

CoolCam 1.2 adds support for running AppleScripts, allowing you to further customize how CoolCam operates. The 'Scripts' folder contains scripts that are automatically executed by CoolCam whenever certain events occur. These are:

- Before Capture - this script is executed immediately before the image is captured
- After Capture - this script is executed immediately after the image has been captured
- On Open - this script is executed when you open the CoolCam application
- On Quit - this script is executed when you quit the CoolCam application

You can modify these scripts using the Script Editor application to customize CoolCam's behavior. For example, you can have CoolCam dial into your ISP before capturing an image, and disconnect after the image has been uploaded. You can also have CoolCam warn you by beeping before an image is captured.
