapped to the display in the same manner. Using the same mapping mode for both the text and objects is required to establish the correct object-to-text ratio as shown in the document on the left side of the preceding figure. Because most Windows applications use logical resolution for this type of display mapping, we suggest that OLE containers also use logical resolution and set up their mapping modes and coordinate transforms accordingly. This allows objects to be moved from one application to another without changing their displayed size.

OLE Property Sets

Property sets store information in such a way that any conforming program can later manipulate the information. Examples of property sets are the character-formatting properties in a word processor or rendering attributes of an element in a drawing program. OLE does not provide any code or interfaces for manipulating property sets, it only specifies a standard data format structure.

Structure of Property Sets

Property sets are made up of a tagged section of values, with the section uniquely identified by a Format Identifier (FMTID). Every property consists of a *property identifier* and a *type indicator* that represents a *value*. Each value stored in a property set has a unique property identifier that names the property. The type indicator describes the representation of the data in the value. For example, if a specific property in a property set holds an animal's scientific name, that name could be stored as a zero-terminated string. Stored along with the name would be a type indicator to indicate the value is a zero-terminated string. The representation of properties is shown below:

Property Identifier	**Type Indicator**	**Value Represented**
PID_ANIMALNAME	VT_LPSTR	Zero-terminated string
PID_LEGCOUNT	VT_I2	WORD

Any application that recognizes the property set format can look at the property with an ID of PID_ANIMALNAME, determine it is a zero-terminated string, and read and write the value. Of course, the given application might not have any information about the property. The standard structure defined by OLE for property sets is generic as it relates to the semantics of the properties being represented; it says nothing about what they mean.

Each property set can have a dictionary associated with it to provide a displayable name for each property ID in the set. An application can read and write this dictionary and can allow end users to choose the displayable names for property IDs.

Examples of Using Property Sets

To illustrate the diverse functionality of property sets, this section presents two samples. The first uses the OLE Document Summary Information property set to show how property sets can be stored within files to allow common access to the information represented. The second example shows how property sets can be transferred between applications or OLE objects as an effective means of communication.

Storing Document Summary Information

The Document Summary Information property set is one of the simplest and most commonly used property sets. Most documents created by applications have a common set of attributes that are useful to users of those documents. These attributes include the name of the document's author, the subject of the document, when it was created, and so on.

In Windows 3.1, each application has a different way of storing this information within its documents. To examine the summary information for a given document, the user has to run the application that created the document, open it, and invoke the application's Summary Information dialog box. For example, the summary information dialog boxes that Microsoft Word 2.0 displays for its documents are shown in the following drawings:

{ewc msdncd, EWGraphic, group10506 0 /a "SDK.wmf"}

{ewc msdncd, EWGraphic, group10506 1 /a "SDK.wmf"}

Unfortunately, no application but Microsoft Word 2.0 can display the summary information for a Microsoft Word 2.0 document. However, with OLE property sets, this limitation can be overcome. This appendix describes one standard property set, the OLE Document Summary Information Property Set. Any application that understands the data format for this property set will be able to access the summary information contained in any document created by an OLE application that also understands the format.

For example, Microsoft Word 6.0 and many other OLE-enabled applications now save their documents using OLE structured storage and the property set standard described here. Thus, applications other than Word 6.0 are able to display the summary information property set for such a file, as long as that file is an OLE structured storage file, and the creating application saved the information in the OLE Property Set format.

For more information about the Document Summary Information property set and implementing it in your applications, see "Guidelines for Implementing the Document Summary Information Property Set" later in this appendix.

Transferring Data Contained in Property Sets

Storing information about the contents of a document is useful, and a standard that would allow all files to share the same information with all applications would be even better. However, this is only one example of how property sets can be used.

Another use for them is in the transfer of data between OLE objects or applications. To better understand the process of transferring data between two OLE objects, consider the following example. A trader on Wall Street relies on large amounts of data to make important financial decisions regarding trades of securities. This market data must be delivered to the trader's workstation in real time (or at least very soon after it was generated).

Assume that, at any given moment during an open day on Wall Street, the trader is interested in the opening, high, low, current, and last closing price of an instrument (a specific stock), and the volume of trading on that stock so far that day. The symbol for the stock will also be needed.

As noted earlier, a property in a property set has three attributes: the property identifier, a value type indicator, and a value. In this example, the following properties can be defined:

Property Identifier	Type Indicator	Value Represented
PID_SYMBOL	VT_LPSTR	Zero-terminated string
PID_OPEN	VT_CY	Currency value
PID_CLOSE	VT_CY	Currency value
PID_HIGH	VT_CY	Currency value
PID_LOW	VT_CY	Currency value
PID_LAST	VT_CY	Currency value
PID_VOLUME	VT_I4	32-bit unsigned integer

Without worrying about how the data is transferred between the data server and the trader's application, think about the data transferred and its format. Every property set must have a FMTID associated with it.

A single data element representing the stock of XYZ during the day might look like this:

```
PID_SYMBOL  contains "XYZ"
PID_OPEN    contains 42-3/4
PID_CLOSE   contains 42-3/4
PID_HIGH    contains 49-1/8
PID_LOW     contains 40-7/8
PID_LAST    contains 47-3/8
PID_VOLUME  contains 123,032
```

During a trading day on Wall Street only a few of the properties of a single instrument change. The opening price doesn't change all day, and the low price may go unchanged for several hours. Using property sets as the data transfer format allows applications to transfer only the data that has changed. For example, at some point during the day the Data Server may update the Traders Application by transferring the following StockQuote property set:

```
PID_SYMBOL  contains "XYZ"
PID_HIGH    contains 49-1/8
PID_LAST    contains 49-1/8
PID_VOLUME  contains 23,321
```

This example demonstrates how property sets can be used as a data transfer format, allowing sparse data representation. Transferring only the changed data enhances the overall performance of the trader's workstation.

Other Uses for Property Sets

Just about any object in the system can be tagged with properties. For example, a printer object can have a property set that includes such information as Location. A user object can have a property set including information like First Name, Last Name, Office, and Phone.

Applications can be written to query a system-wide set of objects based on their properties, for example, displaying all printers located in a certain building.

These examples illustrate the potential power of using property sets.

Notes on Using Property Sets

OLE property sets were designed to store data that is suited to representation as a moderately-sized collection of fine-grained values. Data sets that are too large for this to be feasible should be broken into separate streams and/or storages. The OLE property set data format was not meant to provide a substitute for a database of millions of tiny objects.

OLE Property Set Specification

All data elements within a property set are stored in Intel representation (that is, in little-endian byte order).

OLE defines a standard, serialized data format for property sets, which gives them the following characteristics:

- Property sets allow for different applications to create their own independent property sets to serve the application's needs.
- Property sets can be stored in a single **IStream** instance or in an **IStorage** instance containing multiple streams. Indeed, in the abstract, property sets are simply another data type that can be stored in many different forms of an in-memory or on-disk storage. For recommended conventions on creating the string name for the storage object, see the section "Naming Property Sets" later in this appendix.
- Property sets can be transmitted using the **IDataObject** interface and/or the Clipboard. Because property sets are self-identifying, they are ideal for transferring data between applications.
- Property sets allow for a dictionary of displayable names to be included to further describe the contents. A set of conventions for choosing property names are recommended. For more information on this optional dictionary, see "Property ID Zero" later in this appendix.

The figure below shows the overall structure of a property set:

The property set stream is divided into three major parts:

- Header
- FORMATID/offset pair
- Section containing the actual property set values

The overall length of the property set stream is 256Kb. The following sections of this chapter describe the individual components that make up the property set data format as shown in the previous figure.

Note Previous versions of this document described extensions to the property set stream with more than one section allowed, but that has been revised now to provide for one section in the property stream.

Property Set Header

At the beginning of the property set stream is a header. It consists of a byte-order indicator, a format version, the originating operating system version, the CLSID, and a reserved field. Each offset is the distance in bytes from the start of the whole stream to where the section begins.

The following pseudo-structure illustrates the header:

```
typedef struct tagPROPERTYSETHEADER
{
     // Header
     WORD  wByteOrder ;  // Always 0xFFFE
     WORD  wFormat ;     // Always 0
     WORD  dwOSVer ;     // System version
     CLSID  clsID ;      // Application CLSID
     DWORD  reserved ;   // Should be 1
} PROPERTYSETHEADER;
```

Byte-Order Indicator

The byte-order indicator is a WORD and should always hold the value 0xFFFE. This is the same as the Unicode byte-order indicator. This value is always written in Intel byte order and, thus, appears in the file or stream as 0xFE, 0xFF.

Format Version

The Format Version is a WORD used to indicate the format version of this stream. It should always be zero. The format-version indicator should be checked when reading the property set. If it is not zero, then the stream was written to a different specification and cannot be read by code developed according to the OLE 2 specification.

Originating OS Version

This DWORD should hold the kind of operating system in the high word and the version number of the operating system in the low word. Possible values for the operating system are:

Operating System	Value
32-Bit Windows (Win32)	0x0002
Macintosh	0x0001
16-Bit Windows (Win16)	0x0000

For Windows, the operating system version is the low order word returned by the **GetVersion** function. On Windows, the following code would correctly set the version of the originating operating system:

```
#ifdef WIN32
dwOSVer = (DWORD)MAKELONG( LOWORD(GetVersion()), 2 ) ;
#else
dwOSVer = (DWORD)MAKELONG( LOWORD(GetVersion()), 0 ) ;
#endif
```

CLSID

The CLSID is that of a class that can display and/or provide programmatic access to the property values. If there is no such class, it is recommended that you set this value the same as the Format ID (see below). Alternately, you can set this value to all zeroes; however, using the Format ID allows more flexibility in the future.

Reserved

This DWORD is reserved for future use. Writers of property sets should set this value to 1; readers of property sets should ensure that this value is at least 1.

Format Identifier/Offset Pair

The second part of the property set stream contains one Format Identifier (FMTID)/Offset Pair. The FMTID is the name of the property set; it uniquely identifies how to interpret the contents of the following section. The Offset is the distance of bytes from the *start of the whole stream* to where the section begins.

The following structure is helpful in dealing with Format Identifier/Offset Pairs:

```
typedef struct tagFORMATIDOFFSET
{
     FMTID  fmtid ;     // The name of the section.
     DWORD  dwOffset ;  // The offset for the section
} FORMATIDOFFSET;
```

Format Identifiers

Property set values are stored in a section that is tagged with a unique format identifier. For example, the FMTID for the OLE Document Summary Information property set is:

```
F29F85E0-4FF9-1068-AB91-08002B27B3D9
```

To define a FMTID for the Document Summary Information property set, you would use the **DEFINE_GUID** macro in an include file for the code that manipulates the property set:

```
DEFINE_GUID(FormatID_SummaryInformation, 0xF29F85E0, 0x4FF9, 0x1068, 0xAB,
0x91, 0x08, 0x00, 0x2B, 0x27, 0xB3, 0xD9);
```

Anywhere in your code you need to use the FMTID for the Document Summary Information property set, you can access it through the FormatID_SummaryInformation variable.

When storing property sets in **IStorage** instances, you need to convert the FMTID to a string name for the storage object. For more information on recommended conventions for creating the string name, see the section "Naming Property Sets" later in this appendix.

Allocating Format Identifiers

FMTIDs are created and represented in the same way as OLE CLSIDs and interface IDs. To create a unique FMTID, use the UUIDGEN.EXE program included in the *Win32 SDK*.

Section

This is the third part of the property set stream, as shown in Figure C.2. A section contains:

- byte count for the section (which is inclusive of the byte count itself)
- count of the property values in the section
- array of 32-bit Property ID/Offset pairs
- array of property Type Indicators/Value pairs

Offsets are the distance from the start of the section to the start of the property (type, value) pair. This allows a section to be copied as an array of bytes without any translation of internal structure.

The following pseudo-structures illustrate the format of a section:

```
typedef struct tagPROPERTYSECTIONHEADER
{
     DWORD  cbSection ;    // Size of Section
     DWORD  cProperties ;  // Count of Properties in section
} PROPERTYSECTIONHEADER;

typedef struct tagPROPERTYIDOFFSET
{
     DWORD  propid;   // Name of property
     DWORD  dwOffset; // Offset from start of section to that property
} PROPERTYIDOFFSET;

typedef struct tag SERIALIZEDPROPERTYVALUE
{
     DWORD  dwType;  // Property Type
     BYTE  rgb[];    // Property Value
} SERIALIZEDPROPERTYVALUE ;
```

Size of Section

This DWORD indicates the size of the section. Because the section size is the first four bytes, you can copy sections as an array of bytes.

For example, an empty section (one with zero properties in it) would have a byte count of eight (the DWORD byte count and the DWORD count of properties). The section itself would contain the eight bytes:

```
08 00 00 00 00 00 00 00
```

Count of Properties

This DWORD gives a count of the property values in the section. A property set may contain any number of property values. Readers must be able to handle the case where there are zero properties.

Property ID/Offset Pairs

Following the Count of Properties is an array of Property ID/Offset Pairs. Property IDs are 32-bit values that uniquely identify a property within a section. The Offsets indicate the distance from the start of the section to the start of the property Type/Value Pair. If the offsets are relative to the section, sections can be copied as an array of bytes.

Property IDs are not sorted in any particular order. Properties can be omitted from the stored property set; readers must not rely on a specific order or range of property IDs.

Type Indicators

After the table of Property ID/Offset Pairs comes the actual properties. Each property is stored as a DWORD type followed by the data value.

Type indicators and their associated values are defined in the OLE header files that are shipped with the *Win32 SDK*.

All Type/Value pairs must begin on a 32-bit boundary. Thus values may be followed with null bytes to align the subsequent pair on a 32-bit boundary. Given a count of bytes, the following code will calculate how many bytes are needed to align on a 32-bit boundary:

```
cbAdd = (((cbCurrent + 3) >> 2) << 2) - cbCurrent ;
```

Within a vector of values, each repetition of value must align with its natural alignment rather than with a 32-bit alignment. In practice, this is only significant for types VT_I2 and VT_BOOL (which have two-byte natural alignment). All other types have four-byte natural alignment. Therefore, a property value with type indicator VT_I2 | VT_VECTOR would be:

- A DWORD element count, followed by
- A sequence of packed two-byte integers with no padding between them.

A property value of type identifier VT_LPSTR | VT_VECTOR would be:

- A DWORD element count (**DWORD** *cch*), followed by
- A sequence of strings (**char** *rgch*[]), each of which may be followed by null padding to round to a 32-bit boundary.

The following table lists the standard OLE-defined property type indicators and their meaning:

Type Indicator	Code	Value Representation
VT_EMPTY	0	None. A property set with a type indicator of VT_EMPTY has no data associated with it; that is, the size of the value is zero.
VT_NULL	1	None. This is like a pointer to NULL.
VT_I2	2	Two bytes representing a 2-byte signed int value. This value will be zero-padded to a 32-bit boundary.
VT_I4	3	Four bytes representing a 4-byte signed int value.
VT_R4	4	Four bytes representing a 32-bit IEEE floating point value.
VT_R8	5	Eight bytes representing a 64-bit IEEE floating point value.
VT_CY	6	Eight-byte two's complement integer (scaled by 10,000). This type is commonly used for currency amounts.
VT_DATE	7	Time format used by many applications, it is a 64-bit floating point number representing days since December 31, 1899. This is stored in the same representation as VT_R8. For example, January 1, 1900 is 2.0, while January 2, 1900 is 3.0, and so on.

VT_BSTR	8	Counted, zero-terminated binary string; represented as a DWORD byte count (including the terminating null character) followed by the bytes of data.
VT_BOOL	11	Two bytes representing a Boolean (WORD) value containing 0 (FALSE) or -1 (TRUE). This type must be zero-padded to a 32-bit boundary.
VT_VARIANT	12	Four-byte indicator followed by the corresponding value. This is only used in conjunction with VT_VECTOR.
VT_I8	20	Eight bytes representing a signed integer.
VT_LPSTR	30	Same as VT_BSTR; this is the representation of most strings.
VT_LPWSTR	31	A counted and zero-terminated Unicode string; a DWORD character count (where the count includes the terminating null character) followed by that many Unicode (16-bit) characters. Note that the count is not a byte count, but a WORD count.

VT_FILETIME	64	64-bit **FILETIME** structure, as defined by Win32:
		typedef struct_FILETIME{
		  DWORD dwLowDateTime;
		  DWORD dwHighDateTime;
		}FILETIME;

VT_BLOB	65	DWORD count of bytes, followed by that many bytes of data. The byte count does not include the four bytes for the length of the count itself; an empty BLOB would have a count of zero, followed by zero bytes. This is similar to VT_BSTR but does not guarantee a null byte at the end of the data.
VT_STREAM	66	A VT_LPSTR (DWORD count of bytes followed by a zero-terminated string that many bytes long) that names the stream containing the data. The real value for this property is stored in a stream object, which is a sibling to the Contents stream. This type is only valid for property sets stored in the Contents stream of a storage object.
VT_STORAGE	67	A VT_LPSTR (DWORD count of bytes followed by a zero-terminated string that many bytes long) that names the storage containing the data. The real value for this property is stored in a storage object, which is a sibling to the Contents stream that contains the property set. This type is only valid for property sets stored in the Contents stream of a storage object.

VT_STREAMED_OBJECT	68	Same as VT_STREAM, but indicates that the stream object named in this property contains a serialized object, which is a CLSID followed by initialization data for the class. The named stream is a sibling to the Contents stream that contains the property set. This type is only valid for property sets stored in the Contents stream of a storage object.
VT_STORED_OBJECT	69	Same as VT_STORAGE, but indicates that the storage object named in this property contains an object. This type is only valid for property sets stored in the Contents stream of a storage object.
VT_BLOB_OBJECT	70	An array of bytes containing a serialized object in the same representation as would appear in a VT_STREAMED_OBJECT (VT_LPSTR). The only significant difference between this type and VT_STREAMED_OBJECT is that VT_BLOB_OBJECT does not have the system-level storage overhead as VT_STREAMED_OBJECT. VT_BLOB_OBJECT is more suitable for scenarios involving numerous small objects.
VT_CF	71	An array of bytes containing a Clipboard format identifier followed by the data in that format. That is, following the VT_CF identifier is the data in the format of a VT_BLOB. This is a DWORD count of bytes followed by that many bytes of data in the following format: a LONG followed by an appropriate Clipboard identifier and a property whose value is plain text should use VT_LPSTR, not VT_CF to represent the text. Notice also that an application should choose a single Clipboard format for a property's value when using VT_CF. For more information, see "Clipboard Format Identifiers," later in this appendix.
VT_CLSID	72	A CLSID, which is a DWORD, two WORDs, and eight bytes.
VT_VECTOR	0x1000	If the type indicator is one of the previous values in addition to this bit being set, then the value is a DWORD count of elements, followed by that many repetitions of the value. When VT_VECTOR is combined with VT_VARIANT (VT_VARIANT *must* be combined with VT_VECTOR) the value contains a DWORD element count, a

DWORD type indicator, the first value, a DWORD type indicator, the second value, and so on.

Examples:

VT_LPSTR | VT_VECTOR has a DWORD element count, a DWORD byte count, the first string data, a DWORD byte count, the second string data, and so on.

VT_I2 | VT_VECTOR has a DWORD element count followed by a sequence of two-byte integers, with no padding between them.

New Type Indicators

There is no provision in the OLE specification for adding new type indicators to the list above. However, new types can be defined by using the VT_VARIANT type combined with the VT_VECTOR flag. For example, assume you want to store the following packed structure in a property set:

```
typedef struct tagPACKED
{
     DWORD  dwValue1 ;  // 32 bit value
     WORD   wFlag ;     // 16 bits of flags
     WORD   wValue2 ;   // 16 bit value
} PACKED ;
```

This 64-bit structure could be stored using VT_VARIANT | VT_VECTOR as follows:

```
DWORD  // dwTypeIndicator = VT_VARIANT | VT_VECTOR ;
DWORD  // dwElementCount = 3 ;
DWORD  // dwTypeIndicator = VT_I4 ;
DWORD  // dwValue1 ;
DWORD  // dwTypeIndicator = VT_I2 ;
WORD   // wFlag ;
DWORD  // dwTypeIndicator = VT_I2 ;
WORD   // wValue2 ;
```

Reserved Property IDs

As a designer of property sets you can use any Property ID for your properties except 0, 1, 0xFFFFFFFE, and all negative values. These Property ID values are reserved for use by applications as follows.

Property ID Zero

To enable users of property sets to attach meaning to properties beyond those provided by the type indicator, property ID zero is reserved for an optional dictionary of displayable names for the property set.

The dictionary contains a count of entries in the list followed by a list of dictionary entries.

```
typedef struct tagDICTIONARY
{
     DWORD  cbEntries ;                    // Count of entries in the list
     ENTRY  rgEntry[ cbEntries ] ; // Property ID/String pair
} DICTIONARY ;
```

Each dictionary entry in the list is a Property ID/String pair. This can be illustrated using the following pseudo-structure definition for a dictionary entry (it's a pseudo-structure because the sz[] member is variable in size):

```
typedef struct tagENTRY
{
     DWORD  dwPropID ; // Property ID
     DWORD  cb ;       // Count of characters in the string
     char  sz[cb];     // Zero-terminated string
} ENTRY ;
```

Note the following about property set dictionaries:

- Property ID Zero does not have a type indicator. The DWORD that indicates the count of entries sits in the type indicator position.
- The count of characters in the string (cb) includes the zero character that terminates the string.
- The dictionary is entirely optional. Not all the names of properties in the set need appear in the dictionary. The dictionary can omit entries for properties assumed to be universally known by clients that manipulate the property set. Typically, names for the base property sets for widely accepted standards are omitted, but special purpose property sets may include dictionaries for use by browsers.
- Property names in the dictionary are stored in the code page indicated by Property ID One (see below). For all code pages other than the Unicode code page (1200), each name is byte aligned. Thus, there is no padding between property names with Property ID Zero. If the Unicode code page is specified, the property name strings must be aligned on 32-bit boundaries.
- Property names that begin with the binary Unicode characters 0x0001 through 0x001F are reserved for future use.

The dictionary is stored as a VT_BLOB | VT_VECTOR value. Each BLOB in the vector contains the prerequisite **DWORD** count of bytes followed by a **DWORD** indicating the Property ID followed by the name (a zero-terminated string).

Example Dictionary

The stock market data transfer example (see "Transferring Data Contained in Property Sets," earlier in this appendix) might include a displayable name of "Stock Quote" for the entire set, and "Ticker Symbol" for PID_SYMBOL. If a property set contained just a symbol and the dictionary, the property set section would have a byte stream that looked like the following:

```
Offset     Bytes
; Start of section
0000    43 01 00 00      ; DWORD size of section
0004    03 00 00 00      ; DWORD number of properties in section

; Start of PropID/Offset pairs
0008    00 00 00 00      ; DWORD Property ID (0 == dictionary)
000C    20 00 00 00      ; DWORD offset to property ID
0010    01 00 00 00      ; DWORD Property ID (1 == code page)
0014    D0 00 00 00      ; DWORD offset to property ID
0018    07 00 00 00      ; DWORD Property ID (i.e., PID_SYMBOL)
001C    34 01 00 00      ; DWORD offset to property ID

; Start of Property 0 (which is really the dictionary
0020    08 00 00 00    ; DWORD Number of entries in dictionary
                       ; (Note: No type indicator)
0024    00 00 00 00        ; DWORD dwPropID = 0
0028    18 00 00 00    ; DWORD cb = (wstrlen("Stock Quote")+1)
                       ;      * sizeof(WCHAR) == 24
002C    L"Stock Quote\0"    ; char sz[24]
0044    03 00 00 00     ; DWORD dwPropID = 3 (PID_SYMBOL)
0048    1C 00 00 00     ; DWORD cb = (wstrlen("Ticker Symbol") + 1
                        ;      * sizeof(WCHAR) == 28
004C    L"Ticker Symbol\0"    ; char sz[28]
     ; The dictionary would continue, but may not contain entries for
     ; every possible property. Also entries do not need to be in order
     ; (except dwPropID == 0 must be first).

; Start of Property 1 (code page indicator)
00D0    02 00 00 00    ; DWORD type indicator (VT_12)
00D4    B0 04 00 00    ; USHORT codepage (0x04B0 == 1200 == Unicode)

; Start of Property 7 (PID_SYMBOL)
0134     1E 00 00 00     ; DWORD type indicator (VT_LPWSTR == 1F)
0138     0A 00 00 00     ; DWORD count of bytes
013C    L"MSFT\0"        ; WCHAR sz[5] (incl 2 bytes for the NULL)
```

Property ID One

Property ID One is reserved as an indicator of which code page (Windows) or Script (Macintosh) to use when interpreting the strings in the property set. All string values in the property set must be stored with the same code page. The originating operating system value in the property set header (PROPERTYSETHEADER::dwOSVer) determines whether the code page indicator corresponds to a Windows code page or Macintosh script.

When an application that is not the author of a property set changes a property of type string in the set, it should examine the code page indicator and take one of the following actions:

- Write the new value using the code page found in the code page indicator.
- Rewrite all string values in the property set using the new code page (including the new value), and modify the code page indicator to reflect the new code page.

If an application cannot understand this indicator, it should not modify the property. All writers of property sets must write a code page indicator; however, if the code page indicator is not present, the prevailing code page on the reader's machine must be assumed.

Possible values for the code page are given in the Window 32 API (see the **GetACP** function) and *Inside Macintosh Volume VI,* §*14-111*. For example, the code page US ANSI is represented by 0x04E4 (1252 in decimal) while the code page for Unicode is 0x04B0 (1200 in decimal).

It is recommended that the Unicode code page be used whenever possible. Using the same code page for all property sets is the only way to achieve interoperable property sets on a worldwide basis. In the Unicode code page, note that the count at the start of a VT_LPSTR or VT_BSTR or other eight-bit character quantities in the property set is a **byte** count and not a **character** count. This byte count includes the two zero bytes at the end of the string.

Property ID one is a VT_12 type and thus starts with a DWORD containing the value VT_12 followed by a USHORT indicating the code page.

Property ID 0xFFFFFFFE

Property ID 0xFFFFFFFE (Locale Indicator) is reserved as an indication of the locale for which the property set is written. The default locale for a property set is the system's default locale (LOCALE_SYSTEM_DEFAULT). See the Win32 SDK for more information on LOCALE_SYSTEM_DEFAULT. The default is used in the event that the locale indicator does not exist in the property set.

Applications can choose to support the locale or just get the default behavior. It is recommended that applications allow users to specify a working locale. Such applications should write the user-specified locale identifier to the property. Applications that use the user's default locale (LOCALE_USER_DEFAULT) should write the user's default locale identifier to the property. See the Win32 SDK for more information on LOCALE_USER_DEFAULT.

Applications should also handle the case of a foreign object which is one where the locale is not the application's locale, the user's locale, or the system's locale.

The locale indicator property is of type VT_U4, and therefore consists of a DWORD containing VT_U4 followed by a DWORD containing the Locale Identifier (LCID) as defined in the Win32 SDK.

Other Reserved Property IDs

Property IDs with the high bit set (that is, negative values) are reserved for future use by Microsoft.

Clipboard Format Identifiers

There are five kinds of Clipboard FMTIDs that can occur in VT_CF values: Windows Clipboard Format Values, Macintosh Format Values, Format Identifiers, Clipboard Format Names, and No Format Name. The following table illustrates the representation of each of these five types:

First Four Bytes	Following Value Size	Meaning
-1L	4 bytes (DWORD)	Windows built-in Clipboard Format Value (CF_TEXT).
-2L	4 bytes (DWORD)	Macintosh Format Value (4-byte tag).
-3L	16 bytes (Format ID)	FMTID.
Length of String	Variable	Clipboard format name that has been registered by **RegisterClipboardFormat** (or some Macintosh equivalent, if any). The string length includes the null terminator.
0L	Zero	No format name.

Therefore, the format of a VT_CF value is:

```
DWORD cb ;               // count of bytes that follow (4 + cbTag +
                        // cbData)
DWORD cftag ;               // contains one of the five cftag values
                        // (0,-1,-2,-3, or positive)
BYTE rgcftag[ cbTag ] ;      // cbTag bytes representing the FMTID
BYTE rgData[ cbData ] ; // clipboard data in the specified format
```

For example, if a VT_CF property contained a 4235 byte bitmap that was stored in the Windows CF_DIB (0x08) Clipboard format, the count of bytes would be 4243 (4235 + 4 + 4) or 0x1093. The following stream of bytes would be stored:

```
93 10 00 00 FF FF FF FF 08 00 00 00 ?? ?? ?? ?? ?? ?? ...
|--- cb ---|-- cftag --|- rgcftag -|--- rgData (4235 bytes )...
```

Storing Property Sets

Applications can expose some of the state of their documents so that other applications can locate and read that information. Some examples are a property set describing the author, title, and keywords of a document created with a word processor, or the list of fonts used in a document. This facility is not restricted to documents; it can also be used on embedded objects.

Note If you are storing a property set that is internal to your application, you might not want to follow the guidelines described below. If you want to expose your property set to other applications, you need to follow the guidelines.

To store a property set in a compound file:

1. Create an **IStorage** or **IStream** instance in the same level of the storage structure as its data streams. Prepend the name of your **IStorage** or **IStream** instance with "\005." Stream and storage names that begin with 0x05 are reserved for common property sets that can be shared among applications. Also, streams beginning with that value are limited to 256Kb. The names can be selected from either published names and formats or by assigning the property set a FMTID and deriving the name from the FMTID according to the conventions described in the section "Naming Property Sets".
2. A property set may be stored in a single **IStream** instance or in an **IStorage** instance containing multiple streams. In the case of an **IStorage** instance, the contained stream named "Contents" is the primary stream containing property values, where some values may be names of other streams or storage instances within the storage for this property set.
3. Specify the CLSID of the object class that can display and/or provide programmatic access to the property values. If there is no such class, the the CLSID should be set to CLSID_NULL. For a property set that uses an **IStorage** instance, either set the CLSID of the **IStorage** instance to be the same as that stored in the Contents stream or to CLSID_NULL (the value in a newly created **IStorage** instance).
4. You have the option of specifying displayable names that form the contents of the dictionary.

Some applications can read only implementations of property sets stored as **IStream** instances. Applications should be written to expect that a property set may be stored in either an **IStorage** or **IStream** instance, unless the property set definition indicates otherwise. For example, the Document Summary Information property set's definition says that it can only be stored in a named **IStream** instance. In cases where you are searching for a property set and you don't know whether it is a storage or stream, look for an **IStream** instance with your property set name first. If that fails, look for an **IStorage** instance.

To better understand storing property sets in an **IStorage** implementation, suppose there is a class of applications that edit information about animals. First, a CLSID (CLSID_AnimalApp) is defined for this set of applications so they can indicate that they understand property sets containing animal information (FormatID_AnimalInfo) and others containing medical information (FormatID_MedicalInfo).

```
IStorage (File): "C:\OLE\REVO.DOC"
  IStorage: "\005AnimalInfo", CLSID = CLSID_AnimalApp
    IStream: "Contents"
      WORD dwByteOrder, WORD wFmtVersion, DWORD dwOSVer,
      CLSID CLSID_AnimalApp, DWORD cSections...
      ...
      FormatID = FormatID_AnimalInfo
      Property: Type = PID_ANIMALTYPE, Type = VT_LPSTR, Value = "Dog"
      Property: Type = PID_ANIMALNAME, Type = VT_LPSTR, Value = "Revo"
      Property: Type = PID_MEDICALHISTORY, Type = VT_STREAMED_OBJECT,
              Value = "MedicalInfo"
      ...
    IStream: "MedicalInfo"
      WORD dwByteOrder, WORD wFmtVersion, DWORD dwOSVer,
      CLSID CLSID_AnimalApp, DWORD cSections...
      ...
      FormatID = CLSID_MedicalInfo
      Property: Type = PID_VETNAME, Type = VT_LPSTR, Value = "Dr. Woof"
      Property: Type = PID_LASTEXAM, Type = VT_DATE, Value = ...
```

Note that the class IDs of the **IStorage** and both property sets is CLSID_AnimalApp. This identifies any application that can display and/or provide programmatic access to these property sets. Any application can read the information within the property sets (the point behind property sets), but only applications identified with the class ID of CLSID_AnimalApp can understand the meaning of the data in the property sets.

Naming Property Sets

Property sets are named with FMTIDs, but in **IStorage** and **IStream** instances, they are named with strings with a maximum length of 32 characters. As a result, you need to create string names corresponding to the FMTID.

To create a string name corresponding to the FMTID, first check to determine if the FMTID is one of a fixed set of established values. If it is an already established value, then use the corresponding string name as follows:

FMTID	String Name	Meaning
F29F85E0-4FF9-1068- AB91-08002B27B3D9	"\005SummaryInformation"	OLE Summary Information.

With the exception of the SummaryInformation property set (described in the following section), all other stream and storage objects used to store property sets should be named using the algorithm described in the following steps. The algorithm maps the 16-byte FMTID of the property set to a 31-character string. Storage and stream objects are restricted to 32-character names.

1. Convert the FMTID to little-endian byte order if necessary.
2. Take the 128 bits of the FMTID and treat them as one long bit string by concatenating each of the bytes together. The first bit of the 128 bit value is the most significant bit of the first byte in memory of the FMTID. The last bit of the 128 value is the least significant bit of the last byte in memory of the FMTID.
3. Extend these 128 bits to 130 bits by adding two zero bits to the end.
4. Divide the 130 bits into groups of five bits. There will be 26 groups of five bits each.
5. Consider each of the 26 groups as an integer value and use it as the index into the following array of 32 characters:

   ```
   ABCDEFGHIJKLMNOPQRSTUVWXYZ012345
   ```

   This results a sequence of 26 Unicode characters (one character from each of the 26 groups). Only the uppercase alphabet and numerals are used. No two characters in this range will compare as equal in any locale even when case is ignored.
6. Concatenate "\005" with the resulting 26-character string from step 5 for a total string length of 27 characters.

Note To be compatible with future versions of the operating system, you need to follow the mapping scheme described here.

The following code illustrates this process:

```
#define CCH_MAP         (1 << CBIT_CHARMASK)          // 32
#define CHARMASK        (CCH_MAP - 1)                 // 0x1f
#define CBIT_BYTE             8
#define CBIT_CHARMASK   5
#define CBIT_GUID       (CBIT_BYTE * sizeof(GUID))
#define WC_PROPSET0     ((WCHAR) 0x0005)
#define CWC_PROPSET     (1 + (CBIT_GUID + CBIT_CHARMASK-1)/CBIT_CHARMASK)
#define CWC_PROPSETSZ   (CWC_PROPSET + 1)            // allow null

CHAR awcMap[CCH_MAP + 1] = "abcdefghijklmnopqrstuvwxyz012345";
#define CALPHACHARS           ('z' - 'a' + 1)
```

```
GUID guidSummary =
    { 0xf29f85e0,
      0x4ff9, 0x1068,
      { 0xab, 0x91, 0x08, 0x00, 0x2b, 0x27, 0xb3, 0xd9 } };

WCHAR wszSummary[] = L"SummaryInformation";

// ---------------------------------------------------------------------
// Function:    GuidToPropertySetName
//
// Synopsis:    Map property set GUID to null-terminated UNICODE name
string.
//
//    The awcname parameter is assumed to be a buffer with room for
//    CWC_PROPSETSZ (28) UNICODE characters.  The first character
//    is always WC_PROPSET0 (0x05), as specified by the OLE Appendix
//    C documentation.  The colon character normally used as an NT
//    stream name separator is not written to the caller's buffer.
//
// Arguments:   IN GUID *pguid      -- pointer to GUID to convert
//    OUT WCHAR awcname[] -- output string buffer
//
// Returns:     count of non-NULL characters in the output string buffer
//----------------------------------------------------------------------

    }
      }
      Status = NO_ERROR
  }
    }
fail:
    return(Status);
}
```

The Document Summary Information Property Set

OLE defines a standard common property set for storing summary information about documents. The Document Summary Information property set must be stored in an **IStream** instance off of the root storage object; it is not valid to store the property set in the "Contents" stream of a named **IStorage** instance.

All shared property sets are identified by a stream or storage name prepended with "\005" (or 0x05) to show it is a property set shareable among applications and the Document Summary Information property set is no exception. The name of the stream that contains the Document Summary Information property set is:

```
"\005SummaryInformation"
```

The FMTID for the Document Summary Information property set is:

```
  F29F85E0-4FF9-1068-AB91-08002B27B3D9
```

Use the DEFINE_GUID macro to define the FMTID for the property set:

```
DEFINE_GUID(FormatID_SummaryInformation, 0xF29F85E0, 0x4FF9, 0x1068, 0xAB,
0x91, 0x08, 0x00, 0x2B, 0x27, 0xB3, 0xD9);
```

On an Intel byte-ordered machine, the FMTID has the following representation:

```
  E0 85 9F 4F 68 10 AB 91 08 00 2B 27 B3 D9
```

The following table shows the property names for the Document Summary Information property set, along with the respective property IDs and type indicators.

Property Name	Property ID	Property ID Code	Type
Title	PID_TITLE	0x00000002	VT_LPSTR
Subject	PID_SUBJECT	0x00000003	VT_LPSTR
Author	PID_AUTHOR	0x00000004	VT_LPSTR

Guidelines for Implementing the Document Summary Information Property Set

The following guidelines pertain to the Document Summary Information property set described in the preceding section:

- PID_TEMPLATE refers to an external document containing formatting and styling information. The means by which the template is located is implementation defined.
- PID_LASTAUTHOR is the name stored in User Information by the application. For example, suppose Mary creates a document on her machine and gives it to John, who then modifies and saves it. Mary is the author, John is the last saved by value.
- PID_REVNUMBER is the number of times the File/Save command has been called on this document.
- PID_CREATE_DTM is a read-only property; this property should be set when a document is created, but should not be subsequently changed.
- For PID_THUMBNAIL, applications should store data in CF_DIB or CF_METAFILEPICT format. CF_METAFILEPICT is recommended.
- PID_SECURITY is the suggested security level for the document. By noting the security level on the document, an application other than the originator of the document can adjust its user interface to the properties appropriately. An application should not display any information about a password protected document or allow modifications to enforced read-only or locked-for-annotations documents. Applications should warn the user about read-only recommended if the user attempts to modify properties:

Security Level	**Value**
None	0
Password protected	1
Read-only recommended	2
Read-only enforced	3
Locked for annotations	4

Registering Object Applications

To become functional, object applications must register in the Microsoft® Windows® registry. The registry contains information about the application that is needed to support OLE features. This chapter discusses registering object applications and describes OLE registry entries and the subkeys under which they are entered.

Your installation/setup program must add information to the registry, and its associated subkeys, if it is to perform any of the three following types of installations:

- Installing an object application.
- Installing a container/object application.
- Installing a container application *that allows linking to its embedded objects*.

In all three cases, you must register OLE 2 library (DLL) information as well as application-specific information.

The subkeys are contained in the following registry keys:

HKEY_CLASSES_ROOT\CLSID
HKEY_CLASSES_ROOT\Interface

Note that **HKEY_CLASSES_ROOT** provides compatibility with Windows 3.1 and Windows 95.

For information about OLE registry functions, refer to the following API functions:

- **CoGetTreatAsClass**
- **CoTreatAsClass**
- **OleDoAutoConvert**
- **OleGetAutoConvert**
- **OleSetAutoConvert**
- **SetConvertStg**
- **GetConvertStg**
- **OleRegGetUserType**
- **OleRegEnumFormatEtc**
- **OleRegGetMiscStatus**
- **OleRegEnumVerbs**

For information on the registry, the structure of registry entries, and registry functions, refer to the *Microsoft Win32 Programmer's Reference*.

New Registry Subkeys for 32-bit OLE

This section describes changes made to the Windows NT™ registry to allow it to support 32-bit OLE. The Windows NT registry introduces new subkeys that are specific to 32-bit applications. Otherwise, a 32-bit application is registered in exactly the same manner as a 16-bit application.

The subkeys that are support 16-bit OLE applications are:

LocalServer	Full path to the application '16- or 32-bit'.
InprocServer	Registers a 16-bit in-process server DLL.
InprocHandler	Registers a 16-bit handler DLL.
ProxyStubClsid	Maps an IID to a CLSID in a 16-bit proxy DLL.

For 32-bit OLE applications, the following registry subkeys are added:

LocalServer32	Full path to the application '32-bit'.
InprocServer32	Registers a 32-bit in-process server DLL.
InprocHandler32	Registers a 32-bit handler DLL.
ProxyStubClsid32	Maps an IID to a CLSID in a 32-bit proxy DLL.

Registry Support for 32-bit OLE

The Insertable subkey is a required subkey for 32-bit OLE applications whose objects can be inserted into existing 16-bit applications. Existing 16-bit applications look in the registry for the Insertable key. This key informs the application that the server supports embeddings. If the Insertable key exists, 16-bit applications may also attempt to verify that the server exists on the machine. 16-bit applications typically will retrieve the value of the LocalServer key from the class, and check to see if it is a valid file on the system. Therefore, in order for a 32-bit implementation to be insertable by a 16-bit application, the 32-bit application should register the LocalServer subkey in addition to registering LocalServer32.

For 32-bit local servers, the required entries are InprocHandler32, LocalServer, LocalServer32, and Insertable. For a 32-bit InprocServer, the required entries are InprocHandler32, InprocServer, InprocServer32, and Insertable. Note that the LocalServer entry and the InprocServer entry provide backward compatibility. If they are missing, the class still works, but can't be inserted in 16-bit applications. The InprocServer32 key has a ThreadingModel subkey to support more than one thread per process. See the section "The CLSID Key and Subkeys" later in this appendix for more information.

If a container is searching the registry for a local server, a 32-bit local server has priority over a 16-bit local server. With InprocHandlers and InprocServers, the 16-bit versions have priority with a 16-bit container, and 32-bit versions have priority with a 32-bit container.

Note that ProxyStubClsid32 is required because the IID-to-CLSID mapping may be different for 16- and 32- bit interfaces. The IID-to-CLSID mapping depends on the way the interface proxies are packaged into a set of proxy DLLs.

OLE Registry Entries

This section describes the following OLE registry entries:

- Programmatic Identifiers
- The ProgID Key and Subkeys
- The CLSID Key and Subkeys
- The Version-Independent ProgID Key and Subkeys
- The File Extension Key
- The (Non-Compound) FileType Key and Subkeys
- The New Interface Key and Subkeys

Programmatic Identifiers

Every OLE 2 object class that is to appear in an Insert Object dialog box (also referred to as an "insertable class") must have a programmatic identifier or *ProgID*. This string uniquely identifies a given class and is intended to be in a form that can be read by users. Programmatic identifiers are not guaranteed to be universally unique so they can be used only where name collisions are manageable, such as in achieving compatibility with OLE 1. Also, the ProgID is the "class name" used for an OLE 2 class when it is placed in an object application (OLE 1 server).

The ProgID string must:

- Have no more than 39 characters.
- Contain no punctuation (including underscores) except one or more periods.
- Not start with a digit.
- Be different from the class name of any OLE 1 application, *including the OLE 1 version of the same application*, if there is one.

The user must never see the ProgID in the user interface. If you need a short displayable string for an object, call the **IOleObject::GetUserType** method.

Because it is necessary to make a conversion between the ProgId and the CLSID, it is important to note that there are two kinds of ProgIDs. One depends on the version of the object application (the version-dependent ProgId); and one does not (the version-independent ProgId).

Version-dependent Identifiers

The version-dependent ProgID is the string used when OLE 1 is trying to contact OLE 2 using DDE. Version-dependent ProgID-to-CLSID conversions must be specific, well-defined, and one-to-one.

Version-independent Identifiers

The version-independent ProgID, on the other hand, can be used when a container application creates a chart or table with a toolbar button. In this situation, the application can use the version-independent ProgID to determine the latest version of the needed object application.

The version-independent ProgID is stored and maintained solely by application code. When given the version-independent ProgID, the **CLSIDFromProgID** function returns the CLSID of the current version. The **CLSIDFromProgID** function works on the version-independent ProgID because the subkey, CLSID, is the same as it is for the version-dependent one.

You can call the **IOleObject::GetUserType** method or the **OleRegGetUserType** function to change the identifier to a displayable string.

Converting Identifiers

The **CLSIDFromProgID** and **ProgIdFromCLSID** API functions can be called to convert back and forth between the two representations. These functions use information stored in the registry to perform the conversion.

The ProgID-to-CLSID conversion is done using the **HKEY_LOCAL_MACHINE\SOFTWARE\Classes**\<*ProgID*>\CLSID key. The reverse translation is done using the **HKEY_LOCAL_MACHINE\SOFTWARE\Classes**\CLSID\<*clsid*>\ProgID subkey. This means that the ProgID subkey under **HKEY_LOCAL_MACHINE\SOFTWARE\Classes**\CLSID\<*clsid*> is version-dependent.

The ProgID Key and Subkeys

OLE 2 classes that belong in the Insert Object dialog box each have a ProgID. The value assigned to this key is the name displayed in the dialog box; it should be the same as the "*MainUserTypeName*" of the class. If this class is insertable in an OLE 2 container, the ProgID key must have an immediate subkey named **Insertable**, which must have no value assigned to it.

Note Because OLE 2 provides a built-in OLE 1/OLE 2 compatibility layer, rarely will an OLE 2 class that is insertable in an OLE 2 container not be insertable in an OLE 1 container.

Conventions Used in Examples

In the registry examples in this appendix, **boldface** indicates a literal standard key or subkey, <*italics*> indicates an application-supplied string or value, and <***boldface-italics***> indicates an application-supplied key or subkey. In the first example, "OLE1ClassName," "OLE1UserTypeName," and "CLSID" are all supplied by the application.

Inserting an OLE 2 Object in an OLE 1 Application

If a particular class is insertable in an OLE 1 container, the "ProgID" *root* key will contain a **Protocol\StdFileEditing** subkey with appropriate subkeys **Verb**, **Server**, and so on, as in OLE 1. The **Server** that should be registered here is the full path to the executable file of the OLE 2 object application. An OLE 1 container uses the path and executable file names to launch the OLE 2 object application. The initialization of this application, in turn, loads the OLE 2 compatibility layer. This layer handles subsequent interactions with the OLE 1 container (client), turning them into OLE 2-like requests to the OLE 2 application. An OLE 2 object application doesn't have to take any special action beyond setting up these registry entries to make objects insertable into an OLE 1 container.

The ProgID key and its subkeys appear in the registry as shown in the following example, where "***<Progid>***" is the key, and "**Insertable**," "**Protocol**," "**StdFileEditing**," "**Verb**," and so on are subkeys.

```
<ProgId> = <MainUserTypeName>
        Insertable      // class is insertable in OLE 2 containers
        Protocol
                StdFileEditing  // OLE 1 compatibility info; present if, and only if,
                                // objects of this class are insertable in OLE 1 containers.
                        Server = <full path to the OLE 2 object application>
                        Verb
                                0 = <verb 0>    // Verb entries for the OLE 2
                                                // application must start with zero as the
                                1 = <verb 1>    // primary verb and run consecutively.
        CLSID = <CLSID>         // The corresponding CLSID. Needed by GetClassFile.
        Shell   // Windows 3.1 File Manager Info
                Print
                Open
                Command = <appname.exe> %1
```

To summarize, any root key that has either an **Insertable** or a **Protocol\StdFileEditing** subkey is the ProgID (or OLE 1 class name) of a class that should appear in the Insert Object dialog box. The value of that root key is the name displayed in the Insert Object dialog box.

The values of each key in the example below are used for registering the "Ole 2 In-Place Server Outline" sample application. Set these values as required and used by your application.

Long Form String Subkey Entry

The entry to register the string (long form), such as that used in the Insert New dialog box, is as follows.

```
HKEY_CLASSES_ROOT\OLE2ISvrOtl = Ole 2 In-Place Server Outline
```

The recommended maximum length for the string is 40 characters.

Information for OLE 1 Applications Subkey Entries

To maintain compatibility with OLE 1, you must include specific OLE 1 information. The "server" key entry should contain a full path to the application. The entries for verbs must start with 0 as the primary verb and be consecutively numbered.

```
HKEY_CLASSES_ROOT\OLE2ISvrOtl\protocol\StdFileEditing\server =
     c:\samp\isvrotl.exe
HKEY_CLASSES_ROOT\OLE2ISvrOtl\protocol\StdFileEditing\verb\0 = &Edit
HKEY_CLASSES_ROOT\OLE2ISvrOtl\protocol\StdFileEditing\verb\1 = &Open
```

Windows 3.1 Shell Subkey Entries

These entries are for Windows 3.1 shell printing and File Open use. They should contain the path and filename of the object application. The examples below contain simple entries only; more complicated ones could include DDE entries.

```
HKEY_CLASSES_ROOT\OLE2ISvrOtl\Shell\Print\Command = c:\svr\isvrotl.exe %1
HKEY_CLASSES_ROOT\OLE2ISvrOtl\Shell\Open\Command = c:\svr\isvrotl.exe %1
```

Insertable Subkey Entry

This entry indicates that the object application should appear in the Insert New dialog box's list box when used by OLE 2 container applications.

```
HKEY_CLASSES_ROOT\OLE2ISvrOtl\Insertable
```

Entry Point Subkey

This entry points to the application's OLE 2 information in the registry. To assign a CLSID for your application, run the UUIDGEN.EXE found in the \TOOLS directory of the OLE 2 Toolkit.

```
HKEY_CLASSES_ROOT\OLE2ISvrOtl\CLSID = {00000402-0000-0000-C000-000000000046}
```

The CLSID Key and Subkeys

Most of the OLE 2 object application information is stored in subkeys under the **CLSID** *root* key. The immediate subkey of the **CLSID** key is a string version CLSID. Subkeys of this version of the CLSID indicate where the code that services this class is found. For more information about converting the CLSID, see the **StringFromCLSID** function.

Most of the **CLSID** information is used by the default OLE 2 handler to return various information about the class when it is in the loaded state. Examples of this include the **Verb**, the **AuxUserType**, and the **MiscStatus** entries. The **Insertable** subkey appears under both this key and the **ProgId** key.

```
CLSID
<CLSID> = <Main User Type Name>
        LocalServer = <path to 16- or 32-bit exe>       // local (same machine) server; see "Server ="
                                                                // under ProgID key.
        LocalServer32 = <path to 32-bit exe>            // local (same machine) server; see "Server ="
                                                                // under ProgID key.
        InprocServer = <path to dll>     // in process server; relatively rare for insertable classes.
        InprocServer32 = <path to 32-bit dll>    // in process server; relatively rare for insertable classes.
        InprocHandler = <path to dll>    // in process handler. "OLE2.DLL" for the default OLE 2 handler
        InprocHandler32 = <path to 32-bit dll>  // in process handler. "OLE2.DLL" for the default OLE 2
                                                        // handler
        Verb            // info returned in IOleObject::EnumVerbs().
                verb number = <name, menu flags, verb flags>
        // several examples follow:
                 0 = &Edit, 0, 2  // primary verb; often Edit; on menu; possibly dirties object,
                                        // MF_STRING | MF_UNCHECKED | MF_ENABLED == 0.
                 1 = &Play, 0, 3  // other verb; appears on menu; leaves object clean
                -3 = Hide, 0, 1   // pseudo verb for hiding window; not on menu, opt.
                -2 = Open, 0, 1  // pseudo verb for opening in sep. window; not on menu, opt.
                -1 = Show, 0, 1  // pseudo verb for showing in preferred state; not on menu, opt.
        AuxUserType   // auxiliary user types (main user type above)
                <form of type> = <string>         // See IOleObject::GetUserType(); for example:
                2 = <ShortName>         // key 1 should not be used
                3 = <Application name> // Contains the displayable name of the application. Used when
                                // the actual name of the app is needed (for example in
                                // the Paste Special dialog's result field) Example: Acme Draw
        MiscStatus = <default> // def status used for all aspects; see IOleObject::GetMiscStatus
                <aspect> = <integer>    // exceptions to above;   for example:
                        4 = 1                   // DVASPECT_ICON = OLEMISC_RECOMPOSEONRESIZE
        DataFormats
                DefaultFile = <format>  // default main file/object format of objects of this class.
                GetSet // list of formats for default impl. of EnumFormatEtc; very similar
                                // to Request/SetDataFormats in OLE 1 entries
                        <n> = <format ,aspect, medium, flag>     // in this line,
                                // n  is a zero-based integer index;
                                // format is clipboard format;
                                // aspect is one or more of DVASPECT_*, -1 for "all";
                                // medium is one or more of TYMED_*;
                                // flag is one or more of DATADIR_*.
                                // three examples follow:
                        0 = 3, -1, 32, 1              // CF_METAFILE, all aspects, TYMED_MFPICT,
                                // DATADIR_GET
                        1 = Biff3, 1, 15, 3           // this example shows
                                // Microsoft Excel's Biff format version 3,
                                // DVASPECT_CONTENT,
                                // TYMED_HGLOBAL | TYMED_FILE |
                                // TYMED_ISTREAM | TYMED_ISTORAGE,
                                // (DATADIR_SET | DATADIR_GET)
                        2 = Rich Text Format, 1,1,3
        Insertable      // when present, the class appears in the Insert Object dialog.
                                // (not present for internal classes like the moniker classes)
        ProgID = <ProgID>               // the programmatic identifier for this class.
        TreatAs = <CLSID>                               // see CoGetTreatAs()
        AutoTreatAs = <CLSID>                   //see CoTreatAsClass
        AutoConvertTo = <CLSID>                 // see OleGetAutoConvert()
        Conversion                      // support for Change Type dialog box
                Readable
                        Main = <format,format,format,format, ...>
                Readwritable
                        Main = <format,format,format,format, ...>
        DefaultIcon = <path to exe, index>      // parameters passed to ExtractIcon
        Interfaces = <IID, IID, ...>    // optional. If this key is present, then its values are the
                                             // totality of the interfaces supported by this class: if the
                                             // IID is not in this list, then the interface is never supported
                                             // by an instance of this class.
        VersionIndependentProgID = <VersionIndependentProgID>
```

Existing 16-bit applications look in the registry for the Insertable keyword. This key informs the application that the server supports embeddings. If the Insertable keyword exists, 16-bit applications may also attempt to verify that the server exists on the machine. 16-bit applications typically will retrieve the value of the LocalServer key from the class, and check to see if it is a valid file on the system. Therefore, to be insertable by 16-bit applications, 32-bit applications should register LocalServer in addition to registering LocalServer32.

The InprocServer32 key has a ThreadingModel subkey to support more than one thread per process. You can set the ThreadingModel key to Apartment to support the apartment model threading or to Both to support both the apartment model and free threading. See the chapter "The Component Object Model" for more information on apartment model threading and free threading.

CLSID (Object Class ID) Subkey Entry

The following information creates a *CLSID* subkey under the **CLSID** key. To obtain a CLSID for your application, run the UUIDGEN.EXE found in the \TOOLS directory of the OLE 2 Toolkit.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046} = Ole 2 In-Place Server Outline
```

LocalServer Subkey Entry

This subkey designates the application's location. The LocalServer subkey should contain a full path. The entry can contain command-line arguments. Note that OLE 2 appends the "-Embedding" flag to the string, so the application that uses flags must parse the whole string and check for the -Embedding flag.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\LocalServer = 
c:\samp\isvrotl.exe
```

To run an OLE object server in a separate memory space (Windows NT 3.5 and above only), change the LocalServer key in the registry for the CLSID to the following:

```
cmd /c start /separate <path.exe
```

LocalServer32 Subkey Entry

This subkey designates the location of the 32-bit version of the application. The LocalServer32 subkey should contain a full path. The entry can contain command-line arguments. Note that OLE 2 appends the "-Embedding" flag to the string, so the application that uses flags will need to parse the whole string and check for the -Embedding flag.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\LocalServer32
= c:\samp\isvrotl.exe
```

When OLE starts a 32-bit local server, the server must register a class object within an elapsed time set by the user. By default, the elapsed time value must be at least five minutes, in milliseconds, but cannot exceed the number of milliseconds in 30 days. Applications typically should not set this value which is in the \HKEY_CLASSES_ROOT\Software\Microsoft\OLE2\ServerStartElapsedTime entry.

InprocHandler Subkey Entry

This subkey designates whether the application uses a custom handler. If no custom handler is used, the entry should be set to OLE2.DLL, as shown in the following example.

```
HKEY_-CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\InprocHandler = ole2.dll
```

InprocHandler32 Subkey Entry

This subkey designates whether the application uses a custom handler. If no custom handler is used, the entry should be set to OLE32.DLL, as shown in the following example.

```
HKEY_-CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\InprocHandler32 = ole32.dll
```

Verb Subkey Entry

The verbs to be registered for the application must be numbered consecutively. The first value after the verb string describes how the verb is appended by **AppendMenu** function call. See the *Win32 SDK* documentation for details.

The second value indicates whether the verb will dirty the object. It also indicates whether the verb should appear in the menu (as defined by OLEVERBATTRIB_). For more information, see the **IOleObject::EnumVerbs** method and the **OleRegEnumVerbs** function.

Verb 0: "Edit", MF_UNCHECKED | MF_ENABLED, no OLEVERATTRIB flags

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\Verb\0 =
&Edit,0,0
```

Verb 1: "Open", MF_UNCHECKED | MF_ENABLED, no OLEVERATTRIB flags

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\Verb\1 =
&Open,0,0
```

AuxUserType Subkey Entry

This key describes the short and actual displayable names of the application. See also the **IOleObject::GetUserType** method. The short name is used in the menus, including pop-ups, and the recommended maximum length for the string is 15 characters. A short name example follows.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\AuxUserType\2
= In-Place Outline
```

The long displayable name of the application is used in the Results field of the Paste Special dialog box. This string should contain the actual name of the application (such as "Acme Draw 2.0").

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\AuxUserType\3
= Ole 2 In-Place Server
```

MiscStatus Subkey Entry

The following is an example of a MiscStatus subkey. Refer to the **IOleObject::GetMiscStatus** method description for information on the different settings.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\MiscStatus =
0
```

DataFormats Subkey Entry

The DataFormats subkey lists the default and main data formats supported by the application. This entry is used by the **IDataObject::GetData**, **IDataObject::SetData** and **IDataObject::EnumFormatEtc** methods.

```
The values defined in the following example entry are CF_TEXT,
DVASPECT_CONTENT, TYMED_HGLOBAL, and DATADIR_GET | DATADIR_SET.
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\DataFormats\GetSet\0 = 1,1,1,3
```

The values defined in the following entry are: CF_METAFILEPICT DVASPECT_CONTENT, TYMED_MFPICT, DATADIR_GET.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\DataFormats\GetSet\1 = 3,1,32,1
```

The values defined in the following entry are: 2 = cfEmbedSource, DVASPECT_CONTENT, TYMED_ISTORAGE, and DATADIR_GET.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\DataFormats\GetSet\2 = Embed Source,1,8,1
```

The values defined in the following entry are: 3 = cfOutline, DVASPECT_CONTENT, TYMED_HGLOBAL, and DATADIR_GET | DATADIR_SET.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\DataFormats\GetSet\3 = Outline,1,1,3
```

The following entry declares that the default File Format supported by this application is CF_OUTLINE.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\DataFormats\DefaultFile = Outline
```

Insertable Subkey

The Insertable entry indicates that this application should appear in the Insert New dialog box's list box when used by OLE 2 container applications. Note that this is a duplicate entry of the one above but is required for future use.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\Insertable
```

ProgID Subkey Entry

Every insertable object class has a "programmatic identifier" or ProgID. For information on the creation and syntax of programmatic identifiers, see "**Programmatic Identifiers**" earlier in this chapter.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\ProgID =
OLE2ISvrOtl
```

Conversion Subkey Entry

Conversion information is used by the Convert dialog box to determine what formats the application can read and write. A comma-delimited file format is indicated by a number if it is one of the Clipboard formats defined in WINDOWS.H. A string indicates the format is not one defined in WINDOWS.H (private). Note that in this case the readable and writeable format is CF_OUTLINE (private).

Shown below is an entry that registers a file format the application can read (convert from).

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\Conversion\Readable\Main = Outline,1
```

Shown below is an entry that registers a file format the application can read and write (activate as).

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-
000000000046}\Conversion\Readwritable\Main = Outline,1
```

DefaultIcon Subkey Entry

The DefaultIcon subkey provides default icon information for iconic presentations of objects. This entry contains the full path to the executable name of the object application and the index of the icon within the executable. Applications can use this information to obtain an icon handle with **ExtractIcon**.

```
HKEY_CLASSES_ROOT\CLSID\{00000402-0000-0000-C000-000000000046}\DefaultIcon =
c:\samp\isvrotl.exe,0
```

The Version-Independent ProgID Key and Subkeys

An application must register a version-independent programmatic identifier in the "Version-Independent ProgID" key, that is, a second ProgID referring to its class, one that would not change from version to version, but would remain constant across all versions. This key provides a constant name, referred to as the *MainUserTypeName*. It is used with macro languages and refers to the currently installed version of the application's class. The *MainUserTypeName* must correspond to the name of the latest version of the object application.

```
<VersionIndependentProgID> = <MainUserTypeName>
        CLSID = <CLSID>        // the class id of the newest installed version of that class
        CurVer = <ProgID>      // the ProgID of the newest installed version of that class
```

In addition to the preceding entry, you should add the following entry to the **CLSID** *root* key.

```
CLSID
<CLSID> = <Main User Type Name>
        VersionIndependentProgID = <VersionIndependentProgID>
```

The File Extension Key

If your OLE 2 application can handle requests from the Windows 3.1 File Manager, create the file extension *root* key.

<.ext> = <*ProgID*>   // used by File Manager and by GetClassFile (and thus File Monikers).

The (Non-Compound) FileType Key and Subkeys

Entries under the FileType key are used by the **GetClassFile** function to match patterns against various file bytes in a non-compound file. FileType has *CLSID* subkeys, each of which has a series of subkeys 0, 1, 2, ... These values contain a pattern that, if matched, should yield the indicated *CLSID*. See also the **GetClassFile** function.

```
FileType                    // used by GetClassFile()
        <CLSID>
                <n> = <offset, cb, mask, value> // Offset and cb are limited to 16 bits. Offset can
                                //be negative for file end.
                                // As above, offset and byte count are decimal unless preceded by "0x",
in which
                                // case they are hex. The mask and the pattern are always hex and
cannot be
                                // preceded by "0x". Mask can be omitted, implying a value of all ones.
                                // An example:
                0 = 0, 4, FFFFFFFF, ABCD1234 // This requires that the first 4 bytes be AB CD
                                             // 12 34, in that order,
                1 = 0, 4, FFFFFFFF, 9876543  // or requires that they match 9876543.
                2 = -4, 4, FEFEFEFE          // The last four bytes in the file must be FEFEFEFE
```

The Interface Key and Subkeys

If your application adds a new interface, the Interface key must be completed for OLE 2 to register the new interface. There must be one IID subkey for each new interface.

```
Interface
        <IID> = <textual name of interface>      // for example: "IOleObject"
                ProxyStubClsID = <CLSID       >          // Maps an IID to a CLSID in a 16-bit proxy DLL.
                                                         //Used internally by OLE 2 for interprocess
                                                 // communication.
                ProxyStubClsID32 = <CLSID     >          // Maps an IID to a CLSID in a 32-bit proxy DLL.
                                                         //Used internally by OLE 2 for interprocess
                                                         // communication.
                NumMethods = <integer>           // Number of methods in the interface.
                BaseInterface = <IID>    // Interface from which this was derived. Absence
                                         // of key means IUnknown. Key present but empty value
                                         // means derived from nothing.
```

Note that you must use ProxyStubClsid32 because the IID-to-CLSID mapping may be different for 16- and 32-bit interfaces. The IID-to-CLSID mapping depends on the way the interface proxies are packaged into a set of proxy DLLs.

OLE 1 Compatibility Subkeys

To handle two-way compatibility, the OLE 2 compatibility layer creates OLE 2-style entries for OLE 1 classes it discovers and places them under the CLSID key. When installing an OLE 2 object application on a system that contains an OLE 1 version of the same application, it might be necessary to add "AutoConvertTo" or "TreatAs" subkeys to the *original* OLE 1 application portion of the registry. For more information, see "When the OLE 1 Version is Overwritten."

CLSID
<*CLSID*> = <*OLE1UserTypeName*> // This entry is generated automatically by OLE 2 for an
OLE 1 class.
OLE1Class = <*OLE 1 class name*> // This entry is created the first time an object of
that class
// is inserted in an OLE 2 container**.**
ProgId = <*OLE 1 class name*> // Allows OLE 2 to convert CLSID back to an OLE 1
class name.

OLE 1 Application Entries

When an OLE 1 class is inserted into an OLE 2 container for the first time, a new subkey, **CLSID**, is added *to the original OLE 1 registration information* by the OLE 2 compatibility layer. The value given to this key is a CLSID assigned by OLE 2 to this OLE 1 class as shown in the following portion of the registry.

```
<OLE1ClassName> = <OLE1UserTypeName>
        Protocol
                StdFileEditing
                Verb
        CLSID = <CLSID>
```

Registering OLE 2 Libraries

The OLE 2 libraries require that many internal interfaces be registered. Thus, if your installation program installs the OLE 2 libraries on a machine that does not already have them, it should register OLE 2-specific information during installation.

If your installation program does not install OLE 2 libraries when it finds more recent libraries on the user's drive, it should not register the OLE 2 interface information.

Note When checking the version stamp (using VER.DLL) on existing OLE 2 libraries to determine whether or not to replace them on the user's hard drive, do so on a per file basis.

Accommodating OLE 1 Versions of the Object Application

When the OLE 1 version of an object application is superseded by an OLE 2 version and the OLE 2 version is to be installed in the user's system, such as when upgrading, two situations can arise:

- An OLE 1 version of the application is present on the user's system and the installation process overwrites the OLE 1 executable with the OLE 2 version.
- An OLE 1 version of the application is present on the user's system and the user chooses not to overwrite it with the OLE 2 version.

Note Even if the OLE 1 object application is not on the user's system, the install/setup program for the OLE 2 object application should register the application as capable of servicing its OLE 1 objects. To do this, follow the guidelines presented under "When the OLE 1 Version is Overwritten," and add the following entry to the *CLSID root key*:

<**OLE 1 class name**>/**CLSID =** <*CLSID of OLE 1 application*>

When the OLE 1 Version is Overwritten

When the OLE 1 object application is replaced by the OLE 2 version, do the following. (For the purpose of illustration, the OLE 1 object application is referred to as Ole 1 In-Place Server Outline while the OLE 2 version is Ole 2 In-Place Server Outline, as shown in the dialog box illustrations that follow).

1. Register Ole 2 In-Place Server Outline.
2. Modify (with your install/setup program) the *original* registry entries of Ole 1 In-Place Server Outline by changing the executable path to point to the Ole 2 In-Place Server Outline executable.

   For example, the Server subkey for the OLE 1 executable, named **svrapp.exe** in this example, changes from

   OLE1ISvrOtl\Protocol\StdFileEditing\Server = svrapp.exe

   to

   OLE1ISvrOtl\Protocol\StdFileEditing\Server = isvrotl.exe

   where **isvrotl.exe** is the name of the OLE 2 object application.

   Next, proceed to either step 3 or step 4, depending on whether or not you want OLE 1 objects converted automatically to the OLE 2 format.
3. If Ole 1 In-Place Server Outline objects will be converted automatically to the Ole 2 In-Place Server Outline format when the application is saved, create or modify the following registration database entries:
   a. Modify the *original registry entry* of Ole 1 In-Place Server Outline by changing the "Value of the ProgID = Main User Type Name" key of the entry to Ole 2 In-Place Server Outline.

      For example, where **OLE1ISvrOtl** is the ProgID of the OLE 1 application,

      OLE1ISvrOtl = Ole 1 In-Place Server Outline

      becomes

      OLE1ISvrOtl = Ole 2 In-Place Server Outline
   b. Modify the *original registry entry* of Ole 1 In-Place Server Outline by adding a **NotInsertable** subkey under the ProgID key. For example:

      ```
      HKEY_CLASSES_ROOT\OLE1SvrOtl\NotInsertable
      ```

Note Since the original registry entries for the OLE 1 server application remain (but with a pointer to the OLE 2 object application as shown in the preceding *step 3a*), the OLE 1 ProgID will appear in the Insert Object dialog box of any OLE 2 container application installed on the system. The **NotInsertable** subkey mentioned in *step 3b* prevents the ProgID of the OLE 1 application from appearing in the Insert Object dialog box of OLE 2 containers. The **NotInsertable** subkey overrides any **Insertable** subkey entries for that ProgID key.

   c. Set the "AutoConvertTo = CLSID" subkey entry for Ole 1 In-Place Server Outline *under the CLSID key* to the CLSID of Ole 2 In-Place Server Outline. (See also "OLE 1 Compatibility Subkeys").

      CLSID\{*CLSID of OLE 1 app.***}\AutoConvertTo = {***CLSID of OLE 2 app.***}**

Note You can obtain the CLSID of the OLE 1 object application for inclusion in registration entry file by calling **CLSIDFromProgID**.

   d. Modify the *original registry entry* of Ole 1 In-Place Server Outline by setting the verbs to those of Ole 2 In-Place Server Outline.

      For example, change

      OLE1ISvrOtl\Protocol\StdFileEditing\Verb\0 = &Edit

      to

OLE1ISvrOtl\Protocol\StdFileEditing\Verb\0 = &Edit

OLE1ISvrOtl\Protocol\StdFileEditing\Verb\1 = &Open

4. If the user is allowed to open Acme Draw 1.0 objects and save them back to disk in the Acme Draw 1.0 format:
   a. Set the "TreatAs = CLSID" entry to the CLSID of Ole 2 In-Place Server Outline using the following form.

      CLSID\{*CLSID of OLE 1 app.***}\TreatAs = {***CLSID of OLE 2 app.***}**

   b. Set the Ole 1 In-Place Server Outline verbs to those of Ole 2 In-Place Server Outline as described in the preceding step 3.

When the OLE 1 Version is Not Overwritten

You can install your program so the OLE 1 object application (Ole 1 In-Place Server Outline) is *not* replaced by the OLE 2 version (Ole 2 In-Place Server Outline). Instead, the user is allowed to open Ole 1 In-Place Server Outline objects with the Ole 2 In-Place Server Outline and save them back to disk in the Ole 1 In-Place Server Outline format. To do this, set the "TreatAs = CLSID" entry (Ole 1 In-Place Server Outline's portion of the registry) to the CLSID of Ole 2 In-Place Server Outline (as in step 4 above).

If the OLE 1 version of the application is not overwritten, or if the user does not want to set the "Treat As" option, register the OLE 2 version as a separate and new application.

{ewc msdncd, EWGraphic, group10507 0 /a "SDK.wmf"}

Checking Registration During Run Time

The application should check its registration at the application load time, noting three particular issues:

- If the CLSID(s) that the application services is not present in the registry, the application should register as it does during the original setup.
- If the application's CLSID is present, but has no OLE 2-related information in it, the application should register as it does during the original setup.
- If the path containing server entries (LocalServer and LocalServer32, InprocServer and InprocServer32, and DefaultIcon entries) does not point to the location in which the application is currently installed, the application should rewrite the path entries to point to its current location.

Using the Registry for Localization

It is possible to address a pair of product-localization issues by adding a key to the registry. This key, described below, allows functions to return a specified string instead of a default value or "Unknown."

This section includes the following topics:

- Specifying Unregistered Verbs
- Specifying Unknown User Types

Specifying Unregistered Verbs

It is possible to register OLE 1 object applications (servers) with no specified verbs. In such cases, the application has a single implied verb that is understood to be "edit" by OLE 1 containers. When an OLE 2 application calls the **IOleObject::EnumVerbs** method (or the **OleRegEnumVerbs** function) on an object of this class, one verb is enumerated. By default, the name of the verb is "Edit." To avoid having the string "Edit" as the enumerated verb, a key can be included in the registry. This key is

\Software\Microsoft\OLE1\UnregisteredVerb = <*verbname*>

(where *verbname* is the value that will be returned from the enumeration) and allows for localization of the default verb to a specified string to accommodate a specific language.

Note Do not attempt to register a verb (under ProgID\Protocol\StdFileEditing) for an application that did not register the verb itself.

Specifying Unknown User Types

The OLE 2 default handler's implementation of the **IOleObject::GetUserType** method first examines the registry by calling the **OleRegGetUserType** method. If the object's class is not found in the registry, the User Type from the object's **IStorage** instance is returned. If the class is not found in the object's **IStorage** instance, the string "Unknown" is returned.

By inserting the

\Software\Microsoft\OLE2\UnknownUserType = <*usertype*>

key in the registry, the **IOleObject::GetUserType** method returns the value of the string specified by <*usertype*>. This string can be localized for a different language user-type name, instead of using the "Unknown" string, for the User Type.

Structured Storage

Traditional file systems face challenges when they try to efficiently store multiple kinds of objects in one document. OLE provides a solution: a file system *within* a file. OLE structured storage defines how to treat a single file entity as a structured collection of two types of objects – storages and streams – that act like directories and files. This scheme is called structured storage. The purpose of structured storage is to reduce the performance penalties and overhead associated with storing separate objects in a flat file

The Evolution of File Systems

Years ago, in the days before disk operating systems, each computer was built to run a single, proprietary application, which had complete and exclusive control of the entire machine. The application would write its persistent data directly to a disk, or drum, by sending commands directly to the disk controller. The application was responsible for managing the absolute locations of data on the disk, making sure that it was not overwriting data that was already there, but since the application was the only one running on the machine, this task was not too difficult.

The advent of computer systems that could run more than one application required some sort of mechanism to make sure that applications did not write over each other's data. Application developers addressed this problem by adopting a single standard for marking which disk sectors were in use and which were free. In time, these standards coalesced to become a disk operating system, which provided various services to the applications, including a file system for managing persistent storage. With the advent of a file system, applications no longer had to deal directly with the physical storage medium. Instead, they simply told the file system to write blocks of data to the disk and let the file system worry about how to do it. In addition, the file system allowed applications to create data hierarchies through the abstraction known as a directory. A directory could contain not only files but other directories. which in turn could contain their own files and directories, and so on.

The file system provided a single level of indirection between applications and the disk, and the result was that every application saw a file as a single contiguous stream of bytes on the disk even though the file system was actually storing the file in discontiguous sectors. The indirection freed the applications from having to care about the absolute position of data on a storage device.

Today, virtually all system APIs for file input and output provide applications with some way to write information into a flat file that applications see as a single stream of bytes that can grow as large as necessary until the disk is full. For a long time these APIs have been sufficient for applications to store their persistent information. Applications have made significant innovations in how they deal with a single stream of information to provide features like incremental "fast" saves.

In a world of component objects, however, storing data in a single flat file is no longer efficient. Just as file systems arose out of the need for multiple applications to share the same storage medium, so now, component objects require a system that allows them to share storage within the conceptual framework of a single file. Even though it is possible to store the separate objects using conventional flat file storage, should one of the objects increase in size, or should you simple add another object, it becomes necessary to load the entire file into memory, insert the new object, and then save the whole file. Such a process can be extremely time-consuming.

The solution provided by OLE is to implement a second level of indirection: a file system *within* a file. Instead of requiring that a large contiguous sequence of bytes on the disk be manipulated through a single file handle with a single seek pointer, OLE structured storage defines how to treat a single file system entity as a structured collection of two types of objects – storages and streams – that act like directories and files.

Storages and Streams

OLE provides a set of services collectively called structured storage. The purpose of these services is to reduce the performance penalties and overhead associated with storing separate objects in a flat file. Instead, OLE stores the separate objects in a single, structured file consisting of two main elements: storage objects and stream objects. Together, they function like a file system within a file.

A storage object is analogous to a file system directory. Just as a directory can contain other directories and files, a storage object can contain other storage objects and stream objects. Also like a directory, a storage object tracks the locations and sizes of the storage objects and stream objects nested beneath it.

A stream object is analogous to the traditional notion of a file. Like a file, a stream contains data stored as a consecutive sequence of bytes.

An OLE compound file consists of a root storage object containing at least one stream object representing its native data along with one or more storage objects corresponding to its linked and embedded objects. The root storage object maps to a filename in whatever file system it happens to reside in. Each of the objects inside the document also is represented by a storage object containing one or more stream objects, and perhaps also containing one or more storage objects. In this way, a document can consist of an unlimited number of nested objects.

Structured storage solves the performance problem because whenever a new object is added to a compound file, or an existing object increases in size, the file does not have to be totally rewritten to storage. Instead, the new data is written to the next available location in permanent storage, and the storage object updates the table of pointers it maintains to track the locations of its storage objects and stream objects. At the same time, structured storage enables end users to interact and manage a compound file as if it were a single file rather than a nested hierarchy of separate objects.

Structured storage also provides additional benefits:

- Incremental access. If a user needs access to an object within a compound file, the user can load and save only that object, rather than the entire file.
- Multiple use. More than one end user or application can concurrently read and write information in the same compound file.
- Transaction processing. Users can read or write to OLE compound files in transacted mode, where changes made to the file are buffered and can subsequently either be committed to the file or reversed.
- Low memory saves. Structured storage provides facilities for saving files in low memory situations.

Compound Files

Although you can implement your own structured storage objects and interfaces, OLE provides a standard implementation called Compound Files. Using Compound Files saves you the work of coding your own implementation of structured storage and confers several additional benefits derived from adhering to a defined standard. These benefits include the following:

- File-system and platform independence. Since OLE's Compound Files implementation runs on top of existing flat file systems, compound files stored in FAT, NTFS, or the Macintosh file systems can be opened by applications using any one of the others.
- Browsability. Since the separate objects in a compound file are saved in a standard format and can be accessed using standard OLE interfaces and APIs, any browser utility using these interfaces and APIs can list the objects in the file, even though the data within a given object may be in a proprietary format.
- Access to certain internal data. Since the Compound Files implementation provides standard ways of writing certain types of data – summary information, for example – applications can read this data using OLE interfaces and APIs.

Structured Storage Elements

Structured storage provides the equivalent of a complete file system for storing objects through the following elements:

- The **IStorage**, **IStream**, **ILockBytes**, and **IRootStorage** interfaces, along with a set of related interfaces – **IPersistStorage** , **IPersist**, **IPersistFile**, and **IPersistStream**.
- Helper APIs that facilitate your implementation of structured storage, as well as a second set of APIs for compound files, OLE's implementation of the structured storage interfaces. OLE also provides a set of supporting structures and enumeration values used to organize parameters for interface methods and APIs.
- A set of access modes for regulating access to compound files.

Interfaces

Structured storage services are organized into three categories of interfaces. Each set represents a successive level of indirection, or abstraction, between a compound file, the objects it contains, and the physical media on which these individual components are stored.

The first category of interfaces consists of **IStorage**, **IStream**, and **IRootStorage**. The first two interfaces define how objects are stored *within* a compound file. These interfaces provide methods for opening storage elements, committing and reverting changes, copying and moving elements, and reading and writing streams. These interfaces do not understand the native data formats of the individual objects and therefore have no methods for saving those objects to persistent storage. The **IRootStorage** interface has a single method for associating a compound document with an underlying file system name. Clients are responsible for implementing these interfaces on behalf of their compound files.

The second category of interfaces consists of the **IPersist** interfaces, which objects implement to manage their persistent data. These interfaces provide methods to read the data formats of individual objects and therefore know how to store them. Objects are responsible for implementing these interfaces because clients do not know the native data formats of their nested objects. These interfaces, however, have no knowledge of specific physical storage media.

A third category consists of a single interface, **ILockBytes**, which provides methods for writing files to specific physical media, such as a hard disk or tape drive. OLE provides an **ILockBytes** interface for the operating system's file system.

API Functions

Some of the API functions for structured storage are helper functions that perform a sequence of calls to other API functions and interface methods. You can use these helper functions as short cuts.

Other API functions provide access to OLE's implementation of structured storage, Compound Files.

Still another set of API functions enable you to convert OLE 1 objects to structured storage. You can use these functions to determine if an object class is from OLE 1 and to convert objects between OLE 1 and current OLE storage formats.

Finally, there are API functions for converting and emulating other objects. These functions provide services for one server application to work with data from another application. The data can be converted to the native format of the server application by reading the data from its original format but writing it in the native format of the object application. Or the data can remain in its original format while the server application both reads and writes the data in its original format.

Access Modes

In a world where multiple processes and users can access an object simultaneously, mechanisms for controlling that access are essential. OLE provides these mechanisms by defining access modes for both storage and stream objects. The access mode specified for a parent storage object is inherited by its children, though you can place additional restrictions on the child storage or stream. A nested storage or stream object can be opened in the same mode or in a more restricted mode than that of its parent, but it cannot be opened in a less restricted mode than that of its parent.

You specify access modes by using the values listed in the **STGM** enumeration. These values serve as flags to be passed as arguments to methods in the **IStorage** interface and associated API functions. Typically, several flags are combined in the parameter *grfMode,* using a Boolean OR operation.

The flags fall into six groups: transaction flags, storage creation flags, temporary creation flag, priority flag, access permission flags, and shared access flags. Only one flag from each group can be specified at a time.

Transaction Flags

An object can be opened in either direct or transacted mode. When an object is opened in direct mode, changes are made immediately and permanently. When an object is opened in transacted mode, changes are buffered so they can be explicitly committed or reverted once editing is complete. Committed changes are saved to the object while reverted changes are discarded. Direct mode is the default access mode.

Transacted mode is not required on a parent storage object in order to use it on a nested element. A transaction for a nested element, however, is nested within the transaction for its parent storage object. Therefore, changes made to a child object cannot be committed until those made to the parent are committed, and both are not committed until the root storage object (the top-level parent) is actually written to disk. In other words, the changes move outward: inner objects publish changes to the transactions of their immediate containers.

Storage Creation Flags

Storage creation flags specify what OLE should do if an existing storage, stream, or lockbytes object has the same name as a new storage or stream object that you are creating. The default is to return an error message and not create the new object. You can use only one of these flags in a given creation call.

Temporary Creation Flag

The temporary creation flag indicates that the underlying file is to be automatically destroyed when the root storage object is released. This capability is most useful for creating temporary files.

Priority Flag

The priority flag opens a storage object in priority mode. When it opens an object, an application usually works from a snapshot copy because other applications may also be using the object at the same time. When opening a storage object in priority mode, however, the application has exclusive rights to commit changes to the object.

Priority mode enables an application to read some streams from storage before opening the object in a mode that would require the system to make a snapshot copy to be made. Since the application has exclusive access, it doesn't have to make a snapshot copy of the object. When the application subsequently opens the object in a mode where a snapshot copy is required, the application can exclude from the snapshot the streams it has already read, thereby reducing the overhead of opening the object.

Since other applications cannot commit changes to an object while it is open in priority mode, applications should keep it in that mode for as short a time as possible.

Access Permission Flags

Access permission flags specify the type of access a client application has to an open object: read, write, or read/write. Read permission enables an application to read the contents of a stream but not to write changes to the stream. Write permission enables an application to call a function that commits changes to an object's storage but not to read the contents of the stream. Read/write permission enables an application to either read the object's streams or write to the object's storage.

Shared Access Flags

The shared access flags specify the degree of access other applications can have to an object that your application is opening. You can deny read access, deny write access, or deny all access. You can also specify explicitly that no type of access be denied.

Storage Object Naming Conventions

Storage and stream objects are named according to a set of conventions.

The name of a root storage object is the actual name of the file in the underlying file system. It obeys the conventions and restrictions the file system imposes. Filename strings passed to storage-related methods and functions are passed on, uninterpreted and unchanged, to the file system.

The name of a nested element contained within a storage object is managed by the implementation of the particular storage object. All implementations of storage objects must support nested element names 32 characters in length (including the NULL terminator), although some implementations might support longer names. Whether the storage object does any case conversion is implementation-defined. As a result, applications that define element names must choose names that are acceptable in either situation. The OLE implementation of compound files supports names up to 32 characters in length, and does not perform any case conversion.

IAdviseSink

The **IAdviseSink** interface enables containers and other interested objects to receive notifications of data changes, view changes, and compound-document changes occurring in objects of interest. Container applications, for example, require such notifications to keep cached presentations of their linked and embedded objects up-to-date.

For an advisory connection to exist, the object that is to receive notifications must implement **IAdviseSink**, and the objects in which it is interested must implement one or more of the following: **IOleObject::Advise**, **IDataObject::DAdvise**, **or** **IViewObject::SetAdvise**. Objects implementing **IOleObject** must support all of these methods.

As shown in the following table, an object that has implemented an advise sink registers its interest in receiving certain types of notifications by calling the appropriate method:

Call This Method	**To Register for These Notifications**
IOleObject::Advise	When a document is saved, closed, or renamed.
IDataObject::DAdvise	When a document's data changes.
IViewObject::SetAdvise	When a document's presentation changes.

When an event occurs that applies to a registered notification type, the object application calls the appropriate **IAdviseSink** method. For example, when an embedded object closes, it calls the **IAdviseSink::OnClose** method to notify its container. These notifications are asynchronous, occurring after the events that trigger them

When to Implement

Objects, such as container applications, compound documents, and client sites implement **IAdviseSink** to receive notification of changes in data, presentation, name, or state of their linked and embedded objects. Implementors register for one or more types of notification, depending on their needs.

Notifications for an embedded object originate in the object application and flow to the container by way of the object handler. If the object is a linked object, the OLE link object intercepts the notifications from the object handler and notifies the container directly. All containers, the object handler, and the OLE link object register for OLE notifications. The typical container also registers for view notifications. Data notifications are usually sent to the OLE link object and object handler.

When to Use

Objects call **IAdviseSink** to notify other objects with whom they have an advisory connection of changes in data, view, name, or state.

Note Making synchronous calls within asynchronous methods is not valid, so you cannot make synchronous calls within any of the the **IAdviseSink** interface's methods. For example, an implementation of **IAdviseSink::OnDataChange** cannot contain a call to **IDataObject::GetData**.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IAdviseSink Methods **Description**

OnDataChange	Advises that data has changed.
OnViewChange	Advises that view of object has changed.
OnRename	Advises that name of object has changed.
OnSave	Advises that object has been saved to disk.
OnClose	Advises that object has been closed.

See Also

IAdviseSink2, **IDataAdviseHolder**, **IOleAdviseHolder**, **IOleObject::Advise**, **IOleObject::Unadvise**, **IOleObject::EnumAdvise**

IAdviseSink::OnClose

Notifies all registered advisory sinks that the object has changed from the running to the loaded state.

Void OnClose();

Comments

OnClose notification indicates that an object is making the transition from the running to the loaded state, so that appropriate measures to ensure orderly shutdown should be taken. For example, an object handler must release its pointer to the object.

If the object that is closing is the last open object supported by its OLE server application, then the application can also shut down.

In the case of a link object, the notification that the object is closing should always be interpreted to mean that the connection to the link source has broken.

IAdviseSink::OnDataChange

Notifies a data object's currently registered advise sinks that data in the object has changed.

```
void OnDataChange(
   FORMATETC * pFormatetc,          //Pointer to format information
   STGMEDIUM * pStgmed              //Pointer to storage medium
 );
```

Parameters

pFormatetc
[in] Points to the **FORMATETC** structure, which describes the format, target device, rendering, and storage information of the calling data object.

pStgmed
[in] Points to the **STGMEDIUM** structure, which defines the storage medium (global memory, disk file, storage object, stream object, GDI object, or undefined) and ownership of that medium for the calling data object.

Comments

Object handlers and link objects implement **IAdviseSink::OnDataChange** to receive data-change notifications. They also must call **IDataObject::DAdvise** to set up an advisory connection with the data objects in which they are interested. (See **IDataObject::DAdvise** for more information on how to specify an advisory connection for data objects.)

Containers that take advantage of OLE's caching support do not need to register for data-change notifications, because the information necessary to update the container's presentation of the object, including any changes in its data, are maintained in the object's cache.

Notes to Implementors

If you implement **IAdviseSink::OnDataChange** for a container, remember that this method is asynchronous and that making synchronous calls within asynchronous methods is not valid. Therefore, you cannot call **IDataObject::GetData** to obtain the data you need to update your object. Instead, you either post an internal message or invalidate the rectangle for the changed data by calling **InvalidateRect** and then wait for a WM_PAINT message, at which point you are free to get the data and update the object.

The data itself, which is valid only for the duration of the call, is passed using the storage medium pointed to by *pmedium.* Since the medium is owned by the caller, the advise sink should not free it. Also, if *pmedium* points to an **IStorage** or **IStream**, the sink must not increment the reference count.

See Also

IDataObject::DAdvise

IAdviseSink::OnRename

Notifies all registered advisory sinks that the object has been renamed.

```
Void OnRename(
    IMoniker * pmk          //Points to the IMoniker interface
  );
```

Parameter

pmk
Pointer to the new full moniker of the object.

Comments

OLE link objects normally implement **IAdviseSink::OnRename** to receive notification of a change in the name of a link source or its container. The object serving as the link source calls **OnRename** and passes its new full moniker to the object handler, which forwards the notification to the link object. In response, the link object must update its moniker. The link object, in turn, forwards the notification to its own container.

IAdviseSink::OnSave

Notifies all registered advisory sinks that the object has been saved.

Void OnSave();

Comments

Object handlers and link objects normally implement **IAdviseSink::OnSave** to receive notifications of when an object is saved to disk, either to its original storage (through a Save operation) or to new storage (through a Save As operation). Object Handlers and link objects register to be notified when an object is saved for the purpose of updating their caches, but then only if the advise flag passed during registration specifies ADVFCACHE_ONSAVE. Object handlers and link objects forward these notifications to their containers.

IAdviseSink::OnViewChange

Notifies an object's registered advise sinks that its view has changed.

```
Void OnViewChange(
   DWORD dwAspect,        //A value specifying aspect of object
   LONG lindex            //Currently must be -1
  );
```

Parameters

dwAspect
[in] Specifies the aspect, or view, of the object. Contains a value taken from the enumeration, **DVASPECT**.

lindex
[in] Identifies which piece of the view has changed. Currently only -1 is valid.

Comments

Containers register to be notified when an object's view changes by calling **IViewObject::SetAdvise**. Once registered, the object will call the sink's **IAdviseSink::OnViewChange** method when appropriate. **OnViewChange** can be called when the object is in either the loaded or running state.

Even though **DVASPECT** values are individual flag bits, *dwAspect* may only represent one value. That is, *dwAspect* cannot contain the result of an OR operation combining two or more **DVASPECT** values.

The *lindex* member represents the part of the aspect that is of interest. The value of *lindex* depends on the value of *dwAspect*. If *dwAspect* is either DVASPECT_THUMBNAIL or DVASPECT_ICON, *lindex* is ignored. If *dwAspect* is DVASPECT_CONTENT, *lindex* must be -1, which indicates that the entire view is of interest and is the only value that is currently valid.

IViewObject::SetAdvise

IAdviseSink2

The **IAdviseSink2** interface is an extension of **IAdviseSink** and was defined to prevent overloading the **IAdviseSink::OnRename** method. Without **IAdviseSink2**, embedded objects and link sources, upon being renamed, would both have to notify their containers by calling **IAdviseSink::OnRename**. In applications where different blocks of code might execute depending on which of these two similar events has occurred, using the same method for both events complicates testing and debugging. With **IAdviseSink2**, embedded objects whose name has changed still call **IAdviseSink::OnRename**, but the link object maps this notification to **IAdviseSink2::OnLinkSrcChange**. Making this distinction explicit makes it easier to test and maintain your code.

When to Implement

If your application supports links, you should definitely implement **IAdviseSink2**. Even if your application does not support links, it may do so in future releases. Since the **IAdviseSink2** interface inherits all the methods of **IAdviseSink** without additional overhead, it makes sense to implement **IAdviseSink2** in all cases.

When to Use

When a link source is renamed, the link object should notify its container by calling **IAdviseSink::OnLinkSrcChange**.

Methods in Vtable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IAdviseSink Methods	Description
OnDataChange	Advises that data has changed.
OnViewChange	Advises that view of object has changed.
OnRename	Advises that name of object has changed.
OnSave	Advises that object has been saved to disk.
OnClose	Advises that object has been closed.

IAdviseSink2 Method	Description
OnLinkSrcChange	Advises that link source has changed.

IAdviseSink2::OnLinkSrcChange

Notifies the container that registered the advise sink that a link source has changed, enabling the container to update the link's moniker.

```
void OnLinkSrcChange(
    IMoniker *pmk        //A pointer to the new link source
  );
```

Parameter

pmk
[in] Points to the new link source contained within the link object.

Comments

A container of linked objects implements this method to receive notification in the event of a change in the moniker of its link source.

IAdviseSink2::OnLinkSrcChange is called by the OLE link object when it receives the **OnRename** notification from the link-source (object) application. The link object updates its moniker and sends the **OnLinkSrcChange** notification to containers that have implemented **IAdviseSink2**.

Notes to Implementors

Nothing prevents a link object from notifying its container of the moniker change by calling **IAdviseSink::OnRename** instead of **OnLinkSrcChange**. In practice, however, overloading **OnRename** to mean either that a link object's moniker has changed or that the corresponding link source's moniker has changed makes it difficult for applications to determine which event has, in fact, occurred. If the two events trigger different processing, as will often be the case, then using a different method for each makes the job of determining which event occurred much easier.

IAdviseSink::OnRename

IBindCtx

The **IBindCtx** interface provides access to a bind context, which is an object that stores information about a particular moniker binding operation. You pass a bind context as a parameter when calling many methods of **IMoniker** and in certain API functions related to monikers.

A bind context includes the following information:

- A **BIND_OPTS** structure containing a set of parameters that do not change during the binding operation. When a composite moniker is bound, each component uses the same bind context; a bind context is thus a mechanism for passing the same parameters to each component of a composite moniker.
- A set of pointers to objects that the binding operation has activated. The bind context holds pointers to these bound objects, keeping them loaded and thus eliminating redundant activations if the objects are needed again during subsequent binding operations.
- A pointer to the Running Object Table on the machine of the process that started the bind operation. Moniker implementations that need to access the Running Object Table should use the **IBindCtx::GetRunningObjectTable** method rather than using the **GetRunningObjectTable** API function. This allows future enhancements to the system's **IBindCtx** implementation to modify binding behavior.
- A table of interface pointers, each associated with a string key. This capability enables moniker implementations to store interface pointers under a well-known string so that they can later be retrieved from the bind context. For example, OLE defines several string keys (e.g., "ExceededDeadline", "ConnectManually") that can be used to store a pointer to the object that caused an error during a binding operation.

When to Implement

You do not need to implement this interface. The system provides an **IBindCtx** implementation, accessible using the **CreateBindCtx** API function, that is suitable for all situations.

When to Use

The primary users of **IBindCtx** are those who write their own implementation of the **IMoniker** interface; they must call **IBindCtx** methods from the implementation of several **IMoniker** methods. Another category of **IBindCtx** users are moniker providers (that is, those who hand out monikers that identify their objects). They may need to call **IBindCtx** methods from their implementations of the **IOleItemContainer** or **IParseDisplayName** interfaces.

Moniker clients (that is, those who use monikers to acquire interface pointers to objects) typically don't call many **IBindCtx** methods; they simply pass a bind context as a parameter to the **IMoniker** method they're using. Moniker clients typically perform the following steps:

1. Call the **CreateBindCtx** API function to create a bind context.
2. Optionally, call the **IBindCtx::SetBindOptions** method in order to specify the bind options. Moniker clients rarely perform this step.
3. Pass the bind context as a parameter to the desired **IMoniker** method (most commonly **IMoniker::BindToObject**).
4. Call **IUnknown::Release** on the bind context to release it.

The most common example of moniker clients are applications that act as link containers, that is, container applications that allow their documents to contain linked objects. However, link containers are a special case in that they rarely call **IMoniker** methods directly. Generally, they manipulate linked objects through the **IOleLink** interface; the system-supplied linked object implements this interface and calls the appropriate **IMoniker** methods as needed. Consequently, the linked object is the one that passes bind contexts to the **IMoniker** methods.

Methods in Vtable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IBindCtx Methods	Description
RegisterObjectBound	Registers an object with the bind context.
RevokeObjectBound	Revokes an object's registration.
ReleaseBoundObjects	Releases all registered objects.
SetBindOptions	Sets the binding options.
GetBindOptions	Retrieves the binding options.
GetRunningObjectTable	Retrieves a pointer to the Running Object Table.
RegisterObjectParam	Associates an object with a string key.
GetObjectParam	Returns the object associated with a given string key.
EnumObjectParam	Enumerates all the string keys in the table.
RevokeObjectParam	Revokes association between an object and a string key.

See Also

CreateBindCtx, IMoniker, IOleItemContainer, IParseDisplayName

IBindCtx::EnumObjectParam

Returns a pointer to an enumerator that can return the keys of the bind context's string-keyed table of pointers.

```
HRESULT EnumObjectParam(
  IEnumString **ppenum        //Receives a pointer to an enumerator
 );
```

Parameter

ppenum
[out] Receives an **IEnumString** pointer to the enumerator. If an error occurs, **ppenum* is set to NULL. If **ppenum* is non-NULL, the implementation calls **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
An enumerator was successfully returned.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

This method eturns an **IEnumString** pointer to an enumerator that can return the keys of the bind context's string-keyed table of pointers. The keys returned are the ones previously specified in calls to **IBindCtx::RegisterObjectParam**.

Notes to Callers

A bind context maintains a table of interface pointers, each associated with a string key. This enables communication between a moniker implementation and the caller that initiated the binding operation. One party can store an interface pointer under a string known to both parties so that the other party can later retrieve it from the bind context.

See Also

IBindCtx::RegisterObjectParam, **IEnumString**

IBindCtx::GetBindOptions

Returns the binding options stored in this bind context.

```
HRESULT GetBindOptions(
   BIND_OPTS *pbindopts        //Points to a BIND_OPTS structure
  );
```

Parameter

pbindopts
[in, out] Points to a **BIND_OPTS** structure that receives the current binding parameters. For more information on the **BIND_OPTS** structure, see the "Data Structures" section.

Return Values

S_OK
The stored binding options were successfully returned.

E_UNEXPECTED
Indicates an unexpected error.

Comments

A bind context contains a block of parameters, stored in a **BIND_OPTS** structure, that are common to most **IMoniker** operations and that do not change as the operation moves from piece to piece of a composite moniker.

Notes to Callers

You typically call this method if you are writing your own moniker class (that is, implementing the **IMoniker** interface). You call this method to retrieve the parameters specified by the moniker client.

You must provide the **BIND_OPTS** structure that is filled in by this method. Before calling this method, you must initialize the **cbStruct** field of the structure to the size of the **BIND_OPTS** structure.

See Also

IBindCtx::SetBindOptions

IBindCtx::GetObjectParam

Retrieves the pointer associated with the specified key in the bind context's string-keyed table of pointers.

```
HRESULT GetObjectParam(
   LPOLESTR pszKey,        //Points to the key to be used
   IUnknown **ppunk        //Receives a pointer to the object associated with the key
  );
```

Parameters

pszKey

[in] Points to a zero-terminated string containing the key to search for. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character. Key string comparison is case sensitive.

ppunk

[out] Receives a pointer to the object associated with *pszKey*. If an error occurs, **ppunk* is set to NULL. If **ppunk* is non-NULL, the implementation calls **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK

The pointer associated with the specified key was successfully returned.

E_FAIL

Indicates that no object has been registered with the specified key.

Comments

A bind context maintains a table of interface pointers, each associated with a string key. This enables communication between a moniker implementation and the caller that initiated the binding operation. One party can store an interface pointer under a string known to both parties so that the other party can later retrieve it from the bind context.

The pointer this method retrieves must have previously been inserted into the table using the **IBindCtx::RegisterObjectParam** method.

Notes to Callers

You can call **IBindCtx::GetObjectParam** if you are either a moniker implementor or a sophisticated moniker client.

If you are a moniker client, you can call this method if a binding operation failed to get specific information about the error that occurred. Depending on the error, you may be able to correct the situation and retry the binding operation. See **IBindCtx::RegisterObjectParam** for more information.

If you are a moniker implementor, you can call this method to retrieve information specified by the caller that initiated the binding operation. By convention, you should use key names that begin with the string form of the CLSID of your moniker class (see the **StringFromCLSID** API function).

See Also

IBindCtx::RegisterObjectParam, **IBindCtx::EnumObjectParam**

IBindCtx::GetRunningObjectTable

Returns an interface pointer to the Running Object Table (ROT) for the machine on which this bind context is running.

```
HRESULT GetRunningObjectTable(
   IRunningObjectTable **pprot         //Receives a pointer to the Running Object Table
  );
```

Parameter

pprot

[out] Receives a pointer to the Running Object Table. If an error occurs, **pprot* is set to NULL. If **pprot* is non-NULL, the implementation calls **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK

A pointer to the ROT was returned successfully.

E_OUTOFMEMORY

Indicates insufficient memory.

E_UNEXPECTED

Indicates an unexpected error.

Comments

The Running Object Table is a globally-accessible table on each machine. It keeps track of all the objects that are currently running on the machine.

Notes to Callers

You typically call this method if you are writing your own moniker class (that is, implementing the **IMoniker** interface). You can call this method from your implementation of **IMoniker::BindToObject** or **IMoniker::IsRunning** to check whether a given object is currently running. You can also call this method from your implementation of **IMoniker::GetTimeOfLastChange** to learn when a running object was last modified.

Moniker implementations should always use this method instead of using the **GetRunningObjectTable** API function. This makes it possible for future implementations of **IBindCtx** to modify binding behavior.

See Also

IMoniker, **IRunningObjectTable**

IBindCtx::RegisterObjectBound

Calls the **IUnknown::AddRef** method on the specified object to ensure that the object remains active until the bind context is released. The method stores a pointer to the object in the bind context's internal list of pointers.

```
HRESULT RegisterObjectBound(
  IUnknown *punk        //Pointer to the object being registered
 );
```

Parameter

punk
[in] Points to the object that is being registered as bound.

Return Values

S_OK
The object was successfully registered.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

Notes to Callers

If you are writing your own moniker class (that is, implementing the **IMoniker** interface), you should call this method whenever your implementation activates an object. This happens most often in the course of binding a moniker, but it can also happen while retrieving a moniker's display name, parsing a display name into a moniker, or retrieving the time an object was last modified.

Calling the **IBindCtx::RegisterObjectBound** creates an additional reference to the passed-in object (via **IUnknown::AddRef**); you are still required to release your own copy of the pointer. Note that calling this method twice for the same object creates two references to that object; you can release a reference to an object using the **IBindCtx::RevokeObjectBound** method. All references held by the bind context are released when the bind context itself is released.

Registering an object with a bind context keeps the object active until the bind context is released. Reusing a bind context in a subsequent binding operation (either for another piece of the same composite moniker, or for a different moniker) can make the subsequent binding operation more efficient because it doesn't have to reload that object. This performance improvement is present only if the subsequent binding operation requires some of the same objects as the original one. This performance improvement should be balanced against the costs of keeping objects activated unnecessarily.

Note that **IBindCtx** does not provide a method to retrieve a pointer to an object registered using **IBindCtx::RegisterObjectBound**. Assuming the object has registered itself with the Running Object Table, moniker implementations can use the Running Object Table to retrieve a pointer to the object.

See Also

IBindCtx::ReleaseBoundObjects, **IBindCtx::RevokeObjectBound**, **IRunningObjectTable::GetObject**

IBindCtx::RegisterObjectParam

Stores a pointer to the specified object under the specified key in the bind context's string-keyed table of pointers. The method calls **IUnknown::AddRef** on the stored pointer.

```
HRESULT RegisterObjectParam(
   LPOLESTR pszKey,         //Points to the key to be used
   IUnknown *punk           //Points to the object to be associated with the key
  );
```

Parameters

pszKey
: [in] Points to a zero-terminated string containing the key under which the object is being registered. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character. Key string comparsion is case sensitive.

punk
: [in] Points to the object that is to be registered.

Return Values

S_OK
: The pointer was successfully registered under the specified string.

E_OUTOFMEMORY
: Indicates insufficient memory.

Comments

A bind context maintains a table of interface pointers, each associated with a string key. This enables communication between a moniker implementation and the caller that initiated the binding operation. One party can store an interface pointer under a string known to both parties so that the other party can later retrieve it from the bind context.

Binding operations subsequent to the use of this method can use the **IBindCtx::GetObjectParam** method to retrieve the stored pointer.

Notes to Callers

You can call **IBindCtx::RegisterObjectParam** if you are either a moniker implementor or a sophisticated moniker client.

If you're a moniker implementor and an error occurs during moniker binding, you can use one of the keys predefined by OLE to inform the caller of the cause of an error. The following list describes the keys associated with various error conditions:

MK_E_EXCEEDEDDEADLINE
: If a binding operation exceeds its deadline because a given object is not running, then you should register the object's moniker using the first unused key from the list: "ExceededDeadline", "ExceededDeadline1", "ExceededDeadline2", etc. If the caller later finds the moniker in the Running Object Table, the caller can retry the binding operation.

MK_E_CONNECTMANUALLY
: The "ConnectManually" key indicates a moniker whose binding requires assistance from the end user. The caller can retry the binding operation after showing the moniker's display name to request that the end user manually connect to the object. The most common reasons for returning this value are that a password is needed or that a floppy needs to be mounted.

E_CLASSNOTFOUND
: The "ClassNotFound" key indicates a moniker whose class could not be found (i.e., the server for the object identified by this moniker could not be located). If this key is used in an OLE compound-document situation, the caller can use **IMoniker::BindToStorage** to bind to the object, and then try

to carry out a Treat As... or Convert To... operation to associate the object with a different server. If this is successful, the caller can retry the binding operation.

If you're a moniker client with detailed knowledge of the implementation of the moniker you're using, you can also call this method to pass private information to that implementation.

You can define new strings as keys for storing pointers. By convention, you should use key names that begin with the string form of the CLSID of the moniker class (see the **StringFromCLSID** API function).

If the *pszKey* parameter matches the name of an existing key in the bind context's table, the new object replaces the existing object in the table.

When you register an object using this method, the object is not released until one of the following occurs:

- It is replaced in the table by another object with the same key.
- It is removed from the table by a call to **IBindCtx::RevokeObjectParam**.
- The bind context is released. All registered objects are released when the bind context is released.

See Also

IBindCtx::GetObjectParam, **IBindCtx::RevokeObjectParam**, **IBindCtx::EnumObjectParam**

IBindCtx::ReleaseBoundObjects

Releases all pointers to all objects that were previously registered by calls to **IBindCtx::RegisterObjectBound**.

HRESULT ReleaseBoundObjects(*void***);**

Return Value

S_OK
    The objects were released successfully.

Comments

You rarely call this method directly. This method is called the system's **IBindCtx** implementation when a bind context is released. If a bind context is not released, all of the registered objects remain active.

If the same object has been registered more than once, this method calls the **IUnknown::Release** method on the object the number of times it was registered.

See Also

IBindCtx::RegisterObjectBound

IBindCtx::RevokeObjectBound

Calls the **IUnknown::Release** method on the specified object and removes the pointer to that object from the bind context's internal list of pointers. This undoes a previous call to **IBindCtx::RegisterObjectBound** for the same object.

```
HRESULT RevokeObjectBound(
    IUnknown *punk          //Pointer to the object whose registration is being revoked
  );
```

Parameter

punk
[in] Points to the object to be released.

Return Values

S_OK
The object was released successfully.

MK_E_NOTBOUND
Indicates that *punk* was not previously registered with a call to **IBindCtx::RegisterObjectBound**.

Comments

You rarely call this method. This method is included for completeness.

IBindCtx::RevokeObjectParam

Removes the specified key and its associated pointer from the bind context's string-keyed table of objects. The key must have previously been inserted into the table using the **IBindCtx::RegisterObjectParam** method.

```
HRESULT RevokeObjectParam(
  LPOLESTR pszKey        //Points to the key to be revoked
 );
```

Parameter

pszKey

[in] Points to a zero-terminated string containing the key to remove. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character. Key string comparsion is case sensitive.

Return Values

S_OK

The specified key was successfully removed from the table.

S_FALSE

Indicates that no object has been registered with the specified key.

Comments

A bind context maintains a table of interface pointers, each associated with a string key. This enables communication between a moniker implementation and the caller that initiated the binding operation. One party can store an interface pointer under a string known to both parties so that the other party can later retrieve it from the bind context.

This method is used to remove an entry from the table. If the specified key is found, the bind context releases its reference to the object.

See Also

IBindCtx::RegisterObjectParam

IBindCtx::SetBindOptions

Specifies new values for the binding parameters stored in the bind context. Subsequent binding operations can call **IBindCtx::GetBindOptions** to retrieve the parameters.

```
HRESULT SetBindOptions(
  BIND_OPTS *pbindopts        //Pointer to a BIND_OPTS structure
 );
```

Parameter

pbindopts

[in] Points to a **BIND_OPTS** structure containing the binding parameters. For more information on the **BIND_OPTS** structure, see the "Data Structures" section.

Return Values

S_OK

The parameters were stored successfully.

E_OUTOFMEMORY

Indicates insufficient memory.

Comments

A bind context contains a block of parameters, stored in a **BIND_OPTS** structure, that are common to most **IMoniker** operations and that do not change as the operation moves from piece to piece of a composite moniker.

Notes to Callers

This method can be called by moniker clients, that is, those who use monikers to acquire interface pointers to objects.

When you first create a bind context using the **CreateBindCtx** API function, the fields of the **BIND_OPTS** structure are initialized to the following values:

```
cbStruct = sizeof(BINDOPTS);
grfFlags = 0;
grfMode = STGM_READWRITE;
dwTickCountDeadline = 0;
```

You can use the **IBindCtx::SetBindOptions** method to modify these values before using the bind context, if you want values other than the defaults. See **BIND_OPTS** for more information.

IBindCtx::GetBindOptions

IClassFactory

The **IClassFactory** interface manages the creation of new objects. This interface is supported by class objects associated with CLSIDs.

When to Implement

You must implement this interface for every object definition so objects of that type can be created.

When to Use

Call the methods of this interface when creating new objects through a class object. First, call the **CoGetClassObject** API function to get an **IClassFactory** interface pointer to the class object, and then call the **CreateInstance** method to create an uninitialized object.

It is, however, not always necessary to go through this process to create an object. To create a single uninitialized object, you can, instead, just call **CoCreateInstance**. OLE also provides numerous helper functions (with names of the form **OleCreate***Xxx*) to create compound document objects.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IClassFactory Methods	**Description**
CreateInstance	Creates an uninitialized object.
LockServer	Locks object application open in memory.

See Also

CoGetClassObject, **CoCreateInstance** , **OleCreate**

IClassFactory::CreateInstance

Creates an uninitialized object.

```
HRESULT CreateInstance(
   IUnknown * pUnkOuter,         //Object is or isn't part of an aggregate
   REFIID riid,                  //Interface identifier
   void ** ppvObject             //On return, pointer to interface pointer location
  );
```

Parameters

pUnkOuter

[in] Indicates whether the object is being created as part of an aggregate. If so, you should use *pUnkOuter* to supply a pointer to the controlling unknown of the aggregate that will use the newly created object. If not, *pUnkOuter* should be NULL.

riid

[in]Specifies the IID of the interface to be used to communicate with the newly created object. If *pUnkOuter* is NULL, this parameter is frequently the IID of the initializing interface; if *pUnkOuter* is non-NULL, *riid* must be **IID_IUnknown**.

ppvObject

[out]On return, points to the location of the requested interface pointer. If the object does not support the interface specified in *riid*, *ppvObj* is set to NULL.

Return Values

S_OK

The specified object was created.

CLASS_E_NOAGGREGATION

The *pUnkOuter* parameter was non-NULL and the object does not support aggregation.

E_NOINTERFACE

The object that *ppvObj* points to does not support the interface identified by *riid*.

E_UNEXPECTED

An unexpected error occurred.

E_OUTOFMEMORY

Out of memory.

E_INVALIDARG

One or more arguments are invalid.

Comments

The **IClassFactory** interface is always on a class object. The **CreateInstance** method creates an uninitialized object, which is defined in the code associated with the class object.

The *pUnkOuter* parameter indicates whether the object is being created as part of an aggregate. Object definitions are not required to support aggregation – they must be specifically designed and implemented to support it.

The *riid* parameter specifies the IID (interface ID) of the interface through which you communicate with the new object. If *pUnkOuter* is non-NULL (indicating aggregation), the value of the *riid* parameter must be **IID_IUnknown**. If the object is not part of an aggregate, *riid* often specifies the interface though which the object will be initialized.

For OLE embeddings, the initialization interface is **IPersistStorage**, but in other situations, other interfaces are used. To initialize the object, there must be a subsequent call to an appropriate method in the initializing interface. Common initialization functions include **IPersistStorage::InitNew** (for new, blank embeddable components), **IPersistStorage::Load** (for reloaded embeddable components),

IPersistStream::Load, or **IPersistFile::Load**.

In general, if an application supports one object definition, and the class object is registered for single use, only one object can be created. The application must not create other objects, and a request to do so should return an error from **IClassFactory::CreateInstance**. The same is true for applications that support multiple classes, each with a class object registered for single use; a **CreateInstance** for one class followed by a **CreateInstance** for any of the classes should return an error.

To avoid returning an error, applications that support multiple object definitions with single-use class objects can revoke the registered class object of the first definition by calling **CoRevokeClassObject** when a request for instantiating a second is received. For example, suppose there are two classes, A and B. When **IClassFactory::CreateInstance** is called for class A, revoke the class object for B. When B is created, revoke the class object for A. This solution complicates shutdown because one of the class objects might have already been revoked (and cannot be revoked twice).

IClassFactory::LockServer

Called by the client of a class object to keep an open object application in memory, allowing instances to be created more quickly.

```
HRESULT LockServer(
   BOOL fLock          //Increments or decrements the lock count
  );
```

Parameter

fLock
If **TRUE**, increments the lock count; if **FALSE**, decrements the lock count.

Return Values

S_OK
The specified object was either locked (*fLock* = TRUE) or unlocked from memory (*fLock* = FALSE).

E_FAIL
Indicates an unspecified error.

E_OUTOFMEMORY
Out of memory.

E_UNEXPECTED
An unexpected error occurred.

Comments

IClassFactory::LockServer controls whether an object application is kept in memory. Keeping the application alive in memory allows instances to be created more quickly.

Notes to Callers

Most clients do not need to call this function. It is provided only for the benefit of sophisticated clients that require special performance in the creation of certain kinds of objects.

Notes to Implementors

If the lock count is zero, there are no more objects in use, and the application is not under user control, then the server can be closed. One way to implement **IClassFactory::LockServer** is to call **CoLockObjectExternal**.

The process that locks the object application is responsible for unlocking it. Once the class object is released, there is no mechanism that guarantees the caller connection to the same object definition later (as in the case where a class object is registered as single-use). It is important to count all calls, not just the last one, to **IClassFactory::LockServer**, because calls must be balanced before attempting to release the pointer to the class object or an error results. For every call to **LockServer** with *fLock* set to TRUE, there must be a call to **LockServer** with *fLock* set to FALSE. When the lock count and the class object reference count are both zero, the class object can be freed.

CoLockObjectExternal

IDataAdviseHolder

The **IDataAdviseHolder** interface creates and manages connections between an advise sink and a data object so that the advise sink can receive notification of changes in the data object. The **IDataAdviseHolder** interface also sends the notifications to the advise sinks it currently knows about when changes occur.

The object or container wishing to receive notification of changes in your data object creates an advise sink object with the **IAdviseSink** interface. The object or container application then calls your **IDataObject::DAdvise** method.

Typically, in your **IDataObject** implementation, you delegate handling of the advise sinks to the OLE-provided **IDataAdviseHolder** interface. This interface has methods to keep track of any **IDataObject::DAdvise** calls that your data object has received and to send notification back to the advise sinks as necessary when data has changed.

When to implement

Typically, you use the OLE-provided implementation of **IDataAdviseHolder** to simplify your implementation of the **DAdvise**, **DUnadvise**, and **EnumDAdvise** methods in the **IDataObject** interface.

When to use

Your implementation of **IDataObject** can call the methods in **IDataAdviseHolder**. The first time you receive a call to **IDataObject::DAdvise**, you call the API function **CreateDataAdviseHolder** to create an instance of the OLE-provided implementation of **IDataAdviseHolder**. Then, you delegate your **IDataObject** implementations of the **DAdvise**, **DUnadvise**, and **EnumDAdvise** methods to the corresponding methods in the OLE-provided **IDataAdviseHolder**.

When the data of interest to an advise sink actually changes, you call **IDataAdviseHolder::SendOnDataChange** from your data object to carry out the necessary notifications.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IDataAdviseHolder Methods	Description
Advise	Creates a connection between an advise sink and a data object so the advise sink can receive notification of change in the data object.
Unadvise	Destroys a notification connection previously set up with the **Advise** method.
EnumAdvise	Returns an object that can be used to enumerate the current advisory connections.
SendOnDataChange	Sends a change notification back to each advise sink that is currently being managed.

See Also

IDataObject, **IAdviseSink**

IDataAdviseHolder::Advise

Creates a connection between an advise sink and a data object for receiving notifications.

```
HRESULT Advise(
  IDataObject * pDataObject,      //Specifies the data object for which notifications are requested
  FORMATETC * pFormatetc,         //Description of data that is of interest to the advise sink
  DWORD advf,                     //Flags that specify how the notification takes place
  IAdviseSink * pAdvSink,         //The advise sink requesting notification
  DWORD * pdwConnection           //Identifies the connection for future calls to the Unadvise method
 );
```

Parameters

pDataObject

[in]Points to the data object for which notifications are requested. If data in this object changes, a notification is sent to the advise sinks that have requested notification.

pFormatetc

[in]Points to the specified format, medium, and target device that is of interest to the advise sink requesting notification. For example, one sink may want to know only when the bitmap representation of the data in the the data object changes. Another sink may be interested in only the metafile format of the same object. Each advise sink is notified when the data of interest changes. This data is passed back to the advise sink when notification occurs.

advf

[in]Contains a group of flags for controlling the advisory connection. Valid values are from the enumeration **ADVF**. However, only some of the possible **ADVF** values are relevant for this method. The following table briefly describes the relevant values; a more detailed description can be found in the description of the **ADVF** enumeration.

ADVF Value	Description
ADVF_NODATA	Asks that no data be sent along with the notification.
ADVF_ONLYONCE	Causes the advisory connection to be destroyed after the first notification is sent. An implicit call to **IDataAdviseHolder::Unadvise** is made on behalf of the caller to remove the connection.
ADVF_PRIMEFIRST	Causes an initial notification to be sent regardless of whether or not data has changed from its current state.
ADVF_DATAONSTOP	When specified with ADVF_NODATA, this flag causes a last notification with the data included to be sent before the data object is destroyed. When ADVF_NODATA is not specified, this flag has no effect.

pAdvSink

[in]Points to the advisory sink that receives the change notification.

pdwConnection

[in]Points to the location of a returned token that identifies this connection and can later be used to delete the advisory connection. It deletes the connection by passing it to

IDataAdviseHolder::Unadvise. If this value is zero, the connection was not established.

Return Values

S_OK
The advisory connection was created.

E_INVALIDARG
One or more arguments are invalid.

Comments

Through the connection established through this method, the advisory sink can receive future notifications in a call to **IAdviseSink::OnDataChange**.

An object issues a call to **IDataObject::DAdvise** to request notification on changes to the format, medium, or target device of interest. This data is specified in the *pFormatetc* parameter. The **DAdvise** method in turn calls **IDataAdviseHolder::Advise** and delegates the task of setting up and tracking a connection to the advise holder. When the format, medium, or target device in question changes, the data object calls **IDataAdviseHolder::SendOnDataChange** to actually send the necessary notifications.

The established connection can be deleted by passing the value in *pdwConnection* to **IDataAdviseHolder::Unadvise**.

See also

ADVF, **CreateDataAdviseHolder**, **FORMATETC**, **IDataAdviseHolder::Unadvise**, **IDataObject::DAdvise**

IDataAdviseHolder::EnumAdvise

Returns an object that can be used to enumerate the current advisory connections.

```
HRESULT EnumAdvise(
   IEnumSTATDATA ** ppenumAdvise         //Location for IEnumSTATDATA
  );
```

Parameter

ppenumAdvise
[out]Points to the location where the new enumerator object should be returned. If this value is NULL, there are no connections to advise sinks at this time.

Return Values

S_OK
The enumerator object is successfully instantiated or there are no connections.

E_OUTOFMEMORY
The enumerator object could not be instantiated due to lack of memory.

Comments

The enumerator object returned by this method implements the **IEnumSTATDATA** interface, one of the standard enumerator interfaces that contain the **Next**, **Reset**, **Clone**, and **Skip** methods. **IEnumSTATDATA** enumerates the data stored in an array of **STATDATA** structures. **IDataAdviseHolder::EnumAdvise** is typically called from within **IDataObject::DEnumAdvise**.

Adding more advisory connections while the enumerator object is active has an undefined effect on the enumeration that results from this method.

See Also

IEnum*XXXX*, **IEnumSTATDATA**, **IDataObject::EnumDAdvise**

IDataAdviseHolder::SendOnDataChange

Sends notifications to each advise sink by calling the **IAdviseSink::OnDataChange** method for each advise sink currently being handled in this instance of **IDataAdviseHolder**.

```
HRESULT SendOnDataChange(
  IDataObject * pDataObject,     //Points to the data object that has changed
  DWORD dwReserved,              //Reserved
  DWORD advf                     //Advise flag that specifies how to send the notification
 );
```

Parameters

pDataObject
[in]Points to the data object where the data has just changed. This data object is used in the subsequent calls to **IAdviseSink::OnDataChange**.

dwReserved
[in]Reserved for future use; must be zero.

advf
[in]Contains the advise flag values that specify how the call to **IAdviseSink::OnDataChange** is made. These flag values are from the enumeration **ADVF**. Typically, the value for *advf* is NULL. The only exception occurs when the data object is shutting down and must send a final notification that includes the actual data to sinks that have specified ADVF_DATAONSTOP and ADVF_NODATA in their call to **IDataObject::DAdvise**. In this case, *advf* contains ADVF_DATAONSTOP.

Return Values

S_OK
The call to **IAdviseSink::OnDataChange** was made.

E_OUTOFMEMORY
Ran out of memory and the notifications could not be sent.

Comments

The data object calls this method when it detects a change that would be of interest to an advise sink that has previously requested notification.

Most notifications include the actual data with them. The only exception is if the ADVF_NODATA flag was previously specified when the connection was initially set up in the **IDataAdviseHolder::Advise** method.

Before calling the **IAdviseSink::OnDataChange** method for each advise sink, this method obtains the actual data by calling the **IDataObject::GetData** method for the data object specified in the *pDataObject* parameter.

See Also

ADVF, **IAdviseSink::OnDataChange**

IDataAdviseHolder::Unadvise

Removes a connection between a data object and an advisory sink that was set up through a previous call to the **IDataAdviseHolder::Advise** method. **IDataAdviseHolder::Unadvise** is typically called in **IDataObject::DUnadvise**.

```
HRESULT Unadvise(
  DWORD dwConnection        //Specifies the connection to remove
 );
```

Parameter

dwConnection
Specifies the connection to remove. This value was returned by **IDataAdviseHolder::Advise** when the connection was originally established.

Return Values

S_OK
The specified connection was successfully deleted.

OLE_E_NOCONNECTION
The specified *dwConnection* is not a valid connection.

See Also

IDataAdviseHolder::Advise, **IDataObject::DUnadvise**

IDataObject

The **IDataObject** interface provides data transfer capabilities and notification of changes in data. The format of the transferred data is specified along with the medium through which OLE transfers the data. Optionally, the data can be rendered for a specific target device. In addition to retrieving and storing data, the **IDataObject** interface contains methods to enumerate available formats and to set up an advisory sink for handling change notifications.

A data object is an object that contains an **IDataObject** implementation. Data objects may support all or some of the functions available through the **IDataObject** interface. For example, some data objects do not allow callers to send them data. Other data objects do not support advisory connections and change notifications. However, for those data objects that do support change notifications, OLE provides an object called a data advise holder. Since a data object can have multiple connections, each with their own set of attributes, managing these connections and sending the appropriate notifications gets complex. The data advise holder exists to simplify this task.

When to Implement

You implement the **IDataObject** interface if you are developing a container or server application that is capable of transferring data. For example, if your application allows its data to be pasted or dropped into another application, you must implement the **IDataObject** interface.

OLE provides implementations for its default object handler and its cache.

When to Use

Any application that can receive data uses the methods in the **IDataObject** interface.

When you call the methods in the **IDataObject** interface, you specify a format, a medium, and, optionally, a target device for which the data should be rendered. If you want to be notified when the data changes, you can set up an advisory connection through which notifications can be sent.

Methods in VTable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IDataObject Methods	**Description**
GetData	Renders the data described in a **FORMATETC** structure and transfers it through the **STGMEDIUM** structure.
GetDataHere	Renders the data described in a **FORMATETC** structure and transfers it through the **STGMEDIUM** structure allocated by the caller.
QueryGetData	Determines whether the data object is capable of rendering the data described in the **FORMATETC** structure.
GetCanonicalFormatEtc	Provides a potentially different but logically equivalent **FORMATETC** structure.
SetData	Provides the source data object with

	data described by a **FORMATETC** structure and an **STGMEDIUM** structure.
EnumFormatEtc	Returns an object to enumerate the **FORMATETC** supported by the data object.
DAdvise	Creates a connection between a data object and an advise sink so the advise sink can receive notifications of changes in the data object.
DUnadvise	Destroys a notification previously set up with **DAdvise**.
EnumDAdvise	Returns an object to enumerate the current advisory connections.

IDataObject::DAdvise

Creates a connection between a data object and an advise sink so the advise sink can receive notifications of changes in the data object.

HRESULT DAdvise(
  FORMATETC * *pFormatetc*,   //Description of data that is of interest to the advise sink
  DWORD *advf*,   //Flags that specify how the notification takes place
  IAdviseSink * *pAdvSink*,   //The advise sink that is requesting notification
  DWORD * *pdwConnection*   //Identifies the connection for future calls to the Unadvise method
 );

Parameters

pFormatetc

[in]Points to the particular format, target device, aspect, and medium that will be used for future notifications. For example, one sink may want to know only when the bitmap representation of the data in the the data object changes. Another sink may be interested in only the metafile format of the same object. Each advise sink is notified when the data of interest changes. This data is passed back to the advise sink when notification occurs.

advf

[in]Contains a group of flags for controlling the advisory connection. Valid values are from the enumeration **ADVF**. However, only some of the possible **ADVF** values are relevant for this method. The following table briefly describes the relevant values. You can find a more detailed description in **ADVF**.

ADVF Value	**Description**
ADVF_NODATA	Asks the data object to avoid sending data with the notifications. Typically data is sent. This flag is a way to override the default behavior. When ADVF_NODATA is used, the TYMED member of the **STGMEDIUM** structure that is passed to OnDataChange will usually contain TYMED_NULL. The caller can then retrieve the data with a subsequent **IDataObject::GetData** call.
ADVF_ONLYONCE	Causes the advisory connection to be destroyed after the first change notification is sent. An implicit call to **IDataObject::DUnadvise** is made on behalf of the caller to remove the connection.
ADVF_PRIMEFIRST	Asks for an additional initial notification. The combination of ADVF_ONLYONCE and ADVF_PRIMEFIRST provides, in effect, an asynchronous **IDataObject::GetData** call.
ADVF_DATAONSTOP	When specified with ADVF_NODATA, this flag causes a last notification with the data included to to be sent before the

data object is destroyed.

If used without ADVF_NODATA, **IDataObject::DAdvise** can be implemented in one of the following ways:

- the ADVF_DATAONSTOP can be ignored.
- the object can behave as if ADVF_NODATA was specified.
- a change notification is sent only in the shutdown case. Data changes prior to shutdown do not cause a notification to be sent.

pAdvSink
[in]Points to the advisory sink that will receive the change notification.

pdwConnection
[in]Points to the location of a returned token that identifies this connection. You can use this token later to delete the advisory connection (by passing it to **IDataObject::DUnadvise**). If this value is zero, the connection was not established.

Return Values

S_OK
The advisory connection was created.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

E_OUTOFMEMORY
The connection was not created because the system ran out of memory.

E_NOTIMPL
This method is not implemented for the data object.

DV_E_LINDEX
Invalid value for *lindex*; currently, only -1 is supported.

DV_E_FORMATETC
Invalid value for *pFormatetc*.

OLE_E_ADVISENOTSUPPORTED
The data object does not support change notification.

Comments

The **IDataObject::DAdvise** method creates a connection between the data object and the caller. The caller provides an advisory sink through which the notifications can be sent when the object's data changes. The advise sink issues the call to **IDataObject::DAdvise**. Advisory connections are associated with a particular description of the data. Data clients specify the format, aspect, medium, and/or target device of interest in the **FORMATETC** structure passed in. If the data object does not support one or more of the requested attributes or the sending of notifications at all. It can refuse the connection by returning OLE_E_ADVISENOTSUPPORTED.

Objects used for data transfer typically do not support advisory notifications and return OLE_E_ADVISENOTSUPPORTED from **IDataObject::DAdvise**.

Containers of linked objects can set up advisory connections directly with the bound link source or indirectly via the standard OLE link object that manages the connection. Connections set up with the bound link source are not automatically deleted. The container must explicitly call **IDataObject::DUnAdvise** on the bound link source to delete it. Connections set up through the OLE link object are destroyed when the link object is deleted.

The OLE default link object creates a "wildcard advise" with the link source so OLE can maintain the time of last change. This advise is specifically used to note the time that anything changed. OLE ignores all data formats that may have changed, noting only the time of last change. To allow wildcard advises, set the **FORMATETC** members as follows before calling **IDataObject::DAdvise**:

```
cf == 0;
ptd == NULL;
dwAspect ==-1;
lindex == -1
tymed == -1;
```

The advise flags should also include ADVF_NODATA. Wildcard advises from OLE should always be accepted by applications.

For those data objects that support notifications, a data advise holder object can be used to simplify the implementation of **DAdvise** and the other notification methods in **IDataObject** (**DUnadvise** and **EnumAdvise**). The data advise holder is an object provided by OLE that manages the registration and sending of notifications. With the first invocation of **DAdvise**, the helper function **CreateDataAdviseHolder** can be called to create the data advise holder and provide the data object with a pointer to it. The data object then delegates to the **IDataAdviseHolder::Advise** method in the data advise holder to create the requested connection.

See also

ADVF, **FORMATETC**, **CreateDataAdviseHolder**, **IAdviseSink::OnDataChange**, **IDataObject::DUnAdvise**

IDataObject::DUnadvise

Destroys a previously set up notification

```
HRESULT DUnadvise(
   DWORD dwConnection        //Specifies the connection to remove
  );
```

Parameter

dwConnection
[in]Specifies the connection to remove. This value was returned by **IDataObject::DAdvise** when the connection was originally established.

Return Values

S_OK
The specified connection was successfully deleted.

OLE_E_NOCONNECTION
The specified *dwConnection* is not a valid connection.

OLE_E_ADVISENOTSUPPORTED
This **IDataObject** implementation does not support notification.

Comments

This methods destroys a notification created with a call to the **IDataObject::DAdvise** method.

If the advisory connection being deleted was initially set up using **IDataAdviseHolder::Advise** instead of **IDataObject::DAdvise**, you must call **IDataAdviseHolder::Unadvise** to delete it.

See Also

IDataObject::DAdvise

IDataObject::EnumDAdvise

Returns an object to enumerate the current advisory connections.

```
HRESULT EnumDAdvise(
  IEnumSTATDATA ** ppenumAdvise      //Location for IEnumSTATDATA
 );
```

Parameter

ppenumAdvise
[out]Points to the location where the new enumerator object should be returned. If the returned value is NULL, there are no connections to advise sinks at this time.

Return Values

S_OK
The enumerator object is successfully instantiated or there are no connections.

E_OUTOFMEMORY
The enumerator object could not be instantiated due to lack of memory.

OLE_E_ADVISENOTSUPPORTED
Advisory notifications are not supported by this object.

Comments

The enumerator object returned by this method implements the **IEnumSTATDATA** interface, one of the standard enumerator interfaces that contain the **Next**, **Reset**, **Clone**, and **Skip** methods. **IEnumSTATDATA** enumerates the data stored in an array of **STATDATA** structures.

While this enumeration is in progress, the effect of adding more advisory connections on the subsequent enumeration is undefined.

See Also

IEnumSTATDATA

IDataObject::EnumFormatEtc

Returns an object to enumerate the **FORMATETC** structures that can be used with **IDataObject::GetData** or **IDataObject::SetData**. You use this method when you want to enumerate the **FORMATETC** structures for a data object.

```
HRESULT EnumFormatEtc(
  DWORD dwDirection,                   //Specifies a value from the enumeration DATADIR
  IEnumFORMATETC ** ppenumFormatetc    //Location for IEnumFORMATETC
 );
```

Parameters

dwDirection
[in]Specifies a value from the enumeration **DATADIR**.

```
typedef enum tagDATADIR
{
    DATADIR_GET = 1,
    DATADIR_SET = 2,
} DATADIR;
```

The value DATADIR_GET enumerates the formats that can be passed in **IDataObject::GetData**. The value DATADIR_SET enumerates those formats that can be passed in **IDataObject::SetData**.

ppenumFormatetc
[out]Points to the location where the new enumerator object should be returned.

Return Values

S_OK
Enumerator object was successfully returned.

E_INVALIDARG
One or more arguments are invalid.

E_OUTOFMEMORY
Enumerator object was not returned because the system ran out of memory.

E_NOTIMPL
The direction specified by *dwDirection* is not supported.

OLE_S_USEREG
Requests that OLE enumerate the formats from the registry.

Comments

This method creates and returns an enumerator object that can be used to determine all of the ways the data object can describe data in a **FORMATETC** structure. The enumerator object implements **IEnumFORMATETC**, one of the standard enumerator interfaces. The caller is responsible for calling **IEnumFormatEtc::Release** when it is finished with the enumeration.

If a **FORMATETC** structure is enumerated by **IDataObject::EnumFormatEtc**, there is no guarantee that the format is supported because the formats can change over time. Accordingly, applications should treat the enumeration as a hint of the format types that can be passed.

IDataObject::EnumFormatEtc is called when one of the following actions occurs:

- An application calls **OleSetClipboard**. OLE must determine what data to place on the Clipboard and whether it is necessary to put OLE 1 compatibility formats on the Clipboard.
- Data is being pasted from the Clipboard or dropped. An application uses the first acceptable format.
- The Paste Special dialog box is displayed. The target application builds the list of formats from the **FORMATETC** entries.

Formats can be registered statically in the registration database or dynamically during object initialization. If an object has an unchanging list of formats and these formats are registered in the registration database, it can ask OLE to perform the enumeration using the registration database by calling the helper function **OleRegEnumFormatEtc** or by returning OLE_S_USEREG.

OLE_S_USEREG instructs the default object handler to call **OleRegEnumFormatEtc**. Object applications that are implemented as DLL object applications cannot return OLE_S_USEREG. They must call **OleRegEnumFormatEtc** directly.

Private formats can be enumerated for OLE 1 objects, if they are registered with the RequestDataFormats or SetDataFormats keys in the registration database. Also, private formats can be enumerated for OLE 2 objects, if they are registered with the GetDataFormats or SetDataFormats keys.

For OLE 1 objects whose servers do not have RequestDataFormats or SetDataFormats information registered in the registration database, a call to **EnumFormatEtc** with DATADIR_GET only enumerates the Native and Metafile formats, regardless of whether they support these formats or others. Calling **EnumFormatEtc** with DATADIR_SET on such objects only enumerates Native, regardless of whether the object supports being set with other formats.

The **FORMATETC** structure returned by the enumeration usually indicates a NULL target device (*ptd*). This is appropriate because, unlike the other members of **FORMATETC**, the target device does not participate in the object's decision as to whether it can accept or provide the data in either a **SetData** or **GetData** call.

The TYMED member of **FORMATETC** often indicates that more than one kind of storage medium is acceptable. You should always mask and test for it by using a Boolean OR operator.

See Also

FORMATETC, **OleRegEnumFormatEtc**, **IEnumFormatEtc**, **IDataObject::SetData**, **IDataObject::GetData**

IDataObject::GetCanonicalFormatEtc

Provides a potentially different but logically equivalent **FORMATETC** structure. You use this method when you have different **FORMATETC** structures that may return the same data.

```
HRESULT GetCanonicalFormatEtc(
   FORMATETC * pFormatetcIn,        //Points to the FORMATETC structure that the caller would like to use
   FORMATETC * pFormatetcOut        //Points to the canonical equivalent FORMATETC structure
  );
```

Parameters

pFormatetcIn
: [in]Points to the format, media, and target device that the caller would like to use in a subsequent call to retrieve data, for example, **IDataObject::GetData**. The TYMED member is not significant and should be ignored.

pFormatetcOut
: [out]Points to a **FORMATETC** structure that is canonically equivalent to *pFormatetcIn*. The caller allocates this structure and this method fills in the data. In a subsequent call to retrieve data, for example, **IDataObject::GetData**, the caller uses the *pFormatetcOut* value. This value is NULL if the method returns DATA_S_SAMEFORMATETC. The TYMED member is not significant and should be ignored.

Return Values

S_OK
: The returned **FORMATETC** structure is different from the one that was passed.

E_INVALIDARG
: One or more arguments are invalid.

E_UNEXPECTED
: An unexpected error occurred.

E_OUTOFMEMORY
: Structure was not created because the system ran out of memory.

DATA_S_SAMEFORMATETC
: The **FORMATETC** structures are the same and NULL is returned in *pFormatetcOut*.

DV_E_LINDEX
: Invalid value for *lindex*; currently, only -1 is supported.

DV_E_FORMATETC
: Invalid value for *pFormatetc*.

OLE_E_NOTRUNNING
: Object application is not running.

Comments

A data object can return exactly the same data even though you have specified different **FORMATETC** structures in subsequent requests to retrieve data. For example, the same data can be returned for different target devices if the data is not sensitive to the target devices.

The **IDataObject::GetCanonicalFormatEtc** method provides the canonical equivalent of a specified **FORMATETC** structure. By calling this function prior to retrieving the data object, you can use the canonical equivalent **FORMATETC** in your subsequent call to **IDataObject::GetData**. You can then eliminate unnecessary calls to retrieve data if two different **FORMATETC** structures have the same canonical equivalent.

If the data object never provides device-specific renderings, the implementation of **IDataObject::GetCanonicalFormatEtc** simply copies the input **FORMATETC** to the output

FORMATETC, stores a NULL in the *ptd* field of the output **FORMATETC**, and returns DATA_S_SAMEFORMATETC.

See Also

IDataObject::GetData, **FORMATETC**

IDataObject::GetData

Renders the data described in the specified **FORMATETC** structure and transfers it through the specified **STGMEDIUM** structure. The caller then assumes responsibility for releasing the **STGMEDIUM** structure. You use this method when you want to transfer data from a source object to a target.

```
HRESULT GetData(
  FORMATETC * pFormatetc,     //Points to the data and formats to be transferred
  STGMEDIUM * pmedium         //Points to the storage medium in which the returned data is transferred
 );
```

Parameters

pFormatetc
[in]Points to the format, media, and target device to use when passing the data. If you specify more than one medium by using the Boolean OR operator on the value specified in **TYMED**, **IDataObject::GetData** chooses the medium that best represents the data, does the allocation, and decides what is responsible for the release. The decision is indicated through the value returned in the **IUnknown** returned as part of *pmedium*.

pmedium
[out]Points to the storage medium containing the returned data. The medium is allocated and filled in by **IDataObject::GetData**. **STGMEDIUM** includes a value for the IUnknown to call for releasing the medium.

Return Values

S_OK
Data was successfully retrieved and placed in the storage medium provided.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

E_OUTOFMEMORY
The system did not retrieve data because it ran out of memory.

DV_E_LINDEX
Invalid value for *lindex*; currently, only -1 is supported.

DV_E_FORMATETC
Invalid value for *pFormatetc*.

DV_E_TYMED
Invalid *tymed* value.

DV_E_DVASPECT
Invalid *dwAspect* value.

OLE_E_NOTRUNNING
Object application is not running.

STG_E_MEDIUMFULL
An error occurred when allocating the medium.

Comments

The **IDataObject::GetData** method must check all fields in the **FORMATETC** structure. It is important that **IDataObject::GetData** renders the requested aspect and, if possible, uses the requested medium. If the data object cannot comply with the information specified in the **FORMATETC**, DV_E_FORMATETC is returned. If an attempt to allocate the medium fails, STG_E_MEDIUMFULL is returned. It is important to fill in all of the fields in the **STGMEDIUM**.

Although the caller can specify more than one medium for returning the data, only one medium can actually be returned. The **IDataObject::GetData** method chooses which medium to return. If this initial transfer fails, this method can try one of the other media specified before returning an error.

Data transferred across a stream extends from position zero of the stream pointer through to the position immediately before the current stream pointer (that is, the stream pointer position upon exit).

See Also

IDataObject::GetDataHere, **IDataObject::SetData**, **FORMATETC**, **STGMEDIUM**

IDataObject::GetDataHere

Renders the data described in a **FORMATETC** structure and transfers it through the **STGMEDIUM** structure allocated by the caller. You use this method when you want to transfer data from a source object to a target.

```
HRESULT GetDataHere(
    FORMATETC * pFormatetc,      //Points to the data and formats to be transferred
    STGMEDIUM * pmedium          //Points to the storage medium in which the returned data is transferred
  );
```

Parameters

pFormatetc

[in]Points to the format, media, and target device to use when passing the data. Only one medium can be specified in **TYMED**.

The only values valid for TYMED are TYMED_STORAGE, TYMED_STREAM, TYMED_HGLOBAL, or TYMED_FILE.

pmedium

[out]Points to the storage medium containing the the returned data. The medium is allocated by the caller and filled in by **IDataObject::GetDataHere**. Since the caller allocates the medium, the caller is responsible for freeing the medium. The caller will always get a return value of NULL for the **IUnknown** specified for releasing the medium.

Return Values

S_OK
Data was successfully retrieved and placed in the storage medium provided.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

E_OUTOFMEMORY
The system didn't retrieve data because it ran out of memory.

DV_E_LINDEX
Invalid value for *lindex*; currently, only -1 is supported.

DV_E_FORMATETC
Invalid value for *pFormatetc*.

DV_E_TYMED
Invalid *tymed* value.

DV_E_DVASPECT
Invalid *dwAspect* value.

OLE_E_NOTRUNNING
Object application is not running.

STG_E_MEDIUMFULL
The medium provided by the caller is not large enough to contain the data.

Comments

The **IDataObject::GetDataHere** method is similar to **IDataObject::GetData** except that the caller allocates the medium specified in *pmedium* and is responsible for freeing it. This method copies the data into the actual medium provided by the caller. For example, if the medium is TYMED_HGLOBAL, this method cannot resize the medium or allocate a new hGlobal.

When the transfer medium is a stream, OLE makes assumptions about where the data is being returned and the position of the stream's seek pointer. In a **GetData** call, the data returned is from stream position zero through just before the current seek pointer of the stream (that is, the position on exit). For **GetDataHere**, the data returned is from the stream position on entry through just before the position on exit. Note that some media are not appropriate when you are using **GetDataHere**, including GDI types such as metafiles. The **GetDataHere** method cannot put data into a caller-provided metafile.

See Also

IDataObject::GetData, **FORMATETC**, **STGMEDIUM**

IDataObject::QueryGetData

Determines whether the data object is capable of rendering the data described in the **FORMATETC** structure. Objects attempting a paste or drop operation can call this method before beginning the process. In some cases, the subsequent paste or drop operation may still fail.

```
HRESULT QueryGetData(
  FORMATETC * pFormatetc        //Points to the data and formats to be used for the query
 );
```

Parameter

pFormatetc
[in]Points to the format, media, and target device to use for the query.

Return Values

S_OK
Indicates a subsequent call to **IDataObject::GetData** would probably be successful.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

E_OUTOFMEMORY
The process didn't execute because the system ran out of memory.

DV_E_LINDEX
Invalid value for *lindex*; currently, only -1 is supported.

DV_E_FORMATETC
Invalid value for *pFormatetc*.

DV_E_TYMED
Invalid *tymed* value.

DV_E_DVASPECT
Invalid *dwAspect* value.

OLE_E_NOTRUNNING
Object application is not running.

See Also

IDataObject::GetData, **FORMATETC**

IDataObject::SetData

Transfers data to the source data object.

```
HRESULT SetData(
   FORMATETC * pFormatetc,       //Points to the data and formats used to interpret the data
   STGMEDIUM * pmedium,          //Points to the storage medium in which the data is transferred
   BOOL fRelease                 //Indicates what owns the storage medium after the call is completed
  );
```

Parameters

pFormatetc
[in]Points to the format used by the data object when interpreting the data contained in the storage medium.

pmedium
[in]Points to the storage medium.

fRelease
[in]Indicates what has ownership of the storage medium after the call is complete. If *fRelease* is TRUE, **IDataObject::SetData** takes ownership, freeing the medium after it has been used by calling **ReleaseStgMedium**. If *fRelease* is FALSE, the caller retains ownership and the callee uses the storage medium for the duration of the call only.

Return Values

S_OK
Data was successfully transferred.

E_FAIL
The data was not transferred.

E_NOTIMPL
This method is not implemented for the data object.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

E_OUTOFMEMORY
The data wasn't transferred because the system ran out of memory.

DV_E_LINDEX
Invalid value for *lindex*; currently, only -1 is supported.

DV_E_FORMATETC
Invalid value for *pFormatetc*.

DV_E_TYMED
Invalid *tymed* value.

DV_E_DVASPECT
Invalid *dwAspect* value.

OLE_E_NOTRUNNING
Object application is not running.

Comments

The callee does not take ownership of the data until it has successfully used it and no error code is returned.

The type of medium (TYMED) in the *pformatetc* and *pmedium* parameters must be equal. For example, one cannot be an hGlobal and the other a stream.

IDataObject::GetData, **FORMATETC**, **STGMEDIUM**

IDropSource

The **IDropSource** interface is one of the interfaces you implement to provide drag-and-drop operations in your application. It contains methods used in any application used as a data source in a drag-and-drop operation. The data source application in a drag-and-drop operation is responsible for:

- Determining the data being dragged based on the user's selection.
- Initiating the drag-and-drop operation based on the user's mouse actions.
- Generating some of the visual feedback during the drag-and-drop operation, such as setting the cursor and highlighting the data selected for the drag-and-drop operation.
- Canceling or completing the drag-and-drop operation based on the user's mouse actions.
- Performing any action on the original data caused by the drop operation, such as deleting the data on a drag move.

The **IDropSource** interface contains the methods for generating visual feedback to the end user and for canceling or completing the drag-and-drop operation. The **DoDragDrop** function, **RegisterDragDrop** function, and **RevokeDragDrop** function are also used in drag-and-drop operations.

When to Implement

Implement the **IDropSource** interface if you are developing a container or server application that can act as a data source for a drag-and-drop operation. The **IDropSource** interface is only required during the drag-and-drop operation.

If you implement the **IDropSource** interface, you must also implement the **IDataObject** interface to represent the data being transferred.

The **IDataObject** interface can be the same as the data object offered to the clipboard. Once you have implemented clipboard operations in your application, you can add drag-and-drop operations with only a little extra work.

When to Use

Your **IDropSource** methods are called by the **DoDragDrop** function. Your application calls the **DoDragDrop** function when it detects that the user has initiated a drag-and-drop operation. Then, **DoDragDrop** calls your **IDropSource** methods during the drag-and-drop operation.

For example, **DoDragDrop** calls **IDropSource::GiveFeedback** when you need to change the cursor shape or when you need to provide some other visual feedback. **DoDragDrop** calls **IDropSource::QueryContinueDrag** when there is a change in the mouse button state to determine if the drag-and-drop operation canceled or completed.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IDropSource Methods	**Description**
QueryContinueDrag	Determines whether a drag-and-drop operation should continue.
GiveFeedback	Gives visual feedback to an end user during a drag-and-drop operation.

See Also

DoDragDrop, **IDataObject**, **IDropTarget**

IDropSource::GiveFeedback

Enables a source application to give visual feedback to its end user during a drag-and-drop operation by providing the DoDragDrop function with an enumeration value specifying the visual effect.

```
HRESULT GiveFeedback(
    DWORD dwEffect          //Effect of a drop operation
  );
```

Parameter

dwEffect
[in] Specifies the DROPEFFECT value returned by the most recent call to IDropTarget::DragEnter, IDropTarget::DragOver, or IDropTarget::DragLeave. For a list of values, see the **DROPEFFECT** enumeration.

Return Values

S_OK
The function completed its task successfully using the cursor set by the source application.

DRAGDROP_S_USEDEFAULTCURSORS
The function completed successfully using the OLE-provided, default cursor.

E_INVALIDARG
One or more arguments are invalid.

E_OUTOFMEMORY
Out of memory.

E_UNEXPECTED
An unexpected error occurred.

Comments

When your application detects that the user has started a drag-and-drop operation, you call the DoDragDrop function. **DoDragDrop** enters a loop, calling IDropTarget::DragEnter when the mouse first enters a drop target window, IDropTarget::DragOver when the mouse changes its position within the target window, and IDropTarget::DragLeave when the mouse leaves the target window.

For every call to either **IDropTarget::DragEnter** or **IDropTarget::DragOver**, **DoDragDrop** calls **IDropSource::GiveFeedback**, passing it the DROPEFFECT value returned from the drop target call. **IDropSource::GiveFeedback** is responsible for changing the cursor shape or for changing the highlighted source based on the value of the *dwEffect* parameter.

DoDragDrop calls **IDropTarget::DragLeave** when the mouse has left the target window. Then, **DoDragDrop** calls **IDropSource::GiveFeedback** and passes the DROPEFFECT_NONE value in the *dwEffect* parameter.

The *dwEffect* parameter can include DROPEFFECT_SCROLL, indicating the source should put up the drag-scrolling variation of the appropriate pointer.

OLE defines a recommended set of cursor shapes that your application should use. See the User Interface Guidelines for more information.

Notes to Implementors

This function is called frequently during the DoDragDrop loop so you can gain performance advantages if you optimize your implementation as much as possible.

See Also

DoDragDrop, IDropTarget

IDropSource::QueryContinueDrag

Determines whether a drag-and-drop operation should be continued, canceled, or completed. You do not call this method directly. The OLE **DoDragDrop** function calls this method during a drag-and-drop operation.

```
HRESULT QueryContinueDrag(
  BOOL fEscapePressed,        //Status of escape key since previous call
  DWORD grfKeyState           //Current state of keyboard modifier keys
 );
```

Parameters

fEscapePressed

[in] Specifies whether the Esc key has been pressed since the previous call to **IDropSource::QueryContinueDrag** or to **DoDragDrop** if this is the first call to **QueryContinueDrag**. A TRUE value indicates the end user has pressed the escape key; a FALSE value indicates it has not been pressed.

grfKeyState

[in] Identifies the current state of the keyboard modifier keys on the keyboard. Valid values can be a combination of any of the flags MK_CONTROL, MK_SHIFT, MK_ALT, MK_BUTTON, MK_LBUTTON, MK_MBUTTON, and MK_RBUTTON.

Return Values

S_OK

The drag operation should continue. This result occurs if no errors are detected, the mouse button starting the drag-and-rop operation has not been released, and the Esc key has not been detected.

DRAGDROP_S_DROP

The drop operation should occur completing the drag operation. This result occurs if *grfKeyState* indicates that the key that started the drag-and-drop operation has been released.

DRAGDROP_S_CANCEL

The drag operation should be canceled with no drop operation occurring. This result occurs if *fEscapePressed* is true indicating the Esc key has been pressed.

E_OUTOFMEMORY

Out of memory.

E_UNEXPECTED

An unexpected error occurred.

Comments

The **DoDragDrop** function calls **IDropSource::QueryContinueDrag** whenever it detects a change in the keyboard or mouse button state during a drag-and-drop operation. **IDropSource::QueryContinueDrag** determines whether the drag-and-drop operation should be continued, canceled, or completed based on the contents of the parameters *grfKeyState* and *fEscapePressed*.

See Also

DoDragDrop

IDropTarget

The **IDropTarget** interface is one of the interfaces you implement to provide drag-and-drop operations in your application. It contains methods used in any application that can be a target for data during a drag-and-drop operation. A drop-target application is responsible for:

- Determining the effect of the drop on the target application.
- Incorporating any valid dropped data when the drop occurs.
- Communicating target feedback to the source so the source application can provide appropriate visual feedback such as setting the cursor.
- Implementing drag scrolling.
- Registering and revoking its application windows as drop targets.

The **IDropTarget** interface contains methods that provide all these responsibilities except registering and revoking the application window as a drop target.

When to Implement

Implement the **IDropTarget** interface if you are developing a container or server application that can act as a target for a drag-and-drop operation. The **IDropTarget** interface is associated with your application windows and is instantiated whenever the window is registered as a target for dropped data. You must call the **RegisterDragDrop** function and the **RevokeDragDrop** function to register and remove your application's windows as drop targets.

When to Use

The **DoDragDrop** function calls your **IDropTarget** methods within a loop during the drag-and-drop operation.

For example, **DoDragDrop** calls **IDropTarget::DragEnter** when it detects the mouse has moved over a window that is registered as a drag target. Once the mouse has entered a drag-target window, **DoDragDrop** calls **IDropTarget::DragOver** as the mouse moves through the window and calls **IDropTarget::DragLeave** if the mouse leaves the target window or if the user cancels or completes the drag-and-drop operation. **DoDragDrop** calls **IDropTarget::Drop** when the drop finally occurs if it occurs at all.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IDropTarget Methods	**Description**
DragEnter	Determines whether a drop can be accepted and its effect if it is accepted.
DragOver	Provides target feedback to the user through the **DoDragDrop** function.
DragLeave	Causes the drop target to suspend its feedback actions.
Drop	Drops the data into the target window.

See Also

DoDragDrop, **IDropSource**, **RegisterDragDrop**, **RevokeDragDrop**

IDropTarget::DragEnter

Indicates whether or not a drop can be accepted and the drop's effect if accepted.

```
HRESULT DragEnter(
  IDataObject * pDataObject,    //IDataObject interface for the source data
  DWORD grfKeyState,            //Current state of keyboard modifier keys
  POINTL pt,                    //Current cursor coordinates
  DWORD * pdwEffect             //Effect of the drag-and-drop operation
 );
```

Parameters

pDataObject

[in] Points to the data object being transferred in the drag-and-drop operation. The data is represented in the **IDataObject** interface. If the drop occurs, this data object will be incorporated into the target.

grfKeyState

[in] Identifies the current state of the keyboard modifier keys on the keyboard. Valid values can be a combination of any of the flags MK_CONTROL, MK_SHIFT, MK_ALT, MK_BUTTON, MK_LBUTTON, MK_MBUTTON, and MK_RBUTTON.

pt

[in] Points to the current cursor coordinates in the coordinate space of the drop target window.

pdwEffect

[in, out] Specifies the current effect flag. Valid values are from the **DROPEFFECT** enumeration.

Return Values

S_OK

The function completed its task successfully.

E_OUTOFMEMORY

Out of memory.

E_INVALIDARG

One or more arguments are invalid.

E_UNEXPECTED

An unexpected error occurred.

Comments

The **DoDragDrop** function calls this method the first time the user drags the mouse into the registered window of a drop target.

In the **IDropTarget::DragEnter** method, you must determine the effect of dropping the data on the target by examining the formats and medium specified for the data object along with the state of the modifier keys. The following modifier keys affect the result of the drop:

Key Combination	User-Visible Feedback	Drop Effect
CTRL + SHIFT	=	DROPEFFECT_LINK
CTRL	+	DROPEFFECT_COPY
No keys or SHIFT	None	DROPEFFECT_MOVE

You communicate the effect of the drop back to the source through **DoDragDrop** in the *pdwEffect* parameter. The **DoDragDrop** function then calls **IDropSource::GiveFeedback** so that the source application can display the appropriate visual feedback to the user.

On entry to **IDropTarget::DragEnter**, the *pdwEffect* parameter is set to the effects given to the **DoDragDrop** function. The **IDropTarget::DragEnter** method must choose one of these effects or disable the drop.

Upon return, *pdwEffect* is set to either DROPEFFECT_COPY to copy the dragged data to the target, DROPEFFECT_LINK to create a link to the source data, or DROPEFFECT_MOVE to allow the dragged data to be permanently moved from the source application to the target.

You may also wish to provide appropriate visual feedback in the target window.

See Also

DoDragDrop, **IDropSource**, **IDropTarget**, **RegisterDragDrop**, **RevokeDragDrop**

IDropTarget::DragLeave

Removes target feedback and releases the data object.

HRESULT DragLeave(*void***);**

Return Values

S_OK
The function completed its task successfully.

E_OUTOFMEMORY
Out of memory.

Comments

The **DoDragDrop** function calls this method in either of the following cases:

- When the user drags the cursor out of a given target window.
- When the user cancels the current drag-and-drop operation.

In the **IDropTarget::DragLeave** method, you must remove any target feedback that is currently displayed. You must also release any references you hold to the data transfer object.

See Also

DoDragDrop, **IDropSource**, **IDropTarget**, **RegisterDragDrop**, **RevokeDragDrop**

IDropTarget::DragOver

Provides target feedback to the user and communicates the drop's effect to the **DoDragDrop** function so the effect of the drop can be communicated through the **DoDragDrop** function back to the source.

```
HRESULT DragOver(
  DWORD grfKeyState,       //Current state of keyboard modifier keys
  POINTL pt,               //Current cursor coordinates
  DWORD * pdwEffect        //Effect of the drag-and-drop operation
 );
```

Parameters

grfKeyState
[in] Identifies the current state of the keyboard modifier keys on the keyboard. Valid values can be a combination of any of the flags MK_CONTROL, MK_SHIFT, MK_ALT, MK_BUTTON, MK_LBUTTON, MK_MBUTTON, and MK_RBUTTON.

pt
[in] Points to the current cursor coordinates in the coordinate space of the drop target window.

pdwEffect
[in, out] Specifies the current effect flag. Valid values are from the enumeration DROPEFFECT.

Return Values

S_OK
The function completed its task successfully.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

The **DoDragDrop** function calls this method each time the user moves the mouse across a given target window. **DoDragDrop** exits the loop if the drag-and-drop operation is canceled, if the user drags the mouse out of the target window, or if the drop is completed.

In **IDropTarget::DragOver**, you must provide features similar to **IDropTarget::DragEnter**. You must determine the effect of dropping the data on the target by examining the formats and medium specified for the data object along with the state of the modifier keys. The mouse position may also play a role in determining the effect of a drop. The following modifier keys affect the result of the drop:

Key Combination	User-Visible Feedback	Drop Effect
CTRL + SHIFT	=	DROPEFFECT_LINK
CTRL	+	DROPEFFECT_COPY
No keys or SHIFT	None	DROPEFFECT_MOVE

You communicate the effect of the drop back to the source through **DoDragDrop** in *pdwEffect*. The **DoDragDrop** function then calls **IDropSource::GiveFeedback** so the source application can display the appropriate visual feedback to the user.

On entry to **IDropTarget::DragOver**, the *pdwEffect* parameter is set to the effects given to the **DoDragDrop** function. The **IDropTarget::DragOver** method must choose one of these effects or disable the drop.

Upon return, *pdwEffect* is set to either DROPEFFECT_COPY to copy the dragged data to the target, DROPEFFECT_LINK to create a link to the source data, or DROPEFFECT_MOVE to allow the dragged data to be permanently moved from the source application to the target.

You may also wish to provide appropriate visual feedback in the target window. There may be some target feedback already displayed from a previous call to **IDropTarget::DragOver** or from the initial **IDropTarget::DragEnter**. If this feedback is no longer appropriate, you should remove it.

For efficiency reasons, a data object is not passed in **IDropTarget::DragOver**. The data object passed in the most recent call to **IDropTarget::DragEnter** is available and can be used.

Notes to Implementors

This function is called frequently during the **DoDragDrop** loop so it makes sense to optimize your implementation of the **DragOver** method as much as possible.

See Also

DoDragDrop, **IDropSource**, **IDropTarget**, **RegisterDragDrop**, **RevokeDragDrop**

IDropTarget::Drop

Incorporates the source data into the target window, removes target feedback, and releases the data object.

```
HRESULT Drop(
  IDataObject * pDataObject,     //IDataObject interface for the source data
  DWORD grfKeyState,             //Current state of keyboard modifier keys
  POINTL pt,                     //Current cursor coordinates
  DWORD * pdwEffect              //Effect of the drag-and-drop operation
 );
```

Parameters

pDataObject
[in] Points to the data object being transferred in the drag-and-drop operation. The data is represented in the **IDataObject** interface.

grfKeyState
[in] Identifies the current state of the keyboard modifier keys on the keyboard. Valid values can be a combination of any of the flags MK_CONTROL, MK_SHIFT, MK_ALT, MK_BUTTON, MK_LBUTTON, MK_MBUTTON, and MK_RBUTTON.

pt
[in] Points to the current cursor coordinates in the coordinate space of the drop target window.

pdwEffect
[in, out] Specifies the current effect flag. Valid values are from the enumeration **DROPEFFECT**.

Return Values

S_OK
The function completed its tasks successfully.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

The **DoDragDrop** function calls this method when the user completes the drag-and-drop operation.

In **IDropTarget::Drop**, you must incorporate the data object into the target. You can use the formats available in **IDataObject** along with the current state of the modifier keys to determine how the data is to be incorporated. This can be, for example, linking the data or embedding it.

In addition to incorporating the data, you must also clean up as you do in the **IDropTarget::DragLeave** method:

- Remove any target feedback that is currently displayed.
- Release any references to the data object.

You also pass the effect of this operation back to the source application through **DoDragDrop, **so the source application can clean up after the drag-and-drop operation is complete:

- Remove any source feedback that is currently displaying.
- Make any necessary changes to the data, for example, removing the data if the operation was a move.

IEnum*XXXX*

To allow you to count the number of items of a given type an object maintains, OLE provides a set of enumeration interfaces, one for each type of item.

To use these interfaces, the client asks an object that maintains a collection of items to create an enumerator object. The interface on the enumeration object is one of the enumeration interfaces, all of which have a name of the form **IEnum***Item_name*. Enumeration interfaces are specific to the type of item. All have the same set of methods, and are used in the same way. For example, by repeatedly calling the **Next** method, the client gets successive pointers to each item in the collection.

The following table lists the set of enumeration interfaces that OLE defines, and the items enumerated.

Enumeration Interface Name	**Item Enumerated**
IEnumFORMATETC	An array of **FORMATETC** structures
IEnumMoniker	The components of a moniker, or the monikers in a table.
IEnumOLEVERB	The different verbs available for an object, in order of ascending verb number.
IEnumSTATDATA	An array of **STATDATA** structures which contain advisory connection information for a data object.
IEnumSTATSTG	An array of **STATSTG** structures,which contain statistical information about a storage, stream, or LockBytes object
IEnumString	Strings
IEnumUnknown	Enumerates **IUnknown** interface pointers
IEnumVARIANT	A collection of variants. It allows clients to enumerate heterogeneous collections of objects and intrinsic types when the clients cannot or do not know the specific type(s) of elements in the collection

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IEnum*XXXX* Methods	**Description**
Next	Retrieves a specified number of items in the enumeration sequence.
Skip	Skips over a specified number of items in the enumeration sequence.
Reset	Resets the enumeration sequence to the beginning.
Clone	Creates another enumerator that

contains the same enumeration state
as the current one.

IEnum*XXXX*::Clone

Creates another enumerator that contains the same enumeration state as the current one. Using this function, a client can record a particular point in the enumeration sequence, and then return to that point at a later time. The new enumerator has the same interface as the original one.

HRESULT Clone(
IEnum<ELT_T> ** *ppenum*
);

Parameter

ppenum
[out] On exit, contains the duplicate enumerator. If the function was unsuccessful, this parameter's value is undefined.

Return Values

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
Value of *ppenum* is invalid.

E_UNEXPECTED
An unexpected error occurred.

IEnum*XXXX*::Next

Retrieves the next *celt* items in the enumeration sequence. If there are fewer than the requested number of elements left in the sequence, it retrieves the remaining elements. The number of elements actually retrieved is returned through *pceltFetched* (unless the caller passed in **NULL** for that parameter).

HRESULT Next(
  ULONG *celt***,**
  ELT_T[ ] *rgelt***,**
  ULONG * *pceltFetched*
 );

Parameters

celt
  [in]The number of elements being requested.

rgelt
  [out]Receives an array of size *celt* (or larger) of the elements to be returned. The type of this parameter depends on the item being enumerated.

pceltFetched
  [in, out]On return, contains the number of elements actually returned in *rgelt*. Caller can pass in **NULL** if *celt* is one.

Return Value

S_OK if the number of elements returned is *celt*; S_FALSE otherwise.

IEnum*XXXX*::Reset

Resets the enumeration sequence to the beginning.

HRESULT Reset(*void***);**

Return Value

S_OK

Comments

There is no guarantee that the same set of objects will be enumerated after the reset, because it depends on the collection being enumerated. It can be too expensive for some collections (such as files in a directory) to guarantee this condition.

IEnum*XXXX*::Skip

Skips over the next specified number of elements in the enumeration sequence.

HRESULT Skip(
  ULONG *celt*
 );

Parameter

celt
  [in]The number of elements that are to be skipped.

Return Value

S_OK if the number of elements skipped is *celt*; otherwise S_FALSE.

IEnumFORMATETC

The **IEnumFORMATETC** interface is used to enumerate an array of **FORMATETC** structures. **IEnumFORMATETC** shares the same methods as all enumerator interfaces: **Next**, **Skip**, **Reset**, and **Clone**.

IEnumFORMATETC is implemented by all data objects to support calls to **IDataObject::EnumFormatEtc**. If the data object supports a different set of **FORMATETC** information depending on whether a call is made to **SetData** or **GetData**, the implementation of **IEnumFORMATETC** must be able to operate on both.

The order of formats enumerated through the **IEnumFORMATETC** object should be the same as the order that the formats would be in when placed on the clipboard. Typically, this order starts with private data formats and ends with presentation formats such as CF_METAFILEPICT.

The prototypes of the member functions are as follows:

HRESULT Next(**ULONG** *celt*, **FORMATETC *** *rgelt*, **ULONG *** *pceltFetched)*

HRESULT Skip(**ULONG** *celt*)

HRESULT Reset(*void*)

HRESULT Clone(**IEnumFORMATETC **** *ppenum*)

See Also

OleRegEnumFormatEtc, **FORMATETC**, **IEnum*XXXX***

IEnumMoniker

The **IEnumMoniker** interface is used to enumerate the components of a moniker or to enumerate the monikers in a table of monikers.

When to Implement

You need to implement **IEnumMoniker** if you are writing a new type of moniker and your monikers have an internal structure that can be enumerated. Your implementation of **IMoniker::Enum** must return an enumerator that implements **IEnumMoniker** and can enumerate your moniker's components. If your moniker has no structure that can be enumerated, your **IMoniker::Enum** method can simply return a NULL pointer.

When to Use

Use the **IEnumMoniker** interface if you need to enumerate the components of a composite moniker, or to enumerate the monikers in a table.

OLE defines two interfaces that return an **IEnumMoniker** interface pointer:

- The **IMoniker::Enum** method returns an **IEnumMoniker** implementation that can enumerate forwards or backwards through the components of the moniker. For a description of how two of the system-supplied types of monikers enumerate their components, see **IMoniker - File Moniker Implementation** and **IMoniker - Generic Composite Moniker Implementation**.
- The **IRunningObjectTable::EnumRunning** method returns an **IEnumMoniker** implementation that can enumerate the monikers registered in a Running Object Table.

The prototypes of the member functions are as follows:

HRESULT Next(**ULONG** *celt*, **IMoniker** ***** *rgelt*, **ULONG *** *pceltFetched)*

HRESULT Skip(**ULONG** *celt*)

HRESULT Reset(*void*)

HRESULT Clone(**IEnumMoniker **** *ppenum*)

See Also

IEnum*XXXX*, IMoniker::Enum, IRunningObjectTable::EnumRunning

IEnumOLEVERB

The **IEnumOLEVERB** interface enumerates the different verbs available for an object in order of ascending verb number. An enumerator that implements the **IEnumOLEVERB** interface is returned by the **IOleObject::EnumVerbs** member function.

When to Implement

You typically do not have to implement this interface. The OLE default handler provides an implementation which returns the entries in the registration database. Because calls to **IOleObject::EnumVerb** are always routed through the default handler; an OLE application can let the default handler do the work by implementing **IOleObject::EnumVerb** as a stub that simply returns **OLE_S_USEREG**. This informs the default handler that it should create the enumerator for you.

When to Use

Call this interface if you need to list the verbs than an OLE object supports.

The prototypes of the member functions are as follows:

HRESULT Next(**ULONG** *celt*, **OLEVERB** ***** *rgelt*, **ULONG *** *pceltFetched)*

HRESULT Skip(**ULONG** *celt*)

HRESULT Reset(*void*)

HRESULT Clone(**IEnumOLEVERB **** *ppenum*)

See Also

OLEVERB, **IEnum*XXXX***

IEnumSTATDATA

The **IEnumSTATDATA** interface is used to enumerate through an array of **STATDATA** structures which contain advisory connection information for a data object. **IEnumSTATDATA** shares the same methods as all enumerator interfaces: **Next**, **Skip**, **Reset**, and **Clone**.

IEnumSTATDATA is implemented to enumerate advisory connections. Containers usually call methods that return a pointer to **IEnumSTATDATA** so the container can instruct an object to release each of its advisory connections prior to closing down. Calls to **IDataObject::EnumDAdvise**, **IDataAdviseHolder::EnumAdvise**, and **IOleCache::EnumCache** methods all return a pointer to **IEnumSTATDATA**.

The prototypes of the member functions are as follows:

HRESULT Next(**ULONG** *celt*, **STATDATA *** *rgelt*, **ULONG *** *pceltFetched)*

HRESULT Skip(**ULONG** *celt*)

HRESULT Reset(*void*)

HRESULT Clone(**IEnumSTATDATA **** *ppenum*)

See Also

STATDATA, **IEnum*XXXX***, **IOleCache::EnumCache**, **IDataObject::EnumDAdvise**, **IDataAdviseHolder::EnumAdvise**, **IOleObject::EnumAdvise**

IEnumSTATSTG

The **IEnumSTATSTG** interface is used to enumerate through an array of **STATSTG** structures which contain statistical information about an open storage, stream, or byte array object. **IEnumSTATSTG** shares the same methods as all enumerator interfaces: **Next**, **Skip**, **Reset**, and **Clone**.

IEnumSTATSTG is implemented to enumerate the elements of a storage object. Containers usually call methods that return a pointer to **IEnumSTATSTG** so the container can manage its storage object and the elements within it. Calls to the **IStorage::EnumElements** method returns a pointer to **IEnumSTATDATA**. The caller allocates an array of **STATSTG** structures and the **IEnumSTATSTG** methods fill in each structure with the statistics about one of the nested elements in the storage object. If present, the *lpszName* member of the **STATSTG** structure requires additional memory allocations through the **IMalloc** interface, and the caller is responsible for freeing this memory, if it is allocated, by calling the **IMalloc::Free** method. If the *lpszName* member is NULL, no memory is allocated, and, therefore, no memory needs to be freed.

The prototypes of the member functions are as follows:

HRESULT Next(**ULONG** *celt*, **STATSTG *** *rgelt*, **ULONG *** *pceltFetched)*

HRESULT Skip(**ULONG** *celt*)

HRESULT Reset(*void*)

HRESULT Clone(**IEnumSTATSTG **** *ppenum*)

See Also

CoGetMalloc, **IEnum*XXXX***, **IStorage::EnumElements**, **STATSTG**

IEnumString

IEnumString is defined to enumerate strings. LPWSTR is the type that indicates a pointer to a zero-terminated string of wide, i.e., Unicode, characters.

The prototypes of the member functions are as follows:

HRESULT Next(**ULONG** *celt*, **LPWSTR *** *rgelt*, **ULONG *** *pceltFetched)*

HRESULT Skip(**ULONG** *celt*)

HRESULT Reset(*void*)

HRESULT Clone(**IEnumString **** *ppenum*)

IEnumUnknown

This enumerator enumerates objects with interface **IUnknown**. This enumerator is used by the **IOleContainer** interface to enumerate the objects in a compound document.

The prototypes of the member functions are as follows:

HRESULT Next(**ULONG** *celt*, **IUnknown **** *reelt*, **ULONG *** *pceltFetched*)

HRESULT Skip(**ULONG** *celt*)

HRESULT Reset(*void*)

HRESULT Clone(**IEnumUnknown *** *ppenum*)

IOleContainer

IExternalConnection

The **IExternalConnection** interface enables an embedded object to keep track of external locks on it, thereby enabling the safe and orderly shutdown of the object following silent updates. An object that supports links either to itself or to some portion of itself (a range of cells in a spreadsheet, for example) should implement this interface to prevent possible loss of data during shutdown.

Such data loss can occur when an object happens to have unsaved changes at a time when its stub manager's count of strong external references has reached zero. This situation would arise, for example, at the end of a silent update, when the final link client breaks its connection to the object. With the severing of this connection, the stub manager's count of strong external references would reach zero, causing it to release its pointers to the object and initiate shutdown of the object. When the object calls **IOleClientSite::SaveObject,** its container's return call to **IPersistStorage::Save** would fail because the stub manager would no longer have a pointer to the object. Any unsaved changes to the object would be lost.

If the object manages its own count of external locks, rather than relying on the stub manager to do so, it can save its data before the stub manager has a chance to release its pointers. An object can obtain a count of external connections by implementing the **IExternalConnection** interface. The stub manager calls this interface whenever a new strong external reference is added or deleted. The object combines this count with its own tally of strong internal references to maintain an accurate total of all locks.

When to Implement

All embeddable compound-document objects that support links to themselves or portions of themselves should implement **IExternalConnection** to prevent possible data loss during shutdown. In addition, an in-place container should call **OleLockRunning** to hold a strong lock on its embedded objects.

When to Use

An object's stub manager should call **IExternalConnection** whenever an external connection is added or released.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IExternalConnection Methods	Description
AddConnection	Increments count of external locks.
ReleaseConnection	Decrements count of external locks.

IExternalConnection::AddConnection

Increments an object's count of its strong external connections (links).

```
HRESULT AddConnection(
   DWORD exconn,            //Type of external connection
   DWORD dwreserved         //Used by OLE to pass connection information
  );
```

Parameters

exconn
[out] Specifies the type of external connection to the object. The only type of external connection currently supported by this interface is strong, which means that the object must remain alive as long as this external connection exists. Strong external connections are represented by the value EXTCONN_STRONG = 0x0001, which is defined in the enumeration **EXTCONN**.

dwreserved
Passes information about the connection. This parameter is reserved for use by OLE. Its value can be zero, but not necessarily. Therefore, implementations of **AddConnection** should not contain blocks of code whose execution depends on whether a zero value is returned.

Return Value

DWORD value
The number of reference counts on the object; used for debugging purposes only.

Comments

An object created by a EXE object application relies on its stub manager to call **IExternalConnection::AddConnection** whenever a link client activates and therefore creates an external lock on the object. When the link client breaks the connection, the stub manager calls **IExternalConnection::ReleaseConnection** to release the lock.

Since DLL object applications exist in the same process space as their objects, they do not utilize RPC (remote procedure calls) and therefore do not have stub managers to keep track of external connections. Therefore, DLL object applications that support external links to their objects must implement **IExternalConnection** so link clients can directly call the interface to inform them when connections are added or released.

The following is a typical implementation for the **AddConnection** method:

```
DWORD XX::AddConnection(DWORD extconn, DWORD dwReserved)
   {
      return extconn&EXTCONN_STRONG ? ++m_cStrong : 0;
   }
```

See Also

IExternalConnection::ReleaseConnection, **IRunnableObject::LockRunning**, **OleLockRunning**

IExternalConnection::ReleaseConnection

Decrements an object's count of its strong external connections (links).

```
HRESULT ReleaseConnection(
   DWORD extconn,                 //Type of external connection
   DWORD dwreserved,              //Used by OLE to pass connection information
   BOOL fLastReleaseCloses        //Indicates whether connection is last one or not
  );
```

Parameters

extconn
[out] Specifies the type of external connection to the object. The only type of external connection currently supported by this interface is strong, which means that the object must remain alive as long as this external connection exists. Strong external connections are represented by the value EXTCONN_STRONG = 0x0001, which is defined in the enumeration **EXTCONN**.

dwreserved
Passes information about the connection. This parameter is reserved for use by OLE. Its value can be zero, but not necessarily. Therefore, implementations of **ReleaseConnection** should not contain blocks of code whose execution depends on whether a zero value is returned.

fLastReleaseCloses
TRUE specifies that if the connection being released is the last external lock on the object, the object should close. FALSE specifies that the object should remain open until closed by the user or another process.

Return Value

DWORD value
The number of connections to the object; used for debugging purposes only.

Comments

If *fLastReleaseCloses* equals TRUE, calling **ReleaseConnection** causes the object to shut itself down. Calling this method is the only way in which a DLL object, running in the same process space as the container application, will know when to close following a silent update.

See Also

IExternalConnection::AddConnection

ILockBytes

The **ILockBytes** interface provides a byte array object used by the OLE-provided implementation of compound files. Its methods manipulate the byte array object that provides the physical storage for the root storage object of a compound file. The byte array for an **ILockBytes** implementation is backed by some physical storage, such as a disk file, global memory, or a database; and the **ILockBytes** implementation hides the details of accessing the physical storage.

When to Implement

OLE provides an implementation of the **ILockBytes** interface for its compound files. The OLE-provided **ILockBytes** interface presents a byte array stored in a physical disk file.

Most applications will never implement the **ILockBytes** interface. Instead, applications will typically call the **StgCreateDocfile** function to create a root storage object (in this case, an **IStorage** instance backed by a specified disk file); and this function internally creates an instance of the OLE-provided, file-based **ILockBytes** implementation.

OLE also provides a memory-based **ILockBytes** implementation (see **CreateILockBytesOnHGlobal**).

It is possible for an application to provide its own **ILockBytes** implementation. For example, a database application might want to implement an **ILockBytes** backed by the storage of its relational tables. However, it is strongly recommended that you use the OLE-provided implementations. For a discussion of the advantages of using the OLE implementations rather than creating your own, see the **StgCreateDocfileOnILockBytes** API function.

If you choose to implement your own **ILockBytes** interface, you should consider providing custom marshaling by implementing the **IMarshal** interface as part of your byte array object. The reason for this is that when the OLE-provided implementations of **IStorage** and **IStream** are marshaled to another process, their **ILockBytes** interface pointers are also marshaled to the other process. The default marshaling mechanism creates a proxy **ILockBytes** that transmits method calls back to the original LockBytes object. Custom marshaling can improve efficiency by creating a remote LockBytes object that can access the byte array directly.

When to Use

The **ILockBytes** methods are called by the OLE-provided implementations of **IStorage** and **IStream**, so application programmers do not need to call **ILockBytes** methods. If you write your own **ILockBytes** implementation, you can use the **StgCreateDocfileOnILockBytes** function to create an **IStorage** backed by your **ILockBytes**.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

ILockBytes Methods	**Description**
ReadAt	Reads a specified number of bytes starting at a specified offset from the beginning of the byte array.
WriteAt	Writes a specified number of bytes to a specified location in the byte array.
Flush	Ensures that any internal buffers maintained by the **ILockBytes**

	implementation are written out to the backing storage.
SetSize	Changes the size of the byte array.
LockRegion	Restricts access to a specified range of bytes in the byte array.
UnlockRegion	Removes the access restriction on a range of bytes previously restricted with **ILockBytes::LockRegion**.
Stat	Retrieves a **STATSTG** structure for this byte array object.

ILockBytes::Flush

Ensures that any internal buffers maintained by the **ILockBytes** implementation are written out to the backing storage.

HRESULT Flush(*void***);**

Return Values

S_OK
The flush operation was successful.

STG_E_ACCESSDENIED
The caller does not have permission to access the byte array.

STG_E_MEDIUMFULL
The flush operation is not completed because there is no space left on the storage device.

E_FAIL
General failure writing data.

STG_E_TOOMANYFILESOPEN
Under certain circumstances, **Flush** does a dump-and-close to flush. This can lead to STG_E_TOOMANYFILESOPEN if there are no file handles available.

STG_E_INVALIDHANDLE
An invalid floppy change has been made.

Comments

This method flushes internal buffers to the underlying storage device.

The OLE-provided implementation of compound files uses this method during a transacted commit operation to provide a two-phase commit process that protects against loss of data.

See Also

IStorage::Commit

ILockBytes::LockRegion

Restricts access to a specified range of bytes in the byte array.

```
HRESULT LockRegion(
   ULARGE_INTEGER libOffset,      //Specifies the byte offset for the beginning of the range
   ULARGE_INTEGER cb,             //Specifies the length of the range in bytes
   DWORD dwLockType               //Specifies the type of restriction on accessing the specified
                                  range
  );
```

Parameters

libOffset
[in]Specifies the byte offset for the beginning of the range.

cb
[in]Specifies, in bytes, the length of the range to be restricted.

dwLockType
[in]Specifies the type of restrictions being requested on accessing the range. This parameter uses one of the values from the **LOCKTYPE** enumeration.

Return Values

S_OK
The specified range of bytes was locked.

STG_E_INVALIDFUNCTION
Locking is not supported at all or the specific type of lock requested is not supported.

STG_E_LOCKVIOLATION
Requested lock is supported, but cannot be granted because of an existing lock.

Comments

This method restricts access to the specified range of bytes. Once a region is locked, attempts by others to perform the restricted access must fail with the STG_E_ACCESSDENIED error.

The byte range can extend past the current end of the current byte array. Locking beyond the end of an array is useful as a method of communication between different instances of the byte array object without changing data that is actually part of the byte array. For example, an implementation of compound files could rely on locking past the current end of the array as a means of access control, using specific locked regions to indicate permissions currently granted.

Three types of locking can be supported: locking to exclude other writers, locking to exclude other readers or writers, and locking that allows only one requestor to obtain a lock on the given range, which is usually an alias for one of the other two lock types. A given byte array might support either of the first two types, or both. The lock type is specified by *dwLockType*, using a value from the **LOCKTYPE** enumeration.

To determine the lock types supported by a particular **ILockBytes** implementation, you can examine the *grfLocksSupported* member of the **STATSTG** structure returned by a call to **ILockBytes::Stat**.

Any region locked with **ILockBytes::LockRegion** must later be explicitly unlocked by calling **ILockBytes::UnlockRegion** with exactly the same values for the *libOffset*, *cb*, and *dwLockTyp*e parameters. The region must be unlocked before the stream is released. Two adjacent regions cannot be locked separately and then unlocked with a single unlock call.

Notes to Callers

Since the type of locking supported is optional and can vary in different implementations of **ILockBytes**, you must provide code to deal with the STG_E_INVALIDFUNCTION error.

Notes to Implementors

Support for this method depends on how the storage objects built on top of the **ILockBytes** implementation is used. If you know that, at any given time, only one storage object can be opened on the storage device that underlies the byte array, then your **ILockBytes** implementation does not need to support locking. However, if multiple simultaneous openings of a storage object are possible, then region locking is needed to coordinate them.

A **LockRegion** implementation can choose to support all, some, or none of the lock types. For unsupported lock types, the implementation should return STG_E_INVALIDFUNCTION.

See Also

ILockBytes::Stat, **ILockBytes::UnlockRegion**, **IStream::LockRegion**, **LOCKTYPE**

ILockBytes::ReadAt

Reads a specified number of bytes starting at a specified offset from the beginning of the byte array object.

```
HRESULT ReadAt(
   ULARGE_INTEGER ulOffset,      //Specifies the starting point for reading data
   void *pv,                     //Points to the buffer into which the data is read
   ULONG cb,                     //Specifies the number of bytes to read
   ULONG *pcbRead                //Pointer to location that contains actual number of bytes read
  );
```

Parameters

ulOffset
[in]Specifies the starting point from the beginning of the byte array for reading data.

pv
[in]Points to the buffer into which the byte array is read.

cb
[in]Specifies the number of bytes of data to attempt to read from the byte array.

pcbRead
[out]Pointer to a location where this method writes the actual number of bytes read from the byte array. You can set this pointer to NULL to indicate that you are not interested in this value. In this case, this method does not provide the actual number of bytes read.

Return Values

S_OK
Indicates that the specified number of bytes were read, or the maximum number of bytes were read up to the end of the byte array.

E_FAIL
Data could not be read from the byte array.

STG_E_ACCESSDENIED
The caller does not have permission to access the byte array.

Comments

This method reads bytes from the byte array object. It reports the number of bytes that were actually read. This value may be less than the number of bytes requested if an error occurs or if the end of the byte array is reached during the read.

It is not an error to read less than the specified number of bytes if the operation encounters the end of the byte array. Note that this is the same end of file behavior as found in MS-DOS FAT file system files.

See Also

ILockBytes::WriteAt

ILockBytes::SetSize

Changes the size of the byte array.

```
HRESULT SetSize(
  ULARGE_INTEGER cb      //Specifies the new size of the byte array in bytes
 );
```

Parameter

cb
[in]Specifies the new size of the byte array as a number of bytes.

Return Values

S_OK
The size of the byte array was successfully changed.

STG_E_ACCESSDENIED
The caller does not have permission to access the byte array.

STG_E_MEDIUMFULL
The byte array size is not changed because there is no space left on the storage device.

Comments

This method changes the size of the byte array. If the *cb* parameter is larger than the current byte array, the byte array is extended to the indicated size by filling the intervening space with bytes of undefined value. This operation is similar to the **ILockBytes::WriteAt** method if the seek pointer is past the current end-of-stream.

If the *cb* parameter is smaller than the current byte array, then the byte array is truncated to the indicated size.

Notes to Callers

Callers cannot rely on STG_E_MEDIUMFULL being returned at the appropriate time because of cache buffering in the operating system or network. However, callers must be able to deal with this return code because some **ILockBytes** implementations might support it.

See Also

ILockBytes::ReadAt, **ILockBytes::WriteAt**

ILockBytes::Stat

Retrieves a **STATSTG** structure containing information for this byte array object.

```
HRESULT Stat(
   STATSTG *pstatstg,       //Location for STATSTG structure
   DWORD grfStatFlag        //Values taken from the STATFLAG enumeration
  );
```

Parameters

pstatstg
[out]Points to a **STATSTG** structure where this method places information about this byte array object. The pointer is NULL if an error occurs.

grfStatFlag
[in]Specifies that this method not return some of the fields in the **STATSTG** structure, thus saving a memory allocation operation. Values are taken from the **STATFLAG** enumeration.

Return Values

S_OK
The **STATSTG** structure was successfully returned at the specified location.

E_OUTOFMEMORY
The **STATSTG** structure was not returned due to a lack of memory for the name field in the structure.

STG_E_ACCESSDENIED
The **STATSTG** structure was not returned because the caller did not have access to the byte array.

STG_E_INSUFFICIENTMEMORY
The **STATSTG** structure was not returned due to a lack of memory.

STG_E_INVALIDFLAG
The value for the *grfStateFlag* parameter is not valid.

STG_E_INVALIDPOINTER
The value for the *pStatStg* parameter is not valid.

Comments

The OLE-provided **IStorage::Stat** implementation calls the **ILockBytes::Stat** method to retrieve information about a root storage object. If there is no reasonable name for the byte array, then the OLE-provided **ILockBytes::Stat** method returns NULL in the *pwcsName* field of the **STATSTG** structure.

See Also

STATFLAG, **STATSTG**

ILockBytes::UnlockRegion

Removes the access restriction on a previously locked range of bytes.

```
HRESULT UnlockRegion(
   ULARGE_INTEGER libOffset,       //Specifies the byte offset for the beginning of the range
   ULARGE_INTEGER cb,              //Specifies the length of the range in bytes
   DWORD dwLockType                //Specifies the access restriction previously placed on the range
  );
```

Parameters

libOffset
[in]Specifies the byte offset for the beginning of the range.

cb
[in]Specifies, in bytes, the length of the range that is restricted.

dwLockType
[in]Specifies the type of access restrictions previously placed on the range. This parameter uses a value from the **LOCKTYPE** enumeration.

Return Values

S_OK
The byte range was unlocked.

STG_E_INVALIDFUNCTION
Locking is not supported at all or the specific type of lock requested is not supported.

STG_E_LOCKVIOLATION
The requested unlock cannot be granted.

Comments

This method unlocks a region previously locked with the **ILockBytes::LockRegion** method. Locked regions must later be explicitly unlocked by calling **ILockBytes::UnlockRegion** with exactly the same values for the *libOffset*, *cb*, and *dwLockType* parameters. Two adjacent regions cannot be locked separately and then unlocked with a single unlock call.

See Also

ILockBytes::LockRegion, **LOCKTYPE**

ILockBytes::WriteAt

Writes the specified number of bytes starting at a specified offset from the beginning of the byte array.

```
HRESULT WriteAt(
   ULARGE_INTEGER ulOffset,      //Specifies the starting point for writing data
   void const *pv,               //Points to the buffer containing the data to be written
   ULONG cb,                     //Specifies the number of bytes to write
   ULONG *pcbWritten             //Pointer to location that contains actual number of bytes written
  );
```

Parameters

ulOffset
[in]Specifies the starting point from the beginning of the byte array for the data to be written.

pv
[in]Points to the buffer containing the data to be written.

cb
[in]Specifies the number of bytes of data to attempt to write into the byte array.

pcbRead
[out]Pointer to a location where this method specifies the actual number of bytes written to the byte array. You can set this pointer to NULL to indicate that you are not interested in this value. In this case, this method does not provide the actual number of bytes written.

Return Values

S_OK
Indicates that the specified number of bytes were written.

E_FAIL
A general failure occurred during the write.

STG_E_ACCESSDENIED
The caller does not have sufficient permissions for writing this byte array.

STG_E_MEDIUMFULL
The write operation was not completed because there is no space left on the storage device. The actual number of bytes written is still returned in *pcbWritten*.

Comments

This method writes the specified data at the specified location in the byte array. The number of bytes actually written is always returned in *pcbWritten*, even if an error is returned. If the byte count is zero bytes, the write operation has no effect.

If *ulOffset* is past the end of the byte array and *cb* is greater than zero, **ILockBytes::WriteAt** increases the size of the byte array. The fill bytes written to the byte array are not initialized to any particular value.

See Also

ILockBytes::ReadAt, **ILockBytes::SetSize**

IMalloc

The OLE implementation of **IMalloc** allocates, frees, and manages memory.

The OLE libraries and object handlers call the methods of the **IMalloc** implementation to manage memory. Those implementing object handlers should call **CoGetMalloc** to get a pointer to the **IMalloc** implementation to handle task memory management needs.

The **IMalloc** methods **Alloc**, **Free**, and **Realloc** are similar to the C library functions **malloc**, **free**, and **realloc**. For debugging, refer to the functions **CoRegisterMallocSpy** and **CoRevokeMallocSpy**.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IMalloc Methods	**Description**
Alloc	Allocates a block of memory.
Free	Frees a previously allocated block of memory.
Realloc	Changes the size of a previously allocated block of memory.
GetSize	Returns the size in bytes of a previously allocated block of memory
DidAlloc	Determines if this instance of IMalloc was used to allocate the specified block of memory.
HeapMinimize	Minimizes the heap by releasing unused memory to the operating system.

See Also

CoGetMalloc, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMalloc::Alloc

Allocates a block of memory.

```
void * Alloc(
   ULONG cb        //The size of the requested memory block in bytes
  );
```

Parameter

cb
[in] Specifies the size (in bytes) of the memory block to be allocated.

Return Values

Pointer to the allocated memory block
Memory block allocated successfully.

NULL
Insufficient memory available.

Comments

The **IMalloc::Alloc** method allocates a memory block in essentially the same way that the C Library **malloc** function does.

The initial contents of the returned memory block are undefined - there is no guarantee that the block has been initialized, so you should initialize it in your code. The allocated block may be larger than *cb* bytes because of the space required for alignment and for maintenance information.

If *cb* is zero, **IMalloc::Alloc** allocates a zero-length item and returns a valid pointer to that item. If there is insufficient memory available, **IMalloc::Alloc** returns NULL.

Note Applications should always check the return value from this method, even when requesting small amounts of memory, because there is no guarantee the memory will be allocated.

See Also

IMalloc::Free, **IMalloc::Realloc**, **CoTaskMemAlloc**

IMalloc::DidAlloc

Determines if this allocator was used to allocate the specified block of memory.

```
int DidAlloc(
   void *pv        //The pointer to the memory block
  );
```

Parameter

pv
   Specifies the pointer to the memory block; can be a NULL pointer, in which case, -1 is returned.

Return Values

1
   The memory block was allocated by this **IMalloc** instance.

0
   The memory block was *not* allocated by this **IMalloc** instance.

-1
   DidAlloc is unable to determine whether or not it allocated the memory block.

Comments

Calling **IMalloc::DidAlloc** is useful if a application is using multiple allocations, and needs to know whether a previously allocated block of memory was allocated by a particular allocation.

See Also

IMalloc::Alloc, **IMalloc::HeapMinimize**, **IMalloc::Realloc**

IMalloc::Free

Frees a previously allocated block of memory.

```
void Free(
    void * pv        //Pointer to the memory block to be freed
  );
```

Parameter

pv
  [in] Points to the memory block to be freed.

Comments

IMalloc:Free frees a block of memory previously allocated through a call to **IMalloc::Alloc** or **IMalloc::Realloc**. The number of bytes freed equals the number of bytes that were allocated. After the call, the memory block pointed to by *pv* is invalid and can no longer be used.

Note The *pv* parameter can be NULL. If so, this method has no effect.

See Also

IMalloc::Alloc, **IMalloc::Realloc**, **CoTaskMemFree**

IMalloc::GetSize

Returns the size (in bytes) of a previously allocated memory block previously allocated with **IMalloc::Alloc** or **IMalloc::Realloc**.

```
ULONG GetSize(
    void *pv        //Points to the memory block fo which the size is requested
  );
```

Parameter

pv
    [in] Points to the memory block for which the size is requested.

Return Value

Either the size of the allocated memory block in bytes or, if *pv* is a NULL pointer, -1.

Comments

Returns the size (in bytes) of a memory block previously allocated with **IMalloc::Alloc** or **IMalloc::Realloc**.The size returned is the actual size of the allocation; it may be greater than the size requested when the allocation was made.

See Also

IMalloc::Alloc, **IMalloc::Realloc**

IMalloc::HeapMinimize

Minimizes the heap as much as possible by releasing unused memory to the operating system, coalescing adjacent free blocks and committing free pages.

void HeapMinimize();

Comments

Calling **IMalloc::HeapMinimize** is useful when an application has been running for some time and the heap may be fragmented.

See Also

IMalloc::Alloc, **IMalloc::Free**, **IMalloc::Realloc**

IMalloc::Realloc

Changes the size of a previously allocated memory block.

void *Realloc(
  void ***pv*,**   //The memory block to be reallocated
  ULONG *cb*   //The size of the memory block in bytes
 );

Parameters

pv
  [in] Points to the memory block to be reallocated. It can be a NULL pointer, as discussed in the following Comments section.

cb
  [in] Specifies the size of the memory block (in bytes) to be reallocated. It can be zero, as discussed in the following remarks.

Return Values

Reallocated memory block
  Memory block successfully reallocated.

NULL
  Insufficient memory or *cb* is zero and *pv* is not NULL.

Comments

The initial contents of the returned memory block are undefined - there is no guarantee that the block has been initialized, so you should initialize it in your code. The allocated block may be larger than *cb* bytes because of the space required for alignment and for maintenance information.

The *pv* argument points to the beginning of the memory block. If *pv* is NULL, **IMalloc::Realloc** allocates a new memory block in the same way as **IMalloc::Alloc**. If *pv* is not NULL, it should be a pointer returned by a prior call to **IMalloc::Alloc**.

The *cb* argument specifies the size (in bytes) of the new block. The contents of the block are unchanged up to the shorter of the new and old sizes, although the new block can be in a different location. Because the new block can be in a different memory location, the pointer returned by **IMalloc::Realloc** is not guaranteed to be the pointer passed through the *pv* argument. If *pv* is not NULL and *cb* is zero, then the memory pointed to by *pv* is freed.

IMalloc::Realloc returns a void pointer to the reallocated (and possibly moved) memory block. The return value is NULL if the size is zero and the buffer argument is not NULL, or if there is not enough memory available to expand the block to the given size. In the first case, the original block is freed; in the second, the original block is unchanged.

The storage space pointed to by the return value is guaranteed to be suitably aligned for storage of any type of object. To get a pointer to a type other than **void**, use a type cast on the return value.

See Also

IMalloc::Alloc, **IMalloc::Free**

IMallocSpy

The **IMallocSpy** interface is a debugging interface that allows application developers to monitor (spy on) memory allocation, detect memory leaks and simulate memory failure.

Caution The IMallocSpy interface is intended to be used **only** to debug application code under development. Do not ship this interface to retail customers of your application, because it causes severe performance degradation and could conflict with user-installed software to produce unpredictable results.

When to Implement

Implement this interface to debug memory allocation during application development.

When to Use

IMallocSpy methods are called only by OLE; applications do not call them. An application provides an implementation of **IMallocSpy** (see the OLE SDK for an example); OLE uses this implementation. When an implementation of **IMallocSpy** is registered with **CoRegisterMallocSpy**, OLE calls the pair of **IMallocSpy** methods around the corresponding **IMalloc** method. The call to the pre-method through the return from the corresponding post-method is guaranteed to be thread-safe.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IMallocSpy Methods	**Description**
PreAlloc	Called before invoking **IMalloc::Alloc**.
PostAlloc	Called after invoking **IMalloc::Alloc**.
PreFree	Called before invoking **IMalloc::Free**.
PostFree	Called after invoking **IMalloc::Free**.
PreRealloc	Called before invoking **IMalloc::Realloc**.
PostRealloc	Called after invoking **IMalloc::Realloc**.
PreGetSize	Called before invoking **IMalloc::GetSize**.
PostGetSize	Called after invoking **IMalloc::GetSize**.
PreDidAlloc	Called before invoking **IMalloc::DidAlloc**.
PostDidAlloc	Called after invoking **IMalloc::DidAlloc**.
PreHeapMinimize	Called before invoking **IMalloc::DidAlloc**.
PostHeapMinimize	Called after invoking **IMalloc::HeapMinimize**.

See Also

IMalloc, **CoGetMalloc**, **CoRegisterMallocSpy**

IMallocSpy::PreAlloc

Called just prior to invoking **IMalloc::Alloc**.

```
ULONG PreAlloc(
   ULONG cbRequest        //The byte count passed to IMalloc::Alloc
  );
```

Parameter

cbRequest
The number of bytes in the allocation request the caller is passing to **IMalloc::Alloc**.

Return Value

The byte count actually passed to **IMalloc::Alloc**, which should be greater than or equal to the value of *cbRequest*.

Comments

The **IMallocSpy::PreAlloc** implementation may extend and/or modify the allocation to store debug-specific information with the allocation.

PreAlloc can force memory allocation failure by returning 0, allowing testing to ensure that the application handles allocation failure gracefully in all cases. In this case **PostAlloc** is not called and **Alloc** returns NULL. Forcing allocation failure is effective only if *cbRequest* is not equal to 0. If **PreAlloc** is forcing failure by returning NULL, **PostAlloc** is not called. However, if **IMalloc::Alloc** encounters a real memory failure and returns NULL, **PostAlloc** is called.

The call to **PreAlloc** through the return from **PostAlloc** is guaranteed to be thread safe.

See Also

IMalloc::Alloc, **IMallocSpy::PostAlloc**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PostAlloc

Called just after invoking **IMalloc::Alloc**.

```
void * PostAlloc(
   void * pActual      //Points to the allocation actually done by IMalloc::Alloc
  );
```

Parameter

pActual
Points to the allocation actually done by **IMalloc::Alloc**.

Return Value

The pointer returned to the **IMalloc::Alloc** caller. If debug information is written at the front of the caller's allocation, this should be a forward offset from *pActual*. The value is the same as *pActual* if debug information is appended or if no debug information is attached.

See Also

IMalloc::Alloc, **IMallocSpy::PreAlloc**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PreDidAlloc

Called just prior to invoking **IMalloc::DidAlloc**.

```
void * PreDidAlloc(
   void * pRequest,       //The pointer the caller is passing to IMalloc::DidAlloc
   BOOL fSpyed            //Indicates whether pRequest was allocated while this spy was active
  );
```

Parameters

pRequest
The pointer the caller is passing to **IMalloc::GetSize**.

fSpyed
TRUE if the allocation was done while this spy was active.

Comments

This method is included for completeness; it is not anticipated that developers will implement significant functionality in this method.

Return Value

The pointer whose allocation status is actually determined. This pointer is passed to **PostDidAlloc** as the *fActual* parameter.

See Also

IMalloc::DidAlloc, **IMallocSpy::PostDidAlloc**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PostDidAlloc

Called just prior to invoking **IMalloc::DidAlloc**.

```
int PostDidAlloc(
    void * pRequest       //The original pointer passed to IMalloc::DidAlloc
    BOOL fSpyed           //Indicates whether the allocation was done while this spy was active
    int fActual           //Indicates whether pRequest was actual value used in IMalloc call
  );
```

Parameters

pRequest
The pointer specified in the original call to **IMalloc::DidAlloc**.

fSpyed
TRUE if the allocation was done while this spy was active.

fActual
The actual value returned by **IMalloc::DidAlloc**.

Return Value

The value returned to the caller of **IMalloc::DidAlloc**.

Comments

This method is included for completeness; it is not anticipated that developers will implement significant functionality in this method.

For convenience, *pRequest*, the original pointer specified in the the call to **IMalloc::DidAlloc** is passed to **PostDidAlloc**, along with *fActual*, which is the actual value returned by **IMalloc::DidAlloc** called with the value returned by **IMallocSpy::PreDidAlloc**.

See Also

IMalloc::DidAlloc, **IMallocSpy::PreDidAlloc**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PreFree

Called just before invoking **IMalloc::Free**.

```
void * PreFree(
   void * pRequest,       //The pointer is passing to IMalloc::Free
   BOOL fSpyed            //TRUE if this memory was allocated while the spy was active
 );
```

Parameters

pRequest
The pointer to the block of memory that the caller is passing to **IMalloc::Free**.

fSpyed
The value is TRUE if the *pRequest* parameter of **IMallocSpy::PreFree** was allocated while the spy was installed. This value is also passed to **IMallocSpy::PostFree**.

Return Value

The actual pointer to pass to **IMalloc::Free**.

Comments

If the **PreAlloc** method modified the original allocation, **PreFree** needs to compute the actual pointer to be passed to **IMalloc::Free**. For example, if the **PreAlloc**/**PostAlloc** pair attached a header used to store debug information to the beginning of the user's allocation, then **PreFree** would return a pointer to this header so the true allocation block would be freed.

See Also

IMalloc::Free, **IMallocSpy::PostFree**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PostFree

Called just after invoking **IMalloc::Free**.

```
void PostFree(
    BOOL fSpyed        //Indicates whether the memory block to be freed was allocated while the spy is active
  );
```

Parameter

fSpyed

Boolean that is TRUE if the memory block to be freed was allocated while the current spy was active, otherwise FALSE.

See Also

IMalloc::Free, **IMallocSpy::PreFree**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PreGetSize

Called just prior to invoking **IMalloc::GetSize**.

```
void * PreGetSize(
    void * pRequest,        //Pointer the caller is passing to IMalloc::GetSize
    BOOL fSpyed             //TRUE if allocation done while this spy was active
  );
```

Parameters

pRequest
The pointer the caller is passing to **IMalloc::GetSize**

fSpyed
TRUE if the allocation was done while the spy was active.

Return Value

Pointer to the actual allocation for which the size is to be determined.

Comments

The **PreGetSize** method receives as its *pRequest* parameter the pointer the caller is passing to **IMalloc::GetSize**. It must then return a pointer to the actual allocation, which is then passed to **PostGetSize** as the *pRequest* parameter.

The size determined by **IMalloc::GetSize** is then passed to **IMallocSpy::PostGetSize** as *cbActual*.

Note The size determined by **IMalloc::GetSize** is the value returned by the Win32 API **HeapSize**. On Windows NT, this is the size originally requested. On Windows95, memory allocations are done on eight-byte boundaries. For example, a memory allocation request of 27 bytes on Windows NT would return an allocation of 32 bytes and **GetSize** would return 27. On Windows95, the same request would return an allocation of 28 bytes and **GetSize** would return 28. Implementors of **IMallocSpy::PostGetSize** cannot assume, for example, that if *cbActual* is sizeof(debug_header), that the value is the actual size of the user's allocation.

See Also

IMalloc::GetSize, **IMallocSpy::PostGetSize**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PostGetSize

Called just after invoking **IMalloc::GetSize**.

```
ULONG PostGetSize(
  ULONG cbActual,      //Actual size of the allocation
  BOOL fSpyed          //Indicates whether the allocation was done while a spy was active
 );
```

Parameters

cbActual
The actual number of bytes in the allocation, as returned by **IMalloc::GetSize**.

fSpyed
TRUE if the allocation was done while a spy was active.

Return Values

The size of the allocated memory block in bytes, which is returned to the caller of **IMalloc::GetSize**.

Comments

The size determined by **IMalloc::GetSize** is the value returned by the Win32 API **HeapSize**. On Windows NT, this is the size originally requested. On Windows95, memory allocations are done on eight-byte boundaries. For example, a memory allocation request of 27 bytes on Windows NT would return an allocation of 32 bytes and **GetSize** would return 27. On Windows95, the same request would return an allocation of 28 bytes and **GetSize** would return 28. Implementors of **IMallocSpy::PostGetSize** cannot assume, for example, that if *cbActual* is sizeof(debug_header), that the value is the actual size of the user's allocation.

See Also

IMalloc::GetSize, **IMallocSpy::PreGetSize**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PreHeapMinimize

Called just prior to invoking **IMalloc::HeapMinimize**.

void PreHeapMinimize(*void***);**

Comments

This method is included for completeness; it is not anticipated that developers will implement significant functionality in this method.

See Also

IMalloc::HeapMinimize, **IMallocSpy::PostHeapMinimize**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PostHeapMinimize

Called just after invoking **IMalloc::HeapMinimize**.

void PostHeapMinimize(*void***);**

Comments

This method is included for completeness; it is not anticipated that developers will implement significant functionality in this method.

See Also

IMalloc::HeapMinimize, **IMallocSpy::PreHeapMinimize**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PreRealloc

Called just before invoking **IMalloc::Alloc**.

```
ULONG PreRealloc(
  void * pRequest,              //The pointer the caller is passing to IMalloc::Realloc
  ULONG cbRequest,              //The byte count the caller is passing to IMalloc::Realloc
  void ** ppNewRequest,         //Points to the actual pointer to be reallocated
  BOOL fSpyed                   //Whether the original allocation was "spyed"
 );
```

Parameters

pRequest
The pointer the caller is passing to **IMalloc::Realloc**.

cbRequest
The byte count the caller is passing to **IMalloc::Realloc**.

ppNewRequest
[out] Points to the actual pointer to be reallocated. This may be different from the pointer in *pRequest* if the implementation of **IMallocSpy::PreRealloc** extends or modifies the reallocation. This is an out pointer and should always be stored by **PreRealloc**.

fSpyed
TRUE if the original allocation was done while the spy was active.

Return Value

The actual byte count to be passed to **IMalloc::Realloc**.

Comments

The **IMallocSpy::PreRealloc** implementation may extend and/or modify the allocation to store debug-specific information with the allocation. Thus, the *ppNewRequest* parameter may differ from *pRequest*, which the caller is passing to **IMalloc::Realloc**.

PreRealloc can force memory allocation failure by returning 0, allowing testing to ensure that the application handles allocation failure gracefully in all cases. In this case **PostRealloc** is not called and **Realloc** returns NULL. Forcing allocation failure is effective only if *cbRequest* is not equal to 0. Note that if **PreRealloc** is forcing failure by returning NULL, **PostRealloc** is not called. However, if **IMalloc::Realloc** encounters a real memory failure and returns NULL, **PostRealloc** is called.

See Also

IMalloc::Realloc, **IMallocSpy::PostRealloc**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMallocSpy::PostRealloc

Called after invoking **IMalloc::Realloc**.

```
void * PostRealloc(
    void * pActual,       //The pointer returned by IMalloc::Realloc
    BOOL fSpyed           //Indicates whether the original allocation was "spyed"
  );
```

Parameters

pActual
: Points to the memory block reallocated by **IMalloc::Realloc**.

fSpyed
: If TRUE, the original memory allocation was done while the spy was active.

Return Values

The pointer to be returned to the **IMalloc::Realloc** caller. If debug information is written at the front of the caller's allocation, it should be a forward offset from *pActual*. The value should be the same as *pActual* if debug information is appended or if no debug information is attached.

See Also

IMalloc::Realloc, **IMallocSpy::PreRealloc**, **CoRegisterMallocSpy**, **CoRevokeMallocSpy**

IMarshal

The **IMarshal** interface allows an object to perform custom marshaling of interface pointers.

"Marshaling" is the process of packaging function parameters into data packets in order to send them to a different process or machine. "Unmarshaling" is the process of recovering those parameters when they are received. When a remote function call passes an interface pointer as a function parameter, that pointer is marshaled in such a way that it becomes possible for a client in one process to use that interface pointer to call methods on an object in another process.

OLE marshals an interface pointer by creating a proxy object in the client's process. A client holds an interface pointer to the proxy object and calls methods using that pointer; the proxy marshals the method parameters and sends them to the original process, thus forwarding the method call to the original object. The **IMarshal** interface allows an object to control what kind of proxies are created.

When to Implement

You almost never need to implement this interface. OLE provides a default implementation of **IMarshal** that uses OLE-generated proxy objects; this is suitable for almost all situations. You implement the **IMarshal** interface only if you want to perform custom marshaling; this allows you to write your own proxy objects.

OLE uses your implementation of **IMarshal** in the following manner: When it's necessary to create a remote interface pointer to your object (that is, when a pointer to your object is passed as a parameter in a remote function call), OLE queries your object for the **IMarshal** interface. If your object implements it, OLE uses your **IMarshal** implementation to create the proxy object. If your object does not implement **IMarshal**, OLE uses its standard implementation.

Some situations in which you might want to perform custom marshaling are as follows:

- The objects you are writing keep their state in shared memory. In this case, both the original process and the client process uses proxies that refer to the shared memory. This type of custom marshaling is possible only if the client process is on the same machine as the original process. The compound file implementations of **IStorage** and **IStream** are examples of this type of custom marshaling.
- The objects you are writing are immutable, that is, their state does not change after creation. Instead of forwarding method calls to the original objects, you can simply create copies of those objects in the client process. This technique avoids the cost of context switches (switching from one process to another). Monikers are an example of immutable objects; if you are implementing your own moniker class, you should perform custom marshaling.

Note that these situations do not require you to create a separate class of proxy objects; the same objects are used by both the original process and the client process. In other situations, you may need to write a separate class of proxy objects (with its own CLSID) that forward calls to the original objects, in addition to implementing **IMarshal** on the original objects.

When to Use

You typically do not need to call this interface. OLE is the primary user of this interface.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IMarshal Methods	Description

GetUnmarshalClass	Returns CLSID of unmarshaling code.
GetMarshalSizeMax	Returns size of buffer needed during marshaling.
MarshalInterface	Marshals an interface pointer.
UnmarshalInterface	Unmarshals an interface pointer.
ReleaseMarshalData	Destroys a marshaled data packet.
DisconnectObject	Severs all connections.

See Also

IStdMarshalInfo

IMarshal::DisconnectObject

Severs remote connections (that is, connections from other processes) being maintained on behalf of any interface pointers on the current object.

```
HRESULT IMarshal::DisconnectObject(
  DWORD dwReserved      //Reserved for future use
 );
```

Parameter

dwReserved
[in] Reserved for future use; must be set to zero by the caller. To ensure compatibility with future use, the callee *must not* check for zero.

Return Values

S_OK
The object was disconnected successfully.

E_FAIL
Indicates an unspecified error.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
One or more arguments were invalid.

E_UNEXPECTED
An unexpected error occured.

Comments

This method is called from the originating side (that is, the side doing the marshaling).

This method is called by the **CoDisconnectObject** API function if the object being disconnected implements the **IMarshal** interface. This is analogous to the way the **CoMarshalInterface** API function defers to the **IMarshal::MarshalInterface** method if the object supports **IMarshal**.

Notes to Implementors

If you are doing custom marshaling of immutable objects, your implementation doesn't need to do anything because there are no remote connections.

See Also

CoDisconnectObject

IMarshal::GetMarshalSizeMax

Returns an upper bound on the amount of data that would be written to the marshaling stream in a call to **IMarshal::MarshalInterface**.

```
HRESULT IMarshal::GetMarshalSizeMax(
    REFIID riid,                  //Identifies interface to be marshaled
    void *pv,                     //Points to interface pointer to be marshaled
    DWORD dwDestContext,          //Identifies destination process
    void * pvDestContext,         //Reserved for future use
    DWORD mshlflags,              //Specifies reason for marshaling
    ULONG * pSize                 //Receives upper bound
  );
```

Parameters

riid
[in]Specifies the IID of the interface pointer to be marshaled.

pv
[in]Points to the interface pointer to be marshaled; can be NULL.

dwDestContext
[in] Specifies the destination context, that is, the process in which the unmarshaling will be done. Different marshaling can be done depending on whether the unmarshaling will happen on the local workstation or on a workstation on the network; it's possible for an object to do custom marshaling in one case but not another. The legal values for *dwDestContext* are taken from the enumeration **MSHCTX**. For information on the **MSHCTX** enumeration, see the "Data Structures" section.

pvDestContext
[in] Reserved for use with future **MSHCTX** values.

mshlflags
[in] Specifies why marshaling is taking place. The legal values for *mshlflags* are taken from the enumeration **MSHLFLAGS**. For information on the **MSHLFLAGS** enumeration, see the "Data Structures" section.

pSize
[out]Receives the upper bound on the amount of data that would be written to the marshaling stream.

Return Values

S_OK
Maximum size was returned successfully.

E_FAIL
Indicates that the implementation failed.

E_NOINTERFACE
The specified interface was not supported.

Comments

This method is called from the originating side (that is, the side doing the marshaling). This method is used to preallocate the stream buffer that will be passed to **IMarshal::MarshalInterface**.

Notes to Implementors

The value your implementation returns must be an upper bound; a subsequent call to your implementation of **IMarshal::MarshalInterface** must use no more than the number of bytes returned by this method. The upper bound you return can be used by the caller to preallocate a stream buffer for using during marshaling.

See Also

IMarshal::MarshalInterface

IMarshal::GetUnmarshalClass

Returns the CLSID that should be used to create an uninitialized proxy on the receiving side (that is, the side doing the unmarshaling).

```
HRESULT IMarshal::GetUnmarshalClass(
    REFIID riid,                    //Identifies the interface being marshaled
    void * pv,                      //Points to the interface pointer being marshaled
    DWORD dwDestContext,            //Identifies the destination process
    void * pvDestContext,           //Reserved for future use
    DWORD mshlflags,                //Specifies reason for marshaling
    CLSID * pCid                    //Receives CLSID of proxy
  );
```

Parameters

riid
[in]Specifies the IID of the interface pointer to be marshaled.

pv
[in]Points to the interface pointer to be marshaled; can be NULL.

dwDestContext
[in] Specifies the destination context, that is, the process in which the unmarshaling will be done. Different marshaling can be done depending on whether the unmarshaling will happen on the local workstation or on a workstation on the network; it's possible for an object to do custom marshaling in one case but not another. The legal values for *dwDestContext* are taken from the enumeration **MSHCTX**. For information on the **MSHCTX** enumeration, see the "Data Structures" section.

pvDestContext
[in] Reserved for use with future **MSHCTX** values.

mshlflags
[in] Specifies why marshaling is taking place. Values for *mshlflags* are taken from the enumeration **MSHLFLAGS**. For information on the **MSHLFLAGS** enumeration, see the "Data Structures" section.

pCid
[out] Receives the CLSID to be used to create a proxy on the receiving side (that is, the side doing the unmarshaling).

Return Value

Returns S_OK if successful; otherwise, S_FALSE.

Comments

This method is called from the originating side (that is, the side doing the marshaling).

Notes to Implementors

The CLSID returned by this method identifies the class of the proxy object. This CLSID is typically written to a stream on the originating side and then read from the stream on the receiving side. Note that if you are creating a copy of the original object in the client process (that is, you are implementing custom marshaling for immutable objects), the CLSID returned is the same one as for the original object.

Your implementation can delegate some destination contexts to the standard marshaling implementation, available by calling the **CoGetStandardMarshal** API function. You should always delegate if the *dwDestContext* parameter contains a value that your implementation does not understand; this allows new destination contexts to be defined in the future.

You may want your implementation to use the pointer passed through the *pv* parameter, and, based on information retrieved from that pointer, determine the appropriate CLSID to return. If the *pv* parameter is NULL and your implementation needs that interface pointer, it can call **IUnknown::QueryInterface** on the current object to get it. The *pv* parameter exists merely to improve efficiency.

IMarshal::MarshalInterface

Marshals an interface pointer into the stream, that is, writes the appropriate data into the stream so that your **IMarshal::UnmarshalInterface** method can use that data to initialize a proxy object in another process.

```
HRESULT IMarshal::MarshalInterface(
    IStream *pStm,              //Stream used for marshaling
    REFIID riid,                //Identifies interface being marshaled
    void *pv,                   //Points to interface pointer being marshaled
    DWORD dwDestContext,        //Identifies destination process
    void *pvDestContext,        //Reserved for future use
    DWORD mshlflags             //Specifies reason for marshaling
  );
```

Parameters

pStm
[in]Points to the stream to be used during marshaling.

riid
[in]Specifies the IID of the interface pointer to be marshaled.

pv
[in]Points to the interface pointer to be marshaled; can be NULL.

dwDestContext
[in] Specifies the destination context, that is, the process in which the unmarshaling will be done. Different marshaling can be done depending on whether the unmarshaling will happen on the local workstation or on a workstation on the network; it's possible for an object to do custom marshaling in one case but not another. The legal values for *dwDestContext* are taken from the enumeration **MSHCTX**. For information on the **MSHCTX** enumeration, see the "Data Structures" section.

pvDestContext
[in] Reserved for use with future **MSHCTX** values.

mshlflags
[in]Specifies why marshaling is taking place. The legal values for *mshlflags* are taken from the **MSHLFLAGS** enumeration. For information on the **MSHLFLAGS** enumeration, see the "Data Structures" section.

Return Values

S_OK
The interface pointer was marshaled successfully.

E_FAIL
Indicates that the implementation failed.

E_NOINTERFACE
The specified interface was not supported.

STG_E_MEDIUMFULL
The stream was full.

Comments

This method is called from the originating side (that is, the side doing the marshaling). This method sends information to the receiving side by writing that information into the stream; on the receiving side, the information will be read from the stream and used to initialize a proxy object.

Notes to Implementors

Your implementation of **IMarshal::MarshalInterface** must write to the stream whatever data is needed to initialize the proxy on the receiving side. Your implementation can delegate some destination contexts to the standard marshaling implementation, which is available by calling the **CoGetStandardMarshal** API function. You should always delegate if the *dwDestContext* parameter contains a value that your implementation does not understand; this allows new destination contexts to be defined in the future.

Your implementation cannot assume the stream is large enough to hold all the data; it must still take into account the possibility that the stream may return STG_E_MEDIUMFULL errors. Just before exiting, your implementation should position the seek pointer in the stream immediately after the last byte of data written.

Note that the data marshaled by **IMarshal::MarshalInterface** can be unmarshaled zero or more times; this may happen if the marshaled data is stored in a global table, from which it may be unmarshaled many times by different client processes. Marshalers must be able to handle the result of multiple unmarshalings. For example, suppose the unmarshaling process creates a proxy that forwards calls to a stub interface in the server application; this stub interface must be able to deal with zero or more proxies being created from the same initialization data.

If the *pv* parameter is NULL and your implementation needs that interface pointer, it can call **IUnknown::QueryInterface** on the current object to get it. The *pv* parameter exists merely to improve efficiency.

See Also

CoGetStandardMarshal, **IMarshal::GetMarshalSizeMax**, **IMarshal::GetUnmarshalClass**, **IMarshal::UnmarshalInterface**

IMarshal::ReleaseMarshalData

Destroys a marshaled data packet.

```
HRESULT IMarshal::ReleaseMarshalData(
   IStream * pStm        //Stream used for unmarshaling
  );
```

Parameter

pStm
[in] Points to a stream that contains the data packet which is to be destroyed.

Return Values

S_OK
The data packet was released successfully.

E_FAIL
Indicates an unspecified error.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
One or more arguments were invalid.

E_UNEXPECTED
An unexpected error occured.

IStream errors
See the **IStream** interface for information on possible stream access errors.

Comments

This method is typically called from the receiving side (that is, the side doing the unmarshaling), sometimes via the **CoReleaseMarshalData** or **CoUnmarshalInterface** API functions. However, if the data packet does not arrive on the receiving side or if the appropriate proxy object cannot be successfully created there, this method is called from the originating side (that is, the side doing the marshaling).

As an analogy, the data packet can be thought of as a reference to the original object, just as if it were another interface pointer being held on the object. Like a real interface pointer, that data packet must be released at some point. The use of **IMarshal::ReleaseMarshalData** to release data packets is analogous to the use of **IUnknown::Release** to release interface pointers.

Notes to Implementors

If your implementation stores state information about marshaled data packets, use this method to release the state information associated with the data packet found in *pstm*. Your implementation should also position the seek pointer in the stream past the last byte of data.

See Also

CoUnMarshalInterface, **CoReleaseMarshalData**

IMarshal::UnmarshalInterface

Initializes a newly created proxy and returns an interface pointer to that proxy.

```
HRESULT IMarshal::UnmarshalInterface(
   IStream * pStm,        //Stream used for unmarshaling
   REFIID riid,           //IID of interface pointer desired
   void ** ppv            //Receives the interface pointer
  );
```

Parameters

pStm
[in]Points to the stream from which the interface pointer is to be unmarshaled.

riid
[in]Specifies the IID of the interface pointer desired.

ppv
[out]Receives the interface pointer.

Return Values

S_OK
The interface pointer was unmarshaled successfully.

E_FAIL
Indicates that the implementation failed.

E_NOINTERFACE
The specified interface was not supported.

Comments

This method is called from the receiving side (that is; the side doing the unmarshaling). This method is called on the proxy object itself; that is; the object whose CLSID was returned by **IMarshal::GetUnmarshalClass**.

Notes to Implementors

Your implementation should read the data written to the stream by your implementation of **IMarshal::MarshalInterface** and use that data to initialize the proxy object.

To return the appropriate interface pointer; your implementation can simply call **IUnknown::QueryInterface** on itself, passing the *riid* and *ppv* parameters. However; your implementation is free to create a different object and return a pointer to that object; if you find it necessary.

Just before exiting; your implementation should position the seek pointer in the stream immediately after the last byte of data read. This should be done even if the method exits with an error.

IMessageFilter

This **IMessageFilter** interface allows applications to handle incoming or outgoing messages selectively while waiting for responses from synchronous calls. The ability to filter messages is often useful when a dialog box is being displayed or a lengthy operation is in progress. Performance can be improved when applications handle some messages and defer others.

When to Implement

Implement **IMessageFilter** in place of OLE's default message handling when there is a need to selectively handle incoming or outgoing messages, while at the same time waiting for responses from synchronous calls.

Although not as significant an issue as with 16-bit applications, you may still need to implement **IMessageFilter** as a way of solving deadlocks. **IMessageFilter** is still needed to find out if an application is blocking, so that you can task-switch to that application and give the user an opportunity to deal with the blocking application. For example, if you have Word talking to Excel, with Excel running in the background in formula mode, Excel won't check all calls, thereby blocking further action. **IMessageFilter** would put up a dialog indicating which task is blocking and provide the user with an opportunity to deal with the deadlock.

For applications that do not implement **IMessageFilter**, incoming and outgoing calls to OLE are handled automatically by OLE's default message handling procedures. OLE provides default message handling for each of the conditions that would be handled by an **IMessageFilter** method. For incoming calls, OLE dispatches all calls, regardless of their logical thread ID. For incoming Windows messages or Macintosh events, the default behavior is as though **IMessageFilter::MessagePending** had returned PENDINGMSG_WAITDEFPROCESS. This means that task-switching and window-activation messages are dispatched, as well as WM_TIMER messages. Other input messages are discarded and OLE continues to wait for the reply.

When to Use

You don't call this interface directly. It's provided by the application and called by the system.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IMessageFilter Methods	**Description**
HandleIncomingCall	Provides a single entry point for incoming calls.
RetryRejectedCall	Provides application with opportunity to display dialog offering retry or cancel options or to switch tasks.
MessagePending	Indicates a Windows message has arrived while OLE is waiting to respond to a remote call.

See Also

In the *WIN32 Programmer's Reference*: "Messages and Message Queues"

IMessageFilter::HandleInComingCall

Provides an application with a single entry point for all incoming calls.

```
DWORD HandleInComingCall(
   DWORD dwCallType,                    //Type of incoming call
   HTASK threadIDCaller,                //Task handle calling this task
   DWORD dwTickCount,                   //Elapsed tick count
   LPINTERFACEINFO lpInterfaceInfo      //Points to INTERFACEINFO structure
  );
```

Parameters

dwCallType
   [in] Indicates the kind of incoming call that has been received; valid values are from the enumeration **CALLTYPE**. See the chapter on enumerations for details.

threadIDCaller
   [in] Specifies the handle of the task is calling this task.

dwTickCount
   [in] Specifies the elapsed tick count since the outgoing call was made if *dwCallType* is not CALLTYPE_TOPLEVEL. If *dwCallType* is CALLTYPE_TOPLEVEL, *dwTickCount* should be ignored.

lpInterfaceInfo
   Points to an **INTERFACEINFO** structure that contains information about the incoming call. Can also be NULL.

Return Values

SERVERCALL_ISHANDLED
   The application may be able to process the call.

SERVERCALL_REJECTED
   The application cannot handle the call due to an unforeseen problem, such as network unavailability.

SERVERCALL_RETRYLATER
   The application cannot handle the call at this time. For example, an application might return this value when it is in a user-controlled modal state.

Comments

If implemented, **IMessageFilter::HandleInComingCall** is called when an incoming OLE message is received.

Depending on the application's current state, the call can either be accepted and processed or rejected (permanently or temporarily). If SERVERCALL_ISHANDLED is returned, the application may be able to process the call. Success may depend on the interface for which the call is destined. If the call cannot be processed, OLE returns RPC_E_CALL_REJECTED.

Input-synchronized and asynchronous calls are dispatched even if the application returns SERVERCALL_REJECTED or SERVERCALL_RETRYLATER.

IMessageFilter::HandleInComingCall should not be used to hold off updates to objects during operations such as band printing. For that purpose, use **IViewObject::Freeze**.

You can also use **IMessageFilter::HandleInComingCall** to set up the application's state so the call can be processed in the future.

See Also

IViewObject::Freeze, **CALLTYPE**, **INTERFACEINFO**

IMessageFilter::MessagePending

Called if a Windows message or Macintosh event appears in the queue while OLE is waiting to reply to a remote call.

```
DWORD Create(
  HTASK threadIDCallee,     //Called applications task handle
  DWORD dwTickCount,        //Elapsed tick count
  DWORD dwPendingType       //Call type
 );
```

Parameters

threadIDCallee
[in] Specifies the task handle of the called application that has not yet responded.

dwTickCount
[in] Specifies the number of ticks since the call was made. It is calculated from the Windows **GetTickCount** function, or the Macintosh function, **TickCount**.

dwPendingType
[in] Indicates the type of call made during which a message or event was received. Valid values are from the enumeration **PENDINGTYPE** (where PENDINGTYPE_TOPLEVEL means the outgoing call was not nested within a call from another application and PENDINTGYPE_NESTED means the outgoing call was nested within a call from another application):

Return Values

PENDINGMSG_CANCELCALL
Cancel the outgoing call. This should be returned only under extreme conditions. Canceling a call that has not replied or been rejected can create orphan transactions and lose resources. OLE fails the original call and return RPC_E_CALL_CANCELLED.

PENDINGMSG_WAITNOPROCESS
Continue waiting for the reply and do not dispatch the message unless it is a task-switching or window-activation message. A subsequent message will trigger another call to **IMessageFilter::MessagePending**. Leaving messages or events in the queue enables them to be processed normally, if the outgoing call is completed.

PENDINGMSG_WAITDEFPROCESS
Because of the increased resources available in 32-bit systems, you are unlikely to get this return value. It now indicates the same state as PENDINGMSG_WAITNOPROCESS.

Keyboard and mouse messages are no longer dispatched, as was done with PENDINGMSG_WAITDEFPROCESS. However there are some cases where mouse and keyboard messages could cause the system to deadlock, and in these cases, mouse and keyboard messages are discarded. WM_PAINT messages are dispatched. Task-switching and activation messages are handled as before.

Comments

IMessageFilter::MessagePending is called by OLE after an application has made an OLE method call and, for example, while waiting for the reply, the user selects a menu command or double-clicks an object. Before OLE makes the **IMessageFilter::MessagePending** call, it calculates the elapsed time since the original OLE method call was made. OLE delivers the elapsed time in the *dwTickCount* parameter. In the meantime, OLE does not remove the message from the queue.

Windows messages or Macintosh events that appear in the caller's queue should remain in the queue until sufficient time has passed to ensure that the messages are probably not the result of typing ahead, but are, instead, an attempt to get attention. A two- or three-second delay is recommended. If that amount of time has passed and the call has not been completed, the messages should be flushed from the queue, and a dialog box should be displayed offering the user the choice of retrying (continue waiting) or switching to the task identified by the *threadIDCallee* parameter. This ensures that:

- if calls are completed in a reasonable amount of time, type ahead will be treated correctly.
- if the callee does not respond, type ahead is not misinterpreted and the user is able to act to solve the problem. For example, OLE 1 servers can queue up requests without responding when they are in modal dialogs.

Handling input while waiting for an outgoing call to finish can introduce complications. The application should determine whether to process the message without interrupting the call, continue waiting, or cancel the operation.

When there is no response to the original OLE call, the application can cancel the call and restore the OLE object to a consistent state by calling **IStorage::Revert** on its storage. The object can be released when the container can shut down. However, canceling a call can create orphaned operations and resource leaks. Canceling should be used *only* as a last resort. It is strongly recommended that applications not allow such calls to be canceled.

Caution Returning PENDINGMSG_WAITNOPROCESS can cause the message queue to fill.

See Also

IStorage::Revert

GetTickCount in Win32

IMessageFilter::RetryRejectedCall

Gives the application an opportunity to display a dialog box so the user can retry or cancel the call, or switch to the task identified by *threadIDCallee.*

```
DWORD RetryRejectedCall(
  HTASK threadIDCallee,      //Server task handle
  DWORD dwTickCount,         //Elapsed tick count
  DWORD dwRejectType         //Returned rejection message
 );
```

Parameters

threadIDCallee
 [in] Specifies the handle of the server task that rejected the call.

dwTickCount
 [in] Specifies the number of elapsed ticks since the call was made.

dwRejectType
 [in] Specifies either SERVERCALL_REJECTED or SERVERCALL_RETRYLATER, as returned by the object application.

Return Values

-1
 The call should be canceled. OLE then returns RPC_E_CALL_REJECTED from the original method call.

Value >= 0 and <100
 The call is to be retried immediately.

Value >= 100
 OLE will wait for this many milliseconds and then retry the call.

Comments

OLE calls **RetryRejectedCall** immediately after receiving SERVERCALL_RETRYLATER or SERVERCALL_REJECTED from **IMessageFilter::HandleInComingCall**.

If an application task rejects a call, the application is probably in a state where it cannot handle such calls, possibly only temporarily. When this occurs, OLE calls **IMessageFilter::RetryRejectedCall**.

Applications should silently retry calls that have returned with SERVERCALL_RETRYLATER and show a dialog box only after a reasonable amount of time has passed, say about five seconds. The callee may momentarily be in a state where calls can be handled. The option to wait and retry is provided for special kinds of calling applications, such as background tasks executing macros or scripts, so that they can retry the calls in a nonintrusive way.

If, after a dialog box is displayed, the user chooses to cancel, the call will appear to fail with RPC_E_CALL_REJECTED.

IMoniker

The **IMoniker** interface is used for naming COM objects. An object that implements **IMoniker** is called a "moniker," which is a name that uniquely identifies a COM object.

You can think of a moniker as a generalization of a pathname; in the same way that a pathname identifies a file in the file system, a moniker identifies a COM object. For example, suppose you have an object representing a range of cells in a spreadsheet which is itself embedded in a text document. The moniker for this object would contain information like "c:\work\report.doc\embedobj1\A1:E7." Monikers are more widely applicable than pathnames; whereas pathnames can only identify files, monikers can identify any kind of object, whether it's a file, an embedding, a selection within a document, or something else.

Monikers have a number of useful properties:

- Monikers can be saved to a persistent storage. When a moniker is loaded back into memory, it still identifies the same object it did before.
- Monikers support an operation called "binding," which is the process of locating the object named by the moniker, activating it (loading it in memory) if it isn't already, and returning an interface pointer to it.

As a result of these characteristics, you can treat monikers as a persistent version of a pointer to an object. Suppose your object holds an **ICellRange** pointer to the cell-range object mentioned in the paragraph above. You'd like to save your object and the cell-range object to disk, reload them later, and still have your object hold a pointer to the cell-range object. It's no use saving the **ICellRange** pointer to a disk file, because you can't guarantee that the cell-range object will reside at the same address in memory the next time it's loaded. However, you *can* save a moniker in a file. Then you can re-read the moniker into memory and bind the moniker, which reloads the cell-range object into memory and returns an **ICellRange** pointer to it. You've thus reestablished a connection between two objects after writing them to persistent storage.

Monikers also form the basis for linking in OLE. A linked object contains a moniker that identifies its source. When the user activates the linked object to edit it, the moniker is bound; this loads the link source into memory.

When to Implement

You implement **IMoniker** only if you are writing your own moniker class; this is necessary only if you need to identify objects that cannot be identified using the system-supplied moniker classes.

The system supplies the following moniker classes:

- **File monikers** – based on a path in the file system. File monikers can be used to identify objects that are saved in their own files.
- **Item monikers** – based on a string that identifies an object in a container. Item monikers can be used to identify objects smaller than a file, including embedded objects in a compound document, or a pseudo-object (like a range of cells in a spreadsheet).
- **Generic composite monikers** – consists of two or more monikers of arbitrary type that have been composed together. Generic composite monikers allow monikers of different classes to be used in combination.
- **Anti-monikers** – the inverse of file, item, or pointer monikers. Anti-monikers are used primarily for constructing relative monikers, which are analogous to relative pathnames (such as "..\backup\report.old"), and which specifies a location of an object *relative* to the location of another object).
- **Pointer monikers** – a non-persistent moniker that wraps an interface pointer to an object loaded in memory. Whereas most monikers identify objects that can be saved to persistent storage, pointer monikers identify objects that cannot; they allow such objects to participate in a moniker binding

operation.

These system-supplied moniker classes are sufficient for most situations. Before considering writing your own moniker class, you should make sure that your requirements cannot be satisified by these system-supplied moniker classes. See the description for each moniker class for information on how each one implements the **IMoniker** interface.

If you decide you need to write your own implementation of **IMoniker**, you must also implement the **IROTData** interface on your moniker class. This interface allows your monikers to be registered with the Running Object Table (ROT).

When to Use

You can use monikers whenever you need to create persistent connections between objects. You can also use monikers if you need a naming mechanism more general than pathnames; for example, if you need to designate embedded objects as well as files.

You can use monikers in two ways:

- As a moniker provider; that is, handing out monikers that identify your objects to make them accessible to other parties. When acting as a moniker provider, you need to understand the differences between the various system-supplied moniker classes in order to know which one(s) are appropriate for identifying your objects. You use certain API functions to create monikers, and you must implement other interfaces to allow the monikers you hand out to be bound.
- As a moniker client; that is, using monikers to get interface pointers to objects managed by a moniker provider. When acting as a moniker client, you typically don't need to know the class of the moniker you're using; you simply call methods using an **IMoniker** interface pointer.

The most common example of moniker providers are applications that act as link sources; that is, server applications that support linking and container applications that support linking to the embedded objects in their documents. See the descriptions for the moniker classes and for the moniker creation API functions for information on when to use each class.

The most common example of moniker clients are applications that act as link containers; that is, container applications that allow their documents to contain linked objects. However, link containers are a special case in that they make only infrequent calls to **IMoniker** methods. Generally, they manipulate linked objects through the **IOleLink** interface; the default handler implements this interface and calls the appropriate **IMoniker** methods as needed.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IPersist Methods	**Description**
GetClassID	Returns the object's CLSID.

IPersistStream Methods	**Description**
IsDirty	Checks whether object has been modified.
Load	Loads the object from a stream.
Save	Saves the object to a stream.
GetSizeMax	Returns the buffer size needed to save the object.

IMoniker Methods	Description
BindToObject	Binds to the object named by the moniker.
BindToStorage	Binds to the object's storage.
Reduce	Reduces the moniker to simplest form.
ComposeWith	Composes with another moniker.
Enum	Enumerates component monikers.
IsEqual	Compares with another moniker.
Hash	Returns a hash value.
IsRunning	Checks whether object is running.
GetTimeOfLastChange	Returns time the object was last changed.
Inverse	Returns the inverse of the moniker.
CommonPrefixWith	Finds the prefix that the moniker has in common with another moniker.
RelativePathTo	Constructs a relative moniker between the moniker and another.
GetDisplayName	Returns the display name.
ParseDisplayName	Converts a display name into a moniker.
IsSystemMoniker	Checks whether moniker is one of the system-supplied types.

IMoniker::BindToObject

"Binds" the moniker; that is, returns a pointer to the object identified by the moniker. The binding process involves finding the object, getting it into the running state if it's not already, and acquiring an interface pointer to it.

```
HRESULT BindToObject(
  IBindCtx *pbc,              //Bind context to be used
  IMoniker *pmkToLeft,        //Moniker that precedes this one in the composite
  REFIID riidResult,          //IID of interface pointer requested
  void **ppvResult            //Receives an interface pointer to the object
 );
```

Parameters

pbc
: [in] Points to the bind context to be used for this binding operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the moniker implementation should retrieve information about its environment. For more information, see **IBindCtx**.

pmkToLeft
: [in] Points to the moniker to the left of this moniker, if this moniker is part of a composite. This parameter is primarily used by moniker implementors to enable cooperation between the various components of a composite moniker; moniker clients can usually pass NULL.

riidResult
: [in] Specifies the IID of the interface pointer requested.

ppvResult
: [out] Receives a pointer to the object identified by the moniker. If an error occurs, the implementation sets **ppvResult* to NULL. If **ppvResult* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
: The binding operation was successful.

MK_E_NOOBJECT
: Indicates that the object identifed by this moniker, or some object identified by the composite moniker of which this moniker is a part, could not be found.

MK_E_EXCEEDEDDEADLINE
: Indicates that the binding operation could not be completed within the time limit specified by the bind context's **BIND_OPTS** structure.

MK_E_CONNECTMANUALLY
: Indicates a moniker whose binding requires assistance from the end user. You can retry the binding operation after showing the moniker's display name to request that the end user manually connect to the object. The most common reasons for returning this value are that a password is needed or that a floppy needs to be mounted. The caller should call **IBindCtx::GetObjectParam** with the key "ConnectManually" to retrieve the moniker that caused the error, get the display name, display a dialog box asking the user for a password, and so on.

MK_E_INTERMEDIATEINTERFACENOTSUPPORTED
: An intermediate object was found but it did not support an interface required to complete the binding operation. For example, an item moniker returns this value if its container does not support the **IOleItemContainer** interface.

E_UNEXPECTED
: Indicates an unexpected error.

E_OUTOFMEMORY
Indicates insufficient memory.

STG_E_ACCESSDENIED
Unable to access the storage object.

IOleItemContainer::GetObject errors
Binding to a moniker containing an item moniker can return any of the errors associated with this function.

Comments

The **IMoniker::BindToObject** method implements the primary function of a moniker: returning an interface pointer to the object identified by the moniker.

Notes to Callers

If you are using a moniker as persistent connection between two objects, you activate the connection by calling **IMoniker::BindToObject**.

You typically call **IMoniker::BindToObject** with the following steps:

1. Create a bind context by calling the **CreateBindCtx** API function.
2. Call the **IMoniker::BindToObject** method on the moniker, retrieving an interface pointer.
3. Release the bind context.
4. Use the interface pointer.
5. Release the interface pointer.

Here's a code fragment that illustrates these steps:

```
// pMnk is an IMoniker * that points to a previously-acquired moniker
ICellRange *pCellRange;
IBindCtx *pbc;

CreateBindCtx( 0, &pbc );
pMnk->BindToObject( pbc, NULL, IID_ICellRange, &pCellRange );
pbc->Release();
// pCellRange now points to the object; safe to use pCellRange
pCellRange->Release();
```

You can also use the **BindMoniker** API function, which encapsulates the first three steps described above.

Note that link containers are a special case in that they typically don't need to call **IMoniker::BindToObject** directly. When a user activates a linked object, the link container can typically calls **IOleObject::DoVerb**. The link handler's implementation of **IOleObject::DoVerb** calls **IMoniker::BindToObject** on the moniker stored in the linked object (if it cannot handle the verb).

Notes to Implementors

What your implementation does depends on whether you expect your moniker to have a prefix, that is, whether you expect the *pmkToLeft* parameter to be NULL or not. For example, an item moniker, which identifies an object within a container, expects that *pmkToLeft* identifies the container. An item moniker consequently uses *pmkToLeft* to request services from that container. If you expect your moniker to have a prefix, you should use the *pmkToLeft* parameter (for instance, calling **IMoniker::BindToObject** on it) to request services from the object it identifies.

If you expect your moniker to have no prefix, your **IMoniker::BindToObject** implementation should first check the Running Object Table (ROT) to see if the object is already running. To acquire a pointer to the ROT, your implementation should call **IBindCtx::GetRunningObjectTable** on the *pbc* parameter.

You can then call the **IRunningObjectTable::GetObject** method to see if the current moniker has been registered in the ROT. If so, you can immediately use **IUnknown::QueryInterface** to return the desired interface pointer.

When your **IMoniker::BindToObject** implementation binds to some object, it should call **IBindCtx::RegisterObjectBound** on the *pbc* parameter to store a reference to the bound object in the bind context. This ensures that the bound object remains running until the bind context is released, which can avoid the expense of having a subsequent binding operation load it again later.

If the bind context's **BIND_OPTS** structure specifies the **BINDFLAGS_JUSTTESTEXISTENCE** flag, your implementation has the option of returning NULL in **ppvResult* (although you can also ignore the flag and perform the complete binding operation).

See Also

BindMoniker, **IMoniker::BindToStorage**

IMoniker::BindToStorage

Retrieves an interface pointer to the storage of the object identified by the moniker. Unlike the **IMoniker::BindToObject** method, this method does not run the object identified by the moniker.

```
HRESULT BindToStorage(
   IBindCtx *pbc,            //Bind context to be used
   IMoniker *pmkToLeft,      //Moniker to the left of this one in the composite
   REFIID riid,              //IID of interface pointer requested
   void **ppvObj             //Receives interface pointer to storage
  );
```

Parameters

pbc
[in] Points to the bind context to be used during this binding operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the moniker implementation should retrieve information about its environment. For more information, see **IBindCtx**.

pmkToLeft
[in] Points to the moniker to the left of this moniker, if this moniker is part of a composite. This parameter is primarily used by moniker implementors to enable cooperation between the various components of a composite moniker; moniker clients can usually pass NULL.

riid
[in] Indicates the requested interface pointer to be returned in *ppvObj*. Common interfaces requested include **IStorage**, **IStream**, and **ILockBytes**.

ppvObj
[out] Receives a pointer to the interface identified by *riid*. If an error occurs, the implementation sets **ppvObj* to NULL. If **ppvObj* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
The binding operation was successful.

MK_E_NOSTORAGE
Indicates that the object identified by this moniker does not have its own storage.

MK_E_EXCEEDEDDEADLINE
Indicates that the operation could not be completed within the time limit specified by the bind context's **BIND_OPTS** structure.

MK_E_CONNECTMANUALLY
Indicates that the operation was unable to connect to the storage, possibly because a network device could not be connected to. For more information, see **IMoniker::BindToObject**.

MK_E_INTERMEDIATEINTERFACENOTSUPPORTED
An intermediate object was found but it did not support an interface required for an operation. For example, an item moniker returns this value if its container does not support the **IOleItemContainer** interface.

E_OUTOFMEMORY
Indicates insufficient memory.

STG_E_ACCESSDENIED
Unable to access the storage object.

IOleItemContainer::GetObject errors
Binding to a moniker containing an item moniker can return any of the errors associated with this function.

Comments

There is an important difference between the **IMoniker::BindToObject** and **IMoniker::BindToStorage** methods. If, for example, you have a moniker that identifies a spreadsheet object; calling **IMoniker::BindToObject** provides access to the spreadsheet object itself, while calling **IMoniker::BindToStorage** provides access to the storage object in which the spreadsheet resides.

Notes to Callers

The most common reason for calling the **IMoniker::BindToStorage** method is if you are implementing your own moniker class. You would call this method if your implementation of **IMoniker::BindToObject** needs information from the object identified by their *pmkToLeft* parameter, but it doesn't need to activate that object; all it needs is access to the persistent storage of that object. For example, if your monikers are used to identify objects that can be activated without activating their containers, you may find this method useful. (Note that none of the system-supplied moniker classes use this method in their binding operations.)

You could also call this method if you're a moniker client and you know how to read the storage of the object identified by the moniker you're holding.

Notes to Implementors

Your implementation should locate the persistent storage for the object identified by the current moniker and return the desired interface pointer. Some types of monikers represent pseudo-objects; that is, objects that don't have their own piece of persistent storage. Such objects comprise some portion of the internal state of its container; e.g. a range of cells in a spreadsheet. If your moniker class is this type of moniker, your implementation of **IMoniker::BindToStorage** should return the error MK_E_NOSTORAGE.

If the bind context's **BIND_OPTS** structure specifies the **BINDFLAGS_JUSTTESTEXISTENCE** flag, your implementation has the option of returning NULL in **ppvObj* (although it can also ignore the flag and perform the complete binding operation).

IMoniker::BindToObject

IMoniker::CommonPrefixWith

Creates a new moniker based on the common prefix that this moniker shares with the specified moniker.

```
HRESULT CommonPrefixWith(
  IMoniker *pmkOther,          //Moniker to be used for comparison
  IMoniker **ppmkPrefix        //Receives the prefix
 );
```

Parameters

pmkOther
[in] Points to the moniker to be compared with this one for a common prefix.

ppmkPrefix
[out] Receives a pointer to the moniker that is the common prefix of the this moniker and *pmkOther*. If an error occurs or if there is no common prefix, the implementation sets **ppmkPrefix* to NULL. If **ppmkPrefix* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
A common prefix exists that is neither this moniker nor *pmkOther*.

MK_S_NOPREFIX
No common prefix exists.

MK_S_HIM
The entire *pmkOther* moniker is a prefix of this moniker.

MK_S_US
The two monikers are identical.

MK_S_ME
This moniker is a prefix of the *pmkOther* moniker.

MK_E_NOTBINDABLE
This method was called on a relative moniker. It is not meaningful to take the common prefix on a relative moniker.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

If, for example, you have one moniker that represents the path "c:\projects\secret\art\pict1.bmp" and another moniker that represents the path "c:\projects\secret\docs\chap1.txt." In that case, the common prefix of these two monikers would be a moniker representing the path "c:\projects\secret."

Notes to Callers

The **IMoniker::CommonPrefixWith** method is primarily called by the implementation of the **IMoniker::RelativePathTo** method. Moniker clients rarely need to call this method.

Note that it is not meaningful to take the common prefix on relative monikers. Consequently, you should call this method only if *pmkOther* and this moniker are both absolute monikers (where an absolute moniker is either a file moniker or a generic composite whose left-most component is a file moniker, and where the file moniker represents an absolute path). Do not call this method on relative monikers.

Notes to Implementors

Your implementation should first determine whether *pmkOther* is a moniker of a class that you recognize and for which you can provide special handling (for example, if it is of the same class as this moniker). If so, your implementation should determine the common prefix of the two monikers. Otherwise, it should pass both monikers in a call to the **MonikerCommonPrefixWith** API function, which correctly handles the generic case.

See Also

IMoniker::RelativePathTo, **MonikerCommonPrefixWith**

IMoniker::ComposeWith

Combines the current moniker with another moniker, creating a new, composite moniker.

```
HRESULT ComposeWith(
  IMoniker *pmkRight,           //Moniker to be composed onto this one
  BOOL fOnlyIfNotGeneric,       //Indicates if generic composition permissible
  IMoniker **ppmkComposite      //Receives the composite
 );
```

Parameters

pmkRight
[in] Points to the moniker to compose onto the end of this moniker.

fOnlyIfNotGeneric
[in] Indicates whether the method must perform a non-generic composition. If TRUE, the caller requires a non-generic composition, so the operation should proceed only if *pmkRight* is a moniker class that this moniker can compose with in some way other than forming a generic composite. If FALSE, the method can create a generic composite if necessary.

ppmkComposite
[out] Receives a pointer to the resulting composite moniker. If an error occurs or if the monikers compose to nothing (e.g., composing an anti-moniker with an item moniker or a file moniker), the implementation sets **ppmkComposite* to NULL. If **ppmkComposite* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
Indicates that the monikers were successfully combined.

MK_E_NEEDGENERIC
Indicates that *fOnlyIfNotGeneric* was TRUE, but the monikers could not be composed together without creating a generic composite moniker.

E_OUTOFMEMORY
Indicates insufficient memory.

E_UNEXPECTED
Indicates an unexpected error.

Comments

The process of joining two monikers together is called composition. Sometimes two monikers of specific classes can be combined in a special manner; for example, a file moniker representing an incomplete path and another file moniker representing a relative path can be combined to form a single file moniker representing the complete path. This is an example of "non-generic" composition. "Generic" composition, on the other hand, can connect any two monikers, no matter what their classes. Because a non-generic composition depends on the class of the monikers involved, it can be performed only by an particular class's implementation of the **IMoniker::ComposeWith** method. You can define new types of non-generic compositions if you write a new moniker class. By contrast, generic compositions are performed by the **CreateGenericComposite** API function.

Composition of monikers is an associative operation. That is, if A, B, and C are monikers, then

Comp(Comp(A, B), C)

is always equal to

Comp(A, Comp(B, C))

where Comp() represents the composition operation.

Notes to Callers

If you want to combine two monikers, you should call the **IMoniker::ComposeWith** method rather than calling **CreateGenericComposite** API function; this gives the first moniker a chance to perform a non-generic composition.

A common situation in which you would combine two monikers is if you are a moniker provider using item monikers to identify your objects; for example, if your application is a server that supports linking to portions of a document, or if it's a container that supports linking to embedded objects within its documents. In such a situation, you would do the following:

1. Create an item moniker identifying an object.
2. Get a moniker that identifies the object's container.
3. Call **IMoniker::ComposeWith** on the moniker identifying the container, passing the item moniker as the *pmkRight* parameter.

Most callers of **IMoniker::ComposeWith** should set the *fOnlyIfNotGeneric* parameter to FALSE.

Notes to Implementors

As described above, there are two ways to compose *pmkRight* to your moniker: by performing a generic composition, or by performing a non-generic composition. The latter means seeing if you recognize the *pmkRight* parameter's class and if so, using the contents of *pmkRight* to perform a more intelligent composition.

When writing your moniker class, you must decide if there are any kinds of monikers to which you want to give special treatment (as described above in the example of the file monikers); these don't have to be monikers of your own class. You then implement **IMoniker::ComposeWith** to examine *pmkRight* to check whether it is such a special moniker; possible ways of doing this are to ask *pmkRight* for its class or call **IUnknown::QueryInterface** on it. The most common case of a special moniker is the inverse for your moniker class (that is, whatever you return from your implementation of **IMoniker::Inverse**).

If the *pmkRight* parameter is a moniker of a class that you give special treatment, your implementation of **IMoniker::ComposeWith** should do whatever is appropriate for that special case. If *pmkRight* completely negates the receiver so that the resulting composite is empty, you should pass back **NULL** in *ppmkComposite* and return the status code S_OK.

If the *pmkRight* parameter is not of a class to which you give special treatment, examine *fOnlyIfNotGeneric* to determine what to do next. If *fOnlyIfNotGeneric* is TRUE, pass back NULL through *ppmkComposite* and return the status code MK_E_NEEDGENERIC. If *fOnlyIfNotGeneric* is FALSE, call the **CreateGenericComposite** API to perform the composition generically.

See Also

CreateGenericComposite, **IMoniker::Inverse**

IMoniker::Enum

Returns a pointer to an enumerator that can enumerate the components of the moniker.

```
HRESULT Enum(
  BOOL fForward,                        //Specifies direction of enumeration
  IEnumMoniker **ppenumMoniker          //Receives the enumerator
 );
```

Parameters

fForward

[in] Specifies the enumeration order. TRUE enumerates the monikers from left to right; FALSE enumerates from right to left.

ppenumMoniker

[out] Receives a pointer to an **IEnumMoniker** enumerator for this moniker. If an error occurs or if the moniker has no enumerable components, the implementation sets **ppenumMoniker* to NULL. If **ppenumMoniker* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK

Indicates success. This value is returned even if the moniker does not provide an enumerator (that is, if **ppenumMoniker* equals NULL).

E_OUTOFMEMORY

Indicates insufficient memory.

E_UNEXPECTED

Indicates an unexpected error.

Comments

As examples of enumeration, the **IMoniker::Enum** method for a generic composite moniker creates an enumerator that returns the individual monikers that make up the composite, and the **IMoniker::Enum** method for a file moniker creates an enumerator that returns monikers representing each of the components in the pathname.

Notes to Callers

You would call this method if you want to examine the individual components that make up a composite moniker.

Notes to Implementors

If your monikers have no discernible internal structure, your implementation of this method can simply return S_OK and set **ppenumMoniker* to NULL.

See Also

IEnum*XXXX*

IMoniker::GetDisplayName

Returns the display name – that is, the user-readable representation – of this moniker.

```
HRESULT GetDisplayName(
  IBindCtx *pbc,                  //Bind context to be used
  IMoniker *pmkToLeft,            //Moniker to the left in the composite
  LPOLESTR *ppszDisplayName       //Receives the display name
 );
```

Parameters

pbc
[in] Points to the bind context to be used in this operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the moniker implementation should retrieve information about its environment. For more information, see **IBindCtx**.

pmkToLeft
[in] Points to the moniker to the left of this moniker, if this moniker is part of a composite. This parameter is primarily used by moniker implementors to enable cooperation between the various components of a composite moniker; moniker clients can usually pass NULL.

ppszDisplayName
[out] Receives a pointer to a zero-terminated string containing the display name of this moniker. If an error occurs, **ppszDisplayName* is set to NULL; otherwise, the implementation must use **IMalloc::Alloc** to allocate the string returned in *ppszDisplayName*, and the caller is responsible for calling **IMalloc::Free** to free it. Both caller and callee use the allocator returned by **CoGetMalloc**(MEMCTX_TASK, ...). For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

Return Values

S_OK
Indicates the display name was successfully returned.

MK_E_EXCEEDEDDEADLINE
Indicates that the binding operation could not be completed within the time limit specified by the bind context's **BIND_OPTS** structure.

E_OUTOFMEMORY
Indicates insufficient memory.

E_NOTIMPL
There is no display name.

Comments

As examples of display names, a file moniker's display name is the path the moniker represents, and an item moniker's display name is the string contained in the moniker. However, a display name is not necessarily a complete representation of a moniker's internal state; it is simply a form readable by users. As a result, it is possible (though rare) for two different monikers to have the same display name. There is also no guarantee that the display name of a moniker can be parsed back into that moniker when calling the **MkParseDisplayName** API function with it, though failure to do so is also rare.

Notes to Callers

It's possible that retrieving a moniker's display name may be an expensive operation. For efficiency, you may want to cache the results of the first successful call to **IMoniker::GetDisplayName**, rather than making repeated calls.

Notes to Implementors

If you are writing a moniker class in which the display name does not change, simply cache the display name and return that when requested. If the display name can change over time, getting the current display name might mean that the moniker has to access the object's storage or bind to the object, either of which can be expensive operations. If this is the case, your implementation of **IMoniker::GetDisplayName** should return MK_E_EXCEEDEDDEADLINE if the name cannot be retrieved by the time specified in the bind context's **BIND_OPTS** structure.

A moniker that is intended to be part of a generic composite moniker should include any preceding delimiter (such as '\') as part of its display name. For example, the display name returned by an item moniker includes the delimiter specified when it was created with the **CreateItemMoniker** API function. The display name for a file moniker does not include a delimiter because file monikers always expect to be the leftmost component of a composite.

See Also

IMoniker::ParseDisplayName, **MkParseDisplayName**

IMoniker::GetTimeOfLastChange

Returns a number representing the time the object identified by this moniker was last changed. To be precise, the time returned is the earliest one OLE can identify after which no change has occurred, so this time may be later than the actual time of the last change to the object.

```
HRESULT GetTimeOfLastChange(
   IBindCtx *pbc,              //Bind context to be used
   IMoniker *pmkToLeft,        //Moniker to the left in the composite
   FILETIME *pFileTime         //Receives the time of last change
  );
```

Parameters

pbc
[in] Points to the bind context to be used in this binding operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the moniker implementation should retrieve information about its environment. For more information, see **IBindCtx**.

pmkToLeft
[in] Points to the moniker to the left of this moniker, if this moniker is part of a composite. This parameter is primarily used by moniker implementors to enable cooperation between the various components of a composite moniker; moniker clients can usually pass NULL.

pFileTime
[out] Points to the **FILETIME** structure receiving the time of last change. A value of {0xFFFFFFFF,0x7FFFFFFF} indicates an error (for example, exceeded time limit, information not available).

Return Values

S_OK
Indicates the method returned a time successfully.

MK_E_EXCEEDEDDEADLINE
Indicates that the binding operation could not be completed within the time limit specified by the bind context's **BIND_OPTS** structure.

MK_E_CONNECTMANUALLY
Indicates that the operation was unable to connect to the storage for this object, possibly because a network device could not be connected to. For more information, see **IMoniker::BindToObject**.

MK_E_UNAVAILABLE
The time of the change is unavailable, and will not be available no matter what deadline is used.

E_UNEXPECTED
Indicates an unexpected error.

Comments

Notes to Callers

If you're caching information returned by the object identified by the moniker, you may want to ensure that your information is up-to-date. To do so, you would call **IMoniker::GetTimeOfLastChange** and compare the time returned with the time you last retrieved information from the object.

For the monikers stored within linked objects, **IMoniker::GetTimeOfLastChange** is primarily called by the default handler's implementation of **IOleObject::IsUpToDate**. Container applications call **IOleObject::IsUpToDate** to determine if a linked object (or an embedded object containing linked objects) is up-to-date without actually binding to the object. This enables an application to quickly determine which linked objects require updating when the end user opens a document. The application can then bind only those linked objects that need updating (after prompting the end user to determine whether they should be updated), instead of binding every linked object in the document.

Notes to Implementors

It is important to perform this operation quickly because, for linked objects, this method is called when a user first opens a compound document. Consequently, your **IMoniker::GetTimeOfLastChange** implementation should not bind to any objects. In addition, your implementation should check the deadline parameter in the bind context and return MK_E_EXCEEDEDDEADLINE if the operation cannot be completed by the specified time.

There are a number of strategies you can attempt in your implementations:

- For many types of monikers, the *pmkToLeft* parameter identifies the container of the object identified by this moniker. If this is true of your moniker class, you can simply call **IMoniker::GetTimeOfLastChange** on the *pmkToLeft* parameter, since an object cannot have changed at a date later than its container.
- You can get a pointer to the Running Object Table (ROT) by calling **IBindCtx::GetRunningObjectTable** on the *pbc* parameter, and then calling **IRunningObjectTable::GetTimeOfLastChange**, since the ROT generally records the time of last change.
- You can get the storage associated with this moniker (or the *pmkToLeft* moniker) and return the storage's last modification time.

See Also

IBindCtx::GetRunningObjectTable, **IRunningObjectTable::GetTimeOfLastChange**

IMoniker::Hash

Calculates a 32-bit integer using the internal state of the moniker.

```
HRESULT Hash(
   DWORD *pdwHash       //Receives the hash value
  );
```

Parameter

pdwHash
[out] Receives the hash value.

Return Value

S_OK
Successfully received a 32-bit integer hash value.

Comments

Notes to Callers

You can use the value returned by this method to maintain a hash table of monikers. The hash value determines a hash bucket in the table. To search such a table for a specified moniker, calculate its hash value and then compare it to the monikers in that hash bucket using **IMoniker::IsEqual**.

Notes to Implementors

The hash value must be constant for the lifetime of the moniker. Two monikers that compare as equal using **IMoniker::IsEqual** must hash to the same value.

Marshaling and then unmarshaling a moniker should have no effect on its hash value. Consequently, your implementation of **IMoniker::Hash** should rely only on the internal state of the moniker, not on its memory address.

See Also

IMoniker::IsEqual

IMoniker::Inverse

Returns a moniker that, when composed to the right of this moniker or one of similar structure, will destroy it (that is, will compose to nothing).

```
HRESULT Inverse(
    IMoniker **ppmk        //Receives the inverse of the moniker
  );
```

Parameter

ppmk

[out] Receives a pointer to the inverse moniker. If an error occurs, the implementation sets **ppmk* to NULL. If **ppmk* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK

The inverse moniker has been returned successfully.

MK_E_NOINVERSE

Indicates that the moniker class does not have an inverse.

E_OUTOFMEMORY

Indicates insufficient memory.

Comments

The inverse of a moniker is analogous to the ".." directory in MS-DOS file systems; the ".." directory acts as the inverse to any other directory name, because appending ".." to a directory name results in an empty path. In the same way, the inverse of a moniker typically is also the inverse of all monikers in the same class. However, it is not necessarily the inverse of a moniker of a different class.

The inverse of a composite moniker is a composite consisting of the inverses of the components of the original moniker, arranged in reverse order. For example, if the inverse of A is Inv(A) and the composite of A, B, and C is Comp(A, B, C), then

Inv(Comp(A, B, C))

is equal to

Comp(Inv(C), Inv(B), Inv(A)).

Not all monikers have inverses. Most monikers that are themselves inverses do not have inverses; for example, anti-monikers do not have inverses. Monikers that have no inverse cannot have relative monikers formed from inside the objects they identify to other objects outside.

Notes to Callers

If you're a moniker client, you typically do not know the class of the moniker you're using. If you need to get the inverse of a moniker, you should always call **IMoniker::Inverse** rather than the **CreateAntiMoniker** API function, because you cannot be certain that the moniker you're using considers an anti-moniker to be its inverse.

The **IMoniker::Inverse** method is also called by the implementation of the **IMoniker::RelativePathTo** method, to assist in constructing a relative moniker.

Notes to Implementors

If your monikers have no internal structure, your implementation of **IMoniker::Inverse** can return an anti-moniker using the **CreateAntiMoniker** API function. Whatever you return from **IMoniker::Inverse** is what you must check for in your implementation of **IMoniker::ComposeWith**.

See Also

CreateAntiMoniker, IMoniker::ComposeWith, IMoniker::RelativePathTo

IMoniker::IsEqual

Compares the moniker with a specified moniker and indicates whether they are identical.

HRESULT IsEqual(
  IMoniker ***pmkOtherMoniker**   //Moniker to be used for comparison
 );

Parameter

pmkOtherMoniker
  [in] Points to the moniker to be used for comparison.

Return Values

S_OK
  The two monikers are identical.

S_FALSE
  The two monikers are not identical.

Comments

Previous implementations of the Running Object Table (ROT) called this method. The current implementation of the ROT uses the **IROTData** interface instead.

Notes to Callers

Call this method to determine if two monikers are identical or not. Note that the reduced form of a moniker is considered different from the unreduced form. You should call the **IMoniker::Reduce** method before calling **IMoniker::IsEqual**, because a reduced moniker is in its most specific form. **IMoniker::IsEqual** may return S_FALSE on two monikers before they are reduced, and S_OK after they are reduced.

Notes to Implementors

Your implementation should not reduce the current moniker before performing the comparison. It is the caller's responsibility to call **IMoniker::Reduce** in order to compare reduced monikers.

Note that two monikers that compare as equal must hash to the same value using **IMoniker::Hash**.

See Also

IMoniker::Reduce, **IMoniker::Hash**, **IROTData**

IMoniker::IsRunning

Determines whether the object identified by this moniker is currently loaded and running.

```
HRESULT IsRunning(
  IBindCtx *pbc,                //Bind context to be used
  IMoniker *pmkToLeft,          //Moniker to the left in the composite
  IMoniker *pmkNewlyRunning     //Moniker of a newly running object
 );
```

Parameters

pbc
: [in] Points to the bind context to be used in this binding operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the moniker implementation should retrieve information about its environment. For more information, see **IBindCtx**.

pmkToLeft
: [in] Points to the moniker to the left of this moniker if this moniker is part of a composite. This parameter is primarily used by moniker implementors to enable cooperation between the various components of a composite moniker; moniker clients can usually pass NULL.

pmkNewlyRunning
: [in] Points to the moniker most recently added to the Running Object Table (ROT). This can be NULL. If non-NULL, the implementation can return the results of calling **IMoniker::IsEqual** on the *pmkNewlyRunning* parameter, passing the current moniker. This parameter is intended to enable **IMoniker::IsRunning** implementations that are more efficient than just searching the ROT, but the implementation can choose to ignore *pmkNewlyRunning* without causing any harm.

Return Values

S_OK
: The moniker is running.

S_FALSE
: The moniker is not running.

E_UNEXPECTED
: Indicates an unexpected error.

Comments

Notes to Callers

If speed is important when you're requesting services from the object identified by the moniker, you may want those services *only* if the object is already running (because loading an object into the running state may be time-consuming). In such a situation, you'd call **IMoniker::IsRunning** to determine if the object is running.

For the monikers stored within linked objects, **IMoniker::IsRunning** is primarily called by the default handler's implementation of **IOleLink::BindIfRunning**.

Notes to Implementors

To get a pointer to the Running Object Table (ROT), your implementation should call **IBindCtx::GetRunningObjectTable** on the *pbc* parameter. Your implementation can then call **IRunningObjectTable::IsRunning** to determine whether the object identified by the moniker is running. Note that the object identified by the moniker must have registered itself with the ROT when it first began running.

See Also

IOleLink::BindIfRunning, **IBindCtx::GetRunningObjectTable**, **IRunningObjectTable::IsRunning**

IMoniker::IsSystemMoniker

Indicates whether this moniker is one of the system-supplied moniker classes.

```
HRESULT IsSystemMoniker(
  DWORD *pdwMksys       //Receives value from MKSYS enumeration
 );
```

Parameter

pdwMksys

[out] Receives an integer that is one of the values from the **MKSYS** enumeration. This parameter cannot be NULL. For information on the **MKSYS** enumeration, see the "Data Structures" section.

Return Values

S_OK

The moniker is a system moniker.

S_FALSE

The moniker is not a system moniker.

Comments

Notes to Callers

New values of the **MKSYS** enumeration may be defined in the future; therefore you should explicitly test for each value you are interested in.

Notes to Implementors

Your implementation of this method must return **MKSYS_NONE**. You cannot use this function to identify your own monikers (for example, in your implementation if **IMoniker::ComposeWith**). Instead, you should use your moniker's implementation of **IPersist::GetClassID** or use **IUnknown::QueryInterface** to test for your own private interface.

See Also

IPersist::GetClassID, **MKSYS**

IMoniker::ParseDisplayName

Reads as many characters of the specified display name as it understands and builds a moniker corresponding to the portion read; this procedure is known as "parsing" the display name.

```
HRESULT ParseDisplayName(
  IBindCtx *pbc,                //Bind context to be used
  IMoniker *pmkToLeft,          //Moniker to the left in the composite
  LPOLESTR pszDisplayName,      //Display name
  ULONG *pchEaten,              //Receives number of characters consumed
  IMoniker **ppmkOut            //Receives moniker built from display name
 );
```

Parameters

pbc
[in] Points to the bind context to be used in this binding operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the moniker implementation should retrieve information about its environment. For more information, see **IBindCtx**.

pmkToLeft
[in] Points to the moniker that has been built out of the display name up to this point.

pszDisplayName
[in] Points to a zero-terminated string containing the remaining display name to be parsed. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

pchEaten
[out] Receives the number of characters in *pszDisplayName* that were consumed in this step.

ppmkOut
[out] Receives a pointer to the moniker that was built from *pszDisplayName*. If an error occurs, the implementation sets **ppmkOut* to NULL. If **ppmkOut* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
The parsing operation was completed successfully.

MK_E_SYNTAX
Indicates an error in the syntax of the input components (*pmkToLeft*, this moniker, and *pszDisplayName*). For example, a file moniker returns this error if *pmkToLeft* is non-NULL, and an item moniker returns it if *pmkToLeft* is NULL.

E_OUTOFMEMORY
Indicates insufficient memory.

E_UNEXPECTED
Indicates an unexpected error.

IMoniker::BindToObject errors
Parsing display names may cause binding. Thus, any error associated with this function may be returned.

Comments

Notes to Callers

Moniker clients do not typically call **IMoniker::ParseDisplayName** directly. Instead, they call the **MkParseDisplayName** API function when they want to convert a display name into a moniker (for example, in implementing the Links dialog box for a container application, or for implementing a macro language that supports references to objects outside the document). That API function first parses the initial portion of the display name itself. It then calls **IMoniker::ParseDisplayName** on the moniker it has just created, passing the remainder of the display name and getting a new moniker in return; this step is repeated until the entire display name has been parsed.

Notes to Implementors

Your implementation may be able to perform this parsing by itself if your moniker class is designed to designate only certain kinds of objects. Otherwise, you must get an **IParseDisplayName** interface pointer for the object identified by the moniker-so-far (i.e., the composition of *pmkToLeft* and this moniker) and then return the results of calling **IParseDisplayName::ParseDisplayName**.

There are different strategies for getting an **IParseDisplayName** pointer:

- You can try to get the object's CLSID (for example, by calling **IPersist::GetClassID** on the object), and then call the **CoGetClassObject** API function, requesting the **IParseDisplayName** interface on the class factory associated with that CLSID.
- You can try to bind to the object itself to get an **IParseDisplayName** pointer.
- You can try binding to the object identified by *pmkToLeft* to get an **IOleItemContainer** pointer, and then call **IOleItemContainer::GetObject** to get an **IParseDisplayName** pointer for the item.

Any objects that are bound should be registered with the bind context (see **IBindCtx::RegisterObjectBound**) to ensure that they remain running for the duration of the parsing operation.

See Also

IParseDisplayName, **MkParseDisplayName**

IMoniker::Reduce

Returns a reduced moniker; that is, another moniker that refers to the same object as this moniker but can be bound with equal or greater efficiency.

```
HRESULT Reduce(
  IBindCtx *pbc,               //Bind context to be used
  DWORD dwReduceHowFar,        //How much reduction should be done
  IMoniker **ppmkToLeft,       //Moniker to the left in the composite
  IMoniker **ppmkReduced       //Receives the reduced moniker
 );
```

Parameters

pbc

[in] Points to the bind context to be used in this binding operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the moniker implementation should retrieve information about its environment. For more information, see **IBindCtx**.

dwReduceHowFar

[in] Specifies how far this moniker should be reduced. This parameter must be one of the values from the **MKRREDUCE** enumeration. For more information on the **MKRREDUCE** enumeration, see the "Data Structures" section.

ppmkToLeft

[in, out] On entry, **ppmkToLeft* points to the moniker to the left of this moniker, if this moniker is part of a composite. This parameter is primarily used by moniker implementors to enable cooperation between the various components of a composite moniker; moniker clients can usually pass NULL.

On exit, **ppmkToLeft* is usually set to NULL, indicating no change in the original moniker to the left. In rare situations **ppmkToLeft* is set to non-NULL, indicating that the previous moniker to the left should be disregarded and the moniker returned through **ppmkToLeft* is the replacement. In such a situation, the implementation must call **IUnknown::Release** on the passed-in pointer and call **IUnknown::AddRef** on the returned moniker; the caller must release it later. If an error occurs, the implementation can either leave the parameter unchanged or set it to NULL.

ppmkReduced

[out] Receives a pointer to the reduced form of this moniker, which can be NULL if an error occurs or if this moniker is reduced to nothing. If this moniker cannot be reduced, **ppmkReduced* is simply set to this moniker and the return value is MK_S_REDUCED_TO_SELF. If *ppmkReduced* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**. (This is true even if **ppmkReduced* is set to this moniker.)

Return Values

S_OK

Indicates that this moniker was reduced.

MK_S_REDUCED_TO_SELF

Indicates that this moniker could not be reduced any further, in which case, **ppmkReduced* is this moniker.

MK_E_EXCEEDEDDEADLINE

Indicates that the operation could not be completed within the time limit specified by the bind context's **BIND_OPTS** structure.

E_UNEXPECTED

Indicates an unexpected error.

E_OUTOFMEMORY

Indicates insufficient memory.

Comments

The **IMoniker::Reduce** method is intended for the following uses:

- It enables the construction of user-defined macros or aliases as new kinds of moniker classes. When reduced, the moniker to which the macro evaluates is returned.
- It enables the construction of a kind of moniker that tracks data as it moves about. When reduced, the moniker of the data in its current location is returned.
- On file systems that support an ID-based method of accessing files which is independent of file names; a file moniker could be reduced to a moniker which contains one of these IDs.

The intent of the **MKRREDUCE** flags passed in the *dwReduceHowFar* parameter is to provide the ability to programmatically reduce a moniker to a form whose display name is recognizable to the user. For example, paths in the file system, bookmarks in word-processing documents, and range names in spreadsheets are all recognizable to users. In contrast, a macro or an alias encapsulated in a moniker are not recognizable to users.

Notes to Callers

The scenarios described above are not currently implemented by the system-supplied moniker classes.

You should call **IMoniker::Reduce** before comparing two monikers using the **IMoniker::IsEqual** method, because a reduced moniker is in its most specific form. **IMoniker::IsEqual** may return S_FALSE on two monikers before they are reduced and return S_OK after they are reduced.

Notes to Implementors

If the current moniker can be reduced, your implementation must not reduce the moniker in-place. Instead, it must return a new moniker that represents the reduced state of the current one. This way, the caller still has the option of using the non-reduced moniker (for example, enumerating its components). Your implementation should reduce the moniker *at least* as far as is requested.

See Also

IMoniker::IsEqual, **MKRREDUCE**

IMoniker::RelativePathTo

Returns a moniker that, when composed onto the end of this moniker (or one with a similar structure), yields the specified moniker.

```
HRESULT RelativePathTo(
  IMoniker *pmkOther,          //Moniker to which a relative path should be taken
  IMoniker **ppmkRelPath       //Receives the relative moniker
 );
```

Parameters

pmkOther
[in] Points to the moniker to which a relative path should be taken.

ppmkRelPath
[out] Receives a pointer to the relative moniker. If an error occurs, the implementation sets **ppmkRelPath* to NULL. If **ppmkRelPath* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
A meaningful relative path has been returned.

MK_S_HIM
Indicates that there is no common prefix shared by the two monikers and that the moniker returned in **ppmkRelPath* is *pmkOther*.

MK_E_NOTBINDABLE
Indicates that this moniker is a relative moniker, such as an item moniker. This moniker must be composed with the moniker of its container before a relative path can be determined.

E_OUTOFMEMORY
Indicates insufficient memory.

E_UNEXPECTED
Indicates an unexpected error.

Comments

A relative moniker is analogous to a relative path (such as "..\backup"). For example, suppose you have one moniker that represents the path "c:\projects\secret\art\pict1.bmp" and another moniker that represents the path "c:\projects\secret\docs\chap1.txt." Calling **IMoniker::RelativePathTo** on the first moniker, passing the second one as the *pmkOther* parameter, would create a relative moniker representing the path "..\docs\chap1.txt."

Notes to Callers

Moniker clients typically do not need to call **IMoniker::RelativePathTo**. This method is primarily called by the default handler for linked objects. Linked objects contain both an absolute and a relative moniker to identify the link source (this enables link tracking if the user moves a directory tree containing both the container and source files). The default handler calls this method to create a relative moniker from the container document to the link source (that is, it calls **IMoniker::RelativePathTo** on the moniker identifying the container document, passing the moniker identifying the link source as the *pmkOther* parameter).

If you do call **IMoniker::RelativePathTo**, call it only on absolute monikers; for example, a file moniker or a composite moniker whose leftmost-component is a file moniker, where the file moniker represents an absolute path. Do not call this method on relative monikers.

Notes to Implementors

Your implementation of **IMoniker::RelativePathTo** should first determine whether *pmkOther* is a moniker of a class that you recognize and for which you can provide special handling (for example, if it is of the same class as this moniker). If so, your implementation should determine the relative path. Otherwise, it should pass both monikers in a call to the **MonikerRelativePathTo** API function, which correctly handles the generic case.

The first step in determining a relative path is determining the common prefix of this moniker and *pmkOther*. The next step is to break this moniker and *pmkOther* into two parts each, say (P, myTail) and (P, otherTail) respectively, where P is the common prefix. The correct relative path is then the inverse of myTail composed with otherTail:

Comp(Inv(myTail), otherTail)

Where Comp() represents the composition operation and Inv() represents the inverse operation.

Note that for certain types of monikers, you cannot use your **IMoniker::Inverse** method to construct the inverse of myTail. For example, a file moniker returns an anti-moniker as an inverse, while its **IMoniker::RelativePathTo** method must use one or more file monikers that each represent the path ".." to construct the inverse of myTail.

See Also

IMoniker::Inverse, **IMoniker::CommonPrefixWith**, **MonikerRelativePathTo**

IMoniker - Anti-Moniker Implementation

Anti-monikers are the inverse of the system's implementations of file, item, and pointer monikers. That is, an anti-moniker composed to the right of a file moniker, item moniker, or pointer moniker composes to nothing.

When To Use

If you're a moniker client, you typically do not need to use anti-monikers. When you need the inverse of a moniker, you should call the **IMoniker::Inverse** method. For example, if you need an inverse to remove the last piece of a composite moniker, use **IMoniker::Enum** to enumerate the pieces of the moniker and call **IMoniker::Inverse** on the rightmost piece. You shouldn't use an anti-moniker for this purpose because you can't be sure that the rightmost piece of a composite considers an anti-moniker to be its inverse.

The only situation in which you should explicitly use an anti-moniker is if you are writing a new moniker class and if you have no special requirements for constructing inverses to your monikers. In that situation, you can return anti-monikers from your implementation of **IMoniker::Inverse**. In your implementation of **IMoniker::ComposeWith**, you should then annihilate one of your monikers for every anti-moniker you encounter.

CreateAntiMoniker, **IMoniker**

Comments

IMoniker::BindToObject
This method is not implemented (that is, it returns E_NOTIMPL).

IMoniker::BindToStorage
This method is not implemented (that is, it returns E_NOTIMPL).

IMoniker::Reduce
This method returns MK_S_REDUCED_TO_SELF and passes back the same moniker.

IMoniker::ComposeWith
If *fOnlyIfNotGeneric* is TRUE, this method sets **ppmkComposite* to NULL moniker and returns MK_E_NEEDGENERIC; otherwise, the method returns the result of combining the two monikers into a generic composite. Note that composing a file, item, or pointer moniker to the right of an anti-moniker produces a generic composite rather than composing to nothing, as would be the case if the order of composition were reversed.

IMoniker::Enum
This method returns S_OK and sets **ppenumMoniker* to NULL.

IMoniker::IsEqual
This method returns S_OK if both are anti-monikers; otherwise, it returns S_FALSE.

IMoniker::Hash
This method calculates a hash value for the moniker.

IMoniker::IsRunning
This method checks the ROT to see if the object is running.

IMoniker::GetTimeOfLastChange
This method is not implemented (that is, it returns E_NOTIMPL).

IMoniker::Inverse
This method returns MK_E_NOINVERSE and sets **ppmk* to NULL.

IMoniker::CommonPrefixWith
If the other moniker is also an anti-moniker, the method returns MK_S_US and sets **ppmkPrefix* to this moniker. Otherwise, the method calls the **MonikerCommonPrefixWith** API function. This API

function correctly handles the case where the other moniker is a generic composite.

IMoniker::RelativePathTo

This method returns MK_S_HIM and sets **ppmkRelPath* to the other moniker.

IMoniker::GetDisplayName

For each anti-moniker contained in this moniker, this method return one instance of "\.."

IMoniker::ParseDisplayName

This method is not implemented (that is, it returns E_NOTIMPL).

IMoniker::IsSystemMoniker

This method returns S_OK and indicates MKSYS_ANTIMONIKER.

IMoniker - File Moniker Implementation

File monikers are monikers that represent pathnames in the file system; a file moniker can identify any object that is saved in its own file. To identify objects contained within a file, you can compose monikers of other classes (for example, item monikers) to the right of a file moniker. However, the moniker to the left of a file moniker within a composite must be either another file moniker or an anti-moniker (it is illegal, for example, for an item moniker to appear to the left of a file moniker in a composite).

Note that an anti-moniker is the inverse of an entire file moniker, not the inverse of a component of the pathname that the moniker represents; that is, when you compose an anti-moniker to the right of a file moniker, the entire file moniker is removed. If you want to remove just the rightmost component of the pathname represented by a file moniker, you must create a separate file moniker based on the ".." pathname and then compose that to the end of the file moniker.

When to Use

If you're a moniker client (that is, you're using a moniker to get an interface pointer to an object), you typically don't need to know the class of the moniker you're using; you simply call methods using an **IMoniker** interface pointer.

If you're a moniker provider (that is, you're handing out monikers that identify your objects to make them accessible to moniker clients), you must use file monikers if the objects you're identifying are stored in files. If each object resides in its own file, file monikers are the only type you need. If the objects you're identifying are smaller than a file, you need to use another type of moniker (for example, item monikers) in addition to file monikers.

To use file monikers, you must use the **CreateFileMoniker** API function to create the monikers. In order to allow your objects to be loaded when a file moniker is bound, your objects must implement the **IPersistFile** interface.

The most common example of moniker providers are OLE server applications that support linking. If your OLE server application supports linking only to file-based documents in their entirety, file monikers are the only type of moniker you need. If your OLE server application supports linking to objects smaller than a document (such as sections of a document or embedded objects), you must use item monikers as well as file monikers.

See Also

CreateFileMoniker, **IMoniker**, **IPersistFile**

Comments

IMoniker::BindToObject

This method requires that *pmkToLeft* be NULL. The method looks for the moniker in the ROT, and if found, queries the retrieved object for the requested interface pointer. If the moniker is not found in the ROT, the method loads the object from the file system and retrieves the requested interface pointer.

IMoniker::BindToStorage

This method opens the file specified by the pathname represented by the moniker and returns an **IStorage** pointer to that file. The method supports binding to **IStorage** interface only; if **IStream** or **ILockBytes** is requested in *riid*, the method returns E_UNSPEC, and if other interfaces are requested, this method returns E_NOINTERFACE. **IStream** and **ILockBytes** will be supported in future releases.

IMoniker::Reduce

This method returns MK_S_REDUCED_TO_SELF and passes back the same moniker.

IMoniker::ComposeWith

If *pmkRight* is an anti-moniker, the returned moniker is NULL. If *pmkRight* is a composite whose leftmost component is an anti-moniker, the returned moniker is the composite with the leftmost anti-moniker removed. If *pmkRight* is a file moniker, this method collapses the two monikers into a single file moniker, if possible. If not possible (e.g., if both file monikers represent absolute paths, as in *d:\work* and *e:\reports*), then the returned moniker is NULL and the return value is MK_E_SYNTAX. If *pmkRight* is neither an anti-moniker nor a file moniker, then the method checks the *fOnlyIfNotGeneric* parameter; if it is FALSE, the method combines the two monikers into a generic composite; if it is TRUE, the method sets **ppmkComposite* to NULL and returns MK_E_NEEDGENERIC.

IMoniker::Enum

This method returns S_OK and sets **ppenumMoniker* to NULL. In a future release this method will pass back an enumerator that enumerates the components of the path on which the moniker is based.

IMoniker::IsEqual

This method returns S_OK if **pmkOther* is a file moniker and the paths for both monikers are identical (using a case-insensitive comparison). Otherwise, the method returns S_FALSE.

IMoniker::Hash

This method calculates a hash value for the moniker.

IMoniker::IsRunning

If *pmkNewlyRunning* is non-NULL, this method returns TRUE if that moniker is equal to this moniker. Otherwise, the method asks the ROT whether this moniker is running. The method ignores *pmkToLeft*.

IMoniker::GetTimeOfLastChange

If this moniker is in the ROT, this method returns the last change time registered there; otherwise, it returns the last write time for the file. If the file cannot be found, this method returns MK_E_NOOBJECT.

IMoniker::Inverse

This method returns an anti-moniker (i.e., the results of calling **CreateAntiMoniker**).

IMoniker::CommonPrefixWith

If both monikers are file monikers, this method returns a file moniker that is based on the common components at the beginning of two file monikers. Components of a file moniker can be:

- A machine name of the form \\*server**share*. A machine name is treated as a single component, so two monikers representing the paths "\\myserver\public\work" and "\\myserver\private\games" do not have "\\myserver" as a common prefix.
- A drive designation (for example, "C:").
- A directory or filename.

If the other moniker is not a file moniker, this method passes both monikers in a call to the **MonikerCommonPrefixWith** API function. This API function correctly handles the case where the other moniker is a generic composite.

This method returns MK_E_NOPREFIX if there is no common prefix.

IMoniker::RelativePathTo

This method computes a moniker which when composed to the right of this moniker yields the other moniker. For example, if the path of this moniker is "C:\work\docs\report.doc" and if the other moniker is "C:\work\art\picture.bmp," then the path of the computed moniker would be "..\..\art\picture.bmp."

IMoniker::GetDisplayName

This method returns the pathname that the moniker represents. If this method is called by a 16-bit application, the method checks to see whether the specified file exists and, if so, returns a short name for that file because 16-bit applications are not equipped to handle long filenames.

IMoniker::ParseDisplayName

This method tries to acquire an **IParseDisplayName** pointer, first by binding to the class factory for the object identified by the moniker, and then by binding to the object itself. If either of these binding operations is successful, the file moniker passes the unparsed portion of the display name to the

IParseDisplayName::ParseDisplayName method.

This method returns MK_E_SYNTAX if *pmkToLeft* is non-NULL.

IMoniker::IsSystemMoniker

This method returns S_OK, and passes back MKSYS_FILEMONIKER.

IMoniker - Generic Composite Moniker Implementation

A generic composite moniker is a composite moniker whose components have no special knowledge of each other.

Composition is the process of joining two monikers together. Sometimes two monikers of specific classes can be combined in a special manner; for example, a file moniker representing an incomplete path and another file moniker representing a relative path can be combined to form a single file moniker representing the complete path. This is an example of "non-generic" composition. "Generic" composition, on the other hand, can connect any two monikers, no matter what their classes. Because a non-generic composition depends on the class of the monikers involved, it can be performed only by a particular class's implementation of the **IMoniker::ComposeWith** method. You can define new types of non-generic compositions if you write a new moniker class. By contrast, generic compositions are performed by the **CreateGenericComposite** API function.

When to Use

If you're a moniker client (that is, you're using a moniker to get an interface pointer to an object), you typically don't need to know the class of the moniker you're using, or whether it is a generic composite or a non-generic composite; you simply call methods using an **IMoniker** interface pointer.

If you're a moniker provider (that is, you're handing out monikers that identify your objects to make them accessible to moniker clients), you may have to compose two monikers together. (For example, if you are using an item moniker to identify an object, you must compose it with the moniker identifying the object's container before you hand it out.) You use the **IMoniker::ComposeWith** method to do this, calling the method on the first moniker and passing the second moniker as a parameter; this method may produce either a generic or a non-generic composite.

The only time you should explicitly create a generic composite moniker is if you are writing your own moniker class. In your implementation of **IMoniker::ComposeWith**, you should attempt to perform a non-generic composition whenever possible; if you cannot perform a non-generic composition and generic composition is acceptable, you can call the **CreateGenericComposite** API function to create a generic composite moniker.

See Also

CreateGenericComposite, **IMoniker**

Comments

IMoniker::BindToObject

If *pmkToLeft* is NULL, this method looks for the moniker in the ROT, and if found, queries the retrieved object for the requested interface pointer. If *pmkToLeft* is not NULL, the method recursively calls **IMoniker::BindToObject** on the rightmost component of the composite, passing the rest of the composite as the *pmkToLeft* parameter for that call.

IMoniker::BindToStorage

This method recursively calls **BindToStorage** on the rightmost component of the composite, passing the rest of the composite as the *pmkToLeft* parameter for that call.

IMoniker::Reduce

This method recursively calls **Reduce** for each of its component monikers. If any of the components reduces itself, the method returns S_OK and passes back a composite of the reduced components. If no reduction occurred, the method passes back the same moniker and returns MK_S_REDUCED_TO_SELF.

IMoniker::ComposeWith

If *fOnlyIfNotGeneric* is TRUE, this method sets **pmkComposite* to NULL and returns MK_E_NEEDGENERIC; otherwise, the method returns the result of combining the two monikers by calling the **CreateGenericComposite** API function.

IMoniker::Enum

If successful, this method returns S_OK and passes back an enumerator that enumerates the component monikers that make up the composite; otherwise, the method returns E_OUTOFMEMORY.

IMoniker::IsEqual

This method returns S_OK if the components of both monikers are equal when compared in the left-to-right order.

IMoniker::Hash

This method calculates a hash value for the moniker.

IMoniker::IsRunning

If *pmkToLeft* is non-NULL, this method composes *pmkToLeft* with this moniker and calls **IsRunning** on the result.

If *pmkToLeft* is NULL, this method returns TRUE if *pmkNewlyRunning* is non-NULL and is equal to this moniker.

If *pmkToLeft* and *pmkNewlyRunning* are both NULL, this method checks the ROT to see whether the moniker is running. If so, the method returns S_OK; otherwise, it recursively calls **IMoniker::IsRunning** on the rightmost component of the composite, passing the remainder of the composite as the *pmkToLeft* parameter for that call. This handles the case where the moniker identifies a pseudo-object that is not registered as running; see the Item Moniker implementation of **IMoniker::IsRunning**.

IMoniker::GetTimeOfLastChange

This method creates a composite of *pmkToLeft* (if non-NULL) and this moniker and uses the ROT to retrieve the time of last change. If the object is not in the ROT, the method recursively call **IMoniker::GetTimeOfLastChange** on the rightmost component of the composite, passing the remainder of the composite as the *pmkToLeft* parameter for that call.

IMoniker::Inverse

This method returns a composite moniker that consists of the inverses of each of the components of the original composite, stored in reverse order. For example, if the inverse of *A* is $A_{(-1)}$, then the inverse of the composite $A\ _{(^{\circ})}\ B\ _{(^{\circ})}\ C$ is $C_{(-1)}\ _{(^{\circ})}\ B_{(-1)}\ _{(^{\circ})}\ A_{(-1)}$.

IMoniker::CommonPrefixWith

If the other moniker is a composite, this method compares the components of each composite from left to right. The returned common prefix moniker might also be a composite moniker, depending on how many of the leftmost components were common to both monikers. If the other moniker is not a composite, the method simply compares it to the leftmost component of this moniker.

If the monikers are equal, the method returns MK_S_US and sets **ppmkPrefix* to this moniker. If the other moniker is a prefix of this moniker, the method returns MK_S_HIM and sets **ppmkPrefix* to the other moniker. If this moniker is a prefix of the other, this method returns MK_S_ME and sets **ppmkPrefix* to this moniker.

If there is no common prefix, this method returns MK_E_NOPREFIX and sets **ppmkPrefix* to NULL.

IMoniker::RelativePathTo

This method finds the common prefix of the two monikers and creates two monikers that consist of the remainder when the common prefix is removed. Then it creates the inverse for the remainder of this moniker and composes the remainder of the other moniker on the right of it.

IMoniker::GetDisplayName

This method returns the concatenation of the display names returned by each component moniker of the composite.

IMoniker::ParseDisplayName

This method recursively calls **IMoniker::ParseDisplayName** on the rightmost component of the composite, passing everything else as the *pmkToLeft* parameter for that call.

IMoniker::IsSystemMoniker

This method returns S_OK and indicates MKSYS_GENERICCOMPOSITE.

IMoniker - Item Moniker Implementation

Item monikers are used to identify objects within containers, such as a portion of a document, an embedded object within a compound document, or a range of cells within a spreadsheet. Item monikers are often used in combination with file monikers; a file moniker is used to identify the container while an item moniker is used to identify the item within the container.

An item moniker contains a text string; this string is used by the container object to distinguish the contained item from the others. The container object must implement the **IOleItemContainer** interface; this interface enables the item moniker code to acquire a pointer to an object, given only the string that identifies the object.

When to Use

If you're a moniker client (that is, you're using a moniker to get an interface pointer to an object), you typically don't need to know the class of the moniker you're using; you simply call methods using an **IMoniker** interface pointer.

If you're a moniker provider (that is, you're handing out monikers that identify your objects to make them accessible to moniker clients), you must use item monikers if the objects you're identifying are contained within another object and can be individually identified using a string. You'll also need to use another type of moniker (for example, file monikers) in order to identify the container object.

To use item monikers, you must use the **CreateItemMoniker** API function to create the monikers. In order to allow your objects to be loaded when an item moniker is bound, the container of your objects must implement the **IOleItemContainer** interface.

The most common example of moniker providers are OLE applications that support linking. If your OLE application supports linking to objects smaller than a file-based documents, you need to use item monikers. For a server application that allows linking to a selection within a document, you use the item monikers to identify those objects. For a container application that allows linking to embedded objects, you use the item monikers to identify the embedded objects.

See Also

CreateItemMoniker, **IMoniker**, **IOleItemContainer**

Comments

IMoniker::BindToObject
If *pmkToLeft* is NULL, this method returns E_INVALIDARG. Otherwise, the method calls **IMoniker::BindToObject** on the *pmkToLeft* parameter, requesting an **IOleItemContainer** interface pointer. The method then calls **IOleItemContainer::GetObject**, passing the string contained within the moniker, and returns the requested interface pointer.

IMoniker::BindToStorage
If *pmkToLeft* is NULL, this method returns E_INVALIDARG. Otherwise, the method calls **IMoniker::BindToObject** on the *pmkToLeft* parameter, requesting an **IOleItemContainer** interface pointer. The method then calls **IOleItemContainer::GetObjectStorage** for the requested interface.

IMoniker::Reduce
This method returns MK_S_REDUCED_TO_SELF and passes back the same moniker.

IMoniker::ComposeWith
If *pmkRight* is an anti-moniker, the returned moniker is NULL; if *pmkRight* is a composite whose leftmost component is an anti-moniker, the returned moniker is the composite after the leftmost anti-moniker is removed. If *pmkRight* is not an anti-moniker, the method combines the two monikers into a generic composite if *fOnlyIfNotGeneric* is FALSE; if *fOnlyIfNotGeneric* is TRUE, the method returns a NULL moniker and a return value of MK_E_NEEDGENERIC.

IMoniker::Enum

This method returns S_OK and sets **ppenumMoniker* to NULL.

IMoniker::IsEqual

This method returns S_OK if both monikers are item monikers and their display names are identical (using a case-insensitive comparison); otherwise, the method returns S_FALSE.

IMoniker::Hash

This method calculates a hash value for the moniker.

IMoniker::IsRunning

If *pmkToLeft* is NULL, this method returns TRUE if *pmkNewlyRunning* is non-NULL and is equal to this moniker. Otherwise, the method checks the ROT to see whether this moniker is running.

If *pmkToLeft* is non-NULL, the method calls **IMoniker::BindToObject** on the *pmkToLeft* parameter, requesting an **IOleItemContainer** interface pointer. The method then calls **IOleItemContainer::IsRunning**, passing the string contained within this moniker.

IMoniker::GetTimeOfLastChange

If *pmkToLeft* is NULL, this method returns MK_E_NOTBINDABLE. Otherwise, the method creates a composite of *pmkToLeft* and this moniker and uses the ROT to access the time of last change. If the object is not in the ROT, the method calls **IMoniker::GetTimeOfLastChange** on the *pmkToLeft* parameter.

IMoniker::Inverse

This method returns an anti-moniker (i.e., the results of calling **CreateAntiMoniker**).

IMoniker::CommonPrefixWith

If other moniker is an item moniker that is equal to this moniker, this method sets **ppmkPrefix* to this moniker and returns MK_S_US; otherwise, the method calls the **MonikerCommonPrefixWith** API function. This API function correctly handles the case where the other moniker is a generic composite.

IMoniker::RelativePathTo

This method returns MK_E_NOTBINDABLE and sets **ppmkRelPath* to NULL.

IMoniker::GetDisplayName

This method returns the concatenation of the delimiter and the item name that were specified when the item moniker was created.

IMoniker::ParseDisplayName

If *pmkToLeft* is NULL, this method returns MK_E_SYNTAX. Otherwise, the method calls **IMoniker::BindToObject** on the *pmkToLeft* parameter, requesting an **IOleItemContainer** interface pointer. The method then calls **IOleItemContainer::GetObject**, requesting an **IParseDisplayName** interface pointer to the object identified by the moniker, and passes the display name to **IParseDisplayName::ParseDisplayName**.

IMoniker::IsSystemMoniker

This method returns S_OK and indicates MKSYS_ITEMMONIKER.

IMoniker - Pointer Moniker Implementation

A pointer moniker essentially wraps an interface pointer so that it looks like a moniker and can be passed to those interfaces that require monikers. Binding a pointer moniker is done by calling the pointer's **QueryInterface** method.

Instances of pointer monikers refuse to be serialized, that is, **IPersistStream::Save** will return an error. These monikers can, however, be marshaled to a different process in an RPC call; internally, the system marshals and unmarshals the pointer using the standard paradigm for marshaling interface pointers.

When to Use

Pointer monikers are rarely needed. Use pointer monikers only if you need monikers to identify objects that have no persistent representation. Pointer monikers allow such objects to participate in a moniker-binding operation.

See Also

IMoniker, **CreatePointerMoniker**

Comments

IMoniker::BindToObject
This method queries the wrapped pointer for the requested interface.

IMoniker::BindToStorage
This method queries the wrapped pointer for the requested interface.

IMoniker::Reduce
This method returns MK_S_REDUCED_TO_SELF and passes back the same moniker.

IMoniker::ComposeWith
If *pmkRight* is an anti-moniker, the returned moniker is NULL; if *pmkRight* is a composite whose leftmost component is an anti-moniker, the returned moniker is the composite after the leftmost anti-moniker is removed. If *fOnlyIfNotGeneric* is FALSE, the returned moniker is a generic composite of the two monikers; otherwise, the method sets **ppmkComposite* to NULL and returns MK_E_NEEDGENERIC.

IMoniker::Enum
This method is not implemented (that is, it returns E_NOTIMPL).

IMoniker::IsEqual
This method returns S_OK only if both are pointer monikers and the interface pointers that they wrap are identical.

IMoniker::Hash
This method calculates a hash value for the moniker.

IMoniker::IsRunning
This method always returns S_OK, because the object identified by a pointer moniker must always be running.

IMoniker::GetTimeOfLastChange
This method is not implemented (that is, it returns E_NOTIMPL).

IMoniker::Inverse
This method returns an anti-moniker (i.e., the results of calling **CreateAntiMoniker**).

IMoniker::CommonPrefixWith
If the two monikers are equal, this method returns MK_S_US and sets **ppmkPrefix* to this moniker. Otherwise, the method returns MK_E_NOPREFIX and sets **ppmkPrefix* to NULL.

IMoniker::RelativePathTo
This method is not implemented (that is, it returns E_NOTIMPL).

IMoniker::GetDisplayName

This method is not implemented (that is, it returns E_NOTIMPL).

IMoniker::ParseDisplayName

This method queries the wrapped pointer for the **IParseDisplayName** interface and passes the display name to **IParseDisplayName::ParseDisplayName**.

IMoniker::IsSystemMoniker

This method returns S_OK and indicates MKSYS_POINTERMONIKER.

IOleAdviseHolder

The **IOleAdviseHolder** interface enables object applications to delegate the management of compound document registration requests and notifications to a special object called the OLE advise holder. The OLE advise holder implements the **IOleAdviseHolder** interface, which provides methods for establishing and deleting advisory connections and for sending compound document notifications to advise sinks.

When an object application uses the OLE advise holder, it passes notifications directly to the **IOleAdviseHolder** interface. The advise holder keeps track of which advise sinks are interested in which notifications and passes along the notifications as appropriate.

When to Implement

OLE provides a default implementation of the OLE advise holder as a convenience to programmers. Use of the default implementation is optional because object applications can be written to manage notifications themselves. By using the default code, however, you save yourself the work of re-creating the advise holder's functionality from scratch as part of your implementation of **IOleObject::Advise**. Few applications will require notification capabilities beyond those which the default advise holder provides.

Applications instantiate an OLE advise holder by calling the OLE API function **CreateOleAdviseHolder**. (OLE also provides a data advise holder to manage data notifications. Applications create a data advise holder by calling the OLE API function **CreateDataAdviseHolder**.)

When to Use

Containers and other objects that wish to receive compound document notifications must implement the **IAdviseSink** interface to receive those notifications, and call the **IOleAdviseHolder** interface to establish an advisory connection and inform the object of what specific notifications it wishes to receive.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IOleAdviseHolder Methods	Description
Advise	Establishes advisory connection with sink.
Unadvise	Deletes advisory connection with sink.
EnumAdvise	Lists current advisory connections.
SendOnRename	Advises that name of object has changed.
SendOnSave	Advises that object has been saved.
SendOnClose	Advises that object has been closed.

IOleAdviseHolder::Advise

Establishes an advisory connection between an OLE object and the calling object's advise sink. Through that sink, the calling object can receive notification when the OLE object is renamed, saved, or closed.

```
HRESULT Advise(
   IAdviseSink * pAdvise,         //Pointer to advise sink
   DWORD * pdwConnection          //Pointer to a token
  );
```

Parameters

pAdvise
[in] Points to the advisory sink that should be informed of changes.

pdwConnection
[out] Points to a token that can be passed to the **IOleAdviseHolder::Unadvise** method to delete the advisory connection. The calling object is responsible for calling both **IUnknown::AddRef** and **IUnknown::Release** on this pointer.

Return Values

S_OK
Advisory connections set up successfully.

E_INVALIDARG
pAdvise is NULL.

Comments

Containers, object handlers, and link objects all create advise sinks to receive compound-document notifications (**OnSave**, **OnRename**, **and OnClose**) for objects of interest. They also call **IOleObject::Advise** to establish advisory connections with those objects. Objects whose implementations of **IOleObject::Advise** include a call to **CreateOleAdviseHolder** delegate these calls to **IOleAdviseHolder::Advise**.

If the attempt to establish an advisory connection is successful, the object receiving the call returns a nonzero value through *pdwConnection*. If the attempt fails, the object returns a zero. To delete an advisory connection, the object with the advise sink passes this nonzero token back to the object by calling **IOleAdviseHolder::Unadvise**.

See Also

IOleAdviseHolder::UnAdvise, **IOleAdviseHolder::EnumAdvise**, **IOleObject::Advise**

IOleAdviseHolder::EnumAdvise

Enumerates the advisory connections currently established for an object.

```
HRESULT EnumAdvise(
   IEnumSTATDATA ** ppenumAdvise          //A pointer to a pointer to the new enumerator
  );
```

Parameter

ppenumAdvise

[out] Points to where the new enumerator should be returned. NULL is a legal return value indicating that there are presently no advisory connections on the object. If an error is returned; this parameter must be set to NULL. Each time an OLE advise holder receives a call to **IOleAdviseHolder::EnumAdvise**; it must increase the reference count on the pointer it returns. It is the caller's responsibility to call **IUnknown::Release** when it is done with the pointer.

Return Values

S_OK

Enumerator returned successfully.

E_FAIL

Enumerator could not be returned.

E_NOTIMPL

EnumAdvise is not implemented.

Comments

While an enumeration is in progress; the effect of registering or revoking advisory connections on what is to be enumerated is undefined. The returned enumerator is of type **IEnumSTATDATA**. It enumerates items of type **STATDATA**; which are defined as follows:

```
typedef struct tagSTATDATA {
     FORMATETC          Formatetc;
     DWORD              grfAdvf;
     IAdviseSink *      pAdvise;
     DWORD              dwConnection;
     }STATDATA;
```

See Also

IOleAdviseHolder::Advise, **IOleAdviseHolder::UnAdvise**, **IOleObject::EnumAdvise**

IOleAdviseHolder::SendOnClose

Sends **OnClose** notifications to all advisory sinks currently registered with the advise holder.

HRESULT SendOnClose();

Return Value

S_OK
    Advise sinks were sent OnClose notifications.

See Also

IAdviseSink::OnClose

IOleAdviseHolder::SendOnRename

Sends **IAdviseSink::OnRename** notifications to all advisory sinks currently registered with the advise holder.

```
HRESULT SendOnRename(
    IMoniker *pmk          //Pointer to a IMoniker interface
  );
```

Parameter

pmk
[in] Points to the new full moniker of the object.

Return Value

S_OK
Advise sinks were sent **IAdviseSink::OnRename** notifications.

See Also

IAdviseSink::OnRename

IOleAdviseHolder::SendOnSave

Sends **IAdviseSink::OnSave** notifications to all advisory sinks currently registered with the advise holder.

HRESULT SendOnSave();

Return Value

S_OK
  Advise sinks were sent **IAdviseSink::OnSave** notifications.

See Also

IAdviseSink::OnSave

IOleAdviseHolder::Unadvise

Deletes a previously established advisory connection.

```
HRESULT Unadvise(
   DWORD dwConnection        //A nonzero value
  );
```

Parameter

dwConnection
[in] Contains a nonzero value previously returned by **IOleAdviseHolder::Advise** in *pdwConnection*.

Return Values

S_OK
Advisory connection deleted successfully.

OLE_E_NOCONNECTION
The *dwConnection* parameter does not represent a valid advisory connection.

Comments

Normally, containers call this method at shutdown or when an object is deleted. In certain cases, containers could choose to call this method on objects that are running but not currently visible, as a way of reducing the overhead of maintaining multiple advisory connections.

See Also

IOleAdviseHolder::Advise, **IOleAdviseHolder::EnumAdvise**, **IOleObject::Unadvise**

IOleCache

The **IOleCache** interface provides control of the presentation data that gets cached inside of an object. Cached presentation data is available to the container of the object even when server application is not running or is unavailable.

When to Implement

The **IOleCache** interface can be implemented by an object handler and an in-process server. However, you typically use or aggregate the OLE-provided implementation.

When to Use

The OLE-provided implementation creates a class node for each aspect and format of the data that it stores. In addition to the presentation data, the class node holds the sink pointer for the advisory connection and manages the sending of view notifications to the advise sink.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleCache Methods	Description
Cache	Adds a presentation to the data or view cache.
Uncache	Removes a presentation previously added with **IOleCache::Cache**.
EnumCache	Returns an object to enumerate the current cache connections.
InitCache	Fills the cache with all the presentation data from the data object.
SetData	Fills the cache with specified format of presentation data.

IOleCache::Cache

Specifies the format and other data to be cached inside an embedded object.

```
HRESULT Cache(
   FORMATETC * pFormatetc,     //Points to the data and formats to be cached
   DWORD advf,                 //Flags that control the caching
   DWORD * pdwConnection       //Identifies the connection for future calls to uncache
  );
```

Parameters

pFormatetc

[in]Points to the format and other data to be cached. View caching is specified by passing a zero clipboard format in *pFormatetc*.

advf

[in]Contains a group of flags that control the caching. Valid values can be derived by using an OR operation on the values in the **ADVF** enumeration. However, only some of the possible **ADVF** values are relevant for this method. The following table briefly describes the relevant values and how they control caching. See the **ADVF** enumeration for a more detailed description.

ADVF Value	Description
ADVF_NODATA	Asks the data object to avoid sending data with the notifications. This flag is a way to override the default behavior of sending data with the notification. Typically, this flag is used when the iconic aspect of an object is cached. The cache can then be updated explicitly by calling **IOleCache::SetData**, **IDataObject::SetData**, or **IOleCache2::UpdateCache**.
ADVF_ONLYONCE	Causes the advisory connection to be destroyed after the first notification is sent.
ADVF_PRIMEFIRST	Causes an initial notification to be sent regardless of whether data has changed from its current state.
ADVFCACHE_NOHANDLER	Synonym for ADVFCACHE_FORCEBUILTIN.
ADVFCACHE_FORCEBUILTIN	For cache connections, this flag caches data that requires only code shipped with OLE or the underlying operating system to be present in order to produce it with **IDataObject::GetData** or **IViewObject::Draw**. By specifying this value, the container can ensure that the data can be retrieved even when the object or handler code is not available. This value is used by DLL object applications and object handlers that perform the drawing of their objects.

	ADVFCACHE_FORCEBUILTIN instructs OLE to cache presentation data to ensure that there is a presentation in the cache.
ADVFCACHE_ONSAVE	Updates the cached representation only when the object containing the cache is saved. The cache is also updated when the OLE object changes from the running state back to the loaded state (because a subsequent save operation would require running the object again).

pdwConnection
[out]Points to the location of a returned token that identifies this connection and can later be used to turn caching off (by passing it to **IOleCache::Uncache**). If this value is zero, the connection was not established. The OLE-provided implementation uses nonzero numbers for connection identifiers.

Return Values

S_OK
Requested data or view successfully cached.

E_INVALIDARG
One or more arguments are invalid.

E_OUTOFMEMORY
Ran out of memory.

E_UNEXPECTED
An unexpected error occurred.

CACHE_S_FORMATETC_NOTSUPPORTED
Indicates the cache was created, but the object application does not support the specified format. Cache creation succeeds even if the format is not supported, allowing the caller to fill the cache. If, however, the caller does not need to keep the cache, call **IOleCache::UnCache**.

CACHE_S_SAMECACHE
Indicates a cache already exists for the **FORMATETC** passed to **IOleCache::Cache**. In this case, the new advise flags are assigned to the cache, and the previously assigned connection identifier is returned.

DV_E_LINDEX
Invalid value for *lindex*; currently only -1 is supported.

DV_E_TYMED
The value is not valid for *pFormatetc->tymed*.

DV_E_DVASPECT
The value is not valid for *pFormatetc->dwAspect*.

DV_E_CLIPFORMAT
The value is not valid for *pFormatetc->cfFormat*.

CO_E_NOTINITIALIZED
The cache's storage is not initialized.

DV_E_DVTARGETDEVICE
The value is not valid for *pFormatetc->ptd*.

OLE_E_STATIC
The cache is for static object and it already has a cache node.

Comments

IOleCache::Cache can specify either data caching by passing a valid data format in *pFormatetc* or view (presentation) caching by passing a zero data format in *pFormatetc* as follows:

```
pFormatetc->cfFormat == 0
```

With view caching, the cache object itself decides on the format to cache.

A custom object handler can choose not to store data in a given format. Instead, it can synthesize it on demand when requested.

The *advf* value of ADVFCACHE_FORCEBUILTIN ensures that presentation data can be retrieved after the container document has been moved where the object application or object handler is not available.

When an **IOleCache::Cache** call is made to cache either CF_DIB or CF_BITMAP, the OLE cache implementation will implicitly cache the other format. Thus, the enumerator (**IOleCache::EnumCache**) will have two entries (CF_DIB and CF_BITMAP) for the one cached format. Both of these entries have the same connection ID, so one call to **IOleCache::Uncache** will remove both. CF_DIB and CFBITMAP may also be explicitly cached separately (by two calls to **IOleCache::Cache**).

See Also

ADVF, **IOleCache::Uncache**

IOleCache::EnumCache

Returns an object that can be used to enumerate the current cache connections.

```
HRESULT EnumCache(
  IEnumSTATDATA ** ppenumSTATDATA          //Location for IEnumSTATDATA
 );
```

Parameter

ppenumSTATDATA
[out]Points to the location where the new enumerator object should be returned. If this value is NULL, there are currently no cache connections at this time.

Return Values

S_OK
The enumerator object is successfully instantiated or there are no cache connections. Check the *ppenumSTATDATA* parameter to determine which result occurred. If the *ppenumSTATDATA* parameter is NULL, then there are no cache connections at this time.

E_OUTOFMEMORY
The cache enumerator could not be instantiated due to lack of memory.

Comments

The enumerator object returned by this method implements the **IEnumSTATDATA** interface, one of the standard enumerator interfaces that contain the **Next**, **Reset**, **Clone**, and **Skip** methods. **IEnumSTATDATA** enumerates the data stored in an array of **STATDATA** structures containing information about current cache connections.

See Also

IEnum*XXXX*, **IEnumSTATDATA**, **IOleCache::Cache**

IOleCache::InitCache

Fills the cache as needed using the data provided by the specified data object.

```
HRESULT InitCache(
  IDataObject * pDataObject        //Points to the data object from which the cache is initialized
 );
```

Parameter

pDataObject
[in]Points to the data object from which the cache is to be initialized.

Return Values

S_OK
The cache was filled using the data provided.

E_INVALIDARG
The value for *pDataObject* is not valid.

E_OUTOFMEMORY
The cache could not be initialized due to lack of memory.

OLE_E_NOTRUNNING
The cache is not running.

CACHE_E_NOCACHE_UPDATED
None of the caches were updated.

CACHE_S_SOMECACHES_NOTUPDATED
Only some of the existing caches were updated.

Comments

IOleCache::InitCache is usually used when creating an object from a drag-and-drop operation or from a clipboard paste operation. It fills the cache as needed with presentation data from all the data formats provided by the data object provided on the clipboard or in the drag-and-drop operation. Helper functions like **OleCreateFromData** or **OleCreateLinkFromData** call this method when needed. If a container does not use these helper functions to create compound document objects, it can use **IOleCache::Cache** to set up the cache entries which are then filled by **IOleCache::InitCache**.

See Also

IOleCache::Cache

IOleCache::SetData

Initializes the cache with data in a specified format and on a specified medium.

```
HRESULT SetData(
   FORMATETC * pFormatetc,     //Points to the format of the presentation data to be placed in the cache
   STGMEDIUM * pmedium,        //Points to the storage medium containing the data to be placed in the
                               cache
   BOOL fRelease               //Indicates ownership of the storage medium after this method is
                               completed
  );
```

Parameters

pFormatetc
[in] Points to the format of the presentation data being placed in the cache.

pmedium
[in] Points to the storage medium that contains the presentation data.

fRelease
[in] Indicates ownership of the storage medium after completion of the method. If *fRelease* is TRUE, the cache takes ownership, freeing the medium when it is finished using it. When *fRelease* is FALSE, the caller retains ownership and is responsible for freeing the medium. The cache can only use the storage medium for the duration of the call.

Return Values

S_OK
The cache was filled.

E_OUTOFMEMORY
The cache could not be filled due to a lack of memory.

DV_E_LINDEX
The value is not valid for *pFormatetc->lindex.* Currently, only -1 is supported.

DV_E_FORMATETC
The **FORMATETC** structure is invalid.

DV_E_TYMED
The value is not valid for *pFormatetc->tymed*.

DV_E_DVASPECT
The value is not valid for *pFormatetc->dwAspect*.

OLE_E_BLANK
Uninitialized object.

DV_E_TARGETDEVICE
The object is static and *pFormatetc->ptd* is non-NULL.

STG_E_MEDIUMFULL
The storage medium is full.

Comments

IOleCache::SetData is usually called when an object is created from the Clipboard or through a drag-and-drop operation and Embed Source data is used to create the object.

IOleCache::SetData and **IOleCache::InitCache** are very similar. There are two main differences. The first difference is that while **IOleCache::InitCache** initializes the cache with the any presentation format provided by the data object, **IOleCache::SetData** initializes it with a single format. Second, the **IOleCache::SetData** method ignores the ADVF_NODATA flag while **IOleCache::InitCache** obeys this flag.

A container can use this method to maintain a single aspect of an object, such as the icon aspect of the object.

See Also

IDataObject::SetData, **IOleCache::Cache**

IOleCache::Uncache

Removes a cache connection created in a prior call to **IOleCache::Cache**.

```
HRESULT Uncache(
   DWORD dwConnection        //Specifies the cache connection to remove
  );
```

Parameter

dwConnection

[in]Specifies the cache connection to remove. This non-zero value was returned by **IOleCache::Cache** when the cache was originally established.

Return Values

S_OK

The cache connection was deleted.

OLE_E_NOCONNECTION

No cache connection exists for *dwConnection*.

Comments

The **IOleCache::Uncache** method removes a cache connection that was created in a prior call to **IOleCache::Cache**. It uses the *dwConnection* parameter that was returned by the prior call to **IOleCache::Cache**.

See Also

IOleCache::Cache

IOleCache2

The **IOleCache2** interface allows object clients to selectively update each cache that was created with **IOleCache::Cache**.

When to Implement

The **IOleCache** interface can be implemented by an object handler and an in-process server. However, you typically use or aggregate the OLE-provided implemention.

When to Use

The OLE-provided implementation is an extension to the **IOleCache** interface. The **IOleCache2** interface is used by container applications, object handlers, or in process servers to update one or more of the caches that were created with the **IOleCache::Cache** method. This extended interface was added so client applications can exercise precise control over updates to the caches being maintained.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleCache2 Methods	Description
UpdateCache	Updates the specified cache(s).
DiscardCache	Discards cache(s) found in memory.

IOleCache2::DiscardCache

Discards the caches in memory.

```
HRESULT DiscardCache(
   DWORD dwDiscardOptions      //Save data or discard it
  );
```

Parameter

dwDiscardOptions

Indicates whether data is to be saved prior to the discard. Valid values are from the enumeration **DISCARDCACHE**. Containers that have drawn a large object and need to free up memory may want to specify DISCARDCACHE_SAVEIFDIRTY so that the newest presentation is saved for the next time the object must be drawn.

Containers that have activated an embedded object, made some changes, and then called **IOleObject::Close(**OLECLOSE_NOSAVE) to roll back the changes can specify DISCARDCACHE_NOSAVE to ensure that the native and presentation data are not out of synchronization.

Return Values

S_OK
The cache(s) were discarded according to the value specified in *dwDiscardOptions*.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

OLE_E_NOSTORAGE
There is no storage available for saving the data in the cache.

STG_E_MEDIUMFULL
The storage medium is full.

Comments

The **IOleCache2::DiscardCache** method is commonly used to handle low memory conditions by freeing memory currently being used by presentation caches.

Once discarded, the cache will satisfy subsequent **IDataObject::GetData** calls by reverting to disk-based data.

See Also

DISCARDCACHE, **IOleCache**, **IOleCacheControl**

IOleCache2::UpdateCache

Updates specified cache(s). It updates the cache according to the value of a parameter. This method is used when the application needs precise control over caching.

```
HRESULT UpdateCache(
   IDataObject * pDataObject,          //Points to the data object from which the cache is updated
   DWORD grfUpdt,                      //Specifies the type of cache to update
   LPVOID pReserved                    //Reserved, must be NULL
  );
```

Parameters

pDataObject

[in]Points to the data object from which the cache is updated. Object handlers and in process servers typically pass a non-NULL value. A container application usually passes NULL, and the source is obtained from the currently running object.

grfUpdt

Specifies the type of cache to update. The value is obtained by combining values from the following table:

Cache Control Values	Description
UPDFCACHE_NODATACACHE	Updates caches created by using ADVF_NODATA in the call to **IOleCache::Cache**.
UPDFCACHE_ONSAVECACHE	Updates caches created by using ADVFCACHE_ONSAVE in the call to **IOleCache::Cache**.
UPDFCACHE_ONSTOPCACHE	Updates caches created by using ADVFCACHE_ONSTOP in the call to **IOleCache::Cache**.
UPDFCACHE_NORMALCACHE	Dynamically updates the caches (as is normally done when the object sends out OnDataChange notices).
UPDFCACHE_IFBLANK	Updates the cache if blank, regardless of any other flag specified.
UPDFCACHE_ONLYIFBLANK	Updates only caches that are blank.
UPDFCACHE_ IFBLANKORONSAVECACHE	The equivalent of using an OR operation to combine UPDFCACHE_IFBLANK and UPDFCACHE_ONSAVECACHE.
UPDFCACHE_ALL	Updates all caches.
UPDFCACHE_ ALLBUTNODATACACHE	Updates all caches except those created with ADVF_NODATA in the call to **IOleCache::Cache**. Thus, you can control updates to the caches created with the ADVF_NODATA flag and only update these caches explicitly.

pReserved

Reserved for future use; must be NULL.

Return Values

S_OK
The cache(s) were updated according to the value specified in *grfUpdt*.

E_OUTOFMEMORY
The cache(s) were not updated due to a lack of memory.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

OLE_E_NOTRUNNING
The specified *pDataObject* is not running.

CACHE_E_NOCACHE_UPDATED
None of the caches were updated.

CACHE_S_SOMECACHES_NOTUPDATED
Some of the caches were updated.

See Also

IOleCache, **IOleCacheControl**

IOleCacheControl

The **IOleCacheControl** interface provides proper maintenance of caches. It maintains the caches by connecting the running object's **IDataObject** implementation to the cache allowing the cache to receive notifications from the running object.

When to Implement

The OLE-provided implementation is used by most handlers and in process servers.

When to Use

Object handlers and in process servers use this interface internally to connect the cache part of the handler to the **IDataObject** implementation of the running object. Container applications have no need for this interface; they use **IRunnableObject** or **OleRun** instead.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleCacheControl Methods	Description
OnRun	Notifies the cache when the data object is running so the cache object can establish advise sinks as needed.
OnStop	Notifies the cache to terminate any existing advise sinks.

IOleCacheControl::OnRun

Notifies the cache that the data source object has now entered its running state.

HRESULT OnRun(
  DATAOBJECT * *pDataObject* //Points to the object that is now running
 );

Parameter

pDataObject
 [in]Points to the object that is entering the running state.

Return Values

S_OK
 The cache was notified and *pDataObject* is valid.

E_OUTOFMEMORY
 The cache was not notified because the system ran out of memory.

E_INVALIDARG
 One or more invalid arguments.

E_UNEXPECTED
 An unexpected error occurred.

Comments

When **IOleCacheControl::OnRun** is called, the cache sets up advisory connections as necessary with the source data object so it can receive notifications. The advise sink created between the running object and the cache is destroyed when **IOleCacheControl::OnStop** is called.

Some object handlers or in process servers might use the cache in a passive manner and not call **IOleCacheControl::OnRun**. These applications will need to call **IOleCache2::UpdateCache**, **IOleCache::InitCache**, or **IOleCache::SetData** to fill the cache when necessary to ensure the cache gets updated.

IOleCacheControl::OnRun does not create a reference count on *pDataObject.* It is the responsibility of the caller of **OleRun** to ensure that the lifetime of *pDataObject* lasts until **OnStop** is called. As a result, the caller must be holding a pointer to *pDataObject*.

See Also

IOleCache2::UpdateCache, **IOleCacheControl::OnStop**

IOleCacheControl::OnStop

Notifies the cache it should terminate any existing connection previously given to it by using **IOleCacheControl::OnRun**. No indication is given as to whether a connection existed or not.

HRESULT OnStop( );

Return Values

S_OK
  The cache was notified and the advise sink was successfully removed.

E_OUTOFMEMORY
  The advise sink was not removed because the system ran out of memory.

E_UNEXPECTED
  An unexpected error occurred.

Comments

The data advisory sink between the running object and the cache is destroyed as part of calling **IOleCacheControl::OnStop**.

See Also

IOleCacheControl::OnRun

IOleClientSite

The **IOleClientSite** interface is the primary means by which an embedded object obtains information about the location and extent of its display site; its moniker; its user interface; and other resources provided by its container. An object application calls **IOleClientSite** to request services from the container. A container must provide one instance of **IOleClientSite** for every compound-document object it contains.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IOleClientSite Methods	Description
SaveObject	Saves embedded object.
GetMoniker	Requests object's moniker.
GetContainer	Requests pointer to object's container.
ShowObject	Asks container to display object.
OnShowWindow	Notifies container when object becomes visible or invisible
RequestNewObjectLayout	Asks container to resize display site.

IOleClientSite::GetContainer

Returns a pointer to the container's **IOleContainer** interface.

```
HRESULT GetContainer(
  LPOLECONTAINER FAR* ppContainer        //Points to where the IOleContainer pointer should be returned
 );
```

Parameter

ppContainer
[out] Points to where the object's **IOleContainer** interface pointer is to be returned. If an error is returned, this parameter must be set to NULL.

Return Values

S_OK
The pointer to the container's **IOleContainer** interface was successfully returned.

OLE_E_NOT_SUPPORTED
Client site is in OLE 1 container.

E_NOINTERFACE
The container does not implement the **IOleContainer** interface.

Comments

If a container supports links to its embedded objects, implementing **IOleClientSite::GetContainer** enables link clients to enumerate the container's objects and recursively traverse a containment hierarchy. This method is optional but recommended for all containers that expect to support links to their embedded objects.

Link clients can traverse a hierarchy of compound-document objects by recursively calling **IOleClientSite::GetContainer** to get a pointer to the link source's container; followed by **IOleContainer::QueryInterface** to get a pointer to the container's **IOleObject** interface and; finally, **IOleObject::GetClientSite** to get the container's client site in its container.

Simple containers that do not support links to their embedded objects probably do not need to implement this method. Instead, they can return E_NOINTERFACE and set *ppContainer* to NULL.

IOleClientSite::GetMoniker

Returns a moniker to an object's client site. An object can force the assignment of its own or its container's moniker by specifying a value for *dwAssign*.

```
HRESULT GetMoniker(
    DWORD dwAssign,               //Value specifying how moniker is assigned
    DWORD dwWhichMoniker,         //Value specifying which moniker is assigned
    IMoniker ** ppmk              //Pointer to storage of returned moniker
  );
```

Parameters

dwAssign
: [in] Specifies whether to get a moniker only if one has already exists, force assignment of a moniker, create a temporary moniker, or remove a moniker that has been assigned. In practice you will usually request that the container force assignment of the moniker. Values defining these choices are contained in the enumeration **OLEGETMONIKER**.

dwWhichMoniker
: [in] Specifies whether to return the container's moniker, the object's moniker relative to the container, or the object's full moniker. In practice, you will usually request the object's full moniker. Values defining these choices are contained in the enumeration **OLEWHICHMK**.

ppmk
: [out] Points to where to return the object moniker. If an error is returned, this parameter must be set to NULL. Each time a container receives a call to **IOleClientSite::GetMoniker**, it must increase the reference count on the pointer it returns. It is the caller's responsibility to call Release when it is done with the pointer.

Return Values

S_OK
: Requested moniker returned successfully.

E_FAIL
: An unspecified error occurred.

E_UNEXPECTED
: A serious, unexpected failure has occurred.

E_NOTIMPL
: This container cannot assign monikers to objects. This is the case with OLE 1 containers.

Comments

Containers implement **IOleClientSite::GetMoniker** as a way of passing out monikers for their embedded objects to clients wishing to link to those objects.

When a link is made to an embedded object or to a pseudo-object within it (a range of cells in a spreadsheet; for example), the object needs a moniker to construct the composite moniker indicating the source of the link. If the embedded object does not already have a moniker, it can call **IOleClientSite::GetMoniker** to request one.

Every container that expects to contain links to embeddings should support **IOleClientSite::GetMoniker** to give out OLEWHICHMK_CONTAINER, thus enabling link tracking when the link client and link source files move, but maintain the same relative position.

An object must not persistently store its full moniker or its container's moniker, because these can change while the object is not loaded. For example, either the container or the object could be renamed, in which event, storing the container's moniker or the object's full moniker would make it impossible to for a client to track a link to the object.

In some very specialized cases, an object may no longer need a moniker previously assigned to it and may wish to have it removed as an optimization. In such cases, the object can call **IOleClientSite::GetMoniker** with OLEGETMONIKER_UNASSIGN to have the moniker removed.

See Also

IOleObject::GetMoniker, **IOleObject::SetMoniker**

IOleClientSite::OnShowWindow

Notifies a container when an embedded object's window is about to become visible or invisible. This method does not apply to an object that is activated in place and therefore has no window separate from that of its container.

```
HRESULT OnShowWindow(
    BOOL fShow        //Value indicating if window is becoming visible
  );
```

Parameter

fShow
 [in] Indicates whether an object's window is open (TRUE) or closed (FALSE).

Return Value

S_OK
 Shading or hatching has been successfully added or removed

Comments

An embedded object calls **IOleClientSite::OnShowWindow** to keep its container informed when the object is open in a window. This window may or may not be currently visible to the end user. The container uses this information to shade the object's client site when the object is displayed in a window, and to remove the shading when the object is not. A shaded object, having received this notification, knows that it already has an open window and therefore can respond to being double-clicked by bringing this window quickly to the top, instead of launching its application in order to obtain a new one.

IOleClientSite::RequestNewObjectLayout

Asks container to allocate more or less space for displaying an embedded object.

HRESULT RequestNewObjectLayout();

Return Values

S_OK
Request for new layout succeeded.

E_NOTIMPL
Client site does not support requests for new layout.

Comments

Currently, there is no standard mechanism by which a container can negotiate *how much* room an object would like. When such a negotiation is defined, responding to this method will be optional for containers.

IOleClientSite::SaveObject

Saves the object associated with the client site. This function is synchronous; by the time it returns, the save will be completed.

HRESULT SaveObject();

Parameter

HRESULT **SaveObject(***void***)**

Return Values

S_OK
  The object was saved.

E_FAIL
  The object was not saved.

Comments

An embedded object calls **IOleClientSite::SaveObject** to ask its container to save it to persistent storage when an end user chooses the File Update or Exit commands. The call is synchronous, meaning that by the time it returns, the save operation will be completed.

Calls to **IOleClientSite::SaveObject** occur in most implementations of **IOleObject::Close**. Normally, when a container tells an object to close, the container passes a flag specifying whether the object should save itself before closing, prompt the user for instructions, or close without saving itself. If an object is instructed to save itself, either by its container or an end user, it calls **IOleClientSite::SaveObject** to ask the container application to save the object's contents before the object closes itself. If a container instructs an object not to save itself, the object should not call **SaveObject**.

See Also

IOleObject::Close

IOleClientSite::ShowObject

Tells the container to position the object so it is visible to the user. This method ensures that the container itself is visible and not minimized.

HRESULT ShowObject();

Return Values

S_OK
  Container has tried to make the object visible.

OLE_E_NOT_SUPPORTED
  Client site is in an OLE 1 container.

Comments

After a link client binds to a link source, it commonly calls **IOleObject::DoVerb** on the link source, usually requesting the source to perform some action requiring that it display itself to the user. As part of its implementation of **DoVerb**, the link source can call **IOleClientSite::ShowObject**, which forces the client to show the link source as best it can. If the link source's container is itself an embedded object, it will recursively invoke **IOleClientSite::ShowObject** on its own container.

Having called the **ShowObject** method, a link source has no guarantee of being appropriately displayed because its container may not be able to do so at the time of the call. The **ShowObject** method does not guarantee visibility, only that the container will do the best it can.

See Also

IOleObject::DoVerb

IOleContainer

The **IOleContainer** interface is used to enumerate objects in a compound document or lock a container in the running state. Container and object applications both implement this interface.

When to Implement

Applications that support links and links to embedded objects implement this interface to provide object enumeration, name parsing, and silent updates of link sources. Simple, nonlinking containers do not need to implement **IOleContainer** if it is useful mainly to support links to embedded objects.

When to Use

Call **IOleContainer** to enumerate the objects in a compound document or to lock a container so that silent updates of link sources can be carried out safely.

Many applications inherit the functions of **IOleContainer** by implementing **IOleItemContainer**, which is used to bind item monikers.

Methods in VTable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IParseDisplayName Method	**Description**
ParseDisplayName	Parses object's display name to form moniker.

IOleContainer Methods	**Description**
EnumObjects	Enumerates objects in a container.
LockContainer	Keeps container running until explicitly released.

See Also

IOleItemContainer, **IParseDisplayName**

IOleContainer::EnumObjects

Enumerates objects in the current container.

```
HRESULT EnumObjects(
   DWORD grfFlags,              //Value specifying what is to be enumerated
   IEnumUnknown **ppenum        //Ptr to storage of enumeration
  );
```

Parameters

grfFlags

[in] This value specifies which objects in a container are to be enumerated, as defined in the enumeration **OLECONTF**.

ppenum

[out] Points to an address where the enumerator, of type **IEnumUnknown**, should be returned. If an error is returned, this parameter must be set to NULL. Each time a container receives a call to **EnumObjects**, it must increase the reference count on the pointer the method returns. It is the caller's responsibility to call **IUnknown::Release** when it is done with the pointer.

Return Values

S_OK

Enumerator successfully returned.

E_FAIL

An unspecified error occurred.

E_NOTIMPL

Object enumeration not supported.

Comments

A container should implement **EnumObjects** to enable programmatic clients to find out what objects it holds. This method, however, is not called in standard linking scenarios.

See Also

IEnumUnknown, **IOleItemContainer**, **OLECONTF**

IOleContainer::LockContainer

Keeps an embedded object's container running.

```
HRESULT LockContainer(
    BOOL fLock        //Value indicating lock or unlock
  );
```

Parameter

fLock
[in] Specifies whether to lock (TRUE) or unlock (FALSE) a container.

Return Values

S_OK
Container was locked successfully.

E_FAIL
An unspecified error occurred.

E_OUTOFMEMORY
Container could not be locked due to lack of memory.

Comments

An embedded object calls **IOleContainer::LockContainer** to keep its container running when the object has link clients that require an update. If an end-user selects File Close from the container's menu, however, the container ignores all outstanding **LockContainer** locks and closes the document anyway.

Notes to Callers

When an embedded object changes from the loaded to the running state, it should call **IOleContainer::LockContainer** with the *fLock* parameter set to TRUE. When the embedded object shuts down (transitions from running to loaded), it should call **IOleContainer::LockContainer** with the *fLock* parameter set to FALSE.

Each call to **LockContainer** with *fLock* set to TRUE must be balanced by a call to **LockContainer** with *fLock* set to FALSE. Object applications typically need not call **LockContainer**; the default handler makes these calls automatically for object applications implemented as .EXEs as the object makes the transition to and from the running state. Object applications not using the default handler, such as DLL object applications, must make the calls directly.

An object should have no strong locks on it when it registers in the Running Object Table, but it should be locked as soon as the first external client connects to it. Therefore, following registration of the object in the Running Object Table, object handlers and DLL object applications, as part of their implementation of **IRunnableObject::Run**, should call **IOleContainer::LockContainer(**TRUE**)** to lock the object.

Notes to Implementors

The container must keep track of whether and how many calls to **LockContainer(**TRUE**)** have been made. To increment or decrement the reference count, **IOleContainer::LockContainer** calls **CoLockObjectExternal** with a flag set to match *fLock*.

See Also

CoLockObjectExternal, **IRunnableObject::Run**

IOleInPlaceActiveObject

The **IOleInPlaceActiveObject** interface provides a direct channel of communication between an in-place object and the associated application's outer-most frame window and the document window within the application that contains the embedded object. The communication involves the translation of messages, the state of the frame window (activated or deactivated), and the state of the document window (activated or deactivated). It also informs the object when its needs to resize its borders, and manages modeless dialog boxes.

When to Implement

This interface is implemented by object applications in order to provide support their objects while they are active in place.

When to Use

These methods are used by the in-place object's top-level container to manipulate objects while they are active.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleWindow Methods	Description
GetWindow	Gets a window handle.
ContextSensitiveHelp	Controls enabling of context sensitive help.

IOleInPlaceActiveObject Methods	Description
TranslateAccelerator	Translates messages.
OnFrameWindowActivate	State of container's top-level frame.
OnDocWindowActivate	State of container document window.
ResizeBorder	Alert object of need to resize border space.
EnableModeless	Enable or disable modeless dialog boxes.

See Also

IOleWindow

IOleInPlaceActiveObject::EnableModeless

Enables or disables modeless dialog boxes when the container creates or destroys a modal dialog box.

```
HRESULT EnableModeless(
    BOOL fEnable          //Enable or disable modeless
  );
```

Parameter

fEnable
[in] Specifies TRUE to enable modeless dialog box windows; FALSE to disable them.

Return Value

S_OK
The method completed successfully.

Comments

Notes to Callers

IOleInPlaceActiveObject::EnableModeless is called by the top-level container to enable and disable modeless dialog boxes that the object displays. In order for the container to display a modal dialog box, it must first call the **IOleInPlaceActiveObject::EnableModeless** method, specifying FALSE to disable the object's modeless dialog box windows. When the container is through displaying its modal dialog box, it calls **IOleInPlaceActiveObject::EnableModeless**, specifying TRUE to reenable the object's modeless dialog boxes.

See Also

IOleInPlaceFrame::EnableModeless

IOleInPlaceActiveObject::OnDocWindowActivate

Notifies the active in-place object when the container's document window is activated or deactivated.

```
HRESULT OnDocWindowActivate(
    BOOL fActivate         //State of MDI child document window
  );
```

Parameter

fActivate
[in] Indicates the state of the MDI child document window. It is TRUE if the window is in the act of activating; FALSE if it is in the act of deactivating.

Return Value

S_OK
The method completed successfully.

Comments

Notes to Callers

Call **IOleInPlaceActiveObject::OnDocWindowActivate** when the MDI child document window is activated or deactivated and the object is currently the active object for the document.

Notes to Implementors

You should include code in this method that installs frame-level tools during object activation. These tools include the shared composite menu and/or optional toolbars and frame adornments. You should then take focus. When deactivating, the object should remove the frame-level tools. Note that if you do not call **IOleInPlaceUIWindow::SetBorderSpace** with *pborderwidths* set to NULL, you can avoid having to renegotiate border space.

Note While executing **IOleInPlaceActiveObject::OnDocWindowActivate**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface methods and functions can be called from within **OnDocWindowActivate**.

See Also

PeekMessage, **GetMessage** in Win32

IOleInPlaceActiveObject::OnFrameWindowActivate

Notifies the object when the container's top-level frame window is activated or deactivated.

```
HRESULT OnFrameWindowActivate(
   BOOL fActivate          //State of container's top-level window
  );
```

Parameter

fActivate
[in] Indicates the state of the container's top-level frame window. TRUE if the window is activating; FALSE if it is deactivating.

Return Value

S_OK
The method notified the object successfully.

Comments

Notes to Callers

The container must call **IOleInPlaceActiveObject::OnFrameWindowActivate** when the container's top-level frame window is either being activated or deactivated and the object is the current, active object for the frame.

Note While executing **IOleInPlaceActiveObject::OnFrameWindowActivate**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface methods and functions can be called from within **OnFrameWindowActivate**.

See Also

PeekMessage, **GetMessage** in Win32

IOleInPlaceActiveObject::ResizeBorder

Alerts the object that it needs to resize its border space.

```
HRESULT ResizeBorder(
  LPCRECT prcBorder,                //New outer rectangle for border space
  IOleInPlaceUIWindow pUIWindow,    //Frame or document window border change
  BOOL fFrameWindow                 //Frame window object is or isn't calling ResizeBorder
 );
```

Parameters

prcBorder
[in] Points to a **RECT** structure containing the new outer rectangle within which the object can request border space for its tools.

pUIWindow
[in] Points to the frame or document window object whose border has changed.

fFrameWindow
[in] Specifies TRUE if the frame window object is calling **ResizeBorder**; otherwise, FALSE.

Return Values

S_OK
The method alerted the object successfully.

E_INVALIDARG
One or more arguments are invalid.

E_OUTOFMEMORY
Out of memory.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

IOleInPlaceActiveObject::ResizeBorder is called by the top-level container's document or frame window object when the border space allocated to the object should change. Because the active in-place object is not informed about which window has changed (the frame- or document-level window), **IOleInPlaceActiveObject::ResizeBorder** must be passed the pointer to the window's **IOleInPlaceUIWindow** interface.

Notes to Implementors

In most cases, resizing only requires that you grow, shrink, or scale your ojbect's frame adornments. However, for more complicated adornments, you may be required to renegotiate for border space with calls to **IOleInPlaceUIWindow::RequestBorderSpace** and **IOleInPlaceUIWindow::SetBorderSpace**.

Note While executing **IOleInPlaceActiveObject::ResizeBorder**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface mehtods and functions can be called from within **ResizeBorder**.

See Also

IOleInPlaceUIWindow::GetBorder

PeekMessage, GetMessage in Win32

IOleInPlaceActiveObject::TranslateAccelerator

Processes menu accelerator-key messages from the container's message queue. This method should only be used for objects created by a DLL object application.

```
HRESULT TranslateAccelerator(
    LPMSG lpmsg        //Points to message that may need translating
  );
```

Parameter

lpmsg
[in] Points to the message that might need to be translated.

Return Values

S_OK
The message was translated successfully.

S_FALSE
The message was not translated.

E_INVALIDARG
One or more arguments are invalid.

E_OUTOFMEMORY
Out of memory.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

Active in-place objects must always be given the first chance at translating accelerator keystrokes. You can provide this opportunity by calling **IOleInPlaceActiveObject::TranslateAccelerator** from your container's message loop before doing any other translation. You should apply your own translation only when this method returns S_FALSE.

If you call **IOleInPlaceActiveObject::TranslateAccelerator** for an object that is not created by a DLL object application, the default object handler returns S_FALSE.

Notes to Implementors

An object created by an EXE object application gets keystrokes from its own message pump, so the container does not get those messages.

If you need to implement this method, you can do so by simply wrapping the call to the Window's **TranslateAccelerator** function.

See Also

OleTranslateAccelerator

TranslateAccelerator in Win32

IOleInPlaceFrame

The **IOleInPlaceFrame** interface controls the container's top-level frame window. This control involves allowing the container to insert its menu group into the composite menu, install the composite menu into the appropriate window frame, and remove the container's menu elements from the composite menu. It sets and displays status text relevant to the in-place object. It also enables or disables the frame's modeless dialog boxes, and translates accelerator keystrokes intended for the container's frame.

When to Implement

You will need to implement this interface if you are writing a container application that will be participating in in-place activation.

When to Use

This interface is used by object applications to control the display and placement of composite menus, keystroke accelerator translation, context-sensitive help mode, and modeless dialog boxes.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleWindow Methods	Description
GetWindow	Gets a window handle.
ContextSensitiveHelp	Controls enabling of context-sensitive help.

IOleInPlaceUIWindow Methods	Description
GetBorder	Translates messages.
RequestBorderSpace	State of container's top-level frame.
SetBorderSpace	State of container document window.
SetActiveObject	Alert object of need to resize border space.

IOleInPlaceFrame Methods	Description
InsertMenus	Allows container to insert menus.
SetMenu	Adds a composite menu to window frame.
RemoveMenus	Removes a container's menu elements.
SetStatusText	Sets and displays status text about.
EnableModeless	Enables or disables modeless dialog.
TranslateAccelerator	Translates keystrokes.

See Also

IOleWindow, IOleInPlaceUIWindow

IOleInPlaceFrame::EnableModeless

Enables or disables a frame's modeless dialog boxes.

```
HRESULT EnableModeless(
    BOOL fEnable          //Enable or disable modeless dialog
  );
```

Parameter

fEnable
[in] Specifies whether the modeless dialog boxes are to be enabled by specifying TRUE or disabled by specifying FALSE.

Return Values

S_OK
The dialog box was either enabled or disabled successfully, depending on the value for *fEnable*.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

The active in-place object calls **IOleInPlaceFrame::EnableModeless** to enable or disable modeless dialog boxes that the container might be displaying. To display a modal dialog box, the object first calls **IOleInPlaceFrame::EnableModeless** , specifying FALSE to disable the container's modeless dialog box windows. After completion, the object calls **IOleInPlaceFrame::EnableModeless** specifying TRUE to reenable them.

Notes to Implementors

You should track the value of **EnableModeless** and check it before displaying a dialog box.

See Also

IOleInPlaceActiveObject::EnableModeless

IOleInPlaceFrame::InsertMenus

Allows the container to insert its menu groups into the composite menu to be used during the in-place session.

```
HRESULT InsertMenus(
  HMENU hmenuShared,                          //Handle to empty menu
  LPOLEMENUGROUPWIDTHS lpMenuWidths           //OLEMENUGROUPWIDTHS array
 );
```

Parameters

hmenuShared
[in] Specifies a handle to an empty menu.

lpMenuWidths
[in, out] Points to an **OLEMENUGROUPWIDTHS** array of six LONG values. The container fills in elements 0, 2, and 4 to reflect the number of menu elements it provided in the File, View, and Window menu groups.

Return Values

S_OK
The menu groups were inserted successfully.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

This method is called by object applications when they are first being activated. They call it in order to insert their menus into the frame-level user interface.

The object application asks the container to add its menus to the menu specified in *hmenuShared* and to set the group counts in the **OLEMENUGROUPWIDTHS** array pointed to by *lpMenuWidths*. The object application then adds its own menus and counts. Objects can call **IOleInPlaceFrame::InsertMenus** as many times as necessary to build up the composite menus. The container should use the initial menu handle associated with the composite menu for all menu items in the drop-down menus.

IOleInPlaceFrame::RemoveMenus

Gives the container a chance to remove its menu elements from the in-place composite menu.

HRESULT RemoveMenus(
  HMENU *hmenuShared*   //Handle to in-place composite menu
 );

Parameter

hmenuShared
[in] Specifies a handle to the in-place composite menu that was constructed by calls to **IOleInPlaceFrame::InsertMenus** and the Windows **InsertMenu** function.

Return Values

S_OK
The method completed successfully.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

The object should always give the container a chance to remove its menu elements from the composite menu before deactivating the shared user interface.

Notes to Callers

Called by the object application while it is being UI-deactivated in order to remove its menus.

See Also

IOleInPlaceFrame::SetMenu

InsertMenu in Win32

IOleInPlaceFrame::SetMenu

Installs the composite menu in the window frame containing the object being activated in place.

```
HRESULT SetMenu(
   HMENU hmenuShared,          //Handle to composite menu
   HOLEMENU holemenu,          //Handle to menu descriptor
   HWND hwndActiveObject       //Handle to object's window
  );
```

Parameters

hmenuShared
[in] Specifies a handle to the composite menu constructed by calls to **IOleInPlaceFrame::InsertMenus** and the Windows **InsertMenu** function.

holemenu
[in] Specifies the handle to the menu descriptor returned by the **OleCreateMenuDescriptor** function.

hwndActiveObject
[in] Specifies a handle to a window owned by the object and to which menu messages, commands, and accelerators are to be sent.

Return Values

S_OK
The method completed successfully.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

The object calls **IOleInPlaceFrame::SetMenu** to ask the container to install the composite menu structure set up by calls to **IOleInPlaceFrame::InsertMenus**.

Notes to Implementors

An SDI container's implementation of this method should call the Windows **SetMenu** function. An MDI container should send a WM_MDISETMENU message, using *hmenuShared* as the menu to install. The container should call **OleSetMenuDescriptor** to install the OLE dispatching code.

When deactivating, the container *must* call **IOleInPlaceFrame::SetMenu** specifying NULL to remove the shared menu. This is done to help minimize window repaints. The container should also call **OleSetMenuDescriptor** specifying NULL to unhook the dispatching code. Finally, the object application calls **OleDestroyMenuDescriptor** to free the data structure.

Note While executing **IOleInPlaceFrame::SetMenu**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface methods and functions can be called from within **SetMenu**.

See Also

IOleInPlaceFrame::InsertMenus, **OleSetMenuDescriptor**, **OleDestroyMenuDescriptor**

PeekMessage, **GetMessage** in Win32

IOleInPlaceFrame::SetStatusText

Sets and displays status text about the in-place object in the container's frame window status line.

```
HRESULT SetStatusText(
  LPCOLESTR pszStatusText       //Points to message to display
 );
```

Parameter

pszStatusText
[in] Points to a null-terminated character string containing the message to display.

Return Values

S_OK
The text was displayed.

S_TRUNCATED
Some text was displayed but the message was too long and was truncated.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

E_FAIL
The text could not be displayed.

Comments

Notes to Callers

You should call **SetStatusText** when you need to ask the container to display object text in its frame's status line, if it has one. Because the container's frame window owns the status line, calling **IOleInPlaceFrame::SetStatusText** is the *only* way an object can display status information in the container's frame window. If the container refuses the object's request, the object application can, however, negotiate for border space to display its own status window.

Note When switching between menus owned by the container and the in-place active object, the status bar text is not reflected properly if the object does not call the container's **IOleInPlaceFrame::SetStatusText** method. For example, if, during an in-place session, the user were to select the File menu, the status bar would reflect the action that would occur if the user selected this menu. If the user then selects the Edit menu (which is owned by the in-place object), the status bar text would not change unless the **IOleInPlaceFrame::SetStatusText** happened to be called. This is because there is no way for the container to recognize that one of the object's menus has been made active because all the messages that the container would trap are now going to the object.

Notes to Implementors

To avoid potential problems, all objects being activated in place should process the WM_MENUSELECT message and call **IOleInPlaceFrame::SetStatusText** − even if the object does not usually provide status information (in which case the object can just pass a NULL string for the requested status text).

Note While executing **IOleInPlaceFrame::SetStatusText**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface methods and functions can be called from within **GerBorder**.

See Also

PeekMessage, **GetMessage** in Win32

IOleInPlaceFrame::TranslateAccelerator

Translates accelerator keystrokes intended for the container's frame while an object is active in place.

```
HRESULT TranslateAccelerator(
   LPMSG lpmsg,          //Points to MSG structure
   WORD wID              //Command Identifier value
  );
```

Parameters

lpmsg
[in] Points to an **MSG** structure containing the keystroke message.

wID
[in] Contains the command identifier value corresponding to the keystroke in the container-provided accelerator table. Containers should use this value instead of translating again.

Return Values

S_OK
The keystroke was used.

S_FALSE
The keystroke was not used.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

The **IOleInPlaceFrame::TranslateAccelerator** method is called indirectly by **OleTranslateAccelerator** when a keystroke accelerator intended for the container (frame) is received.

Notes to Implementors

The container application should perform its usual accelerator processing, or use *wID* directly, and then return, indicating whether the keystroke accelerator was processed. If the container is an MDI application and the Windows **TranslateAccelerator** call fails, the container can call the Windows **TranslateMDISysAccel** function, just as it does for its usual message processing.

In-place objects should be given first chance at translating accelerator messages. However, because objects implemented by DLL object applications do not have their own message pump, they receive their messages from the container's message queue. To ensure that the object has first chance at translating messages, a container should always call **IOleInPlaceActiveObject::TranslateAccelerator** before doing its own accelerator translation. Conversely, an executable object application should call **OleTranslateAccelerator** after calling **TranslateAccelerator**, calling **TranslateMessage** and **DispatchMessage** only if both translation functions fail.

Note You should define accelerator tables for containers so they will work properly with object applications that do their own accelerator keystroke translations. Tables should be defined as follows:

```
"char", wID, VIRTKEY, CONTROL
```

This is the most common way to describe keyboard accelerators. Failure to do so can result in keystrokes being lost or sent to the wrong object during an in-place session.

TranslateAccelerator, **TranslateMessage**, **DispatchMessage**, **TranslateMDISysAccel** in Win32

IOleInPlaceObject

The **IOleInPlaceObject** interface manages the activation and deactivation of in-place objects, and determines how much of the in-place object should be visible.

You can obtain a pointer to **IOleInPlaceObject** by calling **QueryInterface** on **IOleObject**.

When to Implement

You must implement this interface if you are writing an object application that will participate in in-place activation.

When to Use

Used by an object's immediate container to activate or deactivate the object.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleWindow Methods	Description
GetWindow	Gets a window handle.
ContextSensitiveHelp	Controls enabling of context sensitive help.

IOleInPlaceObject Methods	Description
InPlaceDeactivate	Deactivate active in-place object.
UIDeactivate	Deactivate and remove UI of active object.
SetObjectRects	Portion of in-place object to be visible.
ReactivateAndUndo	Reactivate previously deactivated object.

See Also

IOleObject, IOleWindow

IOleInPlaceObject::InPlaceDeactivate

Deactivates an active in-place object and discards the object's undo state.

HRESULT InPlaceDeactivate();

Return Values

S_OK
The object was successfully deactivated.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

This method is called by an active object's immediate container to deactivate the active object and discard its undo state.

Notes to Implementors

On return from **IOleInPlaceObject::InPlaceDeactivate**, the object discards its undo state. The object application should not shut down immediately after this call. Instead, it should wait for an explicit call to **IOleObject::Close** or for the object's reference count to reach zero.

Before deactivating, the object application should give the container a chance to put its user interface back on the frame window by calling **IOleInPlaceSite::OnUIDeactivate**.

If the in-place user interface is still visible during the call to **InPlaceDeactivate**, the object application should call its own **IOleInPlaceObject::UIDeactivate** method to hide the user interface. The in-place user interface can be optionally destroyed during calls to **IOleInPlaceObject::UIDeactivate** and **IOleInPlaceObject::InPlaceDeactivate**. But if the user interface has not already been destroyed when the container calls **IOleObject::Close**, then it *must* be destroyed during the call to **IOleObject::Close**.

During the call to **IOleObject::Close**, the object should check to see whether it is still active in place. If so, it should call **InPlaceDeactivate**.

See Also

IOleInPlaceSite::OnInPlaceDeactivate, **IOleInPlaceSite::OnUIDeactivate**, **IOleObject::Close**

IOleInPlaceObject::ReactivateAndUndo

Reactivates a previously deactivated object, undoing the last state of the object.

HRESULT ReactivateAndUndo();

Return Values

S_OK
The object was successfully reactivated.

E_NOTUNDOABLE
Called when the Undo state is not available.

E_INVALIDARG
One or more arguments are invalid.

E_OUTOFMEMORY
Out of memory.

E_UNEXPECTED
An unexpected error occurred.

Comments

If the user chooses the Undo command before the Undo state of the object is lost, the object's immediate container calls **IOleInPlaceObject::ReactivateAndUndo** to activate the user interface, carry out the Undo operation, and return the object to the active state.

IOleInPlaceObject::SetObjectRects

Indicates how much of the in-place object is visible.

```
HRESULT SetObjectRects(
   LPCRECT lprcPosRect,       //The position of the in-place object
   LPCRECT lprcClipRect       //The outer rectangle containing the in-place object's position rectangle
  );
```

Parameters

lprcPosRect
[in] Points to the rectangle containing the position of the in-place object using the client coordinates of its parent window.

lprcClipRect
[in] Points to the outer rectangle containing the in-place object's position rectangle (*PosRect*). This rectangle is relative to the client area of the object's parent window.

Return Values

S_OK
The operation successfully indicated the rectangle.

E_INVALIDARG
One or more arguments are invalid.

E_OUTOFMEMORY
Out of memory.

E_UNEXPECTED
An unexpected error occurred.

Comments

It is possible for *lprcClipRect* to change without *lprcPosRect* changing.

The size of an in-place object's rectangle is *always* calculated in pixels. This is different from other OLE object's visualizations, which are in HIMETRIC.

Note While executing **IOleInPlaceObject::SetObjectRects**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface mehtods and functions can be called form within **SetObjectRects**.

Notes to Callers

The container should call **IOleInPlaceObject::SetObjectRects** whenever the window position of the in-place object and/or the visible part of the in-place object changes.

Notes to Implementors

The object must size its in-place window to match the intersection of *lprcPosRect* and *lprcClipRect*. The object must also draw its contents into the object's in-place window so that proper clipping takes place.

The object should compare its width and height with those provided by its container (conveyed through *lprcPosRect*). If the comparison does not result in a match, the container is applying scaling to the object. The object must then decide whether it should continue the in-place editing in the scale/zoom mode or deactivate.

See Also

IOleInPlaceSite::OnPosRectChange

PeekMessage, **GetMessage** in Win32

IOleInPlaceObject::UIDeactivate

Deactivates and removes the user interface that supports in-place activation.

HRESULT UIDeactivate();

Return Values

S_OK
The in-place UI was deactivated and removed.

E_UNEXPECTED
An unexpected error occurred.

Notes to Callers

This method is called by the object's immediate container when, for example, the user has clicked in the client area outside the object.

If the container has called **IOleInPlaceObject::UIDeactivate**, it should later call **IOleInPlaceObject::InPlaceDeactivate** to properly clean up resources. The container can assume that stopping or releasing the object cleans up resources if necessary. The object must be prepared to do so if **IOleInPlaceObject::InPlaceDeactivate** has not been called. but either **IOleInPlaceObject::UIDeactivate** or **IOleObject::Close** has been called.

Notes to Implementors

Resources such as menus and windows can be either cleaned up or kept in a hidden state until your object is completely deactivated by calls to either **IOleInPlaceObject::InPlaceDeactivate** or **IOleObject::Close**. The object application must call **IOleInPlaceSite::OnUIDeactivate** before doing anything with the composite menus so that the container can first be detached from the frame window. On deactivating the in-place object's user interface, the object is left in a ready state so it can be quickly reactivated. The object stays in this state until the undo state of the document changes. The container should then call **IOleInPlaceObject::InPlaceDeactivate** to tell the object to discard its undo state.

See Also

IOleInPlaceObject::InPlaceDeactivate, **IOleInPlaceSite::OnUIDeactivate**, **IOleInPlaceObject::ReactivateAndUndo**, **IOleObject::Close**

IOleInPlaceSite

The **IOleInPlaceSite** interface manages interaction between the container and the object's in-place client site. Recall that the client site is the display site for embedded objects, and provides position and conceptual information about the object.

This interface provides methods that manage in-place objects. With **IOleInPlaceSite**, you can determine if an object can be activated and manage its activation and deactivation. You can notify the container when one of its objects is being activated and inform the container that a composite menu will replace the container's regular menu. It provides methods that make it possible for the in-place object to retrieve the window object hierarchy, and the position in the parent window where the object should place its in-place activation window. And finally, it manages how the container scrolls the object, its undo state, and notifies the object when its borders have changed.

When to Implement

You must implement this interface if you are writing a container application that will participate in in-place activation.

When to Use

Use this interface to allow your object to control in-place activation from within the container.

The **IOleInPlaceSite** interface pointer is obtained by calling **QueryInterface** on the object's **IOleClientSite** interface.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleWindow Methods	Description
GetWindow	Gets a window handle.
ContextSensitiveHelp	Controls enabling of context-sensitive help.

IOleInPlaceSite Methods	Description
CanInPlaceActivate	Determines if the container can activate the object in place.
OnInPlaceActivate	Notifies the container that one of its objects is being activated in place.
OnUIActivate	Notifies the container that the object is about to be activated in place, and that the main menu will be replaced by a composite menu.
GetWindowContext	Enables an in-place object to retrieve window interfaces that form at the window object hierarchy, and the position in the parent window to locate the object's in-place activation window.
Scroll	Specifies the number of pixels by which the container is to scroll the

	object.
OnUIDeactivate	Notifies the container to reinstall its user interface and take focus.
OnInPlaceDeactivate	Notifies the container that the object is no longer active in place.
DiscardUndoState	Instructs the container to discard its undo state.
DeactivateAndUndo	Deactivate the object and revert to undo state.
OnPosRectChange	Object's extents have changed.

See Also

IOleWindow, IOleClientSite

IOleInPlaceSite::CanInPlaceActivate

Determines whether or not the container can activate the object in place.

HRESULT CanInPlaceActivate();

Return Values

S_OK
  The container allows in-place activation for this object.

S_FALSE
  The container does not allow in-place activation for this object.

E_INVALIDARG
  One or more arguments are invalid.

E_UNEXPECTED
  An unexpected error occurred.

Comments

Only objects being displayed as DVASPECT_CONTENT can be activated in place.

Notes to Callers

IOleInPlaceSite::CanInPlaceActivate is called by the client site's immediate child object when this object must activate in place. This function allows the container application to accept or refuse the activation request.

IOleInPlaceSite::DeactivateAndUndo

Causes the container to end the in-place session, deactivates the object, and revert to its own saved undo state.

HRESULT IOleInPlaceSite::DeactivateAndUndo();

Return Values

S_OK
The method completed successfully.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

Called by the active object when the user invokes undo just after activating the object.

Notes to Implementors

Upon completion of this call, the container should call **IOleInPlaceObject::UIDeactivate** to remove the user interface for the object, activate itself, and undo.

IOleInPlaceSite::DiscardUndoState

Tells the container that the object.no longer has any undo state and that the container should not call IOleInPlaceObject::ReActivateAndUndo.

HRESULT IOleInPlaceSite::DiscardUndoState();

Return Values

S_OK
The method completed successfully.

E_UNEXPECTED
An unexpected error occurred.

Comments

If an object is activated in place and the object's associated object application maintains only one level of undo, there is no need to have more than one entry on the undo stack. That is, once a change has been made to the active object that invalidates its undo state saved by the container, there is no need to maintain this undo state in the container.

Notes to Callers

IOleInPlaceSite::DiscardUndoState is called by the active object while performing some action that would discard the undo state of the object. The in-place object calls this method to notify the container to discard the object's last saved undo state.

See Also

IOleInPlaceSite::DeactivateAndUndo

IOleInPlaceSite::GetWindowContext

Enables the in-place object to retrieve the window interfaces that form the window object hierarchy, and the position in the parent window where the object's in-place activation window should be placed.

```
HRESULT GetWindowContext(
  IOleInPlaceFrame **ppFrame,              //Location to return frame interface pointer
  IOleInPlaceUIWindow **ppDoc,             //Location to return document window pointer
  LPRECT lprcPosRect,                      //Points to position of in-place object
  LPRECT lprcClipRect,                     //Points to in-place object's position rectangle
  LPOLEINPLACEFRAMEINFO lpFrameInfo        //Points to OLEINPLACEFRAMEINFO structure
 );
```

Parameters

ppFrame
[out] Points to where the pointer to the frame interface is to be returned. If an error is returned, this parameter must be set to NULL.

ppDoc
[out] Points to where the pointer to the document window interface is to be returned. NULL is returned through the *ppDoc* pointer if the document window is the same as the frame window. In this case, the object can only use *ppFrame* or border negotiation. If an error is returned, this parameter must be set to NULL.

lprcPosRect
[out] Points to the rectangle containing the position of the in-place object in the client coordinates of its parent window. If an error is returned, this parameter must be set to NULL.

lprcClipRect
[out] Points to the outer rectangle containing the in-place object's position rectangle (*PosRect*). This rectangle is relative to the client area of the object's parent window. If an error is returned, this parameter must be set to NULL.

lpFrameInfo
[out] Points to an **OLEINPLACEFRAMEINFO** structure the container is to fill in with appropriate data. If an error is returned, this parameter must be set to NULL.

Return Values

S_OK
The method completed successfully.

E_INVALIDARG
One or more arguments are invalid (for example, an invalid pointer or parameter).

E_UNEXPECTED
An unexpected error occurred.

Comments

The **OLEINPLACEFRAMEINFO** structure provides data needed by OLE to dispatch keystroke accelerators to a container frame while an object is active in place.

When an object is activated, it calls **GetWindowContext** from its container. The container returns the handle to its in-place accelerator table through the **OLEINPLACEFRAMEINFO** structure. Before calling **GetWindowContext**, the object must provide the size of the **OLEINPLACEFRAMEINFO** structure by filling in the *cb* member, pointed to by *lpFrameInfo*.

IOleInPlaceSite::OnInPlaceActivate

Notifies the container that one of its objects is being activated in place.

HRESULT OnInPlaceActivate();

Return Values

S_OK
The container allows the in-place activation.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

IOleInPlaceSite::OnInPlaceActivate is called by the active, embedded object when it is activated in-place for the first time. The container should note that the object is becoming active.

Notes to Implementors

A container that supports linking to embedded objects must properly manage the running of its in-place objects when they are UI inactive and running in the hidden state. To reactivate the in-place object quickly, a container should *not* call **IOleObject::Close** until the container's **IOleInPlaceSite::DeactivateAndUndo** method is called. To safeguard against the object being left in an unstable state if a linking client updates silently, the container should call **OleLockRunning** to lock the object in the running state. This prevents the hidden in-place object from shutting down before it can be saved in its container.

IOleInPlaceSite::OnInPlaceDeactivate

Notifies the container that the object is no longer active in place.

HRESULT OnInPlaceDeactivate();

Return Values

S_OK
  The method successfully notified the container.

E_UNEXPECTED
  An unexpected error occurred.

Comments

Notes to Callers

IOleInPlaceSite::OnInPlaceDeactivate is called by an in-place object when it is fully deactivated. This function notifies the container that the object has been deactivated, and it gives the container a chance to run code pertinent to the object's deactivation. In particular, **IOleInPlaceSite::OnInPlaceDeactivate** is called as a result of **IOleInPlaceObject::InPlaceDeactivate** being called. Calling **IOleInPlaceSite::OnInPlaceDeactivate** indicates that the object can no longer support Undo.

Notes to Implementors

If the container is holding pointers to the **IOleInPlaceObject** and **IOleInPlaceActiveObject** interface implementations, it should release them after the **IOleInPlaceSite::OnInPlaceDeactivate** call.

See Also

IOleInPlaceObject::InPlaceDeactivate

IOleInPlaceSite::OnPosRectChange

Indicates the object's extents have changed.

```
HRESULT OnPosRectChange(
   LPCRECT lprcPosRect        //Points to rectangle containing the position of in-place object
  );
```

Parameter

lprcPosRect
[in] Points to the rectangle containing the position of the in-place object in the client coordinates of its parent window.

Return Values

S_OK
The method completed successfully.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

The **IOleInPlaceSite::OnPosRectChange** method is called by the in-place object.

Notes to Implementors

When the in-place object calls **IOleInPlaceSite::OnPosRectChange**, the container must call **IOleInPlaceObject::SetObjectRects** to specify the new position of the in-place window and the *ClipRect*. Only then does the object resize its window.

In most cases, the object grows to the right and/or down. There could be cases where the object grows to the left and/or up, as conveyed through *lprcPosRect*. It is also possible to change the object's position without changing its size.

See Also

IOleInPlaceObject::SetObjectRects

IOleInPlaceSite::OnUIActivate

Notifies the container that the object is about to be activated in place and that the object is going to replace the container's main menu with an in-place composite menu.

HRESULT IOleInPlaceSite::OnUIActivate();

Return Values

S_OK
: The container allows the in-place activation.

E_UNEXPECTED
: An unexpected error occurred.

Comments

Notes to Callers

The in-place object calls **IOleInPlaceSite::OnUIActivate** just before activating its user interface.

Notes to Implementors

The container should remove any user interface associated with its own activation. If the container is itself an embedded object, it should remove its document-level user interface.

If there is already an object active in place in the same document, the container should call **IOleInPlaceObject::UIDeactivate** before calling **OnUIDeactivate**.

See Also

IOleInPlaceObject::UIDeactivate

IOleInPlaceSite::OnUIDeactivate

Notifies the container on deactivation that it should reinstall its user interface and take focus, and whether or not the object has an undoable state.

```
HRESULT OnUIDeactivate(
    BOOL fUndoable         //Specifies if object can undo changes
  );
```

Parameter

fUndoable
[in] Specifies whether the object can undo changes. It is TRUE if the object can undo, FALSE if it cannot.

Return Values

S_OK
The method completed successfully.

E_UNEXPECTED
An unexpected error occurred.

Comments

The object indicates whether it can undo changes through the *fUndoable* flag. If the object can undo changes, the container can (by the user invoking the Edit Undo command) call the **IOleInPlaceObject::ReactivateAndUndo** method to undo the changes.

Notes to Callers

IOleInPlaceSite::OnUIDeactivate is called by the site's immediate child object when it is deactivating to notify the container that it should reinstall its own user interface components and take focus. The container should wait for the call to **IOleInPlaceSite::OnUIDeactivate** to complete before fully cleaning up and destroying any composite submenus.

See Also

IOleInPlaceObject::ReactivateAndUndo

IOleInPlaceSite::Scroll

Tells the container to scroll the view of the object by a specified number of pixels.

```
HRESULT Scroll(
   SIZE scrollExtent         //Number of pixels
  );
```

Parameter

scrollExtent
[in] Contains the number of pixels by which to scroll in the *X* and *Y* directions.

Return Values

S_OK
The method successfully executed the view scroll instruction.

E_INVALIDARG
An invalid argument.

E_UNEXPECTED
An unexpected error occurred.

Comments

As a result of scrolling, the object's visible rectangle can change. If that happens, the container should give the new *ClipRect* to the object by calling **IOleInPlaceObject::SetObjectRects**. The intersection of the *ClipRect* and *PosRect* rectangles gives the new visible rectangle. See **IOleInPlaceSite::GetWindowContext** for a discussion of *ClipRect* and *PosRect*.

Notes to Callers

Called by an active, in-place object when it is asking the container to scroll.

See Also

IOleInPlaceObject::SetObjectRects

IOleInPlaceUIWindow

The **IOleInPlaceUIWindow** interface is implemented by container applications and used by object applications to negotiate border space on the document or frame window. The container provides a **RECT** structure in which the object can place toolbars and other similar controls, determines if tools can in fact be installed around the object's window frame, allocates space for the border, and establishes a communication channel between the object and each frame and document window.

The document window may not exist in all applications. When this is the case, **IOleInPlaceSite::GetWindowContext** returns NULL for **IOleInPlaceUIWindow**.

When to Implement

You must implement this interface if you are writing a container application that will participate in-place activation.

When to Use

Used by object applications to negotiate border space on the document or frame window when one of its objects is being activated or to renegotiate border space if the size of the object changes.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleWindow Methods	Description
GetWindow	Gets a window handle.
ContextSensitiveHelp	Controls enabling of context sensitive help.

IOleInPlaceUIWindow Methods	Description
GetBorder	Specifies a RECT structure for toolbars and controls.
RequestBorderSpace	Determines if tools can be installed around object's window frame.
SetBorderSpace	Allocates space for the border.
SetActiveObject	Provides for direct communication between the object and each document and frame window.

See Also

IOleWindow

IOleInPlaceUIWindow::GetBorder

Returns a **RECT** structure in which the object can put toolbars and similar controls while active in place.

```
HRESULT GetBorder(
   LPRECT lprectBorder       //Points to RECT structure
  );
```

Parameter

lprectBorder
   [out] Points to a **RECT** structure where the outer rectangle is to be returned. The **RECT** structure's coordinates are relative to the window being represented by the interface.

Return Values

S_OK
   The rectangle was successfully returned.

E_NOTOOLSPACE
   The object cannot install toolbars in this window object.

E_INVALIDARG
   One or more arguments are invalid.

E_OUTOFMEMORY
   Out of memory.

E_UNEXPECTED
   An unexpected error occurred.

Comments

Notes to Callers

The **IOleInPlaceUIWindow::GetBorder** function, when called on a document or frame window object, returns the outer rectangle (relative to the window) where the object can put toolbars or similar controls.

If the object is to install these tools, it should negotiate space for the tools within this rectangle using **IOleInPlaceUIWindow::RequestBorderSpace** and then call **IOleInPlaceUIWindow::SetBorderSpace** to get this space allocated.

Note While executing **IOleInPlaceUIWindow::GetBorder**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface mehtods and functions can be called from within **GerBorder**.

See Also

IOleInPlaceUIWindow::RequestBorderSpace, **IOleInPlaceUIWindow::SetBorderSpace**

PeekMessage, **GetMessage** in Win32

IOleInPlaceUIWindow::RequestBorderSpace

Determines if there is available space for tools to be installed around the object's window frame while the object is active in place.

```
HRESULT RequestBorderSpace(
   LPCBORDERWIDTHS pborderwidths       //Points to a BORDERWIDTHS structure
  );
```

Parameter

pborderwidths
[in] Points to a **BORDERWIDTHS** structure containing the requested widths (in pixels) needed on each side of the window for the tools.

Return Values

S_OK
The requested space could be allocated to the object.

E_NOTOOLSPACE
The object cannot install toolbars in this window object because the implementation does not support toolbars, or there is insufficient space to install the toolbars.

E_INVALIDARG
One or more invalid arguments (for example, an invalid pointer or parameter).

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Callers

The active in-place object calls **IOleInPlaceUIWindow::RequestBorderSpace** to ask if tools can be installed inside the window frame. These tools would be allocated between the rectangle returned by **IOleInPlaceUIWindow::GetBorder** and the **BORDERWIDTHS** structure specified in the argument to this call.

The space for the tools is not actually allocated to the object until it calls **IOleInPlaceUIWindow::SetBorderSpace**, allowing the object to negotiate for space (such as while dragging toolbars around), but deferring the moving of tools until the action is completed.

The object can install these tools by passing the width in pixels that is to be used on each side. For example, if the object required 10 pixels on the top, 0 pixels on the bottom, and 5 pixels on the left and right sides, it would pass the following **BORDERWIDTHS** structure to **IOleInPlaceUIWindow::RequestBorderSpace**:

```
lpbw->top    = 10
lpbw->bottom =  0
lpbw->lLeft  =  5
lpbw->right  =  5
```

Note While executing **IOleInPlaceUIWindow::RequestBorderSpace**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface methods and functions can be called from within **RequestBorderSpace**.

Notes to Implementors

If the amount of space an active object uses for its toolbars is irrelevant to the container, it can simply return NOERROR as shown in the following **IOleInPlaceUIWindow::RequestBorderSpace** example. Containers should not unduly restrict the display of tools by an active in-place object.

```
HRESULT InPlaceUIWindow_RequestBorderSpace(
    IOleInPlaceFrame *  lpThis,
    LPCBORDERWIDTHS     pborderwidths)
{
    /* Container allows the object to have as much border space as it
    ** wants.
    */
    return NOERROR;
}
```

See Also

IOleInPlaceUIWindow::GetBorder, **IOleInPlaceUIWindow::SetBorderSpace**

PeekMessage, **GetMessage** in Win32

IOleInPlaceUIWindow::SetActiveObject

Provides a direct channel of communication between the object and each of the frame and document windows.

```
HRESULT SetActiveObject(
  IOleInPlaceActiveObject *pActiveObject,     //Points to active in-place object
  LPCOLESTR pszObjName                        //Points to name describing the object
 );
```

Parameters

pActiveObject
: [in] Points to the active in-place object's **IOleInPlaceActiveObject** interface.

pszObjName
: [in] Points to a string containing a name that describes the object an embedding container can use in composing its window title. It can be NULL if the object does not require the container to change its window titles. The *Microsoft Windows User Interface Design Guide* recommends that containers ignore this parameter and always use their own name in the title bar.

Return Values

S_OK
: The method completed successfully.

E_INVALIDARG
: One or more arguments are invalid.

E_UNEXPECTED
: An unexpected error occurred.

Comments

Generally, an embedded object should pass NULL for the *pszObjName* parameter (see "Notes to Implementors" below). However, if you are working in conjunction with a container that does display the name of the in-place active object in its title bar, then you should compose a string in the following form:

<application name> - <object short-type name>

Notes to Callers

IOleInPlaceUIWindow::SetActiveObject is called by the object to establish a direct communication link between itself and the document and frame windows.

When deactivating, the object calls **IOleInPlaceUIWindow::SetActiveObject**, passing NULL for the *pActiveObject* and *pszObjName* parameters.

An object *must* call **IOleInPlaceUIWindow::SetActiveObject** before calling **IOleInPlaceFrame::SetMenu** to give the container the pointer to the active object. The container then uses this pointer in processing **IOleInPlaceFrame::SetMenu** and to pass to **OleSetMenuDescriptor**.

Notes to Implementors

The *Microsoft Windows User Interface Design Guide* recommends that an in-place container ignore the *pszObjName* parameter passed in this method. The guide says "The title bar is not affected by in-place activation. It always displays the top-level container's name."

See Also

IOleInPlaceFrame::SetMenu, **OleSetMenuDescriptor**

IOleInPlaceUIWindow::SetBorderSpace

Allocates space for the border requested in the call to **IOleInPlaceUIWindow::RequestBorderSpace**.

```
HRESULT SetBorderSpace(
   LPCBORDERWIDTHS pborderwidths        //Points to a BORDERWIDTHS structure
  );
```

Parameter

pborderwidths
[in] Points to a **BORDERWIDTHS** structure containing the requested width (in pixels) of the tools. It can be NULL, indicating the object does not need any space.

Return Values

S_OK
The requested space has been allocated to the object.

OLE_E_INVALIDRECT
The rectangle does not lie within the specifications returned by **IOleInPlaceUIWindow::GetBorder**.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

The object must call **IOleInPlaceUIWindow::SetBorderSpace**. It can do any of the following:

1. Use its own toolbars, requesting border space of a specific size; or,
2. Use no toolbars, but force the container to remove its toolbars by passing a valid **BORDERWIDTHS** structure containing nothing but zeros in the *pborderwidths* parameter; or,
3. Use no toolbars but allow the in-place container to leave its toolbars up by passing NULL as the *pborderwidths* parameter.

The **BORDERWIDTHS** structure used in this call would generally have been passed in a previous call to **IOleInPlaceUIWindow::RequestBorderSpace**, which must have returned S_OK.

If an object must renegotiate space on the border, it can call **SetBorderSpace** again with the new widths. If the call to **SetBorderSpace** fails, the object can do a full negotiation for border space with calls to **GetBorder**, **RequestBorderSpace**, and **SetBorderSpace**.

Note While executing **IOleInPlaceUIWindow::SetBorderSpace**, do not make calls to the Windows **PeekMessage** or **GetMessage** functions, or a dialog box. Doing so may cause the system to deadlock. There are further restrictions on which OLE interface methods and functions can be called from within **SetBorderSpace**.

IOleItemContainer

The **IOleItemContainer** interface is used by item monikers when they are bound to the objects they identify.

When any container of objects uses item monikers to identify its objects, it must define a naming scheme for those objects. The container's **IOleItemContainer** implementation uses knowledge of that naming scheme to retrieve an object given a particular name. Item monikers use the container's **IOleItemContainer** implementation during binding.

When to Implement

You must implement **IOleItemContainer** if you're a moniker provider handing out item monikers. Being a moniker provider means handing out monikers that identify your objects to make them accessible to moniker clients. You must use item monikers if the objects you're identifying are contained within another object and can be individually identified using a string.

The most common example of moniker providers are OLE applications that support linking. If your OLE application supports linking to objects smaller than a file-based documents, you need to use item monikers. For a server application that allows linking to a portion of a document (such as selections within a document), you use the item monikers to identify those objects. For a container application that allows linking to embedded objects, you use the item monikers to identify the embedded objects.

You must define a naming scheme for identifying the objects within the container; for example, embedded objects in a document could be identified with names of the form "embedobj1," "embedobj2," and so forth, while ranges of cells in a spreadsheet could be identified with names of the form "A1:E7," "G5:M9," and so forth. (Ranges of cells in a spreadsheet are examples of as "pseudo-objects" because they do not have their own persistent storage, they simply represent a portion of the container's internal state.) You create an item moniker that represents an object's name using the **CreateItemMoniker** API function and hand it out to a moniker client. When an item moniker is bound, your implementation of **IOleItemContainer** must be able to take a name and retrieve the corresponding object.

When to Use

Applications typically do not call **IOleItemContainer** methods directly. The item moniker implementation of **IMoniker** is the primary caller of **IOleItemContainer** methods.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IParseDisplayName Method	Description
ParseDisplayName	Parses object's display name to form moniker.

IOleContainer Methods	Description
EnumObjects	Enumerates objects in a container.
LockContainer	Keeps container running until explicitly released.

IOleItemContainer Methods	Description
GetObject	Returns a pointer to a specified

	object.
GetObjectStorage	Returns a pointer to an object's storage.
IsRunning	Checks whether an object is running.

See Also

CreateItemMoniker, **IMoniker - Item Moniker Implementation**

IOleItemContainer::GetObject

Returns a pointer to the object identified by the specified name.

```
HRESULT GetObject(
   LPOLESTR pszItem,            //Name of the object requested
   DWORD dwSpeedNeeded,         //Speed requirements on binding
   IBindCtx *pbc,               //Bind context to be used
   REFIID riid,                 //IID of interface pointer desired
   void **ppvObject             //Receives interface pointer
  );
```

Parameters

pszItem
[in] Points to a zero-terminated string containing the container's name for the requested object. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

dwSpeedNeeded
[in] Indicates approximately how long the caller will wait to get the object. The legal values for *dwSpeedNeeded* are taken from the enumeration **BINDSPEED**. For information on the **BINDSPEED** enumeration, see the "Data Structures" section.

pbc
[in] Points to the bind context to be used in this binding operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the binding implementation should retrieve information about its environment. For more information, see **IBindCtx**.

riid
[in] Specifies the type of interface pointer requested.

ppvObject
[out] Receives a pointer to the object named by *pszItem*. If an error occurs, the implementation sets **ppvObject* to NULL. If **ppvObject* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
The specified object was successfully returned.

MK_E_EXCEEDEDDEADLINE
The binding operation could not be completed within the time limit specified by the bind context's **BIND_OPTS** structure, or with the speed indicated by the *dwSpeedNeeded* parameter.

MK_E_NOOBJECT
The parameter *pszItem* does not identify a object in this container.

E_NOINTERFACE
The requested interface was not available.

E_OUTOFMEMORY
Insufficient memory.

Comments

The item moniker implementation of **IMoniker::BindToObject** calls this method, passing the name stored within the item moniker as the *pszItem* parameter.

Notes to Implementors

Your implementation of **IOleItemContainer::GetObject** should first determine whether *pszItem* is a valid name for one of the container's objects. If not, you should return MK_E_NOOBJECT.

If *pszItem* names an embedded or linked object, your implementation must check the value of the *dwSpeedNeeded* parameter. If the value is BINDSPEED_IMMEDIATE and the object is not yet loaded, you should return MK_E_EXCEEDEDDEADLINE. If the object is loaded, your implementation should determine whether the object is running (for example, by calling the **OleIsRunning** API function). If it is not running and the *dwSpeedNeeded* value is BINDSPEED_MODERATE, your implementation should return MK_E_EXCEEDEDDEADLINE. If the object is not running and *dwSpeedNeeded* is BINDSPEED_INDEFINITE, your implementation should call the **OleRun** API function to put the object in the running state. Then it can query the object for the requested interface. Note that it is important the object be running before you query for the interface.

If *pszItem* names a pseudo-object, your implementation can ignore the *dwSpeedNeeded* parameter because a pseudo-object is running whenever its container is running. In this case, your implementation can simply query for the requested interface.

If you want more specific information about the time limit than is given by *dwSpeedNeeded*, you can call **IBindCtx::GetBindOptions** on the *pbc* parameter to get the actual deadline parameter.

See Also

IMoniker::BindToObject, **IBindCtx::GetBindOptions**, **OleIsRunning**, **OleRun**

IOleItemContainer::GetObjectStorage

Returns a pointer to the storage for the object identified by the specified name.

```
HRESULT GetObjectStorage(
   LPOLESTR pszItem,          //Name of the object whose storage is requested
   IBindCtx *pbc,             //Bind context to be used
   REFIID riid,               //IID of interface pointer desired
   void **ppvStorage          //Receives interface pointer
  );
```

Parameters

pszItem
[in] Points to a zero-terminated string containing the compound document's name for the object whose storage is requested. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

pbc
[in] Points to the bind context to be used in this binding operation. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the binding implementation should retrieve information about its environment. For more information, see **IBindCtx**.

riid
[in] Identifies the type of interface pointer requested.

ppvStorage
[out] Receives a pointer to the storage of the object named by *pszItem*. If an error occurs, the implementation sets **ppvStorage* to NULL. If **ppvStorage* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
The storage of the specified object was successfully returned.

MK_E_NOOBJECT
The parameter *pszItem* does not identify a object in this container.

MK_E_NOSTORAGE
The object does not have its own independent storage.

E_NOINTERFACE
The requested interface is not available.

E_OUTOFMEMORY
Insufficient memory.

Comments

The item moniker implementation of **IMoniker::GetObjectStorage** calls this method.

Notes to Implementors

If *pszItem* designates a pseudo-object, your implementation should return MK_E_NOSTORAGE, because pseudo-objects do not have their own independent storage. If *pszItem* designates an embedded object, or a portion of the document that has its own storage, your implementation should return the specified interface pointer on the appropriate storage object.

See Also

IOleItemContainer::GetObjectStorage

IOleItemContainer::IsRunning

Indicates whether the object identified by the specified name is running.

```
HRESULT IsRunning(
  LPOLESTR pszItem        //Name of object whose status is being requested
 );
```

Parameter

pszItem
[in] Points to a zero-terminated string containing the container's name for the object. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

Return Values

S_OK
The specified object is running.

S_FALSE
The object is not running.

MK_E_NOOBJECT
The parameter *pszItem* does not identify a object in this container.

Comments

The item moniker implementation of **IMoniker::IsRunning** calls this method.

Notes to Implementors

Your implementation of **IOleItemContainer::IsRunning** should first determine whether *pszItem* identifies one of the container's objects. If it does not, your implementation should return MK_E_NOOBJECT. If the object is not loaded, your implementation should return S_FALSE. If it is loaded, your implementation can call the **OleIsRunning** API function to determine whether it is running.

If *pszItem* names a pseudo-object, your implementation can simply return S_OK because a pseudo-object is running whenever its container is running.

See Also

IMoniker::IsRunning

IOleLink

The **IOleLink** interface is the means by which a linked object provides its container with functions pertaining to linking. The most important of these functions is binding to the link source, that is, activating the connection to the document that stores the linked object's native data. **IOleLink** also defines functions for managing information about the linked object, such as the location of the link source and the cached presentation data for the linked object.

A container application can distinguish between embedded objects and linked objects by querying for **IOleLink**; only linked objects implement **IOleLink**.

When to Implement

You do not have to implement this interface yourself; the system supplies an implementation of **IOleLink** that is suitable for all situations. This implementation is used automatically whenever you create or load a linked object.

When to Use

You must use **IOleLink** if you are writing a container application that allows its documents to contain linked objects. You primarily call **IOleLink** methods in order to implement the Links dialog box. If you use the **OleUIEditLinks** API function to display the Links dialog box, your calls to **IOleLink** methods take place in your implementation of the **IOleUILinkContainer** interface.

Some **IOleLink** methods don't have to be called directly. Instead, you call methods of **IOleObject**; the default linked object provides an implementation of **IOleObject** that often calls methods of **IOleLink**. For example, a container application typically activates a linked object by calling **IOleObject::DoVerb**, which in turn calls **IOleLink::BindToSource**.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleLink Methods	Description
SetUpdateOptions	Sets the update options.
GetUpdateOptions	Returns the update options.
SetSourceMoniker	Sets the moniker for the link source.
GetSourceMoniker	Returns the moniker for the link source.
SetSourceDisplayName	Sets the display name for the link source.
GetSourceDisplayName	Returns the display name for the link source.
BindToSource	Binds the moniker to the link source.
BindIfRunning	Binds the moniker if the source is running.
GetBoundSource	Returns a pointer to the link source if it's running.
UnbindSource	Break connection to the link source.
Update	Update the cached views of the link

source.

See Also

IOleObject, **IOleUILinkContainer**, **OleUIEditLinks**

IOleLink::BindIfRunning

Activates the connection between the linked object and the link source if the link source is already running.

HRESULT BindIfRunning(*void***);**

Return Values

S_OK
: The link source was bound.

S_FALSE
: The link source is not running.

CreateBindCtx, **IMoniker::IsRunning**, or **IOleLink::BindToSource** errors
: Binding the moniker might require calling these functions; therefore, errors generated by these functions may be returned.

Comments

You typically do not need to call **IOleLink::BindIfRunning**. This method is primarily called by the linked object.

Notes on Provided Implementation

The linked object's implementation of **IOleLink::BindIfRunning** checks the Running Object Table (ROT) to determine whether the link source is already running. It checks both the relative and absolute monikers. If the link source is running, **IOleLink::BindIfRunning** calls **IOleLink::BindToSource** to connect the linked object to the link source.

See Also

IOleLink::BindToSource

IOleLink::BindToSource

Activates the connection to the link source by binding the moniker stored within the linked object.

```
HRESULT BindToSource(
  DWORD bindflags,      //Flag in case CLSID of link source is different
  IBindCtx *pbc         //Bind context to be used
 );
```

Parameters

bindflags
: [in] Specifies how to proceed if the link source has a different CLSID from the last time it was bound. If this parameter is zero and the CLSIDs are different, the method fails and returns OLE_E_CLASSDIFF. If the OLELINKBIND_EVENIFCLASSDIFF value from the **OLELINKBIND** enumeration is specified and the CLSIDs are different, the method binds successfully and updates the CLSID stored in the linked object.

pbc
: [in] Points to the bind context to be used in this binding operation. This parameter can be NULL. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the binding implementation should retrieve information about its environment. For more information, see **IBindCtx**.

Return Values

S_OK
: Indicates that the link source is bound.

OLE_E_CLASSDIFF
: Indicates that the link source was not bound because its CLSID has changed. This error is returned only if the OLELINKBIND_EVENIFCLASSDIFF flag is not specified in the *bindflags* parameter.

MK_E_NOOBJECT
: Indicates that the link source could not be found or (if the link source's moniker is a composite) some intermediate object identified in the composite could not be found.

E_UNSPEC
: Indicates that the link's moniker is NULL.

CreateBindCtx errors
: Binding the moniker might require calling this function; therefore, this method may return errors generated by this function.

Comments

Notes to Callers

Typically, your container application does not need to call the **IOleLink::BindToSource** method directly. When it's necessary to activate the connection to the link source, your container typically calls **IOleObject::DoVerb**, **IOleObject::Update**, or **IOleLink::Update**. The linked object's implementation of these methods calls **IOleLink::BindToSource**. Your container can also call the **OleRun** API function, which – when called on a linked object – calls **IOleLink::BindToSource**.

In each of the examples listed above, in which **IOleLink::BindToSource** is called indirectly, the *bindflags* parameter is set to zero. Consequently, these calls can fail with the OLE_E_CLASSDIFF error if the class of the link source is different from what it was the last time the linked object was bound. This could happen, for example, if the original link source was an embedded Lotus spreadsheet that an end user had subsequently converted (using the Change Type dialog box) to an Excel spreadsheet.

If you want your container to bind even though the link source now has a different CLSID, you can call

IOleLink::BindToSource directly and specify OLELINKBIND_EVENIFCLASSDIFF for the *bindflags* parameter. This call binds to the link source and updates the link object's CLSID. Alternatively, your container can delete the existing link and use the **OleCreateLink** API function to create a new linked object.

Notes on Provided Implementation

The linked object caches the interface pointer to the link source acquired during binding.

The linked object's **IOleLink::BindToSource** implementation first tries to bind using a moniker consisting of the compound document's moniker composed with the link source's relative moniker. If successful, it updates the link's absolute moniker. Otherwise, it tries to bind using the absolute moniker, updating the relative moniker if successful.

If **IOleLink::BindToSource** binds to the link source, it calls the compound document's **IOleContainer::LockContainer** implementation to keep the containing compound document alive while the link source is running. **IOleLink::BindToSource** also calls the **IOleObject::Advise** and **IDataObject::DAdvise** implementations of the link source to set up advisory connections. The **IOleLink::UnbindSource** implementation unlocks the container and deletes the advisory connections.

See Also

IDataObject::DAdvise, **IOleContainer::LockContainer**, **IOleLink::Update**, **IOleLink::UnbindSource**, **IOleObject::Advise**, **IOleObject::DoVerb**, **IOleObject::Update**, **OleRun**

IOleLink::GetBoundSource

Returns an **IUnknown** pointer to the link source if the connection is currently active.

```
HRESULT GetBoundSource(
  IUnknown **ppunk        //Receives pointer to link source
 );
```

Parameter

ppunk
[out] Receives an **IUnknown** pointer to the link source. If an error occurs, the implementation sets **ppunk* to NULL. If **ppunk* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
Indicates that a pointer was returned successfully.

E_FAIL
Indicates that the link source is not bound.

Comments

You typically do not need to call **IOleLink::GetBoundSource**.

IOleLink::GetSourceDisplayName

Retrieves the display name of the link source of the linked object.

```
HRESULT GetSourceDisplayName(
   LPOLESTR *ppszDisplayName        //Receives display name of link source
  );
```

Parameter

ppszDisplayName

[out] Receives a pointer to a zero-terminated string containing the display name of the link source. If an error occurs, **ppszDisplayName* is set to NULL; otherwise, the implementation must use **IMalloc::Alloc** to allocate the string returned in *ppszDisplayName*, and the caller is responsible for calling **IMalloc::Free** to free it. Both caller and callee use the allocator returned by **CoGetMalloc**(MEMCTX_TASK, ...). For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

Return Values

S_OK
: The display name was successfully retrieved.

E_FAIL
: The link's moniker is NULL.

CreateBindCtx and **IMoniker::GetDisplayName** errors
: Retrieving the display name requires calling these functions; therefore, this method may return errors generated by these functions.

Comments

Notes to Callers

Your container application can call **IOleLink::GetSourceDisplayName** in order to display the current source of a link.

The current source of a link is displayed in the Links dialog box. If you use the **OleUIEditLinks** API function to display the Links dialog box, you must implement the **IOleUILinkContainer** interface. The dialog box calls your implementations of **IOleUILinkContainer::GetLinkSource** to get the string it should display. Your implementation of that method can call **IOleLink::GetSourceDisplayName**.

Notes on Provided Implementation

The linked object's implementation of **IOleLink::GetSourceDisplayName** calls **IOleLink::GetSourceMoniker** to get the link source moniker, and then calls **IMoniker::GetDisplayName** to get that moniker's display name. This operation is potentially expensive because it might require binding the moniker. All of the system-supplied monikers can return a display name without binding, but there is no guarantee that other moniker implementations can. Instead of making repeated calls to **IOleLink::GetSourceDisplayName**, your container application can cache the name and update it whenever the link source is bound.

See Also

IOleLink::SetSourceDisplayName, **IOleUILinkContainer**, **IMoniker::GetDisplayName**, **OleUIEditLinks**

IOleLink::GetSourceMoniker

Retrieves the moniker identifying the link source of a linked object.

```
HRESULT GetSourceMoniker(
   IMoniker **ppmk          //Receives moniker identifying link source
  );
```

Parameter

ppmk

[out] Receives a pointer to an absolute moniker that identifies the link source. May be NULL if an error occurs. If **ppmk* is non-NULL, the implementation must call **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
The moniker was returned successfully.

MK_E_UNAVAILABLE
No moniker is available.

Comments

Notes to Callers

Your container application can call **IOleLink::GetSourceMoniker** to display the current source of a link in the Links dialog box. Note that this requires your container to use the **IMoniker::GetDisplayName** method to get the display name of the moniker. If you'd rather get the display name directly, your container can call **IOleLink::GetSourceDisplayName** instead of **IOleLink::GetSourceMoniker**.

If you use the **OleUIEditLinks** API function to display the Links dialog box, you must implement the **IOleUILinkContainer** interface. The dialog box calls your implementations of **IOleUILinkContainer::GetLinkSource** to get the string it should display. Your implementation of that method can call **IOleLink::GetSourceMoniker**.

Notes on Provided Implementation

The linked object stores both an absolute and a relative moniker for the link source. If the relative moniker is non-NULL and a moniker is available for the compound document, **IOleLink::GetSourceMoniker** returns the moniker created by composing the relative moniker onto the end of the compound document's moniker. Otherwise, it returns the absolute moniker or, if an error occurs, NULL.

The container specifies the absolute moniker when it calls one of the **OleCreateLink** functions to create a link. The application can call **IOleLink::SetSourceMoniker** or **IOleLink::SetSourceDisplayName** to change the absolute moniker. In addition, the linked object automatically updates the monikers whenever it successfully binds to the link source, or when it is bound to the link source and it receives a rename notification through the **IAdviseSink::OnRename** method.

See Also

IOleLink::SetSourceDisplayName, **IOleLink::SetSourceMoniker**

IOleLink::GetUpdateOptions

Retrieves a value indicating how often the linked object updates its cached data.

```
HRESULT GetUpdateOptions(
   DWORD *pdwUpdateOpt       //Receives update option
  );
```

Parameter

pdwUpdateOpt

[out] Receives the current value for the linked object's update option, indicating how often the linked object updates the cached data for the linked object. The legal values for *pdwUpdateOpt* are taken from the enumeration **OLEUPDATE**. For information on the **OLEUPDATE** enumeration, see the "Data Structures" section.

Return Value

S_OK

The update option was retrieved successfully.

Comments

Notes to Callers

Your container application should call **IOleLink::GetUpdateOptions** to display the current update option for a linked object.

A linked object's current update option is displayed in the Links dialog box. If you use the **OleUIEditLinks** API function to display the Links dialog box, you must implement the **IOleUILinkContainer** interface. The dialog box calls your implementation of **IOleUILinkContainer::GetLinkUpdateOptions** to determine which update option it should display. Your implementation of that method should call **IOleLink::GetUpdateOptions** to retrieve the current update option.

See Also

IOleLink::SetUpdateOptions, **IOleUILinkContainer**, **OleUIEditLinks**

IOleLink::SetSourceDisplayName

Specifies the new link source of a linked object using a display name.

```
HRESULT SetSourceDisplayName(
   LPCOLESTR pszStatusText        //Display name of new link source
  );
```

Parameter

pszStatusText
[in] The display name of the new link source. It may not be NULL.

Return Values

S_OK
The display name was set successfully.

MkParseDisplayName errors
Setting the display name requires calling this function; therefore, this method may return errors generated by this function.

Comments

Notes to Callers

Your container application can call **IOleLink::SetSourceDisplayName** when the end user changes the source of a link or breaks a link. Note that this requires the linked object to create a moniker out of the display name. If you'd rather parse the display name into a moniker yourself, your container can call **IOleLink::SetSourceMoniker** instead of **IOleLink::SetSourceDisplayName**.

If you use the **OleUIEditLinks** API function to display the Links dialog box, you must implement the **IOleUILinkContainer** interface. The dialog box calls your implementations of **IOleUILinkContainer::SetLinkSource** and **IOleUILinkContainer::CancelLink**. Your implementation of these methods can call **IOleLink::SetSourceDisplayName**.

If your container application is immediately going to bind to a newly specified link source, you should call **MkParseDisplayName** and **IOleLink::SetSourceMoniker** instead, and then call **IOleLink::BindToSource** using the bind context from the parsing operation. By reusing the bind context, you can avoid redundant loading of objects that might otherwise occur.

Notes on Provided Implementation

The contract for **IOleLink::SetSourceDisplayName** does not specify when the linked object will parse the display name into a moniker. The parsing can occur before **IOleLink::SetSourceDisplayName** returns, or the linked object can store the display name and parse it only when it needs to bind to the link source. Note that parsing the display name is potentially an expensive operation because it might require binding to the link source. The provided implementation of **IOleLink::SetSourceDisplayName** parses the display name and then releases the bind context used in the parse operation. This can result in running and then stopping the link source server.

If the linked object is bound to the current link source, the implementation of **IOleLink::SetSourceDisplayName** breaks the connection.

For more information on how the linked object stores and uses the moniker to the link source, see **IOleLink::SetSourceMoniker**.

See Also

IOleLink::SetSourceMoniker, **IOleUILinkContainer**, **MkParseDisplayName**, **OleUIEditLinks**

IOleLink::SetSourceMoniker

Specifies the new link source of a linked object using a moniker.

```
HRESULT SetSourceMoniker(
    IMoniker *pmk,          //Moniker identifying new link source
    REFCLSID rclsid         //CLSID of link source
  );
```

Parameters

pmk
[in] Points to a moniker that identifies the new link source of the linked object. A value of NULL breaks the link.

rclsid
[in] Specifies the CLSID of the link source that the linked object should use to access information about the linked object when it is not bound.

Return Value

S_OK
The moniker was set successfully.

Comments

Notes to Callers

Your container application can call **IOleLink::SetSourceMoniker** when the end user changes the source of a link or breaks a link. Note that this requires your container to use the **MkParseDisplayName** API function to create a moniker out of the display name that the end user enters. If you'd rather have the linked object perform the parsing, your container can call **IOleLink::SetSourceDisplayName** instead of **IOleLink::SetSourceMoniker**.

The end user changes the source of a link or breaks a link using the Links dialog box. If you use the **OleUIEditLinks** API function to display the Links dialog box, you must implement the **IOleUILinkContainer** interface. The dialog box calls your implementations of **IOleUILinkContainer::SetLinkSource** and **IOleUILinkContainer::CancelLink**; your implementation of these methods can call **IOleLink::SetSourceMoniker**.

If the linked object is currently bound to its link source, the linked object's implementation of **IOleLink::SetSourceMoniker** closes the link before changing the moniker.

Notes on Provided Implementation

The **IOleLink** contract does not specify how the linked object stores or uses the link source moniker. The provided implementation stores the absolute moniker specified when the link is created or when the moniker is changed; it then computes and stores a relative moniker. Future implementations might manage monikers differently to provide better moniker tracking. The absolute moniker provides the complete path to the link source. The linked object uses this absolute moniker and the moniker of the compound document to compute a relative moniker that identifies the link source relative to the compound document that contains the link.

```
pmkCompoundDoc->RelativePathTo(pmkAbsolute, ppmkRelative)
```

When binding to the link source, the linked object first tries to bind using the relative moniker. If that fails, it tries to bind the absolute moniker.

When the linked object successfully binds using either the relative or the absolute moniker, it automatically updates the other moniker. The linked object also updates both monikers when it is bound to the link source and it receives a rename notification through the **IAdviseSink::OnRename** method. A container application can also use the **IOleLink::SetSourceDisplayName** method to change a link's moniker.

The linked object's implementation of **IPersistStorage::Save** saves both the relative and the absolute moniker.

See Also

IOleLink::GetSourceMoniker, **IOleLink::SetSourceDisplayName**, **IOleUILinkContainer**, **OleUIEditLinks**

IOleLink::SetUpdateOptions

Specifies how often a linked object should update its cached data.

```
HRESULT SetUpdateOptions(
  DWORD dwUpdateOpt        //Update option
 );
```

Parameter

dwUpdateOpt
[in] Specifies how often a linked object should update its cached data. The legal values for *dwUpdateOpt* are taken from the enumeration **OLEUPDATE**. For information on the **OLEUPDATE** enumeration, see the "Data Structures" section.

Return Values

S_OK
The update option was successfully set.

E_INVALIDARG
The *dwUpdateOpt* value is invalid.

Comments

Notes to Callers

Your container application should call **IOleLink::SetUpdateOptions** when the end user changes the update option for a linked object.

The end user selects the update option for a linked object using the Links dialog box. If you use the **OleUIEditLinks** API function to display this dialog box, you must implement the **IOleUILinkContainer** interface. The dialog box calls your **IOleUILinkContainer::SetLinkUpdateOptions** method to specify the update option chosen by the end user. Your implementation of this method should call the **IOleLink::SetUpdateOptions** method to pass the selected option to the linked object.

Notes on Provided Implementation

The default update option is OLEUDPATE_ALWAYS. The linked object's implementation of **IPersistStorage::Save** saves the current update option.

If OLEUDPATE_ALWAYS is specified as the update option, the linked object updates the link's caches in the following situations:

- When the update option is changed from manual to automatic, if the link source is running.
- Whenever the linked object binds to the link source.
- Whenever the link source is running and the linked object's **IOleObject::Close**, **IPersistStorage::Save**, or **IAdviseSink::OnSave** implementations are called.

For both manual and automatic links, the linked object updates the cache whenever the container application calls **IOleObject::Update** or **IOleLink::Update**.

See Also

IOleObject::Update, **IOleLink::GetUpdateOptions**, **IOleLink::Update**, **IOleUILinkContainer**, **OleUIEditLinks**

IOleLink::UnbindSource

Deactivates the connection between a linked object and its link source.

HRESULT UnbindSource(*void***);**

Return Value

S_OK
    Indicates the connection was deactivated.

Comments

You typically do not call **IOleLink::UnbindSource** directly. When it's necessary to deactivate the connection to the link source, your container typically calls **IOleObject::Close** or **IUnknown::Release**; the linked object's implementation of these methods calls **IOleLink::UnbindSource**. The linked object's **IAdviseSink::OnClose** implementation also calls **IOleLink::UnbindSource**.

Notes on Provided Implementation

The linked object's implementation of **IOleLink::UnbindSource** does nothing if the link source is not currently bound. If the link source is bound, **IOleLink::UnbindSource** calls the link source's **IOleObject::Unadvise** and **IDataObject::DUnadvise** implementations to delete the advisory connections to the link source. The **IOleLink::UnbindSource** method also calls the compound document's **IOleClientSite::LockContainer** implementation to unlock the containing compound document. This undoes the lock on the container and the advisory connections that were established in **IOleLink::BindToSource**. **IOleLink::UnbindSource** releases all the linked object's interface pointers to the link source.

See Also

IAdviseSink::OnClose, **IDataObject::DUnadvise**, **IOleObject::Close**, **IOleObject::Unadvise**, **IOleLink::BindToSource**

IOleLink::Update

Updates the compound document's cached data for a linked object. This involves binding to the link source, if it is not already bound.

```
HRESULT Update(
   IBindCtx *pbc          //Bind context to be used
  );
```

Parameter

pbc
[in] Points to the bind context to be used in binding the link source. This parameter can be NULL. The bind context caches objects bound during the binding process, contains parameters that apply to all operations using the bind context, and provides the means by which the binding implementation should retrieve information about its environment. For more information, see **IBindCtx**.

Return Values

S_OK
All caches were updated successfully.

CACHE_E_NOCACHE_UPDATED
The bind operation worked but no caches were updated.

CACHE_S_SOMECACHES_NOTUPDATED
The bind operation worked but not all caches were updated.

OLE_E_CANT_BINDTOSOURCE
Unable to bind to the link source.

Comments

Notes to Callers

Your container application should call **IOleLink::Update** if the end user updates the cached data for a linked object.

The end user can update the cached data for a linked object by choosing the Update Now button in the Links dialog box. If you use the **OleUIEditLinks** API function to display the Links dialog box, you must implement the **IOleUILinkContainer** interface. The dialog box calls your implementations of **IOleUILinkContainer::UpdateLink** when the end user chooses the Update Now button. Your implementation of that method can call **IOleLink::Update**.

Your container application can also call **IOleObject::Update** to update a linked object, because that method – when called on a linked object – calls **IOleLink::Update**.

This method updates both automatic links and manual links. For manual links, calling **IOleLink::Update** or **IOleObject::Update** is the only way to update the caches. For more information on automatic and manual links, see **IOleLink::SetUpdateOptions**.

Notes on Provided Implementation

If *pbc* is non-NULL, the linked object's implementation of **IOleLink::Update** calls **IBindCtx::RegisterObjectBound** to register the bound link source. This ensures that the link source remains running until the bind context is released.

The current caches are left intact if the link source cannot be bound.

IOleUILinkContainer, **OleUIEditLinks**

IOleObject

The **IOleObject** interface is the principal means by which an embedded object provides basic functionality to, and communicates with, its container.

When to Implement

An object application must implement this interface, along with at least IDataObject and IPersistStorage, for each type of embedded object that it supports. Although this interface contains 21 member functions, only three are both essential and nontrivial to implement: **DoVerb**, **SetHostNames**, **and Close**. Six of the member functions are optional: **SetExtent**, **InitFromData**, **GetClipboardData**, **SetColorScheme**, **SetMoniker**, and **GetMoniker**. The latter two member functions are useful mainly for enabling links to embedded objects.

When to Use

Call the methods of this interface to enable a container to communicate with an embedded object. A container must call DoVerb to activate an embedded object, SetHostNames to communicate the names of the container application and container document, and Close to move an object from a running to a loaded state. Calls to all other member functions are optional.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IOleObject Methods	Description
SetClientSite	Informs object of its client site in container.
GetClientSite	Retrieves object's client site.
SetHostNames	Communicates names of container application and container document.
Close	Moves object from running to loaded state.
SetMoniker	Informs object of its moniker.
GetMoniker	Retrieves object's moniker.
InitFromData	Initializes embedded object from selected data.
GetClipboardData	Retrieves a data transfer object from the Clipboard.
DoVerb	Invokes object to perform one of its enumerated actions ("verbs").
EnumVerbs	Enumerates actions ("verbs") for an object.
Update	Updates an object.
IsUpToDate	Checks if object is up to date.
GetUserClassID	Returns an object's class identifier.
GetUserType	Retrieves object's user-type name.
SetExtent	Sets extent of object's display area.

GetExtent	Retrieves extent of object's display area.
Advise	Establishes advisory connection with object.
Unadvise	Destroys advisory connection with object.
EnumAdvise	Enumerates object's advisory connections.
GetMiscStatus	Retrieves status of object.
SetColorScheme	Recommends color scheme to object application.

IOleObject::Advise

Establishes an advisory connection between a compound document object and the calling object's advise sink, through which the calling object receives notification when the compound document object is renamed, saved, or closed.

```
HRESULT Advise(
    IAdviseSink *pAdvSink,        //Pointer to advisory sink
    DWORD *pdwConnection          //Pointer to a token
  );
```

Parameters

pAdvSink
[in] Points to the advise sink of the calling object.

pdwConnection
[out] Points to a token that can be passed to **IOleObject::Unadvise** to delete the advisory connection.

Return Values

S_OK
Advisory connection is successfully established.

E_OUTOFMEMORY
Attempt to establish advisory connection fails, owing to insufficient memory.

Comments

The **Advise** method sets up an advisory connection between an object and its container, through which the object informs the container's advise sink of close, save, rename, and link-source change events in the object. A container calls this method, normally as part of initializing an object, to register its advisory sink with the object. In return, the object sends the container compound-document notifications by calling **IAdviseSink** or **IAdviseSink2**.

If container and object successfully establish an advisory connection, the object receiving the call returns a nonzero value through *pdwConnection* to the container. If the attempt to establish an advisory connection fails, the object returns zero. To delete an advisory connection, the container calls **IOleObject::Unadvise** and passes this nonzero token back to the object.

An object can delegate the job of managing and tracking advisory events to an OLE advise holder, to which you obtain a pointer by calling **CreateOleAdviseHolder**. The returned **IOleAdviseHolder** interface has three methods for sending advisory notifications, as well as **Advise**, **Unadvise**, and **EnumAdvise** methods that are identical to those for **IOleObject**. Calls to **IOleObject:Advise**, **Unadvise**, or **EnumAdvise** are delegated to corresponding methods in the advise holder.

To destroy the advise holder, simply call Release on the **IOleAdviseHolder** interface.

See Also

CreateOleAdviseHolder, **IOleObject::UnAdvise**, **IOleObject::EnumAdvise**, **IOleAdviseHolder::Advise**

IOleObject::Close

Changes an embedded object from the running to the loaded state. Disconnects a linked object from its link source.

```
HRESULT Close(
   DWORD dwSaveOption       //Indicates whether to save object before closing
  );
```

Parameter

dwSaveOption
[in] Indicates whether the object is to be saved as part of the transition to the loaded state. Valid values are taken from the enumeration **OLECLOSE**.

Note The OLE 2 user model recommends that object applications do not prompt users before saving linked or embedded objects, including those activated in place. This policy represents a change from the OLE 1 user model, in which object applications always prompt the user to decide whether to save changes.

Return Values

S_OK
The object closed successfully.

OLE_E_PROMPTSAVECANCELLED
The user was prompted to save but chose the Cancel button from the prompt message box.

Comments

Notes to Callers

A container application calls **IOleObject::Close** when it wants to move the object from a running to a loaded state. Following such a call, the object still appears in its container but is not open for editing. Calling **IOleObject::Close** on an object that is loaded but not running has no effect. Closing a linked object simply means disconnecting it.

Notes to Implementors

Upon receiving a call to **IOleObject::Close**, a running object should do the following:

- If the object has been changed since it was last opened for editing, it should request to be saved, or not, according to instructions specified in *dwSaveOption*. If the option is to save the object, then it should call its container's **IOleClientSite::SaveObject** interface.
- If the object has **IDataObject::DAdvise** connections with ADVF_DATAONSTOP flags, then it should send an OnDataChange notification. See **IDataObject::DAdvise** for details.
- If the object currently owns the Clipboard, it should empty it by calling **OleFlushClipboard**.
- If the object is currently visible, notify its container by calling **IOleClientSite::OnShowWindow** with the *fshow* argument set to FALSE.
- Send **IAdvise::OnClose** notifications to appropriate advise sinks.
- Finally, forcibly cut off all remoting clients by calling **CoDisconnectObject**.

If the object application is a local server (an EXE rather than a DLL), closing the object should also shut down the object application unless the latter is supporting other running objects or has another reason to remain in the running state. Such reasons might include the presence of **IClassFactory::LockServer** locks, end-user control of the application, or the existence of other open documents requiring access to the application.

Calling **IOleObject::Close** on a linked object disconnects it from, but does not shut down, its source application. A source application that is visible to the user when the object is closed remains visible and running after the disconnection and does not send an **OnClose** notification to the link container.

CoDisconnectObject, **IAdviseSink::OnClose**, **IClassFactory::LockServer**, **IDataObject::DAdvise**, **IOleClientSite::OnShowWindow**, **IOleClientSite::SaveObject**, **OLECLOSE**, **OleFlushClipboard**

IOleObject::DoVerb

Requests an object to perform an action in response to an end-user's action. The possible actions are enumerated for the object in **IOleObject::EnumVerbs**.

```
HRESULT DoVerb(
  LONG iVerb,                       //Value representing verb to be performed
  LPMSG lpmsg,                      //Ptr to Windows message
  IOleClientSite *pActiveSite,      //Ptr to active client site
  LONG lindex,                      //Reserved for future use
  HWND hwndParent,                  //Handle of window containing the object
  LPCRECT lprcPosRect               //Ptr to object's display rectangle
 );
```

Parameters

iVerb
[in] The number assigned to the verb in the **OLEVERB** structure returned by **IOleObject::EnumVerbs**.

lpmsg
[in] Points to the MSG structure describing the event (such as a double-click) that invoked the verb.

pActiveSite
[in] Points to the object's active client site, where the event occurred that invoked the verb.

lindex
[in] Reserved for future use; should be zero.

hwndParent
[in] Handle of the document window containing the object. This and *lprcPosRect* together make it possible to open a temporary window for an object, where *hwndParent* is the parent window in which the object's window is to be displayed, and *lprcPosRect* defines the area available for displaying the object window within that parent. A temporary window is useful, for example, to a multimedia object that opens itself for playback but not for editing.

lprcPosRect
[in] Points to the RECT structure containing the coordinates, in pixels, that define an object's bounding rectangle in *hwndParent*. This and *hwndParent* together enable opening multimedia objects for playback but not for editing.

Return Values

S_OK
Object successfully invoked specified verb.

OLE_E_NOT_INPLACEACTIVE
iVerb set to OLEIVERB_UIACTIVATE or OLEIVERB_INPLACEACTIVATE and object is not already visible.

OLE_E_CANT_BINDTOSOURCE
The object handler or link object cannot connect to the link source.

DV_E_LINDEX
Invalid *lindex*.

OLEOBJ_S_CANNOT_DOVERB_NOW
The verb is valid, but in the object's current state it cannot carry out the corresponding action.

OLEOBJ_S_INVALIDHWND
DoVerb was successful but *hwndParent* is invalid.

OLEOBJ_E_NOVERBS
The object does not support any verbs.

OLEOBJ_S_INVALIDVERB

Object does not recognize a positive verb number. Verb is treated as OLEIVERB_PRIMARY.

MK_E_CONNECT
Link source is across a network that is not connected to a drive on this machine.

OLE_E_CLASSDIFF
Class for source of link has undergone a conversion.

E_NOTIMPL
Object does not support in-place activation or does not recognize a negative verb number.

Comments

A "verb" is an action that an OLE object takes in response to a message from its container. An object's container, or a client linked to the object, normally calls **IOleObject::DoVerb** in response to some end-user action, such as double-clicking on the object. The various actions that are available for a given object are enumerated in an **OLEVERB** structure, which the container obtains by calling **IOleObject::EnumVerbs**. **IOleObject::DoVerb** matches the value of *iVerb* against the *iVerb* member of the structure to determine which verb to invoke.

Through **IOleObject::EnumVerbs**, an object, rather than its container, determines which verbs (i.e., actions) it supports. OLE 2 defines seven verbs that are available, but not necessarily useful, to all objects. In addition, each object can define additional verbs that are unique to it. The following table describes the verbs defined by OLE:

Verb	**Description**
OLEIVERB_PRIMARY (0L)	Specifies the action that occurs when an end-user double-clicks the object in its container. The object, not the container, determines this action. If the object supports in-place activation, the primary verb usually activates the object in place.
OLEIVERB_SHOW (-1)	Instructs an object to show itself for editing or viewing. Called to display newly inserted objects for initial editing and to show link sources. Usually an alias for some other object-defined verb.
OLEIVERB_OPEN (-2)	Instructs an object, including one that otherwise supports in-place activation, to open itself for editing in a window separate from that of its container. If the object does not support in-place activation, this verb has the same semantics as OLEIVERB_SHOW.
OLEIVERB_HIDE (-3)	Causes an object to remove its user interface from the view. Applies only to objects that are activated in-place.
OLEIVERB_UIACTIVATE (-4)	Activates an object in place, along with its full set of user-interface tools, including menus, toolbars, and its name in the title bar of the container window. If the object does not support in-place activation, it should return E_NOTIMPL.
OLEIVERB_INPLACEACTIVATE (-5)	Activates an object in place without

	displaying tools, such as menus and toolbars, that end-users need to change the behavior or appearance of the object. Single-clicking such an object causes it to negotiate the display of its user-interface tools with its container. If the container refuses, the object remains active but without its tools displayed.
OLEIVERB_DISCARDUNDOSTATE (-6)	Used to tell objects to discard any undo state that they may be maintaining without deactivating the object.

Note to Callers

Containers call **IOleObject::DoVerb** as part of initializing a newly created object. Before making the call, containers should first call **IOleObject::SetClientSite** to inform the object of its display location and **IOleObject::SetHostNames** to alert the object that it is an embedded object and to trigger appropriate changes to the user interface of the object application in preparation for opening an editing window.

Like the **OleActivate** function in OLE 1, **IOleObject::DoVerb** automatically runs the OLE server application. If an error occurs during verb execution, the object application is shut down.

If an end-user invokes a verb by some means other than selecting a command from a menu (say, by double-clicking or, more rarely, single-clicking an object), the object's container should pass a pointer (*lpmsg*) to a Windows **MSG** structure containing the appropriate message. For example, if the end-user invokes a verb by double-clicking the object, the container should pass a **MSG** structure containing WM_LBUTTONDBLCLK, WM_MBUTTONDBLCLK, or WM_RBUTTONDBLCLK. If the container passes no message, *lpmsg* should be set to NULL. The object should ignore the *hwnd* member of the passed **MSG** structure, but can use all the other **MSG** members.

If the object's embedding container calls **IOleObject::DoVerb**, the client-site pointer (*pClientSite*) passed to **DoVerb** is the same as that of the embedding site. If the embedded object is a link source, the pointer passed to **DoVerb** is that of the linking client's client site.

When **IOleObject::DoVerb** is invoked on an OLE link, it may return OLE_E_CLASSDIFF or MK_CONNECTMANUALLY. The link object returns the former error when the link source has been subjected to some sort of conversion while the link was passive. The link object returns the latter error when the link source is located on a network drive that is not currently connected to the caller's computer. The only way to connect a link under these conditions is to first call **QueryInterface**, ask for **IOleLink**, allocate a bind context, and run the link source by calling **IOleLink::BindToSource**.

Container applications that do not support general in-place activation can still use the *hwndParent* and *lprcPosRect* parameters to support in-place playback of multimedia files. Containers must pass valid *hwndParent* and *lprcPosRect* parameters to **IOleObject::DoVerb**.

Some code samples pass a *lindex* value of -1 instead of zero. The value -1 works but should be avoided in favor of zero. The *lindex* parameter is a reserved parameter, and for reasons of consistency Microsoft recommends assigning a zero value to all reserved parameters.

Notes to Implementors

In addition to the above verbs, an object can define in its **OLEVERB** structure additional verbs that are specific to itself. Positive numbers designate these object-specific verbs. An object should treat any unknown *positive* verb number as if it were the primary verb and return OLE_S_INVALIDVERB to the calling function. The object should ignore verbs with negative numbers that it does not recognize and return E_NOTIMPL.

If the verb being executed places the object in the running state, you should register the object in the Running Object Table (ROT) even if its server application doesn't support linking. Registration is important because the object at some point may serve as the source of a link in a container that supports links to embeddings. Registering the object with the ROT enables the link client to get a pointer to the object directly, instead of having to go through the object's container. To perform the registration, call **IOleClientSite::GetMoniker** to get the full moniker of the object, call the **GetRunningObjectTable** API function to get a pointer to the ROT, and then call **IRunningObjectTable::Register**.

Note When the object leaves the running state, remember to revoke the object's registration with the ROT by calling **IOleObject::Close**. If the object's container document is renamed while the object is running, you should revoke the object's registration and re-register it with the ROT, using its new name. The container should inform the object of its new moniker either by calling **IOleObject::SetMoniker** or by responding to the object's calling **IOleClientSite::GetMoniker**.

When showing a window as a result of **DoVerb**, it is very important for the object to explicitly call **SetForegroundWindow** on its editing window. This ensures that the object's window will be visible to the user even if another process originally obscured it. For more information about **SetForegroundWindow** and **SetActiveWindow**, see the *Win32 SDK*.

GetRunningObjectTable, **IOleClientSite::GetMoniker**, **IOleLink::BindToSource**, **IOleObject::Close**, **IOleObject::EnumVerbs**, **IOleObject::GetMoniker**, **IOleObject::SetMoniker**, **IRunningObjectTable::Register**, **OleRun**

SetForegroundWindow, **SetActiveWindow** in Win32

IOleObject::EnumAdvise

Enumerates the advisory connections registered for an object, so a container can know what to release prior to closing down.

```
HRESULT EnumAdvise(
  IEnumSTATDATA **ppenumAdvise        //Pointer to storage of a struct
 );
```

Parameter

ppenumAdvise
[out] Points to where the new enumerator should be returned. NULL is a legal return value, indicating that the object does not have any advisory connections. If an error is returned, this parameter must be set to NULL. Each time an object receives a call to **EnumAdvise**, it must increase the reference count on the pointer it returns. It is the caller's responsibility to call Release when it is done with the pointer.

Return Values

S_OK
Enumerator returned successfully.

E_FAIL
Unspecified error encountered.

E_NOTIMPL
EnumAdvise is not implemented.

Comments

The **EnumAdvise** method provides a way for containers to keep track of advisory connections registered for their objects. A container normally would call this function so that it can instruct an object to release each of its advisory connections prior to closing down.

IOleObject::EnumAdvise enumerates items of type **STATDATA**. Upon receiving the pointer, the container can then loop through **STATDATA** and call **IOleObject::Unadvise** for each enumerated connection.

The usual way to implement this function is to delegate the call to the **IOleAdviseHolder** interface. Only the *pAdvise* and *dwConnection* members of **STATDATA** are relevant for **IOleObject::EnumAdvise**.

See Also

IOleObject::Advise, **IOleObject::UnAdvise**

IOleObject::EnumVerbs

Exposes a pull-down menu listing the verbs available for an object in ascending order by verb number.

HRESULT EnumVerbs(
  IEnumOleVerb ***ppEnumOleVerb* //Ptr to storage of enumerator
 );

Parameter

ppEnumOleVerb
  [out] Points to where the new enumerator should be returned. If an error is returned, this parameter must be set to NULL. Each time an object receives a call to **EnumVerbs**, it must increase the reference count on the pointer the method returns. It is the caller's responsibility to call Release when it is done with the pointer.

Return Values

S_OK
  Verb(s) enumerated successfully.

OLE_S_USEREG
  Delegate to the default handler to use the entries in the registry to provide the enumeration.

OLEOBJ_E_NOVERBS
  Object does not support any verbs.

Comments

Notes to Callers

Containers call this method to expose a pull-down menu of the verbs available for their embedded objects. You may want your container to call **IOleObject::EnumVerbs** each and every time such a menu is selected in order to enable such objects as media clips, whose verbs may change while they are running, to update their menus. The default verb for a media clip, for example, changes from "Play" before it is activated to "Stop" once it is running.

Notes to Implementors

The default handler's implementation of **IOleObject::EnumVerbs** uses the registry to enumerate an object's verbs. If an object application is to use the default handler's implementation, it should return OLE_S_USEREG.

The enumeration returned is of type **IEnumOLEVERB**:

```
typedef Enum < OLEVERB > IEnumOLEVERB;
```

where **OLEVERB** is defined as:

```
typedef struct tagOLEVERB
{
     LONG    iVerb;
     LPOLESTR   lpszVerbName;
     DWORD   fuFlags;
     DWORD   grfAttribs;
} OLEVERB;
```

The following table describes the members of the **OLEVERB** structure:

OLEVERB Member	Description
iVerb	Verb number being enumerated. If the object supports OLEIVERB_OPEN, OLEIVERB_SHOW

and/or OLEIVERB_HIDE (or another predefined verb), these will be the first verbs enumerated, since they have the lowest verb numbers.

lpszVerbName

Name of the verb.

In Windows, this value, along with optional embedded ampersand characters to indicate accelerator keys, can be passed to the **AppendMenu** function.

On the Macintosh, the following metacharacters may be passed along with this value:

- ! marks the menu item with the subsequent character
- < sets the character style of the item
- (disables the item.

The metacharacters / and ^ are not permitted.

fuFlags

In Windows, a group of flags taken from the flag constants beginning with MF_ defined in **AppendMenu**. Containers should use these flags in building an object's verb menu. All Flags defined in **AppendMenu** are supported except for:

- MF_BITMAP
- MF_OWNERDRAW
- MF_POPUP

grfAttribs

In Windows, a group of flag bits taken from the enumeration **OLEVERBATTRIB**. The flag OLEVERBATTRIB_NEVERDIRTIES indicates that executing this verb will not cause the object to become dirty and is therefore in need of saving to persistent storage.

OLEVERBATTRIB_ONCONTAINERMENU indicates that this verb should be placed on the container's menu of object verbs when the object is selected. OLEIVERB_HIDE, OLEIVERB_SHOW, and OLEIVERB_OPEN never have this value set.

For more information on the Windows **AppendMenu** function, see the Microsoft *Win32 SDK*.

See Also

IOleObject::DoVerb, **OleRegEnumVerbs**

IOleObject::GetClientSite

Obtains a pointer to an embedded object's client site.

```
HRESULT GetClientSite(
  IOleClientSite **ppClientSite      //Storage of pointer to object's client site
 );
```

Parameter

ppClientSite

[out] Points to an address where the returned client-site pointer is stored. If an object does not yet know its client site, or an error has occurred, this parameter must be set to NULL. Each time an object receives a call to **GetClientSite**, it must increase the reference count on the pointer the method returns. It is the caller's responsibility to call Release when it is done with the pointer.

Return Value

S_OK

Client site pointer returned successfully.

Comments

Link clients most commonly call the **IOleObject::GetClientSite** method in conjunction with the **IOleClientSite::GetContainer** method to traverse a hierarchy of nested objects. A link client calls **IOleObject::GetClientSite** to get a pointer to the link source's client site. The client then calls **IOleClientSite::GetContainer** to get a pointer to the link source's container. Finally, the client calls **IOleContainer::QueryInterface** to get **IOleObject** and **IOleObject::GetClientSite** to get the container's client site within its container. By repeating this sequence of calls, the caller can eventually retrieve a pointer to the master container in which all the other objects are nested.

Notes to Callers

The returned client-site pointer will be NULL if an embedded object has not yet been informed of its client site. This will be the case with a newly loaded or created object when a container has passed a NULL client-site pointer to one of the object-creation helper functions but has not yet called **IOleObject::SetClientSite** as part of initializing the object.

See Also

IOleObject::SetClientSite

IOleObject::GetClipboardData

Retrieves a data object containing the current contents of the embedded object on which this method is called. Using the pointer to this data object, it is possible to create a new embedded object with the same data as the original.

```
HRESULT GetClipboardData(
  DWORD dwReserved,              //Not currently implemented
  IDataObject **ppDataObject     //Pointer to storage of interface pointer
 );
```

Parameters

dwReserved
[in] Reserved for future use; must be zero.

ppDataObject
[out] Points to an interface pointer to the data object. If an error is returned, this parameter must be set to NULL. Each time an object receives a call to **GetClipboardData**, it must increase the reference count on the pointer that the method returns. It is the caller's responsibility to call Release when it is done with the pointer.

Return Values

S_OK
The data transfer object is successfully returned.

E_NOTIMPL
GetClipboardData is not supported.

OLE_E_NOTRUNNING
The object is not running.

Comments

You can use the **GetClipboardData** method to convert a linked object to an embedded object, in which case the container application would call **IOleObject::GetClipboardData** and then pass the data received to **OleCreateFromData**. This method returns a pointer to a data object that is identical to what would have been passed to the Clipboard by a standard copy operation.

Notes to Callers

If you want a stable snapshot of the current contents of an embedded object, call **IOleObject::GetClipboardData**. Should the data change, you will need to call the function again for an updated snapshot. If you want the caller to be informed of changes that occur to the data, call **IDataObject::QueryInterface**, then call **IDataObject::DAdvise**.

Notes to Implementors

If you implement this function, you must return an **IDataObject** pointer for an object whose data will not change.

See Also

IDataObject, **IOleObject::InitFromData**, **IUnknown::QueryInterface**, **OleCreateFromData**

IOleObject::GetExtent

Retrieves a running object's current display size.

```
HRESULT GetExtent(
   DWORD dwDrawAspect,          //Value indicating object aspect
   SIZEL *psizel                //Pointer to storage of object size limit
  );
```

Parameters

dwDrawAspect
[in] Describes the aspect of the object whose limit is to be retrieved; the value is obtained from the enumeration **DVASPECT**. The most common value for this method is DVASPECT_CONTENT, which specifies a full rendering of the object within its container.

psizel
[out] Points to where the object's size is to be returned.

Return Values

S_OK
Extent information successfully returned.

E_INVALIDARG
Invalid value for *dwAspect.*

Comments

A container calls **IOleObject::GetExtent** on a running object to retrieve its current display size. If the container can accommodate that size, it will normally do so because the object, after all, knows what size it should be better than the container does. A container normally makes this call as part of initializing an object.

The display size returned by **IOleObject::GetExtent** may differ from the size last set by **IOleObject::SetExtent** because the latter method dictates the object's display space at the time the method is called but does not necessarily change the object's native size, as determined by its application.

Notes to Callers

Because a container can make this call only to a running object, the container must instead call **IViewObject2::GetExtent** if it wants to get the display size of a loaded object from its cache.

Notes to Implementors

Implementation consists of filling the *sizel* structure with an object's height and width.

See Also

IOleObject::SetExtent, **IViewObject2::GetExtent**

IOleObject::GetMiscStatus

Returns a value indicating the status of an object at creation and loading.

```
HRESULT GetMiscStatus(
   DWORD dwAspect,          //Value indicating object aspect
   DWORD *pdwStatus         //Pointer to storage of status information
  );
```

Parameters

dwAspect
[in] The aspect of an object about which status information is being requested. The value is obtained from the enumeration **DVASPECT** (see "FORMATETC Data Structure").

pdwStatus
[out] Points to where the status information is returned. May not be NULL.

Return Values

S_OK
Status information returned successfully.

OLE_S_USEREG
Delegate the retrieval of miscellaneous status information to the default handler's implementation of this method.

CO_E_CLASSNOTREG
There is no CLSID registered for the object.

CO_E_READREGDB
Error accessing the registry.

Comments

A container normally calls **IOleObject::GetMiscStatus** when it creates or loads an object in order to determine how to display the object and what types of behaviors it supports.

Objects store status information in the registry. If the object is not running, the default handler's implementation of **IOleObject::GetMiscStatus** retrieves this information from the registry. If the object is running, the default handler invokes **IOleObject::GetMiscStatus** on the object itself.

The information that is actually stored in the registry varies with individual objects. The status values to be returned are defined in the enumeration **OLEMISC**.

Notes to Implementors

Implementation normally consists of delegating the call to the default handler.

See Also

DVASPECT, **FORMATETC**, **OLEMISC**

IOleObject::GetMoniker

Returns a embedded object's moniker, which the caller can use to link to the object.

```
HRESULT GetMoniker(
  DWORD dwAssign,            //Specifies how moniker is assigned
  DWORD dwWhichMoniker,      //Specifies which moniker is assigned
  IMoniker **ppmk            //Storage of returned pointer
 );
```

Parameters

dwAssign

[in] Determines how the moniker is assigned to the object. Depending on the value of *dwAssign*, **IOleObject::GetMoniker** does one of the following:

- Obtains a moniker only if one has already been assigned,
- Forces assignment of a moniker, if necessary, in order to satisfy the call, or
- Obtains a temporary moniker.

Values for *dwAssign* are specified in the enumeration **OLEGETMONIKER**.

Note You cannot pass OLEGETMONIKER_UNASSIGN when calling **IOleObject::GetMoniker**. This value is valid only when calling **IOleClientSite::GetMoniker**.

dwWhichMoniker

[in] Specifies the form of the moniker being requested. Valid values are taken from the enumeration **OLEWHICHMK**.

ppmk

[out] Points to an address where to return the object's moniker. If an error is returned, this parameter must be set to NULL. Each time an object receives a call to GetMoniker, it must increase the reference count on the pointer the method returns. It is the caller's responsibility to call Release when it is done with the pointer.

Comments

The **IOleObject::GetMoniker** method returns an object's moniker. Like **IOleObject::SetMoniker**, this method is important only in the context of managing links to embedded objects and even in that case is optional. A potential link client that requires an object's moniker to bind to the object can call this method to obtain that moniker. The default implementation of **IOleObject::GetMoniker** calls the **IOleClientSite::GetMoniker**, returning E_UNEXPECTED if the object is not running or does not have a valid pointer to a client site.

See Also

CreateItemMoniker, **IOleClientSite::GetMoniker**, **IOleObject::SetMoniker**, **OLEGETMONIKER**, **OLEWHICHMK**

IOleObject::GetUserClassID

Returns an object's class identifier, the CLSID corresponding to the string identifying the object to an end user.

```
HRESULT GetUserClassID(
   CLSID *pClsid          //Pointer to the class identifier
  );
```

Parameter

pClsid

[out] Points to the class identifier (CLSID) to be returned. An object's CLSID is the binary equivalent of the user-type name returned by **IOleObject::GetUserType**.

Return Values

S_OK

CLSID returned successfully.

E_FAIL

An unspecified error occurred.

Comments

GetUserClassID returns the CLSID associated with the object in the registration database. Normally, this value is identical to the CLSID stored with the object, which is returned by **IPersist::GetClassID**. For linked objects, this is the CLSID of the last bound link source. If the object is running in an application different from the one in which it was created and for the purpose of being edited is emulating a class that the container application recognizes, the CLSID returned will be that of the class being emulated rather than that of the object's own class.

See Also

IOleObject::GetUserType, **IPersist::GetClassID**, **OleDoAutoConvert**, **OleGetAutoConvert**, **OleSetAutoConvert**, **GetConvertStg**, **SetConvertStg**

IOleObject::GetUserType

Retrieves the user-type name of an object for display in user-interface elements such as menus, list boxes, and dialog boxes.

```
HRESULT GetUserType(
   DWORD dwFormOfType,          //Specifies form of type name
   LPOLESTR *pszUserType        //Pointer to storage of string pointer
  );
```

Parameters

dwFormOfType
: [in] A value specifying the form of the user-type name to be presented to users. Valid values are obtained from the **USERCLASSTYPE** enumeration.

pszUserType
: [out] Points to where a pointer to the user-type string will be placed. The caller must free *lpszUserType* using the current **IMalloc** instance. If an error is returned, this parameter must be set to NULL.

Return Values

S_OK
: The object's user-type name is successfully returned.

OLE_S_USEREG
: Delegate to the default handler's implementation using the registry to provide the requested information.

Comments

Containers call **IOleObject::GetUserType** in order to represent embedded objects in list boxes, menus, and dialog boxes by their normal, user-recognizable names. Examples include "Word Document," "Excel Chart," and "Paintbrush Object." The information returned by **IOleObject::GetUserType** is the user-readable equivalent of the binary class identifier returned by **IOleObject::GetUserClassID**.

Notes to Callers

The default handler's implementation of **IOleObject::GetUserType** uses the object's class identifier (the *pClsid* parameter returned by **IOleObject::GetUserClassID**) and the *dwFormOfType* parameter together as a key into the registry. If an entry is found that matches the key exactly, then the user type specified by that entry is returned. If only the CLSID part of the key matches, then the lowest-numbered entry available (usually the full name) is used. If the CLSID is not found, or there are no user types registered for the class, the user type currently found in the object's storage is used.

Notes to Implementors

You can use the implementation provided by the default handler by returning OLE_S_USEREG as your application's implementation of this method. If the user type name is an empty string, the message "Unknown Object" is returned.

You can call the OLE helper function **OleRegGetUserType** to return the appropriate user type.

See Also

IOleObject::SetHostNames, **IOleObject::GetUserClassID**, **OleRegGetUserType**, **ReadFmtUserTypeStg**, **USERCLASSTYPE**

IOleObject::InitFromData

Initializes a newly created object with data from a specified data object, which can reside either in the same container or on the Clipboard.

```
HRESULT InitFromData(
   IDataObject *pDataObject,        //Pointer to data object
   BOOL fCreation,                  //Specifies how object is created
   DWORD dwReserved                 //Not used in OLE 2
  );
```

Parameters

pDataObject
[in] Points to the data object from which the initialization data is to be obtained. This parameter can be NULL, which indicates that the caller wants to know if it is worthwhile trying to send data; that is, whether the container is capable of initializing an object from data passed to it. The data object to be passed can be based on either the current selection within the container document or on data transferred to the container from an external source.

fCreation
[in] TRUE indicates the container is inserting a new object inside itself and initializing that object with data from the current selection; FALSE indicates a more general programmatic data transfer, most likely from a source other than the current selection.

dwReserved
[in] Reserved for future use; must be zero.

Return Values

S_OK
If *pDataObject* is not NULL, the object successfully attempted to initialize itself from the provided data; if *pDataObject* is NULL, the object is able to attempt a successful initialization .

S_FALSE
If *pDataObject* is not NULL, the object made no attempt to initialize itself; if *pDataObject* is NULL, the object cannot attempt to initialize itself from the data provided.

E_NOTIMPL
The object does not support **InitFromData**.

OLE_E_NOTRUNNING
The object is not running and therefore cannot perform the operation.

Comments

This method enables a container document to insert within itself a new object whose content is based on a current data selection within the container. For example, a spreadsheet document may want to create a graph object based on data in a selected range of cells.

Using this method, a container can also replace the contents of an embedded object with data transferred from another source. This provides a convenient way of updating an embedded object.

Notes to Callers

Following initialization, the container should call **IOleObject::GetMiscStatus** to check the value of the **OLEMISC_INSERTNOTREPLACE** bit. If the bit is on, the new object inserts itself following the selected data. If the bit is off, the new object replaces the selected data.

Notes to Implementors

A container specifies whether to base a new object on the current selection by passing either TRUE or FALSE to the *fCreation* parameter.

If *fCreation* is TRUE, the container is attempting to create a *new* instance of an object, initializing it with the selected data specified by the data object.

If *fCreation* is FALSE, the caller is attempting to replace the object's current contents with that pointed to by *pDataObject*. The usual constraints that apply to an object during a paste operation should be applied here. For example, if the type of the data provided is unacceptable, the object should fail to initialize and return S_FALSE.

If the object returns S_FALSE, it cannot initialize itself from the provided data.

See Also

IOleObject::GetMiscStatus, **IDataObject::SetData**

IOleObject::IsUpToDate

Checks recursively whether or not an object is up to date.

HRESULT IsUpToDate();

Return Values

S_OK
Object is up to date.

S_FALSE
Object is not up to date.

OLE_E_UNAVAILABLE
Status of object cannot be determined in a timely manner.

Comments

The **IsUpToDate** method provides a way for containers to check recursively whether or not all objects are up to date.That is, when the container calls this method on the first object, the object in turn calls it for all its own objects, and they in turn for all of theirs, until all objects have been checked.

Notes to Implementors

Because of the recursive nature of **IOleObject:IsUpToDate**, determining whether an object is out-of-date, particularly one containing one or more other objects, can be as time-consuming as simply updating the object in the first place. If you would rather avoid lengthy queries of this type, make sure that **IOleObject::IsUpToDate** returns OLE_E_UNAVAILABLE. In cases where the object to be queried is small and contains no objects itself, thereby making an efficient query possible, this method can return either S_OK or S_FALSE.

See Also

IOleObject::UpDate

IOleObject::SetClientSite

Informs an embedded object of its display location, called a "client site," within its container.

```
HRESULT SetClientSite(
  IOleClientSite *pClientSite        //Pointer to an embedded object's client site
 );
```

Parameter

pClientSite
[in] Points to the container application's client-site interface.

Return Values

S_OK
Client site successfully set.

E_UNEXPECTED
Object is not embedded in a container.

Comments

Within a compound document, each embedded object has its own client site – the place where it is displayed and through which it receives information about its storage, user interface, and other resources. **IOleObject::SetClientSite** is the only method enabling an embedded object to obtain a pointer to its client site.

Notes to Callers

A container can notify an object of its client site either at the time the object is created or, subsequently, when the object is initialized.

When creating or loading an object, a container may pass a client-site pointer (along with other arguments) to one of the following helper functions: **OleCreate**, **OleCreateFromFile**, **OleCreateFromData** or **OleLoad**. These helper functions load an object handler for the new object and call **IOleObject::SetClientSite** on the container's behalf before returning a pointer to the new object.

Passing a client-site pointer informs the object handler that the client site is ready to process requests. If the client site is unlikely to be ready immediately after the handler is loaded, you may want your container to pass a NULL client-site pointer to the helper function. The NULL pointer says that that no client site is available and thereby defers notifying the object handler of the client site until the object is initialized. In response, the helper function returns a pointer to the object, but upon receiving that pointer the container must call **SetClientSite** as part of initializing the new object.

Notes to Implementors

Implementation consists simply of incrementing the reference count on, and storing, the pointer to the client site.

See Also

IOleClientSite, **IOleObject::GetClientSite**, **OleCreate**, **OleCreateFromFile**, **OleCreateFromData**, **OleLoad**

IOleObject::SetColorScheme

Specifies the color palette that the object application should use when it edits the specified object.

```
HRESULT SetColorScheme(
   LOGPALETTE *pLogpal       //Pointer to a structure
  );
```

Parameter

pLogpal
[in] Points to a **LOGPALETTE** structure that specifies the recommended palette.

Return Values

S_OK
Color palette received successfully.

E_NOTIMPL
Object does not support setting palettes.

OLE_E_PALETTE
Invalid **LOGPALETTE** structure pointed to by *lpLogPal*.

OLE_E_NOTRUNNING
Object must be running to perform this operation.

Comments

The **IOleObject::SetColorScheme** method sends the container application's recommended color palette to the object application, which is not obliged to use it.

Notes to Implementors

Upon receiving the palette, the object application should:

1. Allocate and fill in its own **LOGPALETTE** structure with the colors specified in the container application's **LOGPALETTE** structure.
2. Call **CreatePalette** to create a palette from the resulting **LOGPALETTE** structure. This palette can be used to render objects and color menus as the user edits objects in the document.

The first palette entry in the **LOGPALETTE** structure specifies the foreground color recommended by the container. The second palette entry specifies the recommended background color. The first half of the remaining palette entries are fill colors and the second half are colors for the lines and text.

Container applications typically specify an even number of palette entries. If a container specifies an odd number of entries, the object application should assume that the first half of the total entries plus one designate fill colors, while the remainder designate line and text colors. For example, if there are five entries, the first three should be interpreted as fill colors and the last two as line and text colors.

IOleObject::SetExtent

Informs an object of how much display space its container has assigned it.

HRESULT SetExtent(
 DWORD *dwDrawAspect*,
 SIZEL **pSizel*
);

Parameters

dwDrawAspect
 [in] Describes which form, or "aspect," of an object is to be displayed. The object's container obtains this value from the enumeration **DVASPECT** (see "**FORMATETC** Data Structure"). The most common aspect is DVASPECT_CONTENT, which specifies a full rendering of the object within its container. An object can also be rendered as an icon, a thumbnail version for display in a browsing tool, or a print version, which displays the object as it would be rendered using the File Print command.

psizel
 [in] Specifies the size limit for the object.

Return Values

S_OK
 The object has resized successfully.

E_FAIL
 The object's size is fixed.

OLE_E_NOTRUNNING
 The object is not running.

Comments

A container calls **IOleObject::SetExtent** when it needs to dictate to an embedded object the size at which it will be displayed. Often, this call occurs in response to an end user resizing the object window. Upon receiving the call, the object, if possible, should recompose itself gracefully to fit the new window.

Whenever possible, a container seeks to display an object at its finest resolution, sometimes called the object's *native size*. All objects, however, have a default display size specified by their applications, and in the absence of other constraints, this is the size they will use to display themselves. Since an object knows its optimum display size better than does its container, the latter normally requests that size from a running object by calling **IOleObject::GetExtent**. Only in cases where the container cannot accommodate the value returned by the object does it override the object's preference by calling **IOleObject::SetExtent**.

Notes to Callers

You can call **SetExtent** on an object only when the object is running. If a container resizes an object while an object is not running, the container should keep track of the object's new size but defer calling **IOleObject::SetExtent** until a user activates the object. If the OLEMISC_RECOMPOSEONRESIZE bit is set on an object, its container should force the object to run before calling **OleObject::SetExtent**.

As noted above, a container may want to delegate responsibility for setting the size of an object's display site to the object itself, by calling **IOleObject::GetExtent**.

Notes to Implementors

You may want to implement this method so that your object rescales itself to match as closely as possible the maximum space available to it in its container.

If an object's size is fixed, that is, if it cannot be set by its container, **OleObject::SetExtent** should return E_FAIL. This is always the case with linked objects, whose sizes are set by their link sources, not by their containers.

See Also

IAdviseSink::OnViewChange, **IOleObject::GetExtent**, **IViewObject2::GetExtent**

IOleObject::SetHostNames

Provides an object with the name of its container application and the compound document in which it is embedded.

```
HRESULT SetHostNames(
    LPCOLESTR szContainerApp,        //Pointer to name of container application
    LPCOLESTR szContainerObj         //Pointer to name of container document
  );
```

Parameters

szContainerApp
[in] Points to the name of the container application in which the object is running.

szContainerObj
[in] Points to the name of the compound document that contains the object. If you do not wish to display the name of the compound document, you can set this parameter to NULL.

Return Value

S_OK
Window title information set successfully.

Comments

When a container initializes an embedded object, it calls this function to inform the object of the names of both the container application and container document. When the object is opened for editing, it displays these names in the title bar of its window.

Notes to Callers

Call **SetHostNames** only for embedded objects, because for linked objects, the link source supplies its own separate editing window and title bar information.

Notes to Implementors

An object's application of **SetHostNames** should include whatever modifications to its user interface may be appropriate to an object's embedded state. Such modifications typically will include adding and removing menu commands and altering the text displayed in the title bar of the editing window.

The complete window title for an embedded object in an SDI container application or an MDI application with a maximized child window should appear as follows:

<*object application name*> - <*object short type*> in <*container document*>

Otherwise, the title should be:

<*object application name*> - <*container document*>

The "object short type" refers to a form of an object's name short enough to be displayed in full in a list box.

Since these identifying strings are not stored as part of the persistent state of the object, **IOleObject::SetHostNames** must be called each time the object loads or runs.

See Also

IOleObject::GetUserType

IOleObject::SetMoniker

Notifies an object of its container's moniker, the object's own moniker relative to the container, or the object's full moniker.

```
HRESULT SetMoniker(
    DWORD dwWhichMoniker,        //Value specifying moniker being set
    IMoniker *pmk                //Pointer to moniker
  );
```

Parameters

dwWhichMoniker
[in] Specifies which moniker is passed in *pmk*. Values are from the enumeration **OLEWHICHMK**.

pmk
[in] Points to where to return the moniker.

Return Values

S_OK
Moniker successfully set.

E_FAIL
No client site for object.

Comments

A container that supports links to embedded objects must be able to inform an embedded object when its moniker has changed. Otherwise, subsequent attempts by link clients to bind to the object will fail.The **IOleObject::SetMoniker** method provides one way for a container to communicate this information.

The container can pass either its own moniker, an object's moniker relative to the container, or an object's full moniker. In practice, if a container passes anything other than an object's full moniker, each object calls the container back to request assignment of the full moniker, which the object requires to register itself in the running object table.

The moniker of an object relative to its container is stored by the object handler as part of the object's persistent state. The moniker of the object's container, however, must not be persistently stored inside the object because the container can be renamed at any time.

Notes to Callers

A container calls **IOleObject::SetMoniker** when the container has been renamed, and the container's embedded objects currently or can potentially serve as link sources. Containers call **SetMoniker** mainly in the context of linking because an embedded object is already is aware of its moniker. Even in the context of linking, calling this method is optional because objects can call **IOleClientSite::GetMoniker** to force assignment of a new moniker.

Note to Implementors

Upon receiving a call to **SetMoniker**, an object should register its full moniker in the running object table and send OnRename notification to all advise sinks that exist for the object.

See Also

CreateItemMoniker, **IAdviseSink::OnRename**, **IOleClientSite::GetMoniker**, **IOleObject::GetMoniker**

IOleObject::Unadvise

Deletes a previously established advisory connection.

```
HRESULT Unadvise(
  DWORD dwConnection        //A token
 );
```

Parameter

dwConnection
[in] Contains a token of nonzero value, which was previously returned from **IOleObject::Advise** through its *pdwConnection* parameter.

Return Values

S_OK
Advisory connection deleted successfully.

E_FAIL
Unspecified error encountered.

OLE_E_NOCONNECTION
dwConnection is not represent a valid advisory connection.

Comments

Normally, containers call **IOleObject::Unadvise** at shutdown or when an object is deleted. In certain cases, containers can call this method on objects that are running but not currently visible as a way of reducing the overhead of maintaining multiple advisory connections. The easiest way to implement this method is to delegate the call to **IOleAdviseHolder::Unadvise**.

See Also

IOleObject::Advise, **IOleObject::EnumAdvise**, **IOleAdviseHolder::Unadvise**

IOleObject::Update

Updates an object handler's or link object's data or view caches.

HRESULT Update();

Return Values

S_OK
All caches are up to date.

E_FAIL
An unspecified error occurred.

OLE_E_CANT_BINDTOSOURCE
Cannot run object to get updated data. The object is for some reason unavailable to the caller.

CACHE_E_NOCACHE_UPDATED
No caches were updated.

CACHE_S_SOMECACHES_NOTUPDATED
Some caches were not updated.

Comments

The **Update** method provides a way for containers to keep data updated in their linked and embedded objects. A link object can become out-of-date if the link source has been updated. An embedded object that contains links to other objects can also become out of date. An embedded object that does not contain links cannot become out of date because its data is not linked to another source.

Notes to Implementors

When a container calls a link object's **IOleObject::Update** method, the link object finds the link source and gets a new presentation from it. This process may also involve running one or more object applications, which could be time-consuming.

When a container calls an embedded object's **IOleObject::Update** method, it is requesting the object to update all link objects it may contain. In response, the object handler recursively calls **IOleObject::Update** for each of its own linked objects, running each one as needed.

See Also

IOleObject::IsUpToDate

IOleUILinkContainer

The **IOleUILinkContainer** interface is implemented by containers and used by OLE common dialogs. It supports these dialogs by providing the methods needed to manage a container's links.

The **IOleUILinkContainer** methods enumerate the links associated with a container, and specify how they should be updated, automatically or manually. They change the source of a link and obtain information associated with a link. They also open a link's source document, update links, and break a link to the source.

When to Implement

You must implement this interface if you are creating a container application that will use the Links, Change Source, or Update Links dialogs, as well as the Object Properties dialog, which uses this interface indirectly. The Links dialog calls back to the container application to perform OLE functions that manipulate the links within the container.

When to Use

OLE common dialogs use only this interface to manage the properties of a container's links. They can also use it to manage non-OLE (DDE and other container-specific) links.

Methods in Vtable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleUILinkContainer Methods	Description
GetNextLink	Enumerates the links in the container.
SetLinkUpdateOptions	Sets update options.
GetLinkUpdateOptions	Determines current update options for the link.
SetLinkSource	Changes the source of the link.
GetLinkSource	Returns Links dialog information about the link.
OpenLinkSource	Opens a link's source.
UpdateLink	Forces a link to connect to its source and update.
CancelLink	Disconnects selected links.

See Also

OleUIEditLinks, **OleUIChangeSource**, **OleUIUpdateLinks**, **OleUIObjectProperties**, **OLEUIEDITLINKS**

IOleUILinkContainer::CancelLink

Disconnects the selected links.

```
HRESULT CancelLink(
   DWORD dwLink          //Unique 32-bit link identifier
  );
```

Parameter

dwLink
A container-defined unique 32-bit identifier for a single link. Containers can use the pointer to the link's container site for this value.

Return Values

S_OK
Successfully disconnected the selected links.

E_FAIL
Unable to disconnect the selected links.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comments

Notes To Callers

Call **CancelLink** when the user selects the Break Link button from the Links dialog. The link should be converted to a picture. The Links dialog will not be dismissed for OLE links.

Notes To Implementors

For OLE links, **OleCreateStaticFromData** can be used to create a static picture object using the **IDataObject** interface of the link as the source.

See Also

IDataObject, **OleCreateStaticFromData**

IOleUILinkContainer::GetLinkSource

Returns information about a link that can be displayed in the UI.

```
HRESULT GetLinkSource(
    DWORD dwLink,                          //Unique 32-bit link identifier
    LPTSTR FAR* lplpszDisplayName,         //Length of display name portion
    ULONG FAR* lplenFileName,              //Length of filename portion
    LPTSTR FAR* lplpszFullLinkType,        //Full link type string
    LPTSTR FAR* lplpszShortLinkType,       //Short link type string
    BOOL FAR* lpfSourceAvailable,          //Availability of link
    BOOL FAR* lpfIsSelected                //Indicates that link entry should be selected in listbox
  );
```

Parameters

dwLink
A container-defined unique 32-bit identifier for a single link. See **IOleUILinkContainer::GetNextLink**.

lplpszDisplayName
[out] Points to the allocated full link source display name string. The Links dialog will free this string.

lplenFileName
[out] Points to the length of the leading filename portion of the *lplpszDisplayName* string. If the link source is not stored in a file, then **lplenFileName* should be 0. For OLE links, call **IOleLink::GetSourceDisplayName**.

lplpszFullLinkType
[out] Points to the allocated full link type string that is displayed at the bottom of the Links dialog. The Links dialog will free this string. For OLE links, this should be the full User Type name. Use **IOleObject::GetUserType**, specifying USERCLASSTYPE_FULL for *dwFormOfType*.

lplpszShortLinkType
[out] Points to the allocated short link type string that is displayed in the listbox of the Links dialog. The Links dialog will free this string. For OLE links, this should be the short User Type name. Use **IOleObject::GetUserType**, specifying USERCLASSTYPE_SHORT for *dwFormOfType*.

lpfSourceAvailable
Returns FALSE if it is known that a link is unavailable since the link is to some known but unavailable document. Certain options, such as Update Now, are disabled (grayed in the UI) for such cases.

lpfIsSelected
Used to tell the Edit Links dialog that this link's entry should be selected in the dialog's multi-slelection listbox. **OleUIEditLinks** calls this method at least once for each item to be placed in the links list. If none of them return TRUE, then none of them will be selected when the dialog is first displayed. If all of them return TRUE, then all will be displayed. That is, it returns TRUE if this link is currently part of the selection in the underlying document, FALSE if not. Any links that are selected in the underlying document are selected in the dialog; this way, the user can select a set of links and use the dialog to update them or change their source(s) simultaneously.

Return Values

S_OK
Successfully returned link information.

E_FAIL
Unable to return link information.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comments

Notes To Callers

Call this method during dialog initialization, after returning from the Change Source dialog.

See Also

IOleLink::GetSourceDisplayName, **IOleObject::GetUserType**, **USERCLASSTYPE**, **OleUIChangeSource**, **OLEUICHANGESOURCE**

IOleUILinkContainer::GetLinkUpdateOptions

Determine the current update options for a link.

```
HRESULT GetNextLink(
   DWORD dwLink,                          //Unique 32-bit link identifier
   DWORD FAR * lpdwUpdateOpt              //Address to return update option
  );
```

Parameters

dwLink
A container-defined unique 32-bit identifier for a single link. See **IOleUILinkContainer::GetNextLink**.

lpdwUpdateOpt
The address to return the current update options.

Return Values

S_OK
Successfully determined update options.

E_FAIL
Unable to determine update options.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comment

Notes To Implementors

Containers can implement this method for OLE links simply by calling **IOleLink::SetUpdateOptions** on the link object.

See Also

IOleUILinkContainer::GetNextLink, **IOleUILinkContainer::SetLinkUpdateOptions**, **IOleLink::SetUpdateOptions**

IOleUILinkContainer::GetNextLink

Enumerates the links in a container.

```
DWORD GetNextLink(
   DWORD dwLink        //Unique 32-bit link-identifier, indicating the current link
  );
```

Parameter

dwLink
A container-defined unique 32-bit identifier for a single link. This value is only passed to other methods on this interface, so it can be any value that uniquely identifies a link to the container. Containers frequently use the pointer to the link's container site object for this value.

Return Values

Returns a container's link identifiers in sequence; NULL if it has returned the last link.

Notes to Callers

Call this method to enumerate the links in a container. If the value passed in *dwLink* is NULL, then the container should return the first link's 32-bit identifier. If *dwLink* identifies the last link in the container, then the container should return NULL.

See Also

IOleUILinkContainer::SetLinkUpdateOptions, **IOleUILinkContainer::GetLinkUpdateOptions**

IOleUILinkContainer::OpenLinkSource

Opens the link's source.

```
HRESULT OpenLinkSource(
   DWORD dwLink          //Unique 32-bit link identifier
  );
```

Parameter

dwLink
A container-defined unique 32-bit identifier for a single link. Containers can use the pointer to the link's container site for this value.

Return Values

S_OK
Successfully opened the link's source.

E_FAIL
Unable to open the links source.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comments

Notes To Callers

The **OpenLinkSource** method is called when the Open Source button is selected from the Links dialog. For OLE links, call **IOleObject::DoVerb**, specifying OLEIVERB_SHOW for *iVerb*.

See Also

IOleObject::DoVerb, **OLEVERB**

IOleUILinkContainer::SetLinkSource

Changes the source of a link.

```
HRESULT SetLinkSource(
   DWORD dwLink,                 //Unique 32-bit link identifier
   LPTSTR lpszDisplayName,       //Source string to parse
   ULONG FAR* lenFileName,       //The length of the filename portion
   ULONG FAR* pchEaten,          //Number of characters successfully parsed
   BOOL fValidateSource          //Specifies whether or not moniker should be validated
  );
```

Parameters

dwLink
A container-defined unique 32-bit identifier for a single link. See **IOleUILinkContainer::GetNextLink** .

lpszDisplayName
Points to new source string to be parsed.

lenFileName
The length of the leading filename portion of the *lpszDisplayName* string. If the link source is not stored in a file, then *lenFileName* should be 0. For OLE links, call **IOleLink::GetSourceDisplayName**.

pchEaten
[out] Points to the number of characters successfully parsed in *lpszDisplayName*.

fValidateSource
TRUE if the moniker should be validated; for OLE links, **MkParseDisplayName** should be called. FALSE if the moniker should not be validated. If possible, the link should accept the unvalidated source, and mark itself as unavailable.

Return Values

S_OK
Successfully changed the links source.

E_FAIL
Unable to change the links source.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comments

Notes To Callers

Call this method from the Change Source dialog, with *fValidateSource* initially set to TRUE. Change Source can be called directly or from the Links dialog. If this call to **SetLinkSource** returns an error (e.g., **MkParseDisplayName** failed because the source was unavailable), then you should display an Invalid Link Source message, and the user should be allowed to decide whether or not to fix the source. If the user chooses to fix the source, then the user should be returned to the Change Source dialog with the invalid portion of the input string highlighted. If the user chooses not to fix the source, then **SetLinkSource** should be called a second time with *fValidateSource* set to FALSE, and the user should be returned to the Links dialog with the link marked Unavailable.

See Also

MkParseDisplayName

IOleUILinkContainer::SetLinkUpdateOptions

Sets a link's update options to Automatic (OLEUPDATE_ALWAYS) or Manual (OLEUPDATE_ONCALL).

```
HRESULT SetLinkUpdate(
  DWORD dwLink,            //Unique 32-bit link identifier
  DWORD dwUpdateOpt        //Update options
 );
```

Parameters

dwLink
A container-defined unique 32-bit identifier for a single link. See **IOleUILinkContainer::GetNextLink**.

dwUpdateOpt
Specifies the update options, which can be Automatic (OLEUPDATE_ALWAYS) or Manual (OLEUPDATE_ONCALL).

Return Values

S_OK
Successfully set the links update options.

E_FAIL
Unable to set the links update options.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comments

The user selects update options from the Links dialog.

Notes To Implementors

Containers can implement this method for OLE links by simply calling **IOleLink::SetUpdateOptions** on the link object.

See Also

IOleUILinkContainer::GetNextLink, **IOleUILinkContainer::GetLinkUpdateOptions**, **IOleLink::SetUpdateOptions**

IOleUILinkContainer::UpdateLink

Forces selected links to connect to their source and retrieve current information.

```
HRESULT UpdateLink(
  DWORD dwLink,            //Link identifier
  DWORD fErrorMessage,     //Determines whether or not caller should display error message
  DWORD fReserved          //Reserved for future use
 );
```

Parameters

dwLink
A container-defined unique 32-bit identifier for a single link. Containers can use the pointer to the link's container site for this value.

fErrorMessage
Determines whether or not the caller (implementor of **IOleUILinkContainer**) should show an error message upon failure to update a link. The Update Links dialog sets this to FALSE. The Object Properties and Links dialogs set it to TRUE.

fReserved
Reserved for future use. Currently, this parameter should always be set to FALSE.

Return Values

S_OK
Successfully updated linked objects.

E_FAIL
Unable to update linked objects.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comments

Notes To Callers

Call this method with *fErrorMessage* set to TRUE in cases where the user expressly presses a button to have a link updated, that is, presses the Links' Update Now button. Call it with FALSE in cases where the container should never display an error message, that is, where a large set of operations are being performed and the error should be propagated back to the user later, as might occur with the Update links progress meter. Rather than providing one message for each failure, assuming there are failures, provide a single message for all failures at the end of the operation.

Notes To Implementors

For OLE links, call **IOleObject::Update**.

See Also

IOleObject::Update

IOleUILinkInfo

IOleUILinkInfo is an extension of the **IOleUILinkContainer** interface. It returns the time that an object was last updated, which is link information that **IOleUILinkContainer** does not provide.

When To Implement

You must implement this interface so your container can support the "Link" page of the Object Properties dialog. If you are writing a container that does not implement links, you do not need to implement this interface.

Methods in Vtable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleUILinkContainer Methods	Description
GetNextLink	Enumerates the links in the container.
SetLinkUpdateOptions	Sets update options.
GetLinkUpdateOptions	Determines current update options for the link.
SetLinkSource	Changes the source of the link.
GetLinkSource	Returns Links dialog information about link.
OpenLinkSource	Opens a link's source.
UpdateLink	Forces a link to connect to its source and update.
CancelLink	Breaks the link.

IOleUILinkInfo Methods	Description
GetLastUpdate	Determines the last time the object was updated, whether automatically or manually.

IOleUILinkInfo::GetLastUpdate

Indicates when the object was last updated.

```
HRESULT GetLastUpdate(
   DWORD dwLink,                        //Object's identifier
   FILETIME FAR * lpLastUpdate          //Time object was last updated
  );
```

Parameters

dwLink
A container-defined unique 32-bit identifier for a single link. Containers can use the pointer to the link's container site for this value.

lpLastUpdate
Points to the time that the object was last updated.

Return Values

S_OK
Successfully returned link information.

E_FAIL
Unable to return link information.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comment

Notes To Implementors

If the time that the object was last updated is known, copy it to **lpLastUpdate*. If it is not known, then leave **lpLastUpdate* unchanged and Unknown will be displayed in the link page.

IOleUIObjInfo

This interface is implemented by containers and used by the container's Object Properties dialog and by the Convert dialog. It provides information used by the General and View pages of the Object Properties dialog, which display information about the object's size, location, type, and name. It also allows the object to be converted via the Convert dialog. The View page allows the object's icon to be modified from its original form, and its display aspect to be changed (iconic versus content). Optionally, you can have your implementation of this interface allow the scale of the object to be changed.

When To Implement

You must implement this interface so your container application can support the **OleUIObjectProperties** function and the dialog that it implements.

When To Use

Use this interface when you need to get and set information required by the Object Properties dialog, and to support the Convert dialog.

Methods in Vtable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleUILinkContainer Methods	Description
GetNextLink	Enumerates the links in the container.
SetLinkUpdateOptions	Sets update options.
GetLinkUpdateOptions	Determines current update options for the link.
SetLinkSource	Changes the source of the link.
GetLinkSource	Returns Links dialog information about link.
OpenLinkSource	Opens a link's source.
UpdateLink	Forces a link to connect to its source and update.
CancelLink	Breaks the link.

IOleUIObjInfo Methods	Description
GetObjectInfo	Gets general information about the object.
GetConvertInfo	Gets information that is used for the Convert dialog.
ConvertObject	Converts the object once the user selects a destination type.
GetViewInfo	Gets the current icon, aspect, and scale of the object.
SetViewInfo	Sets the current icon, aspect, and scale of the object.

See Also

OleUIObjectProperties

IOleUIObjInfo::ConvertObject

Converts the object to the type of the new CLSID.

```
HRESULT ConvertObject(
   DWORD dwObject,          //32-bit object identifier
   REFCLSID clsidNew        //CLSID to convert the object to
  );
```

Parameters

dwObject
A unique 32-bit identifier for the object.

clsidNew
The CLSID to convert the object to.

Return Values

S_OK
Successfully returned link information.

E_FAIL
Unable to return link information.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comment

Notes To Implementors

Your implementation of **ConvertObject** needs to convert the object to the CLSID specified. The actions taken by the convert operation are similar to the actions taken after calling **OleUIConvert**.

See Also

OleUIConvert

IOleUIObjInfo::GetConvertInfo

Gets the conversion information associated with the specified object.

```
HRESULT GetConvertInfo(
   DWORD dwObject,                          //32-bit object identifier
   CLSID FAR * lpClassID,                   //CLSID of the object
   WORD FAR *lpwFormat,                     //CLIPFORMAT of the object's storage
   CLSID FAR * lpConvertDefaultClassID,     //Default class to convert to
   LPCLSID FAR * lplpClsidExclude,          //Excluded CLSIDs
   UINT FAR * lpcClsidExclude               //Number of CLSIDs in lplpClsidExclude
  );
```

Parameters

dwObject
A unique 32-bit identifier for the object.

lpClassID
[out] Points to the location to return the object's CLSID.

lpwFormat
[out] Points to the clipboard format of the object.

lpConvertDefaultClassID
[out] Points to the default class, selected from the UI, to convert the object to.

lplpClsidExclude
[out] Points to to an array of CLSIDs that should be excluded from the UI for this object. May be NULL, if *lplpClsidExclude* is 0 (zero).

lpcClsidExclude
[out] The number of CLSIDs in *lplpClsidExclude*. May be 0 (zero).

Return Values

S_OK
Successfully returned link information.

E_FAIL
Unable to return link information.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comment

Notes To Implementors

You must fill in the CLSID of the object at a minimum. *lpwFormat* may be left at zero if the format of the storage is unknown.

IOleUIObjInfo::GetObjectInfo

Gets size, type, name and location information about an object.

```
HRESULT GetObjectInfo(
   DWORD dwObject,                    //32-bit object identifier
   DWORD FAR *lpdwObjSize,            //Points to object's size
   LPTSTR FAR *lplpszLabel,           //Points to object's label.
   LPTSTR FAR * lplpszType,           //Points to object's "long" type
   LPTSTR FAR * lplpszShortType,      //Points to object's "short" type
   LPTSTR FAR * lplpszLocation        //Points to the objects source
  );
```

Parameters

dwObject
A unique 32-bit identifier for the object.

lpdwObjSize
[out] The object's size, in bytes, on disk. This may be an approximate value.

lplpszLabel
[out] Points to the object's label. May be NULL, which indicates that the implementation should not fill this in.

lplpszType
[out] Points to the object's "long" type. May be NULL, which indicates that the implementation should not fill this in.

lplpszShortType
[out] Points to the object's "short" type. May be NULL, which indicates that the implementation should not fill this in.

lplpszLocation
[out] Points to the object's source. May be NULL, which indicates that the implementation should not fill this in.

Return Values

S_OK
Successfully returned object information.

E_FAIL
Unable to get object information.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

Comment

The strings and the object's size are displayed in the object properties "General" page.

Notes To Implementors

Your implementation of **GetObjectInfo** should place each of the object's attributes in the out parameters provided. Set *lpdwObjSize* to (DWORD)-1 when the size of the object is unknown. Allocate all strings (the rest of the params) with the OLE task allocator obtained via **CoGetMalloc**, as is standard for all OLE interfaces with [out] string parameters, or you can simply use **CoTaskMemAlloc**.

See Also

CoGetMalloc, **CoTaskMemAlloc**

IOleUIObjInfo::GetViewInfo

Gets the view information associated with the object.

```
HRESULT GetViewInfo(
    DWORD dwObject,                    //32-bit object identifier
    HGLOBAL FAR * phMetaPict,          //Object's current icon
    DWORD * pdvAspect,                 //Object's current aspect
    int * pnCurrentScale               //Object's current scale
  );
```

Parameters

dwObject
A 32-bit identifier for the object.

phMetaPict
The object's current icon. Could be NULL, indicating that the caller is not interested in the object's current presentation.

pdvAspect
The object's current aspect. Could be NULL, indicating that the caller is not interested in the object's current aspect, i.e., DVASPECT_ICONIC or DVASPECT_CONTENT.

pnCurrentScale
The object's current scale. Could be NULL, indicating that the caller is not interested in the current scaling factor applied to the object in the container's view.

Return Values

S_OK
Successfully returned link information.

E_FAIL
Unable to return link information.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comment

Notes To Implementors

You must fill in the object's current icon, aspect, and scale.

See Also

OLEUIVIEWPROPS

IOleUIObjInfo::SetViewInfo

Sets the view information associated with the object.

```
HRESULT SetViewInfo(
   DWORD dwObject,                //32-bit object identifier
   HGLOBAL hMetaPict,             //New icon for the object
   DWORD dvAspect,                //New display aspect
   int nCurrentScale,             //New scale
   BOOL bRelativeToOrig           //Scale relative to origin
  );
```

Parameters

dwObject
A 32-bit identifier for the object.

hMetaPict
The new icon for the object.

dvAspect
The object's new display aspect or view.

nCurrentScale
The object's new scale.

bRelativeToOrig
The scale of the object, relative to the origin. This value is TRUE if the new scale should be relative to the original scale of the object. If FALSE, *nCurrentScale* applies to the object's current size.

Return Values

S_OK
Successfully returned link information.

E_FAIL
Unable to return link information.

E_INVALIDARG
One or more invalid arguments.

E_OUTOFMEMORY
Insufficient memory.

E_ACCESSDENIED
Insufficient access permissions.

Comment

Notes To Implementors

You should apply the new attributes (icon, aspect, and scale) to the object. If *bRelativeToOrig* is set to TRUE, *nCurrentScale* (in percentage units) applies to the original size of the object before it was scaled. If *bRelativeToOrig* is FALSE, *nCurrentScale* applies to the object's current size.

DVASPECT

IOleWindow

The **IOleWindow** interface methods allow an application to obtain the handle to the various windows that participate in in-place activation, and also to enter and exit context-sensitive help mode.

Five other in-place activation interfaces are derived from the **IOleWindow** interface. Containers and objects must implement and use these six interfaces in order to support in-place activation. The following table briefly summarizes each of these interfaces:

IOleWindow	The base interface. Implemented and used by containers and objects to window handles and manage context-sensitive help.
IOleInPlaceObject	Implemented by objects and used by an object's immediate container to activate and deactivate the object.
IOleInPlaceActiveObject	Implemented by objects and used by the top-level container to manipulate the object while it is active. Provides a direct channel of communication between an active object and its frame and document windows.
IOleInPlaceUIWindow	Implemented by containers and used by objects to manipulate the container's document window.
IOleInPlaceFrame	Implemented by containers and used by objects to control the container's frame window.
IOleInPlaceSite	Implemented by containers and used by objects to interact with the in-place client site.

These interfaces can be arranged in three hierarchical levels with various interfaces implemented at each level. Calls that install user-interface menus and frame adornments, activate and switch between windows, and dispatch menu and keystrokes take place between the top-level container and the active object. Calls that support activating, deactivating, scrolling, or clipping span the containment hierarchy, with each level performing the correct actions.

When to Implement

The inherited methods of this interface are implemented by all in-place objects and containers.

When to Use

Use this interface to obtain the window handle to the windows associated with in-place activation (frame, document, parent, and in-place object). It is also used to enter and exit context-sensitive help.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns a pointer to a specified interface.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IOleWindow Methods	Description

GetWindow	Gets a window handle.
ContextSensitiveHelp	Controls enabling of context sensitive help.

See Also

IOleInPlaceObject, **IOleInPlaceActiveObject**, **IOleInPlaceUIWindow**, **IOleInPlaceFrame**, **IOleInPlaceSite**, **OleCreateMenuDescriptor**, **OleDestroyMenuDescriptor**, **OleTranslateAccelerator**

IOleWindow::ContextSensitiveHelp

Determines whether context-sensitive help mode should be entered during an in-place activation session.

```
HRESULT ContextSensitiveHelp(
  BOOL fEnterMode        //Specifies whether or not to enter help mode
 );
```

Parameter

fEnterMode
[in] Specifies TRUE if help mode should be entered; FALSE if it should be exited.

Return Values

S_OK
The help mode was entered or exited successfully, depending on the value passed in *fEnterMode*.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
The argument is invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

Applications can invoke context-sensitive help when the user

- presses SHIFT+F1, then clicks a topic
- presses F1 when a menu item is selected.

When SHIFT+F1 is pressed, either the frame or active object can receive the keystrokes. If the container's frame receives the keystrokes, it calls its containing document's **IOleWindow::ContextSensitiveHelp** method with *fEnterMode* set to TRUE. This propagates the help state to all of its in-place objects so they can correctly handle the mouse click or WM_COMMAND.

If an active object receives the SHIFT+F1 keystrokes, it calls the container's **IOleInPlaceSite::ContextSensitiveHelp** method with *fEnterMode* TRUE, which then recursively calls each of its in-place sites until there are no more to be notified. The container then calls its document's or frame's **ContextSensitiveHelp** method with *fEnterMode* TRUE.

When in context-sensitive help mode, an object that receives the mouse click can either:

1. Ignore the click if it does not support context-sensitive help, or
2. Tell all the other objects to exit context-sensitive help mode with **ContextSensitiveHelp** set to FALSE and then provide help for that context.

An object in context-sensitive help mode that receives a WM_COMMAND should tell all the other in-place objects to exit context-sensitive help mode and then provide help for the command.

If a container application is to support context-sensitive help on menu items, it must either provide its own message filter so that it can intercept the F1 key or ask the OLE library to add a message filter by calling **OleSetMenuDescriptor**, passing valid, non-NULL values for the *lpFrame* and *lpActiveObj* parameters.

See Also

OleSetMenuDescriptor

IOleWindow::GetWindow

Returns the window handle to one of the windows participating in in-place activation (frame, document, parent, or in-place object window).

```
HRESULT GetWindow(
   HWND * phwind         //Where to return window handle
  );
```

Parameter

phwnd
[out] Points to where to return the window handle.

Return Values

S_OK
The window handle was successfully returned.

E_INVALIDARG
One or more arguments are invalid.

E_OUTOFMEMORY
Out of memory.

E_UNEXPECTED
An unexpected error occurred.

E_FAIL
There is no window handle currently attached to this object.

Comments

Five types of windows comprise the windows hierarchy. When a object is active in place, it has access to some or all of these windows:

Window	Description
Frame	The outermost main window where the container application's main menu resides.
Document	The window that displays the compound document containing the embedded object to the user.
Pane	The subwindow of the document window that contains the object's view. Applicable only for applications with split-pane windows.
Parent	The container window that contains that object's view. The object application installs its window as a child of this window.
In-place	The window containing the active in-place object. The object application creates this window and installs it as a child of its hatch window, which is a child of the container's parent window.

Each type of window has a different role in the in-place activation architecture. However, it is not necessary to employ a separate physical window for each type. Many container applications use the same window for their frame, document, pane, and parent windows.

IParseDisplayName

The **IParseDisplayName** interface parses a human-readable display name string to convert it into a moniker. Display name parsing is necessary when the end user inputs a string to identify a component, as in the following situations:

- A compound document application that supports linked components typically supports the Edit:Links... dialog. Through this dialog, the end user can enter a display name to specify a new link source for a specified linked component. The compound document needs to have this input string converted into a moniker.
- A script language such as the macro language of a spreadsheet can allow textual references to a component. The language's interpreter needs to have such a reference converted into a moniker in order to execute the macro.

When to Implement

Compound document applications that support links to embedded components or to pseudo-objects within their documents must provide an implementation of the **IOleItemContainer** interface, which is derived indirectly from **IParseDisplayName**. In effect, such a compound document is providing a namespace for identifying its internal components; and its **IOleItemContainer** implementation (which includes the **IParseDisplayName** implementation) is the interface through which another application can access this namespace. Alternatively, the compound document application can implement **IParseDisplayName** as part of its class object, which is accessible through the **CoGetClassObject** function.

When to Use

If you are implementing your own moniker class, you might need to use this interface from your implementation of **IMoniker::ParseDisplayName**. If you call the **MkParseDisplayName** function, you are indirectly using **IParseDisplayName**.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IParseDisplayName Method	Description
ParseDisplayName	

See Also

IMoniker::ParseDisplayName, **IOleItemContainer**, **MkParseDisplayName**

IParseDisplayName::ParseDisplayName

Parses the display name to extract a component of the string that it can convert into a moniker, using the maximum number of characters from the lefthand side of the string.

```
HRESULT ParseDisplayName(
  IBindCtx *pbc,                  //Pointer to bind context
  LPOLESTR pszDisplayName,        //Pointer to string containing display name
  ULONG *pchEaten,                //Length, in characters, of display name
  IMoniker **ppmkOut              //Pointer to moniker that results
 );
```

Parameters

pbc
[in] Points to the bind context to be used in this binding operation.

pszDisplayName
[in] Points to a zero-terminated string containing the display name to be parsed. For Win32 applications, the **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

pchEaten
[out] Receives the number of characters in the display name that correspond to the *ppmkOut* moniker.

ppmkOut
[out] Receives a pointer to the resulting moniker. If an error occurs, the implementation sets **ppmkOut* to NULL. If **ppmkOut* is non-NULL, the implementation must call *(*ppmkOut)*->**IUnknown::AddRef**; so it is the caller's responsibility to call *(*ppmkOut)*->**IUnknown::Release**.

Return Values

S_OK
Indicates success.

MK_E_SYNTAX
Indicates a syntax error in the display name.

MK_E_NOOBJECT
Indicates that the display name does not identify a component in this namespace.

E_UNEXPECTED
Indicates an unexpected error.

E_OUTOFMEMORY
Indicates insufficient memory.

MkParseDisplayName, **IMoniker::ParseDisplayName**

IPersist

The **IPersist** interface is the base interface for three other persistence-related interfaces: **IPersistStorage**, **IPersistStream**, and **IPersistFile**. These three interfaces are offered by objects that can serialize themselves to a storage, stream, or file. That is, they can save their state for later instantiations, and they can load their saved state, thus transitioning from a passive to a running state.

Typically, the persistence interfaces are implemented by an embedded or linked object. The container application or the default object handler calls the methods in one of the persistence interfaces to have the object save or load itself. Thus, the object that offers a persistence interface can change itself to an active or running state by request of its container application or its object handler.

The **IPersist** interface is the base from which the other persistence interfaces are derived. Its one method returns the class identifier (CLSID) of an object that implements one of the other persistence interfaces.

When to Implement

You must implement the **IPersist** interface whenever you implement any one of the other persistence interfaces: **IPersistStorage**, **IPersistStream**, or **IPersistFile**. Typically, embedded objects implement the **IPersistStorage** interface; linked objects implement the **IPersistFile** interface; and new moniker classes implement the **IPersistStream** interface.

When to Use

The **IPersist** interface is used primarily by the default object handler to get the class identifier of an embedded object. Typically, container applications would not call the **IPersist** interface unless they provide object handlers for specific classes of objects.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IPersist Method	**Description**
GetClassID	Returns the class identifier (CLSID) for the component object.

IPersist::GetClassID

Returns the class identifier (CLSID) the component object. The CLSID is a unique value that identifies the application that can manipulate the component object data.

```
HRESULT GetClassID(
  CLSID *pClassID        //Pointer to CLSID of component object
 );
```

Parameter

pClassID
[out]Points to the location where the CLSID is returned. The CLSID is a globally unique identifier (GUID) that uniquely represents an object class.

Return Values

S_OK
The CLSID was successfully returned.

E_FAIL
The CLSID could not be returned.

Comments

This method returns the class identifier (CLSID) for an object, used in later operations to load object-specific code into the caller's context.

Notes to Callers

Most container applications have no need to call the **IPersist::GetClassID** method directly. A container application might use this method when the container needs to change the CLSID and save the new CLSID for the component object. For example, if the container is treating a component as a different class and an editing operation occurs so that the component object can no longer be edited by its original application. In this case, the container needs to change the CLSID for the component. Typically, in this case, the container calls the **OleSave** helper function which performs all the necessary steps.

The exception would be a container that provides an object handler for certain component objects. In particular, a container application should not get a component object CLSID and then use it to retrieve class specific information from the registry. Instead, the container should use **IOleObject** and **IDataObject** interfaces to retrieve such class-specific information directly from the object.

Notes to Implementors

Typically, a component object simply returns a constant CLSID in its implementation of this method. This is not the case, however, if your component object supports "Treat As" operations in which it edits other classes of components as if they were its own class. If your object is running a component of another class, your implementation of **IPersist::GetClassID** must return the CLSID stored in the component storage.

The implementation of **IPersist::GetClassID** in the default object handler passes the call to the implementation in the component object if the component object is running. Otherwise, the default handler calls the **ReadClassStg** function to read the CLSID that is saved in the component object storage.

If you are writing a custom object handler for your component, you might want to simply delegate this method to the default handler implementation (see **OleCreateDefaultHandler**).

IOleObject::GetUserType, **OleCreateDefaultHandler**, **ReadClassStg**

IPersistFile

The **IPersistFile** interface provides methods for an object to load and save itself in a disk file, instead of saving itself to a storage object. Because the information needed to open a file varies greatly from one application to another, the object must be responsible for opening its disk file.

When to Implement

The **IPersistFile** interface is implemented by any object or container application that can be linked through a file moniker, including the following:

- Any object that supports links to its files or to *pseudo-objects* within its files
- A container application that supports links to component objects within its compound file

Typically, you implement the **IPersistFile** interface as part of an aggregate object that includes other interfaces that are appropriate for the type of moniker binding that is supported.

For example, in either of the cases mentioned above, the moniker for the linked object can be a composite moniker. In the first case, a composite moniker identifies the pseudo-object contained within the file. In the second case, a composite moniker identifies the embedded object contained within the compound file. In either case of composite monikers, you must implement the **IPersistFile** interface as part of same object that also implements the **IOleItemContainer** interface. Then, when the application for the linked object is run, OLE queries for the **IOleItemContainer** interface to locate the embedded object or the pseudo-object contained in the file.

As another example, if the moniker is a simple file moniker (i.e., the link is to the entire file), OLE queries for the interface that the initiator of the bind operation requested. Typically, this is one of the compound document interfaces, such as **IOleObject**, **IDataObject**, or **IPersistStorage**.

When to Use

You call methods in the **IPersistFile** interface to load or save a linked component object in a specified file.

When the application for the linked object is run, OLE calls the **IPersistFile::Load** method. Once the file is loaded, OLE calls **IPersistFile::QueryInterface** to get another interface pointer to the loaded object. The **IPersistFile** interface is typically part of an aggregate object that offers other interfaces.

Note that OLE calls only the **IPersistFile::Load** method. It does not call any of the other **IPersistFile** methods. Typically, applications do not call these methods either. The **IPersistFile::Load** method enables OLE to load a file on behalf of a container application when the container needs to run the application for the linked object. The other **IPersistFile** methods support saving a component to a file, but container applications do not tell a linked object to save itself. It is entirely up to the end user and the application for the linked object to decide when the component should be saved. This differs from the situation for an embedded component, in which the container application uses the **IPersistStorage** interface to provide the storage and to tell the component when to save itself.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IPersistFile Methods	**Description**
IsDirty	Checks an object for changes since it was last saved to its current file.

Load	Opens the specified file and initializes an object from the file contents.
Save	Saves the object into the specified file.
SaveCompleted	Notifies the object that it can revert from NoScribble mode to Normal mode.
GetCurFile	Gets the current name of the file associated with the component.

IPersistFile::GetCurFile

Returns either the absolute path to the object's current working file or, if there is no current working file, the object's default save prompt .

HRESULT GetCurFile(
  LPOLESTR **ppszFileName*   //Pointer to the path for the current file or the default save prompt
 );

Parameter

ppszFileName
 [out]Points to a zero-terminated string containing the path for the current file or the default save prompt. If an error occurs, **ppszFileName* is set to NULL.

Return Values

S_OK
 A valid absolute path was successfully returned.

S_FALSE
 The default save prompt was returned.

E_OUTOFMEMORY
 The operation failed due to insufficient memory.

E_FAIL
 The operation failed due to some reason other than insufficient memory.

Comments

This method returns the current filename or the default save prompt for the object.

This method allocates memory for the string returned in the *ppszFileName* parameter using the **IMalloc::Alloc** method. The caller is responsible for calling the **IMalloc::Free** method to free the string. Both the caller and this method use the allocator returned by **CoGetMalloc**(MEMCTX_TASK, ...).

The **LPOLESTR** type indicates a wide character string (two bytes per character); otherwise, the string has one byte per character.

The filename returned in *ppszFileName* is the name specified in the **IPersistFile::Load** method when the document was loaded; or in **IPersistFile::SaveCompleted** if the document was saved to a different file.

If the object does not have a current working file, it should return the default filename prompt that it would display in a "Save As" dialog. For example, the default save prompt for a word processor object could be:

*.txt

Notes to Callers

OLE does not call the **IPersistFile::GetCurFile** method. Typically, applications do not either.

If you want to perform a "Save" operation on the object, you can call this method before calling **IPersistFile:Save** to determine whether the object has an associated file. If this method returns S_OK, you can then call **IPersistFile::Save** with a NULL filename and a TRUE value for the *fRemember* parameter to tell the object to save itself to its current file. If this method returns S_FALSE, you can use the save prompt returned in the *ppszFileName* parameter to ask the end user to provide a filename. Then, you can call **IPersistFile::Save** with the filename that the user entered to perform a "Save As" operation.

See Also

IPersistFile::Load, **IPersistFile::Save**, **IPersistFile::SaveCompleted**

IPersistFile::IsDirty

Checks an object for changes since it was last saved to its current file.

HRESULT IsDirty(*void***);**

Return Values

S_OK
: The object has changed since it was last saved.

S_FALSE
: The object has not changed since the last save.

Comments

This method checks whether an object has changed since it was last saved so you can avoid losing information in objects that have not yet been saved. The dirty flag for an object is conditionally cleared in the **IPersistFile::Save** method.

Notes to Callers

OLE does not call **IPersistFile::IsDirty**. Typically, applications do not either.

You should treat any error return codes as an indication that the object has changed. In other words, unless this method explicitly returns S_FALSE, you must assume that the object needs to be saved.

Notes to Implementors

An object with no contained objects simply checks its dirty flag to return the appropriate result.

A container object with one or more contained objects must maintain an internal dirty flag that reflects any one contained object being dirty. To do this, the container object should register for data change notifications with each link or embedding (see **IDataObject::DAdvise**). Then, the container can maintain its internal dirty flag that it sets when it receives an **IAdviseSink::OnDataChange** notification. If the container does not register for data change notifications, the **IPersistFile::IsDirty** implementation must call **IPersistStorage::IsDirty** for each of its contained objects to determine whether they have changed.

The container object can clear its dirty flag whenever it is saved, as long as the file saved to is the current working file after the save. In other words, the dirty flag is cleared after a successful "Save" or "Save As" operation, but not after a "Save A Copy As . . ." operation.

See Also

IAdviseSink::OnDataChange, **IDataObject::DAdvise**, **IPersistStorage::IsDirty**

IPersistFile::Load

Opens the specified file and initializes an object from the file contents.

```
HRESULT Load(
  LPCOLESTR pszFileName,        //Pointer to absolute path of the file to open
  DWORD dwMode                  //Specifies the access mode from the STGM enumeration
 );
```

Parameters

pszFileName
[in]Points to a zero-terminated string containing the absolute path of the file to open.

dwMode
[in]Specifies some combination of the values from the **STGM** enumeration to indicate the access mode to use when opening the file. The **IPersistFile::Load** method can treat this value as a suggestion, adding more restrictive permissions if necessary. If *dwMode* is zero, the implementation should open the file using whatever default permissions are used when a user opens the file.

Return Values

S_OK
The object was successfully loaded.

E_NOMEMORY
The object could not be loaded due to a lack of memory.

E_FAIL
The object could not be loaded for some reason other than a lack of memory.

IPersistFile::Load STG_E_* error codes.

Comments

This method loads the object from the specified file. This method is for initialization only and does not show the object to the end user; it is not equivalent to the end user selecting the File Open command.

Notes to Callers

The **BindToObject** method in file monikers calls this method to load an object during a moniker binding operation, that is, when the linked object is run.

Typically, applications do not call this method directly.

Notes to Implementors

Because the information needed to open a file varies greatly from one application to another, the object that implements this method must also open the file specified by the *pszFileName* parameter. Note that this differs from the **IPersistStorage::Load** and **IPersistStream::Load** in which the caller opens the storage or stream and then passes an open storage or stream pointer to the loaded object.

If your application normally uses the OLE-provided compound files, then your **IPersistFile::Load** implementation can simply call the **StgOpenStorage** helper API function to open the storage object in the specified file. Then, you can proceed with the normal document initialization. Applications that do not use storage objects can perform their normal file opening procedures.

When the document has been loaded, your implementation should register the document object in the Running Object Table (see **IRunningObjectTable::Register**).

See Also

IRunningObjectTable::Register, **StgOpenStorage**

IPersistFile::Save

Saves a copy of the object into the specified file.

```
HRESULT Save(
    LPCOLESTR pszFileName,        //Pointer to absolute path of the file where the object is saved
    BOOL fRemember                //Specifies whether the file is to be the current working file or not
  );
```

Parameters

pszFileName
: [in]Points to a zero-terminated string containing the absolute path of the file to which the object should be saved. If *pszFileName* is NULL, the object should save its data to the current file, if there is one.

fRemember
: [in]Indicates whether the *pszFileName* parameter is to be used as the current working file. If TRUE, *pszFileName* becomes the current file and the object should clear its dirty flag after the save. If FALSE, this save operation is a "Save A Copy As ..." operation. In this case, the current file is unchanged and the object should not clear its dirty flag. If *pszFileName* is NULL, the implementation should ignore the *fRemember* flag.

Return Values

S_OK
: The object was successfully saved.

E_FAIL
: The file was not saved.

IPersistFile::Save STG_E_* errors.

Comments

This method saves the object to the specified file. There are three different save scenarios that can use this method:

Save
: The caller calls the **IPersistFile::GetCurFile** method first to determine whether the object has an associated filename. If it does, the caller specifies NULL for the *pszFileName* parameter in this method to indicate that the object should "Save" to its current file. The caller must call the **IPersistFile::SaveCompleted** method to indicate completion.

Save As
: The caller specifies TRUE in the *fRemember* parameter and a non-NULL value for the *pszFileName* parameter to indicate saving to a new file. The caller must call the **IPersistFile::SaveCompleted** method to indicate completion.

Save a Copy As
: The caller specifies FALSE in the *fRemember* parameter and a non-NULL value for the *pszFileName* parameter to save a copy to the specified file.

The implementor must detect which save scenario is being requested by the caller. If the *pszFileName* parameter is NULL, the Save scenario is being requested. If the *pszFileName* parameter is not NULL, use the value of the *fRemember* parameter to distinguish between a Save As and a Save a Copy As call.

In the "Save" or "Save As" scenarios, the **IPersistFile::Save** method clears the internal dirty flag after the save and sends **IAdviseSink::OnSave** notifications to any advisory connections (see also **IOleAdviseHolder::SendOnSave**). Also, in these scenarios, the object is in NoScribble mode until it receives an **IPersistFile::SaveCompleted** call. In NoScribble mode, the object must not write to the file.

In the "Save As" scenario, the implementation should also send **IAdviseSink::OnRename** notifications to any advisory connections (see also **IOleAdviseHolder::SendOnRename**).

In the "Save a Copy As" scenario, the implementation does not clear the internal dirty flag after the save.

Notes to Callers

OLE does not call **IPersistFile::Save**. Typically, applications do not either.

See Also

IOleAdviseHolder::SendOnRename, **IOleAdviseHolder::SendOnSave**, **IPersistFile::GetCurFile**, **IPersistFile::SaveCompleted**

IPersistFile::SaveCompleted

Notifies the object that it can write to its file. It does this by notifying the object that it can revert from NoScribble mode (in which it must not write to its file), to Normal mode (in which it can). The component enters NoScribble mode when it receives an **IPersistFile::Save** call.

```
HRESULT SaveCompleted(
  LPCOLESTR pszFileName        //Pointer to absolute path of the file where the object was saved
 );
```

Parameter

pszFileName
[in]Points to the absolute path of the file where the object was previously saved.

Return Value

S_OK
Returned in all cases.

Comments

This method is called when a call to **IPersistFile::Save** is completed, and the file that was saved is now the current working file (that is, the "Save" or "Save As" scenarios). In these cases, the object has been placed into NoScribble mode so it cannot write to its file. When the save is completed, the object can revert to Normal mode and it is free to write to its file.

Notes to Callers

OLE does not call the **IPersistFile::SaveCompleted** method. Typically, applications do not either.

See Also

IPersistFile::Save

IPersistStorage

The **IPersistStorage** interface enables a container application to pass a storage object to one of its contained objects and to load and save the storage object. This interface supports the structured storage scheme in which each component object has its own storage that is nested within the container's storage.

When to Implement

Any object that can be embedded in a container object must implement the **IPersistStorage** interface. This interface is one of the primary interfaces for a compound document object. It is part of the aggregate object that includes the **IOleObject** and **IDataObject** interfaces.

The OLE default handler for embedded objects provides an implementation of the **IPersistStorage** interface that is used when the object is in the loaded state. Similarly, the OLE default link handler provides an **IPersistStorage** implementation that manages storage for a linked object. These default handlers both interact with the OLE default cache implementation, which has its own **IPersistStorage** implementation.

If you are providing a custom embedding or link handler for your objects, the handler must include an implementation of **IPersistStorage**. You can delegate calls to the default handler so you can take advantage of the default cache implementation.

When to Use

When an OLE container creates a new object, loads an existing object from storage, or inserts a new object in a clipboard or a drag-and-drop operation, the container uses the **IPersistStorage** interface to initialize the object and put it in the loaded or running state. When a component is loaded or running, an OLE container uses the other **IPersistStorage** methods to instruct the component to perform various save operations or to instruct the component to release its storage.

Typically, applications use helper functions such as **OleLoad** or **OleCreate**, rather than calling the **IPersistStorage::Load** or **IPersistStorage::InitNew** methods directly. Similarly, applications typically call the **OleSave** helper function rather than calling **IPersistStorage::Save** directly.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IPersistStorage Methods	**Description**
IsDirty	Indicates whether the object has changed since it was last saved to its current storage.
InitNew	Initializes a new storage object.
Load	Initializes an object from its existing storage.
Save	Saves an object, and any nested objects that it contains, into the specified storage object. The object enters NoScribble mode.
SaveCompleted	Notifies the object that it can revert from NoScribble or HandsOff mode, in

	which in must not write to its storage object, to Normal mode in which it can.
HandsOffStorage	Instructs the object to release all storage objects that have been passed to it by its container and to enter HandsOffAfterSave or HandsOffFromNormal mode.

See Also

IDataObject, **IOleObject**, **OleCreate**, **OleLoad**, **OleSave**

IPersistStorage::HandsOffStorage

Instructs the object to release all storage objects that have been passed to it by its container and to enter HandsOff mode, in which the object cannot do anything and the only operation that works is a close operation.

HRESULT HandsOffStorage(*void***);**

Return Value

S_OK
    The object has successfully entered HandsOff mode.

Comments

This method causes an object to release any storage objects that it is holding and to enter the HandsOff mode until a subsequent **IPersistStorage::SaveCompleted** call. In HandsOff mode, the object cannot do anything and the only operation that works is a close operation.

A container application typically calls this method during a full save or low-memory full save operation to force the component object to release all pointers to its current storage. In these scenarios, the **HandsOffStorage** call comes after calling **OleSave** or **IPersistStorage::Save** for the component object; and it puts the component object in HandsOffAfterSave mode. Calling this method is necessary so the container application can delete the current file as part of a full save, or so it can call the **IRootStorage::SwitchToFile** method as part of a low-memory save.

A container application also calls this method when a component object is in Normal mode to put the component object in HandsOffFromNormal mode.

While the component object is in either HandsOff mode, most operations on the object will fail. Thus, the container should restore the component object to Normal mode as soon as possible. The container application does this by calling the **IPersistStorage::SaveCompleted** method, which passes a storage pointer back to the component object for the new storage object.

Notes to Implementors

This method must release all pointers to the component's current storage object, including pointers to any nested streams and storages. If the component object contains nested component objects, the container application must recursively call this method for any nested component objects that are loaded or running.

See Also

OleSave, **IPersistStorage::Save**, **IPersistStorage::SaveCompleted**, **IRootStorage::SwitchToFile**

IPersistStorage::InitNew

Initializes a new storage object.

```
HRESULT InitNew(
   IStorage *pStg         //Points to the new storage object
  );
```

Parameter

pStg
: [in]Points to the new storage object to initialize and use. The container creates a nested storage object in its storage object (see **IStorage::CreateStorage**). Then, the container calls the **WriteClassStg** function to initialize the new storage object with the component object class identifier (CLSID).

Return Values

S_OK
: The new storage object was successfully initialized.

CO_E_ALREADYINITIALIZED
: The component object has already been initialized by a previous call to either the **IPersistStorage::Load** method or the **IPersistStorage::InitNew** method.

E_OUTOFMEMORY
: The storage object was not initialized due to a lack of memory.

E_FAIL
: The storage object was not initialized due to some reason besides a lack of memory.

Comments

A container application can call this method when it needs to create a new object, for example, with an InsertObject command.

An object that uses the **IPersistStorage** interface must have access to a valid **IStorage** instance at all times while it is running. This includes the time just after the object has been created but before it has been made persistent. The object's container must provide the object with access to an **IStorage** instance during this time by calling **IPersistStorage::InitNew**. Depending on the container's state, a temporary file might need to be created for this purpose.

If the object wants to retain the **IStorage** instance, it must call **IUnknown::AddRef** to increment its reference count.

After the call to **IPersistStorage::InitNew**, the component object is in either the loaded or running state. For example, if the object class has an in-process server, the object will be in the running state. However, if the object uses the default handler, the container's call to **InitNew** only invokes the handler's implementation which does not run the component object. Later if the container runs the component object, the handler calls the **IPersistStorage::InitNew** method for the object.

Notes to Callers

Rather than calling **IPersistStorage::InitNew** directly, you typically call the **OleCreate** helper function which performs the following steps:

1. Calls the **CoCreateInstance** function to create an instance of the object class
2. Queries the new instance for the **IPersistStorage** interface
3. Calls the **IPersistStorage::InitNew** method to initialize the component object

The container application should cache the **PersistStorage** interface for the object for use in later operations on the object.

Notes to Implementors

An implementation of **IPersistStorage::InitNew** should initialize the component object to its default state. In particular, your implementation should perform the following steps to initialize the storage object:

1. Pre-open and cache the pointers to any streams or storages that the component will need to save itself to this storage.
2. Call **IPersistStorage::AddRef** and cache the passed in storage pointer.
3. Call the **WriteFmtUserTypeStg** function to write the native clipboard format and user type string for the component object to the storage object.
4. Set the dirty flag for the component object.

The first two steps are particularly important for ensuring that the component object can save itself in low memory situations. By pre-opening the necessary streams, the component object can guarantee that a save operation to this storage object will not fail due to insufficient memory.

Your implementation of this method should return the CO_E_ALREADYINITIALIZED error code if it receives a call to either the **IPersistStorage::InitNew** method or the **IPersistStorage::Load** method after it is already initialized.

See Also

IPersistStorage::Load, **OleCreate**, **WriteFmtUserTypeStg**

IPersistStorage::IsDirty

Indicates whether the object has changed since it was last saved to its current storage.

HRESULT IsDirty(*void***);**

Return Values

S_OK
The object has changed since it was last saved.

S_FALSE
The object has not changed since the last save.

Comments

This method checks whether an object has changed since it was last saved so you can avoid losing information in the object that has not yet been saved. The dirty flag for an object is conditionally cleared in the **IPersistFile::Save** method.

For example, you could optimize a File:Save operation by calling the **IPersistStorage::IsDirty** method for each component object and then calling the **IPersistStorage::Save** method only for those component objects that are dirty.

Notes to Callers

You should treat any error return codes as an indication that the object has changed. In other words, unless this method explicitly returns S_FALSE, you must assume that the object needs to be saved.

Notes to Implementors

A container object with one or more contained objects must maintain an internal dirty flag that reflects any one contained object being dirty. To do this, the container object should register for data change notifications with each link or embedding (see **IDataObject::DAdvise**). Then, the container can maintain its internal dirty flag that it sets when it receives an **IAdviseSink::OnDataChange** notification. If the container does not register for data change notifications, the **IPersistFile::IsDirty** implementation must call **IPersistStorage::IsDirty** for each of its contained objects to determine whether they have changed.

A component object can clear its dirty flag whenever it is saved, as long as the storage saved to is the current working storage after the save. In other words, the dirty flag is cleared after a successful "Save" or "Save As" operation, but not after a "Save A Copy As . . ." operation.

See Also

IAdviseSink::OnDataChange, **IDataObject::DAdvise**, **IPersistStorage::Save**

IPersistStorage::Load

Initializes an object from its existing storage.

```
HRESULT Load(
   IStorage *pStg         //Pointer to existing storage object for the component object
  );
```

Parameter

pStg
[in]Points to the existing storage object from which the component object is to be loaded.

Return Values

S_OK
The object was successfully loaded.

CO_E_ALREADYINITIALIZED
The object has already been initialized by a previous call to the **IPersistStorage::Load** method or the **IPersistStorage::InitNew** method.

E_OUTOFMEMORY
The object was not loaded due to lack of memory.

E_FAIL
The object was not loaded due to some reason besides a lack of memory.

Comments

This method initializes a component object from an existing storage object. The component object is placed in the loaded state if this method is called by the container application. If called by the default handler, this method places the component object in the running state.

Either the default handler or the component object itself can hold onto the **IStorage** interface while the object is loaded or running.

Notes to Callers

Rather than calling **IPersistStorage::Load** directly, you typically call the **OleLoad** helper function which performs the following steps:

1. Create an uninitialized instance of the component object class
2. Query the new instance for the **IPersistStorage** interface
3. Call the **IPersistStorage::Load** method to initialize the component from the existing storage

You also call this method indirectly when you call the **OleCreateFromData** function or the **OleCreateFromFile** function to insert a component object into a compound file (as in a drag-and-drop or clipboard paste operation).

The container should cache the **IPersistStorage** interface for use in later operations on the component object.

Notes to Implementors

Your implementation should perform the following steps to load a component object:

1. Open the component object's streams in the storage object, and read the necessary data into the object's internal data structures.
2. Clear the component object's dirty flag.
3. Call the **IPersistStorage::AddRef** method and cache the passed in storage pointer.
4. Keep open and cache the pointers to any streams or storages that the component object will need to

save itself to this storage.

5. Perform any other default initialization required for the component object.

Steps 3 and 4 are particularly important for ensuring that the component can save itself in low memory situations. By holding onto pointers to the storage and streams, the component can guarantee that a save operation to this storage will not fail due to insufficient memory.

Your implementation of this method should return the CO_E_ALREADYINITIALIZED error code if it receives a call to either the **IPersistStorage::InitNew** method or the **IPersistStorage::Load** method after it is already initialized.

GetConvertStg, **IPersistStorage::InitNew**, **OleLoad**, **ReadFmtUserTypeStg**, **SetConvertStg**, **WriteFmtUserTypeStg**

IPersistStorage::Save

Saves an object, and any nested objects that it contains, into the specified storage object. The object is placed in NoScribble mode, and it must not write to the specified storage until it receives a call to its **IPersistStorage::SaveCompleted** method.

```
HRESULT Save(
  IStorage *pStgSave,         //Pointer to storage object
  BOOL fSameAsLoad            //Indicates whether the specified storage object is the current one
 );
```

Parameters

pStgSave
[in]Points to the storage object into which the component object is to be saved.

fSameAsLoad
[in]Indicates whether the specified storage object is the current one, which was passed to the object by one of the following calls:

- **IPersistStorage::InitNew** when it was created.
- **IPersistStorage::Load** when it was loaded.
- **IPersistStorage::SaveCompleted** when it was saved to a storage different from its current storage.

This parameter is set to FALSE when performing a Save As or Save A Copy To operation or when performing a full save. In the latter case, this method saves to a temporary file, deletes the original file, and renames the temporary file.

This parameter is set to TRUE to perform a full save in a low-memory situation or to perform a fast incremental save in which only the dirty components are saved.

Return Values

S_OK
The object was successfully saved.

STG_E_MEDIUMFULL
The object was not saved because of a lack of space on the disk.

E_FAIL
The object could not be saved due to errors other than a lack of disk space.

Comments

This method saves an object, and any nested objects it contains, into the specified storage object. It also places the component object into NoScribble mode. Thus, the component object cannot write to its storage object until a subsequent call to the **IPersistStorage::SaveCompleted** method returns the object to Normal mode.

If the storage object is the same as the one it was loaded or created from, the save operation may be able to write incremental changes to the storage object. Otherwise, a full save must be done.

This method recursively calls the **IPersistStorage::Save** method, the **OleSave** function, or the **IStorage::CopyTo** method to save its nested objects.

This method does not call the **IStorage::Commit** method. Nor does it write the class identifier to the storage object. Both of these tasks are the responsibilities of the caller.

Notes to Callers

Rather than calling **IPersistStorage::Load** directly, you typically call the **OleSave** helper function which performs the following steps:

1. Call the **WriteClassStg** function to write the class identifier for the object to the storage.
2. Call the **IPersistStorage::Save** method.
3. If needed, call the **IStorage::Commit** method on the storage object.

Then, a container application performs any other operations necessary to complete the save and calls the **SaveCompleted** method for each component object.

If an embedded object passed the **IPersistStorage::Save** method to its nested objects, it must wait until it receives a call to its **IPersistStorage::SaveCompleted** method before calling the **IPersistStorage::SaveCompleted** method for its nested objects.

See Also

IPersistStorage::InitNew, **IPersistStorage::Load**, **IPersistStorage::SaveCompleted**, **IStorage::Commit**, **IStorage::CopyTo**, **OleSave**, **WriteClassStg**, **WriteFmtUserTypeStg**

IPersistStorage::SaveCompleted

Notifies the object that it can revert from NoScribble or HandsOff mode, in which it must not write to its storage object, to Normal mode, in which it can. The component object enters NoScribble mode when it receives an **IPersistStorage::Save** call.

```
HRESULT SaveCompleted(
  IStorage *pStgNew        //Pointer to the current storage object
 );
```

Parameter

pStgNew
[in]Points to the new storage object, if different from the storage object prior to saving. This pointer can be NULL if the current storage object does not change during the save operation. If the object is in HandsOff mode, this parameter must be non-NULL.

Return Values

S_OK
The object was successfully returned to Normal mode.

E_OUTOFMEMORY
The object remained in HandsOff mode or NoScribble mode due to a lack of memory. Typically, this error occurs when the object is not able to open the necessary streams and storage objects in *pStgNew*.

E_INVALIDARG
The *pStgNew* parameter is not valid. Typically, this error occurs if *pStgNew* is NULL when the object is in HandsOff mode.

E_UNEXPECTED
The object is in Normal mode, and there was no previous call to **IPersistStorage::Save** or **IPersistStorage::HandsOffStorage**.

Comments

This method notifies an object that it can revert to Normal mode and can once again write to its storage object. The object exits NoScribble mode or HandsOff mode.

If the object is reverting from HandsOff mode, the *pStgNew* parameter must be non-NULL. In HandsOffFromNormal mode, this parameter is the new storage object that replaces the one that was revoked by the **IPersistStorage::HandsOffStorage** method. The data in the storage object is a copy of the data from the revoked storage object. In HandsOffAfterSave mode, the data is the same as the data that was most recently saved. It is not the same as the data in the revoked storage object.

If the object is reverting from NoScribble mode, the *pStgNew* parameter can be NULL or non-NULL. If NULL, the component object once again has access to its storage object. If it is not NULL, the component object should simulate receiving a call to its **IPersistStorage::HandsOffStorage** method. If the component object cannot simulate this call, its container must be prepared to actually call the **IPersistStorage::HandsOffStorage** method.

The **IPersistStorage::SaveCompleted** method must recursively call any nested objects that are loaded or running.

If this method returns with an error code, the object is not returned to Normal mode. Thus, the container object can attempt different save strategies.

IPersistStream

The **IPersistStream** interface provides methods for saving and loading objects that use a simple serial stream for their storage needs. The primary purpose of this interface is to support OLE moniker implementations. Each of the OLE-provided moniker interfaces provide an **IPersistStream** implementation through which the moniker saves or loads itself. An instance of the OLE generic composite moniker class calls the **IPersistStream** methods of its component monikers to load or save the components in the proper sequence in a single stream.

OLE containers with embedded and linked component objects do not use this interface; they use the **IPersistStorage** interface instead.

When to Implement

Typically, applications do not implement the **IPersistStream** interface. However, the **IMoniker** interface is derived from the **IPersistStream** interface, so you must implement the **IPersistStream** interface if you are implementing a new moniker class.

When to Use

Typically, applications do not use the **IPersistStream** interface directly. The default link handler uses the **IPersistStream** interface to save and load the monikers that identify the link source. These monikers are stored in a stream in the storage for the linked object. If you are writing a custom link handler for your class of components, you will need to use the **IPersistStream** interface to load and save these monikers.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IPersistStream Methods	**Description**
IsDirty	Checks the object for changes since it was last saved.
Load	Initializes an object from the stream where it was previously saved.
Save	Saves an object into the specified stream and indicates whether the object should reset its dirty flag.
GetSizeMax	Return the size in bytes of the stream needed to save the object.

See Also

IMoniker

IPersistStream::GetSizeMax

Returns the size in bytes of the stream needed to save the object.

```
HRESULT GetSizeMax(
  ULARGE_INTEGER *pcbSize        //Pointer to size of stream needed to save object
 );
```

Parameter

pcbSize
[out]Points to a 64-bit unsigned integer value indicating the size in bytes of the stream needed to save this object.

Return Value

S_OK
The size was successfully returned.

Comments

This method returns the size needed to save an object. You can call this method to determine the size and set the necessary buffers before calling the **IPersistStream::Save** method.

Notes to Implementors

The **GetSizeMax** implementation should return a conservative estimate of the necessary size because the caller might call the **IPersistStream::Save** method with a non-growable stream.

See Also

IPersistStream::Save

IPersistStream::IsDirty

Checks the object for changes since it was last saved.

HRESULT IsDirty(*void***);**

Return Values

S_OK
: The object has changed since it was last saved.

S_FALSE
: The object has not changed since the last save.

Comments

This method checks whether an object has changed since it was last saved so you can avoid losing information in objects that have not yet been saved. The dirty flag for an object is conditionally cleared in the **IPersistStream::Save** method.

Notes to Callers

You should treat any error return codes as an indication that the object has changed. In other words, unless this method explicitly returns S_FALSE, you must assume that the object needs to be saved.

Note that the OLE-provided implementations of the **IPersistStream::IsDirty** method in the OLE-provided moniker interfaces always return S_FALSE because their internal state never changes.

See Also

IPersistStream::Save

IPersistStream::Load

Initializes an object from the stream where it was previously saved.

```
HRESULT Load(
  IStream *pStm        //Pointer to the stream from which the object should be loaded
 );
```

Parameter

pStm
[in]Points to the stream from which the object should be loaded.

Return Values

S_OK
The object was successfully loaded.

E_OUTOFMEMORY
The object was not loaded due to a lack of memory.

E_FAIL
The object was not loaded due to some reason other than a lack of memory.

Comments

This method loads an object from its associated stream. The seek pointer is set as it was in the most recent **IPersistStream::Save** method. This method can seek and read from the stream, but cannot write to it.

On exit, the seek pointer must be in the same position it was in on entry, immediately past the end of the data.

Notes to Callers

Rather than calling **IPersistStream::Load** directly, you typically use the **OleLoadFromStream** function which performs the following steps:

1. Calls the **ReadClassStm** function to get the class identifier from the stream.
2. Calls the **CoCreateInstance** function to create an instance of the object.
3. Queries the instance for **IPersistStream**.
4. Calls **IPersistStream::Load**.

The **OleLoadFromStream** function assumes that objects are stored in the stream with a class identifier followed by the object data. This is the storage pattern used by the generic, composite-moniker implementation provided by OLE.

If the objects are not stored using this pattern, you must call the methods separately yourself.

See Also

CoCreateInstance, **OleLoadFromStream**, **ReadClassStm**

IPersistStream::Save

Saves an object to the specified stream.

```
HRESULT Save(
   IStream *pStm,          //Pointer to the stream where the object is to be saved
   BOOL fClearDirty        //Specifies whether to clear the dirty flag
 );
```

Parameters

pStm
[in]Points to the stream into which the object should be saved.

fClearDirty
[in]Indicates whether to clear the dirty flag after the save is complete. If TRUE, the flag should be cleared. If FALSE, the flag should be left unchanged.

Return Values

S_OK
The object was successfully saved to the stream.

STG_E_CANTSAVE
The object could not save itself to the stream. This error could indicate, for example, that the object contains another object that is not serializable to a stream or that an **IStream::Write** call returned STG_E_CANTSAVE.

STG_E_MEDIUMFULL
The object could not be saved because there is no space left on the storage device.

Comments

This method saves an object into the specified stream and indicates whether the object should reset its dirty flag.

The seek pointer is positioned at the location in the stream at which the object should begin writing its data. The object calls the **IStream::Write** method to write its data.

On exit, the seek pointer must be positioned immediately past the object data. The position of the seek pointer is undefined if an error returns.

Notes to Callers

Rather than calling **IPersistStream::Save** directly, you typically use the **OleSaveToStream** helper function which performs the following steps:

1. Calls **IPersistStream::GetClassID** to get the object's class identifier.
2. Calls the **WriteClassStm** function to write the object's class identifier to the stream.
3. Calls **IPersistStream::Save**.

If you call these methods directly, you can write other data into the stream after the class identifier before calling **IPersistStream::Save**.

The OLE-provided implementation of **IPersistStream** follows this same pattern.

Notes to Implementors

The **IPersistStream::Save** method does not write the class identifier to the stream. The caller is responsible for writing the class identifier.

The **IPersistStream::Save** method can read from, write to, and seek in the stream; but it must not seek to a location in the stream before that of the seek pointer on entry.

See Also

IPersist::GetClassID, **IStream::Write**, **OleSaveToStream**

IRootStorage

The **IRootStorage** interface contains a single method that switches a storage object to a different underlying file and saves the storage object to that file. The save operation occurs even with low memory conditions and uncommitted changes to the storage object. A subsequent call to **IStorage::Commit** is guaranteed to not consume any additional memory.

When to Implement

Storage objects that are based on a file should implement **IRootStorage** in addition to the **IStorage** interface. For storage objects that are not file-based, this interface is not necessary.

OLE provides an implementation of a storage object, including the **IRootStorage** interface, as part of its compound file implementation.

When to Use

The primary use for the **IRootStorage** interface is to save a storage object to a file during low memory conditions. Typically, the container application calls the **IRootStorage** interface to switch to a new file.

You can call **IStorage::QueryInterface** with *IID_IRootStorage* to obtain a pointer to the **IRootStorage** interface.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IRootStorage Method	**Description**
SwitchToFile	Copy the file underlying this root storage object, then associate this storage with the copied file.

See Also

IStorage, **StgCreateDocfile**

IRootStorage::SwitchToFile

Copies the current file associated with the storage object to a new file. The new file is then used for the storage object and any uncommitted changes.

```
HRESULT SwitchToFile(
  LPOLESTR pszFile        //Filename for the new file
 );
```

Parameter

pszFile
Specifies the filename for the new file. It cannot be the name of an existing file. If NULL, this method creates a temporary file with a unique name, and you can call **IStorage::Stat** to retrieve the name of the temporary file.

Return Values

S_OK
The file was successfully copied.

STG_E_MEDIUMFULL
The file was not copied because of insufficient space on the storage device.

STG_E_ACCESSDENIED
The file was not copied because the caller does not have permission to access storage device.

STG_E_INVALIDPOINTER
The file was not copied because the *pszFile* pointer is invalid.

STG_E_FILEALREADYEXISTS
The file was not copied because the new filename (*pszFile*) points to an existing file.

Comments

The **IRootStorage::SwitchToFile** method copies the file associated with the storage object. An OLE container calls **IRootStorage::SwitchToFile** to perform a full save on a file in a low-memory situation. Typically, this is done only after a normal full save operation (i.e., save to temporary file, delete original file, rename temporary file) has failed with an E_OUTOFMEMORY error.

It is illegal to call **IRootStorage::SwitchToFile** if the storage object or anything contained within it has been marshalled to another process. As a consequence, the container must call the **IPersistStorage::HandsOffStorage** method for any element within the storage object that is loaded or running. The **HandsOffStorage** method forces the element to release its storage pointers and enter the hands-off storage mode. The container must also release all pointers to streams or storages that are contained in this root storage. After the full save operation is completed, the container returns the contained elements to normal storage mode.

Notes to Implementors

If you are implementing your own storage objects, the **IRootStorage** methods (including **QueryInterface**, **IUnknown::AddRef**, and **IUnknown::Release**) must not consume additional memory or file handles.

See Also

IPersistStorage::HandsOffStorage, **IPersistStorage::SaveCompleted**, **IStorage::Commit**, **IStorage::Stat**

IROTData

The **IROTData** interface is implemented by monikers to enable the Running Object Table (ROT) to compare monikers against each other.

The ROT uses the **IROTData** interface to test whether two monikers are equal. The ROT must do this when, for example, it checks whether a specified moniker is registered as running.

When to Implement

You must implement **IROTData** if you are writing your own moniker class (that is, writing your own implementation of the **IMoniker** interface), and if your monikers are meant to be registered in the ROT.

When to Use

You typically do not need to use this interface. This interface is used by the system's implementation of the ROT.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IROTData Method	**Description**
GetComparisonData	Retrieve data to allow moniker to be compared with another.

See Also

IMoniker, **IRunningObjectTable**

IROTData::GetComparisonData

Retrieves data from a moniker that can be used to test the moniker for equality against another moniker.

```
HRESULT GetComparisonData(
  PVOID *ppvData,         //Buffer that receives the comparison data
  ULONG cbMax,            //Specifies length of buffer
  PULONG pcbData          //Receives the length of the comparison data
 );
```

Parameters

ppvData
[out] Points to a buffer that receives the comparison data.

cbMax
[in] Specifies the length of the buffer specified in *ppvData*.

pcbData
[out] Receives the length of the comparison data.

Return Values

S_OK
The comparison data was successfully returned.

E_OUTOFMEMORY
The buffer contained insufficient space to return the comparison data.

Comments

The **IROTData::GetComparisonData** method is primarily called by the Running Object Table (ROT). The comparison data returned by the method is tested for binary equality against the comparison data returned by another moniker. The *pcbData* parameter enables the ROT to locate the end of the data returned.

Notes to Implementors

The comparison data that you return must uniquely identify the moniker, while still being as short as possible. The comparison data should include information about the internal state of the moniker, as well as the moniker's CLSID. For example, the comparison data for a file moniker would include the pathname stored within the moniker as well as the CLSID of the file moniker implementation. This makes it possible to distinguish two monikers that happen to store similar state information but are instances of different moniker classes.

The comparison data for a moniker cannot exceed 2048 bytes in length. For composite monikers, the total length of the comparison data for all of its components cannot exceed 2048 bytes; consequently, if your moniker can be a component within a composite moniker, the comparison data you return must be significantly less than 2048 bytes.

If your comparison data is longer than the value specified by the *cbMax* parameter, you must return an error. Note that when **IROTData::GetComparisionData** is called on the components of a composite moniker, the value of *cbMax* becomes smaller for each moniker in sequence.

IMoniker, **IRunningObjectTable**

IRunnableObject

The **IRunnableObject** interface enables a container to control the running of its embedded objects. In the case of an object implemented with a local server, calling IRunnableObject::Run launches the server's .EXE file. In the case of an object implemented with an in-process server, calling the **Run** method causes the object .DLL file to transition into the running state.

When to Implement

Object handlers should implement **IRunnableObject** to provide their containers with a way to run them and manage their running state. DLL object applications should implement **IRunnableObject** to support silent updates of their objects.

When to Use

Containers call **IRunnableObject** to determine if an embedded object is running, to force an object to run, to lock an object into the running state, or to inform an object handler whether its object is being run as either a simple embedding or as a link source.

Methods VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IRunnableObject Methods	Description
GetRunningClass	Returns CLSID of a running object.
Run	Forces an object to run.
IsRunning	Determines if an object is running.
LockRunning	Locks an object into running state.
SetContainedObject	Indicates that an object is embedded.

IRunnableObject::GetRunningClass

Returns the CLSID of a running object.

```
HRESULT GetRunningClass(
  LPCLSID lpClsid         //Pointer to an object's CLSID
 );
```

Parameter

lpClsid
[out] Points to the object's class ID.

Return Values

S_OK
CLSID was returned successfully.

E_INVALIDARG
An argument is invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

If an embedded document was created by an application that is not available on the user's computer, the document, by a call to **CoTreatAsClass**, may be able to display itself for editing by emulating a class that *is* supported on the user's machine. In this case, the CLSID returned by a call to **IRunnableObject::GetRunningClass** will be that of the class being emulated, rather than the document's native class.

See Also

CoTreatAsClass

IRunnableObject::IsRunning

Determines whether an object is currently in the running state.

BOOL IsRunning();

Return Values

TRUE
: The object is in the running state.

FALSE
: The object is not in the running state.

Comments

A container application could call **IRunnableObject::IsRunning** when it needs to know if the server is immediately available. For example, a container's implementation of the **IOleItemContainer::GetObject** method would return an error if the server is not running and the bindspeed parameter specifies BINDSPEED_IMMEDIATE.

An object handler could call **IRunnableObject::IsRunning** when it wants to avoid conflicts with a running server or when the running server might have more up-to-date information. For example, a handler's implementation of **IOleObject::GetExtent** would delegate to the object server if it is running, because the server's information might be more current than that in the handler's cache.

OleIsRunning is a helper function that conveniently repackages the functionality offered by **IRunnableObject::IsRunning**. With the release of OLE 2.01, the implementation of **OleIsRunning** was changed so that it calls **QueryInterface**, asks for **IRunnableObject**, and then calls **IRunnableObject::IsRunning**. In other words, you can use the interface and the helper function interchangeably.

See Also

OleIsRunning

IRunnableObject::LockRunning

Locks an already-running object into its running state or unlocks it from its running state.

```
HRESULT LockRunning(
    BOOL fLock,                   //Flag indicating whether object is locked
    BOOL fLastUnlockCloses        //Flag indicating whether to close object
  );
```

Parameters

fLock
[in] TRUE locks the object into its running state. FALSE unlocks the object from its running state.

fLastUnlockCloses
[in] TRUE specifies that if the connection being released is the last external lock on the object, the object should close. FALSE specifies that the object should remain open until closed by the user or another process.

Return Values

S_OK
If the value of *fLock* is TRUE, the object was successfully locked; if the value of *fLock* is FALSE, the object was successfully unlocked.

E_FAIL
The object was not running.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

Most implementations of **IRunnableObject::LockRunning** call **CoLockObjectExternal**.

OleLockRunning is a helper function that conveniently repackages the functionality offered by **IRunnableObject::LockRunning**. With the release of OLE 2.01, the implementation of **OleLockRunning** was changed to call **QueryInterface**, ask for **IRunnableObject**, and then call **IRunnableObject::LockRunning**. In other words, you can use the interface and the helper function interchangeably.

See Also

CoLockObjectExternal

IRunnableObject::Run

Runs an object.

```
HRESULT Run(
    LPBC lpbc          //Pointer to binding context
  );
```

Parameter

lpbc
    Points to the binding context of the run operation. May be NULL.

Return Values

S_OK
    The object was successfully placed in the running state.

E_OUTOFMEMORY
    Out of memory.

E_UNEXPECTED
    An unexpected error occurred.

Comments

Containers call **IRunnableObject::Run** to force their objects to enter the running state. If the object is not already running, calling **IRunnableObject::Run** can be an expensive operation, on the order of many seconds. If the object is already running, then this method has no effect on the object.

Notes to Callers

When called on a linked object that has been converted to a new class since the link was last activated, **IRunnableObject::Run** may return OLE_E_CLASSDIFF. In this case, the client should call **IOleLink::BindToSource**.

OleRun is a helper function that conveniently repackages the functionality offered by **IRunnableObject::Run**. With the release of OLE 2.01, the implementation of **OleRun** was changed so that it calls **QueryInterface**, asks for **IRunnableObject**, and then calls **IRunnableObject::Run**. In other words, you can use the interface and the helper function interchangeably.

Notes to Implementors

The object should register in the running object table if it has a moniker assigned. The object should not hold any strong locks on itself; instead, it should remain in the unstable, unlocked state. The object should be locked when the first external connection is made to the object.

An embedded object must hold a lock on its embedding container while it is in the running state. The Default handler provided by OLE 2 takes care of locking the embedding container on behalf of objects implemented by an EXE object application. Objects implemented by a DLL object application must explicitly put a lock on their embedding containers, which they do by first calling **IOleClientSite::Getcontainer** to get a pointer to the container, then calling **IOleContainer::LockContainer** to actually place the lock. This lock must be released when **IOleObject::Close** is called.

See Also

IOleLink::BindToSource, **OleRun**

IRunnableObject::SetContainedObject

Notifies an object that it is embedded in an OLE container, which ensures that reference counting is done correctly for containers that support links to embedded objects.

```
HRESULT SetContainedObject(
  BOOL fContained         //Flag indicating whether object is embedded
 );
```

Parameter

fContained
[in] TRUE specifies that the object is contained in an OLE container. FALSE indicates that it is not.

Return Values

S_OK
Object has been marked as a contained embedding.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
The argument is invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

The **IRunnableObject::SetContainedObject** method enables a container to inform an object handler that it is embedded in the container, rather than acting as a link. This call changes the container's reference on the object from strong, the default for external connections, to weak. When the object is running visibly, this method is of little significance because the end-user has a lock on the object. During a silent update of an embedded link source, however, the container should not be able to hold an object in the running state after the link has been broken. For this reason, the container's reference to the object must be weak.

Notes to Callers

A container application must call **IRunnableObject::SetContainedObject** if it supports linking to embedded objects. It normally makes the call immediately after calling **OleLoad** or **OleCreate** and never calls the method again, even before it closes. Moreover, a container almost always calls this method with *fContained* set to TRUE. The use of this method with *fContained* set to FALSE is rare.

Calling **IRunnableObject::SetContainedObject** is optional only when you know that the embedded object will not be referenced by any client other than the container. If your container application does not support linking to embedded objects; it is preferable, but not necessary, to call **IRunnableObject::SetContainedObject**.

OleSetContainedObject is a helper function that conveniently repackages the functionality offered by **IRunnableObject::SetContainedObject**. With the release of OLE 2.01, the implementation of **OleSetContainedObject** was changed to call **QueryInterface**, ask for **IRunnableObject**, and then call **IRunnableObject::SetContainedObject**. In other words, you can use the interface and the helper function interchangeably.

See Also

OleSetContainedObject, OleNoteObjectVisible, CoLockObjectExternal

IRunningObjectTable

The **IRunningObjectTable** interface manages access to the Running Object Table (ROT), a globally accessible lookup table on each workstation. A workstation's ROT keeps track of those objects that can be identified by a moniker and that are currently running on the workstation. When a client tries to bind a moniker to an object, the moniker checks the ROT to see if the object is already running; this allows the moniker to bind to the current instance instead of loading a new one.

The ROT contains entries of the form:

```
(pmkObjectName, pUnkObject)
```

The *pmkObjectName* element is a pointer to the moniker that identifies the running object. The *pUnkObject* element is a pointer to the running object itself. During the binding process, monikers consult the *pmkObjectName* entries in the Running Object Table to see if an object is already running.

Objects that can be named by monikers must be registered with the ROT when they are loaded and their registration must be revoked when they are no longer running.

When to Implement

You do not need to implement this interface. The system provides an implementation of the Running Object Table that is suitable for all situations.

When to Use

You typically use the ROT if you're a moniker provider (that is, you hand out monikers identifying your objects to make them accessible to others) or if you're writing your own moniker class (that is, implementing the **IMoniker** interface).

If you are a moniker provider, you register your objects with the ROT when they begin running and revoke their registrations when they are no longer running. This enables the monikers that you hand out to be bound to running objects. You should also use the ROT to record the object's last modification time. You can get an **IRunningObjectTable** interface pointer to the local ROT by calling the **GetRunningObjectTable** API function.

The most common type of moniker provider is a compound-document link source. This includes server applications that support linking to their documents (or portions of a document) and container applications that support linking to embeddings within their documents. Server applications that do not support linking can also use the ROT to cooperate with container applications that support linking to embeddings.

If you are writing your own moniker class, you use the ROT to determine whether a object is running and to retrieve the object's last modification time. You can get an **IRunningObjectTable** interface pointer to the local ROT by calling the **IBindCtx::GetRunningObjectTable** method on the bind context for the current binding operation. Moniker implementations should always use the bind context to acquire a pointer to the ROT; this allows future implementations of **IBindCtx** to modify binding behavior. Note that you must also implement the **IROTData** interface on your moniker class in order to allow your monikers to be registered with the ROT.

Methods in VTable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IRunningObjectTable Methods	**Description**

Register	Registers an object with the ROT.
Revoke	Revokes an object's registration with the ROT.
IsRunning	Checks whether an object is running.
GetObject	Returns a pointer to an object given its moniker.
NoteChangeTime	Notifies the ROT that an object has changed.
GetTimeOfLastChange	Returns the time an object was last changed.
EnumRunning	Returns an enumerator for the ROT.

See Also

IBindCtx::GetRunningObjectTable, IROTData, GetRunningObjectTable

IRunningObjectTable::EnumRunning

Returns an enumerator that can list the monikers of all the objects currently registered in the Running Object Table (ROT).

```
HRESULT EnumRunning(
  IEnumMoniker **ppenumMoniker        //Receives enumerator for ROT
 );
```

Parameter

ppenumMoniker
[out] Receives a pointer to an **IEnumMoniker** interface to the enumerator. If an error occurs; the implementation sets **ppenumMoniker* to NULL. If **ppenumMoniker* is non-NULL, the implementation calls **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
Indicates that an enumerator was successfully returned.

E_OUTOFMEMORY
Indicates insufficient memory.

Comments

The *ppenumMoniker* enumerator does not enumerate monikers that are registered in the ROT after the enumerator has been created.

The **EnumRunning** method is intended primarily for the use by the system in implementing the Alert Object Table. Note that OLE 2 does not include an implementation of the Alert Object Table.

See Also

IEnum*XXXX*

IRunningObjectTable::GetObject

Determines whether the object identified by the specified moniker is running, and if it is, retrieves a pointer to that object. This method looks for the moniker in the Running Object Table (ROT), and retrieves the pointer registered there.

```
HRESULT GetObject(
   IMoniker *pmkObjectName,        //Moniker identifying object desired
   IUnknown **ppunkObject          //Receives pointer to the object
  );
```

Parameters

pmkObjectName
[in] Points to the moniker to search for in the Running Object Table.

ppunkObject
[out] Receives a pointer to the running object. If the object is not running or if an error occurs, the implementation sets **ppunkObject* to NULL. If **ppunkObject* is non-NULL, the implementation calls **IUnknown::AddRef** on the parameter; it is the caller's responsibility to call **IUnknown::Release**.

Return Values

S_OK
Indicates that *pmkObjectName* was found in the ROT and a pointer was returned.

S_FALSE
Indicates that there is no entry for *pmkObjectName* in the ROT, or that the object it identifies is no longer running (in which case, the entry is revoked).

Comments

This method checks the ROT for the moniker specified by *pmkObjectName*. If that moniker had previously been registered with a call to **IRunningObjectTable::Register**, this method returns the pointer that was registered at that time.

Notes to Callers

Generally, you call the **IRunningObjectTable::GetObject** method only if you are writing your own moniker class (that is, implementing the **IMoniker** interface). You typically call this method from your implementation of **IMoniker::BindToObject**.

However, note that not all implementations of **IMoniker::BindToObject** need to call this method. If you expect your moniker to have a prefix (indicated by a non-NULL *pmkToLeft* parameter to **IMoniker::BindToObject**), you should not check the ROT. The reason for this is that only complete monikers are registered with the ROT, and if your moniker has a prefix, your moniker is part of a composite and thus not complete. Instead, your moniker should request services from the object identified by the prefix (for example, the container of the object identified by your moniker).

See Also

IMoniker::BindToObject

IRunningObjectTable::GetTimeOfLastChange

Returns the time that an object was last modified. The object must have previously been registered with the Running Object Table (ROT). This method looks for the last change time recorded in the ROT.

```
HRESULT GetTimeOfLastChange(
  IMoniker *pmkObjectName,     //Moniker identifying object whose status is desired
  FILETIME *pfiletime          //Object's last change time
 );
```

Parameters

pmkObjectName
[in] Points to the moniker to search for in the ROT.

pfiletime
[out] Points to a **FILETIME** structure that receives the object's last change time.

Return Values

S_OK
Indicates that the last change time was successfully retrieved.

S_FALSE
Indicates that there is no entry for *pmkObjectName* in the ROT, or that the object it identifies is no longer running (in which case, the entry is revoked).

Comments

This method returns the change time that was last reported for this object by a call to **IRunningObjectTable::NoteChangeTime**. If **IRunningObjectTable::NoteChangeTime** has not been called previously, the method returns the time that was recorded when the object was registered.

This method is provided to enable checking whether a connection between two objects (represented by one object holding a moniker that identifies the other) is up-to-date. For example, if one object is holding cached information about the other object, this method can be used to check whether the object has been modified since the cache was last updated. See **IMoniker::GetTimeOfLastChange**.

Notes to Callers

Generally, you call **IRunningObjectTable::GetTimeOfLastChange** only if you are writing your own moniker class (that is, implementing the **IMoniker** interface). You typically call this method from your implementation of **IMoniker::GetTimeOfLastChange**. However, you should do so only if the *pmkToLeft* parameter of **IMoniker::GetTimeOfLastChange** is NULL. Otherwise, you should call **IMoniker::GetTimeOfLastChange** on your *pmkToLeft* parameter instead.

See Also

IMoniker::GetTimeOfLastChange, **IRunningObjectTable::NoteChangeTime**

IRunningObjectTable::IsRunning

Determines whether the object identified by the specified moniker is currently running. This method looks for the moniker in the Running Object Table (ROT).

```
HRESULT IsRunning(
   IMoniker *pmkObjectName        //Moniker identifying the object whose status is desired
  );
```

Parameter

pmkObjectName
[in] Points to the moniker to search for in the Running Object Table.

Return Values

S_OK
Indicates that the object identified by *pmkObjectName* is running.

S_FALSE
Indicates that there is no entry for *pmkObjectName* in the ROT, or that the object it identifies is no longer running (in which case, the entry is revoked).

Comments

This method simply indicates whether a object is running. To retrieve a pointer to a running object, use the **IRunningObjectTable::GetObject** method.

Notes to Callers

Generally, you call the **IRunningObjectTable::IsRunning** method only if you are writing your own moniker class (that is, implementing the **IMoniker** interface). You typically call this method from your implementation of **IMoniker::IsRunning**. However, you should do so only if the *pmkToLeft* parameter of **IMoniker::IsRunning** is NULL. Otherwise, you should call **IMoniker::IsRunning** on your *pmkToLeft* parameter instead.

See Also

IMoniker::IsRunning

IRunningObjectTable::NoteChangeTime

Records the time that a running object was last modified. The object must have previously been registered with the Running Object Table (ROT). This method stores the time of last change in the ROT.

```
HRESULT NoteChangeTime(
   DWORD dwRegister,        //Value identifying registration being updated
   FILETIME *pfiletime      //Time containing object's last change time
  );
```

Parameters

dwRegister
[in] Specifies a value identifying the ROT entry of the changed object. This value was previously returned by **IRunningObjectTable::Register**.

pfiletime
[in] Points to a **FILETIME** structure containing the object's last change time.

Return Values

S_OK
Indicates that the change time was recorded successfully.

E_INVALIDARG
Indicates that *dwRegister* is not a valid ROT entry or *pfiletime* is an invalid pointer.

Comments

The time recorded by this method can be retrieved by calling **IRunningObjectTable::GetTimeOfLastChange**.

This method is provided to enable a program to check whether a connection between two objects (represented by one object holding a moniker that identifies the other) is up-to-date. For example, if one object is holding cached information about the other object, this method can be used to check whether the object has been modified since the cache was last updated. See **IMoniker::GetTimeOfLastChange**.

Notes to Callers

If you're a moniker provider (that is, you hand out monikers identifying your objects to make them accessible to others), you must call the **IRunningObjectTable::NoteChangeTime** method whenever your objects are modified. You must have previously called **IRunningObjectTable::Register** and stored the identifier returned by that method; you use that identifier when calling **IRunningObjectTable::NoteChangeTime**.

The most common type of moniker provider is a compound-document link source. This includes server applications that support linking to their documents (or portions of a document) and container applications that support linking to embeddings within their documents. Server applications that do not support linking can also use the ROT to cooperate with container applications that support linking to embeddings.

When an object is first registered in the ROT, the ROT records its last change time as the value returned by calling **IMoniker::GetTimeOfLastChange** on the moniker being registered.

See Also

IRunningObjectTable::GetTimeOfLastChange, **IMoniker::GetTimeOfLastChange**

IRunningObjectTable::Register

Registers an object and its identifying moniker in the Running Object Table (ROT).

```
HRESULT Register(
  DWORD grfFlags,                 //Specifies a weak or a strong reference
  IUnknown *punkObject,           //Pointer to the object being registered
  IMoniker *pmkObjectName,        //Moniker that identifies the object being registered
  DWORD *pdwRegister              //Receives value identifying the registration
);
```

Parameters

grfFlags
[in] Specifies whether the ROT's reference to *punkObject* is weak or strong. This value must be either zero, indicating a weak reference that does not call **IUnknown::AddRef**; or ROTFLAGS_REGISTRATIONKEEPSALIVE, indicating a strong reference that calls **IUnknown::AddRef** and can keep the object running. If a strong reference is registered, a strong reference is released when the object's registration is revoked. Most callers specify zero, indicating a weak reference.

punkObject
[in] Points to the object that is being registered as running.

pmkObjectName
[in] Points to the moniker that identifies *punkObject*.

pdwRegister
[out] Receives a 32-bit value that can be used to identify this ROT entry in subsequent calls to **IRunningObjectTable::Revoke** or **IRunningObjectTable::NoteChangeTime**. The caller cannot specify NULL for this parameter. If an error occurs, **pdwRegister* is set to zero.

Return Values

S_OK
Indicates that the object was successfully registered.

MK_S_MONIKERALREADYREGISTERED
Indicates that the moniker/object pair was successfully registered, but that another object (possibly the same object) has already been registered with the same moniker.

E_INVALIDARG
Indicates one or more invalid arguments.

E_OUTOFMEMORY
Indicates failure due to insufficient memory.

Comments

This method registers a pointer to an object under a moniker that identifies the object. The moniker is used as the key when the table is searched with **IRunningObjectTable::GetObject**.

Registering a second object with the same moniker, or re-registering the same object with the same moniker, creates a second entry in the ROT. In this case, **IRunningObjectTable::Register** returns MK_S_MONIKERALREADYREGISTERED. Each call to **IRunningObjectTable::Register** must be matched by a call to **IRunningObjectTable::Revoke** because even duplicate entries have different *pdwRegister* identifiers. A problem with duplicate registrations is that there is no way to determine which object will be returned if the moniker is specified in a subsequent call to **IRunningObjectTable::IsRunning**.

Notes to Callers

If you're a moniker provider (that is, you hand out monikers identifying your objects to make them accessible to others), you must call the **IRunningObjectTable::Register** method to register your objects when they begin running. You must also call this method if you rename your objects while they are loaded.

The most common type of moniker provider is a compound-document link source. This includes server applications that support linking to their documents (or portions of a document) and container applications that support linking to embeddings within their documents. Server applications that do not support linking can also use the ROT to cooperate with container applications that support linking to embeddings.

If you're writing a server application, you should register an object with the ROT when it begins running, typically in your implementation of **IOleObject::DoVerb**. The object must be registered under its full moniker, which requires getting the moniker of its container document using **IOleClientSite::GetMoniker**. You should also revoke and re-register the object in your implementation of **IOleObject::SetMoniker**, which is called if the container document is renamed.

If you're writing a container application that supports linking to embeddings, you should register your document with the ROT when it is loaded. If your document is renamed, you should revoke and re-register it with the ROT and call **IOleObject::SetMoniker** for any embedded objects in the document to give them an opportunity to re-register themselves.

You must cache the identifier returned in *pdwRegister*, and use it in a call to **IRunningObjectTable::Revoke** to revoke the registration when the object is no longer running or when its moniker changes. This revocation is important because there is no way for the system to automatically remove entries from the ROT.

The system's implementation of **IRunningObjectTable::Register** calls **IMoniker::Reduce** on the *pmkObjectName* parameter to ensure that the moniker is fully reduced before registration. If a object is known by more than one fully reduced moniker, then it should be registered under all such monikers.

See Also

IMoniker::Reduce, **IOleClientSite::GetMoniker**, **IOleObject::SetMoniker**, **IRunningObjectTable::IsRunning**, **IRunningObjectTable::Revoke**

IRunningObjectTable::Revoke

Removes from the Running Object Table (ROT) an entry that was previously registered by a call to **IRunningObjectTable::Register**.

```
HRESULT Revoke(
  DWORD dwRegister      //Value identifying registration to be revoked
 );
```

Parameter

dwRegister
[in] Specifies a value identifying the ROT entry to revoke. This value was previously returned by **IRunningObjectTable::Register**.

Return Values

S_OK
Indicates that the object's registration was successfully revoked.

E_INVALIDARG
Indicates that *dwRegister* is not valid.

Comments

This method undoes the effect of a call to **IRunningObjectTable::Register**, removing both the moniker and the pointer to the object identified by that moniker.

Notes to Callers

If you're a moniker provider (that is, you hand out monikers identifying your objects to make them accessible to others), you must call the **IRunningObjectTable::Revoke** method to revoke the registration of your objects when they stop running. You must have previously called **IRunningObjectTable::Register** and stored the identifier returned by that method; you use that identifier when calling **IRunningObjectTable::Revoke**.

The most common type of moniker provider is a compound-document link source. This includes server applications that support linking to their documents (or portions of a document) and container applications that support linking to embeddings within their documents. Server applications that do not support linking can also use the ROT to cooperate with container applications that support linking to embeddings.

If you're writing a container application, you must revoke a document's registration when the document is closed. You must also revoke a document's registration before re-registering it when it is renamed.

If you're writing a server application, you must revoke an object's registration when the object is closed. You must also revoke an object's registration before re-registering it when its container document is renamed (see **IOleObject::SetMoniker**).

See Also

IOleObject::SetMoniker, **IRunningObjectTable::Register**

IStdMarshalInfo

The **IStdMarshalInfo** interface returns the CLSID identifying the handler to be used in the destination process during standard marshaling.

Even if an object uses standard marshaling instead of custom marshaling, it can still specify a handler that should be loaded in the client process. Such a handler would handle certain requests locally and delegate others back to the original object (using standard marshaling). To get the CLSID of the handler to be loaded, OLE queries the object for the **IStdMarshalInfo** interface and then the IPersist interface. If neither interface is supported, a standard handler is used.

When to Implement

If you are writing a server application that supports class emulation (that is, if your server can manipulate objects of another type in response to the Activate As option in the Convert dialog box), you must implement the **IStdMarshalInfo** interface

Note that your handler must aggregate the default handler.

When to Use

You typically don't call this interface yourself. OLE queries for this interface when performing standard marshaling.

Methods in VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IStdMarshalInfo Method	Description
GetClassForHandler	

See Also

IMarshal

IStdMarshalInfo::GetClassForHandler

Retrieves the CLSID of the object handler to be used in the destination process during standard marshaling.

```
HRESULT GetClassForHandler(
   DWORD dwDestContext,          //Specifies the destination process
   void * pvDestContext,         //Reserved for future use
   CLSID * pClsid                //Receives the CLSID
  );
```

Parameters

dwDestContext
[in] Specifies the destination context, that is, the process in which the unmarshaling will be done. The legal values for *dwDestContext* are taken from the enumeration **MSHCTX**. For information on the **MSHCTX** enumeration, see the "Data Structures" section.

pvDestContext
[in] Reserved for use with future **MSHCTX** values.

pClsid
[out] On exit, contains the handler's CLSID.

Return Values

S_OK
The CLSID was retrieved successfully.

E_OUTOFMEMORY
Out of memory.

E_INVALIDARG
One or more arguments are invalid.

E_UNEXPECTED
An unexpected error occurred.

Comments

Notes to Implementors

Your implementation of **IStdMarshalInfo::GetClassForHandler** must return your own CLSID. This allows an object created by a different server to behave as one your server created.

IStorage

The **IStorage** interface supports the creation and management of structured storage objects. These storage objects provide hierarchical storage of information within a single file similar to a file system within a file. Storage objects are like the directories in a file system. They provide the structure in a structured storage object. They can contain other storage objects which can be nested indefinitely, or stream objects. Stream objects are like the files within a file system. They contain the actual data content in a storage object.

The **IStorage** interface provides methods for creating and managing the root storage object, child storage objects, and stream objects. These methods can create, open, enumerate, move, copy, rename, or delete the elements in the storage object.

An application must release its **IStorage** pointers when it is done with the storage object to deallocate memory used. The **IStorage** interface provides a **IUnknown::Release** method. There are also methods for changing the date and time of an element.

Storage objects can be opened in direct or transacted mode. In direct mode, changes are immediately reflected in the element that changed. In transacted mode, changes are not reflected in the element until explicitly committed. This feature allows you to revert to a previous version without committing the changes. The **IStorage** interface provides methods for committing changes and reverting to previous versions of the storage object.

Storage objects and their elements have a set of access flags that control how the elements can be used. For example, a stream can be opened in read only mode or read/write mode. See the **STGM** enumeration values for more information on these flags. Storage objects and their elements also have a set of statistics defined by the **STATSTG** structure.

When to Implement

OLE provides an implementation of the **IStorage** interface in compound files. The compound file implementation supports transacted access. OLE provides a set of helper APIs for using the compound file implementation of storage objects.

Container or object applications can implement their own storage objects instead of using the OLE-provided implementation.

When to Use

Container applications use storage objects for compound files. For example, a word processing document could contain a chart. The chart would be provided its own storage object within the root storage object of the containing application while document pages are stored in a separate storage object in the same root storage object.

Since storage object pointers can be marshaled to other processes, applications can share the data in storage objects without having to use global memory. For the OLE-provided implementation of compound files, the custom marshaling facilities in OLE create a remote version of the original object in the new process when the two processes have shared memory access. Thus, the remote version does not need to communicate with the original process to carry out its functions.

While the **IStorage** and **IStream** interfaces are used to deal with the storage object and its elements, the **IPersistStorage** interface actually serializes the storage object and its elements to a disk file.

Methods VTable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.

Release	Decrements the reference count.

IStorage Methods	Description
CreateStream	Creates and opens a stream object with the specified name contained in this storage object.
OpenStream	Opens an existing stream object within this storage object using the specified access permissions in *grfMode*.
CreateStorage	Creates and opens a new storage object within this storage object.
OpenStorage	Opens an existing storage object with the specified name according to the specified access mode.
CopyTo	Copies the entire contents of this open storage object into another storage object. The layout of the destination storage object may differ.
MoveElementTo	Copies or moves a substorage or stream from this storage object to another storage object.
Commit	Reflects changes for a transacted storage object to the parent level.
Revert	Discards all changes that have been made to to the storage object since the last commit operation.
EnumElements	Returns an enumerator object that can be used to enumerate the storage and stream objects contained within this storage object.
DestroyElement	Removes the specified element from this storage object.
RenameElement	Renames the specified element in this storage object.
SetElementTimes	Sets the modification, access, and creation times of the indicated storage element, if supported by the underlying file system.
SetClass	Assigns the specified CLSID to this storage object.
SetStateBits	Stores up to 32 bits of state information in this storage object.
Stat	Returns the STATSTG structure for this open storage object.

IStorage::Commit

Ensures that any changes made to a storage object open in transacted mode are reflected in the parent storage. If the storage object is the root storage, the **IStorage::Commit** method reflects the changes in the actual device, for example, a file on disk. If the storage object is the root storage and is open in direct mode, this method has no effect except for flushing all memory buffers to the disk. For non-root storage objects in direct mode, this method has no effect.

```
HRESULT Commit(
   DWORD grfCommitFlags        //Specifies how changes are to be committed
  );
```

Parameter

grfCommitFlags
[in]Controls how the changes are committed to the storage object. See the **STGC** enumeration for a definition of these values.

Return Values

S_OK
Changes to the storage object were successfully committed to the parent level.

STG_E_INVALIDFLAG
The value for the *grfCommitFlags* parameter is not valid.

STG_E_INVALIDPARAMETER
One of the parameters was not valid.

STG_E_NOTCURRENT
Another open instance of the storage object has committed changes. Thus, the current commit operation may overwrite previous changes.

STG_E_MEDIUMFULL
No space left on device to commit.

STG_E_TOOMANYOPENFILES
The commit operation could not be completed because there are too many open files.

STG_E_REVERTED
The storage object has been invalidated by a revert operation above it in the transaction tree.

Comments

Storage objects can be opened in direct or transacted mode. In direct mode, changes are immediately reflected in the storage object. In transacted mode, changes are accumulated and are not reflected in the storage object until an explicit commit operation is done. The commit operation publishes the currently known changes in this storage object and its children to the next higher level in the storage hierarchy. Transacted mode allows an efficient way to revert to a previous version undoing changes prior to the commit operation.

Changes that have been made to this storage object since it was opened or since the last commit operation are reflected in the storage object. The changes are published to the next level of the storage hierarchy. If the parent is opened in transacted mode, the parent may still revert at a later time, rolling back the changes to this storage object.

Calling **IStorage::Commit** has no effect on currently-opened nested elements of this storage object. They are still valid and can be used. However, the **IStorage::Commit** method does not automatically commit changes to these nested elements. The commit operation publishes only known changes to the next higher level of the storage hierarchy. Thus, transactions to nested levels must be committed to this storage object before they can be committed to higher levels.

For storage objects opened in direct mode, the commit operation does nothing except in the case of a root storage object. In this case, the commit operation is similar to a flush buffer operation ensuring that changes in memory buffers are written to the underlying storage device.

In commit operations, steps must be taken to ensure the robustness of data during the commit process:

- When committing changes to root storage objects, the caller must take care to ensure that the operation successfully completes or that, when failing, the old committed contents of the **IStorage** are still intact and can be restored.
- If this storage object was opened with some of its items excluded, then the caller is responsible for rewriting them before calling commit. Write mode is required on the storage opening for the commit to succeed.
- Unless they prohibit multiple simultaneous writers on the same storage object, applications will usually want to specify at least STGC_ONLYIFCURRENT in the *grfCommitFlags* parameter to prevent the changes made by one writer from inadvertently overwriting the changes made by another.

Note to Callers

The OLE-provided compound files use a two phase commit process unless STGC_OVERWRITE is specified in the *grfCommitFlags* parameter. This two-phase process ensures the robustness of data in case the commit operation fails. First, all new data is written to unused space in the underlying file. If necessary, new space is allocated to the file. Once this step has been successfully completed, a table in the file is updated using a single sector write to indicate that the new data is to be used in place of the old. The old data becomes free space to be used at the next commit. Thus, the old data is available and can be restored in case an error occurs when committing changes. If STGC_OVERWRITE is specified, a single phase commit operation is used.

See Also

STGC, **IStorage::Revert**

IStorage::CopyTo

Copies the entire contents of this open storage object into another storage object.

```
HRESULT CopyTo(
  DWORD ciidExclude,            //Number of elements in rgiidExclude
  IID const * rgiidExclude,     //Array of interface identifiers (IIDs)
  SNB snbExclude,               //Points to a block of stream names in the storage object
  IStorage * pstgDest           //Points to destination storage object
 );
```

Parameters

ciidExclude
: [in]The number of elements in the array pointed to by *rgiidExclude*. If *rgiidExclude* is NULL, then *ciidExclude* is ignored.

rgiidExclude
: [in]Specifies an array of interface identifiers the caller takes responsibility for copying from the source to the destination. This array can include interfaces that this storage object does not support. It can be NULL, indicating that all other interfaces are to be copied. If non-NULL, an array length of zero indicates that no other interfaces are to be copied, only the state exposed by the **IStorage** object.

snbExclude
: [in]Specifies a block of elements in this storage object that are not to be copied to the destination. These elements are not created in the destination. If IID_IStorage is in the *rgiidExclude* array, then this parameter is ignored. This parameter may be NULL.

pstgDest
: [in]Points to the open storage object into which this storage object is to be copied. The destination storage object can be a different implementation of the **IStorage** interface from the source storage object. Thus, **IStorage::CopyTo** can only use publicly available methods of the destination storage object. If *pstgDest* is open in transacted mode, it can be reverted by calling its **IStorage::Revert** method.

Return Values

S_OK
: The storage object was successfully copied.

STG_S_DESTLACKSINTERFACE
: The destination lacks an interface that the source requested to be copied. The lack of an interface does not prevent other parts of the copy operation to be successfully completed.

STG_E_ACCESSDENIED
: The destination storage object is a child of the source storage object.

STG_E_INSUFFICIENTMEMORY
: The copy was not completed due to a lack of memory.

STG_E_INVALIDPOINTER
: The pointer specified for the storage object was invalid.

STG_E_INVALIDPARAMETER
: One of the parameters was invalid.

STG_E_TOOMANYOPENFILES
: The copy was not completed because there are too many open files.

STG_E_MEDIUMFULL
: The copy was not completed because the storage medium is full.

Comments

This method merges elements contained in the source storage object with those already present in the destination. The layout of the destination storage object may differ from the source storage object.

The copy process is recursive, invoking **IStorage::CopyTo** and **IStream::CopyTo** on the elements nested inside the source.

If an attempt is made to copy a stream on top of an existing stream with the same name, the existing destination stream is first removed and then replaced with the source stream. Attempting to copy a source storage object on top of an existing destination storage object does not remove the existing storage. Thus, after the copy operation, the destination **IStorage** contains older elements if they were not replaced by newer ones.

Note to Callers

The following example illustrates using the **CopyTo** method to copy everything possible from the source to the destination:

```
pstg->CopyTo(0, Null, Null, pstgDest)
```

This is the most commonly used form of this operation, used in most Full Save and SaveAs scenarios.

See Also

IStorage::MoveElementTo, **IStorage::Revert**

IStorage::CreateStorage

Creates and opens a new storage object nested within this storage object.

```
HRESULT CreateStorage(
    const wchar_t * pwcsName,      //Points to the name of the new storage object
    DWORD grfMode,                 //Access mode for the new storage object
    DWORD reserved1,               //Reserved; must be zero
    DWORD reserved2,               //Reserved; must be zero
    IStorage ** ppstg              //Points to new storage object
  );
```

Parameters

pwcsName
[in]Points to the name of the newly created storage object. This name can be used later to open or reopen the storage object.

grfMode
[in]Specifies the access mode to use when opening the newly created storage object. See the **STGM** enumeration values for descriptions of the possible values.

reserved1
[in]Reserved for future use; must be zero.

reserved2
[in]Reserved for future use; must be zero.

ppstg
[out]Points to the location where the new **IStorage** interface pointer is returned; only valid if the operation is successful. This parameter is set to NULL if an error occurs.

Return Values

S_OK
The storage object was created successfully.

STG_E_ACCESSDENIED
Insufficient permissions to create storage object.

STG_E_FILEALREADYEXISTS
The name specified for the storage object already exists in the storage object and the *grfmode* flag includes the flag STGM_FAILIFTHERE.

STG_E_INSUFFICIENTMEMORY
The storage object was not created due to a lack of memory.

STG_E_INVALIDFLAG
The value specified for the *grfMode* flag is not a valid **STGM** enumeration value.

STG_E_INVALIDFUNCTION
The specified combination of *grfMode* flags is not supported.

STG_E_INVALIDNAME
Invalid value for *pwcsName*.

STG_E_INVALIDPOINTER
The pointer specified for the storage object was invalid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_TOOMANYOPENFILES
The storage object was not created because there are too many open files.

STG_S_CONVERTED

The existing stream with the specified name was replaced with a new storage object containing a single stream called CONTENTS. The new storage object will be added.

Comments

If an element with the name specified in the *pwcsName* parameter already exists and the *grfMode* parameter includes the STGM_CREATE flag, the existing element is replaced by the new storage object. If the *grfMode* parameter includes the STGM_CONVERT flag, the existing element is converted to a stream object named CONTENTS and the new storage object is created containing the CONTENTS stream object. The destruction of the old element and the creation of the new storage object are both subject to the transaction mode on the parent storage object.

If the storage object already exists and *grfMode* is set to STGM_FAILIFTHERE, this method fails with the return value STG_E-FILEALREADYEXISTS.

Note to Callers

The OLE-provided compound file implementation of the **IStorage::CreateStorage** method does not support the STGM_DELETEONRELEASE flag. Other implementations of **IStorage** might support this flag.

See Also

IStorage::OpenStorage

IStorage::CreateStream

Creates and opens a stream object with the specified name contained in this storage object. All elements within a storage object – including both streams and other storage objects – are kept in the same name space.

```
HRESULT CreateStream(
   const wchar_t * pwcsName,        //Points to the name of the new stream
   DWORD grfMode,                   //Access mode for the new stream
   DWORD reserved1,                 //Reserved; must be zero
   DWORD reserved2,                 //Reserved; must be zero
   IStream ** ppstm                 //Points to new stream object
  );
```

Parameters

pwcsName
[in]Points to the name of the newly created stream. This name can be used later to open or reopen the stream.

grfMode
[in]Specifies the access mode to use when opening the newly created stream. See the **STGM** enumeration values for descriptions of the possible values.

reserved1
[in]Reserved for future use; must be zero.

reserved2
[in]Reserved for future use; must be zero.

ppstm
[out]Points to the location where the new **IStream** interface pointer is returned; only valid if the operation is successful. This parameter is set to NULL if an error occurs.

Return Values

S_OK
The new stream was successfully created

STG_E_ACCESSDENIED
Insufficient permissions to create stream.

STG_E_FILEALREADYEXISTS
The name specified for the stream already exists in the storage object and the *grfmode* flag includes the flag STGM_FAILIFTHERE.

STG_E_INSUFFICIENTMEMORY
The stream was not created due to a lack of memory.

STG_E_INVALIDFLAG
The value specified for the *grfMode* flag is not a valid **STGM** enumeration value.

STG_E_INVALIDFUNCTION
The specified combination of *grfMode* flags is not supported. For example, if this method is called without the STGM_SHARE_EXCLUSIVE flag.

STG_E_INVALIDNAME
Invalid value for *pwcsName*.

STG_E_INVALIDPOINTER
The pointer specified for the stream object was invalid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

STG_E_REVERTED

The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_TOOMANYOPENFILES
The stream was not created because there are too many open files.

Comments

If a stream with the name specified in the *pwcsName* parameter already exists and the *grfMode* parameter includes the STGM_CREATE flag, the existing stream is replaced by a newly created one. The destruction of the old stream and the creation of the new stream object are both subject to the transaction mode on the parent storage object.

If the stream already exists and *grfMode* is set to STGM_FAILIFTHERE, this method fails with the return value STG_E_FILEALREADYEXISTS.

Note to Callers

The OLE-provided compound file implementation of the **IStorage::CreateStream** method does not support the following behaviors:

- The STGM_DELETEONRELEASE flag is not supported.
- Transacted mode is not supported for stream objects.
- Opening the same stream more than once from the same storage is not supported. The STGM_SHARE_EXCLUSIVE flag must be specified.

Other implementations of **IStorage** might support these features.

See Also

IStorage::OpenStream, **IStream**

IStorage::DestroyElement

Removes the specified element from this storage object.

```
HRESULT DestroyElement(
  const wchar_t * pwcsName        //Points to the name of the element to be removed
 );
```

Parameter

pwcsName
[in]Points to the name of the element to be removed from this storage object.

Return Values

S_OK
The element was successfully removed.

STG_E_ACCESSDENIED
The caller does not have sufficient permissions for removing the element.

STG_E_FILENOTFOUND
The element with the specified name does not exist.

STG_E_INSUFFICIENTMEMORY
The element was not removed due to a lack of memory.

STG_E_INVALIDNAME
Invalid value for *pwcsName*.

STG_E_INVALIDPOINTER
The pointer specified for the element was invalid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_TOOMANYOPENFILES
The element was not removed because there are too many open files.

Comments

An existing open instance of this element from the parent becomes invalid after the **IStorage::DestroyElement** call completes.

The removal is subject to committing the changes if the storage object is opened in transacted mode.

IStorage::EnumElements

Returns an enumerator object that can be used to enumerate the storage and stream objects contained within this storage object.

```
HRESULT EnumElements(
    DWORD reserved1,              //Reserved; must be zero
    void * reserved2,             //Reserved; must be NULL
    DWORD reserved3,              //Reserved; must be zero
    IEnumSTATSTG ** ppenum        //Location for IEnumSTATSTG
  );
```

Parameters

reserved1
[in]Reserved for future use; must be zero.

reserved2
[in]Reserved for future use; must be NULL.

reserved3
[in]Reserved for future use; must be zero.

ppenum
[out]Points to the location where the new enumerator object should be returned.

Return Values

S_OK
The enumerator object was successfully returned.

STG_E_INSUFFICIENTMEMORY
The enumerator object could not be created due to lack of memory.

STG_E_INVALIDPARAMETER
One of the parameters was not valid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

Comments

The enumerator object returned by this method implements the **IEnumSTATSTG** interface, one of the standard enumerator interfaces that contain the **Next**, **Reset**, **Clone**, and **Skip** methods. **IEnumSTATSTG** enumerates the data stored in an array of **STATSTG** structures.

The storage object must be open in read mode to allow the enumeration of its elements.

The order in which the elements are enumerated and whether the enumerator is a snapshot or always reflects the current state of the storage object, depends on the **IStorage** implementation. The OLE-provided compound file implementation takes a snapshot.

See Also

IEnumXXXX, **IEnumSTATSTG**, **STATSTG**

IStorage::MoveElementTo

Copies or moves a substorage or stream from this storage object to another storage object.

```
HRESULT MoveElementTo(
    const wchar_t pwcsName,          //Name of the element to be moved
    IStorage * pstgDest,             //Points to destination storage object
    LPWSTR pwcsNewName,              //Points to new name of element in destination
    DWORD grfFlags                   //Specifies a copy or a move
  );
```

Parameters

pwcsName
[in]Specifies the name of the element in this storage object to be moved or copied.

pstgDest
[in]Points to the destination storage object.

pwcsNewName
[in]Points to the new name for the element in its new storage object.

grfFlags
[in]Specifies whether the operation should be a move (STGMOVE_MOVE) or a copy (STGMOVE_COPY). See the **STGMOVE** enumeration.

Return Values

S_OK
The storage object was successfully copied or moved.

STG_E_ACCESSDENIED
The destination storage object is a child of the source storage object.

STG_E_FILENOTFOUND
The element with the specified name does not exist.

STG_E_FILEALREADYEXISTS
The specified file already exists.

STG_E_INSUFFICIENTMEMORY
The copy or move was not completed due to a lack of memory.

STG_E_INVALIDFLAG
The value for the *grfFlags* parameter is not valid.

STG_E_INVALIDNAME
Invalid value for *pwcsName*.

STG_E_INVALIDPOINTER
The pointer specified for the storage object was invalid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_TOOMANYOPENFILES
The copy or move was not completed because there are too many open files.

Comments

The **IStorage::MoveElementTo** method is typically the same as invoking the **IStorage::CopyTo** method on the indicated element and then removing the source element. In this case, the **MoveElementTo** method uses only the publicly available functions of the destination storage object to carry out the move.

If the source and destination storage objects have special knowledge about each other's implementation (for example, they could be different instances of the same implementation), this operation can be implemented efficiently.

See Also

STGMOVE, **IStorage::CopyTo**

IStorage::OpenStorage

Opens an existing storage object with the specified name according to the specified access mode.

```
HRESULT OpenStorage(
   const wchar_t * pwcsName,        //Points to the name of the storage object to open
   IStorage * pstgPriority,         //Points to previous opening of the storage object
   DWORD grfMode,                   //Access mode for the new storage object
   SNB snbExclude,                  //Points to a block of stream names in the storage object
   DWORD reserved,                  //Reserved; must be zero
   IStorage ** ppstg                //Points to opened storage object
  );
```

Parameters

pwcsName
[in]Points to the name of the storage object to open. It is ignored if *pstgPriority* is non-NULL.

pstgPriority
[in]If the *pstgPriority* parameter is not NULL, it is a pointer to a previous opening of an element of the storage object, usually one that was opened in priority mode. The storage object should be closed and re-opened according to *grfMode*. When the **IStorage::OpenStorage** method returns, *pstgPriority* is no longer valid. Use the value returned in the *ppstg* parameter. If the *pstgPriority* parameter is NULL, it is ignored.

grfMode
[in]Specifies the access mode to use when opening the storage object. See the **STGM** enumeration values for descriptions of the possible values.

snbExclude
[in]Either NULL or a non-NULL value that points to a block of stream names in this storage object that are to be emptied as the object is opened. This exclusion happens independent of whether a snapshot copy happens on the open.

reserved
[in]Reserved for future use; must be zero.

ppstg
[out]Points to the location where the **IStorage** interface pointer is returned; only valid if the operation is successful. This parameter is set to NULL if an error occurs.

Return Values

S_OK
The storage object was opened successfully.

STG_E_ACCESSDENIED
Insufficient permissions to open storage object.

STG_E_FILENOTFOUND
The storage object with the specified name does not exist.

STG_E_INSUFFICIENTMEMORY
The storage object was not opened due to a lack of memory.

STG_E_INVALIDFLAG
The value specified for the *grfMode* flag is not a valid **STGM** enumeration value.

STG_E_INVALIDFUNCTION
The specified combination of *grfMode* flags is not supported.

STG_E_INVALIDNAME
Invalid value for *pwcsName*.

STG_E_INVALIDPOINTER
The pointer specified for the storage object was invalid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_TOOMANYOPENFILES
The storage object was not created because there are too many open files.

STG_S_CONVERTED
The existing stream with the specified name was replaced with a new storage object containing a single stream called CONTENTS. The new storage object will be added.

Comments

Root storage objects can be opened with STGM_DELETEONRELEASE, in which case the object is destroyed when it receives its final release. This is useful for creating temporary storage objects.

Note to Callers

The OLE-provided compound file implementation of the **IStorage::OpenStorage** method does not support the following behaviors:

- The STGM_PRIORITY flag is not supported for non-root storages.
- Opening the same storage object more than once from the same parent storage is not supported. The STGM_SHARE_EXCLUSIVE flag must be specified.

Other implementations of **IStorage** might support these features.

See Also

IStorage::CreateStorage

IStorage::OpenStream

Opens an existing stream object within this storage object using the specified access permissions in *grfMode*.

```
HRESULT OpenStream(
    const wchar_t * pwcsName,        //Points to name of stream to open
    void * reserved1,                //Reserved; must be NULL
    DWORD grfMode,                   //Access mode for the new stream
    DWORD reserved2,                 //Reserved; must be zero
    IStream ** ppstm                 //Points to opened stream object
  );
```

Parameters

pwcsName
[in]Points to the name of the stream to open.

reserved1
[in]Reserved for future use; must be NULL.

grfMode
[in]Specifies the access mode to use when opening the stream. See the **STGM** enumeration values for descriptions of the possible values.

reserved2
[in]Reserved for future use; must be zero.

ppstm
[out]Points to the location where the opened **IStream** interface pointer is returned; only valid if the operation is successful. This parameter is set to NULL if an error occurs.

Return Values

S_OK
The stream was successfully opened.

STG_E_ACCESSDENIED
Insufficient permissions to open stream.

STG_E_FILENOTFOUND
The stream with specified name does not exist.

STG_E_INSUFFICIENTMEMORY
The stream was not opened due to a lack of memory.

STG_E_INVALIDFLAG
The value specified for the *grfMode* flag is not a valid **STGM** enumeration value.

STG_E_INVALIDFUNCTION
The specified combination of *grfMode* flags is not supported. For example, if this method is called without the STGM_SHARE_EXCLUSIVE flag.

STG_E_INVALIDNAME
Invalid value for *pwcsName*.

STG_E_INVALIDPOINTER
The pointer specified for the stream object was invalid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_TOOMANYOPENFILES
The stream was not opened because there are too many open files.

Comments

There are restrictions on the permissions that can be given in *grfMode*. For example, the permissions on this storage object restrict the permissions on its streams.

Note to Callers

The OLE-provided compound file implementation of the **IStorage::OpenStream** method does not support the following behaviors:

- The STGM_DELETEONRELEASE flag is not supported.
- Transacted mode is not supported for stream objects.
- Opening the same stream more than once from the same storage is not supported. The STGM_SHARE_EXCLUSIVE flag must be specified.

Other implementations of **IStorage** might support these features.

See Also

IStorage::CreateStream, **IStream**

IStorage::RenameElement

Renames the specified element in this storage object.

```
HRESULT RenameElement(
  const wchar_t * pwcsOldName,        //Points to the name of the element to be changed
  const wchar_t * pwcsNewName         //Points to the new name for the specified element
 );
```

Parameters

pwcsOldName
[in]Points to the name of the element to be changed.

pwcsNewName
[in]Points to the new name for the specified element.

Return Values

S_OK
The element was successfully renamed.

STG_E_ACCESSDENIED
The caller does not have sufficient permissions for renaming the element.

STG_E_FILENOTFOUND
The element with the specified old name does not exist.

STG_E_FILEALREADYEXISTS
The element specified by the new name already exists.

STG_E_INSUFFICIENTMEMORY
The element was not renamed due to a lack of memory.

STG_E_INVALIDNAME
Invalid value for one of the names.

STG_E_INVALIDPOINTER
The pointer specified for the element was invalid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_TOOMANYOPENFILES
The element was not renamed because there are too many open files.

Comments

An element in a storage object cannot be renamed while it is open. The rename operation is subject to committing the changes if the storage is open in transacted mode.

The **IStorage::RenameElement** method is not guaranteed to work in low memory with storage objects open in transacted mode. It may work in direct mode.

IStorage::Revert

Discards all changes that have been made to the storage object since the last commit.

HRESULT Revert(*void***);**

Return Values

S_OK
 The revert operation was successful.

STG_E_INSUFFICIENTMEMORY
 The revert operation could not be completed due to a lack of memory.

STG_E_TOOMANYOPENFILES
 The revert operation could not be completed because there are too many open files.

STG_E_REVERTED
 The object has been invalidated by a revert operation above it in the transaction tree.

Comments

For storage objects opened in transacted mode, the **IStorage::Revert** method discards any uncommitted changes to this storage object or changes that have been committed to this storage object from nested elements.

After this method finishes, any existing elements that were opened from the reverted storage object are invalid and can no longer be used. The error STG_E_REVERTED is returned on all calls except **IStorage::Release** using these openings.

For storage objects opened in direct mode, this method has no effect.

See Also

IStorage::Commit

IStorage::SetClass

Assigns the specified CLSID to this storage object.

```
HRESULT SetClass(
   REFCLSID clsid         //Class identifier to be assigned to the storage object
  );
```

Parameter

clsid
[in]The class identifier that is to be associated with the storage object.

Return Values

S_OK
The CLSID was successfully assigned.

STG_E_ACCESSDENIED
The caller does not have sufficient permissions for assigning a class identifier to the storage object.

STG_E_MEDIUMFULL
Not enough space was left on device to complete the operation.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

Comments

When first created, a storage object has an associated CLSID of CLSID_NULL. You call this method to assign a class identifier to the storage object.

You can retrieve the current CLSID of a storage object with the **IStorage::Stat** method.

See Also

IStorage::Stat

IStorage::SetElementTimes

Sets the modification, access, and creation times of the specified storage element, if supported by the underlying file system.

```
HRESULT SetElementTimes(
  const wchar_t * pwcsName,      //Points to name of element to be changed
  FILETIME const * pctime,       //New creation time for element, or NULL
  FILETIME const * patime,       //New access time for element, or NULL
  FILETIME const * pmtime        //New modification time for element, or NULL
 );
```

Parameters

pwcsName
[in]The name of the storage object element whose times are to be modified. If NULL, the time is set on the root storage rather than one of its elements.

pctime
[in]Either the new creation time for the element or NULL if the creation time is not to be modified.

patime
[in]Either the new access time for the element or NULL if the access time is not to be modified.

pmtime
[in]Either the new modification time for the element or NULL if the modification time is not to be modified.

Return Values

S_OK
The time values were successfully set.

STG_E_ACCESSDENIED
The caller does not have sufficient permissions for changing the element.

STG_E_FILENOTFOUND
The element with the specified name does not exist.

STG_E_INSUFFICIENTMEMORY
The element was not changed due to a lack of memory.

STG_E_INVALIDNAME
Invalid value for the element name.

STG_E_INVALIDPOINTER
The pointer specified for the element was invalid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_TOOMANYOPENFILES
The element was not changed because there are too many open files.

Comments

This method sets time statistics for the specified storage element within this storage object.

Not all file systems support all of the time values. This method sets those times that are supported and ignores the rest. Each of the time value parameters can be NULL; indicating that no modification should occur.

You can retrieve these time values with the **IStorage::Stat** method.

Note to Callers

The OLE-provided compound file implementation maintains modification and change times for internal storage objects. For root storage objects, whatever is supported by the underlying file system (or **ILockBytes**) is supported. The compound file implementation does not maintain any time stamps for internal streams. Unsupported time stamps are reported as zero, enabling the caller to test for support.

See Also

IStorage::Stat

IStorage::SetStateBits

Stores up to 32 bits of state information in this storage object.

```
HRESULT SetStateBits(
   DWORD grfStateBits,          //Specifies new values of bits
   DWORD grfMask                //Specifies mask that indicates which bits are significant
  );
```

Parameters

grfStateBits

[in]Specifies the new values of the bits to set. No legal values are defined for these bits; they are all reserved for future use and must not be used by applications. See the **STGSTATE** enumeration for a definition of these values.

grfMask

[in]A binary mask indicating which bits in *grfStateBits* are significant in this call. See the **STGSTATE** enumeration for a definition of these values.

Return Values

S_OK

The state information was successfully set.

STG_E_ACCESSDENIED

The caller does not have sufficient permissions for changing this storage object.

STG_E_INVALIDFLAG

The value for the *grfStateBits* or *grfMask* parameters are not valid.

STG_E_INVALIDPARAMETER

One of the parameters was invalid.

Comments

You can retrieve the state information with the **IStorage::Stat** method. When a storage object is first created, the value of this state information is zero. The values for the state bits are not defined currently and should not be used by applications.

The state set by this method is for external use only. The OLE-provided compound file implementation does not perform any action based on the state.

See Also

STATSTATE, **IStorage::Stat**

IStorage::Stat

Returns the **STATSTG** structure for this open storage object.

```
HRESULT Stat(
  STATSTG * pstatstg,          //Location for STATSTG structure
  DWORD grfStatFlag            //Values taken from the STATFLAG enumeration
 );
```

Parameters

pstatstg
[out]Points to a **STATSTG** structure where this method places information about the open storage object. This parameter is NULL if an error occurs.

grfStatFlag
[in]Specifies that some of the fields in the **STATSTG** structure are not returned, thus saving a memory allocation operation. Values are taken from the **STATFLAG** enumeration.

Return Values

S_OK
The **STATSTG** structure was successfully returned at the specified location.

STG_E_ACCESSDENIED
The caller does not have sufficient permissions for accessing statistics for this storage object.

STG_E_INSUFFICIENTMEMORY
The **STATSTG** structure was not returned due to a lack of memory.

STG_E_INVALIDFLAG
The value for the *grfStateFlag* parameter is not valid.

STG_E_INVALIDPARAMETER
One of the parameters was invalid.

See Also

STATFLAG, **STATSTG**, **IStorage::SetClass**, **IStorage::SetElementTimes**, **IStorage::SetStateBits**

IStream

The **IStream** interface supports reading and writing data to stream objects. Stream objects are elements nested within a storage object. They are similar to standard files. You use stream objects to store the data for your application.

The **IStream** interface provides methods similar to the MS-DOS FAT file functions. For example, each stream object has its own access rights and a seek pointer. The main difference between a stream object and a DOS file is that streams are not open using a file handle. Instead, you use the **IStream** interface pointer.

The methods in this interface present your object data as a contiguous sequence of bytes which you can read or write. There are also methods for committing and reverting changes on streams open in transacted mode and methods for restricting access to a range of bytes in the stream.

Streams can remain open for long periods of time without consuming file system resources. The **IStream::Release** method is similar to a close function on a file. Once released, the stream object is no longer valid and cannot be used.

When to Implement

OLE provides an implementation of the **IStream** interface that you can use for saving object data. The specification of **IStream** defines more functionality that the OLE implementation supports. For example, the **IStream** interface defines streams up to 2 (64) bytes in length requiring a 64-bit seek pointer. However, the OLE implementation only supports streams up to 2 (32) bytes in length and read and write operations are always limited to 2 (32) bytes at a time. The OLE implementation also does not support stream transactioning or region locking.

Container or object applications can implement their own stream objects instead of using the OLE-provided implementation.

When to Use

If you are writing an object application, you can use the **IStream** interface to store the data for your object.

Since stream objects can be marshaled to other processes, applications can share the data in storage objects without having to use global memory. For the OLE-provided implementation of stream objects, the custom marshaling facilities in OLE create a remote version of the original object in the new process when the two processes have shared memory access. Thus, the remote version does not need to communicate with the original process to carry out its functions.

The remote version of the stream object shares the same seek pointer as the original stream. If you do not want to share the seek pointer, you should use the **IStream::Clone** method to provide a copy of the stream object for the remote process.

Note If you are creating a stream object that is larger than the heap in your machine's memory and you are using an HGLOBAL, the stream object calls **GlobalRealloc** internally whenever it needs more memory. Because **GlobalRealloc** always copies data from the source to the destination, increasing a stream object from 20M to 25M, for example, consumes immense amounts of time. This is due to the size of the increments copied and is worsened if there is less than 45M of memory on the machine because of disk swapping.

The preferred solution is to implement an **IStream** that uses memory allocated by **VirtualAlloc** instead of **GlobalAlloc**. This can reserve a large chunk of virtual address space and then commit memory within that address space as required. No data copying occurs and memory is committed only as it is needed.

Another alternative is to call the **IStream::SetSize** method on the stream object to increase the memory allocation in advance. This is not, however, as efficient as using **VirtualAlloc** as described above.

Methods in Vtable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IStream Methods	Description
Read	Reads a specified number of bytes from the stream object into memory starting at the current seek pointer.
Write	Writes a specified number from bytes into the stream object starting at the current seek pointer.
Seek	Changes the seek pointer to a new location relative to the beginning of the stream, the end of the stream, or the current seek pointer.
SetSize	Changes the size of the stream object.
CopyTo	Copies a specified number of bytes from the current seek pointer in the stream to the current seek pointer in another stream.
Commit	Ensures that any changes made to a stream object open in transacted mode are reflected in the parent storage object.
Revert	Discards all changes that have been made to a transacted stream since the last **IStream::Commit** call.
LockRegion	Restricts access to a specified range of bytes in the stream. Supporting this functionality is optional since some file systems do not provide it.
UnlockRegion	Removes the access restriction on a range of bytes previously restricted with **IStream::LockRegion**.
Stat	Retrieves the **STATSTG** structure for this stream.
Clone	Creates a new stream object that references the same bytes as the original stream but provides a separate seek pointer to those bytes.

IStream::Clone

Creates a new stream object with its own seek pointer that references the same bytes as the original stream.

```
HRESULT Clone(
   IStream ** ppstm          //Points to location for pointer to the new stream object
  );
```

Parameter

ppstm
[out]Points to location for the pointer to the new stream object. If an error occurs, this parameter is NULL.

Return Values

S_OK
The stream was successfully cloned.

STG_E_INSUFFICIENT_MEMORY
The stream was not cloned due to a lack of memory.

STG_E_INVALIDPOINTER
The *ppStm* pointer is not valid.

Comments

This method creates a new stream object for accessing the same bytes but using a separate seek pointer. The new stream object sees the same data as the source stream object. Changes written to one object are immediately visible in the other. Range locking is shared between the stream objects.

The initial setting of the seek pointer in the cloned stream instance is the same as the current setting of the seek pointer in the original stream at the time of the clone operation.

See Also

IStream::CopyTo

IStream::Commit

Ensures that any changes made to a stream object open in transacted mode are reflected in the parent storage. If the stream object is open in direct mode, **IStream::Commit** has no effect other than flushing all memory buffers to the next level storage object. The OLE-provided implementation of streams does not support opening streams in transacted mode.

```
HRESULT Commit(
  DWORD grfCommitFlags        //Specifies how changes are committed
 );
```

Parameter

grfCommitFlags
[in]Controls how the changes for the stream object are committed. See the **STGC** enumeration for a definition of these values.

Return Values

S_OK
Changes to the stream object were successfully committed to the parent level.

STG_E_MEDIUMFULL
The commit operation failed due to lack of space on the storage device.

Comments

This method ensures that changes to a stream object opened in transacted mode are reflected in the parent storage. Changes that have been made to the stream since it was opened or last committed are reflected to the parent storage object. If the parent is opened in transacted mode, the parent may still revert at a later time rolling back the changes to this stream object.

If the stream is open in direct mode, this method ensures that any memory buffers have been flushed out to the underlying storage object. This is much like a flush in traditional file systems.

The **IStream::Commit** method is useful on a direct mode stream when the implementation of the **IStream** interface is a wrapper for underlying file system APIs. In this case, **IStream::Commit** would be connected to the file system's flush call.

Notes to Callers

The OLE-provided implementation of stream objects does not support transacted streams. Also, stream objects only exist within storage objects in this implementation. Thus, the OLE implementation of **IStream::Commit** has no effect other than flushing internal memory buffers to the parent storage object. With this implementation, it does not matter if you commit changes to streams. You can just commit changes for storage objects.

See Also

IStorage::Commit

IStream::CopyTo

Copies a specified number of bytes from the current seek pointer in the stream to the current seek pointer in another stream.

```
HRESULT CopyTo(
  IStream * pstm,                     //Points to the destination stream
  ULARGE_INTEGER cb,                  //Specifies the number of bytes to copy
  ULARGE_INTEGER * pcbRead,           //Pointer to the actual number of bytes read from the source
  ULARGE_INTEGER * pcbWritten         //Pointer to the actual number of bytes written to the destination
 );
```

Parameters

pstm
[in]Points to the destination stream. The stream pointed to by *pstm* can be a new stream or a clone of the source stream.

cb
[in]Specifies the number of bytes to copy from the source stream.

pcbRead
[out]Pointer to the location where this method writes the actual number of bytes read from the source. You can set this pointer to NULL to indicate that you are not interested in this value. In this case, this method does not provide the actual number of bytes read.

pcbWritten
[out]Pointer to the location where this method writes the actual number of bytes written to the destination. You can set this pointer to NULL to indicate that you are not interested in this value. In this case, this method does not provide the actual number of bytes written.

Return Values

S_OK
The stream object was successfully copied.

STG_E_INVALIDPOINTER
The value of one of the pointer parameters is not valid.

STG_E_MEDIUMFULL
The stream is not copied because there is no space left on the storage device.

Comments

This method copies the specified bytes from one stream to another. The seek pointer in each stream instance is adjusted for the number of bytes read or written. This method is equivalent to reading *cb* bytes into memory using **IStream::Read** and then immediately writing them to the destination stream using **IStream::Write**, although **IStream::CopyTo** will be more efficient.

The destination stream can be a clone of the source stream created by calling the **IStream::Clone** method.

If **IStream::CopyTo** returns an error, you cannot assume that the seek pointers are valid for either the source or destination. Additionally, the values of *pcbRead* and *pcbWritten* are not meaningful even though they are returned.

If **IStream::CopyTo** returns successfully, the actual number of bytes read and written are the same.

To copy the remainder of the source from the current seek pointer, specify the maximum large integer value for the *cb* parameter. If the seek pointer is the beginning of the stream, this techniques copies the entire stream.

See Also

IStream::Read, **IStream::Write**, **IStream::Clone**

IStream::LockRegion

Restricts access to a specified range of bytes in the stream. Supporting this functionality is optional since some file systems do not provide it.

```
HRESULT LockRegion(
   ULARGE_INTEGER libOffset,        //Specifies the byte offset for the beginning of the range
   ULARGE_INTEGER cb,               //Specifies the length of the range in bytes
   DWORD dwLockType                 //Specifies the restriction on accessing the specified range
  );
```

Parameters

libOffset
[in]Specifies the byte offset for the beginning of the range.

cb
[in]Specifies, in bytes, the length of the range to be restricted.

dwLockType
[in]Specifies the restrictions being requested on accessing the range.

Return Values

S_OK
The specified range of bytes was locked.

STG_E_INVALIDFUNCTION
Locking is not supported at all or the specific type of lock requested is not supported.

STG_E_LOCKVIOLATION
Requested lock is supported, but cannot be granted because of an existing lock.

Comments

The byte range can extend past the current end of the stream. Locking beyond the end of a stream is useful as a method of communication between different instances of the stream without changing data that is actually part of the stream.

Three types of locking can be supported: locking to exclude other writers, locking to exclude other readers or writers, and locking that allows only one requestor to obtain a lock on the given range, which is usually an alias for one of the other two lock types. A given stream instance might support either of the first two types, or both. The lock type is specified by *dwLockType*, using a value from the **LOCKTYPE** enumeration.

Any region locked with **IStream::LockRegion** must later be explicitly unlocked by calling **IStream::UnlockRegion** with exactly the same values for the *libOffset*, *cb*, and *dwLockTyp*e parameters. The region must be unlocked before the stream is released. Two adjacent regions cannot be locked separately and then unlocked with a single unlock call.

Notes to Callers

Since range locking is not supported by the OLE-provided implementation of streams, calling **IStream::LockRegion** has no effect for this implementation.

Since the type of locking supported is optional and can vary in different implementations of **IStream**, you must provide code to deal with the STG_E_INVALIDFUNCTION error.

Notes to Implementors

Support for this method is optional for implementations of stream objects since it may not be supported by the underlying file system. The type of locking supported is also optional. The STG_E_INVALIDFUNCTION error is returned if the requested type of locking is not supported.

See Also

LOCKTYPE, **IStream::UnlockRegion**

IStream::Read

Reads a specified number of bytes from the stream object into memory starting at the current seek pointer.

```
HRESULT Read(
    void * pv,              //Pointer to buffer into which the stream is read
    ULONG cb,               //Specifies the number of bytes to read
    ULONG * pcbRead         //Pointer to location that contains actual number of bytes read
  );
```

Parameters

pv
[in]Points to the buffer into which the stream is read. If an error occurs, this value is NULL.

cb
[in]Specifies the number of bytes of data to attempt to read from the stream object.

pcbRead
[out]Pointer to a location where this method writes the actual number of bytes read from the stream object. You can set this pointer to NULL to indicate that you are not interested in this value. In this case, this method does not provide the actual number of bytes read.

Return Values

S_OK
Data was successfully read from the stream object.

S_FALSE
The data could not be read from the stream object.

STG_E_ACCESSDENIED
The caller does not have sufficient permissions for reading this stream object.

STG_E_INVALIDPOINTER
One of the pointer values is invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

Comments

This method reads bytes from this stream object into memory. The stream object must be opened in STGM_READ mode. This method adjusts the seek pointer by the actual number of bytes read.

The number of bytes actually read is returned in the *pcbRead* parameter.

Notes to Callers

The actual number of bytes read can be fewer than the number of bytes requested if an error occurs or if the end of the stream is reached during the read operation.

The OLE-provided implementation of **IStream** returns S_OK if the end of the stream was reached during the read. (This is the same as the "end of file" behavior found in the MS-DOS FAT file system.

Some implementations might return an error if the end of the stream is reached during the read. You must be prepared to deal with the error return or S_OK return values on end of stream reads.

See Also

STGMOVE, **IStorage::OpenStream**, **IStream::Write**

IStream::Revert

Discards all changes that have been made to a transacted stream since the last **IStream::Commit** call. For streams open in direct mode and streams using the OLE implementation of **IStream::Revert**, this method has no effect.

HRESULT Revert(*void***);**

Return Values

S_OK
The stream was successfully reverted to its previous version.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

Comments

This method discards changes made to a transacted stream since the last commit operation.

The OLE-provided implementation does not support transacted streams, and this method has no effect in that implementation.

See Also

IStream::Commit

IStream::Seek

Changes the seek pointer to a new location relative to the beginning of the stream, to the end of the stream, or to the current seek pointer.

```
HRESULT Seek(
   LARGE_INTEGER dlibMove,                 //Offset relative to dwOrigin
   DWORD dwOrigin,                         //Specifies the origin for the offset
   ULARGE_INTEGER * plibNewPosition        //Pointer to location containing new seek pointer
 );
```

Parameters

dlibMove

[in]Displacement to be added to the location indicated by *dwOrigin*. If *dwOrigin* is STREAM_SEEK_SET, then this is interpreted as an unsigned value rather than signed.

dwOrigin

[in]Specifies the origin for the displacement specified in *dlibMove.* The origin can the be beginning of the file, the current seek pointer, or the end of the file. See the **STREAM_SEEK** enumeration for the values.

plibNewPosition

[out]Pointer to the location where this method writes the value of the new seek pointer from the beginning of the stream. You can set this pointer to NULL to indicate that you are not interested in this value. In this case, this method does not provide the new seek pointer.

Return Values

S_OK

The seek pointer has been successfully adjusted.

STG_E_INVALIDPOINTER

The value of the *plibNewPosition* parameter is not valid.

STG_E_INVALIDFUNCTION

The value of the *dwOrigin* parameter is not valid.

Comments

This method changes the seek pointer so subsequent reads and writes can take place at a different location in the stream object. It is an error to seek before the beginning of the stream. However, it is not an error to seek past the end of the stream. Seeking past the end of the stream is useful for subsequent writes, as the stream will at that time be extended to the seek position immediately before the write is done.

You can also use this method to obtain the current value of the seek pointer by calling this method with the *dwOrigin* parameter set to STREAM_SEEK_CUR and the *dlibMove* parameter set to 0 so the seek pointer is not changed. The current seek pointer is returned in the *plibNewPosition* parameter.

See Also

STREAM_SEEK, **IStream::Read**, **IStream::Write**

IStream::SetSize

Changes the size of the stream object.

```
HRESULT SetSize(
   ULARGE_INTEGER libNewSize       //Specifies the new size of the stream object
  );
```

Parameter

libNewSize
[in]Specifies the new size of the stream as a number of bytes.

Return Values

S_OK
The size of the stream object was successfully changed.

STG_E_MEDIUMFULL
The stream size is not changed because there is no space left on the storage device.

STG_E_INVALIDFUNCTION
The value of the *libNewSize* parameter is not valid. Since streams cannot be greater than 2 (32) bytes in the OLE-provided implementation, the high DWORD of *libNewSize* must be 0. If it is nonzero, this parameter is not valid.

Comments

This method changes the size of the stream object. You can use this method to preallocate space for the stream. If the *libNewSize* parameteris larger than the current stream size, the stream is extended to the indicated size by filling the intervening space with bytes of undefined value. This operation is similar to the **IStream::Write** method if the seek pointer is past the current end-of-stream.

If the *libNewSize* parameter is smaller than the current stream, then the stream is truncated to the indicated size.

The seek pointer is not affected by the change in stream size.

Calling **IStream::SetSize** is an effective way of trying to obtain a large chunk of contiguous space. However, in the OLE-provided implementation of streams, there is no guarantee that the space will be contiguous.

See Also

IStream::Write

IStream::Stat

Retrieves the **STATSTG** structure for this stream.

```
HRESULT Stat(
  STATSTG * pstatstg,         //Location for STATSTG structure
  DWORD grfStatFlag           //Values taken from the STATFLAG enumeration
 );
```

Parameters

pstatstg
: [out]Points to a **STATSTG** structure where this method places information about this stream object. This pointer is NULL if an error occurs.

grfStatFlag
: [in]Specifies that this method does not return some of the fields in the **STATSTG** structure, thus saving a memory allocation operation. Values are taken from the **STATFLAG** enumeration.

Return Value

S_OK
: The **STATSTG** structure was successfully returned at the specified location.

STG_E_ACCESSDENIED
: The caller does not have sufficient permissions for accessing statistics for this storage object.

STG_E_INSUFFICIENTMEMORY
: The **STATSTG** structure was not returned due to a lack of memory.

STG_E_INVALIDFLAG
: The value for the *grfStateFlag* parameter is not valid.

STG_E_INVALIDPOINTER
: The *pStatStg* pointer is not valid.

See Also

STATFLAG, **STATSTG**

IStream::UnlockRegion

Removes the access restriction on a range of bytes previously restricted with **IStream::LockRegion**.

```
HRESULT UnlockRegion(
   ULARGE_INTEGER libOffset,     //Specifies the byte offset for the beginning of the range
   ULARGE_INTEGER cb,            //Specifies the length of the range in bytes
   DWORD dwLockType              //Specifies the access restriction previously placed on the range
  );
```

Parameters

libOffset
[in]Specifies the byte offset for the beginning of the range.

cb
[in]Specifies, in bytes, the length of the range to be restricted.

dwLockType
[in]Specifies the access restrictions previously placed on the range.

Return Values

S_OK
The byte range was unlocked.

STG_E_INVALIDFUNCTION
Locking is not supported at all or the specific type of lock requested is not supported.

STG_E_LOCKVIOLATION
The requested unlock cannot be granted.

Comments

This method unlocks a region previously locked with the **IStream::LockRegion** method. Locked regions must later be explicitly unlocked by calling **IStream::UnlockRegion** with exactly the same values for the *libOffset*, *cb*, and *dwLockTyp*e parameters. The region must be unlocked before the stream is released. Two adjacent regions cannot be locked separately and then unlocked with a single unlock call.

See Also

LOCKTYPE, **IStream::LockRegion**

IStream::Write

Writes a specified number from bytes into the stream object starting at the current seek pointer.

```
HRESULT Write(
    void const* pv,             //Pointer to buffer from which stream is written
    ULONG cb,                   //Specifies the number of bytes to write
    ULONG * pcbWritten          //Specifies the actual number of bytes written
  );
```

Parameters

pv
[in]Points to the buffer from which the stream should be written.

cb
[in]Specifies the number of bytes of data to attempt to write into the stream.

pcbWritten
[out]Pointer to a location where this method writes the actual number of bytes written to the stream object. You can set this pointer to NULL to indicate that you are not interested in this value. In this case, this method does not provide the actual number of bytes written.

Return Values

S_OK
The data was successfully written into the stream object.

STG_E_MEDIUMFULL
The write operation was not completed because there is no space left on the storage device.

STG_E_ACCESSDENIED
The caller does not have sufficient permissions for writing this stream object.

STG_E_CANTSAVE
Data cannot be written for reasons other than no access or space.

STG_E_INVALIDPOINTER
One of the pointer values is invalid.

STG_E_REVERTED
The object has been invalidated by a revert operation above it in the transaction tree.

STG_E_WRITEFAULT
The write operation was not completed due to a disk error.

Comments

This method writes the specified data to a stream object. The seek pointer is adjusted for the number of bytes actually written. The number of bytes actually written is returned in the *pcbWrite* parameter. If the byte count is zero bytes, the write operation has no effect.

If the seek pointer is currently past the end of the stream and the byte count is non-zero, this method increases the size of the stream to the seek pointer and writes the specified bytes starting at the seek pointer. The fill bytes written to the stream are not initialized to any particular value. This is the same as the end-of-file behavior in the MS-DOS FAT file system.

With a zero byte count and a seek pointer past the end of the stream, this method does not create the fill bytes to increase the stream to the seek pointer. In this case, you must call the **IStream::SetSize** method to increase the size of the stream and write the fill bytes.

Notes to Callers

In the OLE-provided implementation, stream objects are not sparse. Any fill bytes are eventually allocated on the disk and assigned to the stream.

The *pcbWrite* parameter can have a value even if an error occurs.

IUnknown

The **IUnknown** interface lets clients get pointers to other interfaces on a given object through the **QueryInterface** method, and manage the existence of the object through the **IUnknown::AddRef** and **IUnknown::Release** methods. All other COM interfaces are inherited, directly or indirectly, from **IUnknown**. Therefore, the three methods in **IUnknown** are the first entries in the VTable for every interface.

When to Implement

You must implement **IUnknown** as part of every interface. If you are using C++ multiple inheritance to implement multiple interfaces, the various interfaces can share one implementation of **IUnknown**. If you are using nested classes to implement multiple interfaces, you must implement **IUnknown** once for each interface you implement.

When to Use

Use **IUnknown** methods to switch between interfaces on an object, add references, and release objects.

Methods in Vtable Order

IUnknown Methods	Description
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IUnknown::AddRef

The **IUnknown::AddRef** method increments the reference count for a the calling interface on an object. It should be called for every new copy of a pointer to an interface on a given object.

ULONG AddRef(*void***);**

Return Value

Returns an integer from 1 to n, the value of the new reference count. This information is meant to be used for diagnostic/testing purposes only, because, in certain situations, the value may be unstable.

Comments

Objects use a reference counting mechanism to ensure that the lifetime of the object includes the lifetime of references to it. You use **IUnknown::AddRef** to stabilize a copy of an interface pointer. It can also be called when the life of a cloned pointer must extend beyond the lifetime of the original pointer. The cloned pointer must be released by calling **IUnknown::Release.**

Objects must be able to maintain (2 (31))-1 outstanding pointer references. Therefore, the internal reference counter that **IUnknown::AddRef** maintains must be a 32-bit unsigned integer.

Notes to Callers

Call this function for every new copy of an interface pointer that you make. For example, if you are passing a copy of a pointer back from a function, you must call **IUnknown::AddRef** on that pointer. You must also call **IUnknown::AddRef** on a pointer before passing it as an in-out parameter to a function; the function will call **IUnknown::Release** before copying the out-value on top of it.

See Also

IUnknown::Release

IUnknown::QueryInterface

Returns a pointer to a specified interface on a component to which a client currently holds an interface pointer. This function must call **IUnknown::AddRef** on the pointer it returns.

```
HRESULT QueryInterface(
   REFIID iid,             //Specifies the requested interface's IID
   void ** ppvObject       //Receives an indirect pointer to the object
  );
```

Parameters

iid
[in] Specifies the IID of the interface being requested.

ppvObject
[out] Receives a pointer to an interface pointer to the object on return. If the interface specified in *riid* is not supported by the object, *ppvObj* is set to **NULL**.

Return Value

S_OK if the interface is supported, S_FALSE if not.

Comments

The QueryInterface method gives a client access to other interfaces on an object.

For any one object, a specific query for the **IUnknown** interface on any of the object's interfaces must always return the same pointer value. This allows a client to determine whether two pointers point to the same component by calling **QueryInterface** on both and comparing the results. It is specifically not the case that queries for interfaces (even the same interface through the same pointer) must return the same pointer value.

There are four requirements for implementations of **QueryInterface** (In these cases, "must succeed" means "must succeed barring catastrophic failure."):

- The set of interfaces accessible on an object through **IUnknown::QueryInterface** must be static, not dynamic. This means that if a call to **QueryInterface** for a pointer to a specified interface succeeds the first time, it must succeed again, and if it fails the first time, it must fail on all subsequent queries.
- It must be symmetric – if a client holds a pointer to an interface on an object, and queries for that interface, the call must succeed.
- It must be reflexive – if a client holding a pointer to one interface queries successfully for another, a query through the obtained pointer for the first interface must succeed.
- It must be transitive – if a client holding a pointer to one interface queries successfully for a second, and through that pointer queries successfully for a third interface, a query for the first interface through the pointer for the third interface must succeed.

IUnknown::Release

Decrements the reference count for the calling interface on a object. If the reference count on the object falls to 0, the object is freed from memory.

ULONG Release(*void***);**

Return Value

Returns the resulting value of the reference count, which is used for diagnostic/testing purposes only. If you need to know that resources have been freed, use an interface with higher-level semantics.

Comments

If **IUnknown::AddRef** has been called on this object's interface *n* times and this is the *n+1th* call to **IUnknown::Release**, the implementation of **IUnknown::AddRef** must cause the interface pointer to free itself. When the released pointer is the only existing reference to an object (whether the object supports single or multiple interfaces), the implementation must free the object.

Note Aggregation of objects restricts the ability to recover interface pointers.

Notes to Callers

Call this function when you no longer need to use an interface pointer. If you are writing a function that takes an in-out parameter, call **IUnknown::Release** on the pointer you are passing in before copying the out-value on top of it.

See Also

IUnknown::AddRef

IViewObject

The **IViewObject** interface enables an object to display itself directly without passing a data object to the caller. In addition, this interface can create and manage a connection with an advise sink so the caller can be notified of changes in the view object.

The caller can request specific representations and specific target devices. For example, a caller can ask for either an object's content or an iconic representation. Also, the caller can ask the object to compose a picture for a target device that is independent of the drawing device context. As a result, the picture can be composed for one target device and drawn on another device context. For example, to provide a print preview operation, you can compose the drawing for a printer target device but actually draw the representation on the display.

The **IViewObject** interface is similar to **IDataObject**; except that **IViewObject** places a representation of the data onto a device context while **IDataObject** places the representation onto a transfer medium.

Unlike most other interfaces, **IViewObject** cannot be marshaled to another process. This is because device contexts are only effective in the context of one process.

When to Implement

Object handlers and in-process servers that manage their own presentations implement **IViewObject** for use by compound document containers. OLE provides an **IViewObject** implementation for its default object handler's cache.

When to Use

You call **IViewObject** from a container application if you need to draw a contained object on a specific device context. For example, if you want to print the object to a printer, you call the **Draw** method in the **IViewObject** interface.

Methods in VTable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments the reference count.
Release	Decrements the reference count.

IViewObject Methods	**Description**
Draw	Draws a representation of the object onto a device context.
GetColorSet	Returns the logical palette the object uses for drawing.
Freeze	Freezes the drawn representation of an object so it will not change until a subsequent **Unfreeze**.
Unfreeze	Unfreezes the drawn representation of an object.
SetAdvise	Sets up a connection between the view object and an advise sink so that the advise sink can receive notifications of changes in the view object.
GetAdvise	Returns the information on the most recent **SetAdvise**.

IViewObject::Draw

Draws a representation of an object onto the specified device context.

```
HRESULT Draw(
   DWORD dwAspect,                      //Specifies how the object is to be represented
   LONG lindex,                         //Specifies the part of the object to draw
   void * pvAspect,                     //Always NULL
   DVTARGETDEVICE * ptd,                //Specifies the target device in a structure
   HDC hicTargetDev,                    //Specifies the information context for the target device ptd
   HDC hdcDraw,                         //Identifies the device context on which to draw
   const LPRECTL lprcBounds,            //Specifies the rectangle in which the object is drawn
   const LPRECTL lprcWBounds,           //Specifies the window extent and window origin when drawing a metafile
   BOOL (*) (DWORD) pfnContinue,        //Callback function for canceling or continuing the drawing
   DWORD dwContinue                     //Parameter to pass to the callback function pfnContinue
  );
```

Parameters

dwAspect

[in]Specifies how the object is to be represented. Representations include content, an icon, a thumbnail, or a printed document. Valid values are taken from the enumeration **DVASPECT**. See the **DVASPECT** enumeration for more information.

lindex

[in]Indicates the portion of the object that is of interest for the draw operation. Its interpretation varies depending on the value in the *dwAspect* parameter. See the **DVASPECT** enumeration for more information.

pvAspect

[in]Provides more information about the view of the object specified in *dwAspect*. Since none of the current aspects support additional information; *pvAspect* must always be NULL.

ptd

[in]Points to the target device structure that describes the device for which the object is to be rendered. If NULL, the view should be rendered for the default target device (typically the display). A value other than NULL is interpreted in conjunction with *hicTargetDev* and *hdcDraw*. For example, if *hdcDraw* specifies a printer as the device context, the *ptd* parameter points to a structure describing that printer device. The data may actually be printed if *hicTargetDev* is a valid value or it may be displayed in print preview mode if *hicTargetDev* is NULL.

hicTargetDev

[in]Specifies the information context for the target device indicated by the *ptd* parameter from which the object can extract device metrics and test the device's capabilities. If *ptd* is NULL; the object should ignore the value in the *hicTargetDev* parameter.

hdcDraw

[in]Specifies the device context on which to draw.

lprcBounds

[in]Points to a **RECTL** structure specifying the rectangle on *hdcDraw* and in which the object should be drawn. This parameter controls the positioning and stretching of the object.

lprcWBounds

[in]If *hdcDraw* is a metafile device context, the *lprcWBounds* parameter points to a **RECTL** structure specifying the bounding rectangle in the underlying metafile. The rectangle structure contains the window extent and window origin. These values are useful for drawing metafiles. The rectangle indicated by *lprcBounds* is nested inside this *lprcWBounds* rectangle; they are in the same coordinate space.

If *hdcDraw* is not a metafile device context; *lprcWBounds* will be NULL.

pfnContinue
[in]Points to a callback function that the view object should call periodically during a lengthy drawing operation to determine whether the operation should continue or be canceled. This function returns TRUE to continue drawing. It returns FALSE to stop the drawing in which case **IViewObject::Draw** returns DRAW_E_ABORT.

dwContinue
[in]Contains a value to pass as a parameter to the function pointed to by the *pfnContinue* parameter. Typically, *dwContinue* is a pointer to an application-defined structure needed inside the callback function.

Return Values

S_OK
The object was drawn successfully.

E_INVALIDARG
Invalid window boundaries specified for metafile device context.

E_OUTOFMEMORY
Ran out of memory.

OLE_E_BLANK
No data to draw from.

DRAW_E_ABORT
Draw operation aborted.

VIEW_E_DRAW
Error in drawing.

DV_E_LINDEX
Invalid value for *lindex*; currently only -1 is supported.

DV_E_DVASPECT
Invalid value for *dwAspect*.

OLE_E_INVALIDRECT
Invalid rectangle.

Comments

A container application issues a call to **IViewObject::Draw** to create a representation of a contained object. This method draws the specified piece (*lindex*) of the specified view (*dwAspect* and *pvAspect*) on the specified device context (*hdcDraw*). Formatting, fonts, and other rendering decisions are made on the basis of the target device specified by the *ptd* parameter.

There is a relationship between the *dwDrawAspect* value and *lprcbounds* value. The *lprcbounds* value specifies the rectangle on *hdcDraw* into which the drawing is to be mapped. For DVASPECT_THUMBNAIL, DVASPECT_ICON, and DVASPECT_SMALLICON, the object draws whatever it wants to draw, and it maps it into the space given in the best way. Some objects might scale to fit while some might scale to fit but preserve aspect ratio. In addition; some might scale so the drawing appears at full width; but the bottom is cropped. The container can suggest a size via **IOleObject::SetExtent**, but it has no control over the rendering size. In the case of DVASPECT_CONTENT, the **Draw** implementation should either use the extents given by **IOleObject::SetExtent** or use the bounding rectangle given in the *lprcBounds* parameter.

Note to Callers

The value of *hicTargetDevice* is typically an information context for the target device. However, it may be a full device context instead.

Note to Implementors

If you are writing an object handler (such as the default handler) that implements **IViewObject::Draw** by playing a metafile, you have to treat **SetPaletteEntries** metafile records in a special way because of Windows' behavior. The Windows function **PlayMetaFile** sets these palette entries to the foreground. You must override this default by setting them to the background palette. Use **EnumMetaFile** to do this. Enhanced metafiles are always recorded with the background palette so there is no need to do it manually.

See Also

DVASPECT, **OleDraw**

IViewObject::Freeze

Freezes a certain aspect of the object's presentation so that it does not change until the **IViewObject::Unfreeze** method is called. The most common use of this method is for banded printing.

```
HRESULT Freeze(
    DWORD dwAspect,         //Specifies how the object is to be represented
    LONG lindex,            //Specifies the part of the object to draw
    void * pvAspect,        //Always NULL
    DWORD * pdwFreeze       //Points to location containing an identifier to be used in a subsequent call to
                            Unfreeze
  );
```

Parameters

dwAspect
[in]Specifies how the object is to be represented. Representations include content, an icon, a thumbnail, or a printed document. Valid values are taken from the enumeration **DVASPECT**. See the **DVASPECT** enumeration for more information.

lindex
[in]Indicates the portion of the object that is of interest for the draw operation. Its interpretation varies with *dwAspect.* See the **DVASPECT** enumeration for more information.

pvAspect
[in]Provides more information about the view of the object specified in *dwAspect*. Since none of the current aspects support additional information; *pvAspect* must always be NULL.

pdwFreeze
[out]Points to location where an identifying key is returned. This unique key is later used to cancel the freeze by calling **IViewObject::Unfreeze**. This key is an index that the default cache uses to keep track of which object is frozen.

Return Values

S_OK
The presentation was successfully frozen.

VIEW_S_ALREADYFROZEN
Presentation has already been frozen. The value of *pdwFreeze* is the identifying key of the already frozen object.

OLE_E_BLANK
Presentation not in cache.

DV_E_LINDEX
Invalid value for *lindex*; currently; only -1 is supported.

DV_E_DVASPECT
Invalid value for *dwAspect*.

Comments

The **IViewObject::Freeze** method causes the view object to freeze its drawn representation until a subsequent call to **IViewObject::Unfreeze** releases it. After calling **IViewObject::Freeze**; successive calls to **IViewObject::Draw** with the same parameters produce the same picture until **IViewObject::Unfreeze** is called.

IViewObject::Freeze is not part of the persistent state of the object and does not continue across unloads and reloads of the object.

The most common use of this method is for banded printing.

While in a frozen state; view notifications are not sent. Pending view notifications are deferred to the subsequent call to **IViewObject::Unfreeze**.

See Also

DVASPECT, **IViewObject::Unfreeze**

IViewObject::GetAdvise

Retrieves the existing advisory connection on the object if there is one. This method simply returns the parameters used in the most recent call to the **IViewObject::SetAdvise** method.

```
HRESULT GetAdvise(
  DWORD * pdwAspect,          //Points to location of dwAspect parameter from previous SetAdvise
  DWORD * padvf,              //Points to location of advf parameter from previous SetAdvise
  IAdviseSink ** ppAdvSink    //Points to location of pAdvSink parameter from previous SetAdvise
 );
```

Parameters

pdwAspect
[out]Points to location where the *dwAspect* parameter from the previous **SetAdvise** call is returned. If this pointer is NULL, the caller does not permit this value to be returned.

padvf
[out]Points to location where the *advf* parameter from the previous **SetAdvise** call is returned. If this pointer is NULL, the caller does not permit this value to be returned.

ppAdvSink
[out]Points to location where the *pAdvSink* parameter from the previous **SetAdvise** call is returned. If this pointer is NULL, the caller does not permit this value to be returned.

Return Values

S_OK
The existing advisory connection was retrieved.

E_INVALIDARG
An invalid *advf* flag was specified.

E_OUTOFMEMORY
Ran out of memory.

See Also

ADVF, **IAdviseSink**, **IViewObject::SetAdvise**

IViewObject::GetColorSet

Returns the logical palette that the object will use for drawing in its **IViewObject::Draw** method with the corresponding parameters.

```
HRESULT GetColorSet(
    DWORD dwAspect,                 //Specifies how the object is to be represented
    LONG lindex,                    //Specifies the part of the object to draw
    void * pvAspect,                //Always NULL
    DVTARGETDEVICE * ptd,           //Specifies the target device in a structure
    HDC hicTargetDev,               //Specifies the information context for the target device ptd
    LOGPALETTE ** ppColorSet        //Points to LOGPALETTE structure
  );
```

Parameters

dwAspect
[in]Specifies how the object is to be represented. Representations include content, an icon, a thumbnail, or a printed document. Valid values are taken from the enumeration **DVASPECT**. See the **DVASPECT** enumeration for more information.

lindex
[in]Indicates the portion of the object that is of interest for the draw operation. Its interpretation varies with *dwAspect.* See the **DVASPECT** enumeration for more information.

pvAspect
[in]Provides more information about the view of the object specified in *dwAspect*. Since none of the current aspects support additional information; *pvAspect* must always be NULL.

ptd
[in]Points to the target device structure that describes the device for which the object is to be rendered. If NULL, the view should be rendered for the default target device (typically the display). A value other than NULL is interpreted in conjunction with *hicTargetDev* and *hdcDraw*. For example, if *hdcDraw* specifies a printer as the device context, *ptd* points to a structure describing that printer device. The data may actually be printed if *hicTargetDev* is a valid value or it may be displayed in print preview mode if *hicTargetDev* is NULL.

hicTargetDev
[in]Specifies the information context for the target device indicated by the *ptd* parameter from which the object can extract device metrics and test the device's capabilities. If *ptd* is NULL, the object should ignore the *hicTargetDev* parameter.

ppColorSet
[out]Points to location where a **LOGPALETTE** structure is returned. The **LOGPALETTE** structure contains the set of colors that would be used if **IViewObject::Draw** were called with the same parameters for *dwAspect*, *lindex*, *pvAspect*, *ptd*, and *hicTargetDev*. A NULL pointer to the **LOGPALETTE** structure means that the object does not use a palette.

Return Values

S_OK
The set of colors was returned successfully.

S_FALSE
Set of colors is empty or the object will not give out the information.

E_INVALIDARG
One or more arguments are invalid.

OLE_E_BLANK
No presentation data for object.

E_UNEXPECTED

An unexpected error occurred.

DV_E_LINDEX
Invalid value for *lindex*; currently only -1 is supported.

DV_E_DVASPECT
Invalid value for *dwAspect*.

Comments

The **IViewObject::GetColorSet** method recursively queries any nested objects and returns a color set that represents the union of all colors requested. The color set eventually percolates to the top-level container that owns the window frame. This container can call **IViewObject::GetColorSet** on each of its embedded objects to obtain all the colors needed to draw the embedded objects. The container can use the color sets obtained in conjunction with other colors it needs for itself to set the overall color palette.

The OLE-provided implementation of **IViewObject::GetColorSet** looks at the data it has on hand to draw the picture. If CF_DIB is the drawing format; the palette found in the bitmap is used. For a regular bitmap; no color information is returned. If the drawing format is a metafile, the object handler enumerates the metafile looking for a CreatePalette metafile record. If one is found; the handler uses it as the color set.

Note to Implementors

Object applications that rely on the default handler for drawing and that use metafiles for doing so should provide a SetPaletteEntries record when they generate their metafiles. If a SetPaletteEntries record is not found; the default object handler returns S_FALSE.

See Also

DVASPECT

IViewObject::SetAdvise

Sets up a connection between the view object and an advise sink so that the advise sink can be notified about changes in the object's view.

```
HRESULT SetAdvise(
  DWORD dwAspect,           //Specifies the view object for which notification is being
                            requested
  DWORD advf,               //Specifies information about the advise sink
  IAdviseSink * pAdvSink    //Points to the advise sink that is to receive change notifications
 );
```

Parameters

dwAspect
[in]Specifies the view for which the advisory connection is being set up. Valid values are taken from the enumeration **DVASPECT**. See the **DVASPECT** enumeration for more information.

advf
[in]Contains a group of flags for controlling the advisory connection. Valid values are from the enumeration **ADVF**. However, only some of the possible **ADVF** values are relevant for this method. The following table briefly describes the relevant values. See the **ADVF** enumeration for a more detailed description.

ADVF Value	Description
ADVF_ONLYONCE	Causes the advisory connection to be destroyed after the first notification is sent.
ADVF_PRIMEFIRST	Causes an initial notification to be sent regardless of whether data has changed from its current state.

Note that the ADVF_ONLYONCE and ADVF_PRIMEFIRST can be combined to provide an asynchronous call to **IDataObject::GetData**.

pAdvSink
Points to the advisory sink that is to be informed of changes. A NULL value deletes any existing advisory connection.

Return Values

S_OK
The advisory connection was successfully established.

E_INVALIDARG
An invalid *advf* flag was specified.

E_OUTOFMEMORY
Ran out of memory.

OLE_E_ADVISENOTSUPPORTED
Advisory notifications are not supported.

DV_E_DVASPECT
Invalid value for *dwAspect*.

Comments

A container application that is requesting a draw operation on a view object can also register with the **IViewObject::SetAdvise** method to be notified when the presentation of the view object changes. To find out about when an object's underlying data changes, you must call **IDataObject::DAdvise** separately.

To remove an existing advisory connection, call the **IViewObject::SetAdvise** method with *pAdvSink* set to NULL.

If the view object changes, a call is made to the appropriate advise sink through its **IAdviseSink::OnViewChange** method.

At any time; a given view object can support only one advisory connection. Therefore, when **IViewObject::SetAdvise** is called and the view object is already holding onto an advise sink pointer, OLE releases the existing pointer before the new one is registered.

See Also

ADVF, **IAdviseSink**, **IViewObject::GetAdvise**

IViewObject::Unfreeze

Releases a previously frozen drawing. The most common use of this method is for banded printing.

```
HRESULT Unfreeze(
   DWORD dwFreeze        //Identifies the view object that is frozen
  );
```

Parameter

dwFreeze
[in]Contains a key previously returned from **IViewObject::Freeze**. This key determines which object to unfreeze.

Return Values

S_OK
The drawing was unfrozen successfully.

OLE_E_NOCONNECTION
Error in the unfreezing process or the object is currently not frozen.

See Also

IViewObject::Freeze

IViewObject2

The **IViewObject2** interface is an extension to the **IViewObject** interface which returns the size of the drawing for a given view of an object. You can prevent the object from being run if it isn't already running by calling this method instead of **IOleObject::GetExtent**.

Like the **IViewObject** interface, **IViewObject2** cannot be marshaled to another process. This is because device contexts are only effective in the context of one process.

The OLE provided default implementation provides the size of the object in the cache.

When to Implement

Object handlers and in-process servers that manage their own presentations implement **IViewObject2** for use by compound document containers.

When to Use

A container application or object handler calls the **GetExtent** method in the **IViewObject2** interface to get the object's size from its cache.

Methods in Vtable Order

IUnknown Methods	**Description**
QueryInterface	Returns pointers to supported interfaces.
AddRef	Increments reference count.
Release	Decrements reference count.

IViewObject Methods	**Description**
Draw	Draws a representation of the object onto a device context.
GetColorSet	Returns the logical palette the object uses for drawing.
Freeze	Freezes the drawn representation of an object so it will not change until a subsequent **Unfreeze**.
Unfreeze	Unfreezes the drawn representation of an object.
SetAdvise	Sets up a connection between the view object and an advise sink so that the advise sink can receive notifications of changes in the view object.
GetAdvise	Returns the information on the most recent **SetAdvise**.

IViewObject2 Method	**Description**
GetExtent	Returns the size of the view object from the cache.

IViewObject2::GetExtent

Returns the size that the specified view object will be drawn on the specified target device.

```
HRESULT GetExtent(
  DWORD dwAspect,             //Specifies the view object for which the size is being requested
  DWORD lindex,               //Specifies the part of the object to draw
  DVTARGETDEVICE ptd,         //Specifies the target device in a structure
  LPSIZEL lpsizel             //Points to size of object
 );
```

Parameters

dwAspect
: [in]Specifies the requested view of the object whose size is of interest. Valid values are taken from the enumeration **DVASPECT**. See the **DVASPECT** enumeration for more information.

lindex
: [in]Indicates the portion of the object that is of interest. Currently only -1 is valid.

ptd
: [in]Points to the target device for which the object's size should be returned.

lpsizel
: Points to location where the object's size is returned.

Return Values

S_OK
: The object's extent was successfully returned.

OLE_E_BLANK
: An appropriate cache is not available.

E_OUTOFMEMORY
: Insufficient memory to execute this operation.

Comments

The OLE-provided implementation of **IViewObject2::GetExtent** searches the cache for the size of the view object.

The **GetExtent** method in the **IOleObject** interface provides some of the same information as **IViewObject2::GetExtent**.

Note to Callers

To prevent the object from being run if it isn't already running, you can call **IViewObject2::GetExtent** rather than **IOleObject::GetExtent** to determine the size of the presentation to be drawn.

BIND_OPTS

The **BIND_OPTS** structure contains parameters used during a moniker binding operation. A **BIND_OPTS** structure is stored in a bind context; the same bind context is used by each component of a composite moniker during binding, allowing the same parameters to be passed to all components of a composite moniker. See **IBindCtx** for more information about bind contexts.

If you're a moniker client (that is, you use a moniker to acquire an interface pointer to an object), you typically do not need to specify values for the fields of this structure. The **CreateBindCtx** API function creates a bind context with the bind options set to default values that are suitable for most situations; the **BindMoniker** API function does the same thing when creating a bind context for use in binding a moniker. If you want to modify the values of these bind options, you can do so by passing a **BIND_OPTS** structure to the **IBindCtx::SetBindOptions** method. Moniker implementors can pass a **BIND_OPTS** structure to the **IBindCtx::GetBindOptions** method to retrieve the values of these bind options.

The **BIND_OPTS** structure is defined in OBJIDL.IDL.

```
typedef struct tagBIND_OPTS
{
     DWORD cbStruct;
     DWORD grfFlags;
     DWORD grfMode;
     DWORD dwTickCountDeadline;
} BIND_OPTS, *LPBIND_OPTS;
```

Members

cbStruct
Specifies the size of this structure in bytes (that is, the size of the **BIND_OPTS** structure).

grfFlags
Specifies flags that control aspects of moniker binding operations. This value is any combination of the bit flags in the **BINDFLAGS** enumeration. New values may be defined in the future, so moniker implementations should ignore any bits in this field that they do not understand. The **CreateBindCtx** API function initializes this field to zero.

grfMode
Specifies flags that should be used when opening the file that contains the object identified by the moniker. The values are taken from the **STGM** enumeration. The binding operation uses these flags in the call to **IPersistFile::Load** when loading the file. If the object is already running, these flags are ignored by the binding operation. The **CreateBindCtx** API function initializes this field to STGM_READWRITE.

dwTickCountDeadline
Specifies the clock time (in milliseconds, as returned by the **GetTickCount** API function) by which the caller would like the binding operation to be completed. This member lets the caller limit the execution time of an operation when speed is of primary importance. A value of zero indicates that there is no deadline. Callers most often use this capability when calling the **IMoniker::GetTimeOfLastChange** method, though it can be usefully applied to other operations as well. The **CreateBindCtx** API function initializes this field to zero.

Typical deadlines allow for a few hundred milliseconds of execution. This deadline is a recommendation, not a requirement; however, operations that exceed their deadline by a large amount may cause delays for the end user. Each moniker implementation should try to complete its operation by the deadline, or fail with the error MK_E_EXCEEDEDDEADLINE.

If a binding operation exceeds its deadline because one or more objects that it needs are not running, the moniker implementation should register the objects responsible in the bind context using the **IBindCtx::RegisterObjectParam**. The objects should be registered under the parameter names "ExceededDeadline", "ExceededDeadline1", "ExceededDeadline2", and so on. If the caller later finds the object in the Running Object Table, the caller can retry the binding operation.

The **GetTickCount** API function indicates the number of milliseconds since system startup, and wraps back to zero after 2^31 milliseconds. Consequently, callers should be careful not to inadvertently pass a zero value (which indicates no deadline), and moniker implementations should be aware of clock wrapping problems (see the **GetTickCount** API function for more information).

See Also

BIND_FLAGS, **CreateBindCtx**, **IBindCtx::SetBindOptions**

DVTARGETDEVICE

Use the **DVTARGETDEVICE** structure to specify information about the target device for which data is being composed. **DVTARGETDEVICE** contains enough information about a Windows target device so a handle to a device context (hDC) can be created using the Windows **CreateDC** function.

```
typedef struct tagDVTARGETDEVICE
{
     DWORD tdSize;
     WORD  tdDriverNameOffset;
     WORD  tdDeviceNameOffset;
     WORD  tdPortNameOffset;
     WORD  tdExtDevmodeOffset;
     BYTE  tdData[1];
}DVTARGETDEVICE;
```

Members

tdSize
Specifies the size in bytes of the **DVTARGETDEVICE** structure. The initial size is included so the structure can be copied more easily.

tdDriverNameOffset
Specifies the offset in bytes from the beginning of the structure to the device driver name, which is stored as a NULL-terminated string in the *tdData* buffer.

tdDeviceNameOffset
Specifies the offset in bytes from the beginning of the structure to the device name, which is stored as a NULL-terminated string in the *tdData* buffer. This value can be zero to indicate no device name.

tdPortNameOffset
Specifies the offset in bytes from the beginning of the structure to the port name, which is stored as a NULL-terminated string in the *tdData* buffer. This value can be zero to indicate no port name.

tdExtDevmodeOffset
Specifies the offset in bytes from the beginning of the structure to the **DEVMODE** structure retrieved by the calling **ExtDeviceMode**.

tdData
Specifies an array of bytes containing data for the target device. It is not necessary to include empty strings in *tdData* (for names where the offset value is zero).

Comments

Some OLE 1 client applications incorrectly construct target devices by allocating too few bytes in the **DEVMODE** structure for the OLETARGETDEVICE. They typically only supply the number of bytes in the DEVMODE.*dmSize* member. The number of bytes to be allocated should be the sum of DEVMODE.*dmSize* + DEVMODE.*dmDriverExtra*. When a call is made to the **CreateDC** API function with an incorrect target device, the printer driver tries to access the additional bytes and unpredictable results can occur. To protect against a crash and make the additional bytes available, OLE pads the size of OLE 2 target devices created from OLE 1 target devices.

FORMATETC, **IEnumFORMATETC**, **IViewObject**, **OleConvertOLESTREAMToIStorage**

FILETIME

The **FILETIME** data structure is a 64-bit value representing the number of 100-nanosecond intervals since January 1, 1601. It is the means by which Win32 determines the date and time. **FILETIME** is used by the **CoDosDateTimeToFileTime**, **CoFileTimeToDosDateTime**, and **CoFileTimeNow** functions. It is defined as follows:

```
typedef struct STRUCT tagFILETIME
{
     DWORD  dwLowDateTime;
     DWORD  dwHighDateTime;
} FILETIME;
```

Members

dwLowDateTime
The low 32 bits of the Win32 date/time value.

dwHighDateTime
The upper 32 bits of the Win32 date/time value.

Comments

The **FILETIME** data structure is used in the time conversion functions between DOS and Win32.

See Also

CoDosDateTimeToFileTime, **CoFileTimeNow**, **CoFileTimeToDosDateTime**

FORMATETC

The **FORMATETC** structure is a generalized Clipboard format. It is enhanced to encompass a target device, the aspect or view of the data, and a storage medium indicator. Where one might expect to find a Clipboard format, OLE uses a **FORMATETC** data structure instead.

Defined in the **IEnumFORMATETC** interface.

```
typedef struct tagFORMATETC
{
     CLIPFORMAT  cfFormat;
     DVTARGETDEVICE  *ptd;
     DWORD  dwAspect;
     LONG  lindex;
     DWORD  tymed;
}FORMATETC;  *LPFORMATETC;
```

Members

cfFormat

Indicates the particular clipboard format of interest. There are three types of formats recognized by OLE:

- Standard interchange formats, such as CF_TEXT.
- Private application formats understood only by the application offering the format, or by other applications offering similar features.
- OLE formats, which are used to create linked or embedded objects.

ptd

Points to a **DVTARGETDEVICE** structure containing information about the target device for which the data is being composed. A NULL value is used whenever the specified data format is independent of the target device or when the caller doesn't care what device is used. In the latter case, if the data requires a target device, the object should pick an appropriate default device (often the display for visual components). Data obtained from an object with a NULL target device, such as most metafiles, is independent of the target device. The resulting data is usually the same as it would be if the user chose the Save As command from the File menu and selected an interchange format.

dwAspect

Specifies one of the **DVASPECT** enumeration constants that indicate how much detail should be contained in the rendering. A single clipboard format can support multiple aspects or views of the object. Most data and presentation transfer and caching methods pass aspect information. For example, a caller might request an object's iconic picture, using the metafile clipboard format to retrieve it. Note that only one **DVASPECT** value can be used in *dwAspect*. That is, *dwAspect* cannot be the result of a BOOLEAN OR operation on several **DVASPECT** values.

lindex

Identifies part of the aspect when the data must be split across page boundaries. The most common value is -1, which identifies all of the data. For the aspects DVASPECT_THUMBNAIL and DVASPECT_ICON, *lindex* is ignored.

tymed

Specifies one of the **TYMED** enumeration constants which indicate the type of storage medium used to transfer the object's data. Data can be transferred using whatever medium makes sense for the object. For example, data can be passed using global memory, a disk file, or structured storage objects. For more information, see the **TYMED** enumeration.

Comments

The **FORMATETC** structure is used by methods in the data transfer and presentation interfaces as a parameter specifying the data being transferred. For example, the **IDataObject::GetData** method uses the **FORMATETC** structure to indicate exactly what kind of data the caller is requesting.

INTERFACEINFO

The **INTERFACEINFO** structure contains information about incoming calls. The structure is defined as follows:

```
typedef struct tagINTERFACEINFO
{
    LPUNKNOWN  pUnk;
    IID  iid;
    WORD  wMethod;
} INTERFACEINFO,  * LPINTERFACEINFO;
```

Members

pUnk
Points to the object.

iid
Indicates the interface id (iid).

wMethod
Indicates the interface method.

See Also

IMessageFilter::HandleIncomingCall

OBJECTDESCRIPTOR

The **OBJECTDESCRIPTOR** structure is the data structure used for the CF_OBJECTDESRIPTOR and CF_LINKSRCDESCRIPTOR file formats. These formats provide user interface information during data transfer operations, for example, the Paste Special dialog box or target feedback information during drag and drop operations.

Defined in the **IOLETypes** pseudo-interface (*oletyp.idl*).

```
typedef struct tagOBJECTDESCRIPTOR
{
      ULONG cbSize;
      CLSID clsid;
      DWORD dwDrawAspect;
      SIZEL sizel;
      POINTL pointl;
      DWORD dwStatus;
      DWORD dwFullUserTypeName;
      DWORD dwSrcOfCopy;
      /* variable sized string data may appear here */
} OBJECTDESCRIPTOR;
```

Members

cbSize
Specifies the size of structure in bytes

clsid
Specifies the CLSID of the object being transferred. The *clsid* is used to obtain the icon for the Display As Icon option in the Paste Special dialog box and is applicable only if the Embed Source or Embedded Object formats are offered. If neither is offered, the value of *clsid* should be CLSID_NULL. The *clsid* can be retrieved by the source by loading the object and calling the **IOleObject::GetUserClassID** method. Note that for link objects, this value is not the same as the value returned by the **IPersist::GetClassID** method.

dwDrawAspect
Specifies the display aspect of the object. Typically, this value is DVASPECT_CONTENT or DVASPECT_ICON. If the source application did not draw the object originally, the *dwDrawAspect* field contains a zero value (which is not the same as DVASPECT_CONTENT).

sizel
Specifies the true extents of the object (without cropping or scaling) in HIMETRIC units. Setting this field is optional. The value can be (0,0) for applications that do not draw the object being transferred. This field is used primarily by targets of drag-and-drop operations so they can give appropriate feedback to the user.

pointl
Specifies the offset in HIMETRIC units from the upper-left corner of the object where a drag-and-drop operation was initiated. This field is only meaningful for a drag-and-drop transfer operation since it corresponds to the point where the mouse was clicked to initiate the drag-and-drop operation. The value is (0,0) for other transfer situations, such as a Clipboard copy and paste.

dwStatus
Contains a copy of the status flags for the object. These flags are defined by the **OLEMISC** enumeration. If an embedded object is being transferred, they are returned by calling the **IOleObject::GetMiscStatus** method.

dwFullUserTypeName
Specifies the offset for finding the full user type name of the object being transferred. It specifies the offset, in bytes, from the beginning of the **OBJECTDESCRIPTOR** data structure to the null-

terminated string that specifies the full user type name of the object being transferred. The value is zero if the string is not present. This string is used by the destination of a data transfer to create labels in the Paste Special dialog box. The destination application must be able to handle the cases when this string is omitted.

dwSrcOfCopy

Specifies the offset, in bytes, from the beginning of the data structure to the null-terminated string that specifies the source of the transfer. The *dwSrcOfCopy* field is typically implemented as the display name of the temporary moniker that identifies the data source. The value for *dwSrcOfCopy* is displayed in the Source line of the Paste Special dialog box. A zero value indicates that the string is not present. If *dwSrcOfCopy* is zero, the string "Unknown Source" is displayed in the Paste Special dialog box.

IDataObject, **FORMATETC**

OLEINPLACEFRAMEINFO

The **OLEINPLACEFRAMEINFO** structure contains information about the accelerators supported by a container during an in-place session. The structure is defined in the **IOleInPlaceFrame** interface (*inplcf.idl*), and it is used in the **IOleInPlaceSite::GetWindowContext** method and the **OleTranslateAccelerator** API function.

```
typedef struct tagOIFI
{
     UINT cb;
     BOOL fMDIApp;
     HWND hwndFrame;
     HACCEL haccel;
     UINT cAccelEntries;
} OLEINPLACEFRAMEINFO, *LPOLEINPLACEFRAMEINFO;
```

Members

cb
Specifies the size in bytes of this structure. The object server must specify sizeof(**OLEINPLACEFRAMEINFO**) in the structure it passes to **IOleInPlaceSite::GetWindowContext**. The container can then use this size to determine the structure's version.

fMDIApp
Indicates whether the container is an MDI application.

hwndFrame
Specifies a handle to the container's top-level frame window.

haccel
Specifies the handle to the accelerator table that the container wants to use during an in-place editing session.

cAccelEntries
Specifies the number of accelerators in *haccel*.

Comments

When an object is being in-place activated, its server calls the container's **IOleInPlaceSite::GetWindowContext** method which fills in an **OLEINPLACEFRAMEINFO** structure. During an in-place session, the message loop of an EXE server passes a pointer to the **OLEINPLACEFRAMEINFO** structure to **OleTranslateAccelerator**. OLE uses the information in this structure to determine whether a message maps to one of the container's accelerators.

See Also

IOleInPlaceSite::GetWindowContext, **OleTranslateAccelerator**

OLEMENUGROUPWIDTHS

The **OLEMENUGROUPWIDTHS** structure is the mechanism for building a shared menu. It indicates the number of menu items in each of the six menu groups of a menu shared between a container and an object server during an in-place editing session.

The structure is defined in the **IOleInPlaceFrame** interface (*inplcf.idl*). It is used in the **IOleInPlaceFrame::InsertMenus** and **ICDStandardForm::SetMenu** methods, and the **OleCreateMenuDescriptor** API function.

```
typedef struct tagOleMenuGroupWidths
{
     LONG width[6];
} OLEMENUGROUPWIDTHS, * LPOLEMENUGROUPWIDTHS;
```

Member

width

Specifies an array whose elements contain the number of menu items in each of the six menu groups of a shared in-place editing menu. Each menu group can have any number of menu items. The container uses elements 0, 2, and 4 to indicate the number of menu items in its File, View, and Window menu groups. The object server uses elements 1, 3, and 5 to indicate the number of menu items in its Edit, Object, and Help menu groups.

Comments

A container application and an object server use this structure to build a shared menu. The object server initializes to zeros the array elements in an **OLEMENUGROUPWIDTHS** structure and passes a pointer to it along with a menu handle to the container in a call to **IOleInPlaceFrame::InsertMenus**. The container adds its menu items to the menu, and fills in the structure with the number of items in each of its groups (indexes 0, 2, and 4). The server then uses the group width values returned by the container to insert its menu items in the appropriate position in the menu. The server fills in the structure with the number of items in each of its groups (indexes 1, 3, and 5), and then passes the structure to OLE in a call to the **OleCreateMenuDescriptor** API function. This enables OLE to intercept the container's menu messages and redirect the messages generated by the server's menus.

See Also

IOleInPlaceFrame::InsertMenus, **OleCreateMenuDescriptor**

OLEUIBUSY

The **OLEUIBUSY** structure contains information that the OLE 2.01 User Interface Library uses to initialize the Busy dialog box, and space for the library to return information when the dialog is dismissed.

```
typedef struct tagOLEUIBUSY
{
// These IN fields are standard across all OLEUI dialog functions.
     DWORD  cbStruct;
     DWORD  dwFlags;
     HWND  hWndOwner;
     LPCSTR  lpszCaption;
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     HINSTANCE  hInstance;
     LPCSTR  lpszTemplate;
     HRSRC  hResource;

// Specifics for OLEUIBUSY.
     HTASK  hTask;
     HWND FAR *  lphWndDialog;
} OLEUICHANGEICON, *POLEUICHANGEICON, FAR *LPOLEUICHANGEICON;
```

Members

cbStruct
The size of the structure in bytes. This field must be filled on input.

dwFlags
On input, *dwFlags* specifies the initialization and creation flags. On exit, it specifies the user's choices. It may be a combination of the following flags:

BZ_DISABLECANCELBUTTON
Input only: This flag disables the Cancel button.

BZ_DISABLESWITCHTOBUTTON
Input only: This flag disables the Switch To... button.

BZ_DISABLERETRYBUTTON
Input only: This flag disables the Retry button.

BZ_NOTRESPONDINGDIALOG
Input only: This flag generates a Not Responding dialog instead of a Busy dialog. The text is slightly different, and the Cancel button is disabled.

hWndOwner
Identifies the window that owns the dialog box. It should not be NULL.

lpszCaption
Points to a string to be used as the title of the dialog box. If NULL, then the library uses Busy.

lpfnHook
Points to a hook function that processes messages intended for the dialog box. The hook function must return zero to pass a message that it didn't process back to the dialog box procedure in the library. The hook function must return a non zero value to prevent the library's dialog box procedure from processing a message it has already processed.

lCustData
Specifies application-defined data that the library passes to the hook function pointed to by the *lpfnHook* member. The library passes a pointer to the **OLEUIBUSY** structure in the *lParam* parameter of the WM_INITDIALOG message; this pointer can be used to retrieve the *lCustData*

member.

hInstance

Identifies an instance that contains a dialog box template specified by the *lpTemplateName* member.

lpszTemplate

Points to a null-terminated string that specifies the name of the resource file for the dialog box template that is to be substituted for the library's Busy dialog box template.

hResource

A customized template handle.

hTask Input only:

A handle to the task that is blocking.

lphWndDialog

The dialog box's HWND is placed here.

See Also

OleUIBusy

OLEUICHANGEICON

The **OLEUICHANGEICON** structure contains information that the OLE 2.01 User Interface Library uses to initialize the Change Icon dialog box, and it contains space for the library to return information when the dialog box is dismissed.

```
typedef struct tagOLEUICHANGEICON
{
// These IN fields are standard across all OLEUI dialog functions.
     DWORD  cbStruct;
     DWORD  dwFlags;
     HWND  hWndOwner;
     LPCSTR  lpszCaption;
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     HINSTANCE  hInstance;
     LPCSTR  lpszTemplate;
     HRSRC  hResource;

 // Specifics for OLEUICHANGEICON.
     HGLOBAL  hMetaPict;
     CLSID  clsid;
     char  szIconExe[OLEUI_CCHPATHMAX];
     int  cchIconExe;
} OLEUICHANGEICON, *POLEUICHANGEICON, FAR *LPOLEUICHANGEICON;
```

Members

cbStruct
The size of the structure in bytes. This field must be filled on input.

dwFlags
On input, *dwFlags* specifies the initialization and creation flags. On exit, it specifies the user's choices. It can be a combination of the following flags:

CIF_SHOWHELP
Specifies that the dialog box will display a Help button.

CIF_SELECTCURRENT
On input, selects the Current radio button on initialization. On exit, specifies that the user selected Current.

CIF_SELECTDEFAULT
On input, selects the Default radio button on initialization. On exit, specifies that the user selected Default.

CIF_SELECTFROMFILE
On input, selects the From File radio button on initialization. On exit, specifies that the user selected From File.

CIF_USEICONEXE
Input only. Extracts the icon from the executable specified in the *szIconExe* member, instead of retrieving it from the class. This is useful for OLE embedding or linking to non-OLE files.

hWndOwner
Identifies the window that owns the dialog box. It should not be NULL.

lpszCaption
Points to a string to be used as the title of the dialog box. If NULL, then the library uses Change Icon.

lpfnHook

Points to a hook function that processes messages intended for the dialog box. The hook function must return zero to pass a message that it didn't process back to the dialog box procedure in the library. The hook function must return a non-zero value to prevent the library's dialog box procedure from processing a message it has already processed.

lCustData

Specifies application-defined data that the library passes to the hook function pointed to by the *lpfnHook* member. The library passes a pointer to the **OLEUICHANGEICON** structure in the *lParam* parameter of the WM_INITDIALOG message; this pointer can be used to retrieve the *lCustData* member.

hInstance

Identifies an instance that contains a dialog box template specified by the *lpTemplateName* member.

lpszTemplate

Points to a null-terminated string that specifies the name of the resource file for the dialog box template that is to be substituted for the library's Change Icon dialog box template.

hResource

A customized template handle.

hMetaPict

The current and final image. The source of the icon is embedded in the metafile itself.

clsid

Input only. The class to use to get the Default icon.

szIconExe

Input only. The executable to extract the default icon from. This member is ignored unless CIF_USEICONEXE is included in the *dwFlags* parameter and an attempt to retrieve the class icon from the specified CLSID fails.

cchIconExe

Input only. The number of characters in *szIconExe*. This member is ignored unless CIF_USEICONEXE is included in the *dwFlags* member.

See Also

OleUIChangeIcon

OLEUICHANGESOURCE

This structure is used to initialize the standard Change Source dialog box. It allows the user to modify the destination or source of a link. This may simply entail selecting a different file name for the link, or possibly changing the item reference within the file, for example, changing the destination range of cells within spreadsheet that the link is to.

```
typedef struct tagOLEUICHANGESOURCEW
{
// These IN fields are standard across all OLEUI dialog functions.     DWORD
cbStruct;
     DWORDT  dwFlags;
     HWND    hWndOwner;
     LPCWSTR  lpszCaption;
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     HINSTANCE  hInstance;
     LPCWSTR  lpszTemplate;
     HRSRC  hResource;

// INTERNAL ONLY: do not modify these members
     OPENFILENAMEW*  lpOFN;
     DWORD  dwReserved1[4];

// Specifics for OLEUICHANGESOURCE.
     LPOLEUILINKCONTAINERW  lpOleUILinkContainer;
     DWORD  dwLink;
     LPTSTR  lpszDisplayName;
     ULONG  nFileLength;
     LPTSTR  lpszFrom;
     LPTSTR  lpszTo;
} OLEUICHANGESOURCEW, *POLEUICHANGESOURCEW, FAR *LPOLEUICHANGESOURCEW;
```

Members

cbStruct
The size of the structure in bytes.

dwFlags
On input, this field specifies the initialization and creation flags. On exit, it specifies the user's choices. It may be a combination of the following flags:

CSF_SHOWHELP
Enables or shows the Help button.

CSF_VALIDSOURCE
Indicates that the link was validated.

CSF_ONLYGETSOURCE
Disables automatic validation of the link source when the user presses OK. If you specify this flag, you should validate the source when the dialog box returns OK.

hWndOwner
Identifies the window that owns the dialog box.

lpszCaption
Points to a string to be used as the title of the dialog box. If NULL, then the library uses Change Source.

lpfnHook

Points to a hook function that processes messages intended for the dialog box. The hook function must return zero to pass a message that it didn't process back to the dialog box procedure in the library. The hook function must return a non zero value to prevent the library's dialog box procedure from processing a message it has already processed.

lCustData

Specifies application-defined data that the library passes to the hook function pointed to by the *lpfnHook* member. The library passes a pointer to the **OLEUICHANGEICON** structure in the *lParam* parameter of the WM_INITDIALOG message; this pointer can be used to retrieve the *lCustData* member.

hInstance

Identifies a instance that contains a dialog box template specified by the *lpszTemplate* member. This member is ignored if the *lpszTemplate* member is NULL or invalid.

lpszTemplate

Points to a null-terminated string that specifies the name of the resource file for the dialog box template that is to be substituted for the library's Convert dialog box template.

hResource

The resource handle for a custom dialog. If this member is NULL, then the library uses the standard Convert dialog template, or if it is valid, the template named by the *lpszTemplate* member.

lpOFN

Points to the **OPENFILENAME** structure, which contains information used by the operating system to initialize the system-defined Open or Save As dialog boxes.

dwReserved1[4]

Reserved for future use.

lpOleUILinkContainer

Pointsto the container's implementation of the **IOleUILinkContainer** Interface; used to validate the link source. The Edit Links dialog uses this to allow the container to manipulate its links.

dwLink

A container-defined unique 32-bit link identifier used to validate link sources. Used by *lpOleUILinkContainer*.

lpszDisplayName

Points to the complete source display name.

nFileLength

This is the file moniker portion of *lpszDisplayName*.

lpszFrom

The prefix of the source that was changed from.

lpszTo

The prefix of the source to be changed to.

IOleUILinkContainer, **OleUIChangeSource**

OLEUICONVERT

The **OLEUICONVERT** structure contains information that the OLE 2.01 User Interface Library uses to initialize the Convert dialog box, and space for the library to return information when the dialog is dismissed.

```
typedef struct tagOLEUICONVERT
{
// These IN fields are standard across all OLEUI dialog functions.
     DWORD  cbStruct
     DWORD  dwFlags
     HWND  hWndOwner
     LPCSTR  lpszCaption
     LPFNOLEUIHOOK  lpfnHook
     LPARAM  lCustData
     HINSTANCE hInstance
     LPCSTR  lpszTemplate
     HRSRC  hResource

// Specifics for OLEUICONVERT.
     CLSID  clsid;
     CLSID  clsidConvertDefault;
     CLSID  clsidActivateDefault;
     CLSID  clsidNew;
     DWORD  dvAspect;
     WORD  wFormat;
     BOOL  fIsLinkedObject;
     HGLOBAL  hMetaPict;
     LPTSTR  lpszUserType;
     BOOL  fObjectsIconChanged;
     LPTSTR  lpszDefLabel
     UINT  cClsidExclude
     LPCLSID  lpClsidExclude
} OLEUICONVERT, *POLEUICONVERT, FAR *LPOLEUICONVERT;
```

Members

cbStruct

The size of the structure, in bytes. This field must be filled on input.

dwFlags

On input, this field specifies the initialization and creation flags. On exit, it specifies the user's choices. It may be a combination of the following flags:

CF_SHOWHELPBUTTON

Specifies that the dialog will display a Help button. This flag is set on input.

CF_SETCONVERTDEFAULT

Specifies that the class whose CLSID is specified by *clsidConvertDefault* will be used as the default selection. This selection appears in the class listbox when the Convert To radio button is selected. This flag is set on input.

CF_SETACTIVATEDEFAULT

Specifies that the class whose CLSID is specified by *clsidActivateDefault* will be used as the default selection. This selection appears in the class listbox when the Activate As radio button is selected. This flag is set on input.

CF_SELECTCONVERTTO

On input, this flag specifies that Convert To will be initially selected (default behavior). This flag is set on output if Convert To was selected when the user dismissed the dialog.

CF_SELECTACTIVATEAS
On input, this flag specifies that Activate As will be initially selected. This flag is set on output if Activate As was selected when the user dismissed the dialog.

CF_DISABLEDISPLAYASICON
Specifies that the Display As Icon button will be disabled on initialization.

CF_DISABLEACTIVATEAS
Specifies that the Activate As radio button will be disabled on initialization.

CF_HIDECHANGEICON
Hides the Change Icon button in the Convert dialog.

CF_CONVERTONLY
Disables the Activate As radio button in the Convert dialog.

hWndOwner
Identifies the window that owns the dialog box. It should not be NULL.

lpszCaption
Points to a string to be used as the title of the dialog box. If NULL, then the library uses Convert.

lpfnHook
Points to a hook function that processes messages intended for the dialog box. The hook function must return zero to pass a message that it didn't process back to the dialog box procedure in the library. The hook function must return a non-zero value to prevent the library's dialog box procedure from processing a message it has already processed.

lCustData
Specifies application-defined data that the library passes to the hook function pointed to by the *lpfnHook* member. The library passes a pointer to the **OLEUICONVERT** structure in the *lParam* parameter of the WM_INITDIALOG message; this pointer can be used to retrieve the *lCustData* member.

hInstance
Identifies a instance that contains a dialog box template specified by the *lpszTemplate* member. This member is ignored if the *lpszTemplate* member is NULL or invalid.

lpszTemplate
Points to a null-terminated string that specifies the name of the resource file for the dialog box template that is to be substituted for the library's Convert dialog box template.

hResource
The resource handle for a custom dialog. If this member is NULL, then the library uses the standard Convert dialog template, or if it is valid, the template named by the *lpszTemplate* member.

clsid
The CLSID of the object to be converted or activated. This member is set on input.

clsidConvertDefault
The CLSID to use as the default class when Convert To is selected. This member is ignored if the *dwFlags* member does not include CF_SETCONVERTDEFAULT. This member is set on input.

clsidActivateDefault
The CLSID to use as the default class when Activate As is selected. This member is ignored if the *dwFlags* member does not include CF_SETACTIVATEDEFAULT. This member is set on input.

clsidNew
The CLSID of the selected class. This member is set on output.

dvAspect
The aspect of the object. This must be either DVASPECT_CONTENT or DVASPECT_ICON. If *dvAspect* is DVASPECT_ICON on input, then the Display As Icon box is checked and the object's icon is displayed. This member is set on input and output.

wFormat

The data format of the object to be converted or activated.

fIsLinkedObject

TRUE if the object is linked. This member is set on input.

hMetaPict

The METAFILEPICT containing the iconic aspect. This member is set on input and output.

lpszUserType

The User Type name of the object to be converted or activated. If this value is NULL, then the dialog will retrieve the User Type name from the registry. This string is freed on exit.

fObjectsIconChanged

TRUE if the object's icon changed. (that is, if **OleUIChangeIcon** was called and not canceled.). This member is set on output.

lpszDefLabel

The default label to use for the icon. If NULL, the short user type name will be used. If the object is a link, the caller should pass the Display Name of the link source. This is freed on exit.

cClsidExclude

The number of CLSIDs in *lpClsidExclude*.

lpClsidExclude

The list of CLSIDs to exclude from the list.

See Also

OleUIConvert, **OleUIChangeIcon**

OLEUIEDITLINKS

The **OLEUIEDITLINKS** structure contains information that the OLE 2.01 User Interface Library uses to initialize the Edit Links dialog box, and contains space for the library to return information when the dialog is dismissed.

```
typedef struct tagOLEUIEDITLINKS
{
// These IN fields are standard across all OLEUI dialog functions.
     DWORD  cbStruct;
     DWORD  dwFlags;
     HWND  hWndOwner;
     LPCSTR  lpszCaption;
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     HINSTANCE  hInstance;
     LPCSTR  lpszTemplate;
     HRSRC  hResource;

// Specifics for OLEUIEDITLINKS.
     LPOLEUILINKCONTAINER    lpOleUILinkContainer;
} OLEUIEDITLINKS, *POLEUIEDITLINKS, FAR *LPOLEUIEDITLINKS;
```

Members

cbStruct
The size of the structure in bytes. This field must be filled on input.

dwFlags
On input, *dwFlags* specifies the initialization and creation flags. It may be a combination of the following flags:

ELF_SHOWHELP
Specifies that the dialog will display a Help button.

ELF_DISABLEUPDATENOW
Specifies that the Update Now button will be disabled on initialization.

ELF_DISABLEOPENSOURCE
Specifies that the Open Source button will be disabled on initialization.

ELF_DISABLECHANGESOURCE
Specifies that the Change Source button will be disabled on initialization.

ELF_DISABLECANCELLINK
Specifies that the Cancel Link button will be disabled on initialization.

hWndOwner
Identifies the window that owns the dialog box. It should not be NULL.

lpszCaption
Points to a string to be used as the title of the dialog box. If NULL, then the library uses Links.

lpfnHook
Points to a hook function that processes messages intended for the dialog box. The hook function must return zero to pass a message that it didn't process back to the dialog box procedure in the library. The hook function must return a non-zero value to prevent the library's dialog box procedure from processing a message it has already processed.

lCustData
Specifies application-defined data that the library passes to the hook function pointed to by the *lpfnHook* member. The library passes a pointer to the **OLEUIEDITLINKS** structure in the *lParam* parameter of the WM_INITDIALOG message; this pointer can be used to retrieve the *lCustData*

member.

hInstance

Identifies an instance that contains a dialog box template specified by the *lpTemplateName* member.

lpszTemplate

Points to a null-terminated string that specifies the name of the resource file for the dialog box template that is to be substituted for the library's Edit Links dialog box template.

hResource

A customized template handle.

lpOleUILinkContainer

Points to the container's implementation of the **IOleUILinkContainer** Interface. The Edit Links dialog uses this to allow the container to manipulate its links.

See Also

IOleUILinkContainer, **OleUIEditLinks**

OLEUIGNRLPROPS

This structure is used to initialize the General tab of the Object Properties dialog box. A reference to it is passed in as part of the **OLEUIOBJECTPROPS** structure to the **OleUIObjectProperties** function. This tab shows the type and size of an OLE embedding and allows it the user to tunnel to the convert dialog box. This tab also shows the link destination if the object is a link.

```
typedef struct tagOLEUIGNRLPROPS
{
// These IN fields are standard across all OLEUI property pages. DWORD
cbStruct;
     DWORD  dwFlags;
     DWORD  dwReserved1[2];
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     DWORD  dwReserved2[3];

     struct tagOLEUIOBJECTPROPSW* lpOP;
} OLEUIGNRLPROPSW, *POLEUIGNRLPROPSW, FAR* LPOLEUIGNRLPROPSW;
```

Members

cbStruct
The size of the structure in bytes. This field must be filled on input.

dwFlags
There are currently no flags associated with this member. It should be set to 0 (zero).

dwReserved1[2]
Reserved for future use.

lpfnHook
Points to a hook function that processes messages intended for the dialog box. The hook function must return zero to pass a message that it didn't process back to the dialog box procedure in the library. The hook function must return a non zero value to prevent the library's dialog box procedure from processing a message it has already processed.

lCustData
Specifies application-defined data that the library passes to the hook function pointed to by the *lpfnHook* member during WM_INITDIALOG.

dwReserved2[3]
Reserved for future use.

struct tagOLEUIOBJECTPROPSW* *lpOP*
Used internally.

OLEUIINSERTOBJECT

The OLEUIINSERTOBJECT structure contains information that the OLE 2.01 User Interface Library uses to initialize the Insert Object dialog box, and space for the library to return information when the dialog is dismissed.

```
typedef struct tagOLEUIINSERTOBJECT
{
// These IN fields are standard across all OLEUI dialog functions.
     DWORD  cbStruct;
     DWORD  dwFlags;
     HWND  hWndOwner;
     LPCSTR  lpszCaption;
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     HINSTANCE  hInstance;
     LPCSTR  lpszTemplate;
     HRSRC  hResource;
     CLSID  clsid;

// Specifics for OLEUIINSERTOBJECT.
     LPTSTR  lpszFile;
     UINT  cchFile;
     UINT  cClsidExclude;
     LPCLSID  lpClsidExclude;
     IID  iid;

// Specific to create objects if flags say so
     DWORD  oleRender;
     LPFORMATETC  lpFormatEtc;
     LPOLECLIENTSITE  lpIOleClientSite;
     LPSTORAGE  lpIStorage;
     LPVOID FAR *  ppvObj;
     SCODE  sc;
     HGLOBAL  hMetaPict;
} OLEUIINSERTOBJECT, *POLEUIINSERTOBJECT, FAR *LPOLEUIINSERTOBJECT;
```

Members

cbStruct
Size of the structure in bytes. This field must be filled on input.

dwFlags
On input, specifies the initialization and creation flags. On exit, specifies the user's choices. It can be a combination of the following flags:

IOF_SHOWHELP
Specifies that the dialog will display a Help button.

IOF_SELECTCREATENEW
Specifies that the Create New radio button will initially be checked. This cannot be used with IOF_SELECTCREATEFROMFILE.

IOF_SELECTCREATEFROMFILE
Specifies that the Create From File radio button will initially be checked. This cannot be used with IOF_SELECTCREATENEW.

IOF_CHECKLINK
Specifies that the Link check box will initially be checked.

IOF_CHECKDISPLAYASICON
Specifies that the Display As Icon check box will initially be checked, the current icon will be displayed, and the Change Icon button will be enabled.

IOF_CREATENEWOBJECT
Specifies that a new object should be created when the user selects OK to dismiss the dialog box and the Create New radio button was selected.

IOF_CREATEFILEOBJECT
Specifies that a new object should be created from the specified file when the user selects OK to dismiss the dialog box and the Create From File radio button was selected.

IOF_CREATELINKOBJECT
Specifies that a new linked object should be created when the user selects OK to dismiss the dialog box and the user checked the Link check box.

IOF_DISABLELINK
Specifies that the Link check box will be disabled on initialization.

IOF_VERIFYSERVERSEXIST
Specifies that the dialog box should validate the classes it adds to the listbox by ensuring that the server specified in the registration database exists. This is a significant performance factor.

IOF_DISABLEDISPLAYASICON
Specifies that the Display As Icon check box will be disabled on initialization.

IOF_HIDECHANGEICON
Hides the Change Icon button in the Insert Object dialog.

IOF_SHOWINSERTCONTROL
Displays the Insert Control radio button.

IOF_SELECTCREATECONTROL
Displays the Create Control radio button.

hWndOwner
Identifies the window that owns the dialog box. It should not be NULL.

lpszCaption
Points to a string to be used as the title of the dialog box. If NULL, then the library uses Insert Object.

lpfnHook
Points to a hook function that processes messages intended for the dialog box. The hook function must return zero to pass a message that it didn't process back to the dialog box procedure in the library. The hook function must return a non zero value to prevent the library's dialog box procedure from processing a message it has already processed.

lCustData
Specifies application-defined data that the library passes to the hook function pointed to by the *lpfnHook* member. The library passes a pointer to the OLEUIINSERTOBJECT structure in the *lParam* parameter of the WM_INITDIALOG message; this pointer can be used to retrieve the *lCustData* member.

hInstance
Identifies an instance that contains a dialog box template specified by the *lpTemplateName* member.

lpszTemplate
Points to a null-terminated string that specifies the name of the resource file for the dialog box template that is to be substituted for the library's Insert Object dialog box template.

hResource
A customized template handle.

clsid
CLSID for class of the object to be inserted. Filled on output.

lpszFile

Points to the name of the file linked to or insert. Filled on output.

cchFile

The size of *lpszFile* buffer; will not exceed OLEUI_CCHPATHMAX.

cClsidExclude

The number of CLSIDs included in the *lpClsidExclude* list. Filled on input.

lpClsidExclude

A list of CLSIDs to exclude from listing.

iid

The identifier of the requested interface. If **OleUIInsertObject** creates the object, then it will return a pointer to this interface. This parameter is ignored if **OleUIInsertObject** does not create the object.

oleRender

The rendering option. If **OleUIInsertObject** creates the object, then it selects the rendering option when it creates the object. This parameter is ignored if **OleUIInsertObject** does not create the object.

lpFormatEtc

The desired format. If **OleUIInsertObject** creates the object, then it selects the format when it creates the object. This parameter is ignored if **OleUIInsertObject** does not create the object.

lpIOleClientSite

Points to the client site to be used for the object. This parameter is ignored if **OleUIInsertObject** does not create the object.

lpIStorage

Points to the storage to be used for the object This parameter is ignored if **OleUIInsertObject** does not create the object.

ppvObj

Points to the location where the pointer to the object is returned. This parameter is ignored if **OleUIInsertObject** does not create the object.

sc

The result of creation calls. This parameter is ignored if **OleUIInsertObject** does not create the object.

hMetaPict

MetafilePict structure containing the iconic aspect, if it wasn't placed in the object's cache.

See Also

OleUIInsertObject

OLEUILINKPROPS

This structure is used to initialize the Link tab of the Object Properties dialog box.   A reference to it is passed in as part of the OLEUIOBJECTPROPS structure to the **OleUIObjectProperties** function. This tab shows the location, update status, and update time for a link. It allows the user to change the source of the link, toggle its update status between automatic and manual update, open the source, force an update of the link, or break the link (convert it to a static picture).

```
// These IN fields are standard across all OLEUI property pages.

typedef struct tagOLEUILINKPROPSW
{
// These IN fields are standard across all OLEUI property pages.
     DWORD  cbStruct;
     DWORD  dwFlags;
     DWORD  dwReserved1[2];
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     DWORD  dwReserved2[3];

     struct tagOLEUIOBJECTPROPSW* lpOP;
} OLEUILINKPROPSW, *POLEUILINKPROPSW, FAR* LPOLEUILINKPROPSW;
```

cbStruct
  Size of the structure in bytes.

dwFlags
  Contains in-out flags specific to the links page.

dwReserved1[2];
  Reserved for future use.

lpfnHook
  Hook callback (not used in this dialog).

lCustData
  Custom data to pass to hook (not used in this dialog).

dwReserved2[3]
  Reserved for future use.

struct tagOLEUIOBJECTPROPS* *lpOP;*
  Used internally.

See Also

OleUIObjectProperties, **OLEUIOBJECTPROPS**

OLEUIOBJECTPROPS

This structure is used to initialize the standard Object Properties dialog box. It contains references to interfaces used to gather information about the embedding or link, references to three structures that are used to initialize the default tabs – General (OLEUIGNRLPROPS), View (OLEUIVIEWPROPS), and Link (OLEUILINKPROPS), if appropriate – and a standard property-sheet extensibility interface that allows the caller to add additional custom property sheets to the dialog.

```
typedef struct tagOLEUIOBJECTPROPS
{

// These IN fields are standard across all OLEUI property sheets.

     DWORD cbStruct;
     DWORD dwFlags;

// Standard PROPSHEETHEADER used for extensibility
     LPPROPSHEETHEADER       lpPS;

// Data which allows manipulation of the object
     DWORD dwObject;
     LPOLEUIOBJINFO          lpObjInfo;

// Data which allows manipulation of the link
     DWORD dwLink;
     LPOLEUILINKINFO         lpLinkInfo;

// Data specfic to each page
     LPOLEUIGNRLPROPS        lpGP;
     LPOLEUIVIEWPROPS        lpVP;
     LPOLEUILINKPROPS        lpLP;

} OLEUIOBJECTPROPS, *POLEUIOBJECTPROPS, FAR* LPOLEUIOBJECTPROPS;
```

cbStruct
Size of the structure in bytes.

dwFlags
These are the in-out: global flags for the property sheet.

OPF_OBJECTISLINK
The object is a link object and therefore has a link property page.

OPF_NOFILLDEFAULT
Do not fill in default values for the object.

OPF_SHOWHELP
Specifies that the dialog box will display a Help button.

OPF_DISABLECONVERT
Disable the Convert button on the general property page.

lpPS
[in]The standard property sheet header (PROPSHEETHEADER), used for extensibility.

//Data which allows manipulation of the object
dwObject
[in] identifier for the object

lpObjInfo
[in] interface to manipulate object

//Data which allows manipulation of the link

dwLink;

[in] A container-defined unique 32-bit identifier for a single link. Containers can use the pointer to the link's container site for this value.

lpLinkInfo

[in] interface to manipulate link

// Data specific to each page

lpGP

[in] General page data.

lpVP

[in] View page data

lpLP

[in] Link page data.

See Also

OleUIObjectProperties, OLEUIGNRLPROPS, **OLEUIVIEWPROPS**, **OLEUILINKPROPS**

OLEUIPASTEENTRY

This structure is an array of OLEUIPASTEENTRY entries specified in the OLEUIPASTESPECIAL structure for the Paste Special dialog box. Each entry includes a FORMATETC which specifies the formats that are acceptable, a string that is to represent the format in the dialog box's listbox, a string to customize the result text of the dialog, and a set of flags from the OLEUIPASTEFLAG enumeration. The flags indicate if the entry is valid for pasting only, linking only or both pasting and linking. If the entry is valid for linking, the flags indicate which link types are acceptable by OR'ing together the appropriate OLEUIPASTE_LINKTYPE<#> values. These values correspond to the array of link types as follows:

OLEUIPASTE_LINKTYPE1=arrLinkTypes[0]
OLEUIPASTE_LINKTYPE2=arrLinkTypes[1]
OLEUIPASTE_LINKTYPE3=arrLinkTypes[2]
OLEUIPASTE_LINKTYPE4=arrLinkTypes[3]
OLEUIPASTE_LINKTYPE5=arrLinkTypes[4]
OLEUIPASTE_LINKTYPE6=arrLinkTypes[5]
OLEUIPASTE_LINKTYPE7=arrLinkTypes[6]
OLEUIPASTE_LINKTYPE8=arrLinkTypes[7]

arrLinkTypes[] is an array of registered clipboard formats for linking. A maximum of eight link types are allowed.

```
typedef struct tagOLEUIPASTEENTRY
{
     FORMATETC   fmtetc;
     LPCSTR  lpstrFormatName;
     LPCSTR  lpstrResultText;
     DWORD  dwFlags;
     DWORD  dwScratchSpace;
} OLEUIPASTEENTRY, *POLEUIPASTEENTRY, FAR *LPOLEUIPASTEENTRY;
```

Members

fmtetc
The format that is acceptable. The Paste Special dialog checks if this format is offered by the object on the clipboard and if so, offers it for selection to the user.

lpstrFormatName
The string that represents the format to the user. Any %s in this string is replaced by the *FullUserTypeName* of the object on the clipboard and the resulting string is placed in the list box of the dialog. Only one %s is allowed. The presence or absence of %s specifies whether the result-text is to indicate that data is being pasted or that an object that can be activated by an application is being pasted. If %s is present, the resulting text says that an object is being pasted. Otherwise it says that data is being pasted.

lpstrResultText
The string used to customize the resulting text of the dialog when the user selects the format corresponding to this entry. Any %s in this string is replaced by the application name or *FullUserTypeName* of the object on the clipboard. Only one %s is allowed.

dwFlags
The values from OLEUIPASTEFLAG enumeration.

dScratchSpace
The scratch space available to routines that loop through an IEnumFORMATETC* to mark if the *PasteEntry* format is available. This field CAN be left uninitialized.

See Also

OLEUIPASTEFLAG, OleUIPasteSpecial, OLEUIPASTESPECIAL

OLEUIPASTESPECIAL

The OLEUIPASTESPECIAL structure contains information that the OLE 2.01 User Interface Library uses to initialize the Paste Special dialog box, as well as space for the library to return information when the dialog is dismissed.

```
typedef struct tagOLEUIPASTESPECIAL
{
// These IN fields are standard across all OLEUI dialog functions.     DWORD
cbStruct;
     DWORD  dwFlags;
     HWND  hWndOwner;
     LPCSTR  lpszCaption;
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     HINSTANCE  hInstance;
     LPCSTR  lpszTemplate;
     HRSRC  hResource;

// Specifics for OLEUIPASTESPECIAL.
     LPDATAOBJECT  lpSrcDataObj;
     LPOLEUIPASTEENTRY  arrPasteEntries;
     int  cPasteEntries;
     UINT FAR *  arrLinkTypes;
     int  cLinkTypes;
     UINT  cClsidExclude;
     LPCLSID  lpClsidExclude;
     int  nSelectedIndex;
     BOOL    fLink;
     HGLOBAL       hMetaPict;
     SIZEL  sizel;
} OLEUIPASTESPECIAL, *POLEUIPASTESPECIAL, FAR *LPOLEUIPASTESPECIAL;
```

Members

cbStruct
The size of the structure, in bytes. This field must be filled on input.

dwFlags
On input, *dwFlags* specifies the initialization and creation flags. On exit, it specifies the user's choices. It may be a combination of the following flags:

PSF_SHOWHELP
Specifies that the dialog will display a Help button.

PSF_SELECTPASTE
Selects the Paste radio button at dialog startup. This is the default, if PSF_SELECTPASTE or PSF_SELECTPASTELINK are not specified. Also, it specifies the state of the button on dialog termination. IN/OUT flag.

PSF_SELECTPASTELINK
Selects the PasteLink radio button at dialog startup. Also, specifies the state of the button on dialog termination. IN/OUT flag.

PSF_CHECKDISPLAYASICON
Specifies whether the Display As Icon radio button was checked on dialog termination. OUT flag.

PSF_DISABLEDISPLAYASICON
Specifies that the Display As Icon check box will be disabled on initialization.

HIDECHANGEICON

Used to disable the change-icon button in the dialog, which is available to users when they're pasting an OLE object by default. See STAYONCLIPBOARDCHANGE otherwise.

STAYONCLIPBOARDCHANGE

Used to tell the dialog to stay up if the clipboard changes while the dialog is up. If the user switches to another application and copies or cuts something, the dialog will, by default, perform a cancel operation, which will remove the dialog since the options it's in the middle of presenting to the user are no longer up-to-date with respect to what's really on the clipboard.

NOREFRESHDATAOBJECT

Used in conjunction with STAYONCLIPBOARDCHANGE (it doesn't do anything otherwise). If the clipboard changes while the dialog box is up and STAYONCLIPBOARDCHANGE is specified, then NOREFRESHDATAOBJECT indicates that the dialog should NOT refresh the contents of the dialog to reflect the new contents of the clipboard. This is useful if the application is using the paste-special dialog on an IDataObject besides the one on the clipboard, for example, as part of right-mouse drag/drop operation.

hWndOwner

Identifies the window that owns the dialog box. It should not be NULL.

lpszCaption

Points to a string to be used as the title of the dialog box. If NULL, then the library uses Paste Special.

lpfnHook

Points to a hook function that processes messages intended for the dialog box. The hook function must return zero to pass a message that it didn't process back to the dialog box procedure in the library. The hook function must return a non zero value to prevent the library's dialog box procedure from processing a message it has already processed.

lCustData

Specifies application-defined data that the library passes to the hook function pointed to by the *lpfnHook* member. The library passes a pointer to the OLEUIPASTESPECIAL structure in the *lParam* parameter of the WM_INITDIALOG message; this pointer can be used to retrieve the *lCustData* member.

hInstance

Identifies a instance that contains a dialog box template specified by the *lpTemplateName* member.

lpszTemplate

Points to a null-terminated string that specifies the name of the resource file for the dialog box template that is to be substituted for the library's Paste Special dialog box template.

hResource

Customized template handle.

lpsrcDataObj

The source IDataObject* (on the clipboard) for data to paste. This field is filled on input. If *lpSrcDataObj* is NULL when **OleUIPasteSpecial** is called, then **OleUIPasteSpecial** will attempt to retrieve a pointer to an IDataObject from the clipboard. If **OleUIPasteSpecial** succeeds, it is the caller's responsibility to free the IDataObject returned in *lpSrcDataObj*.

arrPasteEntries

The OLEUIPASTEENTRY array which specifies acceptable formats. This field is filled on input.

cPasteEntries

The number of OLEUIPASTEENTRY array entries. This field is filled on input.

arrLinkTypes

A list of link types that are acceptable. Link types are referred to using OLEUIPASTEFLAG in arrPasteEntries. This field is filled on input.

cLinkTypes

The number of link types. This field is filled on input.

cClsidExclude
The number of CLSIDs in *lpClsidExclude*. This field is filled on input.

lpClsidExclude
An array of CLSIDs to exclude from the list of available server objects for a Paste operation. Note that this does not affect Paste Link. An application can prevent embedding into itself by listing its own CLSID in this list. This field is filled on input.

nSelectedIndex
Index of *arrPasteEntries*[] that the user selected. This field is filled on output.

fLink
Indicates whether Paste or Paste Link was selected by the user. This field is filled on output.

hMetaPict
The handle to the Metafile containing the icon and icon title selected by the user. This field is filled on output.

sizel
The size of object as displayed in its source, if the display aspect chosen by the user matches the aspect displayed in the source. If the user chooses a different aspect, then *sizel.cx* and *sizel.cy* are both set to zero. The size of the object as it is displayed in the source is retrieved from the ObjectDescriptor if *fLink* is FALSE and from the LinkSrcDescriptor if *fLink* is TRUE. This field is filled on output.

See Also

OleUIPasteSpecial, **OLEUIPASTEENTRY**, **OLEUIPASTEFLAG**

OLEUIVIEWPROPS

This structure is used to initialize the View tab of the Object properties dialog box. A reference to it is passed in as part of the **OLEUIOBJECTPROPS** structure to the **OleUIObjectProperties** function. This tab allows the user to toggle between "content" and "iconic" views of the object, and change its scaling within the container. It also allows the user to tunnel to the change icon dialog when the object is being displayed iconically.

```
// These IN fields are standard across all OLEUI property pages.

typedef struct tagOLEUIVIEWPROPSA
{
// These IN fields are standard across all OLEUI property pages.
     DWORD  cbStruct;
     DWORD  dwFlags;
     DWORD  dwReserved1[2];
     LPFNOLEUIHOOK  lpfnHook;
     LPARAM  lCustData;
     DWORD  dwReserved2[3];

struct tagOLEUIOBJECTPROPS* lpOP;

int   nScaleMin;
int   nScaleMax;

} OLEUIVIEWPROPSA, *POLEUIVIEWPROPSA, FAR* LPOLEUIVIEWPROPSA;
```

Members

cbStruct
Size of the structure in bytes.

dwFlags
IN-OUT: flags specific to view page

VPF_SELECTRELATIVE
[in] Relative to origin.

VPF_DISABLERELATIVE
[in] Disable relative to origin.

VPF_DISABLESCALE
[in] Disable scale option.

dwReserved1[2]
Reserved for future use.

lpfnHook
Hook callback (not used in this dialog).

lCustDataa
Custom data to pass to hook (not used in this dialog).

dwReserved2[3];
Reserved for future use.

struct tagOLEUIOBJECTPROPS* *lpOP*;
Used internally.

nScaleMin
Minimum value for the scale range.

nScaleMax

Maximum value for the scale range.

OLEVERB

The **OLEVERB** structure is used in the **IEnumOLEVERB** interface to return information describing a verb for an object. Defined in the **IEnumOLEVERB** interface (*eoverb.idl*).

```
typedef struct tagOLEVERB
{
     LONG lVerb;
     LPWSTR lpszVerbName;
     DWORD fuFlags;
     DWORD grfAttribs;
} OLEVERB, * LPOLEVERB;
```

Members

lVerb
Specifies the integer ID associated with this verb.

lpszVerbName
Points to a string that contains the verb's name.

fuFlags
grfAttribs
Specifies some combination of the verb attributes in the **OLEVERBATTRIB** enumeration.

See Also

IEnumOLEVERB, **IOleObject**

RemSNB

The **RemSNB** structure is used for marshaling the **SNB** data type.

Defined in the **IStorage** interface (*storag.idl*).

```
typedef struct tagRemSNB {
     unsigned long ulCntStr;
     unsigned long ulCntChar;
     [size_is(ulCntChar)] wchar_t rgString[];
} RemSNB;
typedef [transmit_as(RemSNB)] wchar_t **SNB;
```

Members

ulCntStr
Specifies the number of strings in the *rgString* buffer.

ulCntChar
Specifies the size in bytes of the *rgString* buffer.

rgString
Points to an array of bytes containing the stream name strings from the SNB.

See Also

IStorage

SNB

A string name block (SNB) is a pointer to an array of pointers to strings, that ends in a NULL pointer. String name blocks are used the **IStorage** interface and API calls that open storage objects. The strings point to contained storage objects or streams that are to be excluded in the open calls.

```
typedef OLESTR **SNB
```

Comments

The SNB should be created by allocating a contiguous block of memory in which the pointers to strings are followed by a NULL pointer, which is then followed by the actual strings.

The marshalling of a string name block is based on the assumption that the SNB passed in was created this way. Although it could be stored in other ways, the SNB created in this manner has the advantage of requiring only one allocation operation and one freeing of memory for all the strings.

STATDATA

The **STATDATA** structure is the data structure used to specify each advisory connection. It is used for enumerating current advisory connections. It holds data returned by the **IEnumSTATDATA** enumerator. This enumerator interface is returned by **IDataObject:DAdvise**. Each advisory connection is specified by a unique **STATDATA** structure.

Defined in *com.h*.

```
typedef struct tagSTATDATA
{
      FORMATETC formatetc;
      DWORD grfAdvf;
      IAdviseSink* pAdvSink;
      DWORD dwConnection;
} STATDATA;
```

Members

formatetc

Specifies the **FORMATETC** structure for the data of interest to the advise sink. The advise sink receives notification of changes to the data specified by this **FORMATETC** structure.

grfAdvf

Specifies the **ADVF** enumeration value that determines when the advisory sink is notified of changes in the data.

pAdvSink

Specifies the pointer for the **IAdviseSink** interface that will receive change notifications.

dwConnection

Specifies the token that uniquely identifies the advisory connection. This token is returned by the method that sets up the advisory connection.

IEnumSTATDATA

STATSTG

The **STATSTG** structure contains statistical information about an open storage, stream, or byte array object. This structure is used in the **IEnumSTATSTG**, **ILockBytes**, **IStorage**, and **IStream** interfaces.

Defined in the **IStream** interface (*stream.idl*).

```
typedef struct tagSTATSTG
{
     LPWSTR pwcsName;
     DWORD type;
     ULARGE_INTEGER cbSize;
     FILETIME mtime;
     FILETIME ctime;
     FILETIME atime;
     DWORD grfMode;
     DWORD grfLocksSupported;
     CLSID clsid;
     DWORD grfStateBits;
     DWORD dwStgFmt;
} STATSTG;
```

Members

pwcsName
Points to a NULL-terminated string containing the name. Space for this string is allocated by the method called and freed by the caller. You can specify not to return this member by specifying the STATFLAG_NONAME value when you call a method that returns a **STATSTG** structure.

type
Indicates the type of storage object. This is one of the values from the **STGTY** enumeration.

cbSize
Specifies the size in bytes of the stream or byte array. Undefined for storage objects; zero is returned for storage objects.

mtime
Indicates the last modification time for this storage, stream, or byte array.

ctime
Indicates the creation time for this storage, stream, or byte array.

atime
Indicates the last access time for this storage, stream or byte array.

grfMode
Indicates the access mode specified when the object was opened. This member is only valid in calls to **Stat** methods.

grfLocksSupported
Indicates the types of region locking supported by the stream or byte array. See the **LOCKTYPES** enumeration for the values available. This member is not used for storage objects.

clsid
Indicates the class identifier for the storage object; set to CLSID_NULL for new storage objects. This member is not used for streams or byte arrays.

grfStateBits
Indicates the current state bits of the storage object, that is, the value most recently set by the **IStorage::SetStateBits** method. This member is not valid for streams or byte arrays.

dwStgFmt
Indicates the format of the storage object. This is one of the values from the **STGFMT** enumeration.

STGMEDIUM

The **STGMEDIUM** structure is a generalized global memory handle used for data transfer operations by the **IAdviseSink**, **IDataObject**, and **IOleCache** interfaces.

Defined in the **IAdviseSink** interface (*advsnk.idl*).

```
typedef struct tagSTGMEDIUM
{
     DWORD tymed;
     [switch_type(DWORD), switch_is((DWORD) tymed)]
     union {
           [case(TYMED_GDI)] HBITMAP hBitmap;
           [case(TYMED_MFPICT)] HMETAFILEPICT hMetafilePict;
           [case(TYMED_ENHMF)] HENHMETAFILE hEnhMetaFile;
           [case(TYMED_HGLOBAL)] HGLOBAL hGlobal;
           [case(TYMED_FILE)] LPWSTR lpszFileName;
           [case(TYMED_ISTREAM)] IStream *pstm;
           [case(TYMED_ISTORAGE)] IStorage *pstg;
           [default] ;
     };
     [unique] IUnknown *pUnkForRelease;
}STGMEDIUM;
typedef STGMEDIUM *LPSTGMEDIUM;
```

Members

tymed
Indicates the type of storage medium. The marshaling and unmarshaling routines use this value to determine which union member was used. This value must be one of the elements of the **TYMED** enumeration.

union member
Specifies a handle, string, or interface pointer that the receiving process can use to access the data being transferred. If *tymed* is TYMED_NULL, the union member is undefined; otherwise, it is one of the following:

hBitmap
Specifies a bitmap handle. The *tymed* member is TYMED_GDI.

hMetafilePict
Specifies a metafile handle. The *tymed* member is TYMED_MFPICT.

hEnhMetaFile
Specifies an enhanced metafile handle. The *tymed* member is TYMED_ENHMF.

hGlobal
Specifies a global memory handle. The *tymed* member is TYMED_HGLOBAL.

lpszFileName
Specifies the path of a disk file that contains the data. The *tymed* member is TYMED_FILE.

pstm
Specifies an **IStream** instance. The *tymed* member is TYMED_ISTREAM.

pstg
Specifies an **IStorage** instance. The *tymed* member is TYMED_ISTORAGE.

pUnkForRelease
Points to an interface instance that allows the sending process to control the way the storage is released when the receiving process calls the **ReleaseStgMedium** API function. If *pUnkForRelease* is NULL, **ReleaseStgMedium** uses default procedures to release the storage; otherwise,

ReleaseStgMedium uses the specified **IUnknown** interface.
