

Q: I get the error "out of processes." How can I increase the size of the kernel's process table?

A: In **Release 1** increasing the size of the process table is done by increasing the value of the system variable `nproc`. `Nproc` can be changed by explicitly specifying the value on the boot command line from the NeXT ROM monitor:

```
NeXT>bsd sdmach nproc=200
```

This will set `nproc` to the decimal number 200. The value may be entered in either decimal or hexadecimal. To enter the value in hexadecimal, precede the number with "0x". The default value is `nproc=0x54` (which is 84 decimal). The new size of `nproc` stays in effect until you reboot the system.

The current value of `nproc` can be gotten from the `nmi>` monitor. On a running system do the following:

Hold down both Command keys while typing the tilde/backquote key (the upper left key on the numeric keypad (this enters the NMI monitor).

At the nmi prompt, query the value of nproc by:

```
nmi>nproc=
```

This returns the current value of nproc in hexadecimal.

Also note that the maximum number of processes in Release 1 that a user can create is 40 (decimal). This limit cannot be increased.

In Releases 2 and 3, nproc is no longer part of the kernel—the process table grows dynamically. The maximum number of user processes has been increased from 40 to 100.
