

For instructions on how to call the DLL from a Delphi application please refer to the sample application included in this ZIP. Refer to DDRV\_VB.WRI as a reference for the functions and their parameters. The syntax in VB is slightly different, but the reference should be easy enough to follow. Just remember these things:

- 1. In VB Sub means Procedure.**
- 2. In VB Function means Function.**
- 3. All strings passed using the "ByVal" keyword in VB are Null terminated strings in Delphi (PChar). Strings are indicated by a proceeding \$. (e.g. a\$)**
- 4. All 2-byte integers (% in VB), 4-byte integers (& in VB) and single precision floats (! in VB) are passed normally.**

When you want to use ddrvexe/dll with your application, just include the file ddrvcnst.pas in your project. It contains everything that you need.
