

name

String

Name of a variable

Get pointer returns a pointer to name, the variable specified by name. The variable does not need to exist before Get pointer is executed. Only variables and arrays can be referenced with this function.

The following example sets a series of variables named CB1, CB2,..., CB20 to 1:

```
For ($i;1;20)
    $p = Get pointer ("CB" + String ($i)) ` Get pointer to next var
    $p»:=1 ` Set the variable
End for
```
