Keywords: NFS, Solaris

Question

When I have a Sun Solaris 2.4 system as an NFS client and a NEXTSTEP 3.3 system as the NFS server, the access starts out very slow. What causes this and is there a way to speed up the access time?

Answer

This problem is caused by a change in the Solaris NFS code in the 2.4 release. The new version of NFS READDIR in the Solaris 2.4 release tries to request more than 1024 bytes of directory data (this gains faster response from the NFS servers that support the larger size). The NEXTSTEP NFS server (and other NFS servers which are based on older NFS source code) fail to respond to this request. Sun Solaris will retransmit the **READDIR** requests and eventually will dynamically change the **rsize** and **wsizes** values for the mount to smaller values. You may verify this on the Sun with **nfsstat -m** command. In about 2 to 5 minutes the **rsize** and **wsizes** will be reduced and the **READDIR** requests to the Next start working!

To workaroud this problem set the **rsize** and **wsize** for the **mount** entries on a Solaris 2.4 NFS client to 1024 for all mounts from NEXTSTEP NFS servers.
