

Features of V39 GadTools

by Mark Ricci

The V39 GadTools library has been upgraded with new features and capabilities that support the enhanced graphic capabilities of the AA chipset. Other improvements include support for IDCMP_GADGETHELP events, more support for IDCMP_GADGETUP events, scalable imagery and a new function, GT_GetGadgetAttrs(), to obtain the values of certain gadget attributes.

This article assumes you are familiar with the previous version of the GadTools library. If not, you should refer to the "GadTools Library" chapter of the Amiga ROM Kernel Reference Manual: Libraries for an in-depth explanation of GadTools. You should also refer to the GadTools Autodoc for complete explanations of the GadTools functions. All tags and constants referenced in this article are defined in `<libraries/gadtools.h>` and `<intuition/intuition.h>`.

The NewLook Menus

For V37, Intuition received a facelift. V37 introduced the "NewLook" rendering scheme, which improved the appearance of most of the elements of the Amiga user interface (windows, system gadgets, standard Boopsi classes, etc.). One element of the Amiga's GUI that escaped the NewLook was the menu system.

For V39, Intuition added the NewLook to its menus. When Intuition renders NewLook menus, it gets the colors for the menu from the Palette Preferences set by the user. Before V39, Intuition used the window's DetailPen and BlockPen to draw the menu and the colors of the MenuItems depended on the MenuItem's IntuiText or Image structure.

GadTools fully supports Intuition's NewLook menus. To make GadTools use the NewLook color scheme for a window's menus, an application needs to do two things. First, it needs to tell Intuition that it wants NewLook menu imagery for the window. It does this when opening the window by passing the `{WA_NewLookMenus, TRUE}` tag/value pair to `OpenWindowTags()`. Second, the application needs to remind GadTools that the window uses NewLook imagery for its menus. The application does this by passing the `{GTMN_NewLookMenus, TRUE}` tag/value pair

to `LayoutMenus()`:

```
struct VisualInfo *vi;

LayoutMenus(menusready, vi, GTMN_NewLookMenus, TRUE, TAG_END);
```

Instead of using the `GTMN_NewLookMenus` tag, it's possible to set the menu colors yourself by using the `GTMN_FrontPen` tag to set the pen number for rendering menu text. In addition to this tag, you must set the screen's `BARDETAILPEN` and `BARTRIMPEN` to match the menu text pen and set the `BARBLOCKPEN` to the color you want for the title bar. However, you cannot control how Intuition complements menu items and you do not automatically get the user's menu color preferences, so you will not get as perfect NewLook menu as you would by leaving it to the system.

Gadgets

Most GadTools gadgets received new attributes in V39. These include new IDCMP events, ability to specify rendering pens, and scalable imagery.

IDCMP Events

Button, integer and string gadgets can send `IDCMP_GADGETDOWN` events by setting the `GA_Immediate` tag to `TRUE`.

Disabling

MX and listview gadgets join the other GadTools gadgets in having a disable attribute. Set `GA_Disabled` tag to `TRUE` to disable, and `FALSE` to re-enable.

Scalable Imagery

Checkbox and MX gadgets are no longer fixed in size. You can scale them to any width and height. If you do not specify scaling, GadTools uses its built-in default dimensions. These dimensions, which are defined in `<libraries/gadtools.h>`, are `CHECKBOXWIDTH` and `CHECKBOXHEIGHT` for checkbox gadgets, and `MXWIDTH` by `MXHEIGHT` for MX gadgets.

To scale a checkbox gadget, set the `GTCB_Scaled` tag to `TRUE`, and set the desired width and height in the `ng_Width` and `ng_Height` fields of the `NewGadget` structure. The default value of `GTCB_Scaled` is `FALSE`, meaning use the default size of 26 by 11, the values of `CHECKBOXWIDTH` and `CHECKBOXHEIGHT`, respectively.

To scale an MX gadget, set the `GTMX_Scaled` tag to `TRUE`, and set the desired width and height in the `ng_Width` and `ng_Height` fields of the `NewGadget` structure. The default value of

possible to set the menu colors yourself by `DrawMenu` for rendering menu text. In addition to this `DrawMenu` `TRIMPEN` to match the menu text pen and the menu bar. However, you cannot control how the menu items automatically get the user's menu color. You can set the menu as you would by leaving it to the

Rendering Pens, Display Format, Justification

Application writers use number, text, and other information to the user. The new attributes provide information.

You can specify any pen for rendering the foreground gadgets. This allows you to use color for emphasis as the foreground color in a text gadget for formatting strings for the displays, e.g., `%lx` in a text gadget. The `Exec RawDoFmt()` function provides details.

Text clipping is another new attribute. It clips the text in a gadget. This prevents the text or number from being too large for the gadget. Along with text clipping, you can center and right justify their displays.

Finally, you can specify the size of the string buffer for formatting their text. This buffer must be large enough for the gadget, as the gadget doesn't do any bounding size of the buffer will cause the gadget to overflow and follow the buffer in memory.

For number gadgets, the `GTNM_FrontPen` tag specifies the pen for rendering the background of the number. The default is `DrawInfo->dri_Pens[TEXTPEN]`. The `GTNM_BackPen` tag specifies the pen for rendering the background of the number. The default is `DrawInfo->dri_Pens[TEXTPEN]`.

`GTNM_Justification` specifies the type of justification for the number flush with the left side of the gadget, `GTJ_LEFT` flushes the number with the left side, and `GTJ_CENTER` centers the number.

`GTNM_Format` specifies the C-language-like format for the number. You must use the `l` (long) modifier. The default is `%lx`. The `Exec RawDoFmt()` function formats the number gadget. See the Autodoc for `RawDoFmt()` for details.

`GTJ_Scaled` is `FALSE`, meaning use the default size of 17 by 9, the values of `MXWIDTH` by `MXHEIGHT`, respectively. If you scale MX gadgets, you must also set the `GTMX_Spacing` tag to `Gadget.ng_TextAttr->ta_YSize + 1` to properly space the buttons with respect to the font.

Rendering Pens, Display Format, Justification, Clipping and Display Size

Application writers use number, text, and to some degree, slider gadgets, to present information to the user. The new attributes for these gadgets improve the presentation of the

They can specify any pen for rendering the foreground and the background of number and text gadgets. This allows you to use color for emphasis or aesthetics. For example, you might use `DrawInfo->dri_Pens[TEXTPEN]` as the foreground color in a text gadget for emphasis. You can also use C-language-like formatting strings for the displays, e.g., `%lx` would give you hexadecimal output in a number gadget. The `Exec RawDoFmt()` function processes this string, so refer to that function for

Text clipping is another new attribute. It clips the display to fit within the borders of the gadget. This prevents the text or number from running over the border of a gadget if it's too long for the gadget. Along with text clipping, the number, text and slider gadgets can left, center and right justify their displays.

Finally, you can specify the size of the string buffer that number and slider gadgets use when formatting their text. This buffer must be large enough to hold the entire string generated by the gadget, as the gadget doesn't do any bounds checking on the buffer. Underestimating the size of the buffer will cause the gadget to overwrite the buffer, overwriting whatever happens to be in the buffer in memory.

For number gadgets, the `GTNM_FrontPen` tag specifies the pen to use for rendering the number. The default is `DrawInfo->dri_Pens[TEXTPEN]`. `GTNM_BackPen` specifies the pen to use for rendering the background of the number. The default is to use the background color of the

`GTJ_Justification` specifies the type of justification within the gadget box. `GTJ_LEFT` renders the number flush with the left side of the gadget, `GTJ_RIGHT` renders the number flush with the right side, and `GTJ_CENTER` centers the number. The default is `GTJ_LEFT`.

`GTJ_Format` specifies the C-language-like formatting string used to display the number. You must use the `l` (long) modifier. The default is ```%ld''`. The gadget passes the formatting string to the `exec.library` function `RawDoFmt()`, which generates the string that appears in the number gadget. See the Autodoc for `RawDoFmt()` for more information on the formatting

If an application changes the default formatting string with the `GTNM_Format` tag, the string the number gadget displays may become significantly longer. For example, if the application uses the format string ``my number is %ld'`, when the gadget processes the formatting string with `RawDoFmt()`, `RawDoFmt()` generates a string at least 14 characters long. By default, the gadget sets aside a 10 byte buffer for `RawDoFmt()` to use, so the formatting string above is too long for the default buffer. The tag `GTNM_MaxNumberLen` sets the size of this buffer.

`GTNM_Clipped` controls text clipping. The default behavior differs between number gadgets with borders and number gadgets without borders. For bordered number gadgets, the default is `TRUE`--clip the display to fit within the gadget borders. For gadgets without borders, the default is `FALSE`--no clipping.

Text gadgets also have a new set of attributes that correspond to the new number gadget attributes. These corresponding tags are: `GTTX_FrontPen`, `GTTX_BackPen`, `GTTX_Justification`, and `GTTX_Clipped`. There is no corresponding text gadget tag for `GTNM_MaxNumberLen` or `GTNM_Format`.

Slider gadgets use the `GTSL_Justification` tag with the constants listed above (`GTJ_LEFT`, `GTJ_RIGHT`, and `GTJ_CENTER`) to control justification of the gadgets numeric display. The `GTSL_MaxPixelLen` tag specifies the maximum pixel size of the level display for any value of the slider. This is primarily useful when dealing with proportional fonts. The default is the font's character width (from the font's `TextFont->tf_XSize` field) multiplied by the value in the `GTSL_MaxLevelLen` tag.

New Gadget-Specific Attributes

MX gadgets can now have titles. The gadget obtains its title from the `ng_GadgetText` field of the `NewGadget` structure. The `GTMX_TitlePlace` tag specifies where to place the title. The possible values are:

<code>PLACETEXT_LEFT</code>	Right-align text on left side
<code>PLACETEXT_RIGHT</code>	Left-align text on right side
<code>PLACETEXT_ABOVE</code>	Center text above
<code>PLACETEXT_BELOW</code>	Center text below

For compatibility reasons, GadTools will not put a title on the MX gadget if the `GTMX_TitlePlace` tag is not present.

Listviews

Listview gadget improvements include forced display of an item, highlighting of the selected item in the listview and custom callback hooks.

GTLV_MakeVisible tag specifies the number of the item that should be forced into the drawing area. It overrides the **GTLV_Top** tag.

V37, a listview identified its currently selected item by displaying it in a text gadget beneath the listview. The tag **GTLV_ShowSelected** specifies how the listview indicates which item is the currently selected item. If set to **NULL**, the listview places a highlight bar over the currently selected item. If **GTLV_ShowSelected** points to a string gadget, the listview displays the selected item in the string gadget in addition to a highlight bar.

can use callback hooks to render a listview's items. The listview in the **V39 Palette Preferences** editor uses a callback hook to display the standard user interface pens. The callback hook makes it possible for each item to display the pen color in addition to the pen number. The pen color appears in a little box at the left edge of each item in the listview.

GTPA_NumColors sets the number of colors to display in the palette gadget. This overrides the **GTPA_Depth** tag and allows numbers that are not powers of 2 (which was a limitation of the **V37 Palette** gadget). The default is 2.

palette gadgets can now have their own array of pen numbers. **GTPA_ColorTable** is a pointer to an array of pen numbers. The array must contain at least as many entries as there are colors displayed in the palette gadget. The default is **NULL** which causes a 1-to-1 mapping of pen numbers. That means if you don't specify this tag, your palette will use pen number 0 through **n-1**, where **n** is the number of colors you set in **GTPA_NumColors**. For example, if you set **GTPA_NumColors** to 6 and don't specify **GTPA_ColorTable**, you will get a pen array of pens 0, 1,

pen array you specify looks like this:

```
UBYTE colors[8]= {1,2,15,6,0,3,8};
```

Setting **GTPA_ColorTable** to this array indicates that the palette pens are 1, 2, 15, 6, 0, 3 and 8, respectively. Note that you have to allocate pens to be certain you can use them and control them. See the *Amiga OS V39 Developer Release Notes* for information on allocating and controlling pens.

cannot use the **GTPA_ColorTable** tag with the **GTPA_ColorOffset** tag. The **GTPA_ColorOffset** tag specifies which pen to use as the first pen of a palette. For example, if you set it to 4, the first pen used in the palette will be pen 4. If you use the **GTPA_ColorTable** tag, the **GTPA_ColorOffset** tag is ignored.

However, you can do color offsets with a color table by setting the value of the **GTPA_ColorOffset** tag to the index of the color in the table.

`GTPA_ColorTable` tag to point to the color table plus the offset you want. In the table above, you could specify pen 6 (the fourth member of the table) as the first pen to use by setting `GTPA_ColorTable` in this manner:

```
CreateGadget(PALETTE_KIND, gad, &ng,
             GTPA_ColorTable, &colors[3],
             TAG_END);
```

Note that the `GTPA_NumColors` tag is not present in the call above. This will default the number of colors to two, so the palette gadget created above will be a two color gadget that uses pens 0 and 0, the fourth and fifth pens in the array.

Obtaining Gadget Attributes

Prior to V39, the only way to obtain the attributes of a GadTools gadget was through the `Co` field of an `IDCMP_GADGETUP` `IntuiMessage`. In addition to having to wait until the user clicked on a gadget, this method limited you to obtaining one attribute at a time.

A new GadTools function, `GT_GetGadgetAttrs()` obtains a gadget's attributes. You may call the function at any time after creating a gadget and for as many attributes as the function supports for that gadget.

`GT_GetGadgetAttrs()` accepts a taglist of the attributes to obtain. An application passes it the address of the gadget, the address of the window containing the gadget, a `NULL` field (this field is reserved for later use and must be `NULL` for now), and a taglist. Each attribute value pair in the taglist supplies the ID of the tag to get (in `ti_Tag`) and an address where `GT_GetGadgetAttrs()` can store the tag's value. Since all tag values are longwords, expect `GT_GetGadgetAttrs()` to copy a longword for each attribute you request. The function returns the number of attributes it obtained.

```
LONG how_many, top_item = 0, selected_item = 0;

how_many = GT_GetGadgetAttrs( listview_gad, win, NULL,
                             GTLV_Top, &top_item,
                             GTLV_Selected, &selected_item,
                             TAG_DONE );
```

`How_many` contains the number of gadget attributes `GT_GetGadgetAttrs()` obtained. `GT_GetGadgetAttrs()` copies the value of the listview top and the selected item into `top_item` and `selected_item`, respectively. *Use longword targets to hold the returned values.*

`GT_GetGadgetAttrs()` supports `GA_Disabled` (`TRUE` if the gadget is disabled; `FALSE` if the gadget is active) for all GadTools gadgets except text and number gadgets. Other attributes are specific to each gadget as follows:

Checkbox - `GTCB_Checked` returns `TRUE` if the checkbox gadget is checked, or `FALSE` if the gadget is not checked.

le - GTCY_Active returns the ordinal number, counting up from zero, of the active choice.

y_Labels returns a pointer to the NULL-terminated array of choices.

ger - GTIN_Number returns the contents of the gadget.

view - GTLV_Top returns the ordinal number, counting up from zero, of the top item.

y_Selected returns the ordinal number of the selected item. **GTLV_Labels** returns a pointer to the List structure associated with the gadget.

- GTMX_Active returns the ordinal number, counting up from zero, of the active selection.

tte - GTPA_Color returns the ordinal number of the selected color. This number corresponds to the selected color's position in the palette's **GTPA_ColorTable** array.

A_ColorOffset returns the ordinal number of the first color used in the palette.

A_ColorTable returns a pointer to the table of pen numbers used for the gadget, if there is

ller - GTSC_Top returns the number of the top line visible in the scroller. **GTSC_Total**

urns the total number of lines in the scroller. **GTSC_Visible** returns the number of visible

er - GTSL_Min returns the minimum value of the slider. **GTSL_Max** returns the maximum value of the slider. **GTSL_Level** returns the current level of the slider.

ng - GTST_String returns a pointer to the gadget's buffer.

t - GTTX_Text returns a pointer to the gadget's buffer.

Message Handling - ExtIntuiMessage Structure

With V39, the IntuiMessage structure has been extended to allow for tablet support. The GadTools message handling functions--**GT_FilterIMsg()**, **GT_GetIMsg()**, **GT_PostFilterIMsg()**, and **GT_ReplyIMsg()**--work with the extended IntuiMessage structure, ExtIntuiMessage, but are backwards compatible with IntuiMessage.

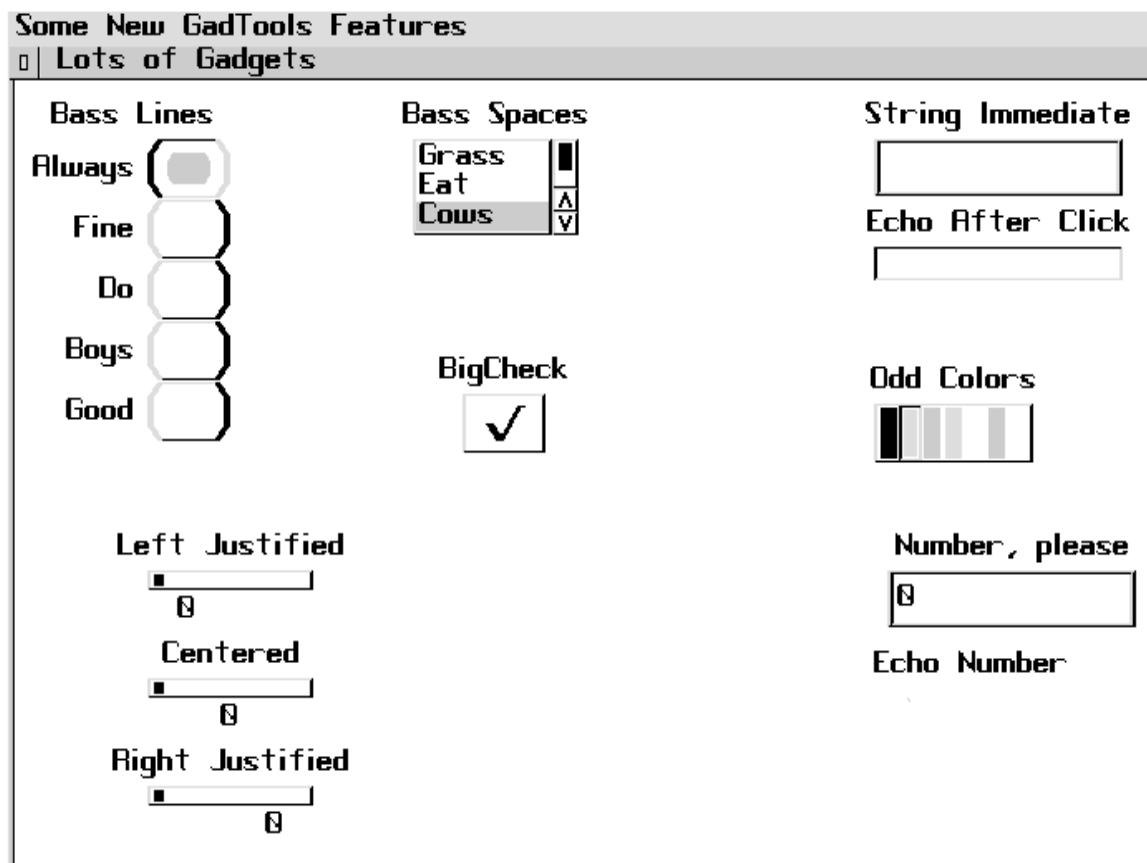

GadTools gadgets support Intuition's gadget help feature. You enable this by calling the *Intuition.library* function **HelpControl()**. Gadget help is either on or off for all GadTools gadgets in a window; you cannot selectively enable it for certain gadgets as you can with

Intuition gadgets. For more information, refer to page IV-114 of the ``Boopsi in Release 3'' article in the January/February 1993 issue of Amiga Mail.

Bevel Box

Bevel boxes now come in three types that you specify with `GTBB_FrameType`. `BBFT_BUTTON` generates the type of box used around button gadgets. `BBFT_RIDGE` generates the type of box used for string gadgets. `BBFT_ICONDROPBOX` generates a box suitable for a standard icon drop box imagery. The default is `BBFT_BUTTON`. These frame types are similar to the Boopsi imageclass frame types `FRAME_BUTTON`, `FRAME_RIDGE`, and `FRAME_ICONDROPBOX`, that are pictured on page IV-120 of the ``Boopsi in Release 3'' article in the January/February 1993 issue of
