

## 3.2 Release Notes: UserManager

### **New Features**

The following features have been added to the UserManager application since Release 2.0.

- UserManager sets the default language of the user when the user's home directory is created.
- UserManager is integrated with SimpleNetworkStarter to allow the selection of home directory servers from a pop-up list in the simple entry form.
- UserManager starts adding users after 100 instead of 21.

### **Known Problems and Limitations**

The following are known problems present in the UserManager.

- UserManager requires **/aliases**, **/groups**, and **/users** to exist before it allows you to edit a user in any given domain.
- UserManager doesn't sort home directories in the pop-up list.
- Home directories can only be created on file systems that have root access. This includes all local file systems. It also includes NFS file systems which are exported with options **anon=0**, or **root=yourhost** (where yourhost is the computer that UserManager is being run on.)
- The user's password can't be pasted into or cut from either the short or long entry form.
- The alert panel for user creation doesn't list the users language.
- A user can't be created if an e-mail alias by the same name already exists.
- The selection of home directories and the value for the UID are dependant on the NetInfo domain selected. They aren't verified or tested against any other domain.
