Chapter 1

Introduction

Ersatz-11 is a software replacement for PDP-11 minicomputer systems. When running on typical PC hardware, it substantially outperforms any PDP-11 model ever produced by DEC, outpaces all known aftermarket clone CPUs, and is the fastest PC-to-PDP-11 software emulator available at any price. Yet it is the most inexpensive PDP-11 replacement product on the market.

The achievable performance continues to increase as new 80x86 compatible CPUs are released, so future upgrades are possible without requiring that a new PDP-11 CPU board be purchased. The emulated system is configured using simple commands, allowing the flexibility to easily duplicate almost any existing system. The configuration of the emulated system can be changed at any time, even while the system is running. Wherever possible, E11 provides useful defaults, to simplify the configuration process. It will choose between Q-bus and Unibus controller models depending on the emulated CPU type, and will auto-compute “floating” CSR and vector addresses, for devices that use them. In all cases these defaults can be overridden with SET commands.

Ersatz-11 emulates the entire PDP-11 system in software, including most standard disks, tapes, serial devices, and network interfaces. E11 is intended to boot and run any PDP-11 operating system. It has been tested with RT-11 (all flavors), RSX-11M, RSX-11M-PLUS, RSTS/E, IAS, TSX-Plus, 2.9BSD and 2.11BSD UNIX, DSM-11, DOS/BATCH, Fuzzball (BOS), and XXDP+.

Emulated configuration

- PDP-11/23, PDP-11/24, PDP-11/34a, PDP-11/40, PDP-11/44, PDP-11/45, PDP-11/53, PDP-11/70, PDP-11/73, PDP-11/83, PDP-11/84, PDP-11/93, or PDP-11/94 CPU with individually selectable features
- FP11/FPF11/FPJ11 (etc.) floating point processor, FIS floating instruction set option, KE11 extended arithmetic element (EAE)
- 248 KB–350 KB main memory (approx.)
- Many different models of disks, tapes, serial and network devices (see tables below).

1.1 Emulated block device types

<i>dev name</i>	<i>controller type(s)</i>	<i>drive type(s)</i>
DC:	RC11	RS64 fixed-head disks
DF:/RF:	RF11	RS11 fixed-head disks
DK:/RK:	RK11D	RK02, RK05 front-loading cartridge drives
DL:	RL11 ¹ , RLV11, RLV12	RL01, RL02 top-loading cartridge drives
DM:	RK611 ²	RK06, RK07 top-loading cartridge drives
DO:	(virtual)	Ersatz-11 interface to host file system (for DO.SYS/DOS.TSK)
DP:	RP11C	RP02, RP03 pack drives
DS:	RH11, RH70	RS03/RS04 fixed-head disks
DT:	TC11	TU55/TU56 DECtape
DU:	UDA50, KDA50, RQDX3, RQZX1	RA60, RA70-73, RA80-82, RA90/92, RC25, RD31-32, RD50-54, RX33/RX50 MSCP disks
DX:	RX11, RXV11	RX01 8" SS SD floppy
DY:	RX211, RXV21	RX02 8" SS DD (or DS DD) floppy
HD:	(virtual)	Ersatz-11 hypothetical disk with simplified interface (for HD.SYS)
PD:	RXT11	RX01 8" SS SD floppy (PDT-11/150 microcomputer)

¹ "RL211" was used as a marketing name in systems with RL02 drives, but is the identical controller to the RL11.

² "RK711" was used as a marketing name in systems with RK07 drives, but is the identical controller to the RK611.

1.2 Emulated sequential device types

<i>dev name</i>	<i>controller type(s)</i>	<i>drive type(s)</i>
CT:	TA11	TU60 DECassette dual cassette tape
MM:	RH11/RH70 + TM03	TE16, TU45, TU77 Massbus magtape drives
MS:	TS11, TSU05/TSV05, M7454, TQK25	TS04, TS05, TU80 magtape drives, TK25 cartridge tape drive
MT:	TM11	TS03, TU10 magtape drives
MU:	KLESI, TQK50, TQK70	TU81, TK50, TK70 TMSCP tapes
PR:/PC:	PC11	PC04 high speed paper tape reader/punch

1.3 Emulated serial device types

<i>dev name</i>	<i>port type(s)</i>	<i>description</i>
LP:	LP11, LPV11	Line printer interfaces
TT:	DL11, DLV11	Single serial line units

1.4 Emulated network device types

<i>dev name</i>	<i>port type(s)</i>	<i>description</i>
NI:	NI1010A, NI2010A	Interlan Unibus/Q-bus Ethernet interfaces
XE:	DELUA	Unibus Ethernet interfaces

1.5 PC hardware support

- Block devices: DOS disk image files, raw floppy drives, raw CD-ROM drives
- Tape devices: DOS tape image files
- Character devices: Emulated VT100 on SVGA (can flip between up to 12 virtual screens), COM, LPT, Sound Blaster MIDI ports

- Network devices: NE2000 clones, packet drivers

This is a stripped-down demonstration version of Ersatz-11, which when used for commercial purposes may only be installed for an evaluation period limited to 30 days. After this time, commercial users must either buy E11 (either the “Lite” or full version), or delete all copies of the demo version in their possession. *There is no limitation on hobby/personal use of this demo package.* Commercial use is defined as anything having to do with the operation of a for-profit business. Older versions of Ersatz-11 (V1.1A and earlier) had no such limitation on use, so this notice does not apply to them, however they are no longer supported by D Bit.

This demo version of Ersatz-11 is available by anonymous FTP from <ftp.dbit.com>. The directory is `pub/e11`.

The emulator speed depends on the application. In general E11 on any speed Pentium II, Pentium III, or Athlon runs on the order of five times the speed of a PDP-11/93. In real mode versions of E11, writing MMU registers is an expensive operation which slows down multiuser OSes, compared to RT-11FB for example. This is far less of a factor in the full version of E11, which has an entirely different MMU implementation due to running in protected mode. Meanwhile, E11’s disk I/O is much faster than that of real PDP-11s, especially when run under an operating system which provides good disk caching.

The FP11 floating point processor emulation currently requires a math coprocessor. If the PC has none, then the emulated PDP-11 will have no FPP either. Intel Pentium CPUs that have the floating point divider bug are detected and a workaround is used to get correct results at a slight speed penalty (for DIVF/DIVD only). The FIS emulation does not require a math coprocessor, but does require an 80386 or later CPU.

The system has been tested under the XXDP+ diagnostic monitor. It passes the KD11EA diagnostics DFKAA, DFKAB, and DFKAC, and the FP11A diagnostics DFFPA, DFFPB, and DFFPC. It does not work with MMU diagnostics due to the absence of the maintenance mode. It has been found that passing or failing DEC diagnostics does not bear much relation to actual operation with real-world software and operating systems, because the diagnostics are designed mainly to detect known failure modes of real DEC hardware, and not to verify new implementations.

1.6 Device names

With the exception of PC files, just about every I/O device used by Ersatz-11 has a device name ending in a colon (“:”). This applies to both emulated PDP-11 devices and real PC hardware devices. Each device (disk unit, serial line, etc.) has a name that normally conforms to the following prototype:

dev[*c*][*u*]:

- dev* Alphabetic device name identifying the device type: always two letters for emulated PDP-11 devices, variable for PC hardware devices.
- c* Optional letter (A–Z) identifying which of the (potentially) multiple controllers of the same type is controlling this particular device. Specified only with controllers that can support multiple devices. A reasonable default is used if it is omitted, generally the first or only controller of that type. The controller letter is always displayed in output from the SHOW command for devices where it is meaningful, so the name given by SHOW will have the letter even if you didn’t specify one. In the demo version of E11, the RH11/RH70 Massbus controllers, TC11 DECTape controllers, and HD: pseudo disks are the only controller types of which there may be more than one. All other types will always use controller A so the default is always the only choice.
- u* Optional unit number identifying the device; default is the first unit on the controller. The unit number should be omitted when referring to the controller as a whole (e.g. SET commands).

The two-letter device names for emulated PDP-11 devices are taken from the names used by the popular PDP-11 operating systems. Where possible, synonyms are available to ensure that the device names will be familiar to users of each operating system. For example, DELUA ports may be referred to using either the RSTS/RSX name (“XE:”), or the RT-11 name (“NU:”), and similarly, RK05 disk units may be called “DK:” or “RK:”.

However E11 uses a more consistent naming system than these operating systems do, since the first two letters of a PDP-11 device name *always* depend on the controller type.

In some cases this leads to differences, for example “TTu:” (or “KBu:”, which is a synonym) refers specifically to a DL11/DLV11 serial port, while in RSX and RSTS, *all* terminal ports are mapped to one of these names regardless of the port type. But in E11, a serial port located on a DZ11/DZV11 is always “YZcu:”. As a result, the device names used by E11’s command language may not necessarily be identical to those used by the operating system for the same devices.

The device names for PC hardware are the same as those used by DOS for those devices that actually have names in DOS. So CON: refers to the first video session, COM1:–COM4: are serial ports (AUX: is a synonym for COM1:), and LPT1:–LPT4: are parallel ports (PRN: is a synonym for LPT1:). For other devices a short mnemonic name is used, with an optional letter identifying the controller for devices like multi-port serial interfaces where a port number alone isn’t enough to uniquely identify the device. Note that PDP-11 unit numbers always start at 0 (TT0:, DU0:, MU0: etc.) while PC unit numbers generally start at 1 (COM1, LPT1).

For a very few devices (both real and emulated), identifying the controller and unit isn’t enough since there may be multiple slaves attached to the same master unit. In this case the device name is expanded to look like “*dev*[*c*][*u*][*_*s**]:”, where *s* is the optional slave number within unit *u*. This form is rarely used since it only makes sense on emulated Massbus tape drives with multiple slaves attached to the same formatter, or on SCSI devices with multiple LUNs within the same target such as the old Adaptec ACB-4000A SCSI/MFM bridge boards. In any case if *s* is omitted (as well as the preceding underscore) a reasonable default is used.

1.7 Filenames

A few rules apply to PC files referenced using E11 commands. When a reference is made to an existing file, without a drive name or directory path in the file specification, E11 searches for it first in the current directory, then in the directory where the E11 executable file is located (under DOS V3.0 and later), then in the directories listed in the PATH environment variable. A filename may be enclosed in single (') or double (") quotes to allow lower case or special characters in the name, however this is only useful when running on a system that supports the "long filenames" extended DOS calls. Path elements must be separated by "\ " characters, except when the file specification is enclosed in single or double quotes in which case either forward slashes or backslashes may be used. Each command that takes a filename has a default extension which is added when none is supplied by the user.

Typical default extensions are:

<i>.ext</i>	<i>type of file</i>	<i>relevant command</i>
.CMD	command file	@[<i>d:path\</i>] <i>filename</i>
.DSK	disk image file	MOUNT
.INI	init file	/INITFILE switch
.LOG	log file	LOG
.PAP	paper tape image file	MOUNT PR:/PP:
.PDP	binary memory image	LOAD, DUMP
.TAP	tape image file	MOUNT

1.8 Notes

1.8.1 Interrupts

The interrupt system is somewhat complicated, mainly due to some assumptions in DEC OSES (particularly RSX and RT-11 SJ) about how many instructions are guaranteed to be executed after writing a command to a device CSR, before the device will complete the operation and interrupt. Since MS-DOS doesn't support asynchronous I/O (unless you go to extremes which wouldn't have made sense in a CPU-bound program like an instruction set simulator), it's natural to have most emulated device I/O appear to the PDP-11 to be instantaneous (although this is an illusion, the PC takes time between emulated PDP-11 instructions to do the transfer), with the completion interrupt occurring before the instruction following the one that started the transfer. Unfortunately this causes trouble with some drivers that assume that they are guaranteed the time to execute a certain number of instructions before the completion interrupt occurs.

This is not actually a bug if it works on all real PDP-11 models, but it leads to incorrect operation if the emulated hardware appears to be fast enough to complete an operation before the expected minimum number of instructions is executed. Under testing, RSX appeared to issue `WAIT` instructions for TTY output which was assumed not to have completed yet a few dozen instructions after writing a character to a DL11 (thus hanging the system), and similarly the RT-11 SJ (but not FB/XM) keyboard interrupt service routine runs with interrupts enabled on the assumption that another keyboard interrupt couldn't possibly happen before the current ISR finishes (when this does happen the ISR recurses and the characters are put in the buffer in reverse order, which was happening with VT100 keypad keys in E11).

The solution to these problems is to use a queueing system, so that the interrupt (and in most cases the transfer itself) doesn't occur until a pre-set number of instruction fetches after the instruction that started the transfer. The default delays are intended to be adequate for most users. However when troubleshooting with custom operating systems, this is a good place to experiment if E11 appears to work with your application using certain emulated devices, but not others. Much less trouble has been experienced with disks and tapes, so by default most of them are set to execute all functions in one instruction time. The RSX MSCP initialization sequence is an exception, so the default delays are tuned appropriately. The RK11 handler in DOS/BATCH requires an unusually slow disk controller, so in order to use that you must first issue a command like `SET DELAY RK11D *=8000`. For reasons given above, the character-at-a-time devices have larger default delay counts. RK05/06/07 seek completion attentions may be delayed still further beyond acknowledging the seek command so as not to confuse overlapped seek drivers. However you'll get faster results using a non-overlapped driver if one is supplied with your OS. Since all your emulated disks will typically be on one physical PC disk with only one head carriage, there's nothing to overlap anyway.

1.8.2 Host systems

D Bit occasionally receives inquiries from users who want Ersatz-11 to be ported to architectures other than the 80x86, and/or operating systems other than Linux and DOS. Currently there are no plans to do this. Besides the expense and difficulty of moving software between radically different host systems, D Bit considers its ability to provide adequate customer support to be of primary importance, and this would not be possible if there were many different versions of E11. Also, some popular operating systems are simply not designed to be responsive or reliable enough for trouble-free use in typical PDP-11 applications.

Rather than produce poorly supported versions of E11 for a myriad of host systems which provide more hindrance than help to the task of emulating a PDP-11 system, D Bit has chosen to focus its efforts on the 80x86 architecture

under Linux and DOS. This hardware has the best price:performance ratio of anything currently available, it's what the vast majority of E11 customers are already running anyway, and its programming architecture lends itself well to efficient PDP-11 emulation. The two supported operating systems are inexpensive and easy to install, they provide a good set of helpful services to E11 but also allow easy access to hardware so that Ersatz-11 has the control it needs, adequate DOS emulation is available in a variety of other operating systems, so that again, most users already have a system which is capable of running E11.

1.8.3 Copyright and licensing

Ersatz-11 is Copyright © 1994-2000 by Digby's Bitpile, Inc. All rights reserved. Distribution of this document and/or the `INSTALL.EXE` auto-installing executable file (demo version only) in unmodified form, without charge, is allowed pursuant to the usage restrictions given at the beginning of this document. Anything else is strictly forbidden.

1.9 Acknowledgments

D Bit would like to thank the many people who provided technical help and debugging input. Bob Supnik, formerly of DEC, and Alan Sieving of QED provided valuable details of poorly documented PDP-11 instruction set semantics. Many people have helped debug Ersatz-11 with their configurations. Frank Borger's (U. Chicago) work with RT-11SJ and IAS has been particularly impressive, as have Paul Koning's (Xedia) insights into RSTS and Eduard Vopicka's (Prague University of Economics) and John Shilling's (JSA) help with RSX. Chip Charlot (formerly of Mentec), and Dave Carroll of Mentec have provided invaluable technical help and encouragement.

1.10 History

31-Oct-1993; development started.

V0.8 BETA, 29-Mar-1994; initial release.

V0.9 BETA, 05-Jul-1994; many bug fixes (mainly trap handling, MMU emulation, DIV instruction, and VT100 reverse video), added RX211 emulation, multiple DL11s, and 50 Hz KW11L mode.

V1.0 BETA, 14-Nov-1994; more bug fixes, added FP11A, RK611/RK06-07, LP11, D-space, and supervisor mode emulation. Also CALCULATE, HELP, INITIALIZE, LOG, SET/SHOW CPU, SET DR LPTn:, SET SCROLL, SHOW MMU commands, VT100 graphics/underline, changed to .EXE file (ran out of space in unified code/data segment in .COM file).

V1.1 BETA, 22-Mar-1995; still more bug fixes (IAS finally works), DELUA Ethernet emulation, disk LOGging, indirect command files, workaround for Pentium FDIV bug, help text moved to file, Russian HD: device (and RT-11 driver), PC11, display general registers on parallel port LED board.

V2.0 DEMO, 20-Jul-1997; many bug fixes as usual, limited 22-bit MMU with and without Unibus map. MMU SR1 mechanized, TOY clock, CPU emulation extended to include 11/24, 11/44, 11/45, 11/70, 11/94. Added RXT11/RX01, RK02/RK05, RS03/RS04, TU56, TU10, TU60, TE16/TU45/TU77 device emulation. Definable keyboard. Loadable ROM/EEPROM. Many new floppy types, which may now be used with any disk controller type.

(Many intermediate V2.0x full versions were released throughout 1997 and 1998.)

V2.1 Full version, 01-Apr-1999; runs in protected mode with full 22-bit MMU. MSCP, TMSCP, RMxx/RPxx, TS11, DZ11/DZV11, DHU11/DHV11, DEQNA device emulation. Support for Q/Unibus bridges. Boca, Chase PCI-FAST, Digi, RocketPort/PCI, SBMIDI serial drivers. NE2000 Ethernet driver. Physical port drivers for SCSI disk/tape drives, RAM disks/tapes. FLOATING address calculation, DEFAULT controller types. PDP-11/23, 53, 73, 83, 84, 93 CPU types added. Demo/Lite versions have a subset of these features.

V2.1A, 01-Oct-1999; concatenated image files to form one large disk, CDROMx: driver, other minor improvements and bug fixes.

V2.2, 01-Apr-2000; DH11, DM11BB, DR11C, VT11, Interlan NI1010A/NI2010A emulation, FIS instruction set, KE11 EAE, mini-assembler. Hardware drivers added or extended for DCI-1300 digital I/O boards, SVGA graphics, ISA RocketPorts, BCI-2004/BCI-2104 bus adapters, multiple physical serial devices. SCSI disk partitioning added. Most disk "write headers" commands perform low-level format. Documentation overhauled.

Chapter 2

Installation and Configuration

2.1 System requirements

Installation of Ersatz-11 requires the following:

- Intel 80x86-compatible PC with 80186 or later CPU (80386 required to emulate FIS option)
- At least 640 KB of available system memory.
- 1 MB of available disk space for Ersatz-11 itself, plus space for all disk image files (equivalent to the size of the disk drives they replace).
- Microsoft MS-DOS, IBM PC-DOS, Caldera DR-DOS, or a DOS session in Windows, OS/2, or Linux.

Running Ersatz-11 under plain DOS gives better response time to external events, and better access to non-standard PC hardware. However running in a DOS session under another operating system typically gives a dramatic increase in disk speed due to the improved disk caching. So the decision of which host operating system to use should be based on the exact needs of the PDP-11 system.

Issues to consider when selecting the host operating system:

- DOS itself has essentially no disk caching, and the add-on disk caches that are available typically do not work well with large disks and don't take advantage of the large amounts of RAM found on modern PCs. However DOS allows E11 unlimited access to special hardware (such as bus adapters), and it's generally very stable, inexpensive, and easy to install. And it's small enough that in some cases, an entire E11 system can boot and run from a single floppy disk.
- Windows 95/98 has good disk caching, and doesn't interfere much with hardware access, but it has a very poor task scheduler. It significantly reduces the amount of CPU time that E11 gets when it is not the foreground (or full-screen) window, and often fails to deliver clock interrupts to E11, so the PDP-11's clock can appear to stop. Even if E11 is in the foreground window, Windows will occasionally suspend E11's execution for several seconds to perform housekeeping functions, which degrades response time and causes the PDP-11 clock to lose time.

- Windows NT has good disk caching and a true pre-emptive scheduler, but it has very bad DOS emulation. All accesses to hardware are intercepted and virtualized by the operating system, not accesses just to devices that are being shared with other programs. As a result, there's no way to access Ethernet ports or raw SCSI disk/tape drives or bus adapters, or anything else besides the basic core PC peripherals (screen, keyboard, display, COM/LPT ports etc.). Also, Windows NT isn't very reliable about delivering clock interrupts to E11, so the PDP-11 clock loses time.
- OS/2 has excellent disk caching (for native partition types), a true pre-emptive scheduler, good DOS emulation, and allows E11's built-in device drivers free access to hardware. Disadvantages of OS/2 are that it's difficult to obtain, not well supported, and has poor caching of FAT partitions.

2.2 Installation

Installation is very straightforward. Simply insert the distribution disk into a floppy drive and type:

```
C:\>a:install
```

If the floppy drive is not drive A:, substitute the actual drive letter in the above command. The installation program will prompt for a directory into which to install, and will then extract all the E11 files from the distribution disk. The files are as follows:

<i>file</i>	<i>contents</i>
E11.EXE	executable
E11.HLP	"HELP" data file
E11.PDF	this document, readable with Adobe Acrobat
HD*.*	source and binaries for RT-11 HD: driver
DO*.*	source and binaries for RT-11 DO: driver
KED.COM	keyscripts for using cursor keys with KED/EDT

E11's home directory is also a sensible place to put disk image files (*.DSK) and the E11.INI initialization file (see below), since E11 will look there if these files aren't found in the current working directory.

Drivers for most of the PC hardware that E11 controls are built into E11 itself, so there is often no need to load any external drivers or TSR programs. However there are some exceptions. These are listed below, along with the device emulations or drivers that may require them, and examples of typical lines that would be added to the CONFIG.SYS and/or AUTOEXEC.BAT files to load the drivers. The drivers themselves are supplied by the hardware vendor and/or the operating system.

<i>driver</i>	<i>needed by</i>	<i>typical command line</i>
Packet Driver	DEQNA/ DELUA	PCIPKT 0x60 (in AUTOEXEC.BAT)
Mouse	VT11	DEVICE=C:\MOUSE\MOUSE.SYS (in CONFIG.SYS) or C:\MOUSE\MOUSE (in AUTOEXEC.BAT)
CD-ROM	CDROM:	DEVICE=C:\SBCD\SBIDE.SYS /D:MSCD001 /V (in CONFIG.SYS) and C:\DOS\MSCDEX /D:MSCD001 (in AUTOEXEC.BAT)

Whether or not the above drivers will be needed depends on the configuration of the emulated system. Most common configurations don't require any of them. If needed, these drivers are installed by adding lines similar to the above examples to the CONFIG.SYS and/or AUTOEXEC.BAT files, using a text editor.

2.3 Configuration

Ersatz-11 is configured using a text file named "E11.INI," which is normally kept in E11's home directory. This file may be created using any text editor. It contains a series of commands which are read and processed in order every time E11 starts up. Lines which start with a ";" or "!" character are treated as comments, and ignored. Each individual serial line or emulated disk or tape unit is created with a one-line command. Typically there will also be additional commands to define the emulated CPU model, set any non-standard device addresses or device types, and finally the initialization file usually ends with a BOOT command which boots the emulated PDP-11's operating system. The table below summarizes which command is used to add each device type to the system. The syntax of each specific command is described in chapter 9.

<i>device type</i>	<i>command to create</i>
CPU	SET CPU
disk drive	MOUNT
tape transport	MOUNT
TTY line	ASSIGN
line printer	ASSIGN
network port	ASSIGN

Below is a typical E11.INI file. This file is read by Ersatz-11 every time it starts up, and the commands are executed in sequence, as if they were typed at the keyboard.

```

;
; Set PDP-11/44 CPU model
;
set cpu 44
;
; Mount disk and tape units
;
mount du0: rsx11m.dsk
mount du1: ra81.dsk
mount mm0: dump.tap
;
; Add extra DL11 terminal lines and LP11 printer port
;
assign tt1: con2:
assign tt2: con3:
assign lp0: lpt1:
;
; Define DELUA Ethernet port using RealTek PCI NE2000 clone
;
assign xe0: ne2000a:

```

```

;
; Boot MSCP disk unit 0 (and switch keyboard to PDP-11 console)
;
boot du0:
;
; Control returns to the next line when the user presses Shift-Enter
; or the system halts on its own (e.g. SHUTUP.TSK)
;
quit

```

The “boot” command starts the PDP-11 operating system and directs keyboard input to the PDP-11 system console. The user can press Shift-Enter at any time to pop up an E11 command prompt where additional commands may be entered interactively. If there are unread lines remaining in “E11.INI” (i.e. following the “boot” command), they will be read at that time. In this example, the program will exit immediately when Shift-Enter is pressed because it causes the “quit” command to be read.

There are a few more basic options which are entered as switches on the E11 startup command line, rather than being contained in the “E11.INI” initialization file:

```

/HELP (syn. /?)  Display a simple list of switches and their meanings, and exit without starting E11.
/INITFILE:file[.INI]  Read the specified initialization command file instead of E11.INI.
/MEMORY:nnnn  Set the maximum possible emulated memory size of the PDP-11 to nnnn (decimal)
                kilobytes. By default this maximum is 248 KB. The reason this switch exists is so that
                you can enlarge PDP-11 memory past the default in real mode versions, (how much
                depends on what device drivers and TSRs you have loaded), or reduce it if memory is
                so tight that ASSIGN, LOG, or MOUNT commands fail for lack of it (they will give error
                messages if this is the case), or in any case if you want to emulate a PDP-11 with less
                memory than E11's default.
/NOINITIALIZE  Do not read the E11.INI initialization command file.

```

When configuring the system for the first time, it is best to exactly duplicate the system which is being replaced. There may be a strong temptation to expand the system, now that PDP-11 peripherals are effectively “free” for the asking. But such changes can cause conflicts with existing software, which may contain hard-coded device names or other hidden assumptions about the system configuration. These problems may be avoidable, if system expansion is postponed until after the existing system is brought up as-is.

Note that some operating systems do little or no autosizing and may have problems if the hardware being emulated by E11 differs from the one for which the operating system was generated. In particular you may run into trouble if your OS depends on any static memory allocation (if E11 is emulating a different amount of memory than what the system expects), or if it is built for Q22 I/O and E11 is emulating a PDP-11/44 with Unibus map registers, or anything like that. Also, the routine in RSX-11M-PLUS that counts the number of registers in an RH70 depends on PDP-11/70 autoincrement semantics, and will get the wrong answer if you set the CPU type to PDP-11/44. This normally causes no problems, since real PDP-11/44s can't have RH70s, but this and other “impossible” situations can be easily created in E11.

One thing to watch out for, is that some software has hard-coded assumptions about how fast the hardware operates in relation to the CPU. See section 1.8.1 for a discussion of interrupt timing. This can lead to strange behavior,

such as devices that simply hang, or supposedly I/O bound tasks that consume 100% of the CPU. These problems can generally be solved by experimenting on the relevant emulated devices with the `SET DELAY` command. If the system doesn't operate correctly with the default delay counts, but springs to life when they're increased to large numbers, then it's just a simple matter of tuning the numbers to get delays which are long enough that the system works reliably, but still give good performance. Ideally the PDP-11 device drivers should be updated so that they will operate correctly with "infinitely" fast hardware, since this will allow it to get the best possible performance out of *any* fast PDP-11 replacement, but the `SET DELAY` command allows the user to work around these problems without having to touch the PDP-11 software.

Chapter 3

Transferring the PDP-11 Operating System to the PC

In order to run an exact copy of a real PDP-11 system, the contents of the PDP-11's disk(s) must be accessible to Ersatz-11 to be used as emulated disks. In most cases, this means importing a byte-by-byte copy of each entire disk into a large "image" file which is the same size as the entire PDP-11 disk. Note that this is very different from importing the individual *files* from the PDP-11 disk. In some cases the files can be reassembled into a disk image, but if possible it's better to download the disk(s) as a single large image. The fewer transformations the data go through, the fewer opportunities for mistakes that could lead to file damage.

Getting a snapshot of a bootable disk from an existing PDP-11 into a PC file can be tricky, there are many ways to do it and which choice is the best one depends on what software and hardware are available, and what media or protocols the PDP-11 and PC have in common. D Bit can help with some forms of media translation, call or send email for information. DEC, Mentec, and S&H are all now willing to sell PDP-11 OS licenses to emulator users, there doesn't seem to be an issue about the lack of a CPU serial number. So ordering the latest OS version is straightforward, and with the right peripherals the installation kits can be booted directly by E11 and installed on emulated disk(s).

Disk images have been successfully loaded from real PDP-11s using Kermit, or Process Software TCP/IP, or DECnet and Pathworks, or (as a last resort) an OS-supplied DUMP command on the PDP-11 with the output captured with a PC terminal program and then massaged back into binary with a simple utility program. Also, PUTR (available from ftp.dbit.com, see below) can build bootable RT-11 image files using a floppy disk distribution kit, without the need for booting a real PDP-11.

3.1 SCSI disks

The easiest way of all to move any PDP-11 OS to the PC is using a SCSI disk drive. If you were already using a PDP-11 SCSI controller, you should be able to move the disk directly over to a PC SCSI controller, and either read it into an image file (using PUTR.COM) or use it directly (using the SCSI disk support in the full version of E11). Iomega Zip and Jaz drives, and Fujitsu DynaMO 3.5" magneto-optical drives, are inexpensive and work very well with both Ersatz-11 and PUTR.COM, and they provide a cheap, fast, easy way to transfer files or whole

disks between real PDP-11s and E11.

Even if the PDP-11 didn't already have a SCSI controller, it might be worth obtaining a used one if a non-trivial amount of data must be transferred, unless the PDP-11 operating system is too old to support SCSI MSCP devices. Adding support for it to the operating system might require a SYSGEN in some cases, but for RSX, BRUSYS will support a DU: controller regardless of whether your usual monitor is built with the DU: driver. Older versions of RSTS can both backup and restore without ever booting a monitor at all, and the backups are self-booting and include a copy of the backup utility, so restoring them on the target system is easy. New versions of RSTS require that the backups be made under timesharing, but they can still be restored in INIT.SYS.

3.2 SCSI tapes

Magnetic tape can be a convenient way to import PDP-11 data to the PC, as long as a PC tape drive can be found which will read the PDP-11 media. The DEC TZ30 and TK50Z-GA SCSI drives use TK50 tapes, and a variety of companies still make SCSI 9-track tape drives. Images of these tapes may be taken using D Bit's DOS SCSI tape utility (available from <ftp://ftp.dbit.com/pub/ibmpc/util/st.exe>) and the resulting .TAP files may be mounted under E11.

3.3 Kermit

Kermit is a protocol for transferring files over serial lines. It provides very good reliability, and requires no special hardware, but it can be slow. At 9600 baud with the default Kermit protocol parameters (no long packets or sliding windows), binary file transfers can take almost an hour per megabyte. This may be acceptable if the system has small disks or the transfer can be performed over a weekend or during some other time when the PDP-11 is not busy with other work. Kermit protocol support is included in most terminal programs, and Kermit software is available at little or no cost for most computers and operating systems, including the following PDP-11 versions:

- KSERVE — D Bit's server-only Kermit for RT-11, available from <http://www.dbit.com/pub/pdp11/rt11/kserve.mac>
- K11 — Columbia's official PDP-11 Kermit program, supports all major DEC/Mentec/S&H operating systems, see <http://www.columbia.edu/kermit/pdp11.html>
- KRT — Billy Youdelman's version of K11, enhanced for RT-11 and TSX-Plus, also at <http://www.columbia.edu/kermit/pdp11.html>

It's very important to issue SET FILE TYPE BINARY commands to the Kermit programs at both ends before beginning a Kermit transfer of a PDP-11 disk. The other settable Kermit parameters are less critical, as they mainly affect the speed with which the transfer will proceed. Of the above Kermits, only KSERVE is able to download an entire raw disk. The others can download files but not entire raw disks. In some cases it may be possible to get around this limitation by using PDP-11 system utilities (such as RT-11's COPY/FILE/DEV command) to copy an entire raw disk into a file on another, larger disk, and then use Kermit to download that file. Or, if no larger disk is available, it may be possible to break the disk into several pieces (each small enough to fit into the free space on another disk) and copy them to files one at a time, sending each to the PC via Kermit and then deleting it.

3.4 Ethernet

Ethernet can be a very effective way to transfer PDP-11 data to a PC. Unfortunately Ethernet hardware is not nearly as common on PDP-11s as it is on PCs, but used Q-bus/Unibus Ethernet boards are available very cheaply from used equipment dealers. So if the PDP-11 has software support for an Ethernet board, it may be worth buying one just to transfer the disks.

The main problem with using Ethernet on PDP-11s is the availability of compatible protocols. If a PDP-11 operating system supports Ethernet, it usually uses DECnet, while PCs are more likely to support TCP/IP. However software to support either protocol is available on both PCs and PDP-11s, it's just a matter of getting it.

- Alan Baldwin's excellent free TCP/IP packages for RT-11 and TSX-Plus are available via FTP from `shop-pdp.kent.edu`.
- Megan Gentry's "RTEFTP" RT-11 Ethernet file transfer program is available from `ftp://ftp.std.com/pub/mbg/pdp11/rt11/tools/rteftp/`. It uses its own private protocol and can communicate only with other computers running RTEFTP, however it's fast, very easy to set up, and can transfer raw disks.
- JSA Stackware, a commercial TCP/IP package for RSX, is available from JSA. It provides Telnet and FTP access in both directions.
- Process Software's TCP/IP package for the PDP-11 is also a commercial product, available from Process Software (`www.process.com`).
- DECnet/DOS and Pathworks for DOS are no longer available, but they were able to connect to DECnet hosts. So if you already have it, it may be useful for transferring disks.

Some of the above programs are not able to transfer entire raw disks over the Ethernet. In this case the same workarounds as used with Kermit transfers may be applied, to copy raw disks to files and then transfer the files.

3.5 ASCII serial dump

Most DEC operating systems provide a utility (typically named DUMP or DMP) which can dump a file or device out to the terminal in octal or hexadecimal. If this program is used to dump out the entire disk, a PC terminal program can be used to capture the output, and it can be translated back to a binary disk image on the PC. This should only be used as a last resort because there's no error checking or correction, and the transfer is very slow because of the inefficient encoding and extra header/trailer/address information that's normally displayed with each block.

If possible the transfer should be done using hexadecimal rather than octal, the transfer will go faster since each word is displayed as only four characters instead of six. On an RSX system, this can be done with the following commands:

```
>INS $DMP
>DMO ddu:/DEV/LOCK=V (if ddu: is the system disk)
>MOU ddu:/FOR (if ddu: is not the system disk)
```

```
>DMP TI:=ddu:/BL:0/WD
```

The file produced by capturing the output from the above command can be translated back into a binary disk image using the “HEX2DSK” program, available from <ftp://ftp.dbit.com/pub/ibmpc/util/>. Source code is included so the program can be modified for other dump display formats if needed. RT-11 has a DUMP/TERMINAL command, which is similar to RSX’s DMP command but gives a different output format.

Since there is no error detection at all, disks transferred in this manner should be downloaded twice, and the resulting files should be compared, as a test to make sure the dump wasn’t corrupted by line errors or buffer overruns.

3.6 System-specific notes

RT-11 is the easiest operating system to transplant. For one thing, an RT-11 Kermit server is available (at <ftp://ftp.dbit.com/pub/pdp11/rt11/kserve.mac>) which is able to download an entire raw disk image over a serial line. This can take a long time but it just about guarantees that the configuration will be duplicated exactly, just don’t forget to type SET FILE TYPE BINARY and REMOTE SET FILE TYPE BINARY to make sure both participating Kermits agree not to try to treat the binary data as text. Failing that, you can use KSERVE, or any of several other file transfer methods, to download the individual files (still in binary mode) into a DOS directory. Then use D Bit’s “PUTR” program (available at <ftp://ftp.dbit.com/pub/putr/>) to build a blank RT-11 disk image, copy the files into it (be sure to use PUTR’s COPY/B command to copy in binary mode), and make the disk bootable with PUTR’s BOOT command.

Note

The RT-11 DL: and DM: device handlers expect to find a bad block replacement table in block 1 of a disk. If something else is there (like the pack label in Files-11 and RDS 1.1 and later, or the master file directory in RDS 0.0), they will replace blocks at random and you’ll get a corrupted disk image. So either modify your Kermit (etc.) to use the appropriate .SPFUN instead of .READ, or don’t use RT-11 programs to read non-RT-11 disks.

RSTS images can be assembled from individual files using Paul Koning’s freely available “flx” program, see below. All you need to build a bootable pack are the files from SY:[0,1], flx knows how to do the HOOK operation and make the pack bootable.

RSX is more difficult to move since currently there is no DOS software that knows how to build a bootable disk from its component files. If you don’t have an easy way to take a raw snapshot of the whole disk (K11.TSK currently can’t do it), the best bet is to dump the disk to tape and then restore the tape on the PC, assuming you have suitable tape drives on both. Stand-alone BRU (a.k.a. BRUSYS) is the easiest way to do this. After copying the entire disk to tape, build a bootable BRUSYS tape for E11 (HELP BRU STAND under RSX will tell you how). Then use PUTR.COM to build a blank disk image file of the appropriate type, and boot E11 from the BRUSYS tape, with the empty disk image file mounted. Once BRUSYS has started, you can physically switch tapes, or else pop up an E11 prompt and MOUNT the (first) backup tape if you’re using tape image files. Then run FMT (if needed) and BAD on the blank disk, and finally run BRU to restore the tape. If you want to use tape image files instead of using a real tape drive (required on E11 Demo and E11 Lite, since they don’t support SCSI tapes), you can use D Bit’s DOS SCSI tape utility (available from <ftp://ftp.dbit.com/pub/ibmpc/util/st.exe>) to copy between real tapes and E11 tape image files.

3.7 Utilities

PUTR.COM, a companion program to E11, is available from <ftp://ftp.dbit.com/pub/putr/>, and knows how to read and write RT-11 and OS/8 format volumes on a variety of media, as well as how to read RSTS/E volumes. It can write blank container files with the serial numbers and (empty) bad block data filled in correctly, and format many types of DEC floppies, and SCSI disks too, which can be useful with any OS. It can also read and write TU58 DECTape II tapes, if the drive is connected to a PC COM port. Assembly language source is included.

Paul Koning (former RSTS/E developer) has written a very complete program named “flx” for manipulating files in RSTS disk images. Among other things it can build a bootable disk given the files from [0,1]. It's available from <ftp://ftp.dbit.com/pub/flx/> and is written in portable C, so it can be used with any emulator (or with real disk packs on a VAX). A DOS executable is included with the sources.

Chapter 4

Disk Devices

Ersatz-11 emulates a wide variety of disk drive and controller models. These are created using one MOUNT command (see page 57) for each drive unit needed. Generally each emulated disk unit must be connected to an emulated disk device (e.g. a large file on the PC's disk) which is at least as large as the disk it emulates. The connection is device-independent, any emulated disk can be connected to any of the physical disk device types that E11 supports. The controller itself is created implicitly when its first drive is mounted, and can be deleted by dismounting all of its drives. The controller type (RL11, UDA50 etc.) is implied by the device name used in the MOUNT command, and the same device name syntax is the same as most DEC operating systems.

E11 has sensible defaults for all disk parameters, so in most cases a MOUNT command for each unit is all that is needed. If necessary, the default drive parameters can be overridden using MOUNT switches, and the default controller parameters can be overridden using a separate SET command, which may be given before or after the drives are mounted. The defaults are as follows:

<i>parameter</i>	<i>default</i>	<i>how to override</i>
controller model	based on SET CPU QBUS setting	SET <i>ddc: model</i> (e.g. SET DUA: RQDX3)
controller CSR/vector	DEC default addresses, "floating" addresses are calculated automatically if appropriate	SET <i>ddc: CSR=xxxxxx VECTOR=yyy</i>
drive model	based on size of container file	MSCP/TMSCP drives: /TYPE: <i>type</i> switch (e.g. /TYPE:RD54) non-MSCP/TMSCP drives: / <i>type</i> switch (e.g. /RK06)
write protection	disabled	/WP or /RO switch

After a drive are mounted, a SHOW *ddcu:* command (e.g. SHOW DUA0:) will display the actual drive parameters for that unit, as well as the controller parameters for the controller to which it is attached. The controller CSR, vector, and type (i.e. controller model) can be changed explicitly at any time with a SET command. If these parameters are defaulted, their actual values can also be changed implicitly at any time, by a change in the SET CPU setting (which can make a defaulted controller type switch between the Unibus and Q-bus models of that controller), and

by changes in the configuration of other devices that use “floating” CSRs and/or vectors (if this controller is set to be a floating device, as DUB: and DYB: normally are).

4.1 PC disk devices

The MOUNT command establishes a connection between an emulated PDP-11 disk drive unit, and a PC file or device which will be used to hold the actual disk data. Generally this file or device must be at least as large as the PDP-11 disk unit that is being emulated. E11 supports several different forms of physical media to be used for emulating disks. The connections are made on a per-unit basis so it is possible to mix units attached to different types of physical media within the same emulated PDP-11 disk controller. The supported types of physical media are described below, along with the syntax of the MOUNT command for each type. The /RONLY (syn. /WPROTECT switch may be specified on any MOUNT command, to lock the disk against writes.

4.1.1 Disk image files

Command syntax:

```
MOUNT ddcu: [d: path\]filename[.DSK] [switches]
```

Special switches: none

A disk image file contains a byte-by-byte image of a PDP-11 disk, presumably loaded from a real PDP-11 using Kermit or DECnet or some equivalent, or built using PUTR.COM or FLX.EXE or RT11.EXE or a similar utility (see chapter 3). The file is the same size as the total capacity of the PDP-11 disk drive it replaces. The file is located using E11’s usual rules, see section 1.7 for details.

There are two types of image files, “block” and “sector” images. “Block” images contain the disk data as it would be read in sequential block order, which for most PDP-11 disks is the same as the raw device order. This is the most common format and is normally used by default. “Sector” images apply to floppy disks only. RX01, RX02, and RX50 disks are organized using a soft interleave layout to increase their speed when used with controllers that have only one sector buffer. The PDP-11 device handlers (and/or controllers) for these disks handle the soft interleave so it is normally invisible to the PDP-11 user program, so images made of these disks using something like the RT-11 “COPY/FILE/DEV” command will be normal block images. When a block image file is accessed as a virtual PDP-11 floppy disk, Ersatz-11 does the inverse of the soft interleave so that when the PDP-11 driver does the interleave, the blocks come out in the correct order.

However if the image is taken using special software (such as the COPFLP.MAC program available from ftp.dbit-.com), or on a non-DEC computer, it may be more natural for the image file to be in raw sector order, i.e. starting with track 0 sector 1, then track 0 sector 2, track 0 sector 3 etc. In this case Ersatz-11 should not alter the interleave, and in fact it should do the interleave itself if the file is mounted as something other than a virtual floppy drive (since PDP-11 drivers for other devices don’t do the floppy-style interleave).

By default, Ersatz-11 guesses whether a file is a block or a sector image based on the file size:

<i>size (bytes)</i>	<i>type</i>
256,256	RX01 sector image
512,512	RX02 sector image
1,025,024	“RX03” (DS RX02) sector image
(anything else)	block image

Block images of RX01/02/03 disks are slightly smaller because the interleave scheme leaves out track 0, so they can be distinguished by size alone, unless padding was added during transfer or something else altered the file size. RX50 image files are the same size either way (the RX50 soft interleave scheme uses all sectors of the disk) so by default they are assumed to be block images. The defaults may be overridden with the “/BLOCK” and “/SECTOR” switches on the MOUNT command.

Since DEC’s 8” floppy interleave scheme doesn’t use track 0, data from this track do not normally appear in a block image file. However some non-standard software may need to use track 0, so the RX11, RX211, and RXT11 emulations relocate it beyond the end of the block image, if the file is enlarged by the size of one cylinder to be the same size as the equivalent sector image file. Use “/BLOCK” to specify that it’s still a block image.

<i>type</i>	<i>base size (bytes)</i>	<i>extra size (bytes)</i>
RX01	252,928	3,328
RX02	505,856	6,656
“RX03”	1,011,712	13,312

If the base file sizes are used, these files work as regular block images and track 0 does not exist. Any attempt to write track 0 is a no op, and any attempt to read track 0 returns hex E5 in every data byte, as if the disk were freshly formatted.

Note

The Demo and Lite versions of E11 limit the combined size of all image files to 32 MB. E11 versions prior to 2.0 did not have this restriction, but they are no longer supported by D Bit.

Disk caching done by the host system

Ersatz-11 has no control over any caching of disk writes that the host operating system may do, so it is important that you QUIT out of the simulator to make sure all the pseudo-disk files get closed properly, rather than simply switching the computer off, after shutting down your PDP-11 operating system. Otherwise there is the possibility that a write-back disk cache might not have written all of the PDP-11’s data to disk. In practice no problems have been observed, but trouble is theoretically possible so care should be taken. The floppy disk support controls the hardware directly so as long as the PDP-11 is done with the disk it’s OK to take it out of the drive.

Also, the emulator has no control over “Green PC” BIOSes which spin down hard drives after a specified period of inactivity (this is especially common on laptops). When E11 accesses the drive after it’s been shut down, the BIOS will pause several seconds while it spins the drive back up. During this period E11 is not running, so the simulated PDP-11 may drop incoming characters (but not necessarily, E11 maintains a small FIFO buffer on each line at interrupt level) and its clock will lose a few seconds. If this is a problem you may have to disable this BIOS feature.

The files are located using E11's usual rules, see section 1.7 for details.

4.1.2 Raw floppy disk drives

Command syntax:

`MOUNT ddcu: d: [switches]`

Special switches: drive type, one of the following:

<i>switch</i>	<i>drive type</i>	<i>size in blocks</i>	<i>disk types</i>
/RX01	5.25" or 8" SS SD	494	RX01
/RX02	5.25" or 8" SS DD	988	RX01, RX02
/RX03	5.25" or 8" DS DD	1,976	RX01, RX02, RX03
/RX23	3.5" 1.44 MB	2,880	RX23, RX24
/RX24	3.5" 720 KB	1,440	RX24
/RX26	3.5" 2.88 MB	5,760	RX23, RX24, RX26
/RX33	5.25" 1.2 MB	2,400	RX33, RX50, "RX52"
/RX50	5.25" SS DD	800	RX50
/RX52	5.25" DS DD	1,600	RX50, "RX52"
/MY	5.25" DS DD	1,600	MY: (Russian PDP-11 clones)

Floppy disk drives may be used to emulate any block-replaceable device supported by E11. "*d*:" is the drive letter, i.e. A: or B: for the first or second floppy drive. A command switch specifies the drive type, the default type is RX23, RX24, RX26, or RX33 depending on the type set for that drive in the PC's BIOS setup.

As shown in the table above, most drive types support one or two smaller disk formats in addition to their own. This means that any disk type supported by a given drive type may be inserted at any time with no need to re-MOUNT the drive. E11 will automatically detect the format of the new disk and adjust to the new geometry. Size changes are passed along to emulated PDP-11 controllers that understand them, i.e. the DU:, DY:, and HD: controllers.

Note that confusion is possible if a floppy disk has a different total number of blocks than the device being emulated. The PDP-11 OS may try to access areas off the end of the disk (which results in a controller-specific I/O error) or may not use all of the disk, and in particular writing a blank file system (with an OS-specific "initialize volume" command) will result in a directory structure that doesn't match the actual volume size. Care should be exercised to avoid trouble. Like disk types are of course not a problem, so for example "MOUNT DX0: B: /RX01" will mount a real RX01 disk to be used as an emulated RX01 disk. The HD: device works with any size device, so all floppy types may be mounted on HD: if you have the "HD.SYS" device handler (under RT-11). If the disk already has a correct directory structure for its actual size, and is mounted to emulate a device of at least that size, most operating systems (with device-independent file systems) will be able to read and write the disk correctly. For example, if you initialize an RX23 floppy with RT-11 directory structure using the PUTR utility under DOS, and then "MOUNT DL0: A: /RX23" in E11 (using the 1.44 MB RX23 disk to emulate a 5 MB RL01 pack), RT-11 will be able to access all files on the disk, and can write new files without data corruption, only the RT-11 INITIALIZE and SQUEEZE commands need to be avoided.

Most of the floppy disk formats supported by E11 are exact equivalents to PC formats. Not all of them were ever supported by DEC for use on PDP-11s in particular, but some were supported by aftermarket controllers. The RX01/02/03 formats use 1.2 MB disks, specially formatted (by E11 or the PUTR utility) to have the exact same

geometry as their 8" counterparts. The RX01 format is in fact identical to the IBM 3740 format used on DEC's 8" disks, so if a Shugart style 8" drive is attached to the PC floppy disk controller using a special cable (or D Bit's "FDADAP" adapter board, see <http://www.dbit.com/fdadap.html>), it will be possible to read/write/format real RX01 disks. DEC uses a modified MFM format for RX02 disks, which the PC hardware is incapable of using, so E11 substitutes the IBM System/34 compatible format for the RX02/RX03 workalike disks.

The RX01 format is not guaranteed to work (on either 5.25" or 8" drives) because most PC current floppy controllers don't have a working single density mode (the PC BIOS is hard-coded for double density so manufacturers have dropped support for "unneeded" features). However some floppy controller chips made by SMC, Goldstar, and Western Digital are known to work with single density mode. These chips usually contain "37C65" in the part number and use a 16/32 MHz clock plus a 9.6 MHz clock rather than the single 24 MHz clock used by many other controllers, so it may be useful to shop for a floppy controller board that has two crystals on it instead of one, in the absence of better information. The "CompatiCard IV" controller that was made by Micro Solutions, Inc. works with single density disks and is supported by E11.

In addition to the PC formats and 8" workalike formats, E11 also supports several 5.25" formats. RX50 disks are supported using a 1.2 MB drive. "RX52" is E11's name for double-sided RX50 disks, which were never sold by DEC, but may have been planned (for the Professional series at least). "MY" is the device name for the DS DD 5.25" disks used on the Russian DVK-x PDP-11 clones. The low-level format is the same as the "RX52" but there is no software sector interleave. "MX" disks are not able to be supported by the PC disk controller so E11 can't use them.

E11 can format all the disk types that it supports. Currently the easiest way to get at this feature is using the "set density" command of the RX211 controller, which can be executed by running `FORMAT.SAV` under RT-11 (using commands like "`FORMAT DY0:`" or "`FORMAT DY0:/SINGLE`"), or the `SPEC%()` function under RSTS. E11 chooses which of the formats (supported by a given floppy drive type) to use based on the size of the emulated disk, it uses whichever format is the same size as the emulated volume being formatted, or the next larger format if there's no exact match.

Ersatz-11 also supports the "format floppy disk" commands of the RQDX3 and RQZX1 controllers, so utilities that would work with those controllers will work with E11.

4.1.3 Raw CD-ROM drives

Command syntax:

`MOUNT ddcu: CDROMd:`

Special switches: none

The CD-ROM drive whose DOS drive letter is specified by "*d*" is accessed using the DOS `MSCDEX.EXE` (or `DR-DOS NWCDEX.EXE`) driver. Note that this is a synchronous interface so PDP-11 emulation is stalled while reading from a CD. More importantly, the Windows 9x version of the `MSCDEX` interface refuses to access the first sixteen sectors of the disk, which are unused on ISO-9660 disks, but are needed on disks written in a PDP-11 disk format. The workaround is to use real DOS.

4.2 Emulated PDP-11 disk devices

This section describes each PDP-11 disk drive type that Ersatz-11 emulates, and defines the device-specific MOUNT command switches that apply to each emulated disk type.

<i>name</i>	<i>units</i>	<i>controller</i>	<i>drive/volume switches</i>
DC:	0-3	RC11	(none, always RS64)
DF:	0-7	RF11	(none, always RS11)
(syn. RF:)			
DK:	0-7	RK11D	/RK02, /RK05 (syn. /RK03)
(syn. RK:)			
DL:	0-3	RL11	/RL01, /RL02
DM:	0-7	RK611	/RK06, /RK07
DP:	0-7	RP11C	/RP02, /RP03, geometry switches
DS:	0-7	RH11/RH70	/RS03, /RS04
DT:	0-7	TC11	(none, always TU55/TU56 DECtape)
DU:	0-65535	MSCP	/TYPE: <i>xxxxy</i>
DX:	0-1	RX11	(none, always RX01)
DY:	0-1	RX211	/RX01, /RX02, /SS, /DS
HD:	0-15	virtual	(none, file size is all that matters)
PD:	0-1	RXT11	(none, always RX01)

“Geometry switches” for DP: refers to `/CYLINDERS:n`, `/HEADS:n`, and `/SECTORS:n`, which may be used to specify non-standard drive dimensions. This allows compatibility with some clone controllers, which allowed extended drive sizes and/or untranslated SMD drive geometry to be used instead of the standard DEC geometry. In some cases the PDP-11 drivers may have been patched to use the non-standard geometry, these switches allow duplicating that hardware configuration so that the patched drivers will run unchanged under E11.

4.2.1 DC: — RC11/RS64

This emulation is included for completeness, it is not expected that anyone has a practical use for it. It is an early drive, with a fixed platter and fixed heads yielding very low capacity (128 KB). There are few if any surviving units today, and no current PDP-11 operating system version is known to support it. Since there is only one possible drive type, no switches are required to select it.

MOUNT DC: drive switches:	
/WPROTECT	enable write protection (syn. /RONLY)

SET DC: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

4.2.2 DF: — RF11/RS11 (called RF: in RT-11)

The RS11 is another fixed-head disk, and is a PDP-11 version of the RS08 disk for the PDP-8. It was word-addressable and more popular than the RS64, as it was larger (512 KB) and more reliable. Due to their high speed

for the time, RS11s were commonly used for swapping, so it may make sense to use a RAM disk to emulate an RS11. E11 allows write protecting the entire unit (with the `/WPROT` or `/RO` switch), but it does not emulate the RS11's switch panel which allowed write-protecting the disk in individual 32 KB segments.

MOUNT DF: drive switches:	
<code>/WPROTECT</code>	enable write protection (syn. <code>/RONLY</code>)

SET DF: controller parameters:	
<code>CSR=nnnnnn</code>	set CSR address to <i>nnnnnn</i> octal
<code>VECTOR=nnn</code>	set vector address to <i>nnn</i> octal

4.2.3 DK: — RK02, RK03, RK05 DECpack (called RK: in RT-11)

These front-loading cartridge drives were very popular in the 1970s thanks to their low cost and small size (a 10.5" rack-mount box). The disks are similar to the IBM 2315, and many other minicomputer manufacturers used a similar form factor. The RK02 holds 1.2 MB, while the RK03 and RK05 hold 2.5 MB. E11 does not distinguish between the RK03 and RK05 because they have identical geometries. The RK02 is no longer supported by current versions of PDP-11 operating systems. It is unusual in that it stores 256 bytes per sector (the RK03 and RK05 use 512-byte sectors). Be careful when using odd image file sizes with the DK: emulation, if you intend a disk to be used as an RK05 but it's not quite 4800 blocks long, E11 will auto-detect it as an RK02, which probably isn't what you want. Use an `/RK05` switch to be sure.

MOUNT DK: drive switches:	
<code>/RK02</code>	set drive type to RK02 (1.2 MB cartridge drive)
<code>/RK03</code>	set drive type to RK03 (2.5 MB cartridge drive)
<code>/RK05</code>	set drive type to RK05 (2.5 MB cartridge drive)
<code>/WPROTECT</code>	enable write protection (syn. <code>/RONLY</code>)

SET DK: controller parameters:	
<code>CSR=nnnnnn</code>	set CSR address to <i>nnnnnn</i> octal
<code>VECTOR=nnn</code>	set vector address to <i>nnn</i> octal

4.2.4 DL: — RL01, RL02

The RL01 and RL02 are top-loading cartridge drives which hold 5 and 10 MB, respectively. DEC marketed them successfully as a replacement for the RK05, and they were extremely popular in the 1980s, due to their reliability, small size (a 10.5" rack-mount box) and the relatively low price of the drives (however the cartridges were very expensive). New RL01 and RL02 cartridges come with a bad block table written by the manufacturer in the last track, which the PDP-11s are careful never to overwrite. Some utilities check for this table and will complain if it is not present, so be sure to get the whole disk when making image files. The PUTR utility (available from ftp.dbit.com) knows how to write a null bad block track when creating an empty image file (using its `FORMAT ... /RL0x` command).

MOUNT DL: drive switches:	
<code>/RL01</code>	set drive type to RL01 (5 MB cartridge drive)
<code>/RL02</code>	set drive type to RL02 (10 MB cartridge drive)
<code>/WPROTECT</code>	enable write protection (syn. <code>/RONLY</code>)

SET DL: controller parameters:	
CSR= <i>nnnnnnn</i>	set CSR address to <i>nnnnnnn</i> octal
CSR=FLOATING	set CSR address to be auto-configured
DEFAULT	set controller type to default (RL11 for Unibus, RLV12 for Q-bus)
RL11	set controller type to RL11 (Unibus)
RLV11	set controller type to RLV11 (Q18)
RLV12	set controller type to RLV12 (Q22 with BAE register)
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal
VECTOR=FLOATING	set vector address to be auto-configured

4.2.5 DM: — RK06, RK07

The RK06 and RK07 are top-loading twin-platter cartridge drives with capacities of about 13 and 27 MB, respectively. They were mounted on free-standing low-boy cabinets and were sort of a poor man's Massbus drive, even the geometry and register layouts are similar but there are only two platters (one timing surface, three data surfaces), the disks turn at only 2400 RPM, and the control bus is serial rather than parallel. The drives could be dual-ported but this configuration was rare.

MOUNT DM: drive switches:	
/RK06	set drive type to RK06 (13 MB cartridge drive)
/RK07	set drive type to RK07 (27 MB cartridge drive)
/WPROTECT	enable write protection (syn. /RONLY)

SET DM: controller parameters:	
CSR= <i>nnnnnnn</i>	set CSR address to <i>nnnnnnn</i> octal
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

4.2.6 DP: — RP02, RP03

These are top-loading 12-platter pack drives originally designed to be used with the PDP-10 series, but adapted for the PDP-11. The RP02 holds 20 MB per pack, while the RP03 holds 40 MB. RT-11 can't use a whole RP03 at once due to the RT-11 file structure's limit of 32 MB per volume, so it makes an RP03 look like two 20 MB disks. Although these were fairly early drives and weren't very widely used, the programming model is straightforward and as a result, aftermarket controllers that emulate them using SMD drives are common. Some of these controllers supported special drive geometries to give extended capacity and/or use the untranslated SMD sector addressing. In order to emulate these configurations, E11 supports the /CYLINDERS:*n*, /HEADS:*n*, and /SECTORS:*n* switches so that the user may specify custom disk dimensions.

MOUNT DP: drive switches:	
/CYLINDERS: <i>n</i>	set non-standard number of cylinders
/HEADS: <i>n</i>	set non-standard number of heads
/RP02	set drive type to RP02 (20 MB 12-platter pack drive)
/RP03	set drive type to RP03 (40 MB 12-platter pack drive)
/SECTORS: <i>n</i>	set non-standard number of sectors
/SERIAL: <i>nnnn</i>	set drive serial number (4 decimal digits)
/WPROTECT	enable write protection (syn. /RONLY)

SET DP: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

4.2.7 DS: — RS03, RS04

The RS03 and RS04 are fixed-head Massbus disks that hold 512 KB and 1024 KB, respectively. As with the RS11, these were used for swapping and other cases where speed is critical, so mounting them as RAM disks would work well.

MOUNT DS: drive switches:	
/RS03	set drive type to RS03 (512 KB fixed-head disk)
/RS04	set drive type to RS04 (1024 KB fixed-head disk)
/WPROTECT	enable write protection (syn. /RONLY)

SET DS: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
RH11	set controller type to RH11
RH70	set controller type to RH70
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

4.2.8 DT: — TU55, TU56 DECTape

Although it's actually 3/4" magnetic tape, DECTape is block-replaceable and uses a fixed number of fixed-size blocks, so really it behaves more like disks do than tapes. It puts 578 512-byte blocks on a 260' tape, and was very popular for off-line storage in the early 1970s when hard disk space was expensive, and floppy disks were not yet widely available. The TU55 is a single-transport drive, while the TU56 has two independent transports, so it takes two MOUNT DT*n*: commands to define a TU56. That difference is invisible to the PDP-11 so there's no switch to tell them apart.

MOUNT DT: drive switches:	
/WPROTECT	enable write protection (syn. /RONLY)

SET DT: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

4.2.9 DU: — MSCP disks

MSCP (the Mass Storage Control Protocol) is a flexible, device-independent protocol which allows any disk device (up to 2 TB) to connect to any of DEC's later computers. It was used in all of DEC's PDP-11 disk controllers from the mid-1980s on. DEC imposed an artificial limit of four drives per controller, upon which some versions of some PDP-11 operating systems depend. Also, DEC wants unit numbers to be unique within a system (i.e. if there's a unit 0 on one controller there should be no unit 0 on any other controller), and the maximum allowable unit number varies from one device type to another, depending on the method used to assign a unit number to a drive

(unit select cap for the “ready” light, DIP switches, etc.). Unlike many of DEC’s own drives, E11 implements the full 16-bit unit numbers specified by MSCP, so the amount of available memory is the only limit on unit numbers or the number of drives per controller. Even so, care should be taken to observe the limitations that the PDP-11 operating system imposes on MSCP configuration.

MSCP provides a way for the PDP-11 to find out the model name of each drive, which can be one to three letters followed by two decimal digits. This is largely a cosmetic feature, since MSCP already has ways for the PDP-11 to find out a disk’s size and whether it’s fixed or removable, so most of the time the name is meaningless. But all the same, the drive type can be set to any appropriate string using the “/TYPE:*name*” switch on the MOUNT command. The default drive type string is “RA81” for image files, or the actual drive type (“RX50” etc.) for floppies.

In some cases the drive type is important, for example some of the programs that format floppy disks on RQDX3 and RQZX1 controllers will refuse to go ahead unless they believe that the drive is an RX33, so you should use “/TYPE:RX33” when mounting a floppy drive which is to be formatted using standard software.

MSCP requires that each volume (except for floppy disks) contain a relocation control table (RCT) at the end of the disk, with a minimum length of one block. This table is used for remapping bad blocks and making the volume appear to be error-free. Since all current PC disk media (except floppy disks) provide some form of invisible bad block remapping of their own, they are already error-free, so there is no real need for this feature. Some aftermarket SCSI controllers provided a one-block RCT anyway, by deducting one block from the reported size of the volume. E11 can be set to do the same thing using the /RCT switch.

MOUNT DU: drive switches:	
/NORCT	don’t deduct one block for relocation control table
/RCT	deduct one block for relocation control table
/TYPE: <i>xxxxyy</i>	set drive type to <i>xxxxyy</i> (1-3 letters, 2 digits)
/WPROTECT	enable write protection (syn. /RONLY)

SET DU: controller parameters:	
CSR= <i>nnnnnnn</i>	set CSR address to <i>nnnnnnn</i> octal
CSR=FLOATING	set CSR address to be auto-configured
DEFAULT	set controller type to default (UDA50A for Unibus, RQDX3 for Q-bus)
KDA50	set controller type to KDA50
RQDX3	set controller type to RQDX3
RQZX1	set controller type to RQZX1
UDA50	set controller type to UDA50
UDA50A	set controller type to UDA50A

4.2.10 DX: — RX01

The RX01 is a single sided, single density floppy disk drive which uses 8” disks with the standard IBM 3740 format, the same as was commonly used in CP/M systems. The RX01 is a dual-drive system. If only one of the two units is MOUNTed, the other one will still appear to be there, since the RX11/RXV11 controller has no way of reporting whether a drive is present or not, but any attempts to do I/O to the missing drive will return error status.

E11 can read and write actual RX01 floppy disks, using an 8” drive attached to a PC floppy controller (with an adapter such as D Bit’s FDADAP board) which supports single density.

MOUNT DX: drive switches:	
/WPROTECT	enable write protection (syn. /RONLY)

SET DX: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
CSR=FLOATING	set CSR address to be auto-configured
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal
VECTOR=FLOATING	set vector address to be auto-configured

4.2.11 DY: — RX02, “RX03”

The RX02 is a double-density follow-on product to the RX01. It holds twice as much data per disk, and also uses DMA instead of programmed I/O to copy between PDP-11 memory and the on-board sector buffer, so there’s less CPU overhead. DEC apparently planned a double-sided upgrade, which became commonly know as the “RX03” but was never actually released. However there are connectors for the extra heads on the drive’s controller board (most of the “brains” of the RX01 and RX02 systems are actually in the drive), and DEC even documented the register fields that have to do with using double-sided disks, and the RT-11 V4.0 DY.MAC driver includes support (disabled under conditionals) for double-sided disks, but it was removed in later versions.

E11 includes the double-sided support in its emulation. The /SS and /DS switches can be used when mounting the drive to set the number of sides, and SET DY: SS (or DS) can be issued at any time to change it. This may be necessary when swapping disks in a real floppy drive, because unlike 8” drives, 5.25” drives have no way of distinguishing single- from double-sided disks, so it can’t be done automatically.

RSTS/E uses the names DX: and DY: interchangeably to refer to an 8” floppy drive, which may be either an RX01 or RX02. Early versions of E11 did the same thing and used a SET command to set the actual controller type, but it was decided that it would be better to be consistant and have the device name always reflect the device type. This may mean that the device name needed to emulate an existing drive under E11 is different from the name that had been used to refer to the same drive under RSTS/E.

MOUNT DY: drive switches:	
/DS	double-sided disk
/RX01	single-density disk
/RX02	double-density disk
/SS	single-sided disk
/WPROTECT	enable write protection (syn. /RONLY)

SET DY: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
CSR=FLOATING	set CSR address to be auto-configured
DS ¹	disk in drive is double-sided
SS ¹	disk in drive is single-sided
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal
VECTOR=FLOATING	set vector address to be auto-configured

¹really a drive option — unit must be mounted before this option is set

4.2.12 HD: — Hypothetical disk

This is a hypothetical disk device which exists only in Ersatz-11. Its original definition was based on reverse-engineering the `HD_SYS.EXE` device emulation that came with the so-called “Russian” LSI-11/2 emulator which used to be floating around the Internet, so that E11 would be able to boot disk images intended for that emulator. However that emulation was not very useful, since it (apparently) had no provision for interrupts or memory beyond 64 KB or drives bigger than 32 MB. The current emulation has been extended to support 22-bit addressing, up to 16 drives of up to 2 TB each, and it uses interrupts to signal completion so the system doesn’t have to stall during I/O. The main reason it’s interesting is that it supports variably sized devices like MSCP does, but with a much simpler programming model so that PDP-11 drivers can be written which require far less memory than MSCP drivers. An RT-11 driver (`HD.MAC`) is included with E11, and one for Fuzzball is available from ftp.dbit.com.

MOUNT HD: drive switches:	
<code>/WPROTECT</code>	enable write protection (syn. <code>/RONLY</code>)

SET HD: controller parameters:	
<code>CSR=nnnnnn</code>	set CSR address to <i>nnnnnn</i> octal
<code>VECTOR=nnn</code>	set vector address to <i>nnn</i> octal

4.2.13 PD: — PDT-11/150 RX01

The PDT-11/150 was a microcomputer based on the LSI-11 chipset. It had no expansion bus, and used a pair of 8085A processors to simulate the approximate equivalent of a small PDP-11/03 configuration, but it could be built more cheaply, and sold as a “smart” terminal system for data entry etc. It used RX01 drives but instead of an RXV11 controller (which would have required a Q-bus), it used a WD1771 floppy controller chip, which one of the 8085As used to simulate an almost-RXV11-like interface, which was called the RXT11. It’s just different enough from the RXV11 to be incompatible with regular RX01 software, so E11 provides it as a separate emulation.

MOUNT PD: drive switches:	
<code>/WPROTECT</code>	enable write protection (syn. <code>/RONLY</code>)

SET PD: controller parameters:	
<code>CSR=nnnnnn</code>	set CSR address to <i>nnnnnn</i> octal
<code>VECTOR=nnn</code>	set vector address to <i>nnn</i> octal

Chapter 5

Tape Devices

The full range of standard PDP-11 magtape drives and controllers can be emulated under Ersatz-11. Tape drives are configured in the same way as disks, with a `MOUNT` command to set up each emulated tape unit. The defaults for controller and drive parameters also work the same way as disks, with the controller model based on the emulated CPU type and the CSR and vector computed according to “floating” address rules if necessary. However the default tape drive models are essentially chosen arbitrarily, since unlike disks, there’s no point in trying to guess the drive model based on the size of the PC file or device that’s being used to emulate a tape drive, because the amount of data on a tape is variable anyway. In any case, the default drive and controller parameters can be overridden with `MOUNT` switches and `SET` commands, the same way they can with disks. The `/RONLY` (syn. `/WPROTECT` switch may be specified on any `MOUNT` command, to lock the tape against writes.

5.1 PC tape devices

As with disks, E11 uses a device-independent interface to connect any emulated tape drive to any real tape device. This connection is made with a `MOUNT` command, and the current configuration of an emulated tape can be displayed with a `SHOW` command.

5.1.1 Tape image files

Command syntax:

```
MOUNT ddcu: [d: path\]filename[.TAP] [switches]
```

Special switches: `/MAXRECORD:n`

A tape image file contains a byte-by-byte image of tape data, with headers and trailers on each record to maintain the blocking data from the real tape. Each record looks like this:

```
.LONG   LEN       ;32-bit record length, LSB first, byte-aligned
```

```
.BLKB  LEN      ;LEN bytes of data
.LONG  LEN      ;the length again, for backspacing
```

A tape mark appears as a single 32-bit 0. The MOUNT command for an image file may include a /MAXRECORD:*n* switch, which sets the maximum possible record length that can be read or written on that unit. The default is 16384 bytes. E11's memory usage may be decreased slightly by using a smaller number, but data will be lost if the PDP-11 attempts to read or write records larger than the specified maximum. Both ANSI and DOS-11 labeled tapes normally have a maximum record length of 512 bytes, but BRU tapes and UNIX "tar" tapes use longer records. As with disks, there are also /RONLY (syn. /WPROTECT), and /RW switches, to optionally write lock a tape drive. The file is located using E11's usual rules, see section 1.7 for details. If the file does not exist, it is created as a zero-length file in the current working directory.

5.2 Emulated PDP-11 tape devices

This section describes the emulated PDP-11 tape drive models, and defines the device-specific MOUNT command switches that apply to each.

<i>name</i>	<i>units</i>	<i>controller</i>	<i>drive/volume switches</i>
CT:	0-1	TA11	(none, always TU60 DECcassette)
MM:	0-7	RH11/RH70, TM03	/TE16, /TU45, /TU77, /SERIAL: <i>nnnn</i>
MS:	0-7	TS11 etc.	(none, always matches controller)
MT:	0-7	TM11	(none, software can't tell)
MU:	0-65535	TMSCP	/TYPE: <i>xxxyy</i>

5.2.1 CT: — TU60 DECcassette

The TU60 was designed to provide cheap off-line storage using ordinary audio cassette tapes. Under the CAPS-11 cassette programming system, it could be used as the system's only mass storage device. It uses programmed I/O rather than DMA, so tape data bytes are transferred one at a time. Unlike other tape devices, the TU60 requires the PDP-11 to know the record length ahead of time when reading a record, and gives an error if the PDP-11 attempts to read more or less than the correct number of bytes. The "LOG CT*n*:" command may be used to find out whether a PDP-11 program is trying to read the wrong record size.

The TA11/TU60 cassette tape system requires a mandatory load point gap (i.e. tape mark) on all tapes. E11 simulates this internally so that the load point gap does not appear on the physical medium. This allows the emulated TU60 general access to tapes that may have been created using some other device (or emulated device), where an extra tape mark at BOT would violate the labeling standards.

MOUNT CT: drive switches:	
/WPROTECT	enable write protection (syn. /RONLY)

SET CT: controller parameters:	
CSR= <i>nnnnnnn</i>	set CSR address to <i>nnnnnnn</i> octal
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

5.2.2 MM: — TE16/TU16, TU45, TU77

These tapes all use the TM02 or TM03 Massbus tape formatter to control up to eight slaves. The formatter itself uses one of the eight possible Massbus unit numbers (typically 0), and the resulting two-level unit selection scheme slightly complicates the device naming, since it appears nowhere else. As a result, the most common naming convention for “MM*n*:” device names uses the unit number *n* to refer to the slave number within the single formatter, rather than the Massbus unit number (which is what referred to by the unit number with all Massbus disks), and the formatter is Massbus unit 0.

E11 uses an extended MM: device name syntax similar to that used by RSX, where each slave’s device name looks like “MM*cu_s*:”. *c* is a letter indicating which RH11/RH70 controller connects to the TM03 formatter. The default in this version of E11 is “C”, the letter may change in future versions but in any case it refers to the default tape Massbus adapter at (17)772040. *u* is the Massbus unit number of the formatter, which defaults to 0 and is in the range 0–7. *s* is the slave number (within a TM03 formatter) of the tape transport, which also defaults to 0 and is in the range 0–7. If a number is present but no “_”, that number is the slave number, not the Massbus unit number.

The effect is that if the controller letter and Massbus unit number are omitted leaving a device name like “MM3:”, this name has the same meaning as the usual RT-11 or RSTS name, which is: default tape RH11 (the one at (17)772040), default formatter (0), slave 3. Meanwhile additional fields may be supplied to identify any of the 64 possible slaves on any of the (currently 3) possible Massbusses, so “MMA2.5:” refers to the first RH11, TM03 formatter 2, slave 5. This same name format may also be used in any other E11 command (e.g. BOOT, LOG) that takes a device name.

The MOUNT MM: command has switches to identify the drive model, but their only effect is to set the value of the “drive type” register. From a PDP-11 software point of view, all drives attached to a TM03 formatter look the same, the only difference is speed. There is also a /SERIAL:*nnnn* switch, which sets the value of the “drive serial number” register.

MOUNT MM: drive switches:	
/SERIAL: <i>nnnn</i>	set drive serial number (4 decimal digits)
/TE16	set drive type to TE16 (45 IPS NRZI/PE)
/TU45	set drive type to TU45 (75 IPS NRZI/PE)
/TU77	set drive type to TU77 (125 IPS NRZI/PE)
/WPROTECT	enable write protection (syn. /RONLY)

SET MM: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
RH11	set controller type to RH11
RH70	set controller type to RH70
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

5.2.3 MS: — TK25, TS04, TS05, TU80

These drives are microcomputer-controlled and have a programming model which is like a simplified version of TMSCP. There are no drive type switches because each controller model supports only one drive type anyway, so the drive type can be controlled implicitly by changing the controller type with a SET command. The TK25 is a cartridge tape, while the others are 9-track magtapes, but they all look similar from the PDP-11 operating system’s point of view.

DEC's earlier controllers support only one drive per controller so PDP-11 operating systems normally use the unit number to distinguish between separate controllers. Like later controllers, E11 allows up to 8 units per controller, so E11 uses the controller letter to distinguish between multiple controllers, the same as with most other device types. This means that when emulating a typical DEC system with one unit per controller, drives that the operating system calls MS0:, MS1:, and MS2:, will be called MSA0:, MSB0:, and MSC0: by E11, since they're the first and only slaves on three separate controllers. This only comes up with there is more than one MS: style tape drive, which is rare.

MOUNT MS: drive switches:	
/WPROTECT	enable write protection (syn. /RONLY)

SET MS: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
DEFAULT	set controller type to default (TU80 for Unibus, TSV05 for Q-bus)
EXTFEAT	enable extended features
NOEXTFEAT	disable extended features
TQK25	set controller type to TQK25 (Q22 TK25 controller)
TS11	set controller type to TS11 (Unibus TS04 controller)
TSU05	set controller type to TSU05 (Unibus TS05 controller)
TSV05	set controller type to TSV05 (Q22 TS05 controller)
TU80	set controller type to TU80 (Unibus TU80 controller, M7454 module)
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal
VECTOR=FLOATING	set vector address to be auto-configured

5.2.4 MT: — TS03, TU10

The TU10 is a vacuum column tape drive which interfaces to the PDP-11 through a classic Unibus interface, made up of a number of flip chip modules on a wire wrap backplane. The TS03 is a very small tension arm drive which uses up just 10.5" of rack space, and uses a physically smaller controller made with higher density modules. However they both look the same to software, so there are no drive type switches to distinguish them. The 7-track version of the TU10 is not supported.

MOUNT MT: drive switches:	
/WPROTECT	enable write protection (syn. /RONLY)

SET MT: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

5.2.5 MU: — TMSCP tapes

TMSCP (the Tape Mass Storage Control Protocol) is a device-independent protocol for connecting arbitrary tape drives to any of DEC's later computers. It doesn't particularly reduce the amount of implementation-specific quirks that must be dealt with (tapes never had anywhere near the amount of device-specific details as disks do to begin with), but it provides symmetry with the MSCP protocol for disks, and some systems are able to capitalize on this by sharing code between the disk and tape drivers. DEC generally didn't have more than one tape drive per TMSCP controller, but as with MSCP disks, E11 has no such artificial limits. However this means it may be

possible to configure a system which is incompatible with the PDP-11 operating system's TMSCP driver, so it is best to define a separate controller for each drive anyway.

As with MSCP disks, the `/TYPE:xxxyy` switch sets the unit type name, which may be up to three letters and up to two decimal digits. The default is TU81.

MOUNT MU: drive switches:	
<code>/TYPE:xxxyy</code>	set drive type to <i>xxxyy</i> (1-3 letters, 2 digits)
<code>/WPROTECT</code>	enable write protection (syn. <code>/RONLY</code>)

SET MU: controller parameters:	
<code>CSR=nnnnnn</code>	set CSR address to <i>nnnnnn</i> octal
<code>CSR=FLOATING</code>	set CSR address to be auto-configured
<code>DEFAULT</code>	set controller type to default (KLESI for Unibus, TQK50 for Q-bus)
<code>KLESI</code>	set controller type to KLESI (Unibus TU81 controller)
<code>TQK50</code>	set controller type to TQK50 (Q22 TK50 controller)
<code>TQK70</code>	set controller type to TQK70 (Q22 TK70 controller)
<code>TUK50</code>	set controller type to TUK50 (Unibus TK50 controller)

Chapter 6

Serial Lines

E11 has flexible support for serial and line printer devices. As with disks and tapes, any supported PC serial device may be used to emulate any emulated PDP-11 character device, and once again E11 chooses sensible defaults for the controller types and CSR/vector addresses based on the emulated CPU type and the configuration of “floating” devices, so in many cases no **SET** commands will be needed.

Each serial line is created with an **ASSIGN** command. **TT0:**, the system console, is connected to **CON1:** (the first emulated VT100 session, displayed on the PC video display) when E11 starts up, but it can be reassigned to any other screen or serial port with an **ASSIGN TT0:** command. If it is assigned to an RS232 serial port, the E11 prompt can no longer be popped up using Shift-Enter, because this key combination does not correspond to any ASCII character that could be sent over a serial line. So by default, a **BREAK** condition on the console serial port will bring up the “E11>” prompt. If this is inconvenient, the **SET BREAK** command can be used to define one ASCII character which will cause the prompt to pop up. For example, putting a **SET BREAK 20** command in the E11.INI initialization file will make the prompt pop up whenever **CTRL/P** is typed on the console terminal.

Output to any serial or printer device can be captured to a PC file using E11’s **LOG** command. For example, **LOG TT0: FOO** will cause all data displayed on the console terminal to be saved in **FOO.LOG**, until logging is turned off with a **LOG TT0:** command (with no filename).

An **ASSIGN** command will fail if the specified PC port doesn’t exist, or if the device’s currently **SET IRQ** is already in use and not **SHAREd**, or if the new **ASSIGN** command would steal **TT0:**’s device for some other port. There must always be something attached to **TT0:** since that’s E11’s console terminal.

Note that Ersatz-11 does not flag an error if the **ASSIGN** command assigns a **TT:** port to a printer, or **ASSIGN** an **LP:** port to a screen, even though these are usually not likely to be useful combinations. The reason both port types use the same pool of devices is so that they can both access **COM** ports, since serial terminals and serial printers are both reasonable devices. **LP:** ports attached to serial ports or video screens respond to **XON/XOFF** flow control. One good reason to **ASSIGN** an **LP:** port to a VT100 session is that a **LOG** command will capture the output to a

file, and there's no need to actually pop up that session and see it on the screen.

6.1 PC serial devices

<i>name</i>	<i>units</i>	<i>type</i>	<i>switches</i>
CON <i>u</i> :	1-12	video console	(none)
COM <i>u</i> :	1-4	PC COM port	/FIFO[: <i>n</i>], /NOFIFO, serial options
LPT <i>u</i> :	1-4	PC LPT port	
SBMIDI:	none	Sound Blaster MIDI port	

6.1.1 Serial options common to all devices

E11 has a set of “serial options” which are common to all serial device types, and are used to set communications parameters. These options may be used as either a switch (with a preceding “/” character) on the `ASSIGN` command when the port is created, or as a separate `SET` command any time thereafter. For example:

```
ASSIGN TT1:COM2: /MODE:1200,N,8,1
SET TT1: MODE=2400,E,7,1
```

The first command will create TT1: and attach it to COM2. The line parameters are set to 1200 baud, no parity, 8 data bits, and one stop bit. The second command will change the existing TT1: port to use 2400 baud, even parity, 7 data bits, and one stop bit. The option name may be separated from its parameters by either a “:” or “=” character.

Note that some emulated port types allow the communications parameters to be set by the PDP-11 operating system. E11 allows this by default, but in some cases the user may want to override the PDP-11's parameters, for example to set a port to a higher baud rate than the PDP-11 equivalent supports. In this case the `/LOCK` switch will be useful when creating the port (usually in combination with a `/MODE` switch). The `SET ddcu: LOCK` and `SET ddcu: UNLOCK` commands can be used to lock and unlock the port's communications parameters after the port has already been created.

The device-independent serial `ASSIGN` switches are as follows:

<code>/DTR: <i>value</i></code>	Sets the state of the DTR (data terminal ready) modem control signal. <i>value</i> may be <code>ON</code> or <code>OFF</code> to force DTR to be permanently asserted or deasserted, regardless of the value selected through the emulated PDP-11 port. Or, <i>value</i> may be <code>DTR</code> (which is the default setting), to make the real DTR pin track the value of the emulated DTR signal from the emulated PDP-11 port.
<code>/LOCK</code>	Locks communication mode parameters (baud rate, data bits etc.) against being changed by the PDP-11 port. This is useful for setting a port that has programmable parameters (e.g. a DZ11 line) to a non-standard speed without having the PDP-11 operating system set it back to a lower speed when initializing the emulated side of the port.
<code>/MODE: <i>bps, par, dbits, sbits</i></code>	Sets communication mode parameters to the values specified. <i>Bps</i> is the number of bits per second (range of allowable values depends on the specific serial hardware). <i>Par</i> is the parity specified as one letter: <u>E</u> ven, <u>O</u> dd, <u>N</u> one, <u>M</u> ark, <u>S</u> pace (not all serial hardware

supports all types). *Dbits* is the number of data bits, generally 5–8 although some PC port types can only do 7–8. *Sbits* is the number of stop bits, 1–2 (on most ports, “2” actually means 1.5 if *dbits* is 5).

If no `/MODE` switch is specified, newly ASSIGNED ports are initialized by default to 9600 baud, no parity, 8 data bits, 1 stop bit, i.e. `/MODE:9600,N,8,1`.

`/RTS:value` Sets the state of the RTS (request to send) modem control signal. *value* may be `ON` or `OFF` to force RTS to be permanently asserted or deasserted, regardless of the value selected through the emulated PDP-11 port. Or, *value* may be `RTS` (which is the default setting), to make the real RTS pin track the value of the emulated RTS signal from the emulated PDP-11 port.

Some newer modems use the RTS signal incorrectly to mean “ready to receive,” and if it is not asserted they will refuse to send data to the PC. The `/RTS:ON` switch circumvents this problem. Other possible solutions include using a specially wired modem cable to hold RTS asserted, or using the `AT&R1` modem command to change the modem’s behavior.

`/STD:value` This switch is included for completeness only. It works like the `/DTR` and `/RTS` switches, but it controls the secondary transmit data pin, which is pin 11 on a Bell 202 modem. Since none of the supported PC serial devices drives this pin, the switch has no visible effect.

`/TXMAX:n` This switch sets the maximum number of transmitted characters that will be buffered for transmission by that port. Once the port has accepted this number of characters from the PDP-11, it waits for all of them to be transmitted before accepting more characters. This value should be set low enough to get acceptable response to `XON/XOFF` characters (it may take up to *n* characters for the PDP-11 to react and suspend output), but high enough to get adequate throughput. The default value is 16. LA120 teleprinters are particularly sensitive to `XON/XOFF` response time, so they require a low `/TXMAX` value.

`TXMAX:n` is available only as an `ASSIGN` switch, it may not appear in a `SET` command.

`/UNLOCK` The opposite of the `/LOCK` switch, unlocks the port’s `/MODE` parameters so that they may be altered by the PDP-11 port (on port types where this is possible such as the DZ11 and DHU11). This is the default so there’s normally no reason to use it as an `ASSIGN` switch, however it may be useful as a `SET` keyword once the port has been assigned.

The sections that follow describe each physical PC serial (or serial-like) device that E11 supports, along with the command syntax needed to use them as emulated PDP-11 serial ports. As with disk and tape units, the ports are created on a line-by-line basis so there is no need to use the same kind of physical port for all emulated ports of a given type.

6.1.2 Video consoles

Command syntax:

`ASSIGN ddcu: CONn:`

Special switches: none

The specified PDP-11 terminal port is connected to one of twelve simulated VT100s that can normally be put up on the screen by pressing Alt and the function key corresponding to the screen number (F1–F12). Note that the screens assigned to F11 and F12 are not accessible on the old 84-key AT keyboard, unless other keys are redefined to reach them. When one screen is being displayed on the PC screen, the others (up to 11) are maintained invisibly in memory, so they will be up to date whenever another Alt/F n keypress switches the screen to display one of the hidden sessions.

This is only the default behavior of the function keys, if they are redefined using `DEFINE KEYPRESS` commands then other keys will need to be defined to switch displays, using the “PRIMARY n ” and “SECONDARY n ” keysript commands.

If there are two video adapters on the PC (e.g., an SVGA and a Hercules monochrome card), then one VT100 session may be displayed on each. Using the default keyscripts, the Alt-function keys choose which of the 12 possible screens is displayed on the primary monitor, and the Ctrl-function keys choose which is on the secondary monitor. Note that it is not possible to display the same session on both monitors at once. If this is attempted then whichever monitor was previously showing that session, switches to displaying the lowest-numbered available screen which is not already being displayed.

`COM n` : is the only device that may be used with the “VT:” VT11 vector graphics display processor emulation. Rather than running as an emulated VT100 in text mode the way true serial devices do, VT11 sessions run in graphics mode and require an SVGA card with at least 1 MB of memory. See section 8.5 for details.

6.1.3 COM ports

Command syntax:

```
SET COM $n$ : PORT= $nnnn$  IRQ $n$  (if needed)
ASSIGN  $ddcu$ : COM $n$ : [ $switches$ ]
```

Special switches: `/NOFIFO`, `/FIFO`, `/FIFO: n`

The PDP-11 port is connected to the specified PC COM port. Any changes to the default I/O port address and IRQ settings must be made with a `SET COM n : PORT= $nnnn$ IRQ n` command before assigning a PDP-11 port to the COM port. The baud rate, number of data bits, etc. for a COM port may be set with a `/MODE` switch, see section 6.1.1 for more information. These parameters may also be changed using a `SET` command once the port is assigned to a PDP-11 device.

The “`/NOFIFO`,” “`/FIFO`,” and “`/FIFO: n` ” switches control usage of the receive FIFOs on the 16550A (etc.) UART chips used in almost all current PC COM ports. These FIFOs greatly reduce interrupt traffic and enabling them normally increases the maximum throughput of the system, however they can make input appear “bursty,” especially at low baud rates. “`/NOFIFO`” disables the receive FIFOs, “`/FIFO`” enables them, and “`/FIFO: n` ” enables them only when the baud rate is at least n . The setting is “`/FIFO:4800`” by default for ports that have FIFOs, ports that don’t are always set to “`/NOFIFO`” regardless of the switch given.

SET COM n : controller parameters (must be issued before the ASSIGN that uses this port):	
IRQ n	set IRQ number (0–15)
PORT= $nnnn$	set I/O port address to $nnnn$ hex
SHARE	enable ISA IRQ sharing (must come after IRQ n)

The default IRQ for COM ports is IRQ4 if the I/O port address is 300 (hex) or more, or IRQ3 for 2FF (hex) or less. These defaults have been traditional since IBM XTs were the standard, and most multi I/O boards will be set up this way. However it's not uncommon with newer boards for COM3 to use IRQ5 and COM4 to use IRQ2 (or IRQ9 really, which is effectively the same on an AT) by default.

6.1.4 PC line printer port

Command syntax:

```
SET LPTn: [PORT=nnnn] [IRQn] [NOIRQ] [[NO]BIOS] (if needed)
ASSIGN ddcu: LPTn: [switches]
```

Special switches: none

The PDP-11 port is connected to the specified PC LPT port. Any changes to the default I/O port address and IRQ settings must be made with a `SET LPTn: PORT=nnnn IRQn` command before assigning a PDP-11 port to the LPT port. Some LPT ports do not work well with interrupts — for example, if there are multiple LPT ports they may all try to drive IRQ7 at once, or it's possible that a printer may not generate the ACK signal correctly. In many cases this problem can be circumvented by using the `SET LPTn: NOIRQ` command before assigning the port. This tells E11 to use timers and polled I/O for printer output, which works well with most late model printers. However some older printers with less buffering may experience very poor performance with this setting, printing only one or two dozen characters per second. With these printers it is best to resolve the IRQ problem and use interrupts.

Printers may also be accessed using the PC BIOS, by issuing a `SET LPTn: BIOS` command before assigning the port. This is mainly useful for remote printing using network software that captures BIOS output and forwards it to a network print server. For a locally attached printer it's better to use the default NOBIOS setting.

LPT output is passed transparently, so you'll need to make sure that your OS and printer agree on whether lines end in <CRLF> or just <LF>, and on whose responsibility it is to expand tabs and form feeds.

SET LPTn: controller parameters (must be issued before the ASSIGN that uses this port):	
BIOS	use BIOS calls for I/O instead of driving hardware directly
IRQn	set IRQ number (0–15)
NOBIOS	use E11's internal driver for I/O instead of BIOS calls
NOIRQ	use polled I/O instead of interrupts
PORT=nnnn	set I/O port address to nnnn hex
SHARE	enable ISA IRQ sharing (must come after IRQn)

6.1.5 Sound Blaster MIDI port

Command syntax:

```
SET SBMIDI: [PORT=nnnn] [IRQn] (if needed)
ASSIGN ddcu: SBMIDI: [switches]
```

Special switches: none

The PDP-11 port is connected to the MIDI port on a Creative Labs Sound Blaster 16 compatible sound board. This allows connecting electronic musical instruments (synthesizers, etc.) to the sound board using a special cable. The default I/O port address and IRQ settings are taken from the `BLASTER` environment variable, `330/IRQ5` are used if this variable is not defined. Any changes to these defaults must be made with a `SET SBMIDI: PORT=nnnn IRQn` command before assigning a PDP-11 port to the MIDI port. The communications parameters are not changeable on a MIDI port.

The Sound Blaster MIDI port supports interrupt-driven I/O only when receiving characters, so E11 must use polled I/O to transmit. This means that PDP-11 emulation may stall for up to one character time while the port driver is waiting to start a new character transmission, so the `SBMIDI:` port should not be used on systems where there are other real-time tasks running. This has nothing to do with emulated interrupts provided for PDP-11 software, those work in both directions, but transmitting a character can stop all PDP-11 instruction execution for several hundred microseconds.

SET SBMIDI: controller parameters (must be issued before the ASSIGN that uses this port):	
IRQ <i>n</i>	set IRQ number (0-15)
PORT= <i>nnnn</i>	set I/O port address to <i>nnnn</i> hex
SHARE	enable ISA IRQ sharing (must come after IRQ <i>n</i>)

6.2 Emulated PDP-11 serial devices

This section describes each PDP-11 serial device type emulated by Ersatz-11.

<i>name</i>	<i>units</i>	<i>controller</i>	<i>notes</i>
LP <i>u</i> :	0-3	LP11/LPV11	
TT <i>u</i> :	0-15	DL11/DLV11	KB <i>u</i> : and YL <i>u</i> : are synonyms

6.2.1 LP: — LP11, LPV11 line printer ports

These ports connect a single line printer, using device registers which look similar to the transmitter half of a DL11/DLV11 serial line unit. They normally use a Data Products compatible parallel interface to connect to the printer. Converter boxes are available from Black Box Corporation to allow connecting such a line printer to a PC RS232 serial port.

SET LP: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
MODE= <i>b, p, d, s</i>	set communications parameters
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

6.2.2 TT: — DL11, DLV11 single serial line units

These are the standard single-line serial ports. Every PDP-11 has at least one, which is used for the console terminal. By default Ersatz-11 connects the console terminal to CON1:, which is the same VT100 session that E11 uses for its own command prompt. The DLV11J 4-line serial card actually appears to software as four separate DLV11 ports, so it can be configured in E11 using four ASSIGN commands.

SET TT: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
CSR=FLOATING	set CSR address to be auto-configured
MODE= <i>b, p, d, s</i>	set communications parameters
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal
VECTOR=FLOATING	set vector address to be auto-configured

Chapter 7

Network Devices

Ersatz-11 emulates several types of network interfaces. Once again each emulated port is created with an **ASSIGN** command, and is connected to a real PC Ethernet port.

DECnet is very demanding in its use of Ethernet hardware. In order to avoid needing an address resolution protocol layer, it modifies the port's Ethernet address to incorporate the protocol address, and it also makes use of multicast addressing features. These capabilities are rarely used outside of DECnet, and D Bit has found that many drivers supplied by hardware vendors appear to have been debugged against TCP/IP stacks only, and the calls that have to do with multicast address lists and changing the Ethernet address may not work properly, or at worst may crash the system when called.

In many cases there are several different packet drivers available for the same board so if you run into trouble, an Internet search may turn up a better driver for your board. E11's built-in NE2000 driver has been tested extensively and supports all needed features, including setting the Ethernet address, maintaining the multicast address list, and controlling the filters for the promiscuous and receive-all-multicasts modes.

Extensive logging available for network devices. When applied to Ethernet interfaces, the **LOG** command can log any combination transmitted data, received data, and device commands.

7.1 PC network devices

<i>name</i>	<i>type</i>	<i>switches</i>
NE2000c:	NE2000 clone	(none)
PKTD:	Packet Driver	/INT: <i>vv</i>

7.1.1 NE2000: — NE2000 and compatibles

Command syntax:

SET NE2000*c*: [ISA] [PCI] [AUTO] [PORT=*nnnn*] [IRQ*n*] (if needed)
 ASSIGN *ddu*: NE2000*c*: [*proto*₁ *proto*₂ *proto*₃ ...]

Special switches: none

The “NE2000*c*” device refers to a Novell NE2000 (or compatible) Ethernet board, accessed using E11’s own internal driver. This requires much less software overhead than using a DOS packet driver, and common PCI boards (such as those based on the RealTek RTL8029 chip) are supported as well as the older ISA ones. The “*c*” parameter is an optional letter specifying which NE2000 board to use (default is “A”, meaning the first or only one). The port/IRQ values and controller type should be set with “SET NE2000*c*: ...” commands prior to issuing the ASSIGN command, except for PCI NE2000 clones where E11 obtains the port/IRQ values from the PCI BIOS. By default the controller type is “AUTO”, which means that E11 should first try to locate a PCI board and failing that, should assume that there’s an ISA board located at the specified port/IRQ values. Setting the controller type to “PCI” tells E11 that it’s definitely a PCI board, so the port/IRQ values are ignored (the values obtained from the PCI BIOS are used instead), and an error message is given if no PCI board exists. A controller type of “ISA” tells E11 to skip the PCI probe and definitely use the supplied port/IRQ values.

SET NE2000 <i>c</i> : controller parameters (must be issued before the ASSIGN that uses this board):	
AUTO	auto-detect ISA vs. PCI port type (default)
IRQ <i>n</i>	set IRQ number (0–15)
ISA	port type is ISA (or PCMCIA), use IRQ/PORT settings
PCI	port type is PCI, obtain board information from PCI BIOS
PORT= <i>nnnn</i>	set I/O port address to <i>nnnn</i> hex
SHARE	enable ISA IRQ sharing (must come after IRQ <i>n</i>)

7.1.2 PKTD: — Packet drivers

Command syntax:

ASSIGN *ddu*: PKTD: [*switches*] [*proto*₁ *proto*₂ *proto*₃ ...]

Special switches: /INT:*nn*

The PKTD: device uses a DOS Packet Driver to access the physical Ethernet board. If specified, “/INT:*nn*” gives the hexadecimal 80x86 interrupt vector to which the packet driver is attached. If the interrupt vector is not given, then the range of vectors from 20 to FF (hex) is searched until a packet driver is found that isn’t already in use by another simulated Ethernet port. A list of hex 16-bit *DIX* protocol numbers, up to ten total, may be specified in network byte order (e.g. IP is 0800), in which case E11 asks the packet driver to pass only frames of those types. This may allow E11 to coexist with other protocol stacks running on the same PC, as long as they each use different sets of protocol numbers and neither one needs to change the port’s physical address after the other is loaded, and in any case it may be helpful for shielding the PDP-11 operating system from unwanted broadcast traffic.

DECnet requires the ability to change the address (it wants the physical address to be based on the protocol address to avoid the additional overhead of performing address resolution over the network, as TCP/IP does), so in general running DECnet under E11 will require either that no other network software be running on the same interface, or that you install a second Ethernet board for E11’s exclusive use. This is because the packet driver refuses to change the physical address once the board is already in use so as not to surprise protocol stacks that were already running when the change was made and thought they knew their own address.

Freeware packet drivers for a wide variety of Ethernet interfaces are available via anonymous FTP from many sources including ftp.crynwr.com, and are typically included on the driver disk that comes with the adapter. Ersatz-11 requires packet drivers that conform to version 1.09 or later of the packet driver specification as published by FTP Software.

7.2 Emulated PDP-11 network devices

This section describes each PDP-11 network device type emulated by Ersatz-11.

<i>name</i>	<i>units</i>	<i>controller</i>
NI <i>u</i> :	0-1	Interlan NI1010A, NI2010A Unibus/Q-bus Ethernet
XE <i>u</i> :	0-3	DELUA Unibus Ethernet

7.2.1 NI: — Interlan NI1010A, NI2010A Ethernet ports

The Interlan boards were early Ethernet interfaces, and have a simpler programming model than DEC's own Ethernet boards. Fuzzball and UNIX contain Interlan drivers. They were available in both Unibus (NI1010A) and Q-bus (NI2010A) versions, and the Q-bus version could be switched between 18- and 22-bit addressing. By default, E11 chooses the NI: device type based on the SET CPU QBUS setting.

SET NI: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
DEFAULT	set controller type to default (NI1010A for Unibus, NI2010A_Q22 for Q-bus)
NI1010A	set controller type to NI1010A
NI2010A_Q18	set controller type to NI2010A with Q18 addressing
NI2010A_Q22	set controller type to NI2010A with Q22 addressing
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

7.2.2 XE: — DELUA Ethernet port

The DELUA is a Unibus Ethernet board in a single hex-height module. It is a compatible upgrade to the DEUNA, which was two hex-height modules and was slower and consumed more power. It is a sophisticated board which offloads a lot of processing from the PDP-11. The board contains its own echo server (for the ECT loopback protocol, 90-00) and generates system ID packets, both automatically (on a timer) and in response to requests from other nodes. It also maintains a “counters” page with transmit/receive statistics.

SET XE: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
CSR=FLOATING	set CSR address to be auto-configured
DEUNA	set controller type to DEUNA
DELUA	set controller type to DELUA (default)
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal
VECTOR=FLOATING	set vector address to be auto-configured

Chapter 8

Miscellaneous Devices

This chapter describes devices which don't fit into any of the major categories covered in the preceding chapters. This includes graphics displays, paper tape I/O, and the interface to the PC's native file system.

Miscellaneous PDP-11 devices:

<i>name</i>	<i>unit(s)</i>	<i>controller</i>	<i>command to create</i>	<i>type</i>
(none)			LOAD/ROM	ROM devices
DO:	0-3	virtual	MOUNT	PC file interface
PP:	0	PC11	MOUNT	paper tape punch
PR:	0	PC11	MOUNT	paper tape reader
VT:	0	VT11	ASSIGN	vector graphics processor

8.1 ROM devices

Command syntax:

```
LOAD/[EEP]ROM [/BANKED] [d: path\]filename[.PDP] start[:end]
```

Special switches: /BANKED, /EEPROM, /ROM

E11 can simulate ROM devices, either simple unbanked ones such as the M9312 bootstrap/diagnostic board, or banked ones like the BDV11 board or the on-board ROM in the later quad-height Q-bus CPU modules.

ROM data are loaded from the specified binary file, which is located using E11's usual search rules (see section 1.7). More than one ROM device can be loaded, so for example the individual 128-byte device bootstraps in a M9312 style ROM board (or the on-board equivalents in a PDP-11/24 or PDP-11/44 CPU) can be loaded from separate files with separate commands.

For linear (non-banked) ROMs, a starting address in the I/O page must be specified. The data from the file will appear starting at that address. If an ending address is specified, the file must be at least long enough to reach that address. If no ending address is given, the length of the emulated ROM is the same as the length of the binary

file.

A M9312-style bootstrap/diagnostic ROM board can be configured and started with the following commands:

```
E11>LOAD/ROM DIAGBOOT.ROM 17765000
E11>LOAD/ROM RL02BOOT.ROM 17773000
E11>LOAD/ROM MSCPBOOT.ROM 17773200
...
E11>G0 165020
000000 000000 000000 000000
@
```

This is just an example of what can be done. Normally there would be no point in using the M9312 boot ROMs since E11 contains its own bootstraps for all bootable devices that it emulates. Anyway there may be legal problems with copying the ROMs into image files, since they are copyrighted by DEC.

For banked ROMs, the `/BANKED` switch must be used. The data from the file will appear through a 512.-byte window, and the page which is visible is selected by the PDP-11 using the page control register (PCR), which for emulation purposes is considered by E11 to be part of the CPU board (since in most cases, it is).

There are two styles of page control register. `SET CPU KDF11` (or `SET CPU BDV11`) selects the style used in the KDF11 on-board ROM (or the BDV11 boot/diagnostic board). `SET CPU KDJ11` selects the style used in the on-board ROM of the KDJ11x CPU boards.

The starting address for banked ROM windows is either (17)773000 or (17)765000. The windows must be 512. bytes long, which is E11's default anyway so there's no need to give the end of the address range. The `/EEPROM` switch means that the memory is actually EEPROM (as used on the KDJ11x CPU boards), and must go in the window starting at (17)765000. This is the default, so there's no need to give any address range at all with `LOAD/EEPROM`. Note that while the memory can be written, the data written are not saved to the file from which the EEPROM was loaded. Regular ROM data go in the window starting at (17)773000, so this is the default for `LOAD/ROM`.

ROM devices can be removed at any time using the `UNLOAD` command. The switches and defaults are the same as for `LOAD`, so the starting address of the ROM to remove need not be specified if the `/BANKED` switch is used.

8.2 DO: — PC file access pseudo-device

Command syntax:

`MOUNT DO n :`

Special switches: none

DO: refers to the "DOS file device". This is a pseudo-device which allows privileged PDP-11 programs and/or device drivers to read and write native PC files from within the emulated PDP-11. It is compatible with the supplied `DO.SYS` device driver for RT-11, and the `DOS.TSK` program for RSX which is available from ftp.dbit.com. The command to create a DOS file device is simply "MOUNT DO n :", since there is no particular physical PC device attached to the physical side of the emulation. In E11 prior to V2.2, one DOS file device was always configured,

but now they must be created explicitly. Normally there's no reason to have more than one, so you can recreate the V2.1A behavior by simply adding "MOUNT DO:" to your E11.INI initialization command file.

8.3 PP: — PC04 paper tape punch

Command syntax:

MOUNT PP: [*d:path*]*filename*[.PAP]

Special switches: none

The PC04 is a high speed paper tape reader/punch, interfaced to the PDP-11 through a PC11 interface. This command attaches the specified PC file to the output half of the device, so that data bytes sent to the punch will be written to the file instead.

8.4 PR: — PC04 paper tape reader

Command syntax:

MOUNT PR: [*d:path*]*filename*[.PAP]

Special switches: none

This command attaches the specified PC file to the input half of the PC11/PC04, so that input bytes will come from the file instead. The BOOT PR: command supports binary executable tape images written in the Absolute Loader format (e.g. by the LINK /LDA command in RT-11). The SET PR: REWIND command will reset the tape to begin reading at the beginning of the file on the next access.

SET PR: controller parameters:	
REWIND	rewind tape to beginning

8.5 VT: — VT11 vector graphics display processor

Command syntax:

ASSIGN VT: CON*n*:

Special switches: none

The VT11 vector graphics display processor consists of three hex-height boards in a 4-slot backplane. It maintains the picture on a VR14 or VR17 monitor by constantly scanning a display list held in PDP-11 memory, and refreshing each vector many times per second. It can be used with a DEC model 375 light pen, and an LK40 ASCII keyboard.

In order to emulate a VT11, E11 requires a Super VGA graphics card with a VESA BIOS and at least 1 MB of

video memory. The VT11 is assigned to one of the twelve possible virtual console sessions, so it can be popped up with an Alt-function key just like an emulated VT100 session, except of course that it runs the display in graphics mode.

If a mouse is present, it is used to emulate the DEC model 375 light pen. The crosshairs indicate the mouse position continuously (since a mouse can't be lifted away from the screen like a real light pen), so the left mouse button is used to indicate whether a light pen "hit" should be allowed to register. The PC keyboard takes the place of the LK40 keyboard on a GT40 system, so all keyboard input typed to a VT11 session is sent to TT0:.

SET VT: controller parameters:	
CSR= <i>nnnnnn</i>	set CSR address to <i>nnnnnn</i> octal
VECTOR= <i>nnn</i>	set vector address to <i>nnn</i> octal

Chapter 9

Commands

Ersatz-11 recognizes many keyboard commands. These are entered at the “E11>” prompt, which appears whenever the PDP-11 is halted (e.g. at startup) but may be brought up at any time by pressing Shift-Enter or Alt-SysReq, or by pressing the BREAK key on a serial terminal if the console terminal (TT0:) has been ASSIGNED to a COM port. The SET BREAK command can define a regular ASCII character that pops up a prompt if these methods are all inconvenient. Some versions of the Windows DOS box intercept Alt-SysReq, but Shift-Enter still works. Commands (and parameters and switches) may generally be shortened to any unique abbreviation. Note that E11 is multithreaded and PDP-11 code continues to be executed while you are entering commands at the prompt, if you haven’t HALTed it.

@file[.CMD]

Accepts input from the specified file as if it had been typed at the E11 prompt. The default extension is “.CMD”, and search rules are the same as for the E11.INI initialization file (see section 1.7). Command files may be nested up to four deep. Lines read from the file are not echoed.

ASSEMBLE [/switches] [addr]

Starts the mini-assembler at the specified address, in the specified address space (syntax and defaults are the same as for the LIST command). E11 will prompt with the address, and you can type in lines of PDP-11 assembly code, which E11 will translate to machine language and deposit into PDP-11 memory at that address. E11 keeps prompting for more lines (at updated addresses) until the user enters a blank line, or types CTRL/C. The syntax is a subset of the standard MACRO-11 syntax. Simple expressions are allowed in operands but there is no symbol table, macro processor, or conditional assembly. Only the .BYTE, .WORD, .BLKB, .BLKW, .ASCII, and .ASCIZ pseudo-operations are supported.

Example:

```
E11>a 1000
001000 mov    #1022,r5      ;point at string
001004 tstb  @#177564      ;is port ready?
001010 bpl   1004          ;spin until it is
001012 movb (r5)+,@#177566 ;send next character
001016 bne  1004          ;loop unless it was a NUL
```

```

001020 halt                ;stop in that case
001022 .asciz /Hello there/<15><12> ;test string
001040 ^C
E11>g 1000
Hello there

%HALT
R0/000000 R1/000000 R2/000000 R3/000000 CM=K PM=K PRI0=0
R4/000000 R5/001040 SP/000000 PC/001022 N=0 Z=1 V=0 C=0
001022 add      (r5)+,(r0)
E11>

```

ASSIGN *pdp11dev*: *pcdev*: [*switches*]

Assigns a physical PC device to emulate the specified PDP-11 serial or network device. See chapter 6 for information about serial devices, and chapter 7 for information about network devices.

pdp11dev is the name of the PDP-11 device name being created. It conforms to the syntax defined in section 1.6. The first two letters define the device type, and are generally the same as the PDP-11 operating system's name for that device.

pcdev is the name of the PC device which will emulate this PDP-11 device. Within each class of peripherals (serial, network), any PC device may be used to emulate any similar PDP-11 device.

The optional *switches* consist of keywords which begin with a forward slash character (“/”). Some switches take a value, which is preceded by a “:” or “=” character. The acceptable switches vary depending on the device names used, see the section describing the device for more information.

BOOT *ddu*: [*/switches*]

Boots the system from the specified disk, magnetic tape, DECTape, network device, or paper tape. The disk/tape must have been mounted with the MOUNT command, unless it is a real device attached through a bus adapter. The optional switch is an OS name. Useful switches are /RT11 and /RSTS. /RSX is accepted too but has no special effect. This has to do with the method used to pass time and date information to a newly booted monitor. RT-11 ignores the time and date passed at 005000 unless the NOP in word 000000 of the bootstrap is cleared to 0 (HALT) and the bootstrap is entered at 000002. RSTS uses the time and date at 001000 (in a different format from RT-11) regardless of whether its NOP was cleared, but later versions of RSTS save the first word of the bootstrap and execute it later, so they will halt if the system was booted the RT-11 way. Hence Note that the OS switches are meaningful only on block devices. If you prefer to set the time and date manually then the switch is not needed. RSX doesn't have a way to pass the time and date to a fresh monitor, so you'll have to use “F12” with a TIM command, or else use the TOY.TSK program (available on ftp.dbit.com) to read the TOY clock, which can be enabled on any emulated CPU type by putting ASR as the last item on the SET CPU command line. Recent RSX-11M-PLUS versions have a built in TIM /SYN command to do this, which works if the CPU type is PDP-11/93 or PDP-11/94.

There is also a /HALT switch, which tells E11 to go as far as loading block 0 into core and setting up the registers, but to stop there. This can be handy for debugging boot blocks.

The BOOT PR: command expects a tape image in absolute binary format, as produced by the “LINK /LDA” command under RT-11.

CALCULATE *expr*
& *expr* (synonym)

Calculates the value of a 32-bit expression and displays the result in octal, decimal, hex, ASCII and radix-50. The operators are * / + -, unary + - ^C (where “^C” means logical complement), and (), with the usual precedence. & and ! are the bitwise AND and OR operators, and have the same precedence as * and +, respectively. Numbers are either octal digit strings, or decimal if they contain 8 or 9 or end in “.”, or hex if preceded by “^X”, or radix-50 triplets if preceded by “^R”. General register contents may be specified using the names R0–R5 (with a “’” suffix to indicate the other register set, when emulating a PDP-11 with dual register sets) or SP or PC, R\$ or PS means the processor status word, and something of the form “’a” means the ASCII value of the character “a”.

E11 can accept expressions in most of the commands or switches which take numeric arguments. The default radix depends on the particular command or switch.

DEFINE **KEYPRESS** *keyname* = *statement*
DEFINE **KEYRELEASE** *keyname* = *statement*

Defines the action taken when the specified key is pressed or released. Keyboard operation is defined using a simple script language, which allows the user to bind a small script to any possible keypress or keyrelease, which is executed whenever that key is pressed (**DEFINE** **KEYPRESS**) or released (**DEFINE** **KEYRELEASE**). When E11 is first started, the keyboard is initialized with a set of scripts which define the action of a VT100-like keyboard with a US English layout. Just like user definitions, these default scripts may be displayed with the **SHOW** **KEYPRESS** and **SHOW** **KEYRELEASE** commands. By default most keys do nothing on release and have no **KEYRELEASE** definition, except for the Alt, Ctrl, and Shift keys. Using the “E11.INI” initialization file, the user may easily redefine some or all of the keyboard as required. The keyscript language is described in Appendix A, and the list of key names that E11 accepts is in section A.3.

DEFINE **LED** *ledname* = *flag*

Defines which flag is tracked by each keyboard LED. LED names are CAPS, NUM, and SCROLL. The flag may be the name of any flag (read-only or read/write) from the keyboard script language, in which case the LED turns on when the flag is set and turns off when the flag is clear. Or it may be NONE to turn the LED off permanently. Flag names and meanings are described in section A.4.

DEASSIGN *ddu*:

Disables the specified character or network device. Deassigning TT0: is not allowed (either explicitly, or implicitly by **ASSIGN**ing its PC device to another PDP-11 device).

DEPOSIT [*/switches*] *addr val₁ val₂ ...*

Deposits the word(s) *val₁*, *val₂* etc. starting at memory address “*addr*,” which is forced even. An error message is returned if an attempt is made to access a nonexistent CSR in the I/O page (bus timeout). The address space to use is specified by the switch(es), or the space used in the last **EXAMINE** or **DEPOSIT** command is used by default if none are given. See the **EXAMINE** command for a list of valid switches.

DISMOUNT *ddcu*:

Dismounts the specified mass storage device (see **MOUNT**).

DUMP [*/switches*] [*d:path\filename* [.PDP]] [*s₁:e₁ s₂:e₂ ... s_n[:e_n]]*]

With no switches, dumps PDP-11 memory to the specified DOS file (default extension is “.PDP”). Any number of address ranges “ $s_i:e_i$ ” may be given, and data will be dumped to the file from each range in the order given in the command line. The last range may have no ending address, in which case file data are dumped until the end of memory. If no ranges are given at all the default is to dump all of PDP-11 memory starting at 000000.

With either the “/ROM” or “/EEPROM” switch, dumps a range of ROM or EEPROM to the file. The ROM/EEPROM must have been created with “LOAD/ROM” or “LOAD/EEPROM”. Only one address range may be specified. It must begin at the beginning of the ROM but may end before the end of the ROM. The “/BANKED” switch can dump all of a banked ROM if only the starting address is given (rather than dumping only up to the first 512. bytes), in this case the starting address can be omitted too, (17)773000 is the default for “/ROM” and (17)765000 is the default for “/EEPROM”. If no ending address is given, the default is to dump out the whole ROM.

EXAMINE [*/switches*] [*addr* [*end*]]

Examines the word at memory address *addr*, which is forced even. If *end* is specified then a range of words is displayed. If both are missing then the 8 words following the last location accessed with EXAMINE or DEPOSIT are displayed. An error message is returned if an attempt is made to access a nonexistent CSR in the I/O page (bus timeout). The address space to use is specified by the switch(es), or the space used in the last EXAMINE or DEPOSIT or MAP command is used by default if none are given.

Switches:

<i>switch</i>	<i>space</i>
/CURRENT	Current CPU mode, specified by $PSW_{15:14}$
/PREVIOUS	Previous CPU mode, specified by $PSW_{13:12}$
/KERNEL	Kernel mode
/SUPERVISOR	Supervisor mode
/USER	User mode
/INSTRUCTIONS	I space (within one of the above modes)
/DATA	D space (within one of the above modes)
/PHYSICAL	Physical 22-bit address space (default if MMU disabled)

Note that the address space switch(es), if any, must be given before the address expression on the command line, to avoid ambiguity since the switch character (“/”) is used for division in expressions.

FPREGISTER [*r v₁ v₂ [v₃ v₄]*]

Sets or displays the FPP registers. *r* is the FP accumulator number, 0–5, and v_1-v_4 are two or four 16-bit octal words to write in the register (sorry, not decimal). If no arguments are given then the octal contents of all six ACs are given, along with octal displays of the FPS, FEC, and FEA, and also a bit-by-bit display of FPS.

GO [*addr*]

Starts the machine at the specified address, or at the address currently in the program counter if none is given.

HALT

If the machine is running, halts it and displays the registers. Otherwise a no op.

HELP [*command*]

Explains use of Ersatz-11 commands. Just type “HELP” for a list.

INITIALIZE

Initializes all emulated I/O devices, disables the MMU, sets the CPU mode to “kernel.”

LIST [*/switches*] [*addr*]

Disassembles eight instructions starting at the specified address if it is given, or otherwise at the first address following the last one disassembled by the most recent LIST or REGISTER command. The address space to use is specified by the switch(es), or the space from the last LIST command is used if none are given. The default for LIST is set to /CURRENT /INSTRUCTIONS after each register dump, either from a REGISTER command or from the register display from a STEP command or CPU halt. See the EXAMINE command for a list of valid switches.

LOAD [*/switches*] [*d:path\filename*].PDP] [*s*₁:*e*₁ *s*₂:*e*₂ ... *s*_{*n*}:*e*_{*n*}]

With no switches, loads the specified DOS file into PDP-11 memory (default extension is “.PDP”). Any number of address ranges “*s*_{*i*}:*e*_{*i*}” may be given, and data from the file will be loaded into each range in the order given in the command line. The last range may have no ending address, in which case file data are loaded until end of file is reached. If no ranges are given at all the default is to load the file at 000000. This command may be useful with binary files produced by Strobe Data Inc.’s PDPXASM cross-assembler.

With either the “/ROM” or “/EEPROM” switch, creates a ROM/EEPROM page and loads its contents from the file. The ROM contains a linear copy of the file contents, unless the “/BANKED” switch is also given, in which case it is banked through a 512.-byte window at either (17)773000 or (17)765000, using the page control register (see the “PCR” option under SET CPU). Only one address range may be given. If “/BANKED” switch is specified, the address range must be exactly 512. bytes long and must begin at one of the addresses given above. If “/EEPROM” is specified, the starting address must be (17)765000, so this address will be used by default, otherwise (17)773000 is the default. Otherwise, if only the starting address is given, the size of the ROM depends on the size of the file. If an ending address is given, the file must be large enough to fill that address range.

LOG *ddcu*: [[*d:path\filename*].LOG] [/APPEND]

(where *dd* is LP or TT.)

Logs all output to the specified character device in the specified file. If no filename is specified, any existing log file for that device is closed. The /APPEND switch means to append to an existing log file, rather than replacing it. The default filename extension is “.LOG”.

LOG *ddcu*: [[*d:path\filename*].LOG] [/APPEND]

(where *dd* is CT, DC, DF, DK, DL, DM, DP, DS, DT, DU, DX, DY, PD, MM, MS, MT, MU, DO, or HD.)

Logs commands sent to the TA11, RC11, RF11, RK11D, RL11, RK611, RP11C, RS03/04, TC11, MSCP, RX11, RX211, RXT11, TM03, TS11, TM11, or TMSCP controller, or the DOS file device or HD_SYS.EXE pseudo-controller, to the specified file. If no file is specified, the current log file, if any, is closed. The unit number is insignificant (except for Massbus devices, which effectively have separate controllers for each unit), all commands to the controller are logged regardless of the currently selected unit. The /APPEND switch means to append to an existing log file, rather than replacing it.

LOG XEn: [[*d:path\filename*].LOG] [*switches*]

LOG NI*n*: [[*d:path\filename*].LOG] [*switches*]

Controls logging of Ethernet events. If a filename is specified then the log file is opened. If switches are specified they specify what events are to be logged. “/[NO]COMMANDS” controls logging of port commands, “/[NO]RECEIVE” controls logging of received frames, and “/[NO]TRANSMIT” controls logging of transmitted frames. The switches may be specified when the log file is first opened, or later in LOG commands with the filename parameter missing to change what is being logged without having to open a new log file. If neither the filename nor any switches are specified, any existing log file for that device is closed. If no switches are specified when the file is first opened, the default is “/RECEIVE /TRANSMIT”. In addition, the /APPEND switch means to append to an existing log file, rather than replacing it.

MAP [*switches*] *addr*

Displays the physical address corresponding to the specified virtual address. The switches to specify the virtual address space are the same as the ones used with the EXAMINE command.

MOUNT *pdp11dev*: [*pdp11switches*] *pcdev* [*pdp11switches and/or pcswitches*]

Mounts a PC file or device as the specified PDP-11 block device. The PDP-11 disk/tape controller of the appropriate type is created if it did not already exist.

pdp11dev is the name of the PDP-11 device name being created. It conforms to the syntax defined in section 1.6. The first two letters define the controller type, and are generally the same as the PDP-11 operating system’s name for that device.

pcdev is the name of the PC device or filename to be used to emulate this particular PDP-11 drive. The possible names are described in chapters 4 and 5.

Switches specific to the controller type may appear either after the PDP-11 device name or after the PC device (or file) name, and are typically used to specify the drive type in case the controller supports more than one drive type. If no drive type switch is specified, the default type is usually based on the size of the PC device. All emulated controller types support the “/RO[NLY]” (syn. “/WP[ROTECT]”) switch, which has the same pressing the WRITE PROT (etc.) button on a real drive, and works even in cases like the RX01 where the real hardware had no write protection facility. A “/RW” switch exists for completeness and allows read/write access to the device, which is the default behavior. See chapters 4 and 5 for more information.

PRIMARY *n*

Switches the session number (in the range 1–12) being displayed on the primary (or only) video monitor. This command is equivalent to pressing Alt-F*n* on the keyboard, except that it may be issued from an initialization file or serial console without requiring that key combination to be typed manually on the PC keyboard.

PROCEED [*break*]

Continues PDP-11 execution at the address currently in the program counter. If “*break*” is specified, then it is the virtual address of a single hard breakpoint, where the PDP-11 is guaranteed to stop if an instruction fetch is attempted starting at that address, regardless of what mode the computer is executing in, and regardless of whether the contents of that location have changed since the breakpoint was set. This can be handy for tracing code that hasn’t been loaded yet. Note that hard breakpoints and single stepping with the STEP command interfere with the operation of the PDP-11 T bit, so don’t combine them with a debugger (or CPU traps diagnostic program) running on the PDP-11 or you’ll get strange behavior.

QUIT

Exit the simulator, closing all image and log files and resetting all devices that were in use.

REGISTER [*r val*]

reg=val

flag=val

If “*r*” and “*val*” are given, sets register “*r*” (0–7) in the current register set to contain “*val*.” Otherwise displays the values of all eight registers, the condition codes, the current and previous processor modes, and the current interrupt priority level. Registers and condition code flags may also be set by typing the register name, an equals sign, and the new value at the command prompt. Any expression that works with CALCULATE is valid in this case, so for example one may type “PC=PC-2.” The CPU priority may be set in the same way using “PRIO= *val*”, where *val* is from 0 to 7. Also the current mode and previous mode may be set with “CM=*x*” and “PM=*x*”, where *x* is K, S, or U for kernel, supervisor, or user mode.

SECONDARY *n*

Switches the session number (in the range 1–12) being displayed on the secondary video monitor (if any). This command is equivalent to pressing Ctrl-F*n* on the keyboard, except that it may be issued from an initialization file or serial console without requiring that key combination to be typed manually on the PC keyboard.

SET BREAK {*nnn* | NONE}

Sets the octal value of an ASCII character that can be used in place of a serial BREAK signal to pop up an E11 prompt. For example, “SET BREAK 020” will cause any CTRL/P character typed on TT0: to bring up an E11 prompt. The default value is “NONE”, meaning that all ASCII characters are passed through and only a serial BREAK, or a keyscript PROMPT command, will bring up the prompt. This command is intended for use in cases where the console (TT0:) has been ASSIGNED to a real serial port, connected to a terminal (or terminal program) that has difficulty generating BREAK signals.

SET CLOCK 14318*nnn*

Informs E11 of the actual frequency (in Hertz, as a decimal number) of the PC motherboard’s 14.318 MHz system clock used to derive the 50/60 Hz clock, among other things. This frequency is supposed to be 14318180 Hz (which is what E11 assumes by default), but if your PDP-11 OS’s clock gains or loses time at this setting due to the oscillator frequency being slightly off, you can use SET CLOCK to make slight changes, and E11 will adjust its math accordingly. The correct value can be determined experimentally, or measured using test equipment (this would require a very accurate frequency counter to be useful though). Setting values wildly different from 14318180 may produce unexpected results.

SET CPU *item* [*item* ...]

This command changes the emulated CPU type, either by changing to a new model all at once, or on a feature-by-feature basis. Each keyword enables a particular feature, or disables it if preceded by “NO”. Any number of keywords may be specified in one line, and they are applied left to right so for example “SET CPU 44 NOFPP” will create a PDP-11/44 and then delete its floating point processor. This gives you the ability to roll your own CPU, which need not correspond to any actual existing PDP-11 model. Changing the CPU’s type while it is running will work but is likely to crash the PDP-11 operating system. SHOW CPU displays the current settings of all options.

E11 does not emulate cache memory, since that would greatly slow down emulation rather than speeding it up. Maintenance features such as “write wrong parity” are not emulated either, since again they would needlessly add huge overhead and anyway since the data paths being tested by these modes are all different on a PC, PDP-11

diagnostic software would not gain any useful information by exercising them. So for these cases E11's emulation is limited to creating the appropriate registers in the I/O page so software can read and write them without losing data or receiving unexpected bus timeout errors. Note that if RSTS/E sees a parity CSR or KTJ11B maintenance CSRs it attempts to exercise them, giving a fatal error if they do not work. To avoid this problem, the CPU configuration given by SET CPU 94 has NOKTJ11B and NOPARCSR by default as a workaround. These CSRs may still be enabled for software that needs them with SET CPU 94 KTJ11B PARCSR, however both RT-11 and RSX11M+ will work with the default setting.

SET CPU options:

<i>number</i>	Set all CPU options to match PDP-11/ <i>number</i> model. Recognized values are 23, 24, 34, 35 (syn. 40), 44, 45 (syn. 50 or 55), 53, 70, 73, 83, 84, 93, 94.
ASH31	J11 CPU bug with 31-bit shifts using ASH/ASHC.
ASR	KDJ11E additional status register (TOY clock etc.).
CCR	Cache control register (at (17)777746).
CD	Cache disable bit in PDRs.
CDR[= <i>n</i>]	KDJ11x configuration/display register (at (17)777524), <i>n</i> is 8-bit DIP switch value.
CHR	Cache hit register (at (17)777752).
CHRNZ	If CHR is present, reads as non-zero.
CMDR	PDP-11/44 cache memory data register (at (17)777754).
CPUERR	CPU error register.
CSM	CSM instruction (requires SUPMODE to work).
DESTFIRST	Evaluate destination operand first in dual operand instructions with mode 0 source. Effect is to use incremented/decremented value of register as source with mode 2-5 destination using same register, or PC+2 for mode 07 source and mode 67 or 77 destination.
DSPACE	Split I/D space.
DUALREGSET	Dual register set.
EAE	KE11 Extended Arithmetic Element.
EIS	Extended (integer) Instruction Set.
EIS16	EIS instructions with odd destination set condition codes based on 16-bit result.
FIS	Floating Instruction Set (FIS option for PDP-11/35,40 and LSI-11).
FPA	Floating point accelerator, sets KDJ11x MR bit indicating FPJ11 present.
FPBACKOUT	J-11 SR1 behavior, autoinc/dec is always undone on aborted FPP instruction.
FPP	FP11 floating-point instruction set.
HALT4	HALT in user mode traps to 4 instead of 10.
JMP4	JMP <i>Rn</i> or JSR <i>Rn</i> traps to 4 instead of 10.
JMPPLUS2	JMP (R)+ and JSR X, (R)+ jump to incremented value of R (R+2).
KTJ11B	KTJ11B Unibus adapter maintenance registers.
MFPT[= <i>n</i>]	MFPT instruction (returns <i>n</i> in R0).
LKS7	Bit 7 (monitor) of LKS clock status register is mechanized.
MBR	PDP-11/70 microprogram break register (at (17)777770).
MSEA	Memory system error address register (at (17)777740/2).
MSER	Memory system error register (at (17)777744).
MMTRAPS	11/45,55,70-style memory management traps, 3-bit ACF.
MMU	Memory management unit.
MMU22	22-bit MMU (must use UMAP too if emulating Unibus CPU).
MR[= <i>n</i>]	Maintenance register (at (17)777750). If <i>n</i> <16., KDJ11x-style maintenance register which reads <i>n</i> as model code in bits 7:4. If <i>n</i> =44, PDP-11/44 style MR, and if <i>n</i> =70, PDP-11/70 style MR.
MXPS	MFPS, MTPS instructions.
ODD	Odd address trapping.

PARCSR	Parity/ECC memory CSR address (at (17)772100).
PCR[= <i>x</i>]	KDF11/BDV11 page control register and read/write register if <i>x</i> ="KDF11", or KDJ11 CSR/page control register if <i>x</i> ="KDJ11" (at (17)777520/2).
PIRQ	11/45-style 7-level software interrupts.
PSWIO	PSW accessible from I/O space (at (17)777776).
QBUS	Q-bus exists (otherwise Unibus).
SIZE	11/70 system size registers (at (17)777760/2).
SPL	SPL instruction.
SR	Switch register/display register (at (17)777570).
SR1	MMU status register 1.
STACKLIM	PDP-11/70 stack limit register (at (17)777774).
SUPMODE	Supervisor mode.
SYSID[= <i>n</i>]	PDP-11/70 system ID register (at (17)777764), returns <i>n</i> when read.
TSTSET	J-11 TSTSET, WRTLCK instructions.
UMAP	Unibus map (maps 18-bit I/O bus to 22-bit memory).
UNDOAUTO	Undo mode 2/3 autoincrements on bus error etc.

SET DELAY *device* *c*₁:*n*₁ *c*₂:*n*₂ ...

SET DELAY *device* *:*n*

Sets the number of instructions that the specified command opcodes appear to take to complete on the indicated device. The *device* may be DELUA, DL11, DOSFILE (the DOS file access pseudo-device), KW11L, LP11, PC11, RC11, RF11, RK11D, RK611, RL11, RP11C, RS03 or RS04 (synonyms), RX11 or RX211 (synonyms), TA11, TC11, TM03, TM11, or TS11. There may be an arbitrary number of parameters of the form "*c*:*n*" or "*c*=*n*", where *c* is the octal opcode for the command (or "*" for all commands for this device) and *n* is the decimal number of PDP-11 instructions to delay before signaling completion of the command.

The reason that device commands, such as "*read sector*" on an RX02, or "*transmit character*" on a DL11, delay signaling completion (by raising a "*ready*" flag and/or triggering an interrupt) instead of completing right away (which would seem natural in an emulator) is that some OS software contains assumptions that at least a certain number of instructions are guaranteed to be executed before a device is able to interrupt, even when interrupts from that device are enabled. The default interrupt delays are set for the "worst case", so that each one is long enough to avoid any known (or suspected) problems with DEC OS software. The SET DELAY command may be useful in cases where your OS needs a longer delay than the default, or in cases where your OS's treatment of a device is "clean" and you can gain a noticeable I/O speed increase by setting all the delays for that device to 1, or in cases where you're debugging OS software and want to test against variety of interrupt rates.

Note that some devices don't have numbered command opcodes per se, but the SET DELAY command syntax requires one anyway for consistency, and pseudo opcode numbers are assigned if necessary. On DL11 SLUs, opcode "0" refers to the delay between reading a character from the receiver buffer, and getting the interrupt for the next character (only if it's the second or later character of a function key sequence on an emulated VT100, all other keyboard interrupts correspond to actual asynchronous events). Opcode "1" refers to the delay between writing a character to the transmitter buffer, and getting the completion interrupt (for emulated VT100s — COM and LPT ports use real completion interrupts). Similarly, PC11 opcode "0" refers to how long it takes to read a character from paper tape, and opcode "1" refers to how long it takes to write one. An LP11 has only one opcode, which is "0" and corresponds to the same thing as opcode "1" of a DL11. An RK611 has only opcodes 0-17, but the SET DELAY command defines an opcode "20" which refers to the delay between the interrupt that acknowledges reception of a head movement command (which is itself delayed), and the "attention" interrupt which signals completion of the head movement. The RK11D emulation has a similar dummy opcode "10" which means the same thing, and the TA11 emulation has a dummy opcode "10" which defines the delay between character interrupts within a block. A KW11L has no opcodes, so opcode "0" sets the delay between simulated interrupts which are used to

catch up if clock interrupts are missed due to native PC file I/O taking more than 16.67 ms (or 20 ms in 50 Hz clock mode) to complete.

```
SET DISPLAY NONE
SET DISPLAY PORT n
SET DISPLAY LPTn:
```

If PORT is specified, specifies the 80x86 I/O address (as an expression with the same syntax as used by the CALCULATE command) of a word port which when written as a word, sets the 16-bit display register. Building the trivial hardware to support this is left as an exercise to the reader.

If a PC LPT port name is given, it specifies a port which has a multiplexed LED board plugged into it, and E11 will refresh each half on alternate 60 Hz (50 Hz) clock ticks. There's a little flicker but it works and requires no chips or power supply, just build your board so that the D0–D7 lines (pins 2–9 of the DB25) drive the anodes of the both the D0–7 and D8–15 LEDs (through the same set of eight 100 ohm resistors since only one set of LEDs will have their cathodes grounded at a time). Then add two NPN switching transistors (2N3904 etc.), one for each byte, with the emitters grounded (pin 25), each collector connected to the cathodes of all 8 LEDs for the appropriate byte, and the bases connected through 1K current limiting resistors to $\overline{\text{STROBE}}$ (pin 1) for the D0–D7 side, or $\overline{\text{INTT}}$ (pin 16) for the D8–D15 side. A bare PC board is available from D Bit at cost (\$14.68 plus shipping for the current batch, 12/94).

If NONE is specified, then the current DR value is available only from the SHOW DISPLAY command (the default condition).

```
SET DISPLAY {DR | BDR | R0 | PC}
```

Sets what register is displayed on a hardware LED display register (either the parallel port kind described above or the kind that plugs into a bus slot and is addressed by a word OUT instruction). By default the DR is displayed (i.e. the last word written to (17)777570), but the BDR (boot/diagnostic display register, i.e. the last byte written to (17)777524), or R0 or the PC may be selected instead, since the null jobs in some operating systems display a pattern in R0 (and the PC in some cases) during a WAIT instruction. The pattern may be used to get a rough idea of system load, and the R0/WAIT method is a standard way to display a number on the PDP-11/70, which has no display register address. For completeness, registers R1–R5 or SP may be selected too.

```
SET HERTZ {50 | 60}
SET HZ {50 | 60}
```

Sets the frequency of the KW11L line clock (startup default is 60). Ersatz-11 reprograms the PC timer chip for this rate to simulate line time clock interrupts, and then maintains a count in software so that it knows when to trigger BIOS 18.2 Hz interrupts; there is some jitter due to the BIOS interval being rounded down to the previous KW11L interrupt, but there is no cumulative error so the DOS clock is still correct when you exit from E11.

```
SET IDLE [NO]RELEASE
```

Sets the behavior when the emulated CPU is idle, i.e. halted or executing a WAIT instruction. RELEASE means to ask the host OS to release the current time slice. This way E11 won't hog 100% of the host CPU's time for no reason, however in OS/2's DOS box this is taken as a sign that E11 will be idle for some time so its priority gets reduced as a result, so this option should not be used. NORELEASE means E11 should just keep looping until there's something for it to do.

```
SET KEYBOARD [NO]SWAP
```

SWAP sets the keyboard handler to exchange the functions of the **Caps Lock** and left **Ctrl** keys for people who don't like the IBM Enhanced Keyboard. **NOSWAP** sets the handler back so that the keys work as marked.

SET [NO]SCOPE

Sets whether the console terminal is a scope or a hardcopy terminal, for the purpose of handling rubout characters typed at the "E11>" prompt. Mainly useful if the console is redirected to a COM port with a DECwriter (etc.) plugged into it. Also determines whether typing ^L at the command prompt will attempt to clear the screen.

SET SCROLL {HARD | SOFT}

Selects the mechanism used for video scrolling in emulated VT100 sessions. **HARD** scrolling offers superior performance (it works by programming the video board(s) to change the start address of the screen each time a full-screen scroll is needed), but may expose problems in video virtualization in GUI DOS boxes, or cause problems with TSRs that use the display. **SOFT** scrolling does things the slow obvious way, by copying the whole screen a line up on each line feed, and ought to work with anything. **HARD** scrolling is the default. You should try putting **SET SCROLL SOFT** in your **E11.INI** file if your display gets scrambled a few lines into each attempted E11 session.

SET SWITCH *n*

SET SWITCH PORT *n*

If **PORT** is specified, specifies the 80x86 I/O address (as an expression with the same syntax as used by the **CALCULATE** command) of a word port which when read as a word, gives the current 16-bit switch register value. Otherwise (**PORT** not specified), sets the value of the emulated SR to *n* (again as a **CALCULATE**-style expression).

SET *pcdevcu*: ...

Sets parameters for the specified PC device, with the optional controller letter and/or line number given using the usual device name syntax, see section 1.6. **SET** commands for real PC devices must be issued before the first **ASSIGN** or **MOUNT** command which uses that PC device. The PC device names are the same as those used on the right hand side of an **ASSIGN** or **MOUNT** command.

The rest of the command line consists of keywords appropriate to that device type. The valid **SET** parameters for each PC device type are listed in the section that describes that device. Multiple keywords may be specified on the same **SET** command, they will be processed in left-to-right order. The following **SET** parameters are common to many PC devices:

IRQ*n* Sets the IRQ number (0–15) used by an ISA (or PCMCIA) board to generate interrupts.

PORT=*nnnn* Sets the base I/O port address (in 80x86 I/O space) used by the board. Numbers are hex by default as long as they start with a digit (0–9), otherwise any expression may be used, the same as with **CALCULATE**.

SHARE Specified after an **IRQ*n*** parameter, **SHARE** means that the device has special ISA IRQ sharing hardware (as documented in the *IBM AT Technical Reference Manual*) so that more than one device may use the same IRQ at once. This hardware is relatively rare, most devices do not support this option.

Note that without this hardware, no more than one device may be actively using the ISA IRQ at the same time. So for example if you have a mouse attached to COM1 using IRQ4 and it has been

initialized by a mouse driver, E11 will not be able to use COM3 if it also uses IRQ4. An error message will be given if you try to issue an **ASSIGN** command for COM3.

SET commands are parsed left to right, and ISA IRQ sharing is disabled by an **IRQ n** keyword, so the **SHARE** keyword must appear to the right of the **IRQ n** keyword, or on a subsequent **SET** command.

PCI IRQ sharing works differently from ISA IRQ sharing, and does not need to be enabled explicitly with a **SET** command.

SET ddcu: ...

Sets parameters for the specified PDP-11 device. Possible parameters are as follows:

- BOOTSTRAP=option** Selects whether incoming *MOP* boot frames will be honored, specifies either the **BOOT** command parameters, or **DISABLE** (default) to disable network-initiated booting. Remote booting is not yet supported, so this command has no visible effect.
- CSR=nnnnnn** Sets the base CSR address to *nnnnnn* octal.
- CSR=FLOATING** Sets the base CSR address according to the PDP-11 floating CSR rules, for devices that support this scheme. CSR addresses for all floating devices are recomputed every time the device configuration is changed. **SHOW** commands will display “(F)” after an address that was chosen using **FLOATING**.
- ctrltype** Set controller type. This is mainly used to distinguish between Unibus and Q-bus versions of controllers, which differ in number of address bits used and whether they go through the Unibus map, and in some cases in other ways as well. **DEFAULT** means to choose a default controller type based on whether **SET CPU QBUS** is in effect. **SHOW** commands will display “(D)” after a controller type which was chosen using **DEFAULT**.
- DS/SS** Sets the disk to be single-sided or double-sided. Real RX211s autodetect this but 3.5” and 5.25” disks don’t have a separate index hole for DS disks, so the number of sides must be set explicitly.
- MODE** Sets the mode parameters for the specified port using a syntax similar to the DOS **MODE** command. The four parameters “*bps, par, dbits, sbits*” set the decimal number of bits per second (which unlike DOS **MODE**, may not be abbreviated, so “96” really means 96 baud not 9600), a single letter indicating the parity (“E” for even, “O” for odd, “N” for none, “M” for mark, “S” for space), a decimal number of data bits (5–8), and a decimal number of stop bits (1–2). This is mainly useful for DL11 type ports where the communications parameters are not set by software, for mux ports any parameters set with **SET MODE** will be overridden by the values written to the mux by the driver in the PDP-11 OS. Note that the set of valid baud rate values depends on the hardware emulating that port, if the value specified is not available E11 will use the closest rate the device supports.
- REWIND** Rewind the paper tape, so that subsequent input will start over at the beginning of the **MOUNTed** file.
- RH11** Sets this Massbus adapter (specified by controller letter, unit number is meaningless) to be an RH11. 18-bit addressing, goes through Unibus map if one is configured with **SET CPU UMAP**. This is the default for all Massbus disks and tapes.
- RH70** Sets this Massbus adapter to be an RH70. 22-bit absolute addressing, RHBAE/RHCS3 registers exist.
- VECTOR=nnn** Sets the base vector address to *nnn* octal.

VECTOR=FLOATING Sets the base vector address according to the PDP-11 floating vector rules, for devices that support this scheme. Vector addresses for all floating devices are recomputed every time the device configuration is changed. **SHOW** commands will display “(F)” after an address that was chosen using **FLOATING**.

SHOW BDR

Shows the current value of the boot/diagnostic display register (last value written to (17)777524).

SHOW BREAK

Shows the octal ASCII value of the character that can be used in place of a serial **BREAK** signal to bring up an E11 prompt. Default is **NONE**, meaning that only a genuine serial **BREAK** signal, or **PROMPT** keyscript command, will bring up the prompt, and all ASCII characters are passed through.

SHOW CLOCK

Shows the current assumed frequency, in Hz, of the PC motherboard's 14.318 MHz clock, used to generate the KW11L 50/60 Hz clock.

SHOW CPU

Shows emulated CPU type, along with breakdown of features, as well as the CPU type of the host processor.

SHOW CSR *addr*

Shows the name of the device register at the specified octal I/O page address.

SHOW DELAY *device*

Shows the currently active list of interrupt delay counts for the specified device, starting with the delay for opcode number 0. See **SET DELAY** for details.

SHOW DISPLAY

Shows the current value of the display register (last value written to (17)777570).

SHOW HERTZ

SHOW HZ

Shows the current frequency, in Hz, of the emulated KW11L line clock. The default is 60.

SHOW IDLE

Shows the **SET IDLE** setting, either **RELEASE** (release the host CPU when idle) or **NORELEASE** (keep polling until there is something to do).

SHOW KEYPRESS *keyname*

SHOW KEYRELEASE *keyname*

Shows the script currently bound to the keypress or keyrelease event for the specified key, if one is defined. See `DEFINE KEYPRESS` for key names.

`SHOW LED ledname`

Shows the name of the flag (from the keyboard script language) whose value is being tracked by the specified LED, or “NONE” if the LED has been disabled. LED names are `CAPS`, `NUM`, and `SCROLL`. See section A.4 for a list of flag names.

`SHOW MEMORY`

Shows the amount of PC memory used by Ersatz-11, how much of that memory is emulated PDP-11 memory, and how much PC memory is free. Free memory must be available in order to use the `ASSIGN`, `LOG`, or `MOUNT` commands.

`SHOW MMU [{KERNEL | SUPERVISOR | USER} [INSTRUCTION | DATA]]`

Shows the current mapping registers for the specified space. Defaults are `KERNEL` and `INSTRUCTION` space.

`SHOW VERSIONS`

Shows the version numbers of Ersatz-11, the operating system, and any other relevant interfaces.

`SHOW ddcu:`

Shows the configuration of the specified PDP-11 or PC device. The actual data shown are dependent on the device type, in general the display contains the information that can be `SET` for that device (e.g. controller type, or CSR/vector addresses), and for PDP-11 devices the name of the PC file or device attached with `ASSIGN` or `MOUNT` is shown. Not all devices support `SHOW`.

In the output from a `SHOW ddcu:` command, “(D)” following a controller type means that the controller type is set to “DEFAULT” and the displayed type is the default based on the “`SET CPU [NO]QBUS`” setting. Similarly, “(F)” following a CSR or vector value means that that parameter is set to “FLOATING” and the value given is the one currently in use based on the system configuration.

The default controller types and floating CSR or vector addresses are selected only for controllers that have actually been created with an `ASSIGN` or `MOUNT` command. If the controller does not currently exist then a defaulted type will simply be listed as “DEFAULT” and floating addresses will be listed as “FLOATING”.

`STEP [count]`

Executes the specified number (default=1) of single instruction steps and displays the updated registers after each. Note that if real time clock interrupts are enabled and the CPU priority is below 6, `STEP` will immediately enter the clock interrupt service routine instead of executing the instruction at the current PC. An easy workaround is to disable clock interrupts with “`D 17777546 0`” before using `STEP`, and then reenablen them with “`D 17777546 100`” before continuing regular execution.

`UNLOAD [/switches] [address]`

Unloads a ROM or EEPROM page previously loaded with “`LOAD`”. Either the “`/ROM`” or “`/EEPROM`” switch is required, “`/BANKED`” may be given to invoke the default starting addresses of (17)773000 for “`/ROM`” and (17)765000

for “/EEPROM”, otherwise the starting address of the ROM must be given.

Appendix A

Keyboard Script Language

The script language used by E11's `DEFINE KEYPRESS` and `DEFINE KEYRELEASE` commands is powerful, yet very easy to use. Unlike some systems where keys can have only characters or strings bound to them, E11 allows the user to attach a small script to each key so that more complicated operations can be defined. In particular, there's nothing special about the shift keys (Ctrl, Alt, Shift), they can be redefined to be data keys and vice versa.

When defining a new keyscript, it may be helpful to use a `SHOW` command to display the existing default keyscript for that key, or a similar one, and use it as the basis for writing the new keyscript. To make the keyboard send a character or string to the system, simply enclose that character or string in single or double quotes. `IF` statements can be used to send different strings depending on the state of a variety of flags (including the current state of the Alt, Ctrl, and Shift keys).

`NONREPEATING` and `NOREPEATS` commands are used in many of the default keyscripts to emulate the autorepeat behavior of the VT100 keyboard precisely. `NONREPEATING` tells E11 that this keyscript should not be autorepeated even if the key is held down (like the VT100 Esc, Tab, and Return keys), and `NOREPEATS` means that while this key is pressed, all other keys should be prevented from autorepeating (which is what the VT100 Ctrl key does). There are numerous other special-purpose commands that allow such things as sending the current date and/or time in a variety of formats, popping up the E11 command prompt, and switching the video display to show another session.

Multiple statements in a single key definition may be separated by `:"` or `\` characters and count as one statement (for the purposes of the `IF/ELSEIF/ELSE/ENDIF` construct). If a line ends with `&` (with no white space following) it is continued on the next line, and any characters after the first `!` that is not inside single or double quotes are considered a comment and are ignored (up until the trailing `&` if one is present). This should be familiar to BASIC-PLUS users.

A.1 Default keyboard layout

The keypad layout generated by E11's predefined keyscripts may take a little getting used to but it's intended to be familiar if your fingers are already comfortable using KED or EDT on a real VT100. Just don't look at the keypad, the keys are where you expect in spite of having the wrong labels. Similarly, the `CTRL` characters on the main keyboard are in the same places as on a VT100, including the non-alphabetic ones (e.g. `CTRL/SPACE` generates `NUL`, `CTRL/~` generates `RS`, etc.). The "backspace" key generates `DEL` because that's what DEC operating systems

normally use, use CTRL/H to get a backspace character. Line feed is CTRL/J, and on 104-key keyboards it's also the "context menu" key next to the right-hand Ctrl key.

The keypad digits and "." key work as marked (you must be in Num Lock mode to get this on 84-key keyboard, it doesn't matter on 101- or 104-key keyboards). The keys around the top and right edges of the keypad are *not* as marked, but correspond to the PF1–PF4, hyphen, comma, and ENTER keys of the VT100. The comma key is missing unless you have an 84-key AT keyboard. Northgate *Omnikey 102* keyboards have an "=" key where the VT100 comma belongs but unfortunately there is no way for software to distinguish it from the =/+ key on the main keyboard so E11 can't use it as a comma, F8 must be used instead. To get the normal function of the Num Lock key (and Esc, Scroll Lock, and Sys Req on an 84-key AT keyboard), press Alt, Ctrl, or Shift at the same time (it doesn't matter which). The VT100 keypad hyphen, comma, period, and ENTER keys are also available as the F6, F8, F9, and F10 keys (see below). On an IBM AT 84-key keyboard (which has the F-keys stacked vertically) this gives the same layout as the right-hand edge of a VT100 keypad.

If your keyboard has an F12 key, pressing it will send the current date and time in the format "*hh:mm:ss dd-mm-yyyy*," unless you DEFINE it to do otherwise. This is intended to be useful when starting an RSX or IAS system.

A.2 Keyboard script statement descriptions

string

Sends the specified string. The string may be any combination of double quoted strings ('*string*'), single quoted

strings (*'string'*), and single ASCII characters (`CHR$(n)`), all concatenated with plus signs (+). Note that PDP-11 serial ports normally have only one or two characters worth of input buffering, and E11 currently buffers 32 characters per port in addition to that (this number may increase in the future), so it is not possible to send arbitrarily long strings.

AMPM

Sends "AM" or "PM" depending on whether the time read by `GETTIME` is before or after noon.

CLEAR *flag*

Clears a read/write flag. See section A.4 for a list of flag names.

DAY1

Sends the 1- or 2-digit day of the month (1–31) as read by `GETTIME`.

DAY2

Sends the 2-digit day of the month (01–31) as read by `GETTIME`.

GETTIME

Reads the current date and time (as an atomic operation to avoid race conditions) and stores it internally for use by `HOUR2/MINUTE2/SECOND2` etc. `GETTIME` should be executed once before any sequence of commands that sends the various date/time fields. This is done explicitly, instead of having each individual command get the time itself before sending its field, in order to ensure that all the fields are coordinated and don't contain mismatched data if the clock rolls over while the date/time string is being composed. Without a preceding `GETTIME` statement, the statements that send the individual parts of the date/time will send garbage.

HOUR1

Sends the 1- or 2-digit hour of the day (0–23) as read by `GETTIME`.

HOUR12

Sends the 1- or 2-digit hour (1–12) as read by `GETTIME`.

HOUR2

Sends the 2-digit hour of the day (00–23) as read by `GETTIME`.

HUNDREDTH2

Sends the 2-digit hundredth of a second (00–99) as read by `GETTIME`.

```
IF <expr1> THEN &
  [statement1] &
ELSEIF <expr2> THEN &
  [statement2] &
...

```

```
ELSE &
  [statement3] &
ENDIF
```

Executes statements conditionally. The expressions may be made up of any combination of read-only and read/write flags (see section A.4 for a list of flag names), the operators AND, NOT, OR, and XOR, and parentheses (to override the default binary operator precedence, which is NOT, AND, and OR/XOR from highest to lowest with OR and XOR being equal).

If the expression after the IF is true, the statement (which may actually be multiple statements separated by “:” or “\” characters) following the THEN is executed, and after that execution then skips to after the ENDIF. Otherwise the expression following the ELSEIF (if any) is similarly tested, followed by any successive ELSEIFs if the first fails. Finally the ELSE clause (if any) is executed if no (ELSE)IF was true. This is pretty much the same as FORTRAN-77 or any language with block-structured IFs.

The ELSEIF keyword is provided as a convenience to avoid excessive nesting:

```
IF a THEN &
  x &
ELSEIF b THEN &
  y &
ELSE &
  z &
ENDIF
```

is equivalent to:

```
IF a THEN &
  x &
ELSE &
  IF b THEN &
    y &
  ELSE &
    z &
  ENDIF &
ENDIF
```

LETTER *string1*

Acts as a normal alphabetic (“letter”) key. *String1* is a one-character string. If CTRL is true, *string1* is sent with the high 3 bits set to 0. Otherwise if CAPS or SHIFT is true then *string1* is sent with bit 5 set to 0. Otherwise *string1* is sent with bit 5 set to 1. This has the effect of converting it to lower or upper case as appropriate, and converting it to the correct control character if CTRL is true, assuming it’s a US-ASCII alphabetic character.

MINUTE2

Sends the 2-digit minute (00–59) as read by GETTIME.

MONTH1

Sends the 1- or 2-digit month (1–12) as read by GETTIME.

MONTH2

Sends the 2-digit month (01–12) as read by `GETTIME`.

MONTH3

Sends the 3-letter English month abbreviation (`Jan–Dec`) as read by `GETTIME`.

NONDATA

Specifies that the current key is not a data key and should not generate keyclick (if E11 supports it in the future) or count from a “`SET flag FOR n`” prefix.

NONREPEATING

Specifies that the current key should not auto-repeat.

NOREPEATS

Specifies that the current key should prevent all other keys from auto-repeating until it is released.

NUMBER *string2*

Acts as a normal numeric (“number”) key. *String2* is a two-character string. If `CTRL` is true, nothing is sent. Otherwise if `SHIFT` is true then the second character of *string2* is sent. Otherwise the first character of *string2* is sent.

PRESS *keyname*

Executes the “keypress” script for the specified key, i.e. the script defined by `DEFINE KEYPRESS` for that key.

PRIMARY *n*

Changes the screen on the primary video (or only) display to screen *n* (1–12).

PROMPT

Pops up an E11 command prompt. The primary video display is switched to `TT0:`’s screen if it is not already there.

RELEASE *keyname*

Executes the “keyrelease” script for the specified key, i.e. the script defined by `DEFINE KEYRELEASE` for that key.

RSTSAMPM

Sends “AM” or “M” or “PM” depending on the time read by `GETTIME`, using the unusual rules used by pre-V9.0 versions of RSTS/E:

00:00–00:00:59.99 is PM (the minute starting at midnight)

00:01–11:59:59.99 is AM as usual

12:00–12:00:59.99 is M (the minute starting at noon)

12:01–23:59:59.99 is PM as usual

SECOND2

Sends the 2-digit second (00–59) as read by **GETTIME**.

SECONDARY *n*

Changes the screen on the secondary video display to screen *n* (1–12). This is useful only on systems with two video displays, and performs no operation on systems with only one.

SET *flag* [FOR *n*]

Sets a read/write flag. See section A.4 for a list of flag names. If the “FOR *n*” modifier is given, it means that the flag is set for the specified non-zero number of data keystrokes, and then automatically clears after the script for the *n*th keystroke is executed. This is used for the prefix keys common on non-English keyboards, and can also be useful for handicapped users. Note that the current key (the one whose keyscript contains this “SET ... FOR *n*” command) counts from the total unless a **NONDATA** statement is part of its definition.

Example using **SET** to redefine the right-hand **Alt** key as an “acute accent” prefix key, which makes the vowel keys send the ISO Latin-1 codes for the same letters with acute accents when pressed immediately afterwards:

```
DEFINE KEYPRESS RALT = SET FLAG1 FOR 1 : NONDATA
DEFINE KEYPRESS A = IF FLAG1 THEN LETTER CHR$(193) ELSE LETTER 'A' ENDIF
DEFINE KEYPRESS E = IF FLAG1 THEN LETTER CHR$(201) ELSE LETTER 'E' ENDIF
DEFINE KEYPRESS I = IF FLAG1 THEN LETTER CHR$(205) ELSE LETTER 'I' ENDIF
DEFINE KEYPRESS O = IF FLAG1 THEN LETTER CHR$(211) ELSE LETTER 'O' ENDIF
DEFINE KEYPRESS U = IF FLAG1 THEN LETTER CHR$(218) ELSE LETTER 'U' ENDIF
```

TOGGLE *flag*

Toggles a read/write flag. See section A.4 for a list of flag names.

UCMONTH3

Sends the 3-letter upper case English month abbreviation (JAN–DEC) as read by **GETTIME**.

YEAR2

Sends the 2-digit year (00–99) as read by **GETTIME**.

YEAR4

Sends the 4-digit year (1980–2099) as read by **GETTIME**.

A.3 Key names

This section defines the key names used for **DEFINE KEYPRESS**, **DEFINE KEYRELEASE** commands, and **PRESS**, **RELEASE** statements. Keycap descriptions are for US English keyboards and may differ on keyboards designed for other languages. For most of these keyboards the physical layout is close to the US layout so name of the key that would

be in the same position on a US keyboard should be used in script language definitions. Keys labeled “EKB only” exist only on the 101-key “Enhanced” keyboard and the 104-key “Windows 95” keyboard. It is not considered an error to bind keyscripts to them even when only an 84-key AT keyboard is present, but keyscripts for keys that are missing will never be executed.

,	
*	* key on keypad, or  key if present
,	
-	
.	
/	
0–9	Numeric keys (top row of main keyboard)
;	
=	
A–Z	Alphabetic keys
BACKSPACE	Backspace key (top right of main keyboard)
CAPSLOCK	Caps Lock key
CONTEXT	Context Menu key (104-key keyboard only)
DARROW	Down arrow key (EKB only)
DEL	Del (EKB only)
END	End (EKB only)
ENTER	Enter
ESC	Esc
F1–F12	Function keys (F11, F12 are on EKB only)
HOME	Home (EKB only)
INS	Ins (EKB only)
KP0–KP9	Numeric keys on keypad
KPENTER	Enter key on keypad (EKB only)
KPMINUS	- key on keypad
KPPERIOD	. key on keypad
KPPLUS	+ key on keypad
KPSLASH	/ key on keypad (EKB only)
LALT	Left (or only) Alt key
LARROW	Left arrow key (EKB only)
LCTRL	Left (or only) Ctrl key
LSHIFT	Left Shift key
LWIND	Left “Windows” key (104-key keyboard only)
NUMLOCK	Num Lock key
PAUSE	Pause key (EKB only) — N.B. most keyboards send the “release” code for this key immediately after the “press” code, rather than waiting until the user actually releases the key, so it would not be useful to try to redefine this key as a shift key
PGDN	PgDn (EKB only)
PGUP	PgUp (EKB only)

PRSCR	Print Screen key (EKB only)
RALT	Right Alt key (EKB only)
RARROW	Right arrow key (EKB only)
RCTRL	Right Ctrl key (EKB only)
RSHIFT	Right Shift key
RWIND	Right “Windows” key (104-key keyboard only)
SCRLOCK	Scroll Lock key
SPACE	Space bar
SYSREQ	Sys Req (84-key keyboard only)
TAB	Tab
UARROW	Up arrow key (EKB only)
[
\	
]	
‘	

In addition to the above, the following keywords define keys that don’t exist on most keyboards, for completeness in case they are useful on special-purpose keyboards:

KEY00	Sends scan code 00 hex
KEY55	Sends scan code 55 hex
KEY56	Sends scan code 56 hex (unmarked key on some keyboards made by Focus)
KEY59	Sends scan code 59 hex
KEY5A	Sends scan code 5A hex
KEY5E	Sends scan code 5E hex
KEY5F	Sends scan code 5F hex

A.4 Flags

The keyboard script language has a number of boolean flags, which may be used in keyscripts and `DEFINE LED` commands. They are broken into two groups: read/write flags, and read-only flags.

A.4.1 Read/write flags

Read/write flags can be tested or modified by keyscripts. Their values may be used in `IF` expressions or `DEFINE LED` commands, or they may be changed using `SET`, `CLEAR`, and `TOGGLE` statements. The descriptions below are only defaults used by E11’s initial keyboard definitions, the user is free to redefine them at will.

CAPS	Caps Lock state
FLAG n	User-defined flags ($n=1-4$), reserved for user keyscripts
LALT	Left (or only) Alt key state

LCTRL	Left (or only) Ctrl key state
LSHIFT	Left Shift key state
NUM	Num lock state
RALT	Right Alt key state
RCTRL	Right Ctrl key state
RSHIFT	Right Shift key state
SCROLL	Scroll lock state

A.4.2 Read-only flags

Read-only flags can be tested by keyscripts but not modified. Consequently they may be used in IF expressions or DEFINE LED commands only, the values are maintained and updated by E11 itself.

ALT	OR of LALT and RALT
APPKEYPAD	Applications keypad mode (ESC =)
CHARSETA	Character set A (UK) is currently selected
CHARSETB	Character set B (US) is currently selected
CHARSET0	Character set 0 (graphics) is currently selected
CHARSET1	Character set 1 (undefined) is currently selected
CTRL	OR of LCTRL and RCTRL
CURSORKEY	Cursor key mode (ESC [?1h)
EKB	True: 101-key Enhanced (or 104-key W95) keyboard, false: 84-key AT keyboard
G0	G0 character set is selected (SI)
G1	G1 character set is selected (SO)
L1	keyboard LED 1 is lit (ESC [1q)
L2	keyboard LED 2 is lit (ESC [2q)
L3	keyboard LED 3 is lit (ESC [3q)
L4	keyboard LED 4 is lit (ESC [4q)
NEWLINE	Newline mode (ESC [20h)
SHIFT	OR of LSHIFT and RSHIFT
VT52	VT52 mode (ESC [?2l)

Appendix B

Debugging Features

Ersatz-11 provides a full assortment of debugging commands. These can be useful for PDP-11 program development, and can also be invaluable for troubleshooting configuration problems, or for providing detailed information to D Bit when reporting a problem in Ersatz-11 itself.

Real PDP-11s all provide some form of programmer's console. This can be either a traditional binary "switches and lights" front panel, an octal keypad and LED display, a simple ASCII console emulator program running out of ROM, or the "Micro-ODT" program implemented in microcode in systems based on the LSI-11, DCF11, and DCJ11 chip sets. Regardless of the implementation, the programmer's console provides some way to examine and deposit memory, inspect and modify the general registers and processor status word, and control program execution.

E11 provides all of this functionality, as well as many more features, using the interactive "E11>" command prompt, which can be popped up at any time by pressing Shift-Enter. Most of the commands related to program debugging can be abbreviated to one letter, to save typing, and the user can further streamline the debugging process by binding often-used commands to a single keystroke using `DEFINE` `KEYPRESS` commands.

Debugging commands:	
ASSEMBLE	Assemble PDP-11 code into memory
C= (etc.)	Set condition flag value
CALCULATE	Evaluate an expression (abbreviation = "&")
CM= (etc.)	Set current/previous processor mode
DEPOSIT	Deposit into memory or I/O page registers
DUMP	Dump memory to a file
EXAMINE	Examine memory or I/O page registers
FPREGISTER	Display/change floating point registers
GO	Start program execution
HALT	Halt program execution
INITIALIZE	Initialize CPU (like RESET instruction)
LIST	List disassembled PDP-11 code
LOAD	Load a binary file into memory
LOG	Log disk/tape/Ethernet controller commands to a file
MAP	Translate virtual address to physical address
PRIO=	Set processor priority
PROCEED	Proceed with execution, with an optional breakpoint
RO= (etc.)	Set general register value
REGISTER	Display general registers and PSW fields
SET DISPLAY	Set up hardware display register
SET SWITCH	Set up switch register (real or virtual)
SHOW CSR	Display name of any I/O page register
SHOW DISPLAY	Inspect value of display register
SHOW MEMORY	Show E11 memory usage
SHOW MMU	Display MMU maps
SHOW VERSIONS	Show version numbers of E11 and host OS
STEP	Execute one (or several) single program step

B.1 Displaying and modifying memory

Memory may be displayed or modified one word at a time using the EXAMINE and DEPOSIT commands. Both can accept switches that define the virtual address space to use. If no switches are specified, the default is to use the same space as the previous EXAMINE or DEPOSIT command. Any switch used on either command sets the default for both commands.

These commands can also operate on multiple memory words. Normally when only one address is specified, the EXAMINE command will display just one word, but if a starting and ending address is specified, that entire range, no matter how large, is displayed on the terminal. If an EXAMINE command is given with no address whatever, it displays eight words starting at the word following the last EXAMINE command. Multiple words can be entered into memory by simply entering more than one number following the address in a DEPOSIT command. The numbers are entered into consecutive words of memory starting at the specified address. For convenience, these commands may be abbreviated to E and D.

B.2 Assembly and disassembly

The **ASSEMBLE** and **LIST** commands display or modify memory in very much the same way as the **EXAMINE** and **DEPOSIT** commands, except that they accept and display assembly language source instead of octal data. Both commands accept optional switches to set the virtual address space to use, and if no switches are specified the default is to use the same virtual address space from the previous **ASSEMBLE** or **LIST** command.

The **ASSEMBLE** command starts the assembler at the specified address, or if no address is specified the default is to continue assembly at the next address following the last line assembled by the previous **ASSEMBLE** command. E11 prompts for each line, giving the address where it will be entered into memory. Entering a blank line (or typing CTRL/C) returns to the E11 command prompt.

The **LIST** command lists eight lines of code starting at the specified address, or if no address is specified then eight lines of code are disassembled following the last line displayed by the previous **LIST** command or **REGISTER** display. Two addresses can be given, to produce a disassembly of all code in that range of addresses.

B.3 Registers

The PDP-11 registers may be displayed at any time using a **REGISTER** command (**R** for short). This displays all of the registers and PSW flags at once. Individual registers may be displayed using commands like **& R3**. Any value that is displayed by the **REGISTER** command may be set using the same keywords as is used in the display. For example, if the register dump includes **"C=1"** and **"PM=U"** to indicate that the carry flag is set and the previous mode is "user", it is possible to clear the carry flag by typing **"C=0"**, or change the previous mode to "supervisor" by typing **"PM=S"**. And of course the general registers may be changed with commands such as **"R3=100"**, or even **"SP=SP+4"**.

The FP11 floating point processor state may be inspected using the **FPREGISTER** command. However it is less flexible than the regular **REGISTER** command, all register values are displayed and set using octal numbers.

B.4 Breakpoints and single-stepping

The **PROCEED** command takes an optional numeric argument, which is a PC value. PDP-11 instruction execution will halt whenever that address is reached. This is done using address comparison, rather than by depositing anything into memory (regular PDP-11 debuggers do breakpoints by inserting a **BPT** instruction into memory), which means it works even if the memory contents are overwritten before the breakpoint is reached.

STEP allows proceeding one instruction at a time. If a numeric argument is specified, it gives the number of steps to perform, with a default of one step. This command can be abbreviated to **S** so that it may be typed quickly. For even greater convenience, a key may be redefined to enter this command with a single keystroke. For example:

```
def key kpplus = 'step'+chr$(13)
```

This will cause a step to be executed every time the keypad + key is pressed.

The **GO** command starts execution at full speed, with no breakpoints or single stepping. An optional starting

address may be given. If it is omitted, execution continues at the current PC value. Unlike some versions of ODT, E11 does not issue an implied INIT pulse with either the GO or PROCEED command. If necessary the system may be initialized, including all emulated devices and bus adapters, using a separate INITIALIZE command.

B.5 Memory mapping

E11 can display the current status of the memory management unit at any time using the SHOW MMU command. There are two optional arguments, the mode (KERNEL, SUPERVISOR, or USER) and the space (INSTRUCTION or DATA). Both may be abbreviated to one letter, and the defaults are KERNEL INSTRUCTION. The display for each page gives the starting virtual address, starting physical address, block limits, access, and the A (accessed) and W (written) dirty bits. Also, the current values of MMR0 through MMR3 are displayed (MMR3 is omitted if the current CPU emulation doesn't include MMR3).

The MAP command may be used to compute a physical address, given a virtual address. It takes the same switches as the EXAMINE and DEPOSIT commands, to give the mode and space parameters for the virtual address. It displays the resulting 22-bit physical address, as if it had been processed by the MMU during a PDP-11 instruction. However, like the EXAMINE and DEPOSIT commands, the MMU's status is not affected by this command, so the A bit will not be modified in this page's PDR, and no MMU abort will occur if the page is marked "no access" or the address is outside of the range of valid blocks in that page.

The SHOW CSR command displays a one-line description of an emulated CSR on the I/O page, given its address. It works only on devices which are currently configured.

B.6 Device logging

Although the controller LOG commands are provided mainly as an aid to reporting Ersatz-11 problems to D Bit, they can be invaluable to users who are debugging device drivers or boot blocks. When logging is enabled for a given disk, tape, or network controller, every command issued to that controller by the PDP-11 is recorded in the log file with a time stamp. Other parameters such as buffer addresses and lengths, unit numbers, disk addresses, and tape record lengths, are recorded too, and for some devices the command's completion status is saved as well. For Ethernet devices, switches on the LOG command line give independent control over logging of host commands, transmitted packets, and received packets.

B.7 Loading and dumping memory

The LOAD and DUMP commands may be used to transfer between PDP-11 memory and files on the host system. An optional series of address ranges may be specified to do scatter/gather transfers. If no addresses are specified, the transfer starts at the beginning of memory and goes until the end of the files (for LOAD) or the end of memory (for DUMP).

B.8 Switch and display registers

The `SET SWITCH` and `SHOW DISPLAY` commands give access to emulated switch and display registers, which work the same way as those on the binary front panels on early PDP-11 models. The switch/display register is located at address 17777570 as long as a `SET CPU SR` command, or some other `SET CPU nn` command which includes `SR`, has been issued. This provides a crude one-word I/O register which can be accessed by a program running in kernel mode, for things like displaying checkpoint information during debugging.

Simple hardware can be attached to E11's switch register and display register emulations using `SET` commands. A simple display register which connects to an LPT port is available from D Bit as a bare PC board.

Appendix C

Dates and Times

Ersatz-11 has several features that facilitate passing date and time information back and forth between the host system and the PDP-11 operating system. The PC clock can be read or written from the PDP-11, and E11 can simulate a software bootstrap of RT-11 and RSTS/E so that these systems will pick up the current time as if they were started with a warm boot from a monitor that was already running.

C.1 Booting

RT-11 and RSTS/E both have methods for discovering whether they were software booted by another similar system which was running immediately before them, and if so they can “inherit” the time and date from that system. E11’s `BOOT` command can simulate this situation. If you use it with a `/RT11` or `/RSTS` switch, it obtains the current PC date and time and passes it on to the PDP-11 operating system.

E11’s keyscrip language has commands which allow composing a time and/or date string in almost any format, so that it may be entered with a single keystroke. The default keyscrip for the F12 key sends the current time and date in a format accepted by recent versions of RSX, so it may be pressed in response to the date/time prompt at system startup. See Appendix A for information on keyscrip commands, and type `SHOW KEY F12` at the E11 command prompt to see how the existing binding works.

Newer versions of DEC operating systems have support for the KDJ11E TOY clock, which E11 emulates using the host operating system’s clock. For example, the RSX `“TIM /SYN”` command will read the RSX time from the PC, and `“TIM /SETTOY”` will set the PC clock from the RSX time. These commands work only if RSX has detected a KDJ11E-based CPU (i.e. PDP-11/93 or PDP-11/94), however E11 can add the TOY clock to any CPU emulation by adding `ASR` to the end of the `SET CPU` command (since the TOY clock is accessed through the Additional Status Register). A `TOY.TSK` program is available from `ftp.dbit.com` which has `/SYN` and `/SETTOY` switches which work just like the `TIM` command, but with no restriction on the CPU type, and it doesn’t have the year 2000 problem that `TIM /SYN` did in earlier versions of RSX.

C.2 PC clock

PCs don't have a 50/60 Hz line frequency clock, so E11 simulates the KW11L style clock by reprogramming the PC's crystal-controlled interval timer for 50 or 60 Hz (the `SET HZ` command selects which frequency, the default is 60 Hz). These speeds can not be produced precisely by the PC's interval timer (it uses rather odd numbers since its master clock is the 14.31818 MHz ISA bus clock fed into a divide-by-12 counter), so E11 programs it as close as possible to the right value, and then uses fractional math to decide when to insert "leap ticks" so that the average rate will be exactly 50 or 60 Hz. In practice, this is not perfectly accurate because many (or most) PCs don't have a very accurate 14.31818 MHz clock to begin with. So their clocks tend to gain or lose time regardless of what applications software or operating system is running.

E11's solution to this is the `SET CLOCK` command, which allows adjustment of the actual master clock frequency value (which can be specified in 1 Hz increments) which E11 uses to calculate the interval clock divisor and schedule leap ticks. There's no need to actually measure the master clock frequency on the PC's motherboard, simply experimenting with values can greatly improve the accuracy and of course letting the system run for a while and then checking its clock will allow you to figure out the exact drift.

C.3 Year 2000 issues

Ersatz-11 has no year 2000 issues of its own. It does very little manipulation of dates, and when dates are handled internally it uses 16 bits to hold the year, which is enough to last until the year 65,535 AD. However problems do occur when translating dates to and from the formats required by the various PDP-11 operating systems, the PC operating system, and the KDJ11E TOY clock. Also the `YEAR2` keyscript command sends only 2-digit years, but it's there for the specific purpose of working with non-Y2K-compliant PDP-11 software. If the PDP-11 software can handle 4-digit dates, use `YEAR4` instead, which is what's used in the default keyscript for F12 anyway.

C.3.1 KDJ11E TOY clock

The Dallas Semiconductor DS1215 clock chip used in the KDJ11E battery-backed time-of-year ("TOY") clock contains only two digits for the year. Therefore it inherently suffers from the year 2000 bug, and so must any accurate emulation of it, including the one in E11, otherwise it would be incompatible with PDP-11 software designed for the real thing. However this is not as bad as it might seem. Since the TOY clock is used only to hold the *current* time, the only ambiguity that the PDP-11 software has to resolve is what century it is *now*. This is as opposed to dates held in data bases, file systems timestamps, etc., which can represent past and future dates and so must not be ambiguous. The latest versions of the PDP-11 operating systems have been updated to use a 100-year window when interpreting the year read from the TOY clock. For example 80-99 can be taken to mean 1980-1999, and 00-79 would mean 2000-2079. Future PDP-11 operating system releases can move this window (at this point 00-99 might as well mean 2000-2099), so this scheme can be extended indefinitely.

C.3.2 Dates in RT-11

Older versions of RT-11 used only 5 bits to store the year, as the number of years since 1972. This format stops working on 01-Jan-2004, and the older RT-11 versions have year 2000 problems too so they've already stopped working anyway. Newer versions of RT-11 adapt two previously unused bits in the date word to extend the year

offset to 7 bits, which will last until 31-Dec-2099. RT-11 V5.7 is the first version that fully implements this change in all utilities as well as the monitor. TSX-Plus V6.50 also supports the 7-bit year field, so when installed on top of RT-11 V5.7 it too will last until 31-Dec-2099.

C.3.3 Dates in RSX

RSX's internal date format uses a 16-bit word to hold the number of years since 1900. This format will last for many millennia, and it's unusual in that it allows going back all the way to 1900 so that dates in the low 2000s really are ambiguous when expressed in only two digits. Current versions of RSX accept four-digit years in user commands and process them correctly, but older versions are limited to two-digit years which are all assumed to be in the 1900s. Also, the Files-11 ODS-1 disk structure used by RSX and IAS uses only 2-digit years, stored as ASCII digits rather than binary values. Newer versions of RSX extend this format for several more centuries by allowing the "10s" digit to take on the value of characters which follow "9" in the ASCII code.

C.3.4 Dates in RSTS/E

RSTS/E uses the same date format as the old DOS/BATCH system. This consists of the number of years since 1970, times 1000 (decimal), plus the day within the year, stored as a 16-bit word. In older versions of RSTS/E this word was signed, so its maximum usable value was 32365., or 31-Dec-2002. Again, year 2000 problems with INIT.SYS's time/date parser prevented getting even that far. Newer versions of RSTS/E have changed to using an unsigned date word (negative values were never allowed anyhow), so now it lasts until 31-Dec-2035. Unfortunately RSTS/E's extension to the date format is not applicable to the few remaining DOS/BATCH systems, since DOS/BATCH uses the sign bit of the date word in directory entries to flag a file as contiguous, so it's not available for expansion of the date word. Multiplying the year offset by 1000 makes for very sparse usage of the available date word values, so there is room for expansion of the date format (using day-within-year values from 367 to 999) if that ever becomes necessary.

C.3.5 Dates in Fuzzball

Although the Fuzzball operating system emulates the RT-11 system calls, it actually uses its own 14-bit date format internally instead of RT-11's format. This is encoded as the number of days since 01-Jan-1972, so it runs out in 2016. Fuzzball has year 2000 problems, but replacement modules are available from ftp.dbit.com to make it work until 2016. The date format could be extended to 16 bits, but that would require relocating the flags that currently go in the high 2 bits of the date word, and the .GDAT system call would require an incompatible change to support that.

C.3.6 Dates in Unix

Unix (and Unix-compatible) systems normally store dates as a signed number containing the number of seconds since midnight UTC on 01-Jan-1970. The type that this value is stored in ("`time_t`") is normally a 32-bit signed integer (in some cases this is true even on Unix systems that run on 64-bit processors), which means that this format will run out in early 2038. This limit applies both to PDP-11 Unix systems being run under emulation, as well as 80x86 Unix or Linux systems being used as the host environment for Ersatz-11.
