

Handling Multiple Assigns with Conventional Directories

One of the features introduced by Release 2 is Multiple Assigning. This feature allows an AmigaDOS assign to carry over several directories which can be on different volumes. This makes it possible to split up assigns such as *libs:* and *fonts:*.

The article "Directory Scanning" on page II-49 contains an example called *find.c* that illustrates scanning a path that can contain a multiassign. However, besides being rather complicated, *find.c* makes a special case of scanning assigns, which isn't necessary (*find.c* also did something evil--*find.c* uses DOSBase's private pointer to the *utility.library*, essentially using the *utility.library* without opening it). The method needed to scan a multiassign directory also works on conventional directories.

Scanning a multiassign requires calling the *dos.library* function `GetDeviceProc()` in a loop to see each directory of the multiassign. Using `GetDeviceProc()`, the application doesn't have to concern itself with the differences between assigns, multiassigns, and volumes. The application just keeps calling `GetDeviceProc()` until it gets back a NULL.

```
struct DevProc *GetDeviceProc( STRPTR name, struct DevProc *dp );
```

The name can be any valid dos path. If there is a device name present, `GetDeviceProc()` will find the device's entry in the dos list and copy some information into a `DevProc` structure:

```
struct DevProc {
    struct MsgPort *dvp_Port; /* Device's Message port, also called a Process identifier */
    BPTR          dvp_Lock; /* Lock on root of assign or lock on root of volume */
    ULONG        dvp_Flags;
    struct DosList *dvp_DevNode; /* DON'T TOUCH OR USE! */
};
```

The important fields here are `dvp_Lock` and `dvp_Port`. The `dvp_Lock` field is a lock on the root of the object named in `GetDeviceProc()`. It serves as a starting point in locating the named object. If the object name contains an assign (i.e. "libs:"), `dvp_Lock` is the root of the assign. For example, on a typical Release 2 system, the *libs:* assign refers to the *libs* directory on the *System2.0:* volume. Calling `GetDeviceProc()` on "libs:" in this case will yield a lock on *System2.0:libs*.

If the named object contains a dos volume, `dvp_Lock` is either a lock on the root of the dos volume or NULL. If the object named in `GetDeviceProc()` contains a non-filesystem device (i.e.,

``ser:" , ``par:" , ``prt:" , etc.) or it does not contain a device name, `dvp_Lock` is NULL.

The `dvp_Port` field points to a message port. This message port is connected to the handler process of a DOS device. The handler process controls a DOS device. DOS functions (like the `Lock()` function) use this message port to talk to the handler process of the named object. For example, from the ``libs:" example above, the `dvp_Port` field refers to the message port of the handler process for the *System2.0*: volume.

Note that `dvp_Lock` is only a lock on the root of the named object. If the named object is a path several directories deep (for example, *libs:gadgets/colorwheel.gadget*), it's up to the application to handle the rest of the path. The application also has to handle the case where the named object is a path without a device name.

Although an application can send DOS packets directly to the message port (`dvp_Port`) of a handler process, normally it is easier to use functions from `dos.library`. The *multilist.c* example uses the `Lock()` function to lock the named object. *Multilist* has to do something a little unorthodox to use `Lock()`. `Lock()` accepts a path name to the object to lock. `Lock()` understands absolute paths (i.e. paths with a logical device name like ``df1:" or ``libs:") and relative paths. If `Lock()` receives an absolute path name, `Lock()` can find the device's handler process using the logical device name in the absolute path. For a relative path, `Lock()` does not have enough information to find the named object, so it assumes the path is relative to the current directory and file system (each process has a current directory and file system).

This makes `Lock()` a little more difficult to use in *multilist.c* because, when processing an absolute path, *multilist* has to process the logical device name separately from the rest of the path. It has to use `GetDeviceProc()` to find the root of a logical device name (which can be an assign, multiassign, volume name, etc.) then it has to strip the logical device name from the absolute path. Without a logical device name, the path has become relative rather than absolute. The path is now relative to `dvp_Lock` and `dvp_Port`. In order for `Lock()` to work with this relative path, *multilist* must temporarily set the current directory and file system to the values in `dvp_Lock` and `dvp_Port`, respectively.

Note that the Autodoc for `GetDeviceProc()` says to check `IoErr()` for `ERROR_NO_MORE_ENTRIES` after receiving a NULL from `GetDeviceProc()`. Due to a bug, DOS does not set the error value correctly. Also note that the Autodoc says to check the `DevProc` structure's `dvp_Flags` field for the `DVPF_ASSIGN` flag. This was necessary in the 2.00 and 2.01 releases of the operating system due to a bug in DOS, but is no longer necessary.

The following example, *multilist.c*, accepts an arbitrary path name and lists the contents of it. The function `DoAllAssigns()` does all of the multiassign work. `DoAllAssigns()` accepts a path and a function pointer. It gets a lock on the object named in the path, and passes the lock to the function.

This example is based on a Usenet posting by Randell Jesup.

```

/* multilist.c -- execute me to compile me
sc data=near nominc strmer streq nostkchk saveds ign=73 multilist
slink FROM LIB:c.o multilist.o TO multilist LIB LIB:sc.lib LIB:amiga.lib
quit
*/

/* This example illustrates how to scan DOS file names without
/* having to make a special case for assigns and multiassigns.
/* The DoAllAssigns() routine accepts an arbitrary dos path and
/* a pointer to a function. DoAllAssigns() will call this function
/* passing it a lock to the object named in the path.
*/
