Handling Multiple Assigns with Conventional Directories

One of the features introduced by Release 2 is Multiple Assigning. This feature allows an AmigaDOS assign to carry over several directories which can be on different volumes. This makes it possible to split up assigns such as *libs:* and *fonts:*.

The article ``Directory Scanning'' on page II-49 contains an example called *find.c* that illustrates scanning a path that can contain a multiassign. However, besides being rather complicated, *find.c* makes a special case of scanning assigns, which isn't necessary (*find.c* also did something evil--*find.c* uses DOSBase's private pointer to the *utility.library*, essentially using the *utility.library* without opening it). The method needed to scan a multiassign directory also works on conventional directories.

Scanning a multiassign requires calling the *dos.library* function GetDeviceProc() in a loop to see each directory of the multiassign. Using GetDeviceProc(), the application doesn't have to concern itself with the differences between assigns, multiassigns, and volumes. The application just keeps calling GetDeviceProc() until it gets back a NULL**.**

```
struct DevProc *GetDeviceProc( STRPTR name, struct DevProc *dp );
```

The name can be any valid dos path. If there is a device name present, GetDeviceProc() will find the device's entry in the dos list and copy some information into a DevProc structure:

```
struct DevProc {
   struct MsgPort *dvp_Port;   /* Device's Message port, also called a Process identifier */
   BPTR           dvp_Lock;   /* Lock on root of assign or lock on root of volume */
   ULONG          dvp_Flags;
   struct DosList *dvp_DevNode;/* DON'T TOUCH OR USE! */
};
```

The important fields here are dvp_Lock and dvp_Port. The dvp_Lock field is a lock on the root of the object named in GetDeviceProc(). It serves as a starting point in locating the named object. If the object name contains an assign (i.e. ``libs:''), dvp_Lock is the root of the assign. For example, on a typical Release 2 system, the *libs:* assign refers to the *libs* directory on the *System2.0:* volume. Calling GetDeviceProc() on ``libs:'' in this case will yield a lock on *System2.0:libs*.

If the named object contains a dos volume, dvp_Lock is either a lock on the root of the dos volume or NULL**. If the object named in GetDeviceProc() contains a non-filesystem device (i.e.,**

``ser:", ``par:", ``prt:", etc.) or it does not contain a device name, dvp_Lock is NULL**.**

The dvp_Port field points to a message port. This message port is connected to the handler process of a DOS device. The handler process controls a DOS device. DOS functions (like the Lock() function) use this message port to talk to the handler process of the named object. For example, from the ``libs:" example above, the dvp_Port field refers to the message port of the handler process for the *System2.0:* volume.

Note that dvp_Lock is only a lock on the root of the named object. If the named object is a path several directories deep (for example, *libs:gadgets/colorwheel.gadget*), it's up to the application to handle the rest of the path. The application also has to handle the case where the named object is a path without a device name.

Although an application can send DOS packets directly to the message port (dvp_Port) of a handler process, normally it is easier to use functions from dos.library. The *multilist.c* example uses the Lock() function to lock the named object. *Multilist* has to do something a little unorthodox to use Lock(). Lock() accepts a path name to the object to lock. Lock() understands absolute paths (i.e. paths with a logical device name like ``df1:" or ``libs:") and relative paths. If Lock() receives an absolute path name, Lock() can find the device's handler process using the logical device name in the absolute path. For a relative path, Lock() does not have enough information to find the named object, so it assumes the path is relative to the current directory and file system (each process has a current directory and file system).

This makes Lock() a little more difficult to use in *multilist.c* because, when processing an absolute path, *multilist* has to process the logical device name separately from the rest of the path. It has to use GetDeviceProc() to find the root of a logical device name (which can be an assign, multiassign, volume name, etc.) then it has to strip the logical device name from the absolute path. Without a logical device name, the path has become relative rather than absolute. The path is now relative to dvp_Lock and dvp_Port. In order for Lock() to work with this relative path, *multilist* must temporarily set the current directory and file system to the values in dvp_Lock and dvp_Port, respectively.

Note that the Autodoc for GetDeviceProc() says to check IoErr() for ERROR_NO_MORE_ENTRIES **after receiving a** NULL **from GetDeviceProc(). Due to a bug, DOS does not set the error value correctly. Also note that the Autodoc says to check the DevProc structure's dvp_Flags field for the** DVPF_ASSIGN **flag. This was necessary in the 2.00 and 2.01 releases of the operating system due to a bug in DOS, but is no longer necessary.**

The following example, *multilist.c*, accepts an arbitrary path name and lists the contents of it. The function DoAllAssigns() does all of the multiassign work. DoAllAssigns() accepts a path and a function pointer. It gets a lock on the object named in the path, and passes the lock to the function.
This example is based on a Usenet posting by Randell Jesup.

```
;/* multilist.c -- execute me to compile me
sc data=near nominc strmer streq nostkchk saveds ign=73 multilist
slink FROM LIB:c.o multilist.o TO multilist LIB LIB:sc.lib LIB:amiga.lib
quit
*/

/* This example illustrates how to scan DOS file names without      */
/* having to make a special case for assigns and multiassigns.      */
/* The DoAllAssigns() routine accepts an arbitrary dos path and     */
/* a pointer to a function.  DoAllAssigns() will call this function */
/* passing it a lock to the object named in the path.               */
