```
AppKeyMap.o/AlterAppKeyMap                          AppKeyMap.o/AlterAppKeyMap

    NAME
        AlterAppKeyMap -- Changes keyboard mappings for a keymap

    SYNOPSIS
        AlterAppKeyMap(mykeymap, keyarray, arrayentries);

        void AlterAppKeyMap(struct KeyMap *,
                            struct MyKey *,
                            UWORD);

    FUNCTION
        Using an array of MyKey structures (which describe a series of
        rawkeys), this function    changes the rawkey's corresponding
        mapping values in mykeymap.  Only call this function on
        a private copy of a KeyMap (including its data).

    INPUTS
        mykeymap = pointer to a KeyMap structure.  AlterAppKeyMap() will
          make changes to this KeyMap's data, so this KeyMap should
          be a private copy of a KeyMap (including the data the KeyMap
          points to).

        keyarray  = pointer to an array of struct MyKey (from
          appkeymap.h):

              struct MyKey
              {
                UBYTE RawCode;      /* RawCode of character to change      */
                                    /* in the KeyMap.  Correponds to the   */
                                    /* Lo/HiKeyMap structures from the     */
                                    /* KeyMap structure.                   */
                UBYTE MapType;      /* The Lo/HiKeyMapTypes field.         */
                UBYTE Capsable;     /* This TRUE/FALSE state of this bit   */
                                    /* gets translated to the correspond-  */
                                    /* bit in KeyMap.Lo/HiCapsable.        */
                UBYTE Repeatable;   /* This TRUE/FALSE state of this bit   */
                                    /* gets translated to the correspond-  */
                                    /* bit in KeyMap.Lo/HiRepeatable.      */
                ULONG Map;    /* Map data for key.  This points to   */
                                    /* data for the rawkey.  Its format    */
                                    /* depends on the key type. This field */
                                    /* correponds to KeyMap.Lo/HiKeyMap.   */
              };

          arrayentries = The number of MyKey entries in keyarray.

    RESULT
        For each MyKey entry in keyarray, AlterKeyMap() finds the correpsonding
        raw key      entry in mykeymap and changes the data to match the entry
        in keyarray.  AlterKeyMap() makes changes directly to the KeyMap's
        data, so don't call this function on a system copy of a keymap, make
        a copy of it.

        Note that the console.device's CD_ASKKEYMAP only copies a KeyMap
        structure, which is only a set of pointers.  If you want to customize
        a copy of a keymap, you also have to duplicate the data that
        the KeyMap references.  If you do not duplicate the keymap data when
        customizing a keymap, you'll write over data that many keymaps are
        currently using.

        This function assumes that the keymap passed to it was duplicated
        using the CreateAppKeyMap() function.  CreateAppKeyMap() puts
        the keymap tables in a specific order and AlterAppKeyMap()
        expects to find the tables in that order.  Only call AlterAppKeyMap()
        on keymaps duplicated with CreateAppKeyMap().

```

```
AppKeyMap.o/CreateAppKeyMap                         AppKeyMap.o/CreateAppKeyMap

    NAME
        CreateAppKeyMap -- Create a new KeyMap by duplicating an existing one.

    SYNOPSIS
        newkeymap = CreateAppKeyMap(origkeymap);

        struct KeyMap *CreateAppKeyMap(struct KeyMap *);

    FUNCTION
        This function accepts a pointer to a KeyMap structure and duplicates it.
        CreateAppKeyMap() allocates the memory for a KeyMap structure and all
        the tables associated with that keymap.

    INPUTS
        origkeymap = points to a KeyMap to duplicate.

    RESULT
        If successful, this function returns a pointer to a duplicate of
        origkeymap.  CreateAppKeyMap() duplicates all of the tables that
        origkeymap references, so an application can make changes to the
        duplicate.  If CreateAppKeyMap() fails, it returns NULL.  The
        DeleteAppKeyMap() function deallocates the resources allocated
        by CreateAppKeyMap().

        CreateAppKeyMap() places the duplicate tables in an order so
        that a "Lo" table (for example, KeyMap.km_LoKeyMap) is immediately
        followed by the corresponding "Hi" table (KeyMap.km_HiKeyMap).
        This allows application to reference the two tables as one using
        the raw key value as an index.

AppKeyMap.o/DeleteAppKeyMap                         AppKeyMap.o/DeleteAppKeyMap

    NAME
        DeleteAppKeyMap -- Relinquish the resources allocated by
                           CreateAppKeyMap.

    SYNOPSIS
        DeleteAppKeyMap(mykeymap);

        void DeleteAppKeyMap(struct KeyMap *);

    FUNCTION
        This function accepts a pointer to a keymap allocated by
        CreateAppKeyMap() and deallocates the resources allocated
        by that function.

    INPUTS
        mykeymap = points to a KeyMap to deallocate.

    RESULT
        Frees memory previously used by mykeymap and its associated tables.

quit
*/

/* appkeymap.c - subroutines to create/delete an application keymap
 *               by modifying a copy of a keymap
 *
 * The modifications made to the keymap are controlled by the "mykeys" array.
 * To create more complex keymappings, see the Rom Kernel Manual Libraries
 * keymap library chapter (p 821 et al).
 *
 * NOTE: disabling all numeric pad keys creates a good keymap for use
 * with either keymap.library MapANSI() or commodities InvertString().
 * If you used a default keymap with the above functions, numeric keypad
 * raw key values would be returned for keys which are available with
 * fewer keypresses on numeric pad than on the normal keyboard.
 * It is generally preferable to have the normal keyboard raw values
 * since many applications attach special meanings to numeric pad keys.
