AbortProc (3.1)

BOOL CALLBACK AbortProc(*hdc, error***)**

```
HDC hdc;      /* handle of device context */
int error;    /* error value              */
```

The **AbortProc** function is an application-defined callback function that is called when a print job is to be canceled during spooling.

Parameter	Description
hdc	Identifies the device context.
error	Specifies whether an error has occurred. This parameter is zero if no error has occurred; it is **SP_OUTOFDISK** if Print Manager is currently out of disk space and more disk space will become available if the application waits. If this parameter is SP_OUTOFDISK, the application need not cancel the print job. If it does not cancel the job, it must yield to Print Manager by calling the **PeekMessage** or **GetMessage** function.

Returns

The callback function should return TRUE to continue the print job or FALSE to cancel the print job.

Comments

An application installs this callback function by calling the **SetAbortProc** function. **AbortProc** is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition file.

See Also

GetMessage, **PeekMessage**, **SetAbortProc**

CallWndProc (3.1)

LRESULT CALLBACK CallWndProc(*code, wParam, lParam***)**

```
int code;          /* process-message flag                 */
WPARAM wParam;     /* current-task flag                    */
LPARAM lParam;     /* address of structure with message data */
```

The **CallWndProc** function is a library-defined callback function that the system calls whenever the **SendMessage** function is called. The system passes the message to the callback function before passing the message to the destination window procedure.

Parameter	Description
code	Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If the *code* parameter is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing.
wParam	Specifies whether the message is sent by the current task. This parameter is nonzero if the message is sent; otherwise, it is NULL.
lParam	Points to a structure that contains details about the message. The following shows the order, type, and description of each member of the structure:

Member	Description
lParam	Contains the *lParam* parameter of the message.
wParam	Contains the *wParam* parameter of the message.
uMsg	Specifies the message.
hWnd	Identifies the window that will receive the message.

Returns

The callback function should return zero.

Comments

The **CallWndProc** callback function can examine or modify the message as necessary. Once the function returns control to the system, the message, with any modifications, is passed on to the window procedure.

This callback function must be in a dynamic-link library.

An application must install the callback function by specifying the **WH_CALLWNDPROC** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

CallWndProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

CallNextHookEx, **SendMessage**, **SetWindowsHookEx**

CBTProc (3.1)

LRESULT CALLBACK CBTProc(*code, wParam, lParam***)**

```
int code;          /* CBT hook code                  */
WPARAM wParam;     /* depends on the code parameter  */
LPARAM lParam;     /* depends on the code parameter  */
```

The **CBTProc** function is a library-defined callback function that the system calls before activating, creating, destroying, minimizing, maximizing, moving, or sizing a window; before completing a system command; before removing a mouse or keyboard event from the system message queue; before setting the input focus; or before synchronizing with the system message queue.

The value returned by the callback function determines whether to allow or prevent one of these operations.

Parameter	Description
code	Specifies a computer-based-training (CBT) hook code that identifies the operation about to be carried out, or a value less than zero if the callback function should pass the *code, wParam,* and *lParam* parameters to the **CallNextHookEx** function. The *code* parameter can be one of the following:

Code	Meaning
HCBT_ACTIVATE	Indicates that the system is about to activate a window.
HCBT_CLICKSKIPPED	Indicates that the system has removed a mouse message from the system message queue. A CBT application that must install a journaling playback filter in response to the mouse message should do so when it receives this hook code.
HCBT_CREATEWND	Indicates that a window is about to be created. The system calls the callback function before sending the **WM_CREATE** or **WM_NCCREATE** message to the window. If the callback function returns TRUE, the system destroys the window--the **CreateWindow** function returns NULL, but the **WM_DESTROY** message is not sent to the window. If the callback function returns FALSE, the window is created normally. At the time of the HCBT_CREATEWND notification, the window has been created, but its final size and position may not have been determined, nor has its parent window been established. It is possible to send messages to the newly created window, although the window has not yet received **WM_NCCREATE** or **WM_CREATE** messages. It is possible to change the Z-order of the newly created window by modifying the **hwndInsertAfter** member of the **CBT_CREATEWND** structure.
HCBT_DESTROYWND	Indicates that a window is about to be destroyed.
HCBT_KEYSKIPPED	Indicates that the system has removed a keyboard message from the system message queue. A CBT application that must install a journaling playback filter in response to the keyboard message should do so when it receives this hook code.
HCBT_MINMAX	Indicates that a window is about to be minimized or maximized.

	HCBT_MOVESIZE	Indicates that a window is about to be moved or sized.
	HCBT_QS	Indicates that the system has retrieved a **WM_QUEUESYNC** message from the system message queue.
	HCBT_SETFOCUS	Indicates that a window is about to receive the input focus.
	HCBT_SYSCOMMAND	Indicates that a system command is about to be carried out. This allows a CBT application to prevent task switching by hot keys.
wParam	This parameter depends on the *code* parameter. See the following Comments section for details.	
lParam	This parameter depends on the *code* parameter. See the following Comments section for details.	

Returns

For operations corresponding to the following CBT hook codes, the callback function should return zero to allow the operation, or 1 to prevent it:

HCBT_ACTIVATE
HCBT_CREATEWND
HCBT_DESTROYWND
HCBT_MINMAX
HCBT_MOVESIZE
HCBT_SYSCOMMAND

The return value is ignored for operations corresponding to the following CBT hook codes:

HCBT_CLICKSKIPPED
HCBT_KEYSKIPPED
HCBT_QS

Comments

The callback function should not install a playback hook except in the situations described in the preceding list of hook codes.

This callback function must be in a dynamic-link library.

An application must install the callback function by specifying the **WH_CBT** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

CBTProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

The following table describes the *wParam* and *lParam* parameters for each HCBT_ constant.

Constant	wParam	lParam
HCBT_ACTIVATE	Specifies the handle of the window about to be activated.	Specifies a long pointer to a **CBTACTIVATESTRUCT** structure that contains the handle of the currently active window and specifies whether the activation is changing because of a mouse click.
HCBT_CLICKSKIPPED	Identifies the mouse message removed from the system message queue.	Specifies a long pointer to a **MOUSEHOOKSTRUCT** structure that contains the hit-test code and the handle of the window for which the mouse

		message is intended. For a list of hit-test codes, see the description of the WM_NCHITTEST message.
HCBT_CREATEWND	Specifies the handle of the new window.	Specifies a long pointer to a **CBT_CREATEWND** data structure that contains initialization parameters for the window.
HCBT_DESTROYWND	Specifies the handle of the window about to be destroyed.	This parameter is undefined and should be set to 0L.
HCBT_KEYSKIPPED	Identifies the virtual key code.	Specifies the repeat count, scan code, key-transition code, previous key state, and context code. For more information, see the description of the WM_KEYUP or WM_KEYDOWN message.
HCBT_MINMAX	Specifies the handle of the window being minimized or maximized.	The low-order word specifies a show-window value (SW_) that specifies the operation. For a list of show-window values, see the description of the **ShowWindow** function. The high-order word is undefined.
HCBT_MOVESIZE	Specifies the handle of the window to be moved or sized.	Specifies a long pointer to a **RECT** structure that contains the coordinates of the window.
HCBT_QS	This parameter is undefined; it should be set to 0.	This parameter is undefined and should be set to 0L.
HCBT_SETFOCUS	Specifies the handle of the window gaining the input focus.	The low-order word specifies the handle of the window losing the input focus. The high-order word is undefined.
HCBT_SYSCOMMAND	Specifies a system-command value (SC_) that specifies the systemcommand. For more information about system command values, see the description of the WM_SYSCOMMAND message.	If *wParam* is SC_HOTKEY, the low-order word of *lParam* contains the handle of the window that task switching will bring to the foreground. If *wParam* is not SC_HOTKEY and a System-menu command is chosen with the mouse, the low-order word of *lParam* contains the x-coordinate of the cursor and the high-order word contains the y-coordinate. If neither of these conditions is true, *lParam* is undefined.

CPlApplet (3.1)

LONG CALLBACK* CPlApplet(*hwndCPl, msg, lParam1, lParam2***)**

```
HWND hwndCPl;       /* handle of Control Panel window */
UINT msg;           /* message                        */
LPARAM lParam1;     /* first message parameter        */
LPARAM lParam2;     /* second message parameter       */
```

The **CPlApplet** function serves as the entry point for a Control Panel dynamic-link library (DLL). This function is supplied by the application.

Parameter	Description
hwndCPl	Identifies the main Control Panel window.
msg	Specifies the message being sent to the DLL.
lParam1	Specifies 32 bits of additional message-dependent information.
lParam2	Specifies 32 bits of additional message-dependent information.

Returns

The return value depends on the message.

Comments

Use the *hwndCPl* parameter for dialog boxes or other windows that require a handle of a parent window.

DdeCallback (3.1)

#include <ddeml.h>

HDDEDATA CALLBACK DdeCallback(*type, fmt, hconv, hsz1, hsz2, hData, dwData1, dwData2***)**

```
UINT type;          /* transaction type                 */
UINT fmt;           /* clipboard data format            */
HCONV hconv;        /* handle of conversation           */
HSZ hsz1;           /* handle of string                 */
HSZ hsz2;           /* handle of string                 */
HDDEDATA hData;     /* handle of global memory object   */
DWORD dwData1;      /* transaction-specific data        */
DWORD dwData2;      /* transaction-specific data        */
```

The **DdeCallback** function is an application-defined dynamic data exchange (DDE) callback function that processes DDE transactions sent to the function as a result of DDE Management Library (**DDEML**) calls by other applications.

Parameter	Description
type	Specifies the type of the current transaction. This parameter consists of a combination of transaction-class flags and transaction-type flags. The following table describes each of the transaction classes and provides a list of the transaction types in each class.

Value	Meaning
XCLASS_BOOL	A DDE callback function should return TRUE or FALSE when it finishes processing a transaction that belongs to this class. Following are the XCLASS_BOOL transaction types: **XTYP_ADVSTART** **XTYP_CONNECT**
XCLASS_DATA	A DDE callback function should return a DDE data handle, CBR_BLOCK, or NULL when it finishes processing a transaction that belongs to this class. Following are the XCLASS_DATA transaction types: **XTYP_ADVREQ** **XTYP_REQUEST** **XTYP_WILDCONNECT**
XCLASS_FLAGS	A DDE callback function should return DDE_FACK, DDE_FBUSY, or DDE_FNOTPROCESSED when it finishes processing a transaction that belongs to this class. Following are the XCLASS_FLAGS transaction types: **XTYP_ADVDATA** **XTYP_EXECUTE** **XTYP_POKE**
XCLASS_NOTIFICATION	The transaction types that belong to this class are for notification purposes only. The return value from the callback function is ignored. Following are the XCLASS_NOTIFICATION transaction types:

XTYP_ADVSTOP
XTYP_CONNECT_CONFIRM
XTYP_DISCONNECT
XTYP_ERROR
XTYP_MONITOR
XTYP_REGISTER
XTYP_XACT_COMPLETE
XTYP_UNREGISTER

fmt	Specifies the format in which data is to be sent or received.
hconv	Identifies the conversation associated with the current transaction.
hsz1	Identifies a string. The meaning of this parameter depends on the type of the current transaction. For more information, see the description of the transaction type.
hsz2	Identifies a string. The meaning of this parameter depends on the type of the current transaction. For more information, see the description of the transaction type.
hData	Identifies DDE data. The meaning of this parameter depends on the type of the current transaction. For more information, see the description of the transaction type.
dwData1	Specifies transaction-specific data. For more information, see the description of the transaction type.
dwData2	Specifies transaction-specific data. For more information, see the description of the transaction type.

Returns
The return value depends on the transaction class.

Comments
The callback function is called asynchronously for transactions that do not involve creating or terminating conversations. An application that does not frequently accept incoming messages will have reduced DDE performance because **DDEML** uses messages to initiate transactions.

An application must register the callback function by specifying its address in a call to the **DdeInitialize** function. **DdeCallback** is a placeholder for the application- or library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition file.

See Also
DdeEnableCallback, **DdeInitialize**

DebugProc (3.1)

LRESULT CALLBACK DebugProc(*code, wParam, lParam***)**

```
int code;          /* hook code                                    */
WPARAM wParam;     /* type of hook about to be called              */
LPARAM lParam;     /* address of structure with debugging information */
```

The **DebugProc** function is a library-defined callback function that the system calls before calling any other filter installed by the **SetWindowsHookEx** function. The system passes information about the filter about to be called to the **DebugProc** callback function. The callback function can examine the information and determine whether to allow the filter to be called.

Parameter	Description
code	Specifies the hook code. Currently, HC_ACTION is the only positive valid value. If this parameter is less than zero, the callback function must call the **CallNextHookEx** function without any further processing.
wParam	Specifies the task handle of the task that installed the filter about to be called.
lParam	Contains a long pointer to a **DEBUGHOOKINFO** structure.

Returns

The callback function should return TRUE to prevent the system from calling another filter. Otherwise, the callback function must pass the filter information to the **CallNextHookEx** function.

Comments

An application must install this callback function by specifying the **WH_DEBUG** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

CallWndProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

CallNextHookEx, **SetWindowsHookEx**, **DEBUGHOOKINFO**

DialogProc (2.x)

BOOL CALLBACK DialogProc(*hwndDlg, msg, wParam, lParam***)**

```
HWND hwndDlg;       /* handle of dialog box          */
UINT msg;           /* message                       */
WPARAM wParam;      /* first message parameter       */
LPARAM lParam;      /* second message parameter      */
```

The **DialogProc** function is an application-defined callback function that processes messages sent to a modeless dialog box.

Parameter	Description
hwndDlg	Identifies the dialog box.
msg	Specifies the message.
wParam	Specifies 16 bits of additional message-dependent information.
lParam	Specifies 32 bits of additional message-dependent information.

Returns

Except in response to the **WM_INITDIALOG** message, the dialog box procedure should return nonzero if it processes the message, and zero if it does not. In response to a WM_INITDIALOG message, the dialog box procedure should return zero if it calls the **SetFocus** function to set the focus to one of the controls in the dialog box. Otherwise, it should return nonzero, in which case the system will set the focus to the first control in the dialog box that can be given the focus.

Comments

The dialog box procedure is used only if the dialog box class is used for the dialog box. This is the default class and is used if no explicit class is given in the dialog box template. Although the dialog box procedure is similar to a window procedure, it must not call the **DefWindowProc** function to process unwanted messages. Unwanted messages are processed internally by the dialog box window procedure.

DialogProc is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition file.

CreateDialog, **CreateDialogIndirect**, **CreateDialogIndirectParam**, **CreateDialogParam**, **DefWindowProc**, **SetFocus**, **WM_INITDIALOG**

DriverProc (3.1)

LRESULT CALLBACK DriverProc(*dwDriverIdentifier, hDriver, msg, lParam1, lParam2***)**

```
DWORD dwDriverIdentifier;   /* identifies installable driver    */
HDRVR hDriver;              /* handle of installable driver     */
UINT msg;                   /* message                          */
LPARAM lParam1;             /* first message parameter          */
LPARAM lParam2;             /* second message parameter         */
```

The **DriverProc** function processes the specified message.

Parameter	Description
dwDriverIdentifier	Specifies an identifier of the installable driver.
hDriver	Identifies the installable driver. This parameter is a unique handle that Windows assigns to the driver.
msg	Identifies a message that the driver must process. Following are the messages that Windows or an application can send to an installable driver:

Message	Description
DRV_CLOSE	Notifies the driver that it should decrement (decrease by one) its usage count and unload the driver if the count is zero.
DRV_CONFIGURE	Notifies the driver that it should display a custom-configuration dialog box. (This message should be sent only if the driver returns a nonzero value when the **DRV_QUERYCONFIGURE** message is processed.)
DRV_DISABLE	Notifies the driver that its allocated memory is about to be freed.
DRV_ENABLE	Notifies the driver that it has been loaded or reloaded, or that Windows has been enabled.
DRV_FREE	Notifies the driver that it will be discarded.
DRV_INSTALL	Notifies the driver that it has been successfully installed.
DRV_LOAD	Notifies the driver that it has been successfully loaded.
DRV_OPEN	Notifies the driver that it is about to be opened.
DRV_POWER	Notifies the driver that the device's power source is about to be turned off or turned on.
DRV_QUERYCONFIGURE	Determines whether the driver supports the **DRV_CONFIGURE** message. The message displays a private configuration dialog box.
DRV_REMOVE	Notifies the driver that it is about to be removed from the system.

lParam1	Specifies the first message parameter.
lParam2	Specifies the second message parameter.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The **DriverProc** function is the main function within a Windows installable driver; it is supplied by the

driver developer.

When the *msg* parameter is **DRV_OPEN**, *lParam1* is the string following the driver filename from the SYSTEM.INI file and *lParam2* is the value given as the *lParam* parameter in the call to the **OpenDriver** function.

When the *msg* parameter is **DRV_CLOSE**, *lParam1* and *lParam2* are the same values as the *lParam1* and *lParam2* parameters in the call to the **CloseDriver** function.

See Also
CloseDriver, **OpenDriver**

EnumChildProc (2.x)

BOOL CALLBACK EnumChildProc(*hwnd, lParam***)**

```
HWND hwnd;          /* handle of child window     */
LPARAM lParam;      /* application-defined value  */
```

The **EnumChildProc** function is an application-defined callback function that receives child window handles as a result of a call to the **EnumChildWindows** function.

Parameter	Description
hwnd	Identifies a child window of the parent window specified in the **EnumChildWindows** function.
lParam	Specifies the application-defined value specified in the **EnumChildWindows** function.

Returns

The callback function must return nonzero to continue enumeration; to stop enumeration, it must return zero.

Comments

The callback function can carry out any desired task.

An application must register this callback function by passing its address to the **EnumChildWindows** function. The **EnumChildProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also

EnumChildWindows

EnumFontFamProc (3.1)

int CALLBACK EnumFontFamProc(*lpnlf, lpntm, FontType, lParam***)**

```
LOGFONT FAR* lpnlf;        /* address of structure with logical-font data  */
TEXTMETRIC FAR* lpntm;     /* address of structure with physical-font data*/
int FontType;              /* type of font                                 */
LPARAM lParam;             /* address of application-defined data          */
```

The **EnumFontFamProc** function is an application-defined callback function that retrieves information about available fonts.

Parameter	Description
lpnlf	Points to a NEWLOGFONT structure that contains information about the logical attributes of the font. This structure is locally-defined and is identical to the Windows **LOGFONT** structure except for two new members. The NEWLOGFONT structure has the following form:

```
struct tagNEWLOGFONT {                  /* nlf */
    int   lfHeight;
    int   lfWidth;
    int   lfEscapement;
    int   lfOrientation;
    int   lfWeight;
    BYTE  lfItalic;
    BYTE  lfUnderline;
    BYTE  lfStrikeOut;
    BYTE  lfCharSet;
    BYTE  lfOutPrecision;
    BYTE  lfClipPrecision;
    BYTE  lfQuality;
    BYTE  lfPitchAndFamily;
    BYTE  lfFaceName[LF_FACESIZE];
    BYTE  lfFullName[2 * LF_FACESIZE]; /* TrueType only */
    BYTE  lfStyle[LF_FACESIZE];        /* TrueType only */
} NEWLOGFONT;
```

The **lfFullName** and **lfStyle** members are appended to a **LOGFONT** structure when a TrueType font is enumerated in the **EnumFontFamProc** function.

The **lfFullName** member is a character array specifying the full name for the font. This name contains the font name and style name.

The **lfStyle** member is a character array specifying the style name for the font.

For example, when bold italic Arial® is enumerated, the last three members of the NEWLOGFONT structure contain the following strings:

lfFaceName = "Arial";
lfFullName = "Arial Bold Italic";
lfStyle = "Bold Italic";

See the description of the **LOGFONT** structure for a description of the other members of the structure.

lpntm	Points to a **NEWTEXTMETRIC** structure that contains information about the physical attributes of the font, if the font is a TrueType font. If the font is not a TrueType font, this parameter points to a **TEXTMETRIC** structure.
FontType	Specifies the type of the font. This parameter can be a combination of the following masks:

DEVICE_FONTTYPE
RASTER_FONTTYPE
TRUETYPE_FONTTYPE

lParam Points to the application-defined data passed by **EnumFontFamilies**.

Returns

This function must return a nonzero value to continue enumeration; to stop enumeration, it must return zero.

Comments

An application must register this callback function by passing its address to the **EnumFontFamilies** function. The **EnumFontFamProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

The AND (&) operator can be used with the RASTER_FONTTYPE, DEVICE_FONTTYPE, and TRUETYPE_FONTTYPE constants to determine the font type. If the RASTER_FONTTYPE bit is set, the font is a raster font. If the TRUETYPE_FONTTYPE bit is set, the font is a TrueType font. If neither bit is set, the font is a vector font. A third mask, DEVICE_FONTTYPE, is set when a device (for example, a laser printer) supports downloading TrueType fonts or when the font is a device-resident font; it is zero if the device is a display adapter, dot-matrix printer, or other raster device. An application can also use the DEVICE_FONTTYPE mask to distinguish GDI-supplied raster fonts from device-supplied fonts. GDI can simulate bold, italic, underline, and strikeout attributes for GDI-supplied raster fonts, but not for device-supplied fonts.

EnumFontFamilies, **EnumFonts**, **LOGFONT**, **NEWTEXTMETRIC**, **OUTLINETEXTMETRIC**, **TEXTMETRIC**

EnumFontsProc (3.1)

int CALLBACK EnumFontsProc(*lplf, lpntm, FontType, lpData***)**

```
LOGFONT FAR* lplf;          /* address of logical-font data structure   */
NEWTEXTMETRIC FAR* lpntm;   /* address of physical-font data structure */
int FontType;               /* type of font                             */
LPARAM lpData;              /* address of application-defined data      */
```

The **EnumFontsProc** function is an application-defined callback function that processes font data from the **EnumFonts** function.

Parameter	Description
lplf	Points to a **LOGFONT** structure that contains information about the logical attributes of the font.
lpntm	Points to a **NEWTEXTMETRIC** structure that contains information about the physical attributes of the font, if the font is a TrueType font. If the font is not a TrueType font, this parameter points to a **TEXTMETRIC** structure. The **TEXTMETRIC** structure is identical to **NEWTEXTMETRIC** except that it does not include the last four members.
FontType	Specifies the type of the font. This parameter can be a combination of the following masks: DEVICE_FONTTYPE RASTER_FONTTYPE TRUETYPE_FONTTYPE
lpData	Points to the application-defined data passed by the **EnumFonts** function.

Returns

This function must return a nonzero value to continue enumeration; to stop enumeration, it must return zero.

Comments

An application must register this callback function by passing its address to the **EnumFonts** function. The **EnumFontsProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

The AND (&) operator can be used with the RASTER_FONTTYPE, DEVICE_FONTTYPE, and TRUETYPE_FONTTYPE constants to determine the font type. If the RASTER_FONTTYPE bit is set, the font is a raster font. If the TRUETYPE_FONTTYPE bit is set, the font is a TrueType font. If neither bit is set, the font is a vector font. A third mask, DEVICE_FONTTYPE, is set when a device (for example, a laser printer) supports downloading TrueType fonts or when the font is a device-resident font; it is zero if the device is a display adapter, dot-matrix printer, or other raster device. An application can also use the DEVICE_FONTTYPE mask to distinguish GDI-supplied raster fonts from device-supplied fonts. GDI can simulate bold, italic, underline, and strikeout attributes for GDI-supplied raster fonts, but not for device-supplied fonts.

EnumMetaFileProc (3.1)

int CALLBACK EnumMetaFileProc(*hdc, lpht, lpmr, cObj, lParam***)**

```
HDC hdc;                    /* handle of device context              */
HANDLETABLE FAR* lpht;      /* address of table of object handles    */
METARECORD FAR* lpmr;       /* address of metafile record            */
int cObj;                   /* number of objects in handle table     */
LPARAM lParam;              /* address of application-defined data   */
```

The **EnumMetaFileProc** function is an application-defined callback function that processes metafile data from the **EnumMetaFile** function.

Parameter	Description
hdc	Identifies the special device context that contains the metafile.
lpht	Points to a table of handles associated with the objects (pens, brushes, and so on) in the metafile.
lpmr	Points to a metafile record contained in the metafile.
cObj	Specifies the number of objects with associated handles in the handle table.
lParam	Points to the application-defined data.

Returns

The callback function must return a nonzero value to continue enumeration; to stop enumeration, it must return zero.

Comments

An application must register this callback function by passing its address to the **EnumMetaFile** function.

The **EnumMetaFileProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also

EnumMetaFile

EnumObjectsProc (3.1)

int CALLBACK EnumObjectsProc(*lpLogObject, lpData***)**

void FAR* *lpLogObject;* /* address of object */
LPARAM *lpData;* /* address of application-defined data */

The **EnumObjectsProc** function is an application-defined callback function that processes object data from the **EnumObjects** function.

Parameter	Description
lpLogObject	Points to a **LOGPEN** or **LOGBRUSH** structure that contains information about the attributes of the object.
lpData	Points to the application-defined data passed by the **EnumObjects** function.

Returns

This function must return a nonzero value to continue enumeration; to stop enumeration, it must return zero.

Comments

An application must register this callback function by passing its address to the **EnumObjects** function. The **EnumObjectsProc** function is a placeholder for the application-supplied function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

Example

The following example retrieves the number of horizontally hatched brushes and fills **LOGBRUSH** structures with information about each of them:

```
#define MAXBRUSHES 50

GOBJENUMPROC lpProcCallback;
HGLOBAL hglbl;
LPBYTE lpbCountBrush;

lpProcCallback = (GOBJENUMPROC) MakeProcInstance(
    (FARPROC) Callback, hinst);

hglbl = GlobalAlloc(GMEM_FIXED, sizeof(LOGBRUSH)
    * MAXBRUSHES);
lpbCountBrush = (LPBYTE) GlobalLock(hglbl);
*lpbCountBrush = 0;
EnumObjects(hdc, OBJ_BRUSH, lpProcCallback,
    (LPARAM) lpbCountBrush);

FreeProcInstance((FARPROC) lpProcCallback);

int FAR PASCAL Callback(LPLOGBRUSH lpLogBrush, LPBYTE pbData)
{
    /*
     * The pbData parameter contains the number of horizontally
     * hatched brushes; the lpDest parameter is set to follow the
     * byte reserved for pbData and the LOGBRUSH structures that
     * have been filled with brush information.
     */

    LPLOGBRUSH lpDest =
        (LPLOGBRUSH) (pbData + 1 + (*pbData * sizeof(LOGBRUSH)));
```

```
    if (lpLogBrush->lbStyle ==
            BS_HATCHED && /* if horiz hatch */
            lpLogBrush->lbHatch == HS_HORIZONTAL) {
        *lpDest++ = *lpLogBrush; /* fills structure with brush info */
        (*pbData) ++;            /* increments brush count          */
        if (*pbData >= MAXBRUSHES)
            return 0;
    }

    return 1;
}
```

EnumPropFixedProc (2.x)

BOOL CALLBACK EnumPropFixedProc(*hwnd, lpsz, hData***)**

```
HWND hwnd;        /* handle of window with property      */
LPCSTR lpsz;      /* address of property string or atom  */
HANDLE hData;     /* handle data of property data        */
```

The **EnumPropFixedProc** function is an application-defined callback function that receives a window's property data as a result of a call to the **EnumProps** function.

Parameter	Description
hwnd	Identifies the handle of the window that contains the property list.
lpsz	Points to the null-terminated string associated with the property data identified by the *hData* parameter. The application specified the string and data in a previous call to the **SetProp** function. If the application passed an atom instead of a string to **SetProp**, the *lpsz* parameter contains the atom in the low-order word and zero in the high-order word.
hData	Identifies the property data.

Returns

The callback function must return TRUE to continue enumeration; it must return FALSE to stop enumeration.

Comments

This form of the property-enumeration callback function should be used in applications and dynamic-link libraries with fixed data segments and in dynamic libraries with movable data segments that do not contain a stack.

The following restrictions apply to the callback function:

- The callback function must not yield control or do anything that might yield control to other tasks.
- The callback function can call the **RemoveProp** function. However, **RemoveProp** can remove only the property passed to the callback function through the callback function's parameters.
- The callback function should not attempt to add properties.

The **EnumPropFixedProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also

EnumPropMovableProc, **EnumProps**, **RemoveProp**, **SetProp**

EnumPropMovableProc (2.x)

BOOL CALLBACK EnumPropMovableProc(*hwnd, lpsz, hData***)**

```
HWND hwnd;        /* handle of window with property      */
LPCSTR lpsz;      /* address of property string or atom  */
HANDLE hData;     /* handle of property data             */
```

The **EnumPropMovableProc** function is an application-defined callback function that receives a window's property data as a result of a call to the **EnumProps** function.

Parameter	Description
hwnd	Identifies the handle of the window that contains the property list.
lpsz	Points to the null-terminated string associated with the data identified by the *hData* parameter. The application specified the string and data in a previous call to the **SetProp** function. If the application passed an atom instead of a string to **SetProp**, the *lpsz* parameter contains the atom.
hData	Identifies the property data.

Returns

The callback function must return TRUE to continue enumeration; to stop enumeration, it must return FALSE.

Comments

This form of the property-enumeration callback function should be used in applications with movable data segments and in dynamic libraries whose movable data segments also contain a stack. This form is required since movement of the data will invalidate any long pointer to a variable on the stack, such as the *lpsz* parameter. The data segment typically moves if the callback function allocates more space in the local heap than is currently available.

The following restrictions apply to the callback function:

- The callback function must not yield control or do anything that might yield control to other tasks.
- The callback function can call the **RemoveProp** function. However, **RemoveProp** can remove only the property passed to the callback function through the callback function's parameters.
- The callback function should not attempt to add properties.

The **EnumPropMovableProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also

EnumPropFixedProc, **EnumProps**, **RemoveProp**, **SetProp**

EnumTaskWndProc (2.x)

BOOL CALLBACK EnumTaskWndProc(*hwnd, lParam***)**

```
HWND hwnd;          /* handle of a window          */
LPARAM lParam;      /* application-defined value   */
```

The **EnumTaskWndProc** function is an application-defined callback function that receives the window handles associated with a task as a result of a call to the **EnumTaskWindows** function.

Parameter	Description
hwnd	Identifies a window associated with the task specified in the **EnumTaskWindows** function.
lParam	Specifies the application-defined value specified in the **EnumTaskWindows** function.

Returns

The callback function must return TRUE to continue enumeration; to stop enumeration, it must return FALSE.

Comments

The callback function can carry out any desired task.

The **EnumTaskWndProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also

EnumTaskWindows

EnumWindowsProc (2.x)

BOOL CALLBACK EnumWindowsProc(*hwnd, lParam***)**

```
HWND hwnd;          /* handle of parent window   */
LPARAM lParam;      /* application-defined value  */
```

The **EnumWindowsProc** function is an application-defined callback function that receives parent window handles as a result of a call to the **EnumWindows** function.

Parameter	Description
hwnd	Identifies a parent window.
lParam	Specifies the application-defined value specified in the **EnumWindows** function.

Returns

The callback function must return nonzero to continue enumeration; to stop enumeration, it must return zero.

Comments

The callback function can carry out any desired task.

The **EnumWindowsProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also

EnumWindows

GetMsgProc (3.1)

LRESULT CALLBACK GetMsgProc(*code, wParam, lParam***)**

```
int code;          /* process-message flag  */
WPARAM wParam;     /* undefined             */
LPARAM lParam;     /* pointer to MSG structure  */
```

The **GetMsgProc** function is a library-defined callback function that the system calls whenever the **GetMessage** function has retrieved a message from an application queue. The system passes the retrieved message to the callback function before passing the message to the destination window procedure.

Parameter	Description
code	Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this parameter is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing.
wParam	Specifies a NULL value.
lParam	Points to an **MSG** structure that contains information about the message.

Returns

The callback function should return zero.

Comments

The **GetMsgProc** callback function can examine or modify the message as desired. Once the callback function returns control to the system, the **GetMessage** function returns the message, with any modifications, to the application that originally called it. The callback function does not require a return value.

This callback function must be in a dynamic-link library (DLL).

An application must install the callback function by specifying the **WH_GETMESSAGE** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

GetMsgProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition (.DEF) file.

See Also

CallNextHookEx, **GetMessage**, **SetWindowsHookEx**

GrayStringProc (2.x)

BOOL CALLBACK GrayStringProc(*hdc, lpData, cch***)**

```
HDC hdc;          /* handle of device context       */
LPARAM lpData;    /* address of string to be drawn */
int cch;          /* length of string to be drawn   */
```

The **GrayStringProc** function is an application-defined callback function that draws a string as a result of a call to the **GrayString** function.

Parameter	Description
hdc	Identifies a device context with a bitmap of at least the width and height specified by the *cx* and *cy* parameters passed to the **GrayString** function.
lpData	Points to the string to be drawn.
cch	Specifies the length, in characters, of the string.

Returns

The callback function should return TRUE to indicate success. Otherwise it should return FALSE.

Comments

The callback function must draw an image relative to the coordinates (0,0).

GrayStringProc is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also

GrayString

HardwareProc (3.1)

LRESULT CALLBACK HardwareProc(*code, wParam, lParam***)**

```
int code;       /* hook code                                  */
WPARAM wParam;  /* undefined                                  */
LPARAM lParam;  /* address of structure with event information*/
```

The **HardwareProc** function is an application-defined callback function that the system calls whenever the application calls the **GetMessage** or **PeekMessage** function and there is a hardware event to process. Mouse events and keyboard events are not processed by this hook.

Parameter	Description
code	Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this value is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing. If this value is HC_NOREMOVE, the application is using the **PeekMessage** function with the **PM_NOREMOVE** option, and the message will not be removed from the system queue.
wParam	Specifies a NULL value.
lParam	Points to a **HARDWAREHOOKSTRUCT** structure.

Returns

The callback function should return zero to allow the system to process the message; it should be 1 if the message is to be discarded.

Comments

This callback function should not install a playback hook because the function cannot use the **GetMessageExtraInfo** function to get the extra information associated with the message.

The callback function must use the Pascal calling convention and must be declared **FAR**. An application must install the callback function by specifying the **WH_HARDWARE** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

HardwareProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition (.DEF) file.

See Also

CallNextHookEx, **GetMessageExtraInfo**, **SetWindowsHookEx**, **HARDWAREHOOKSTRUCT**

JournalPlaybackProc (3.1)

LRESULT CALLBACK JournalPlaybackProc(*code, wParam, lParam***)**

```
int code;          /* process-message flag          */
WPARAM wParam;     /* undefined                     */
LPARAM lParam;     /* address of structure for message */
```

The **JournalPlaybackProc** function is a library-defined callback function that a library can use to insert mouse and keyboard messages into the system message queue. Typically, a library uses this function to play back a series of mouse and keyboard messages that were recorded earlier by using the **JournalRecordProc** function. Regular mouse and keyboard input is disabled as long as a **JournalPlaybackProc** function is installed.

Parameter	Description
code	Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this parameter is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing.
wParam	Specifies a NULL value.
lParam	Points to an **EVENTMSG** structure that represents the message being processed by the callback function.

Returns

The callback function should return a value that represents the amount of time, in clock ticks, that the system should wait before processing the message. This value can be computed by calculating the difference between the **time** members of the current and previous input messages. If the function returns zero, the message is processed immediately.

Comments

The **JournalPlaybackProc** function should copy an input message to the *lParam* parameter. The message must have been recorded by using a **JournalRecordProc** callback function, which should not modify the message.

Once the function returns control to the system, the message continues to be processed. If the *code* parameter is HC_SKIP, the filter function should prepare to return the next recorded event message on its next call.

This callback function should reside in a dynamic-link library.

An application must install the callback function by specifying the **WH_JOURNALPLAYBACK** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

JournalPlaybackProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

CallNextHookEx, **JournalRecordProc**, **SetWindowsHookEx**, **EVENTMSG**

JournalRecordProc (3.1)

LRESULT CALLBACK JournalRecordProc(*code, wParam, lParam***)**

```
int code;          /* process-message flag          */
WPARAM wParam;     /* undefined                     */
LPARAM lParam;     /* address of structure for message */
```

The **JournalRecordProc** function is a library-defined callback function that records messages that the system removes from the system message queue. Later, a library can use a **JournalPlaybackProc** function to play back the messages.

Parameter	Description
code	Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this parameter is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing.
wParam	Specifies a NULL value.
lParam	Points to an **MSG** structure.

Returns

The callback function should return zero.

Comments

A **JournalRecordProc** callback function should copy but not modify the messages. After control returns to the system, the message continues to be processed. The callback function does not require a return value.

This callback function must be in a dynamic-link library.

An application must install the callback function by specifying the **WH_JOURNALRECORD** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

JournalRecordProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

CallNextHookEx, **JournalPlaybackProc**, **SetWindowsHookEx**

KeyboardProc (3.1)

LRESULT CALLBACK KeyboardProc(*code, wParam, lParam***)**

```
int code;          /* process-message flag          */
WPARAM wParam;     /* virtual-key code              */
LPARAM lParam;     /* keyboard-message information  */
```

The **KeyboardProc** function is a library-defined callback function that the system calls whenever the application calls the **GetMessage** or **PeekMessage** function and there is a **WM_KEYUP** or **WM_KEYDOWN** keyboard message to process.

Parameter	Description
code	Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this value is HC_NOREMOVE, the application is using the **PeekMessage** function with the **PM_NOREMOVE** option, and the message will not be removed from the system queue. If this value is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing.
wParam	Specifies the virtual-key code of the given key.
lParam	Specifies the repeat count, scan code, extended key, previous key state, context code, and key-transition state, as shown in the following table. (Bit 0 is the low-order bit):

Bit	Description
0-15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16-23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).
24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.
25-26	Not used.
27-28	Used internally by Windows.
29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.
30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.
31	Specifies the key-transition state. The value is 1 if the key is being released, or it is 0 if the key is being pressed.

Returns

The callback function should return 0 if the message should be processed by the system; it should return 1 if the message should be discarded.

Comments

This callback function must be in a dynamic-link library.

An application must install the callback function by specifying the **WH_KEYBOARD** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

KeyboardProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

CallNextHookEx, **GetMessage**, **PeekMessage**, **SetWindowsHookEx**

LibMain (2.x)

int CALLBACK LibMain(*hinst, wDataSeg, cbHeapSize, lpszCmdLine***)**

HINSTANCE *hinst;* /* handle of library instance */
WORD *wDataSeg;* /* library data segment */
WORD *cbHeapSize;* /* default heap size */
LPSTR *lpszCmdLine;* /* command-line arguments */

The **LibMain** function is called by the system to initialize a dynamic-link library (DLL). A DLL must contain the **LibMain** function if the library is linked with the file LIBENTRY.OBJ.

Parameter	Description
hinst	Identifies the instance of the DLL.
wDataSeg	Specifies the value of the data segment (DS) register.
cbHeapSize	Specifies the size of the heap defined in the module-definition file. (The LibEntry routine in LIBENTRY.OBJ uses this value to initialize the local heap.)
lpszCmdLine	Points to a null-terminated string specifying command-line information. This parameter is rarely used by DLLs.

Returns

The function should return 1 if it is successful. Otherwise, it should return 0.

Comments

The **LibMain** function is called by LibEntry, which is called by Windows when the DLL is loaded. The LibEntry routine is provided in the LIBENTRY.OBJ module. LibEntry initializes the DLL's heap (if a **HEAPSIZE** value is specified in the DLL's module-definition file) before calling the **LibMain** function.

Example

The following example shows a typical **LibMain** function:

```
int CALLBACK LibMain(HINSTANCE hinst, WORD wDataSeg, WORD cbHeap,
    LPSTR lpszCmdLine )
{
    HGLOBAL    hgblClassStruct;
    LPWNDCLASS lpClassStruct;
    static HINSTANCE hinstLib;

    /* Has the library been initialized yet? */

    if (hinstLib == NULL) {
        hgblClassStruct = GlobalAlloc(GHND, sizeof(WNDCLASS));
        if (hgblClassStruct != NULL) {
            lpClassStruct = (LPWNDCLASS) GlobalLock(hgblClassStruct);
            if (lpClassStruct != NULL) {

                /* Define the class attributes. */

                lpClassStruct->style = CS_HREDRAW | CS_VREDRAW |
                    CS_DBLCLKS | CS_GLOBALCLASS;
                lpClassStruct->lpfnWndProc = DllWndProc;
                lpClassStruct->cbWndExtra = 0;
                lpClassStruct->hInstance = hinst;
                lpClassStruct->hIcon = NULL;
                lpClassStruct->hCursor = LoadCursor(NULL, IDC_ARROW);
                lpClassStruct->hbrBackground =
                    (HBRUSH) (COLOR_WINDOW + 1);
```

```
                lpClassStruct->lpszMenuName = NULL;
                lpClassStruct->lpszClassName = "MyClassName";

                hinstLib = (RegisterClass(lpClassStruct)) ?
                    hinst : NULL;

                GlobalUnlock(hgblClassStruct);
            }

            GlobalFree(hgblClassStruct);
        }
    }
    return (hinstLib ? 1 : 0);  /* return 1 = success; 0 = fail */
}
```

LineDDAProc (3.1)

void CALLBACK LineDDAProc(*xPos, yPos, lpData***)**

```
int xPos;          /* x-coordinate of current position      */
int yPos;          /* y-coordinate of current position      */
LPARAM lpData;     /* address of application-defined data   */
```

The **LineDDAProc** function is an application-defined callback function that processes coordinates from the **LineDDA** function.

Parameter	Description
xPos	Specifies the x-coordinate of the current point.
yPos	Specifies the y-coordinate of the current point.
lpData	Points to the application-defined data.

Returns
This function does not return a value.

Comments
An application must register this function by passing its address to the **LineDDA** function.

LineDDAProc is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition file.

See Also
LineDDA

LoadProc (2.x)

HGLOBAL CALLBACK LoadProc(*hglbMem, hinst, hrsrcResInfo***)**

```
HGLOBAL hglbMem;      /* handle of object containing resource */
HINSTANCE hinst;      /* handle of application instance       */
HRSRC hrsrcResInfo;   /* handle of a resource                 */
```

The **LoadProc** function is an application-defined callback function that receives information about a resource to be locked and can process that information as needed.

Parameter	Description
hglbMem	Identifies a memory object that contains a resource. This parameter is NULL if the resource has not yet been loaded.
hinst	Identifies the instance of the module whose executable file contains the resource.
hrsrcResInfo	Identifies the resource. The resource must have been created by using the **FindResource** function.

Returns

The return value is a global memory handle for memory that was allocated using the **GMEM_DDESHARE** flag in the **GlobalAlloc** function.

Comments

If an attempt to lock the memory object identified by the *hglbMem* parameter fails, this means the resource has been discarded and must be reloaded.

LoadProc is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition file.

See Also

FindResource, **GlobalAlloc**, **SetResourceHandler**

MessageProc (3.1)

LRESULT CALLBACK MessageProc(*code, wParam, lParam***)**

```
int code;       /* message type                          */
WPARAM wParam;  /* undefined                             */
LPARAM lParam;  /* address of structure with message data */
```

The **MessageProc** function is an application- or library-defined callback function that the system calls after a dialog box, message box, or menu has retrieved a message, but before the message is processed. The callback function can process or modify the messages.

Parameter	Description
code	Specifies the type of message being processed. This parameter can be one of the following values:

Value	Meaning
MSGF_DIALOGBOX	Messages inside a dialog box or message box procedure are being processed.
MSGF_MENU	Keyboard and mouse messages in a menu are being processed.

If the *code* parameter is less than zero, the callback function must pass the message to **CallNextHookEx** without further processing and return the value returned by **CallNextHookEx**.

wParam	Specifies a NULL value.
lParam	Points to an **MSG** structure.

Returns

The callback function should return a nonzero value if it processes the message; it should return zero if it does not process the message.

Comments

The **WH_MSGFILTER** filter type is the only task-specific filter. A task may install this filter.

An application must install the callback function by specifying the **WH_MSGFILTER** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

MessageProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

CallNextHookEx, **SetWindowsHookEx**, **MSG**

MouseProc (3.1)

LRESULT CALLBACK MouseProc(*code, wParam, lParam***)**

```
int code;          /* process-message flag                    */
WPARAM wParam;     /* message identifier                      */
LPARAM lParam;     /* address of MOUSEHOOKSTRUCT structure*/
```

The **MouseProc** function is a library-defined callback function that the system calls whenever an application calls the **GetMessage** or **PeekMessage** function and there is a mouse message to be processed.

Parameter	Description
code	Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this value is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing. If this value is HC_NOREMOVE, the application is using a **PeekMessage** function with the **PM_NOREMOVE** option, and the message will not be removed from the system queue.
wParam	Specifies the identifier of the mouse message.
lParam	Points to a **MOUSEHOOKSTRUCT** structure containing information about the mouse.

The callback function should return 0 to allow the system to process the message; it should return 1 to discard the message.

Comments

This callback function should not install a **JournalPlaybackProc** callback function.

An application must install the callback function by specifying the **WH_MOUSE** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

MouseProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the library's module-definition file.

See Also

CallNextHookEx, **GetMessage**, **PeekMessage**, **SetWindowsHookEx**

NotifyProc (2.x)

BOOL CALLBACK NotifyProc(*hglbl***)**

HGLOBAL *hglbl;* /* handle of global memory object */

The **NotifyProc** function is a library-defined callback function that the system calls whenever it is about to discard a global memory object allocated with the **GMEM_NOTIFY** flag.

Parameter	Description
hglbl	Identifies the global memory object being discarded.

Returns

The callback function should return nonzero if the system is to discard the memory object, or zero if it should not.

Comments

The callback function is not necessarily called in the context of the application that owns the routine. For this reason, the callback function should not assume it is using the stack segment of the application. The callback function should not call any routine that might move memory.

The callback function must be in a fixed code segment of a dynamic-link library.

NotifyProc is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition statement.

GlobalNotify

ShellProc (3.1)

LRESULT CALLBACK ShellProc(*code, wParam, lParam***)**

```
int code;          /* process-message flag  */
WPARAM wParam;     /* current-task flag     */
LPARAM lParam;     /* undefined             */
```

The **ShellProc** function is a library-defined callback function that a shell application can use to receive useful notifications from the system.

Parameter	Description
code	Specifies a shell-notification code. This parameter can be one of the following values:

Value	Meaning
HSHELL_ACTIVATESHELLWINDOW	The shell application should activate its main window.
HSHELL_WINDOWCREATED	A top-level, unowned window was created. The window exists when the system calls a **ShellProc** function.
HSHELL_WINDOWDESTROYED	A top-level, unowned window is about to be destroyed. The window still exists when the system calls a **ShellProc** function.

Parameter	Description
wParam	Specifies additional information the shell application may need. The interpretation of this parameter depends on the value of the *code* parameter, as follows:

code	***wParam***
HSHELL_ACTIVATESHELLWINDOW	Not used.
HSHELL_WINDOWCREATED	Specifies the handle of the window being created.
HSHELL_WINDOWDESTROYED	Specifies the handle of the window being destroyed.

Parameter	Description
lParam	Reserved; not used.

Returns

The return value should be zero.

Comments

An application must install this callback function by specifying the **WH_SHELL** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHook** function.

ShellProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

DefHookProc, **SendMessage**, **SetWindowsHook**

SysMsgProc (3.1)

LRESULT CALLBACK SysMsgProc(*code, wParam, lParam***)**

```
int code;          /* message type                */
WPARAM wParam;     /* undefined                   */
LPARAM lParam;     /* pointer to an MSG structure */
```

The **SysMsgProc** function is a library-defined callback function that the system calls after a dialog box, message box, or menu has retrieved a message, but before the message is processed. The callback function can process or modify messages for any application in the system.

Parameter	Description
code	Specifies the type of message being processed. This parameter can be one of the following values:

Value	Meaning
MSGF_DIALOGBOX	Messages inside a dialog box or message box procedure are being processed.
MSGF_MENU	Keyboard and mouse messages in a menu are being processed.

If the *code* parameter is less than zero, the callback function must pass the message to the **CallNextHookEx** function without further processing and return the value returned by **CallNextHookEx**.

wParam	Must be NULL.
lParam	Points to the **MSG** structure to contain the message. The **MSG** structure has the following form:

Returns

The return value should be nonzero if the function processes the message. Otherwise, it should be zero.

Comments

This callback function must be in a dynamic-link library (DLL).

An application must install this callback function by specifying the **WH_SYSMSGFILTER** filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

SysMsgProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

CallNextHookEx, **MessageBox**, **SetWindowsHookEx**

TimerProc (2.x)

void CALLBACK TimerProc(*hwnd, msg, idTimer, dwTime***)**

```
HWND hwnd;      /* handle of window for timer messages */
UINT msg;       /* WM_TIMER message                    */
UINT idTimer;   /* timer identifier                    */
DWORD dwTime;   /* current system time                 */
```

The **TimerProc** function is an application-defined callback function that processes **WM_TIMER** messages.

Parameter	Description
hwnd	Identifies the window associated with the timer.
msg	Specifies the **WM_TIMER** message.
idTimer	Specifies the timer's identifier.
dwTime	Specifies the current system time.

Returns

This function does not return a value.

Comments

TimerProc is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition file.

See Also

KillTimer, **SetTimer**, **WM_TIMER**

WEP (3.0)

int CALLBACK WEP(*nExitType***)**

int *nExitType;* /* type of exit */

The **WEP** (Windows exit procedure) callback function performs cleanup for a dynamic-link library (DLL) before the library is unloaded. This function is called by Windows. Although a **WEP** function was required for every dynamic-link library in previous versions of the Windows operating system, for version 3.1 the **WEP** function is optional. Most dynamic-link libraries use the **WEP** function.

Parameter	Description
nExitType	Specifies whether all of Windows is shutting down or only the individual library. This parameter can be either WEP_FREE_DLL or WEP_SYSTEM_EXIT.

Returns

The return value should be 1 if the function is successful.

Comments

For Windows version 3.1, **WEP** is called on the stack of the application that is terminating. This enables **WEP** to call Windows functions. In Windows version 3.0, however, **WEP** is called on a KERNEL stack that is too small to process most calls to Windows functions. These calls, including calls to global-memory functions, should be avoided in a **WEP** function for Windows 3.0. Calls to MS-DOS functions go through a KERNEL intercept and can also overflow the stack in Windows 3.0. There is no general reason to free memory from the global heap in a **WEP** function, because the kernel frees this kind of memory automatically.

In some low-memory conditions, **WEP** can be called before the library initialization function is called and before the library's DGROUP data-segment group has been created. A **WEP** function that relies on the library initialization function should verify that the initialization function has been called. Also, **WEP** functions that rely on the validity of DGROUP should check for this. The following procedure is recommended for dynamic-link libraries in Windows 3.0; for Windows 3.1, only step 3 is necessary.

1. Verify that the data segment is present by using a **lar** instruction and checking the present bit. This will indicate whether DS has been loaded. (The DS register always contains a valid selector.)
2. Set a flag in the data segment when the library initialization is performed. Once the **WEP** function has verified that the data segment exists, it should test this flag to determine whether initialization has occurred.
3. Declare **WEP** in the **EXPORTS** section of the module-definition file for the DLL. Following is an example declaration:

   ```
   WEP  @1  RESIDENTNAME
   ```

   The keyword **RESIDENTNAME** makes the name of the function (**WEP**) resident at all times. (It is not necessary to use the ordinal reference 1.) The name listed in the **LIBRARY** statement of the module-definition file must be in uppercase letters and must match the name of the DLL file.

Windows calls the **WEP** function by name when it is ready to remove the DLL. Under low-memory conditions, it is possible for the DLL's nonresident-name table to be discarded from memory. If this occurs, Windows must load the table to determine whether a **WEP** function was declared for the DLL. Under low-memory conditions, this method could fail, causing a fatal exit. Using the **RESIDENTNAME** option forces Windows to keep the name entry for **WEP** in memory whenever the DLL is in use.

In Windows 3.0, **WEP** must be placed in a fixed code segment. If it is placed instead in a discardable segment, under low-memory conditions Windows must load the **WEP** segment from disk so that the **WEP** function can be called before the DLL is discarded. Under certain low-memory conditions, attempting to load the segment containing **WEP** can cause a fatal exit. When **WEP** is in a fixed segment, this situation cannot occur. (Because fixed DLL code is also page-locked, you should minimize the

amount of fixed code.)

If a DLL is explicitly loaded by calling the **LoadLibrary** function, its **WEP** function is called when the DLL is freed by a call to the **FreeLibrary** function. (The **FreeLibrary** function should not be called from within a **WEP** function.) If the DLL is implicitly loaded, **WEP** is also called, but some debugging applications will indicate that the application has been terminated before **WEP** is called.

The **WEP** functions of dependent DLLs can be called in any order. This order depends on the order in which the usage counts for the DLLs reach zero.

FreeLibrary, **LibMain**, **RegisterClass**, **UnRegisterClass**

WindowProc (2.x)

LRESULT CALLBACK WindowProc(*hwnd, msg, wParam, lParam***)**

```
HWND hwnd;          /* handle of window          */
UINT msg;           /* message                   */
WPARAM wParam;      /* first message parameter   */
LPARAM lParam;      /* second message parameter  */
```

The **WindowProc** function is an application-defined callback function that processes messages sent to a window.

Parameter	Description
hwnd	Identifies the window.
msg	Specifies the message.
wParam	Specifies 16 bits of additional message-dependent information.
lParam	Specifies 32 bits of additional message-dependent information.

Returns

The return value is the result of the message processing. The value depends on the message being processed.

Comments

The **WindowProc** name is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition file.

See Also

DefWindowProc, **RegisterClass**, **WNDCLASS**

WinMain (2.x)

int PASCAL WinMain(*hinstCurrent, hinstPrevious, lpCmdLine, nCmdShow***)**

```
HINSTANCE hinstCurrent;     /* handle of current instance      */
HINSTANCE hinstPrevious;    /* handle of previous instance     */
LPSTR lpszCmdLine;          /* address of command line         */
int nCmdShow;               /* show-window type (open/icon)    */
```

The **WinMain** function is called by the system as the initial entry point for a Windows application.

Parameter	Description
hinstCurrent	Identifies the current instance of the application.
hinstPrevious	Identifies the previous instance of the application.
lpszCmdLine	Points to a null-terminated string specifying the command line for the application.
nCmdShow	Specifies how the window is to be shown. This parameter can be one of the following values:

Value	Meaning
SW_HIDE	Hides the window and passes activation to another window.
SW_MINIMIZE	Minimizes the specified window and activates the top-level window in the system's list.
SW_RESTORE	Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position (same as SW_SHOWNORMAL).
SW_SHOW	Activates a window and displays it in its current size and position.
SW_SHOWMAXIMIZED	Activates a window and displays it as a maximized window.
SW_SHOWMINIMIZED	Activates a window and displays it as an icon.
SW_SHOWMINNOACTIVE	Displays a window as an icon. The window that is currently active remains active.
SW_SHOWNA	Displays a window in its current state. The window that is currently active remains active.
SW_SHOWNOACTIVATE	Displays a window in its most recent size and position. The window that is currently active remains active.
SW_SHOWNORMAL	Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position (same as SW_RESTORE).

Returns

The return value is the return value of the **PostQuitMessage** function if the function is successful. This function returns NULL if it terminates before entering the message loop.

Comments

The **WinMain** function calls the instance-initialization function and, if no other instance of the program is running, the application-initialization function. It then performs a message retrieval-and-dispatch loop that is the top-level control structure for the remainder of the application's execution. The loop is terminated when a **WM_QUIT** message is received, at which time this function exits the application instance by returning the value passed by the **PostQuitMessage** function.

Example

The following example uses the **WinMain** function to initialize the application (if necessary), initialize the instance, and establish a message loop:

```
int PASCAL WinMain(HINSTANCE hinstCurrent, HINSTANCE hinstPrevious,
    LPSTR lpszCmdLine, int nCmdShow)
{
    MSG msg;

    if (hinstPrevious == NULL)                /* other instances?      */
        if (!InitApplication(hinstCurrent))   /* shared items          */
            return FALSE;                     /* initialization failed */

    /* Perform initializations for this instance. */

    if (!InitInstance(hinstCurrent, nCmdShow))
        return FALSE;

    /* Get and dispatch messages until WM_QUIT message. */

    while (GetMessage(&msg, NULL, 0, 0)) {
        TranslateMessage(&msg); /* translates virtual key codes    */
        DispatchMessage(&msg);  /* dispatches message to window    */
    }
    return (int) msg.wParam;    /* return value of PostQuitMessage */
}
```

See Also
DispatchMessage, **GetMessage**, **PostQuitMessage**, **TranslateMessage**

WordBreakProc (3.1)

int CALLBACK WordBreakProc(*lpszEditText, ichCurrentWord, cbEditText, action***)**

```
LPSTR lpszEditText;     /* address of edit text    */
int ichCurrentWord;     /* index of starting point */
int cbEditText;         /* length of edit text     */
int action;             /* action to take          */
```

The **WordBreakProc** function is an application-defined callback function that the system calls whenever a line of text in a multiline edit control must be broken.

Parameter	Description
lpszEditText	Points to the text of the edit control.
ichCurrentWord	Specifies an index to a word in the buffer of text that identifies the point at which the function should begin checking for a word break.
cbEditText	Specifies the number of bytes in the text.
action	Specifies the action to be taken by the callback function. This parameter can be one of the following values:

Value	Action
WB_LEFT	Look for the beginning of a word to the left of the current position.
WB_RIGHT	Look for the beginning of a word to the right of the current position.
WB_ISDELIMITER	Check whether the character at the current position is a delimiter.

Returns

If the *action* parameter specifies WB_ISDELIMITER, the return value is non zero (TRUE) if the character at the current position is a delimiter, or zero if it is not. Otherwise, the return value is an index to the begining of a word in the buffer of text.

Comments

A carriage return (CR) followed by a linefeed (LF) must be treated as a single word by the callback function. Two carriage returns followed by a linefeed also must be treated as a single word.

An application must install the callback function by specifying the procedure-instance address of the callback function in a **EM_SETWORDBREAKPROC** message.

WordBreakProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also

SendMessage, **EM_SETWORDBREAKPROC**

Callback functions (3.1)

AbortProc	Processes a canceled print job
CallWndProc	Filters messages sent by the SendMessage function
CBTProc	Allows a CBT application to prevent an operation
CPlApplet	Processes messages for a Control Panel DLL
DdeCallback	Processes **DDEML** transactions
DebugProc	Examines data before it is sent to a hook
DialogProc	Processes messages sent to a modeless dialog box
DriverProc	Processes messages for an installable driver
EnumChildProc	Receives child window handles during enumeration
EnumFontFamProc	Retrieves information about available fonts
EnumFontsProc	Retrieves information about available fonts
EnumMetaFileProc	Processes metafile data
EnumObjectsProc	Processes object data
EnumPropFixedProc	Receives enumerated property data for a window
EnumPropMovableProc	Receives enumerated property data for a window
EnumTaskWndProc	Processes task window handles during enumeration
EnumWindowsProc	Receives parent window handles during enumeration
GetMsgProc	Filters messages retrieved by the GetMessage function
GrayStringProc	Outputs text for the GrayString function
HardwareProc	Filters nonstandard hardware messages
JournalPlaybackProc	Places recorded events into the system queue
JournalRecordProc	Records event messages
KeyboardProc	Filters keyboard messages
LibMain	Initializes a dynamic-link library
LineDDAProc	Processes line data
LoadProc	Receives and processes resource information
MessageProc	Filters dialog box, message box, or menu messages
MouseProc	Filters mouse messages
NotifyProc	Determines whether to discard a global memory object
ShellProc	Receives notifications from the system
SysMsgProc	Filters dialog box, message box, or menu messages
TimerProc	Processes **WM_TIMER** messages
WEP	Cleans up and exits a dynamic-link library
WindowProc	Processes messages sent to a window
WinMain	Initializes an application and processes message loop
WordBreakProc	Determines line breaks in an edit control

CommDlgExtendedError (3.1)

#include commdlg.h

DWORD CommDlgExtendedError(void)

The **CommDlgExtendedError** function identifies the cause of the most recent error to have occurred during the execution of one of the following common dialog box procedures:

- **ChooseColor**
- **ChooseFont**
- **FindText**
- **GetFileTitle**
- **GetOpenFileName**
- **GetSaveFileName**
- **PrintDlg**
- **ReplaceText**

Returns

The return value is zero if the prior call to a common dialog box procedure was successful. The return value is CDERR_DIALOGFAILURE if the dialog box could not be created. Otherwise, the return value is a nonzero integer that identifies an error condition.

Comments

Following are the possible **CommDlgExtendedError** return values and the meaning of each:

Value	Meaning
CDERR_FINDRESFAILURE	Specifies that the common dialog box procedure failed to find a specified resource.
CDERR_INITIALIZATION	Specifies that the common dialog box procedure failed during initialization. This error often occurs when insufficient memory is available.
CDERR_LOADRESFAILURE	Specifies that the common dialog box procedure failed to load a specified resource.
CDERR_LOCKRESFAILURE	Specifies that the common dialog box procedure failed to lock a specified resource.
CDERR_LOADSTRFAILURE	Specifies that the common dialog box procedure failed to load a specified string.
CDERR_MEMALLOCFAILURE	Specifies that the common dialog box procedure was unable to allocate memory for internal structures.
CDERR_MEMLOCKFAILURE	Specifies that the common dialog box procedure was unable to lock the memory associated with a handle.
CDERR_NOHINSTANCE	Specifies that the ENABLETEMPLATE flag was set in the **Flags** member of a structure for the corresponding common dialog box but that the application failed to provide a corresponding instance handle.
CDERR_NOHOOK	Specifies that the ENABLEHOOK flag was set in the **Flags** member of a structure for the corresponding common dialog box but that the application failed to provide a pointer to a corresponding hook function.
CDERR_NOTEMPLATE	Specifies that the ENABLETEMPLATE flag was set in the **Flags** member of a structure for the corresponding common dialog box but that the application failed to provide a corresponding template.
CDERR_REGISTERMSGFAIL	Specifies that the **RegisterWindowMessage** function returned

	an error value when it was called by the common dialog box procedure.
CDERR_STRUCTSIZE	Specifies as invalid the **lStructSize** member of a structure for the corresponding common dialog box.
CFERR_NOFONTS	Specifies that no fonts exist.
CFERR_MAXLESSTHANMIN	Specifies that the size specified in the **nSizeMax** member of the **CHOOSEFONT** structure is less than the size specified in the **nSizeMin** member.
FNERR_BUFFERTOOSMALL	Specifies that the buffer for a filename is too small. (This buffer is pointed to by the **lpstrFile** member of the structure for a common dialog box.)
FNERR_INVALIDFILENAME	Specifies that a filename is invalid.
FNERR_SUBCLASSFAILURE	Specifies that an attempt to subclass a list box failed due to insufficient memory.
FRERR_BUFFERLENGTHZERO	Specifies that a member in a structure for the corresponding common dialog box points to an invalid buffer.
PDERR_CREATEICFAILURE	Specifies that the **PrintDlg** function failed when it attempted to create an information context.
PDERR_DEFAULTDIFFERENT	Specifies that an application has called the **PrintDlg** function with the DN_DEFAULTPRN flag set in the **wDefault** member of the **DEVNAMES** structure, but the printer described by the other structure members does not match the current default printer. (This happens when an application stores the **DEVNAMES** structure and the user changes the default printer by using Control Panel.) To use the printer described by the **DEVNAMES** structure, the application should clear the DN_DEFAULTPRN flag and call the **PrintDlg** function again. To use the default printer, the application should replace the **DEVNAMES** structure (and the **DEVMODE** structure, if one exists) with NULL; this selects the default printer automatically.
PDERR_DNDMMISMATCH	Specifies that the data in the **DEVMODE** and **DEVNAMES** structures describes two different printers.
PDERR_GETDEVMODEFAIL	Specifies that the printer driver failed to initialize a **DEVMODE** structure. (This error value applies only to printer drivers written for Windows versions 3.0 and later.)
PDERR_INITFAILURE	Specifies that the **PrintDlg** function failed during initialization.
PDERR_LOADDRVFAILURE	Specifies that the **PrintDlg** function failed to load the device driver for the specified printer.
PDERR_NODEFAULTPRN	Specifies that a default printer does not exist.
PDERR_NODEVICES	Specifies that no printer drivers were found.
PDERR_PARSEFAILURE	Specifies that the **PrintDlg** function failed to parse the strings in the [devices] section of the WIN.INI file.
PDERR_PRINTERNOTFOUND	Specifies that the [devices] section of the WIN.INI file did not contain an entry for the requested printer.
PDERR_RETDEFFAILURE	Specifies that the PD_RETURNDEFAULT flag was set in the **Flags** member of the **PRINTDLG** structure but that either the **hDevMode** or **hDevNames** member was nonzero.
PDERR_SETUPFAILURE	Specifies that the **PrintDlg** function failed to load the required resources.

ChooseColor, **ChooseFont**, **FindText**, **GetFileTitle**, **GetOpenFileName**, **GetSaveFileName**, **PrintDlg**, **ReplaceText**

CDERR_FINDRESFAILURE

Specifies that the common dialog box procedure failed to find a specified resource.

CDERR_INITIALIZATION

Specifies that the common dialog box procedure failed during initialization. This error often occurs when insufficient memory is available.

CDERR_LOADRESFAILURE

Specifies that the common dialog box procedure failed to load a specified resource.

CDERR_LOCKRESFAILURE

Specifies that the common dialog box procedure failed to lock a specified resource.

CDERR_LOADSTRFAILURE

Specifies that the common dialog box procedure failed to load a specified string.

CDERR_MEMALLOCFAILURE

Specifies that the common dialog box procedure was unable to allocate memory for internal structures.

CDERR_MEMLOCKFAILURE

Specifies that the common dialog box procedure was unable to lock the memory associated with a handle.

CDERR_NOHINSTANCE

Specifies that the ENABLETEMPLATE flag was set in the **Flags** member of a structure for the corresponding common dialog box but that the application failed to provide a corresponding instance handle.

CDERR_NOHOOK

Specifies that the ENABLEHOOK flag was set in the **Flags** member of a structure for the corresponding common dialog box but that the application failed to provide a pointer to a corresponding hook function.

CDERR_NOTEMPLATE

Specifies that the ENABLETEMPLATE flag was set in the **Flags** member of a structure for the corresponding common dialog box but that the application failed to provide a corresponding template.

CDERR_REGISTERMSGFAIL

Specifies that the **RegisterWindowMessage** function returned an error value when it was called by the common dialog box procedure.

CDERR_STRUCTSIZE

Specifies as invalid the **lStructSize** member of a structure for the corresponding common dialog box.

CFERR_NOFONTS

Specifies that no fonts exist.

CFERR_MAXLESSTHANMIN

Specifies that the size specified in the **nSizeMax** member of the **CHOOSEFONT** structure is less than the size specified in the **nSizeMin** member.

FNERR_BUFFERTOOSMALL

Specifies that the buffer for a filename is too small. (This buffer is pointed to by the **lpstrFile** member of the structure for a common dialog box.)

FNERR_INVALIDFILENAME

Specifies that a filename is invalid.

FNERR_SUBCLASSFAILURE

Specifies that an attempt to subclass a list box failed due to insufficient memory.

FRERR_BUFFERLENGTHZERO

Specifies that a member in a structure for the corresponding common dialog box points to an invalid buffer.

PDERR_CREATEICFAILURE

Specifies that the **PrintDlg** function failed when it attempted to create an information context.

PDERR_DEFAULTDIFFERENT

Specifies that an application has called the **PrintDlg** function with the DN_DEFAULTPRN flag set in the **wDefault** member of the **DEVNAMES** structure, but the printer described by the other structure members does not match the current default printer. (This happens when an application stores the **DEVNAMES** structure and the user changes the default printer by using Control Panel.) To use the printer described by the **DEVNAMES** structure, the application should clear the DN_DEFAULTPRN flag and call the **PrintDlg** function again. To use the default printer, the application should replace the **DEVNAMES** structure (and the **DEVMODE** structure, if one exists) with NULL; this selects the default printer automatically.

PDERR_DNDMMISMATCH

Specifies that the data in the **DEVMODE** and **DEVNAMES** structures describes two different printers.

PDERR_GETDEVMODEFAIL

Specifies that the printer driver failed to initialize a **DEVMODE** structure. (This error value applies only to printer drivers written for Windows versions 3.0 and later.)

PDERR_INITFAILURE

Specifies that the **PrintDlg** function failed during initialization.

PDERR_LOADDRVFAILURE

Specifies that the **PrintDlg** function failed to load the device driver for the specified printer.

PDERR_NODEFAULTPRN

Specifies that a default printer does not exist.

PDERR_NODEVICES

Specifies that no printer drivers were found.

PDERR_PARSEFAILURE

Specifies that the **PrintDlg** function failed to parse the strings in the [devices] section of the WIN.INI file.

PDERR_PRINTERNOTFOUND

Specifies that the [devices] section of the WIN.INI file did not contain an entry for the requested printer.

PDERR_RETDEFFAILURE

Specifies that the PD_RETURNDEFAULT flag was set in the **Flags** member of the **PRINTDLG** structure but that either the **hDevMode** or **hDevNames** member was nonzero.

PDERR_SETUPFAILURE

Specifies that the **PrintDlg** function failed to load the required resources.

ChooseColor (3.1)

#include commdlg.h

BOOL ChooseColor(*lpcc***)**

CHOOSECOLOR FAR* *lpcc;* /* address of structure with initialization data*/

The **ChooseColor** function creates a system-defined dialog box from which the user can select a color.

Parameter	Description
lpcc	Points to a **CHOOSECOLOR** structure that initially contains information necessary to initialize the dialog box. When the **ChooseColor** function returns, this structure contains information about the user's color selection.

Returns

The return value is nonzero if the function is successful. It is zero if an error occurs, if the user chooses the Cancel button, or if the user chooses the Close command on the System menu (often called the Control menu) to close the dialog box.

Errors

Use the **CommDlgExtendedError** function to retrieve the error value, which may be one of the following:

CDERR_FINDRESFAILURE
CDERR_INITIALIZATION
CDERR_LOCKRESFAILURE
CDERR_LOADRESFAILURE
CDERR_LOADSTRFAILURE
CDERR_MEMALLOCFAILURE
CDERR_MEMLOCKFAILURE
CDERR_NOHINSTANCE
CDERR_NOHOOK
CDERR_NOTEMPLATE
CDERR_STRUCTSIZE

Comments

The dialog box does not support color palettes. The color choices offered by the dialog box are limited to the system colors and dithered versions of those colors.

If the hook function (to which the **lpfnHook** member of the **CHOOSECOLOR** structure points) processes the **WM_CTLCOLOR** message, this function must return a handle for the brush that should be used to paint the control background.

Example

The following example initializes a **CHOOSECOLOR** structure and then creates a color-selection dialog box:

```
/* Color variables */

CHOOSECOLOR cc;
COLORREF clr;
COLORREF aclrCust[16];
int i;

/* Set the custom color controls to white. */

for (i = 0; i < 16; i++)
    aclrCust[i] = RGB(255, 255, 255);
```

```
/* Initialize clr to black. */

clr = RGB(0, 0, 0);

/* Set all structure fields to zero. */

memset(&cc, 0, sizeof(CHOOSECOLOR));

/* Initialize the necessary CHOOSECOLOR members. */

cc.lStructSize = sizeof(CHOOSECOLOR);
cc.hwndOwner = hwnd;
cc.rgbResult = clr;
cc.lpCustColors = aclrCust;
cc.Flags = CC_PREVENTFULLOPEN;

if (ChooseColor(&cc))
    .
    . /* Use cc.rgbResult to select the user-requested color. */
    .
```

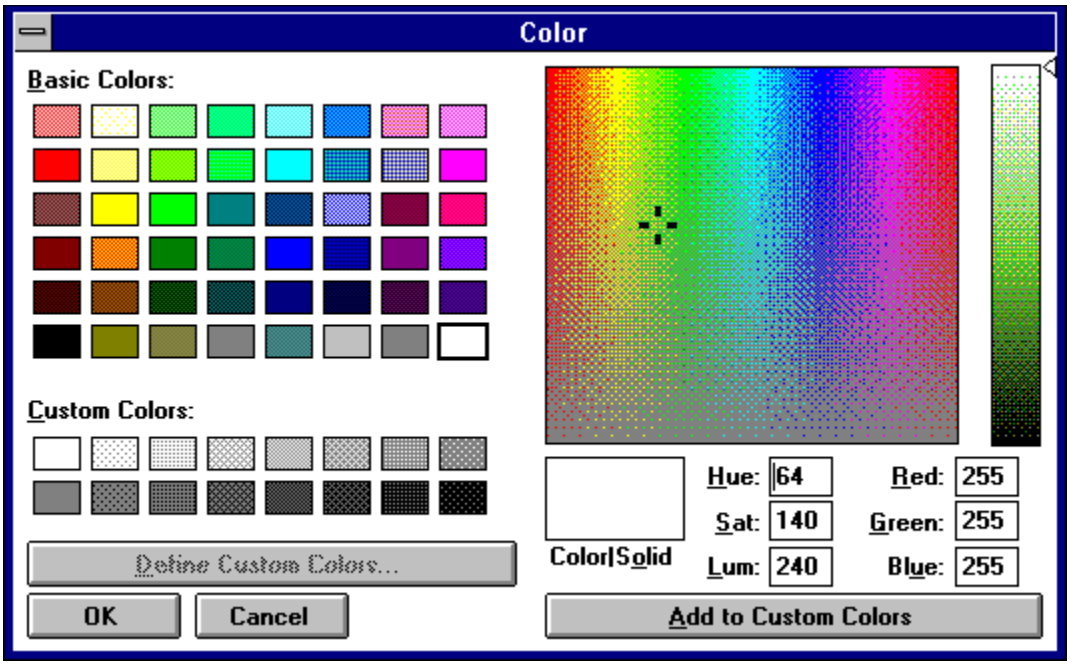
CHOOSECOLOR

The following shows how the dialog box normally appears:



ChooseFont function (3.1)

#include commdlg.h

BOOL ChooseFont(*lpcf***)**

CHOOSEFONT FAR**lpcf;* /* address of structure with initialization data*/

The **ChooseFont** function creates a system-defined dialog box from which the user can select a font, a font style (such as bold or italic), a point size, an effect (such as strikeout or underline), and a color.

Parameter	Description
lpcf	Points to a **CHOOSEFONT** structure that initially contains information necessary to initialize the dialog box. When the **ChooseFont** function returns, this structure contains information about the user's font selection.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **CommDlgExtendedError** function to retrieve the error value, which may be one of the following:

CDERR_FINDRESFAILURE
CDERR_INITIALIZATION
CDERR_LOCKRESFAILURE
CDERR_LOADRESFAILURE
CDERR_LOADSTRFAILURE
CDERR_MEMALLOCFAILURE
CDERR_MEMLOCKFAILURE
CDERR_NOHINSTANCE
CDERR_NOHOOK
CDERR_NOTEMPLATE
CDERR_STRUCTSIZE
CFERR_MAXLESSTHANMIN
CFERR_NOFONTS

Example

The following example initializes a **CHOOSEFONT** structure and then displays a font dialog box:

```
LOGFONT lf;
CHOOSEFONT cf;

/* Set all structure fields to zero. */

memset(&cf, 0, sizeof(CHOOSEFONT));

cf.lStructSize = sizeof(CHOOSEFONT);
cf.hwndOwner = hwnd;
cf.lpLogFont = &lf;
cf.Flags = CF_SCREENFONTS | CF_EFFECTS;
cf.rgbColors = RGB(0, 255, 255); /* light blue */
cf.nFontType = SCREEN_FONTTYPE;

ChooseFont(&cf);
```

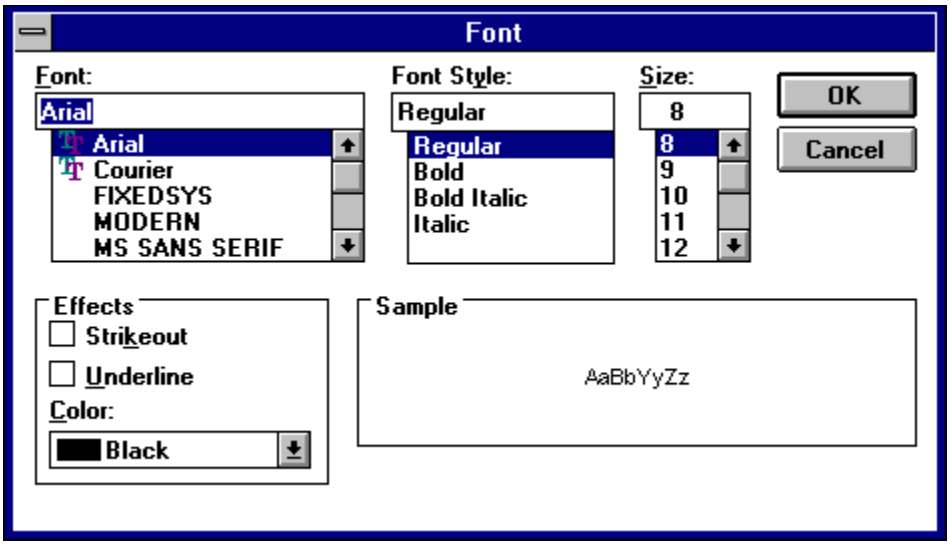
CHOOSEFONT

The following shows how the dialog box normally appears:



FindText (3.1)

#include commdlg.h

HWND FindText(*lpfr***)**

FINDREPLACE FAR* *lpfr;* /* address of structure with initialization data*/

The **FindText** function creates a system-defined modeless dialog box that makes it possible for the user to find text within a document. The application must perform the search operation.

Parameter	Description
lpfr	Points to a **FINDREPLACE** structure that contains information used to initialize the dialog box. When the user makes a selection in the dialog box, the system fills this structure with information about the user's selection and then sends a message to the application. This message contains a pointer to the **FINDREPLACE** structure.

Returns

The return value is the window handle of the dialog box if the function is successful. Otherwise, it is NULL. An application can use this window handle to communicate with or to close the dialog box.

Errors

Use the **CommDlgExtendedError** function to retrieve the error value, which may be one of the following values:

CDERR_FINDRESFAILURE
CDERR_INITIALIZATION
CDERR_LOCKRESFAILURE
CDERR_LOADRESFAILURE
CDERR_LOADSTRFAILURE
CDERR_MEMALLOCFAILURE
CDERR_MEMLOCKFAILURE
CDERR_NOHINSTANCE
CDERR_NOHOOK
CDERR_NOTEMPLATE
CDERR_STRUCTSIZE
FRERR_BUFFERLENGTHZERO

Comments

The dialog box procedure for the Find dialog box passes user requests to the application through special

messages. The *lParam* parameter of each of these messages contains a pointer to a **FINDREPLACE** structure. The procedure sends the messages to the window identified by the **hwndOwner** member of the **FINDREPLACE** structure. An application can register the identifier for these messages by specifying the "commdlg_FindReplace" string in a call to the **RegisterWindowMessage** function.

For the TAB key to function correctly, any application that calls the **FindText** function must also call the **IsDialogMessage** function in its main message loop. (The **IsDialogMessage** function returns a value that indicates whether messages are intended for the Find dialog box.)

If the hook function (to which the **lpfnHook** member of the **FINDREPLACE** structure points) processes the **WM_CTLCOLOR** message, this function must return a handle of the brush that should be used to paint the control background.

Example

The following example initializes a **FINDREPLACE** structure and calls the **FindText** function to display the Find dialog box:

```
FINDREPLACE fr;

/* Set all structure fields to zero. */

memset(&fr, 0, sizeof(FINDREPLACE));

fr.lStructSize = sizeof(FINDREPLACE);
fr.hwndOwner = hwnd;
fr.lpstrFindWhat = szFindWhat;
fr.wFindWhatLen = sizeof(szFindWhat);

hDlg = FindText(&fr);

break;
```

In addition to initializing the members of the **FINDREPLACE** structure and calling the **FindText** function, an application must register the special FINDMSGSTRING message and process messages from the dialog box.

The following example registers the message by using the **RegisterWindowMessage** function:

```
UINT uFindReplaceMsg;

/* Register the FindReplace message. */

uFindReplaceMsg = RegisterWindowMessage(FINDMSGSTRING);
```

After the application registers the FINDMSGSTRING message, it can process messages by using the **RegisterWindowMessage** return value. The following example processes messages for the Find dialog box and then calls its own SearchFile function to locate the string of text. If the user is closing the dialog box (that is, if the **Flags** member of the **FINDREPLACE** structure is FR_DIALOGTERM), the handle is invalidated and the procedure returns zero.

```
LRESULT CALLBACK MainWndProc(HWND hwnd, UINT msg, WPARAM wParam,
    LPARAM lParam)
{
    FINDREPLACE FAR* lpfr;

    if (msg == uFindReplaceMsg) {
        lpfr = (FINDREPLACE FAR*) lParam;
        if (lpfr->Flags & FR_DIALOGTERM) {
            hDlg = NULL;
```

```
            return 0;
        }
        SearchFile((BOOL) (lpfr->Flags & FR_DOWN),
            (BOOL) (lpfr->Flags & FR_MATCHCASE));
        return 0;
    }
```

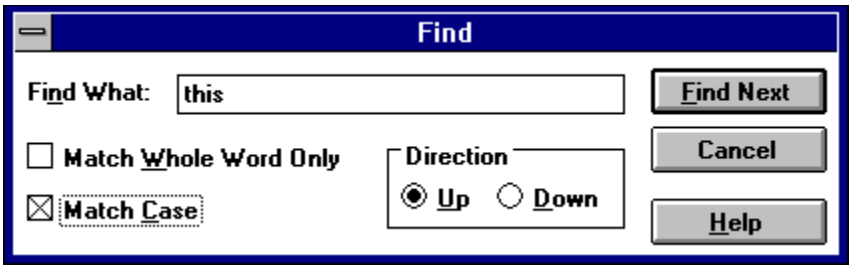
IsDialogMessage, **RegisterWindowMessage**, **ReplaceText**, **FINDREPLACE**

The following shows how the find dialog box appears:



GetFileTitle (3.1)

#include commdlg.h

int GetFileTitle(*lpszFile, lpszTitle, cbBuf***)**

LPCSTR *lpszFile;* /* pointer to filename (including drive and directory) */
LPSTR *lpszTitle;* /* address of buffer that receives filename */
UINT *cbBuf;* /* length of buffer */

The **GetFileTitle** function returns the title of the file identified by the *lpszFile* parameter.

Parameter	Description
lpszFile	Points to the name and location of an MS-DOS file.
lpszTitle	Points to a buffer into which the function is to copy the name of the file.
cbBuf	Specifies the length, in bytes, of the buffer to which the *lpszTitle* parameter points.

Returns

The return value is zero if the function is successful. The return value is a negative number if the filename is invalid. The return value is a positive integer that specifies the required buffer size, in bytes, if the buffer to which the *lpszTitle* parameter points is too small.

Comments

The function returns an error value if the buffer pointed to by the *lpszFile* parameter contains any of the following:

- An empty string
- A string containing a wildcard (*), opening bracket ([), or closing bracket (])
- A string that ends with a colon (:), slash mark (/), or backslash (\)
- A string whose length exceeded the length of the buffer
- An invalid character (for example, a space or unprintable character).

The required buffer size includes the terminating null character.

GetOpenFileName (3.1)

#include commdlg.h

BOOL GetOpenFileName(*lpofn***)**

OPENFILENAME FAR* *lpofn;* /* address of initialization data structure */

The **GetOpenFileName** function creates a system-defined dialog box that makes it possible for the user to select a file to open.

Parameter	Description
lpofn	Points to an **OPENFILENAME** structure that contains information used to initialize the dialog box. When the **GetOpenFileName** function returns, this structure contains information about the user's file selection.

Returns

The return value is nonzero if the user selects a file to open. It is zero if an error occurs, if the user chooses the Cancel button, if the user chooses the Close command on the System menu to close the dialog box, or if the buffer identified by the **lpstrFile** member of the **OPENFILENAME** structure is too small to contain the string that specifies the selected file.

Errors

The **CommDlgExtendedError** function retrieves the error value, which may be one of the following values:

CDERR_FINDRESFAILURE
CDERR_INITIALIZATION
CDERR_LOCKRESFAILURE
CDERR_LOADRESFAILURE
CDERR_LOADSTRFAILURE
CDERR_MEMALLOCFAILURE
CDERR_MEMLOCKFAILURE
CDERR_NOHINSTANCE
CDERR_NOHOOK
CDERR_NOTEMPLATE
CDERR_STRUCTSIZE
FNERR_BUFFERTOOSMALL
FNERR_INVALIDFILENAME
FNERR_SUBCLASSFAILURE

Comments

If the hook function (to which the **lpfnHook** member of the **OPENFILENAME** structure points) processes the **WM_CTLCOLOR** message, this function must return a handle of the brush that should be used to paint the control background.

Example

The following example copies file-filter strings into a buffer, initializes an **OPENFILENAME** structure, and then creates an Open dialog box.

The file-filter strings are stored in the resource file in the following form:

```
STRINGTABLE
BEGIN
  IDS_FILTERSTRING  "Write Files(*.WRI)|*.wri|Word Files(*.DOC)|*.doc|"
END
```

The replaceable character at the end of the string is used to break the entire string into separate strings, while still guaranteeing that all the strings are continguous in memory.

```
OPENFILENAME ofn;
char szDirName[256];
char szFile[256], szFileTitle[256];
UINT  i, cbString;
char  chReplace;    /* string separator for szFilter */
char  szFilter[256];
HFILE hf;

/* Get the system directory name, and store in szDirName */

GetSystemDirectory(szDirName, sizeof(szDirName));
szFile[0] = '\0';

if ((cbString = LoadString(hinst, IDS_FILTERSTRING,
        szFilter, sizeof(szFilter))) == 0) {
    ErrorHandler();
    return 0L;
}
chReplace = szFilter[cbString - 1]; /* retrieve wildcard */

for (i = 0; szFilter[i] != '\0'; i++) {
    if (szFilter[i] == chReplace)
       szFilter[i] = '\0';
}

/* Set all structure members to zero. */

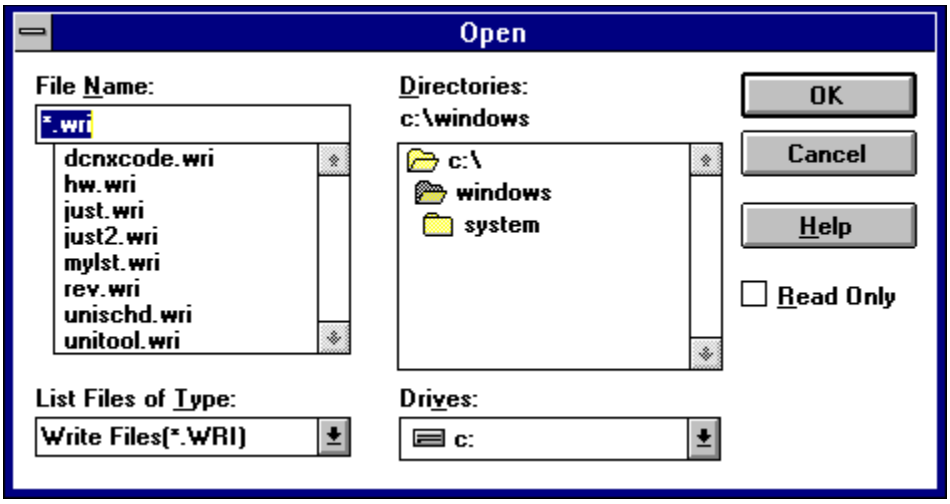
memset(&ofn, 0, sizeof(OPENFILENAME));

ofn.lStructSize = sizeof(OPENFILENAME);
ofn.hwndOwner = hwnd;
ofn.lpstrFilter = szFilter;
ofn.nFilterIndex = 1;
ofn.lpstrFile= szFile;
ofn.nMaxFile = sizeof(szFile);
ofn.lpstrFileTitle = szFileTitle;
ofn.nMaxFileTitle = sizeof(szFileTitle);
ofn.lpstrInitialDir = szDirName;
ofn.Flags = OFN_SHOWHELP | OFN_PATHMUSTEXIST | OFN_FILEMUSTEXIST;

if (GetOpenFileName(&ofn)) {
    hf = _lopen(ofn.lpstrFile, OF_READ);
        .
        . /* Perform file operations. */
        .
}
else
    ErrorHandler();
```

See Also
GetSaveFileName, **OPENFILENAME**

The following shows how the open dialog box normally appears:



GetSaveFileName (3.1)

#include commdlg.h

BOOL GetSaveFileName(*lpofn***)**

OPENFILENAME FAR* *lpofn;* /* address of initialization data */

The **GetSaveFileName** function creates a system-defined dialog box that makes it possible for the user to select a file to save.

Parameter	Description
lpofn	Points to an **OPENFILENAME** structure that contains information used to initialize the dialog box. When the **GetSaveFileName** function returns, this structure contains information about the user's file selection.

Returns

The return value is nonzero if the user selects a file to save. It is zero if an error occurs, if the user clicks the Cancel button, if the user chooses the Close command on the System menu to close the dialog box, or if the buffer identified by the **lpstrFile** member of the **OPENFILENAME** structure is too small to contain the string that specifies the selected file.

Errors

The **CommDlgExtendedError** retrieves the error value, which may be one of the following values:

CDERR_FINDRESFAILURE
CDERR_INITIALIZATION
CDERR_LOCKRESFAILURE
CDERR_LOADRESFAILURE
CDERR_LOADSTRFAILURE
CDERR_MEMALLOCFAILURE
CDERR_MEMLOCKFAILURE
CDERR_NOHINSTANCE
CDERR_NOHOOK
CDERR_NOTEMPLATE
CDERR_STRUCTSIZE
FNERR_BUFFERTOOSMALL
FNERR_INVALIDFILENAME
FNERR_SUBCLASSFAILURE

Comments

If the hook function (to which the **lpfnHook** member of the **OPENFILENAME** structure points)

processes the **WM_CTLCOLOR** message, this function must return a handle for the brush that should be used to paint the control background.

Example

The following example copies file-filter strings (filename extensions) into a buffer, initializes an **OPENFILENAME** structure, and then creates a Save As dialog box.

The file-filter strings are stored in the resource file in the following form:

```
STRINGTABLE
BEGIN
  IDS_FILTERSTRING  "Write Files(*.WRI)|*.wri|Word Files(*.DOC)|*.doc|"
END
```

The replaceable character at the end of the string is used to break the entire string into separate strings, while still guaranteeing that all the strings are continguous in memory.

```
OPENFILENAME ofn;
char szDirName[256];
char szFile[256], szFileTitle[256];
UINT  i, cbString;
char  chReplace;    /* string separator for szFilter */
char  szFilter[256];
HFILE hf;

/*
 * Retrieve the system directory name, and store it in
 * szDirName.
 */

GetSystemDirectory(szDirName, sizeof(szDirName));

if ((cbString = LoadString(hinst, IDS_FILTERSTRING,
        szFilter, sizeof(szFilter))) == 0) {
    ErrorHandler();
    return 0;
}

chReplace = szFilter[cbString - 1]; /* retrieve wildcard */

for (i = 0; szFilter[i] != '\0'; i++) {
    if (szFilter[i] == chReplace)
       szFilter[i] = '\0';
}

/* Set all structure members to zero. */

memset(&ofn, 0, sizeof(OPENFILENAME));

/* Initialize the OPENFILENAME members. */

szFile[0] = '\0';

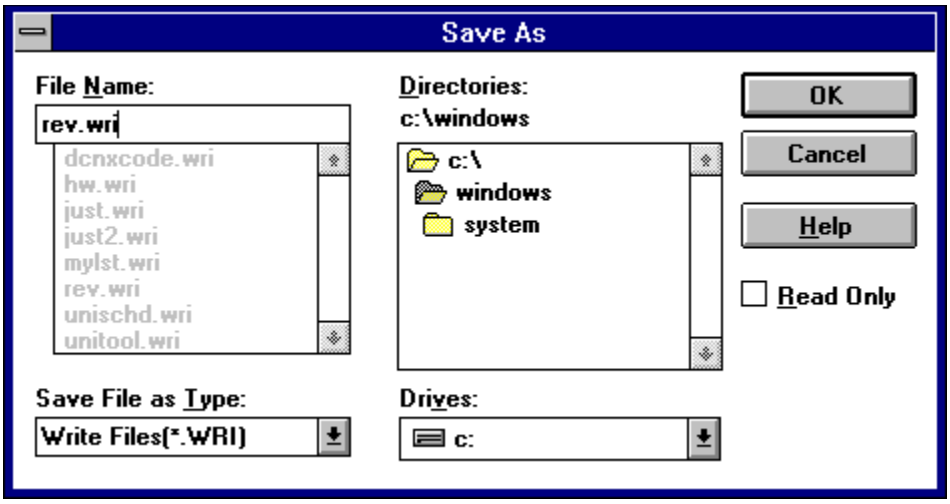
ofn.lStructSize = sizeof(OPENFILENAME);
ofn.hwndOwner = hwnd;
ofn.lpstrFilter = szFilter;
ofn.lpstrFile= szFile;
```

```
ofn.nMaxFile = sizeof(szFile);
ofn.lpstrFileTitle = szFileTitle;
ofn.nMaxFileTitle = sizeof(szFileTitle);
ofn.lpstrInitialDir = szDirName;
ofn.Flags = OFN_SHOWHELP | OFN_OVERWRITEPROMPT;

if (GetSaveFileName(&ofn)) {
    .
    . /* Perform file operations. */
    .
}
else
    ErrorHandler();
```

See Also
GetOpenFileName, **OPENFILENAME**

The following shows how the save dialog box appears:



PrintDlg function (3.1)

#include commdlg.h

BOOL PrintDlg(*lppd***)**

PRINTDLG FAR* *lppd;* /* address of structure with initialization data*/

The **PrintDlg** function displays a Print dialog box or a Print Setup dialog box. The Print dialog box makes it possible for the user to specify the properties of a particular print job. The Print Setup dialog box makes it possible for the user to select additional job properties and configure the printer.

Parameter	Description
lppd	Points to a **PRINTDLG** structure that contains information used to initialize the dialog box. When the **PrintDlg** function returns, this structure contains information about the user's selections.

Returns

The return value is nonzero if the function successfully configures the printer. The return value is zero if an error occurs, if the user chooses the Cancel button, or if the user chooses the Close command on the System menu to close the dialog box. (The return value is also zero if the user chooses the Setup button to display the Print Setup dialog box, chooses the OK button in the Print Setup dialog box, and then chooses the Cancel button in the Print dialog box.)

Errors

Use the **CommDlgExtendedError** function to retrieve the error value, which may be one of the following:

CDERR_FINDRESFAILURE	PDERR_CREATEICFAILURE
CDERR_INITIALIZATION	PDERR_DEFAULTDIFFERENT
CDERR_LOADRESFAILURE	PDERR_DNDMMISMATCH
CDERR_LOADSTRFAILURE	PDERR_GETDEVMODEFAIL
CDERR_LOCKRESFAILURE	PDERR_INITFAILURE
CDERR_MEMALLOCFAILURE	PDERR_LOADDRVFAILURE
CDERR_MEMLOCKFAILURE	PDERR_NODEFAULTPRN
CDERR_NOHINSTANCE	PDERR_NODEVICES
CDERR_NOHOOK	PDERR_PARSEFAILURE
CDERR_NOTEMPLATE	PDERR_PRINTERNOTFOUND

CDERR_STRUCTSIZE	PDERR_RETDEFFAILURE
	PDERR_SETUPFAILURE

Example

The following example initializes the **PRINTDLG** structure, calls the **PrintDlg** function to display the Print dialog box, and prints a sample page of text if the return value is nonzero:

```
PRINTDLG pd;

/* Set all structure members to zero. */

memset(&pd, 0, sizeof(PRINTDLG));

/* Initialize the necessary PRINTDLG structure members. */

pd.lStructSize = sizeof(PRINTDLG);
pd.hwndOwner = hwnd;
pd.Flags = PD_RETURNDC;

/* Print a test page if successful */

if (PrintDlg(&pd) != 0) {
    Escape(pd.hDC, STARTDOC, 8, "Test-Doc", NULL);

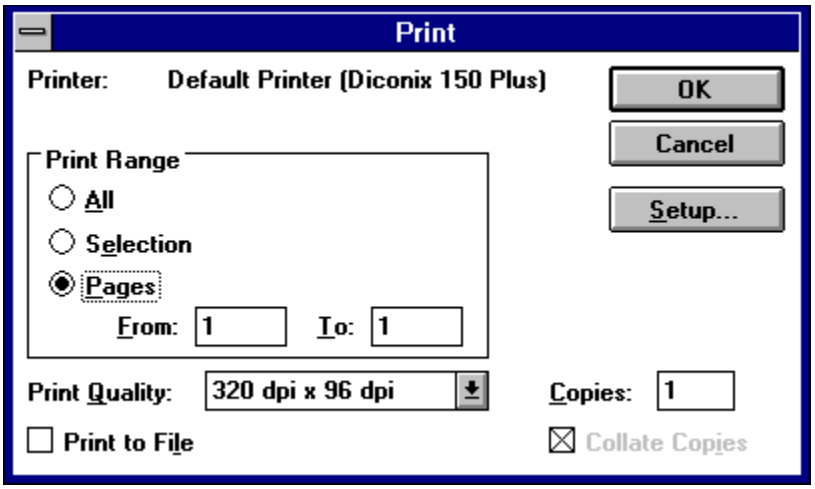
    /* Print text and rectangle */

    TextOut(pd.hDC, 50, 50, "Common Dialog Test Page", 23);
    Rectangle(pd.hDC, 50, 90, 625, 105);
    Escape(pd.hDC, NEWFRAME, 0, NULL, NULL);
    Escape(pd.hDC, ENDDOC, 0, NULL, NULL);
    DeleteDC(pd.hDC);
    if (pd.hDevMode != NULL)
       GlobalFree(pd.hDevMode);
    if (pd.hDevNames != NULL)
       GlobalFree(pd.hDevNames);
}
else
    ErrorHandler();
```

See Also

PRINTDLG

The following shows how the print dialog box normally appears:



ReplaceText (3.1)

#include commdlg.h

HWND ReplaceText(*lpfr***)**

FINDREPLACE FAR* *lpfr;* /* address of structure with initialization data*/

The **ReplaceText** function creates a system-defined modeless dialog box that makes it possible for the user to find and replace text within a document. The application must perform the actual find and replace operations.

Parameter	Description
lpfr	Points to a **FINDREPLACE** structure that contains information used to initialize the dialog box. When the user makes a selection in the dialog box, the system fills this structure with information about the user's selection and then sends a message to the application. This message contains a pointer to the **FINDREPLACE** structure.

Returns

The return value is the window handle of the dialog box, or it is NULL if an error occurs. An application can use this handle to communicate with or to close the dialog box.

Errors

Use the **CommDlgExtendedError** function to retrieve the error value, which may be one of the following:

CDERR_FINDRESFAILURE
CDERR_INITIALIZATION
CDERR_LOADRESFAILURE
CDERR_LOADSTRFAILURE
CDERR_LOCKRESFAILURE
CDERR_MEMALLOCFAILURE
CDERR_MEMLOCKFAILURE
CDERR_NOHINSTANCE
CDERR_NOHOOK
CDERR_NOTEMPLATE
CDERR_STRUCTSIZE
FRERR_BUFFERLENGTHZERO

Comments

The dialog box procedure for the **ReplaceText** function passes user requests to the application through special messages. The *lParam* parameter of each of these messages contains a pointer to a

FINDREPLACE structure. The procedure sends the messages to the window identified by the **hwndOwner** member of the **FINDREPLACE** structure. An application can register the identifier for these messages by specifying the commdlg_FindReplace string in a call to the **RegisterWindowMessage** function.

For the TAB key to function correctly, any application that calls the **ReplaceText** function must also call the **IsDialogMessage** function in its main message loop. (The **IsDialogMessage** function returns a value that indicates whether messages are intended for the Replace dialog box.)

Example

This example initializes a **FINDREPLACE** structure and calls the **ReplaceText** function to display the Replace dialog box:

```
FINDREPLACE fr;
char szFindWhat[256] = "";      /* string to find    */
char szReplaceWith[256] = "";   /* string to replace */

/* Set all structure fields to zero. */

memset(&fr, 0, sizeof(FINDREPLACE));

fr.lStructSize = sizeof(FINDREPLACE);
fr.hwndOwner = hwnd;
fr.lpstrFindWhat = szFindWhat;
fr.wFindWhatLen = sizeof(szFindWhat);
fr.lpstrReplaceWith = szReplaceWith;
fr.wReplaceWithLen = sizeof(szReplaceWith);

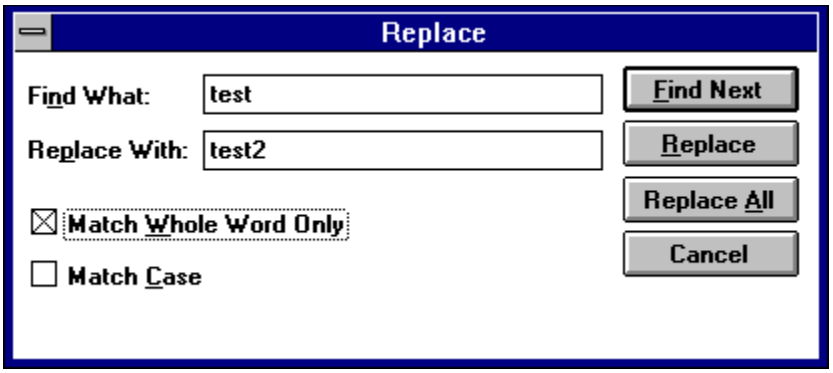
hDlg = ReplaceText(&fr);
```

In addition to initializing the members of the **FINDREPLACE** structure and calling the **ReplaceText** function, an application must register the special FINDMSGSTRING message and process messages from the dialog box. Refer to the description of the **FindText** function for an example that shows how an application registers and processes a message.

See Also

FindText, **IsDialogMessage**, **RegisterWindowMessage**, **FINDREPLACE**

The following shows how the replace dialog box appears:



Common dialog box functions (3.1)

CommDlgExtendedError	Retrieves error data for common dialog box procedure
ChooseColor	Creates a color-selection dialog box
ChooseFont function	Creates a font-selection dialog box
FindText	Creates a find-text dialog box
GetFileTitle	Retrieves a filename
GetOpenFileName	Creates an open-filename dialog box
GetSaveFileName	Creates a save-filename dialog box
PrintDlg function	Creates a print-text dialog box
ReplaceText	Creates a replace-text dialog box

DdeAbandonTransaction (3.1)

#include <ddeml.h>

BOOL DdeAbandonTransaction(*idInst, hConv, idTransaction***)**

```
DWORD idInst;          /* instance identifier       */
HCONV hConv;           /* handle of conversation    */
DWORD idTransaction;   /* transaction identifier    */
```

The **DdeAbandonTransaction** function abandons the specified asynchronous transaction and releases all resources associated with the transaction.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hConv	Identifies the conversation in which the transaction was initiated. If this parameter is NULL, all transactions are abandoned (the *idTransaction* parameter is ignored).
idTransaction	Identifies the transaction to terminate. If this parameter is NULL, all active transactions in the specified conversation are abandoned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR
DMLERR_UNFOUND_QUEUE_ID

Comments

Only a dynamic data exchange (**DDE**) client application should call the **DdeAbandonTransaction** function. If the server application responds to the transaction after the client has called **DdeAbandonTransaction**, the system discards the transaction results. This function has no effect on synchronous transactions.

DdeClientTransaction, **DdeGetLastError**, **DdeInitialize**, **DdeQueryConvInfo**

DdeAccessData (3.1)

#include <ddeml.h>

BYTE FAR* DdeAccessData(*hData, lpcbData***)**

HDDEDATA *hData;* /* handle of global memory object */
DWORD FAR* *lpcbData;* /* pointer to variable that receives data length */

The **DdeAccessData** function provides access to the data in the given global memory object. An application must call the **DdeUnaccessData** function when it is finished accessing the data in the object.

Parameter	Description
hData	Identifies the global memory object to access.
lpcbData	Points to a variable that receives the size, in bytes, of the global memory object identified by the *hData* parameter. If this parameter is NULL, no size information is returned.

Returns

The return value points to the first byte of data in the global memory object if the function is successful. Otherwise, the return value is NULL.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR

Comments

If the *hData* parameter has not been passed to a Dynamic Data Exchange Management Library (**DDEML**) function, an application can use the pointer returned by **DdeAccessData** for read-write access to the global memory object. If *hData* has already been passed to a DDEML function, the pointer can only be used for read-only access to the memory object.

Example

The following example uses the **DdeAccessData** function to obtain a pointer to a global memory object, uses the pointer to copy data from the object to a local buffer, then frees the pointer:

```
HDDEDATA hData;
LPBYTE lpszAdviseData;
DWORD cbDataLen;
DWORD i;
char szData[128];

lpszAdviseData = DdeAccessData(hData, &cbDataLen);
for (i = 0; i < cbDataLen; i++)
    szData[i] = *lpszAdviseData++;
DdeUnaccessData(hData);
```

See Also

DdeAddData, **DdeCreateDataHandle**, **DdeFreeDataHandle**, **DdeGetLastError**, **DdeUnaccessData**

DdeAddData (3.1)

#include <ddeml.h>

HDDEDATA DdeAddData(*hData, lpvSrcBuf, cbAddData, offObj***)**

HDDEDATA *hData;* /* handle of global memory object */
void FAR* *lpvSrcBuf;* /* address of source buffer */
DWORD *cbAddData;* /* length of data */
DWORD *offObj;* /* offset within global memory object */

The **DdeAddData** function adds data to the given global memory object. An application can add data beginning at any offset from the beginning of the object. If new data overlaps data already in the object, the new data overwrites the old data in the bytes where the overlap occurs. The contents of locations in the object that have not been written to are undefined.

Parameter	Description
hData	Identifies the global memory object that receives additional data.
lpvSrcBuf	Points to a buffer containing the data to add to the global memory object.
cbAddData	Specifies the length, in bytes, of the data to be added to the global memory object.
offObj	Specifies an offset, in bytes, from the beginning of the global memory object. The additional data is copied to the object beginning at this offset.

Returns

The return value is a new handle of the global memory object if the function is successful. The new handle should be used in all references to the object. The return value is zero if an error occurs.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_MEMORY_ERROR
DMLERR_NO_ERROR

Comments

After a data handle has been used as a parameter in another Dynamic Data Exchange Management Library (**DDEML**) function or returned by a **DDE** callback function, the handle may only be used for read access to the global memory object identified by the handle.

If the amount of global memory originally allocated is not large enough to hold the added data, the **DdeAddData** function will reallocate a global memory object of the appropriate size.

Example

The following example creates a global memory object, uses the **DdeAddData** function to add data to the object, and then passes the data to a client with an **XTYP_POKE** transaction:

```
DWORD idInst;           /* instance identifier     */
HDDEDATA hddeStrings;   /* data handle             */
HSZ hszMyItem;          /* item-name string handle */
DWORD offObj = 0;       /* offset in global object */
char szMyBuf[16];       /* temporary string buffer */
HCONV hconv;            /* conversation handle     */
DWORD dwResult;         /* transaction results     */
BOOL fAddAString;       /* TRUE if strings to add  */

/* Create a global memory object. */

hddeStrings = DdeCreateDataHandle(idInst, NULL, 0, 0,
```

```
    hszMyItem, CF_TEXT, 0);

/*
 * If a string is available, the application-defined function
 * IsThereAString() copies it to szMyBuf and returns TRUE. Otherwise,
 * it returns FALSE.
 */

while ((fAddAString = IsThereAString())) {

    /* Add the string to the global memory object. */

    DdeAddData(hddeStrings,             /* data handle        */
        &szMyBuf,                       /* string buffer      */
        (DWORD) strlen(szMyBuf) + 1,    /* character count    */
        offObj);                        /* offset in object   */

    offObj = (DWORD) strlen(szMyBuf) + 1; /* adjust offset */
}

/* No more data to add, so poke it to the server. */

DdeClientTransaction((void FAR*) hddeStrings, -1L, hconv, hszMyItem,
    CF_TEXT, XTYP_POKE, 1000, &dwResult);
```

DdeClientTransaction (3.1)

#include <ddeml.h>

HDDEDATA DdeClientTransaction(*lpvData, cbData, hConv, hszItem, uFmt, uType, uTimeout, lpuResult***)**

```
void FAR* lpvData;      /* address of data to pass to server  */
DWORD cbData;           /* length of data                     */
HCONV hConv;            /* handle of conversation             */
HSZ hszItem;            /* handle of item-name string         */
UINT uFmt;              /* clipboard data format              */
UINT uType;             /* transaction type                   */
DWORD uTimeout;         /* timeout duration                   */
DWORD FAR* lpuResult;   /* points to transaction result       */
```

The **DdeClientTransaction** function begins a data transaction between a client and a server. Only a dynamic data exchange (**DDE**) client application can call this function, and only after establishing a conversation with the server.

Parameter	Description
lpvData	Points to the beginning of the data that the client needs to pass to the server. Optionally, an application can specify the data handle (HDDEDATA) to pass to the server, in which case the *cbData* parameter should be set to -1. This parameter is required only if the *uType* parameter is **XTYP_EXECUTE** or XTYP_POKE. Otherwise, this parameter should be NULL.
cbData	Specifies the length, in bytes, of the data pointed to by the *lpvData* parameter. A value of -1 indicates that *lpvData* is a data handle that identifies the data being sent.
hConv	Identifies the conversation in which the transaction is to take place.
hszItem	Identifies the data item for which data is being exchanged during the transaction. This handle must have been created by a previous call to the **DdeCreateStringHandle** function. This parameter is ignored (and should be set to NULL) if the *uType* parameter is XTYP_EXECUTE.
uFmt	Specifies the standard clipboard format in which the data item is being submitted or requested. For more information about standard clipboard formats, see the **Clipboard formats** topic.
uType	Specifies the transaction type. This parameter can be one of the following values:

Value	Meaning
XTYP_ADVSTART	Begins an advise loop. Any number of distinct advise loops can exist within a conversation. An application can alter the advise loop type by combining the **XTYP_ADVSTART** transaction type with one or more of the following flags:

Value	Meaning
XTYPF_NODATA	Instructs the server to notify the client of any data changes without actually sending the data. This flag gives the client the option of ignoring the notification or requesting the changed data from the server.
XTYPF_ACKREQ	Instructs the server to wait until the client acknowledges that it received the previous data item before sending the next data item. This flag

prevents a fast server from sending data faster than the client can process it.

XTYP_ADVSTOP	Ends an advise loop.
XTYP_EXECUTE	Begins an execute transaction.
XTYP_POKE	Begins a poke transaction.
XTYP_REQUEST	Begins a request transaction.

uTimeout Specifies the maximum length of time, in milliseconds, that the client will wait for a response from the server application in a synchronous transaction. This parameter should be set to TIMEOUT_ASYNC for asynchronous transactions.

lpuResult Points to a variable that receives the result of the transaction. An application that does not check the result can set this value to NULL. For synchronous transactions, the low-order word of this variable will contain any applicable DDE_ flags resulting from the transaction. This provides support for applications dependent on DDE_APPSTATUS bits. (It is recommended that applications no longer use these bits because they may not be supported in future versions of the **DDE** Management Library.) For asynchronous transactions, this variable is filled with a unique transaction identifier for use with the **DdeAbandonTransaction** function and the **XTYP_XACT_COMPLETE** transaction.

Returns

The return value is a data handle that identifies the data for successful synchronous transactions in which the client expects data from the server. The return value is TRUE for successful asynchronous transactions and for synchronous transactions in which the client does not expect data. The return value is FALSE for all unsuccessful transactions.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_ADVACKTIMEOUT
DMLERR_BUSY
DMLERR_DATAACKTIMEOUT
DMLERR_DLL_NOT_INITIALIZED
DMLERR_EXECACKTIMEOUT
DMLERR_INVALIDPARAMETER
DMLERR_MEMORY_ERROR
DMLERR_NO_CONV_ESTABLISHED
DMLERR_NO_ERROR
DMLERR_NOTPROCESSED
DMLERR_POKEACKTIMEOUT
DMLERR_POSTMSG_FAILED
DMLERR_REENTRANCY
DMLERR_SERVER_DIED
DMLERR_UNADVACKTIMEOUT

Comments

When the application is finished using the data handle returned by the **DdeClientTransaction** function, the application should free the handle by calling the **DdeFreeDataHandle** function.

Transactions can be synchronous or asynchronous. During a synchronous transaction, the **DdeClientTransaction** function does not return until the transaction completes successfully or fails. Synchronous transactions cause the client to enter a modal loop while waiting for various asynchronous events. Because of this, the client application can still respond to user input while waiting on a synchronous transaction but cannot begin a second synchronous transaction because of the activity associated with the first. The **DdeClientTransaction** function fails if any instance of the same task has a synchronous transaction already in progress.

During an asynchronous transaction, the **DdeClientTransaction** function returns after the transaction is

begun, passing a transaction identifier for reference. When the server's **DDE** callback function finishes processing an asynchronous transaction, the system sends an **XTYP_XACT_COMPLETE** transaction to the client. This transaction provides the client with the results of the asynchronous transaction that it initiated by calling the **DdeClientTransaction** function. A client application can choose to abandon an asynchronous transaction by calling the **DdeAbandonTransaction** function.

Example

The following example requests an advise loop with a **DDE** server application:

```
HCONV hconv;
HSZ hszNow;
HDDEDATA hData;
DWORD dwResult;

hData = DdeClientTransaction(
    (LPBYTE) NULL, /* pass no data to server */
    0,             /* no data                */
    hconv,         /* conversation handle    */
    hszNow,        /* item name              */
    CF_TEXT,       /* clipboard format       */
    XTYP_ADVSTART, /* start an advise loop   */
    1000,          /* time-out in one second */
    &dwResult);    /* points to result flags */
```

DdeCmpStringHandles (3.1)

#include <ddeml.h>

int DdeCmpStringHandles(*hsz1, hsz2***)**

HSZ *hsz1;* /* handle of first string */
HSZ *hsz2;* /* handle of second string */

The **DdeCmpStringHandles** function compares the values of two string handles. The value of a string handle is not related to the case of the associated string.

Parameter	Description
hsz1	Specifies the first string handle.
hsz2	Specifies the second string handle.

Returns

The return value can be one of the following:

Value	Meaning
-1	The value of *hsz1* is either 0 or less than the value of *hsz2.*
0	The values of *hsz1* and *hsz2* are equal (both can be 0).
1	The value of *hsz2* is either 0 or less than the value of *hsz1.*

Comments

An application that needs to do a case-sensitive comparison of two string handles should compare the string handles directly. An application should use **DdeCompStringHandles** for all other comparisons to preserve the case-sensitive nature of dynamic data exchange (**DDE**).

The **DdeCompStringHandles** function cannot be used to sort string handles alphabetically.

Example

This example compares two service-name string handles and, if the handles are the same, requests a conversation with the server, then issues an **XTYP_ADVSTART** transaction:

```
HSZ hszClock;   /* service name */
HSZ hszTime;    /* topic name   */
HSZ hsz1;       /* unknown server          */
HCONV hConv;    /* conversation handle     */
DWORD dwResult; /* result flags            */
DWORD idInst;   /* instance identifier     */

/*
 * Compare unknown service name handle with the string handle
 * for the clock application.
 */

if (!DdeCmpStringHandles(hsz1, hszClock)) {

    /*
     * If this is the clock application, start a conversation
     * with it and request an advise loop.
     */

    hConv = DdeConnect(idInst, hszClock, hszTime, NULL);
    if (hConv != (HCONV) NULL)
        DdeClientTransaction(NULL, 0, hConv, hszNow,
            CF_TEXT, XTYP_ADVSTART, 1000, &dwResult);
```

```
}
```

DdeAccessData, **DdeCreateStringHandle**, **DdeFreeStringHandle**

DdeConnect (3.1)

#include <ddeml.h>

HCONV DdeConnect(*idInst, hszService, hszTopic, pCC***)**

DWORD *idInst;*	/* instance identifier */
HSZ *hszService;*	/* handle of service-name string */
HSZ *hszTopic;*	/* handle of topic-name string */
CONVCONTEXT FAR* *pCC;*	/* address of structure with context data*/

The **DdeConnect** function establishes a conversation with a server application that supports the specified service name and topic name pair. If more than one such server exists, the system selects only one.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hszService	Identifies the string that specifies the service name of the server application with which a conversation is to be established. This handle must have been created by a previous call to the **DdeCreateStringHandle** function. If this parameter is NULL, a conversation will be established with any available server.
hszTopic	Identifies the string that specifies the name of the topic on which a conversation is to be established. This handle must have been created by a previous call to the **DdeCreateStringHandle** function. If this parameter is NULL, a conversation on any topic supported by the selected server will be established.
pCC	Points to the **CONVCONTEXT** structure that contains conversation-context information. If this parameter is NULL, the server receives the default **CONVCONTEXT** structure during the **XTYP_CONNECT** or **XTYP_WILDCONNECT** transaction.

Returns

The return value is the handle of the established conversation if the function is successful. Otherwise, it is NULL.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_NO_CONV_ESTABLISHED
DMLERR_NO_ERROR

Comments

The client application should not make assumptions regarding which server will be selected. If an instance-specific name is specified in the *hszService* parameter, a conversation will be established only with the specified instance. Instance-specific service names are passed to an application's dynamic data exchange callback function during the **XTYP_REGISTER** and **XTYP_UNREGISTER** transactions.

All members of the default **CONVCONTEXT** structure are set to zero except **cb**, which specifies the size of the structure, and **iCodePage**, which specifies CP_WINANSI (the default code page).

Example

The following example creates a service-name string handle and a topic-name string handle, then attempts to establish a conversation with a server that supports the service name and topic name. If the attempt fails, the example retrieves an error value identifying the reason for the failure.

```
DWORD idInst = 0L;
HSZ hszClock;
```

```
HSZ hszTime;
HCONV hconv;
UINT uError;

hszClock = DdeCreateStringHandle(idInst, "Clock", CP_WINANSI);
hszTime = DdeCreateStringHandle(idInst, "Time", CP_WINANSI);

if ((hconv = DdeConnect(
    idInst,                 /* instance identifier              */
    hszClock,               /* server's service name            */
    hszTime,                /* topic name                       */
    NULL)) == NULL) {       /* use default CONVCONTEXT          */
    uError = DdeGetLastError(idInst);
}
```

See Also

DdeConnectList, **DdeCreateStringHandle**, **DdeDisconnect**, **DdeDisconnectList**, **DdeInitialize**, **CONVCONTEXT**, **XTYP_CONNECT**, **XTYP_REGISTER**, **XTYP_UNREGISTER**

DdeConnectList (3.1)

#include <ddeml.h>

HCONVLIST DdeConnectList(*idInst, hszService, hszTopic, hConvList, pCC***)**

```
DWORD idInst;                   /* instance identifier                 */
HSZ hszService;                 /* handle of service-name string       */
HSZ hszTopic;                   /* handle of topic-name string         */
HCONVLIST hConvList;            /* handle of conversation list         */
CONVCONTEXT FAR* pCC;           /* address of structure with context data*/
```

The **DdeConnectList** function establishes a conversation with all server applications that support the specified service/topic name pair. An application can also use this function to enumerate a list of conversation handles by passing the function an existing conversation handle. During enumeration, the Dynamic Data Exchange Management Library (**DDEML**) removes the handles of any terminated conversations from the conversation list. The resulting conversation list contains the handles of all conversations currently established that support the specified service name and topic name.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hszService	Identifies the string that specifies the service name of the server application with which a conversation is to be established. If this parameter is NULL, the system will attempt to establish conversations with all available servers that support the specified topic name.
hszTopic	Identifies the string that specifies the name of the topic on which a conversation is to be established. This handle must have been created by a previous call to the **DdeCreateStringHandle** function. If this parameter is NULL, the system will attempt to establish conversations on all topics supported by the selected server (or servers).
hConvList	Identifies the conversation list to be enumerated. This parameter should be set to NULL if a new conversation list is to be established.
pCC	Points to the **CONVCONTEXT** structure that contains conversation-context information. If this parameter is NULL, the server receives the default **CONVCONTEXT** structure during the **XTYP_CONNECT** or **XTYP_WILDCONNECT** transaction.

Returns

The return value is the handle of a new conversation list if the function is successful. Otherwise, it is NULL. The handle of the old conversation list is no longer valid.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALID_PARAMETER
DMLERR_NO_CONV_ESTABLISHED
DMLERR_NO_ERROR
DMLERR_SYS_ERROR

Comments

An application must free the conversation-list handle returned by this function, regardless of whether any conversation handles within the list are active. To free the handle, an application can call the **DdeDisconnectList** function.

All members of the default **CONVCONTEXT** structure are set to zero except **cb**, which specifies the size of the structure, and **iCodePage**, which specifies CP_WINANSI (the default code page).

Example

The following example uses the **DdeConnectList** function to establish a conversation with all servers

that support the System topic, counts the servers, allocates a buffer for storing the server's service-name string handles, and then copies the handles to the buffer:

```
HCONVLIST hconvList; /* conversation list       */
DWORD idInst;        /* instance identifier     */
HSZ hszSystem;       /* System topic            */
HCONV hconv = NULL;  /* conversation handle     */
CONVINFO ci;         /* holds conversation data */
UINT cConv = 0;      /* count of conv. handles  */
HSZ *pHsz, *aHsz;    /* point to string handles */

/* Connect to all servers that support the System topic. */

hconvList = DdeConnectList(idInst, NULL, hszSystem, NULL, NULL);

/* Count the number of handles in the conversation list. */

while ((hconv = DdeQueryNextServer(hconvList, hconv)) != NULL) cConv++;

/* Allocate a buffer for the string handles. */

hconv = NULL;
aHsz = (HSZ *) LocalAlloc(LMEM_FIXED, cConv * sizeof(HSZ));

/* Copy the string handles to the buffer. */

pHsz = aHsz;
while ((hconv = DdeQueryNextServer(hconvList, hconv)) != NULL) {
    DdeQueryConvInfo(hconv, QID_SYNC, (PCONVINFO) &ci);
    DdeKeepStringHandle(idInst, ci.hszSvcPartner);
    *pHsz++ = ci.hszSvcPartner;
}

.
. /* Use the handles; converse with servers. */
.

/* Free the memory, and terminate conversations. */

LocalFree((HANDLE) aHsz);
DdeDisconnectList(hconvList);
```

DdeCreateDataHandle (3.1)

#include <ddeml.h>

HDDEDATA DdeCreateDataHandle(*idInst, lpvSrcBuf, cbInitData, offSrcBuf, hszItem, uFmt, afCmd***)**

```
DWORD idInst;       /* instance identifier                    */
void FAR* lpvSrcBuf;/* address of source buffer               */
DWORD cbInitData;   /* length of global memory object         */
DWORD offSrcBuf;    /* offset from beginning of source buffer */
HSZ hszItem;        /* handle of item-name string             */
UINT uFmt;          /* clipboard data format                  */
UINT afCmd;         /* creation flags                         */
```

The **DdeCreateDataHandle** function creates a global memory object and fills the object with the data pointed to by the *lpvSrcBuf* parameter. A dynamic data exchange (**DDE**) application uses this function during transactions that involve passing data to the partner application.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
lpvSrcBuf	Points to a buffer that contains data to be copied to the global memory object. If this parameter is NULL, no data is copied to the object.
cbInitData	Specifies the amount, in bytes, of memory to allocate for the global memory object. If this parameter is zero, the *lpvSrcBuf* parameter is ignored.
offSrcBuf	Specifies an offset, in bytes, from the beginning of the buffer pointed to by the *lpvSrcBuf* parameter. The data beginning at this offset is copied from the buffer to the global memory object.
hszItem	Identifies the string that specifies the data item corresponding to the global memory object. This handle must have been created by a previous call to the **DdeCreateStringHandle** function. If the data handle is to be used in an **XTYP_EXECUTE** transaction, this parameter must be set to NULL.
uFmt	Specifies the standard clipboard format of the data.
afCmd	Specifies the creation flags. This parameter can be HDATA_APPOWNED, which specifies that the server application that calls the **DdeCreateDataHandle** function will own the data handle that this function creates. This makes it possible for the server to share the data handle with multiple clients instead of creating a separate handle for each request. If this flag is set, the server must eventually free the shared memory object associated with this handle by using the **DdeFreeDataHandle** function. If this flag is not set, after the data handle is returned by the server's **DDE** callback function or used as a parameter in another DDE Management Library function, the handle becomes invalid in the application that creates the handle.

Returns

The return value is a data handle if the function is successful. Otherwise, it is NULL.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_MEMORY_ERROR
DMLERR_NO_ERROR

Comments

Any locations in the global memory object that are not filled are undefined.

After a data handle has been used as a parameter in another **DDEML** function or has been returned by a **DDE** callback function, the handle may be used only for read access to the global memory object identified by the handle.

If the application will be adding data to the global memory object (using the **DdeAddData** function) so that the object exceeds 64K in length, then the application should specify a total length (*cbInitData* + *offSrcData*) that is equal to the anticipated maximum length of the object. This avoids unnecessary data copying and memory reallocation by the system.

Example

The following example processes the **XTYP_WILDCONNECT** transaction by returning a data handle to an array of **HSZPAIR** structures--one for each topic name supported:

```
#define CTOPICS 2

UINT type;
UINT fmt;
HSZPAIR ahp[(CTOPICS + 1)];
HSZ ahszTopicList[CTOPICS];
HSZ hszServ, hszTopic;
WORD i, j;

if (type == XTYP_WILDCONNECT) {

     /*
      * Scan the topic list, and create array of HSZPAIR
      * structures.
      */

    j = 0;
    for (i = 0; i < CTOPICS; i++) {
        if (hszTopic == (HSZ) NULL ||
                hszTopic == ahszTopicList[i]) {
            ahp[j].hszSvc = hszServ;
            ahp[j++].hszTopic = ahszTopicList[i];
        }
    }

    /*
     * End the list with an HSZPAIR structure that contains NULL
     * string handles as its members.
     */

    ahp[j].hszSvc = NULL;
    ahp[j++].hszTopic = NULL;

    /*
     * Return a handle to a global memory object containing the
     * HSZPAIR structures.
     */

    return DdeCreateDataHandle(
        idInst,          /* instance identifier     */
        &ahp,            /* points to HSZPAIR array */
        sizeof(HSZ) * j, /* length of the array     */
        0,               /* start at the beginning  */
        NULL,            /* no item-name string     */
```

```
        fmt,              /* return the same format  */
        0);               /* let the system own it   */
}
```

DdeAccessData, **DdeFreeDataHandle**, **DdeGetData**, **DdeInitialize**, **XTYP_EXECUTE**

DdeCreateStringHandle (3.1)

#include <ddeml.h>

HSZ DdeCreateStringHandle(*idInst, lpszString, codepage***)**

DWORD *idInst;* /* instance identifier */
LPCSTR *lpszString;* /* address of null-terminated string */
int *codepage;* /* code page */

The **DdeCreateStringHandle** function creates a handle that identifies the string pointed to by the *lpszString* parameter. A dynamic data exchange (**DDE**) client or server application can pass the string handle as a parameter to other DDE Management Library functions.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
lpszString	Points to a buffer that contains the null-terminated string for which a handle is to be created. This string may be any length.
codepage	Specifies the code page used to render the string. This value should be either CP_WINANSI or the value returned by the **GetKBCodePage** function. A value of zero implies CP_WINANSI.

Returns

The return value is a string handle if the function is successful. Otherwise, it is NULL.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR
DMLERR_SYS_ERROR

Comments

Two identical strings always correspond to the same string handle. String handles are unique across all tasks that use the DDEML. That is, when an application creates a handle for a string and another application creates a handle for an identical string, the string handles returned to both applications are identical--regardless of case.

The value of a string handle is not related to the case of the string it identifies.

When an application has either created a string handle or received one in the callback function and has used the **DdeKeepStringHandle** function to keep it, the application must free that string handle when it is no longer needed.

An instance-specific string handle is not mappable from string handle to string to string handle again. This is shown in the following example, in which the **DdeQueryString** function creates a string from a string handle and then **DdeCreateStringHandle** creates a string handle from that string, but the two handles are not the same:

```
DWORD idInst;
DWORD cb;
HSZ hszInst, hszNew;
PSZ pszInst;

DdeQueryString(idInst, hszInst, pszInst, cb, CP_WINANSI);
hszNew = DdeCreateStringHandle(idInst, pszInst, CP_WINANSI);
/* hszNew != hszInst ! */
```

Example

The following example creates a service-name string handle and a topic-name string handle and then attempts to establish a conversation with a server that supports the service name and topic name. If the attempt fails, the example obtains an error value identifying the reason for the failure.

```
DWORD idInst = 0L;
HSZ hszClock;
HSZ hszTime;
HCONV hconv;
UINT uError;

hszClock = DdeCreateStringHandle(idInst, "Clock", CP_WINANSI);
hszTime = DdeCreateStringHandle(idInst, "Time", CP_WINANSI);

if ((hconv = DdeConnect(
    idInst,                 /* instance identifier                */
    hszClock,               /* server's service name              */
    hszTime,                /* topic name                         */
    NULL)) == NULL) {       /* use default CONVCONTEXT            */

    uError = DdeGetLastError(idInst);
}
```

DdeAccessData, **DdeCmpStringHandles**, **DdeFreeStringHandle**, **DdeInitialize**, **DdeKeepStringHandle**, **DdeQueryString**

DdeDisconnect (3.1)

#include <ddeml.h>

BOOL DdeDisconnect(*hConv***)**

HCONV *hConv;* /* handle of conversation */

The **DdeDisconnect** function terminates a conversation started by either the **DdeConnect** or **DdeConnectList** function and invalidates the given conversation handle.

Parameter	Description
hConv	Identifies the active conversation to be terminated.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_NO_CONV_ESTABLISHED
DMLERR_NO_ERROR

Comments

Any incomplete transactions started before calling **DdeDisconnect** are immediately abandoned. The **XTYP_DISCONNECT** transaction type is sent to the dynamic data exchange (**DDE**) callback function of the partner in the conversation. Generally, only client applications need to terminate conversations.

See Also

DdeConnect, **DdeConnectList**, **DdeDisconnectList**, **XTYP_DISCONNECT**

DdeDisconnectList (3.1)

#include <ddeml.h>

BOOL DdeDisconnectList(*hConvList***)**

HCONVLIST *hConvList;* /* handle of conversation list */

The **DdeDisconnectList** function destroys the given conversation list and terminates all conversations associated with the list.

Parameter	Description
hConvList	Identifies the conversation list. This handle must have been created by a previous call to the **DdeConnectList** function.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR

Comments

An application can use the **DdeDisconnect** function to terminate individual conversations in the list.

See Also

DdeConnect, **DdeConnectList**, **DdeDisconnect**, **XTYP_DISCONNECT**

DdeEnableCallback (3.1)

#include <ddeml.h>

BOOL DdeEnableCallback(*idInst, hConv, uCmd***)**

DWORD *idInst;* /* instance identifier */
HCONV *hConv;* /* handle of conversation */
UINT *uCmd;* /* the enable/disable function code */

The **DdeEnableCallback** function enables or disables transactions for a specific conversation or for all conversations that the calling application currently has established.

After disabling transactions for a conversation, the system places the transactions for that conversation in a transaction queue associated with the application. The application should reenable the conversation as soon as possible to avoid losing queued transactions.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hConv	Identifies the conversation to enable or disable. If this parameter is NULL, the function affects all conversations.
uCmd	Specifies the function code. This parameter can be one of the following values:

Value	Meaning
EC_ENABLEALL	Enables all transactions for the specified conversation.
EC_ENABLEONE	Enables one transaction for the specified conversation.
EC_DISABLE	Disables all blockable transactions for the specified conversation. A server application can disable the following transactions: **XTYP_ADVSTART** **XTYP_ADVSTOP** **XTYP_EXECUTE** **XTYP_POKE** **XTYP_REQUEST** A client application can disable the following transactions: **XTYP_ADVDATA** **XTYP_XACT_COMPLETE**

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_NO_ERROR
DMLERR_INVALIDPARAMETER

Comments

An application can disable transactions for a specific conversation by returning CBR_BLOCK from its dynamic data exchange (**DDE**) callback function. When the conversation is reenabled by using the **DdeEnableCallback** function, the system generates the same transaction as was in process when the conversation was disabled.

DdeConnect, **DdeConnectList**, **DdeDisconnect**, **DdeInitialize**

DdeFreeDataHandle (3.1)

#include <ddeml.h>

BOOL DdeFreeDataHandle(*hData***)**

HDDEDATA *hData;* /* handle of global memory object */

The **DdeFreeDataHandle** function frees a global memory object and deletes the data handle associated with the object.

Parameter	Description
hData	Identifies the global memory object to be freed. This handle must have been created by a previous call to the **DdeCreateDataHandle** function or returned by the **DdeClientTransaction** function.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR

Comments

An application must call **DdeFreeDataHandle** under the following circumstances:

- To free a global memory object that the application allocated by calling the **DdeCreateDataHandle** function if the object's data handle was never passed by the application to another Dynamic Data Exchange Management Library (**DDEML**) function
- To free a global memory object that the application allocated by specifying the HDATA_APPOWNED flag in a call to the **DdeCreateDataHandle** function
- To free a global memory object whose handle the application received from the **DdeClientTransaction** function

The system automatically frees an unowned object when its handle is returned by a dynamic data exchange (**DDE**) callback function or used as a parameter in a **DDEML** function.

Example

The following example creates a global memory object containing help information, then frees the object after passing the object's handle to the client application:

```
DWORD idInst;
HSZ hszItem;
HDDEDATA hDataHelp;

char szDdeHelp[] = "DDEML test server help:\r\n"\
    "\tThe 'Server' (service) and 'Test' (topic) names may change.\r\n"\
    "Items supported under the 'Test' topic are:\r\n"\
    "\tCount:\tThis value increments on each data change.\r\n"\
    "\tRand:\tThis value is changed after each data change. \r\n"\
    "\t\tIn Runaway mode, the above items change after a request.\r\n"\
    "\tHuge:\tThis is randomly generated text data >64k that the\r\n"\
    "\t\ttest client can verify. It is recalculated on each\r\n"\
    "\t\trequest. This also verifies huge data poked or executed\r\n"\
    "\t\tfrom the test client.\r\n"\
    "\tHelp:\tThis help information.  This data is APPOWNED.\r\n";

    /* Create global memory object containing help information. */
```

```
if (!hDataHelp) {
    hDataHelp = DdeCreateDataHandle(idInst, szDdeHelp,
        strlen(szDdeHelp) + 1, 0, hszItem, CF_TEXT, HDATA_APPOWNED);
}

.
. /* Pass help information to client application. */
.

/* Free the global memory object. */

if (hDataHelp)
    DdeFreeDataHandle(hDataHelp);
```

See Also

DdeAccessData, **DdeCreateDataHandle**

DdeFreeStringHandle (3.1)

#include <ddeml.h>

BOOL DdeFreeStringHandle(*idInst, hsz***)**

DWORD *idInst;* /* instance identifier */
HSZ *hsz;* /* handle of string */

The **DdeFreeStringHandle** function frees a string handle in the calling application.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hsz	Identifies the string handle to be freed. This handle must have been created by a previous call to the **DdeCreateStringHandle** function.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

An application can free string handles that it creates with the **DdeCreateStringHandle** function but should not free those that the system passed to the application's dynamic data exchange (**DDE**) callback function or those returned in the **CONVINFO** structure by the **DdeQueryConvInfo** function.

Example

The following example frees string handles during the **XTYP_DISCONNECT** transaction:

```
DWORD idInst = 0L;
HSZ hszClock;
HSZ hszTime;
HSZ hszNow;
UINT type;

if (type == XTYP_DISCONNECT) {

    DdeFreeStringHandle(idInst, hszClock);
    DdeFreeStringHandle(idInst, hszTime);
    DdeFreeStringHandle(idInst, hszNow);

    return (HDDEDATA) NULL;
}
```

See Also

DdeCmpStringHandles, **DdeCreateStringHandle**, **DdeInitialize**, **DdeKeepStringHandle**, **DdeQueryString**

DdeGetData (3.1)

#include <ddeml.h>

DWORD DdeGetData(*hData, pDest, cbMax, offSrc***)**

HDDEDATA *hData;*	/* handle of global memory object */
void FAR* *pDest;*	/* address of destination buffer */
DWORD *cbMax;*	/* amount of data to copy */
DWORD *offSrc;*	/* offset to beginning of data */

The **DdeGetData** function copies data from the given global memory object to the specified local buffer.

Parameter	Description
hData	Identifies the global memory object that contains the data to copy.
pDest	Points to the buffer that receives the data. If this parameter is NULL, the **DdeGetData** function returns the amount, in bytes, of data that would be copied to the buffer.
cbMax	Specifies the maximum amount, in bytes, of data to copy to the buffer pointed to by the *pDest* parameter. Typically, this parameter specifies the length of the buffer pointed to by *pDest.*
offSrc	Specifies an offset within the global memory object. Data is copied from the object beginning at this offset.

Returns

If the *pDest* parameter points to a buffer, the return value is the size, in bytes, of the memory object associated with the data handle or the size specified in the *cbMax* parameter, whichever is lower.

If the *pDest* parameter is NULL, the return value is the size, in bytes, of the memory object associated with the data handle.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALID_HDDEDATA
DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR

Example

The following example copies data from a global memory object to a local buffer and then fills the **TIME** structure with data from the buffer:

```
HDDEDATA hData;
char szBuf[32];

typedef struct {
    int hour;
    int minute;
    int second;
} TIME;

DdeGetData(hData, (LPBYTE) szBuf, 32L, 0L);
sscanf(szBuf, "%d:%d:%d", &nTime.hour, &nTime.minute,
    &nTime.second);
```

See Also

DdeAccessData, **DdeCreateDataHandle**, **DdeFreeDataHandle**

DdeGetLastError (3.1)

#include <ddeml.h>

UINT DdeGetLastError(*idInst***)**

DWORD *idInst;* /* instance identifier */

The **DdeGetLastError** function returns the most recent error value set by the failure of a Dynamic Data Exchange Management Library (**DDEML**) function and resets the error value to DMLERR_NO_ERROR.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.

Returns

The return value is the last error value. Following are the possible **DDEML** error values:

Value	Meaning
DMLERR_ADVACKTIMEOUT	A request for a synchronous advise transaction has timed out.
DMLERR_BUSY	The response to the transaction caused the DDE_FBUSY bit to be set.
DMLERR_DATAACKTIMEOUT	A request for a synchronous data transaction has timed out.
DMLERR_DLL_NOT_INITIALIZED	A **DDEML** function was called without first calling the **DdeInitialize** function, or an invalid instance identifier was passed to a DDEML function.
DMLERR_DLL_USAGE	An application initialized as APPCLASS_MONITOR has attempted to perform a **DDE** transaction, or an application initialized as APPCMD_CLIENTONLY has attempted to perform server transactions.
DMLERR_EXECACKTIMEOUT	A request for a synchronous execute transaction has timed out.
DMLERR_INVALIDPARAMETER	A parameter failed to be validated by the DDEML. Some of the possible causes are as follows: The application used a data handle initialized with a different item-name handle than that required by the transaction. The application used a data handle that was initialized with a different clipboard data format than that required by the transaction. The application used a client-side conversation handle with a server-side function or vise versa. The application used a freed data handle or string handle. More than one instance of the application used the same object.
DMLERR_LOW_MEMORY	A **DDEML** application has created a prolonged race condition (where the server application outruns the client), causing large amounts of memory to be consumed.
DMLERR_MEMORY_ERROR	A memory allocation failed.
DMLERR_NO_CONV_ESTABLISHED	A client's attempt to establish a conversation has failed.
DMLERR_NOTPROCESSED	A transaction failed.

DMLERR_POKEACKTIMEOUT	A request for a synchronous poke transaction has timed out.
DMLERR_POSTMSG_FAILED	An internal call to the **PostMessage** function has failed.
DMLERR_REENTRANCY	An application instance with a synchronous transaction already in progress attempted to initiate another synchronous transaction, or the **DdeEnableCallback** function was called from within a **DDEML** callback function.
DMLERR_SERVER_DIED	A server-side transaction was attempted on a conversation that was terminated by the client, or the server terminated before completing a transaction.
DMLERR_SYS_ERROR	An internal error has occurred in the DDEML.
DMLERR_UNADVACKTIMEOUT	A request to end an advise transaction has timed out.
DMLERR_UNFOUND_QUEUE_ID	An invalid transaction identifier was passed to a **DDEML** function. Once the application has returned from an **XTYP_XACT_COMPLETE** callback, the transaction identifier for that callback is no longer valid.

Example

The following example calls the **DdeGetLastError** function if the **DdeCreateDataHandle** function fails:

```
DWORD idInst;
HDDEDATA hddeMyData;
HSZPAIR ahszp[2];
HSZ hszClock, hszTime;

/* Create string handles. */

hszClock = DdeCreateStringHandle(idInst, (LPSTR) "Clock",
    CP_WINANSI);
hszTime = DdeCreateStringHandle(idInst, (LPSTR) "Time",
    CP_WINANSI);

/* Copy handles to an HSZPAIR structure. */

ahszp[0].hszSvc   = hszClock;
ahszp[0].hszTopic = hszTime;
ahszp[1].hszSvc   = (HSZ) NULL;
ahszp[1].hszTopic = (HSZ) NULL;

/* Create a global memory object. */

hddeMyData = DdeCreateDataHandle(idInst, ahszp,
        sizeof(ahszp), 0, NULL, CF_TEXT, 0);
    if (hddeMyData == NULL)

        /*
         * Pass error value to application-defined error handling
         * function.
         */

        HandleError(DdeGetLastError(idInst));
```

See Also

DdeInitialize

DdeInitialize (3.1)

#include <ddeml.h>

UINT DdeInitialize(*lpidInst, pfnCallback, afCmd, uRes***)**

```
DWORD FAR* lpidInst;        /* address of instance identifier      */
PFNCALLBACK pfnCallback;    /* address of callback function        */
DWORD afCmd;                /* array of command and filter flags */
DWORD uRes;                 /* reserved                            */
```

The **DdeInitialize** function registers an application with the Dynamic Data Exchange Management Library (**DDEML**). An application must call this function before calling any other DDEML function.

Parameter	Description
lpidInst	Points to the application-instance identifier. At initialization, this parameter should point to 0L. If the function is successful, this parameter points to the instance identifier for the application. This value should be passed as the *idInst* parameter in all other **DDEML** functions that require it. If an application uses multiple instances of the DDEML dynamic link library, the application should provide a different callback function for each instance. If *lpidInst* points to a nonzero value, this implies a reinitialization of the DDEML. In this case, *lpidInst* must point to a valid application-instance identifier.
pfnCallback	Points to the application-defined **DDE** callback function. This function processes DDE transactions sent by the system. For more information, see the description of the **DdeCallback** callback function.
afCmd	Specifies an array of APPCMD_ and CBF_ flags. The APPCMD_ flags provide special instructions to the **DdeInitialize** function. The CBF_ flags set filters that prevent specific types of transactions from reaching the callback function. Using these flags enhances the performance of a **DDE** application by eliminating unnecessary calls to the callback function. This parameter can be a combination of the following flags:

Flag	Meaning
APPCLASS_MONITOR	Makes it possible for the application to monitor **DDE** activity in the system. This flag is for use by DDE monitoring applications. The application specifies the types of DDE activity to monitor by combining one or more monitor flags with the APPCLASS_MONITOR flag. For details, see the following Comments section.
APPCLASS_STANDARD	Registers the application as a standard (nonmonitoring) **DDEML** application.
APPCMD_CLIENTONLY	Prevents the application from becoming a server in a **DDE** conversation. The application can be only a client. This flag reduces resource consumption by the DDEML. It includes the functionality of the CBF_FAIL_ALLSVRXACTIONS flag.
APPCMD_FILTERINITS	Prevents the **DDEML** from sending **XTYP_CONNECT** and **XTYP_WILDCONNECT** transactions to the application until the application has created its string handles and registered its service names or has turned off filtering by

	a subsequent call to the **DdeNameService** or **DdeInitialize** function. This flag is always in effect when an application calls **DdeInitialize** for the first time, regardless of whether the application specifies this flag. On subsequent calls to **DdeInitialize**, not specifying this flag turns off the application's service-name filters; specifying this flag turns on the application's service-name filters.
CBF_FAIL_ALLSVRXACTIONS	Prevents the callback function from receiving server transactions. The system will return DDE_FNOTPROCESSED to each client that sends a transaction to this application. This flag is equivalent to combining all CBF_FAIL_ flags.
CBF_FAIL_ADVISES	Prevents the callback function from receiving **XTYP_ADVSTART** and **XTYP_ADVSTOP** transactions. The system will return DDE_FNOTPROCESSED to each client that sends an XTYP_ADVSTART or XTYP_ADVSTOP transaction to the server.
CBF_FAIL_CONNECTIONS	Prevents the callback function from receiving **XTYP_CONNECT** and **XTYP_WILDCONNECT** transactions.
CBF_FAIL_EXECUTES	Prevents the callback function from receiving **XTYP_EXECUTE** transactions. The system will return DDE_FNOTPROCESSED to a client that sends an XTYP_EXECUTE transaction to the server.
CBF_FAIL_POKES	Prevents the callback function from receiving **XTYP_POKE** transactions. The system will return DDE_FNOTPROCESSED to a client that sends an XTYP_POKE transaction to the server.
CBF_FAIL_REQUESTS	Prevents the callback function from receiving **XTYP_REQUEST** transactions. The system will return DDE_FNOTPROCESSED to a client that sends an XTYP_REQUEST transaction to the server.
CBF_FAIL_SELFCONNECTIONS	Prevents the callback function from receiving **XTYP_CONNECT** transactions from the application's own instance. This prevents an application from establishing a **DDE** conversation with its own instance. An application should use this flag if it needs to communicate with other instances of itself but not with itself.
CBF_SKIP_ALLNOTIFICATIONS	Prevents the callback function from

		receiving any notifications. This flag is equivalent combining all CBF_SKIP_ flags.
	CBF_SKIP_CONNECT_CONFIRMS	Prevents the callback function from receiving **XTYP_CONNECT_CONFIRM** notifications.
	CBF_SKIP_DISCONNECTS	Prevents the callback function from receiving **XTYP_DISCONNECT** notifications.
	CBF_SKIP_REGISTRATIONS	Prevents the callback function from receiving **XTYP_REGISTER** notifications.
	CBF_SKIP_UNREGISTRATIONS	Prevents the callback function from receiving **XTYP_UNREGISTER** notifications.
uRes	Reserved; must be set to 0L.	

Returns

The return value is one of the following:

DMLERR_DLL_USAGE
DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR
DMLERR_SYS_ERROR

Comments

An application that uses multiple instances of the **DDEML** must not pass DDEML objects between instances.

A **DDE** monitoring application should not attempt to perform DDE (establish conversations, issue transactions, and so on) within the context of the same application instance.

A synchronous transaction will fail with a DMLERR_REENTRANCY error if any instance of the same task has a synchronous transaction already in progress.

A **DDE** monitoring application can combine one or more of the following monitor flags with the APPCLASS_MONITOR flag to specify the types of DDE activity to monitor:

Flag	Meaning
MF_CALLBACKS	Notifies the callback function whenever a transaction is sent to any **DDE** callback function in the system.
MF_CONV	Notifies the callback function whenever a conversation is established or terminated.
MF_ERRORS	Notifies the callback function whenever a **DDE** error occurs.
MF_HSZ_INFO	Notifies the callback function whenever a **DDE** application creates, frees, or increments the use count of a string handle or whenever a string handle is freed as a result of a call to the **DdeUninitialize** function.
MF_LINKS	Notifies the callback function whenever an advise loop is started or ended.
MF_POSTMSGS	Notifies the callback function whenever the system or an application posts a **DDE** message.
MF_SENDMSGS	Notifies the callback function whenever the system or an application sends a **DDE** message.

Example

The following example obtains a procedure-instance address for a **DDE** callback function, then initializes the application with the DDEML.

```
DWORD idInst = 0L;
```

```
FARPROC lpDdeProc;

lpDdeProc = MakeProcInstance((FARPROC) DDECallback, hInst);
if (DdeInitialize((LPDWORD) &idInst, (PFNCALLBACK) lpDdeProc,
        APPCMD_CLIENTONLY, 0L))
    return FALSE;
```

DdeClientTransaction, **DdeConnect**, **DdeCreateDataHandle**, **DdeEnableCallback**, **DdeNameService**, **DdePostAdvise**, **DdeUninitialize**

DdeKeepStringHandle (3.1)

#include <ddeml.h>

BOOL DdeKeepStringHandle(*idInst, hsz***)**

DWORD *idInst;* /* instance identifier */
HSZ *hsz;* /* handle of string */

The **DdeKeepStringHandle** function increments the usage count (increases it by one) associated with the given handle. This function makes it possible for an application to save a string handle that was passed to the application's dynamic data exchange (**DDE**) callback function. Otherwise, a string handle passed to the callback function is deleted when the callback function returns.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hsz	Identifies the string handle to be saved.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Example
The following example is a portion of a **DDE** callback function that increases the usage count and saves a local copy of two string handles:

```
HSZ hsz1;
HSZ hsz2;
static HSZ hszServerBase;
static HSZ hszServerInst;
DWORD idInst;

case XTYP_REGISTER:

    /* Keep the handles for later use. */

    DdeKeepStringHandle(idInst, hsz1);
    DdeKeepStringHandle(idInst, hsz2);
    hszServerBase = hsz1;
    hszServerInst = hsz2;
    .
    . /* Finish processing the transaction. */
    .
```

See Also
DdeCreateStringHandle, **DdeFreeStringHandle**, **DdeInitialize**, **DdeQueryString**

DdeNameService (3.1)

#include <ddeml.h>

HDDEDATA DdeNameService(*idInst, hsz1, hszRes, afCmd***)**

```
DWORD idInst;     /* instance identifier              */
HSZ hsz1;         /* handle of service-name string */
HSZ hszRes;       /* reserved                         */
UINT afCmd;       /* service-name flags               */
```

The **DdeNameService** function registers or unregisters the service names that a dynamic data exchange (**DDE**) server supports. This function causes the system to send **XTYP_REGISTER** or **XTYP_UNREGISTER** transactions to other running DDE Management Library (**DDEML**) client applications.

A server application should call this function to register each service name that it supports and to unregister names that it previously registered but no longer supports. A server should also call this function to unregister its service names just before terminating.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hsz1	Identifies the string that specifies the service name that the server is registering or unregistering. An application that is unregistering all of its service names should set this parameter to NULL.
hszRes	Reserved; should be set to NULL.
afCmd	Specifies the service-name flags. This parameter can be one of the following values:

Value	Meaning
DNS_REGISTER	Registers the given service name.
DNS_UNREGISTER	Unregisters the given service name. If the *hsz1* parameter is NULL, all service names registered by the server will be unregistered.
DNS_FILTERON	Turns on service-name initiation filtering. This filter prevents a server from receiving **XTYP_CONNECT** transactions for service names that it has not registered. This is the default setting for this filter. If a server application does not register any service names, the application cannot receive **XTYP_WILDCONNECT** transactions.
DNS_FILTEROFF	Turns off service-name initiation filtering. If this flag is set, the server will receive an **XTYP_CONNECT** transaction whenever another **DDE** application calls the **DdeConnect** function, regardless of the service name.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_DLL_USAGE
DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR

Comments

The service name identified by the *hsz1* parameter should be a base name (that is, the name should contain no instance-specific information). The system generates an instance-specific name and sends it along with the base name during the **XTYP_REGISTER** and **XTYP_UNREGISTER** transactions. The receiving applications can then connect to the specific application instance.

Example

The following example initializes an application with the **DDEML**, creates frequently used string handles, and registers the application's service name:

```
HSZ hszClock;
HSZ hszTime;
HSZ hszNow;
HINSTANCE hinst;
DWORD idInst = 0L;
FARPROC lpDdeProc;

/* Initialize the application for the DDEML. */

lpDdeProc = MakeProcInstance((FARPROC) DdeCallback, hinst);
if (!DdeInitialize((LPDWORD) &idInst, (PFNCALLBACK) lpDdeProc,
        APPCMD_FILTERINITS | CBF_FAIL_EXECUTES, 0L)) {

    /* Create frequently used string handles. */

    hszTime = DdeCreateStringHandle(idInst, "Time", CP_WINANSI);
    hszNow = DdeCreateStringHandle(idInst, "Now", CP_WINANSI);
    hszClock = DdeCreateStringHandle(idInst, "Clock", CP_WINANSI);

    /* Register the service name. */

    DdeNameService(idInst, hszClock, (HSZ) NULL, DNS_REGISTER);

}
```

See Also

DdeConnect, **DdeConnectList**, **DdeInitialize**, **XTYP_REGISTER**, **XTYP_UNREGISTER**

DdePostAdvise (3.1)

#include <ddeml.h>

BOOL DdePostAdvise(*idInst, hszTopic, hszItem***)**

DWORD *idInst;* /* instance identifier */
HSZ *hszTopic;* /* handle of topic-name string */
HSZ *hszItem;* /* handle of item-name string */

The **DdePostAdvise** function causes the system to send an **XTYP_ADVREQ** transaction to the calling (server) application's dynamic data exchange (**DDE**) callback function for each client that has an advise loop active on the specified topic or item name pair. A server application should call this function whenever the data associated with the topic or item name pair changes.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hszTopic	Identifies a string that specifies the topic name. To send notifications for all topics with active advise loops, an application can set this parameter to NULL.
hszItem	Identifies a string that specifies the item name. To send notifications for all items with active advise loops, an application can set this parameter to NULL.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors
Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_DLL_USAGE
DMLERR_NO_ERROR

Comments
A server that has nonenumerable topics or items should set the *hszTopic* and *hszItem* parameters to NULL so that the system will generate transactions for all active advise loops. The server's **DDE** callback function returns NULL for any advise loops that do not need to be updated.

If a server calls **DdePostAdvise** with a topic/item/format name set that includes the set currently being handled in a **XTYP_ADVREQ** callback, a stack overflow may result.

Example
The following example calls the **DdePostAdvise** function whenever the time changes:

```
typedef struct { /* tm */
    int hour;
    int minute;
    int second;
} TIME;

TIME tmTime;
DWORD idInst;
HSZ hszTime;
HSZ hszNow;
TIME tmCurTime;

    .
    . /* Fill tmCurTime with the current time. */
```

```
    .

/* Check for any change in second, minute, or hour. */

if ((tmCurTime.second != tmTime.second) ||
        (tmCurTime.minute != tmTime.minute) ||
        (tmCurTime.hour   != tmTime.hour)) {

    /* Send the current time to the clients. */

    DdePostAdvise(idInst, hszTime, hszNow);
```

DdeInitialize, **XTYP_ADVREQ**

DdeQueryConvInfo (3.1)

#include <ddeml.h>

UINT DdeQueryConvInfo(*hConv, idTransaction, lpConvInfo***)**

HCONV *hConv;*	/* handle of conversation	*/
DWORD *idTransaction;*	/* transaction identifier	*/
CONVINFO FAR* *lpConvInfo;*	/* address of structure with conversation data	*/

The **DdeQueryConvInfo** function retrieves information about a dynamic data exchange (**DDE**) transaction and about the conversation in which the transaction takes place.

Parameter	Description
hConv	Identifies the conversation.
idTransaction	Specifies the transaction. For asynchronous transactions, this parameter should be a transaction identifier returned by the **DdeClientTransaction** function. For synchronous transactions, this parameter should be QID_SYNC.
lpConvInfo	Points to the **CONVINFO** structure that will receive information about the transaction and conversation. The **cb** member of the **CONVINFO** structure must specify the length of the buffer allocated for the structure.

Returns

The return value is the number of bytes copied into the **CONVINFO** structure, if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_NO_CONV_ESTABLISHED
DMLERR_NO_ERROR
DMLERR_UNFOUND_QUEUE_ID

Example

The following example fills a **CONVINFO** structure with information about a synchronous conversation and then obtains the names of the partner application and topic:

```
DWORD idInst;
HCONV hConv;
CONVINFO ci;
WORD wError;
char szSvcPartner[32];
char szTopic[32];
DWORD cchServ, cchTopic;

if (!DdeQueryConvInfo(hConv, QID_SYNC, &ci))
    wError = DdeGetLastError(idInst);

else {
    cchServ = DdeQueryString(idInst, ci.hszSvcPartner,
        (LPSTR) &szSvcPartner, sizeof(szSvcPartner),
        CP_WINANSI);
    cchTopic =DdeQueryString(idInst, ci.hszTopic,
        (LPSTR) &szTopic, sizeof(szTopic),
        CP_WINANSI);
}
```

See Also
DdeConnect, **DdeConnectList**, **DdeQueryNextServer**, **CONVINFO**

DdeQueryNextServer (3.1)

#include <ddeml.h>

HCONV DdeQueryNextServer(*hConvList, hConvPrev***)**

HCONVLIST *hConvList;* /* handle of conversation list */
HCONV *hConvPrev;* /* previous conversation handle */

The **DdeQueryNextServer** function obtains the next conversation handle in the given conversation list.

Parameter	Description
hConvList	Identifies the conversation list. This handle must have been created by a previous call to the **DdeConnectList** function.
hConvPrev	Identifies the conversation handle previously returned by this function. If this parameter is NULL, this function returns the first conversation handle in the list.

Returns

The return value is the next conversation handle in the list if the list contains any more conversation handles. Otherwise, it is NULL.

Example

The following example uses the **DdeQueryNextServer** function to count the number of conversation handles in a conversation list and to copy the service-name string handles of the servers to a local buffer:

```
HCONVLIST hconvList; /* conversation list       */
DWORD idInst;        /* instance identifier     */
HSZ hszSystem;       /* System topic            */
HCONV hconv = NULL;  /* conversation handle     */
CONVINFO ci;         /* holds conversation data */
UINT cConv = 0;      /* count of conv. handles  */
HSZ *pHsz, *aHsz;    /* point to string handles */

/* Connect to all servers that support the System topic. */

hconvList = DdeConnectList(idInst, NULL, hszSystem, NULL, NULL);

/* Count the number of handles in the conversation list. */

while ((hconv = DdeQueryNextServer(hconvList, hconv)) != NULL) cConv++;

/* Allocate a buffer for the string handles. */

hconv = NULL;
aHsz = (HSZ *) LocalAlloc(LMEM_FIXED, cConv * sizeof(HSZ));

/* Copy the string handles to the buffer. */

pHsz = aHsz;
while ((hconv = DdeQueryNextServer(hconvList, hconv)) != NULL) {
    DdeQueryConvInfo(hconv, QID_SYNC, (PCONVINFO) &ci);
    DdeKeepStringHandle(idInst, ci.hszSvcPartner);
    *pHsz++ = ci.hszSvcPartner;
}

.
. /* Use the handles; converse with servers. */
```

.

```
/* Free the memory, and terminate conversations. */

LocalFree((HANDLE) aHsz);
DdeDisconnectList(hconvList);
```

See Also
DdeConnectList, **DdeDisconnectList**

DdeQueryString (3.1)

#include <ddeml.h>

DWORD DdeQueryString(*idInst, hsz, lpsz, cchMax, codepage***)**

DWORD *idInst;* /* instance identifier */
HSZ *hsz;* /* handle of string */
LPSTR *lpsz;* /* address of destination buffer */
DWORD *cchMax;* /* length of buffer */
int *codepage;* /* code page */

The **DdeQueryString** function copies text associated with a string handle into a buffer.

The string returned in the buffer is always null-terminated. If the string is longer than (*cchMax* - 1), only the first (*cchMax* - 1) characters of the string are copied.

If the *lpsz* parameter is NULL, this function obtains the length, in bytes, of the string associated with the string handle. The length does not include the terminating null character.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.
hsz	Identifies the string to copy. This handle must have been created by a previous call to the **DdeCreateStringHandle** function.
lpsz	Points to a buffer that receives the string. To obtain the length of the string, this parameter should be set to NULL.
cchMax	Specifies the length, in bytes, of the buffer pointed to by the *lpsz* parameter. If the string is longer than (*cchMax* - 1), it will be truncated. If the *lpsz* parameter is set to NULL, this parameter is ignored.
codepage	Specifies the code page used to render the string. This value should be either CP_WINANSI or the value returned by the **GetKBCodePage** function.

Returns

The return value is the length, in bytes, of the returned text (not including the terminating null character) if the *lpsz* parameter specified a valid pointer. The return value is the length of the text associated with the *hsz* parameter (not including the terminating null character) if the *lpsz* parameter specified a NULL pointer. The return value is NULL if an error occurs.

Example

The following example uses the **DdeQueryString** function to obtain a service name and topic name that a server has registered:

```
UINT type;

HSZ hsz1;
HSZ hsz2;
char szBaseName[16];
char szInstName[16];

if (type == XTYP_REGISTER) {

    /* Copy the base service name to a buffer. */

    DdeQueryString(idInst, hsz1, (LPSTR) &szBaseName,
        sizeof(szBaseName), CP_WINANSI);

    /* Copy the instance-specific service name to a buffer. */
```

```
    DdeQueryString(idInst, hsz2, (LPSTR) &szInstName,
        sizeof(szInstName), CP_WINANSI);
    return (HDDEDATA) TRUE;
}
```

See Also

DdeCmpStringHandles, **DdeCreateStringHandle**, **DdeFreeStringHandle**, **DdeInitialize**

DdeReconnect (3.1)

#include <ddeml.h>

HCONV DdeReconnect(*hConv***)**

HCONV *hConv;* /* handle of conversation to reestablish */

The **DdeReconnect** function allows a client Dynamic Data Exchange Management Library (**DDEML**) application to attempt to reestablish a conversation with a service that has terminated a conversation with the client. When the conversation is reestablished, the DDEML attempts to reestablish any preexisting advise loops.

Parameter	Description
hConv	Identifies the conversation to be reestablished. A client must have obtained the conversation handle by a previous call to the **DdeConnect** function.

Returns

The return value is the handle of the reestablished conversation if the function is successful. The return value is NULL if the function fails.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_NO_CONV_ESTABLISHED
DMLERR_NO_ERROR

Example

The following example shows the context within which an application should call the **DdeReconnect** function:

```
HDDEDATA EXPENTRY DdeCallback(wType, wFmt, hConv, hsz1,
    hsz2, hData, dwData1, dwData2)
WORD wType;       /* transaction type                */
WORD wFmt;        /* clipboard format                */
HCONV hConv;      /* handle of the conversation      */
HSZ hsz1;         /* handle of a string              */
HSZ hsz2;         /* handle of a string              */
HDDEDATA hData;   /* handle of a global memory object */
DWORD dwData1;    /* transaction-specific data       */
DWORD dwData2;    /* transaction-specific data       */
{
    BOOL fAutoReconnect;

    switch (wType) {
        case XTYP_DISCONNECT:
            if (fAutoReconnect) {
                DdeReconnect(hConv); /* attempt to reconnect */
            }
            return 0;

        .
        . /* Process other transactions. */
        .
    }
}
```

See Also
DdeConnect, **DdeDisconnect**

DdeSetUserHandle (3.1)

#include <ddeml.h>

BOOL DdeSetUserHandle(*hConv,id, hUser***)**

```
HCONV hConv;      /* handle of conversation     */
DWORD id;         /* transaction identifier     */
DWORD hUser;      /* application-defined value  */
```

The **DdeSetUserHandle** function associates an application-defined 32-bit value with a conversation handle and transaction identifier. This is useful for simplifying the processing of asynchronous transactions. An application can use the **DdeQueryConvInfo** function to retrieve this value.

Parameter	Description
hConv	Identifies the conversation.
id	Specifies the transaction identifier of an asynchronous transaction. An application should set this parameter to QID_SYNC if no asynchronous transaction is to be associated with the *hUser* parameter.
hUser	Identifies the value to associate with the conversation handle.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR
DMLERR_UNFOUND_QUEUE_ID

See Also

DdeQueryConvInfo

DdeUnaccessData (3.1)

#include <ddeml.h>

BOOL DdeUnaccessData(*hData***)**

HDDEDATA *hData;* /* handle of global memory object */

The **DdeUnaccessData** function frees a global memory object. An application must call this function when it is finished accessing the object.

Parameter	Description
hData	Identifies the global memory object.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Errors

Use the **DdeGetLastError** function to retrieve the error value, which may be one of the following:

DMLERR_DLL_NOT_INITIALIZED
DMLERR_INVALIDPARAMETER
DMLERR_NO_ERROR

Example

The following example obtains a pointer to a global memory object, uses the pointer to copy data from the object to a local buffer, and then uses the **DdeUnaccessData** function to free the object:

```
HDDEDATA hData;
LPBYTE lpszAdviseData;
DWORD cbDataLen;
DWORD i;
char szData[128];

lpszAdviseData = DdeAccessData(hData, &cbDataLen);
for (i = 0; i < cbDataLen; i++)
    szData[i] = *lpszAdviseData++;
DdeUnaccessData(hData);
```

See Also

DdeAccessData, **DdeAddData**, **DdeCreateDataHandle**, **DdeFreeDataHandle**

DdeUninitialize (3.1)

#include <ddeml.h>

BOOL DdeUninitialize(*idInst***)**

DWORD *idInst;* /* instance identifier */

The **DdeUninitialize** function frees all Dynamic Data Exchange Management Library (**DDEML**) resources associated with the calling application.

Parameter	Description
idInst	Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The **DdeUninitialize** function terminates any conversations currently open for the application. If the partner in a conversation fails to terminate its end of the conversation, the system may enter a modal loop while it waits for the conversation to terminate. A timeout period is associated with this loop. If the timeout period expires before the conversation has terminated, a message box appears that gives the user the choice of waiting for another timeout period (Retry), waiting indefinitely (Ignore), or exiting the modal loop (Abort).

An application should wait until its windows are no longer visible and its message loop has terminated before calling this function.

DdeDisconnect, **DdeDisconnectList**, **DdeInitialize**

DDE functions (3.1)

DdeAbandonTransaction	Abandons an asynchronous transaction
DdeAccessData	Accesses a **DDE** global memory object
DdeAddData	Adds data to a **DDE** global memory object
DdeClientTransaction	Begins a **DDE** data transaction
DdeCmpStringHandles	Compares two **DDE** string handles
DdeConnect	Establishes a conversation with a server application
DdeConnectList	Establishes multiple **DDE** conversations
DdeCreateDataHandle	Creates a **DDE** data handle
DdeCreateStringHandle	Creates a **DDE** string handle
DdeDisconnect	Terminates a **DDE** conversation
DdeDisconnectList	Destroys a **DDE** conversation list
DdeEnableCallback	Enables or disables one or more **DDE** conversations
DdeFreeDataHandle	Frees a global memory object
DdeFreeStringHandle	Frees a **DDE** string handle
DdeGetData	Copies data from a global memory object to a buffer
DdeGetLastError	Returns an error value set by a **DDEML** function
DdeInitialize	Registers an application with the **DDEML**
DdeKeepStringHandle	Increments the usage count for a string handle
DdeNameService	Registers or unregisters a service name
DdePostAdvise	Prompts a server to send advise data to a client
DdeQueryConvInfo	Retrieves information about a **DDE** conversation
DdeQueryNextServer	Obtains the next handle in a **DDE** conversation list
DdeQueryString	Copies string-handle text into a buffer
DdeReconnect	Reestablishes a **DDE** conversation
DdeSetUserHandle	Associates a user-defined handle with a transaction
DdeUnaccessData	Frees a **DDE** global memory object
DdeUninitialize	Frees **DDEML** resources associated with an application

XTYP_ADVDATA (3.1)

```
#include <ddeml.h>

XTYP_ADVDATA
hszTopic = hsz1;     /* handle of topic-name string */
hszItem = hsz2;      /* handle of item-name string  */
hDataAdvise = hData; /* handle of the advise data   */
```

A client's **DDE** callback function can receive this transaction after the client has established an advise loop with a server. This transaction informs the client that the value of the data item has changed.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name.
hszItem	Value of *hsz2.* Identifies the item name.
hDataAdvise	Value of *hData.* Identifies the data associated with the topic/item name pair. If the client specified the XTYPF_NODATA flag when it requested the advise loop, this parameter is NULL.

Returns

A **DDE** callback function should return DDE_FACK if it processes this transaction, DDE_FBUSY if it is too busy to process this transaction, or DDE_FNOTPROCESSED if it denies this transaction.

Comments

An application need not free the data handle obtained during this transaction. If the application needs to process the data after the callback function returns, however, it must copy the data associated with the data handle. An application can use the **DdeGetData** function to copy the data.

See Also

DdeClientTransaction, **DdePostAdvise**, **XTYP_ADVREQ**, **XTYP_ADVSTART**, **XTYP_ADVSTOP**

XTYP_ADVREQ (3.1)

```
#include <ddeml.h>

XTYP_ADVREQ
hszTopic = hsz1;           /* handle of topic-name string     */
hszItem = hsz2;            /* handle of item-name string      */
cAdvReq = LOWORD(dwData1); /* count of remaining transactions */
```

The system sends this transaction to a server after the server calls the **DdePostAdvise** function. This transaction informs the server that an advise transaction is outstanding on the specified topic/item name pair and that data corresponding to the topic/item name pair has changed.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name.
hszItem	Value of *hsz2.* Identifies the item name that has changed.
cAdvReq	Value of the low-order word of *dwData1.* Specifies the count of XTYP_ADVREQ transactions that remain to be processed on the same topic/item/format name set, within the context of the current call to the **DdePostAdvise** function. If the current XTYP_ADVREQ transaction is the last one, the count is zero. A server can use this count to determine whether to create an HDATA_APPOWNED data handle for the advise data. If the **DDEML** issued the XTYP_ADVREQ transaction because of a late-arriving DDE_FACK transaction flag from a client, the low-order word is set to CADV_LATEACK. The DDE_FACK transaction flag arrives late when a server is sending information faster than a client can process it.

Returns

The server should call the **DdeCreateDataHandle** function to create a data handle that identifies the changed data and then should return the handle. If the server is unable to complete the transaction, it should return NULL.

Comments

A server cannot block this transaction type; the CBR_BLOCK return value is ignored.

See Also

DdeCreateDataHandle, **DdeInitialize**, **DdePostAdvise**, **XTYP_ADVSTART**, **XTYP_ADVSTOP**, **XTYP_ADVDATA**

XTYP_ADVSTART (3.1)

```
#include <ddeml.h>

XTYP_ADVSTART
hszTopic = hsz1;     /* handle of topic-name string */
hszItem = hsz2;      /* handle of item-name string  */
```

A server's **DDE** callback function receives this transaction when a client specifies XTYP_ADVSTART for the *wType* parameter of the **DdeClientTransaction** function. A client uses this transaction to establish an advise loop with a server.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name.
hszItem	Value of *hsz2.* Identifies the item name.

Returns

To allow an advise loop on the specified topic/item name pair, a server's **DDE** callback function should return a nonzero value. To deny the advise loop, it should return zero. If the callback function returns a nonzero value, any subsequent call by the server to the **DdePostAdvise** function on the same topic/item name pair will cause the system to send a **XTYP_ADVREQ** transaction to the server.

Comments

If a client requests an advise loop on a topic/item/format name set for which an advise loop is already established, the **DDEML** does not create a duplicate advise loop. Instead, the DDEML alters the advise loop flags (XTYPF_ACKREQ and XTYPF_NODATA) to match the latest request.

If the server application specified the CBF_FAIL_ADVISES flag in the **DdeInitialize** function, this transaction is filtered.

See Also

DdeClientTransaction, **DdeInitialize**, **DdePostAdvise**, **XTYP_ADVREQ**, **XTYP_ADVSTOP**

XTYP_ADVSTOP (3.1)

```
#include <ddeml.h>

XTYP_ADVSTOP
hszTopic = hsz1;     /* handle of topic-name string */
hszItem = hsz2;      /* handle of item-name string  */
```

A server's **DDE** callback function receives this transaction when a client specifies XTYP_ADVSTOP for the *wType* parameter of the **DdeClientTransaction** function. A client uses this transaction to end an advise loop with a server.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name.
hszItem	Value of *hsz2.* Identifies the item name.

Returns

This transaction does not return a value.

Comments

If the server application specified the CBF_FAIL_ADVISES flag in the **DdeInitialize** function, this transaction is filtered.

See Also

DdeClientTransaction, **DdeInitialize**, **DdePostAdvise**, **XTYP_ADVREQ**, **XTYP_ADVSTART**

XTYP_CONNECT (3.1)

```
#include <ddeml.h>

XTYP_CONNECT
hszTopic = hsz1;                  /* handle of topic-name string      */
hszService = hsz2;                /* handle of service-name string    */
pcc = (CONVCONTEXT FAR *)dwData1; /* address of CONVCONTEXT structure */
fSameInst = (BOOL) dwData2;       /* same instance flag               */
```

A server's **DDE** callback function receives this transaction when a client specifies a service name that the server supports and a topic name that is not set to NULL in a call to the **DdeConnect** function.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name.
hszService	Value of *hsz2.* Identifies the service name.
pcc	Value of *dwData1.* Points to a **CONVCONTEXT** data structure that contains context information for the conversation. If the client is not a **DDEML** application, this parameter should be set to zero.
fSameInst	Value of *dwData2.* Specifies whether the client is the same application instance as the server. If this parameter is TRUE, the client is the same instance; if this parameter is FALSE, the client is a different instance.

Returns

To allow the client to establish a conversation on the specified service/topic name pair, a server's **DDE** callback function should return a nonzero value. To deny the conversation, it should return zero. If the callback function returns a nonzero value and a conversation is successfully established, the system passes the conversation handle to the server by issuing an **XTYP_CONNECT_CONFIRM** transaction to the server's DDE callback function (unless the server specified the CBF_FAIL_CONNECT_CONFIRMS flag in the **DdeInitialize** function).

Comments

If the server application specified the CBF_FAIL_CONNECTIONS flag in the **DdeInitialize** function, this transaction is filtered.

A server cannot block this transaction type; the CBR_BLOCK return value is ignored.

See Also

DdeConnect, **DdeInitialize**, **CONVCONTEXT**, **XTYP_CONNECT_CONFIRM**

XTYP_CONNECT_CONFIRM (3.1)

```
#include <ddeml.h>

XTYP_CONNECT_CONFIRM
hszTopic = hsz1;            /* handle of topic-name string   */
hszService = hsz2;          /* handle of service-name string */
fSameInst = (BOOL) dwData2; /* same instance flag            */
```

A server's **DDE** callback function receives this transaction to confirm that a conversation has been established with a client and to provide the server with the conversation handle. The system sends this transaction as a result of a previous **XTYP_CONNECT** or **XTYP_WILDCONNECT** transaction.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name on which the conversation has been established.
hszService	Value of *hsz2.* Identifies the service name on which the conversation has been established.
fSameInst	Value of *dwData2.* Specifies whether the client is the same application instance as the server. If this parameter is a nonzero value, the client is the same instance. If this parameter is zero, the client is a different instance.

Returns

This transaction does not return a value.

Comments

If the server application specified the CBF_FAIL_CONFIRMS flag in the **DdeInitialize** function, this transaction is filtered.

A server cannot block this transaction type; the CBR_BLOCK return value is ignored.

See Also

DdeConnect, **DdeConnectList**, **DdeInitialize**, **XTYP_CONNECT**, **XTYP_WILDCONNECT**

XTYP_DISCONNECT (3.1)

```
#include <ddeml.h>

XTYP_DISCONNECT
fSameInst = (BOOL) dwData2;  /* same instance flag */
```

An application's **DDE** callback function receives this transaction when the application's partner in a conversation uses the **DdeDisconnect** function to terminate the conversation.

Parameter	Description
fSameInst	Value of *dwData2.* Specifies whether the partners in the conversation are the same application instance. If this parameter is TRUE, the partners are the same instance. If this parameter is FALSE, the partners are different instances.

Returns

This transaction does not return a value.

Comments

If the application specified the CBF_SKIP_DISCONNECTS flag in the **DdeInitialize** function, this transaction is filtered.

The application can obtain the status of the terminated conversation by calling the **DdeQueryConvInfo** function while processing this transaction. The conversation handle becomes invalid after the callback function returns.

An application cannot block this transaction type; the CBR_BLOCK return value is ignored.

See Also

DdeDisconnect, **DdeQueryConvInfo**

XTYP_ERROR (3.1)

```
#include <ddeml.h>

XTYP_ERROR
wErr = LOWORD(dwData1); /* error value */
```

A **DDE** callback function receives this transaction when a critical error occurs.

Parameter	Description
wErr	Value of *dwData1.* Specifies the error value. Currently, only the DMLERR_LOW_MEMORY error value is supported. It means that memory is low--advise, poke, or execute data may be lost, or the system may fail.

Returns

This transaction does not return a value.

Comments

An application cannot block this transaction type; the CBR_BLOCK return value is ignored. The **DDEML** attempts to free memory by removing noncritical resources. An application that has blocked conversations should unblock them.

XTYP_EXECUTE (3.1)

```
#include <ddeml.h>

XTYP_EXECUTE
hszTopic = hsz1;    /* handle of the topic-name string */
hDataCmd = hData;   /* handle of the command string    */
```

A server's **DDE** callback function receives this transaction when a client specifies XTYP_EXECUTE for the *wType* parameter of the **DdeClientTransaction** function. A client uses this transaction to send a command string to the server.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name.
hDataCmd	Value of *hData.* Identifies the command string.

Returns

A server's **DDE** callback function should return DDE_FACK if it processes this transaction, DDE_FBUSY if it is too busy to process this transaction, or DDE_FNOTPROCESSED if it denies this transaction.

Comments

If the server application specified the CBF_FAIL_EXECUTES flag in the **DdeInitialize** function, this transaction is filtered.

An application need not free the data handle obtained during this transaction. If the application needs to process the string after the callback function returns, however, the application must copy the command string associated with the data handle. An application can use the **DdeGetData** function to copy the data.

See Also

DdeClientTransaction, **DdeInitialize**

XTYP_MONITOR (3.1)

```
#include <ddeml.h>

XTYP_MONITOR
hDataEvent = hData;      /* handle of event data */
fwEvent = dwData2;       /* event flag           */
```

The **DDE** callback function of a DDE debugging application receives this transaction whenever a DDE event occurs in the system. An application can receive this transaction only if it specified the APPCLASS_MONITOR flag when it called the **DdeInitialize** function.

Parameter	Description
hDataEvent	Value of *hData.* Identifies a global memory object that contains information about the **DDE** event. The application should use the **DdeAccessData** function to obtain a pointer to the object.
fwEvent	Value of *dwData2.* Specifies the **DDE** event. This parameter may be one of the following values:

Value	Meaning
MF_CALLBACKS	The system sent a transaction to a **DDE** callback function. The global memory object contains a **MONCBSTRUCT** structure that provides information about the transaction.
MF_CONV	A **DDE** conversation was established or terminated. The global memory object contains a **MONCONVSTRUCT** structure that provides information about the conversation.
MF_ERRORS	A **DDE** error occurred. The global memory object contains a **MONERRSTRUCT** structure that provides information about the error.
MF_HSZ_INFO	A **DDE** application created or freed a string handle or incremented the use count of a string handle, or a string handle was freed as a result of a call to the **DdeUninitialize** function. The global memory object contains a **MONHSZSTRUCT** structure that provides information about the string handle.
MF_LINKS	A **DDE** application started or ended an advise loop. The global memory object contains a **MONLINKSTRUCT** structure that provides information about the advise loop.
MF_POSTMSGS	The system or an application posted a **DDE** message. The global memory object contains a **MONMSGSTRUCT** structure that provides information about the message.
MF_SENDMSGS	The system or an application sent a **DDE** message. The global memory object contains a **MONMSGSTRUCT** structure that provides information about the message.

Returns

The callback function should return zero if it processes this transaction.

See Also

DdeAccessData, **DdeInitialize**, **MONCBSTRUCT**, **MONCONVSTRUCT**, **MONERRSTRUCT**, **MONHSZSTRUCT**, **MONLINKSTRUCT**, **MONMSGSTRUCT**

XTYP_POKE (3.1)

```
#include <ddeml.h>

XTYP_POKE
hszTopic = hsz1;     /* handle of topic-name string */
hszItem = hsz2;      /* handle of item-name string  */
hDataPoke = hData;   /* handle of data for server   */
```

A server's **DDE** callback function receives this transaction when a client specifies XTYP_POKE as the *wType* parameter of the **DdeClientTransaction** function. A client uses this transaction to send unsolicited data to the server.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name.
hszItem	Value of *hsz2.* Identifies the item name.
hDataPoke	Value of *hData.* Identifies the data that the client is sending to the server.

Returns

A server's **DDE** callback function should return DDE_FACK if it processes this transaction, DDE_FBUSY if it is too busy to process this transaction, or DDE_FNOTPROCESSED if it denies this transaction.

Comments

If the server application specified the CBF_FAIL_POKES flag in the **DdeInitialize** function, this transaction is filtered.

See Also

DdeClientTransaction, **DdeInitialize**

XTYP_REGISTER (3.1)

```
#include <ddeml.h>

XTYP_REGISTER
hszBaseServName = hsz1; /* handle of base service-name string     */
hszInstServName = hsz2; /* handle of instance service-name string */
```

A **DDE** callback function receives this transaction type whenever a **DDEML** server application uses the **DdeNameService** function to register a service name or whenever a non-DDEML application that supports the System topic is started.

Parameter	Description
hszBaseServName	Value of *hsz1.* Identifies the base service name being registered.
hszInstServName	Value of *hsz2.* Identifies the instance-specific service name being registered.

Returns

This transaction does not return a value.

Comments

If the application specified the CBF_SKIP_REGISTRATIONS flag in the **DdeInitialize** function, this transaction is filtered.

An application cannot block this transaction type; the CBR_BLOCK return value is ignored.

An application should use the *hszBaseServName* parameter to add the service name to the list of servers available to the user. An application should use the *hszInstServName* parameter to identify which application instance has started.

See Also

DdeInitialize, **DdeNameService**, **XTYP_UNREGISTER**

XTYP_REQUEST (3.1)

```
#include <ddeml.h>

XTYP_REQUEST
hszTopic = hsz1;     /* handle of topic-name string */
hszItem = hsz2;      /* handle of item-name string  */
```

A **DDE** server callback function receives this transaction when a client specifies XTYP_REQUEST for the *wType* parameter of the **DdeClientTransaction** function. A client uses this transaction to request data from a server.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name.
hszItem	Value of *hsz2.* Identifies the item name that has changed.

Returns

The server should call the **DdeCreateDataHandle** function to create a data handle that identifies the changed data and then should return the handle. The server should return NULL if it is unable to complete the transaction. If the server returns NULL, the client receives a DDE_FNOTPROCESSED acknowledgment flag.

Comments

If the server application specified the CBF_FAIL_REQUESTS flag in the **DdeInitialize** function, this transaction is filtered.

If responding to this transaction requires lengthy processing, the server can return CBR_BLOCK to suspend future transactions on the current conversation and then process the transaction asynchronously. When the server has finished and the data is ready to pass to the client, the server can call the **DdeEnableCallback** function to resume the conversation.

See Also

DdeClientTransaction, **DdeCreateDataHandle**, **DdeEnableCallback**, **DdeInitialize**

XTYP_UNREGISTER (3.1)

```
#include <ddeml.h>

XTYP_UNREGISTER
hszBaseServName = hsz1; /* handle of base service-name string     */
hszInstServName = hsz2; /* handle of instance service-name string */
```

A **DDE** callback function receives this transaction type whenever a **DDEML** server application uses the **DdeNameService** function to unregister a service name or whenever a non-DDEML application that supports the System topic is terminated.

Parameter	Description
hszBaseServName	Value of *hsz1.* Identifies the base service name being unregistered.
hszInstServName	Value of *hsz2.* Identifies the instance-specific service name being unregistered.

Returns

This transaction does not return a value.

Comments

If the application specified the CBF_SKIP_REGISTRATIONS flag in the **DdeInitialize** function, this transaction is filtered.

An application cannot block this transaction type; the CBR_BLOCK return value is ignored.

An application should use the *hszBaseServName* parameter to remove the service name from the list of servers available to the user. An application should use the *hszInstServName* parameter to identify which application instance has terminated.

See Also

DdeInitialize, **DdeNameService**, **XTYP_REGISTER**

XTYP_WILDCONNECT (3.1)

```
#include <ddeml.h>

XTYP_WILDCONNECT
hszTopic = hsz1;                  /* handle of topic-name string      */
hszService = hsz2;                /* handle of service-name string    */
pcc = (CONVCONTEXT FAR *)dwData1; /* address of CONVCONTEXT structure */
fSameInst = (BOOL) dwData2;       /* same-instance flag               */
```

A server's **DDE** callback function receives this transaction when a client specifies a service name that is set to NULL, a topic name that is set to NULL, or both in a call to the **DdeConnect** function. This transaction allows a client to establish a conversation on each of the server's service/topic name pairs that matches the specified service name and topic name.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name. If this parameter is NULL, the client is requesting a conversation on all topic names that the server supports.
hszService	Value of *hsz2.* Identifies the service name. If this parameter is NULL, the client is requesting a conversation on all service names that the server supports.
pcc	Value of *dwData1.* Points to a **CONVCONTEXT** data structure that contains context information for the conversation. If the client is not a **DDEML** application, this parameter is set to zero.
fSameInst	Value of *dwData2.* Specifies whether the client is the same application instance as the server. If this parameter is TRUE, the client is same instance. If this parameter is FALSE, the client is a different instance.

Returns

The server should return a data handle that identifies an array of **HSZPAIR** structures. The array should contain one structure for each service/topic name pair that matches the service/topic name pair requested by the client. The array must be terminated by a NULL string handle. The system sends the **XTYP_CONNECT_CONFIRM** transaction to the server to confirm each conversation and to pass the conversation handles to the server. If the server specified the CBF_SKIP_CONNECT_CONFIRMS flag in the **DdeInitialize** function, it cannot receive these confirmations.

To refuse the XTYP_WILDCONNECT transaction, the server should return NULL.

Comments

If the server application specified the CBF_FAIL_CONNECTIONS flag in the **DdeInitialize** function, this transaction is filtered.

A server cannot block this transaction type; the CBR_BLOCK return code is ignored.

See Also

DdeConnect, **DdeInitialize**, **CONVCONTEXT**, **XTYP_CONNECT_CONFIRM**

XTYP_XACT_COMPLETE (3.1)

```
#include <ddeml.h>

XTYP_XACT_COMPLETE
hszTopic = hsz1;       /* handle of topic-name string */
hszItem = hsz2;        /* handle of item-name string  */
hDataXact = hData;     /* handle of transaction data  */
dwXactID = dwData1;    /* transaction identifier      */
fwStatus = dwData2;    /* status flag                 */
```

A **DDE** client callback function receives this transaction when an asynchronous transaction, initiated by a call to the **DdeClientTransaction** function, has concluded.

Parameter	Description
hszTopic	Value of *hsz1.* Identifies the topic name involved in the completed transaction.
hszItem	Value of *hsz2.* Identifies the item name involved in the completed transaction.
hDataXact	Value of *hData.* Identifies the data involved in the completed transaction, if applicable. If the transaction was successful but involved no data, this parameter is TRUE. If the transaction was unsuccessful, this parameter is NULL.
dwXactID	Value of *dwData1.* Contains the transaction identifier of the completed transaction.
fwStatus	Value of *dwData2.* Contains any applicable DDE_ status flags in the low-order word. This provides support for applications dependent on DDE_APPSTATUS bits. It is recommended that applications no longer use these bits--future versions of the **DDEML** may not support them.

Returns

This transaction does not return a value.

Comments

An application need not free the data handle obtained during this transaction. If the application needs to process the data after the callback function returns, however, the application must copy the data associated with the data handle. An application can use the **DdeGetData** function to copy the data.

XTYP_POKE	Sends unsolicited data to a server
XTYP_REGISTER	Registers a service name
XTYP_REQUEST	Requests data from a server
XTYP_UNREGISTER	Unregisters a service name
XTYP_WILDCONNECT	Requests multiple **DDE** conversations
XTYP_XACT_COMPLETE	Confirms completion of an asynchronous transaction

DragAcceptFiles (3.1)

#include shellapi.h

void DragAcceptFiles(*hwnd, fAccept***)**

```
HWND hwnd;      /* handle of the registering window          */
BOOL fAccept;   /* flag for whether dropped files are accepted */
```

The **DragAcceptFiles** function registers whether a given window accepts dropped files.

Parameter	Description
hwnd	Identifies the window registering whether it accepts dropped files.
fAccept	Specifies whether the window specified by the *hwnd* parameter accepts dropped files. An application should set this value to TRUE to accept dropped files or FALSE to discontinue accepting dropped files.

Returns

This function does not return a value.

Comments

When an application calls **DragAcceptFiles** with *fAccept* set to TRUE, Windows File Manager (WINFILE.EXE) sends the specified window a **WM_DROPFILES** message each time the user drops a file in that window.

See Also

WM_DROPFILES

DragFinish (3.1)

#include shellapi.h

void DragFinish(*hDrop***)**

HDROP *hDrop;* /* handle of memory to free */

The **DragFinish** function releases memory that Windows allocated for use in transferring filenames to the application.

Parameter	Description
hDrop	Identifies the internal data structure that describes dropped files. This handle is passed to the application in the *wParam* parameter of the **WM_DROPFILES** message.

Returns

This function does not return a value.

See Also

WM_DROPFILES

DragQueryFile (3.1)

#include shellapi.h

UINT DragQueryFile(*hDrop, iFile, lpszFile, cb***)**

```
HDROP hDrop;      /* handle of structure for dropped files      */
UINT iFile;       /* index of file to query                     */
LPSTR lpszFile;   /* address of buffer for returned filename */
UINT cb;          /* size of buffer for filename                */
```

The **DragQueryFile** function retrieves the number of dropped files and their filenames.

Parameter	Description
hDrop	Identifies the internal data structure containing filenames for the dropped files. This handle is passed to the application in the *wParam* parameter of the **WM_DROPFILES** message.
iFile	Specifies the index of the file to query. The index of the first file is 0. If the value of the *iFile* parameter is -1, **DragQueryFile** returns the number of files dropped. If the value of the *iFile* parameter is between zero and the total number of files dropped, **DragQueryFile** copies the filename corresponding to that value to the buffer pointed to by the *lpszFile* parameter.
lpszFile	Points to a null-terminated string that contains the filename of a dropped file when the function returns. If this parameter is NULL and the *iFile* parameter specifies the index for the name of a dropped file, **DragQueryFile** returns the required size, in bytes, of the buffer for that filename.
cb	Specifies the size, in bytes, of the *lpszFile* buffer.

Returns

When the function copies a filename to the *lpszFile* buffer, the return value is the number of bytes copied. If the *iFile* parameter is 0xFFFF, the return value is the number of dropped files. If *iFile* is between zero and the total number of dropped files and if *lpszFile* is NULL, the return value is the required size of the *lpszFile* buffer.

See Also

DragQueryPoint, **WM_DROPFILES**

DragQueryPoint (3.1)

#include shellapi.h

BOOL DragQueryPoint(*hDrop, lppt***)**

HDROP *hDrop;* /* handle of structure for dropped file */
POINT FAR* *lppt;* /* address of structure for cursor coordinates */

The **DragQueryPoint** function retrieves the window coordinates of the cursor when a file is dropped.

Parameter	Description
hDrop	Identifies the internal data structure that describes the dropped file. This structure is returned in the *wParam* parameter of the **WM_DROPFILES** message.
lppt	Points to a **POINT** structure that the function fills with the coordinates of the position at which the cursor was located when the file was dropped.

Returns

The return value is nonzero if the file is dropped in the client area of the window. Otherwise, it is zero.

Comments

The **DragQueryPoint** function fills the **POINT** structure with the coordinates of the position at which the cursor was located when the user released the left mouse button. The window for which coordinates are returned is the window that received the **WM_DROPFILES** message.

See Also

DragQueryFile, **POINT**, **WM_DROPFILES**

Drag-drop functions (3.1)

DragAcceptFiles	Registers whether a window accepts dropped files
DragFinish	Releases memory allocated for dropping files
DragQueryFile	Retrieves the filename of a dropped file
DragQueryPoint	Retrieves the mouse position when a file is dropped

FMExtensionProc (3.1)

#include <wfext.h>

HMENU FAR PASCAL FMExtensionProc(*hwnd, wMsg, lParam***)**

HWND *hwnd;* /* handle of the extension window */
WORD *wMsg;* /* menu-item identifier or message */
LONG *lParam;* /* additional message information */

The **FMExtensionProc** function, an application-defined callback function, processes menu commands and messages sent to a File Manager extension dynamic-link library (DLL).

Parameter	Description
hwnd	Identifies the File Manager window. An extension DLL should use this handle to specify the parent for any dialog boxes or message boxes that the DLL may display and to send request messages to File Manager.
wMsg	Specifies the message. This parameter may be one of the following values:

Value	Meaning
1-99	Identifier for the menu item that the user selected.
FMEVENT_INITMENU	User selected the extension's menu.
FMEVENT_LOAD	File Manager is loading the extension DLL.
FMEVENT_SELCHANGE	Selection in File Manager's directory window, or Search Results window, changed.
FMEVENT_UNLOAD	File Manager is unloading the extension DLL.
FMEVENT_USER_REFRESH	User chose the Refresh command from the Window menu.

lParam	Specifies 32 bits of additional message-dependent information.

Returns
The callback function should return the result of the message processing. The actual return value depends on the message that is processed.

Comments
Whenever File Manager calls the **FMExtensionProc** function, it waits to refresh its directory windows (for changes in the file system) until after the function returns. This allows the extension to perform large numbers of file operations without excessive repainting by the File Manager. The extension does not need to send the **FM_REFRESH_WINDOWS** message to notify File Manager to repaint its windows.

See Also
FM_REFRESH_WINDOWS, **FMS_LOAD**

UndeleteFile

#include <wfext.h>

int CALLBACK UndeleteFile(*hwndParent, lpszDir***)**

HWND *hwndParent;* /* handle of File Manager window */
LPSTR *lpszDir;* /* address of name of initial directory */

The **UndeleteFile** function is an application-defined callback function that File Manager calls when the user chooses the Undelete command from the File Manager File menu.

Parameter	Description
hwndParent	Identifies the File Manager window. An "undelete" dynamic-link library (DLL) should use this handle to specify the parent window for any dialog box or message box the DLL may display.
lpszDir	Points to a null-terminated string that contains the name of the initial directory.

Returns

The return value is one of the following, if the function is successful:

Value	Meaning
-l	An error occurred.
IDOK	A file was undeleted. File Manager will repaint its windows.
IDCANCEL	No file was undeleted.

File Manager Extension Functions (3.1)

FMExtensionProc	Processes messages for a File Manager extension
UndeleteFile	Processes the File Manager Undelete command

FMEVENT_INITMENU

The FMEVENT_INITMENU message is sent to an extension dynamic-link library (DLL) when the user selects the menu for the extension from File Manager's menu bar. The extension can use this notification to initialize menu items in the menu.

Parameter	Description
lParam	Specifies the menu handle in the high-order word. The low-order word specifies the delta value for the menu item.

Returns

This message does not return a value.

Comments

An extension receives this message only when the user selects the top-level menu. If the extension contains submenus, it must initialize them at the same time as the top-level menu.

See Also

FMExtensionProc

FMEVENT_LOAD

The FMEVENT_LOAD message is sent to an extension dynamic-link library (DLL) when File Manager is loading the DLL.

Parameter	Description
lParam	Points to an **FMS_LOAD** structure that specifies the menu-item delta value. An extension DLL should save the menu-item delta value and fill the other structure members with information about the extension.

Returns

This message does not return a value.

Comments

An application should fill the **dwSize**, **szMenuName**, and **hMenu** members. It should also save the value of the **wMenuDelta** member and use it to identify menu items when modifying the menu. For more information, see the description of the **FMS_LOAD** structure.

See Also

FMExtensionProc, **FMS_LOAD**

FMEVENT_SELCHANGE

The FMEVENT_SELCHANGE message is sent to an extension dynamic-link library (DLL) when the user selects a filename in File Manager's directory window or Search Results window.

Parameter	Description
lParam	Not used.

Returns

This message does not return a value.

Comments

Changes in the tree half of the directory window do not produce this message.

Because the user can change the selection many times, the extension DLL must return promptly after processing this message to avoid slowing the selection process for the user.

See Also

FMExtensionProc, **FMEVENT_UNLOAD**

FMEVENT_UNLOAD

The FMEVENT_UNLOAD message is sent to an extension dynamic-link library (DLL) when File Manager is unloading the DLL.

Parameter	Description
lParam	Not used.

Returns

This message does not return a value.

Comments

The *hwnd* and *hMenu* values passed with the **FMEVENT_LOAD** and **FMEVENT_INITMENU** messages may not be valid at the time of this message.

See Also

FMExtensionProc, **FMEVENT_INITMENU**, **FMEVENT_LOAD**

FMEVENT_USER_REFRESH

The FMEVENT_USER_REFRESH message is sent to an extension dynamic-link library (DLL) when the user invokes File Manager's Refresh command in the Window menu. The extension can use this notification to update its menu.

Parameter	Description
lParam	Not used.

Returns

This message does not return a value.

See Also

FMExtensionProc

FM_GETDRIVEINFO

A File Manager extension sends an FM_GETDRIVEINFO message to retrieve drive information from the active File Manager window.

Parameter	Description
wParam	Not used.
lParam	Points to an **FMS_GETDRIVEINFO** structure that receives drive information.

Returns

The return value is always nonzero.

Comments

If a -1 is returned in the **dwTotalSpace** or **dwFreeSpace** members of the **FMS_GETDRIVEINFO** structure, the extension library must compute the value or values.

See Also

FMExtensionProc, **FMS_GETDRIVEINFO**

FM_GETFILESEL

A File Manager extension sends an FM_GETFILESEL message to retrieve information about a selected file from the active File Manager window (either the directory window or the Search Results window).

Parameter	Description
wParam	Specifies the zero-based index of the selected file to retrieve.
lParam	Points to an **FMS_GETFILESEL** structure that receives information about the selection.

Returns

The return value is the zero-based index of the selected file that was retrieved.

Comments

An extension can use the **FM_GETSELCOUNT** message to obtain the count of selected files.

The **szName** member of the **FMS_GETFILESEL** structure consists of an OEM character string. Before displaying this string, an extension should use the **OemToAnsi** function to convert the string to a Windows ANSI character string. If a string is to be passed to the file system (MS-DOS), an extension should not convert it.

See Also

FMExtensionProc, **FM_GETFILESELLFN**, **FM_GETSELCOUNT**, **FM_GETSELCOUNTLFN**, **OemToAnsi**, **FMS_GETFILESEL**

FM_GETFILESELLFN

A File Manager extension sends an FM_GETFILESELLFN message to retrieve information about a selected file from the active File Manager window (either the directory window or the Search Results window). The selected file can have a long filename.

Parameter	Description
wParam	Specifies the zero-based index of the selected file to retrieve.
lParam	Points to an **FMS_GETFILESEL** structure that receives information about the selection.

Returns

The return value is the zero-based index of the selected file that was retrieved.

Comments

Only extensions that support long filenames (for example, network-aware extensions) should use this message.

An extension can use the **FM_GETSELCOUNT** message to obtain the count of selected files.

The **szName** member of the **FMS_GETFILESEL** structure consists of an OEM character string. Before displaying this string, an extension should use the **OemToAnsi** function to convert the string to a Windows ANSI character string. If a string is to be passed to the file system (MS-DOS), an extension should not convert it.

See Also

FMExtensionProc, **FM_GETFILESEL**, **FM_GETSELCOUNT**, **FM_GETSELCOUNTLFN**, **OemToAnsi**, **FMS_GETFILESEL**

FM_GETFOCUS

A File Manager extension sends a FM_GETFOCUS message to retrieve the type of the File Manager window that has the input focus.

Parameter	Description
wParam	Not used.
lParam	Not used.

Returns

The return value indicates the type of File Manager window that has input focus. It can have one of the following values:

Value	Meaning
FMFOCUS_DIR	Directory portion of a directory window
FMFOCUS_TREE	Tree portion of a directory window
FMFOCUS_DRIVES	Drive bar of a directory window
FMFOCUS_SEARCH	Search Results window

FM_GETSELCOUNT

A File Manager extension sends a FM_GETSELCOUNT message to retrieve a count of the selected files in the directory or the Search Results window, depending on which is the active window.

Parameter	Description
wParam	Not used.
lParam	Not used.

Returns

The return value is the number of selected files.

See Also

FM_GETFILESEL, **FM_GETFILESELLFN**, **FM_GETSELCOUNTLFN**

FM_GETSELCOUNTLFN

A File Manager extension sends an FM_GETSELCOUNTLFN message to retrieve the number of selected files in the directory or the Search Results window, depending on which is the active window. The count includes files that have long filenames.

Parameter	Description
wParam	Not used.
lParam	Not used.

Returns

The return value is the number of selected files.

Comments

Only extensions that support long filenames (for example, network-aware extensions) should use this message.

See Also

FM_GETFILESEL, **FM_GETFILESELLFN**, **FM_GETSELCOUNT**

FM_REFRESH_WINDOWS

A File Manager extension sends an FM_REFRESH_WINDOWS message to cause File Manager to repaint either its active window or all of its windows.

Parameter	Description
wParam	Specifies whether File Manager repaints its active window or all of its windows. If this parameter is nonzero, File Manager repaints all of its windows. If this parameter is zero, File Manager repaints only its active window.
lParam	Not used.

Returns

This message does not return a meaningful value.

Comments

File system changes caused by an extension are automatically detected by File Manager. An extension should use this message only in situations where drive connections are made or canceled.

See Also

FMExtensionProc

FM_RELOAD_EXTENSIONS

A File Manager extension (or another application) sends an FM_RELOAD_EXTENSIONS message to cause File Manager to reload all extension dynamic-link libraries (DLLs) listed in the [AddOns] section of the WINFILE.INI file.

Parameter	Description
wParam	Not used.
lParam	Not used.

Returns

This message does not return a meaningful value.

Comments

Other applications can use the **PostMessage** function to send this message to File Manager. To obtain the appropriate File Manager window handle, an application can specify "WFS_Frame" as the *lpszClassName* parameter in a call to the **FindWindow** function.

See Also

FindWindow, **FMExtensionProc**, **PostMessage**

File Manager Extension Messages (3.1)

FMEVENT_INITMENU
FMEVENT_LOAD
FMEVENT_SELCHANGE
FMEVENT_UNLOAD
FMEVENT_USER_REFRESH

FM_GETDRIVEINFO	Retrieves drive data from active window
FM_GETFILESEL	Retrieves data about a selected file
FM_GETFILESELLFN	Retrieves data about a selected file
FM_GETFOCUS	Retrieves the type of the File Manager focus window
FM_GETSELCOUNT	Retrieves the count of selected files
FM_GETSELCOUNTLFN	Retrieves the count of selected files
FM_REFRESH_WINDOWS	Repaints File Manager's windows
FM_RELOAD_EXTENSIONS	Reloads File Manager extension DLLs

AbortDoc (3.1)

int AbortDoc(*hdc***)**

HDC *hdc;* /* handle of device context */

The **AbortDoc** function terminates the current print job and erases everything drawn since the last call to the **StartDoc** function. This function replaces the ABORTDOC printer escape for Windows version 3.1.

Parameter	Description
hdc	Identifies the device context for the print job.

Returns

The return value is greater than or equal to zero if the function is successful. Otherwise, it is less than zero.

Comments

Applications should call the **AbortDoc** function to terminate a print job because of an error or if the user chooses to cancel the job. To end a successful print job, an application should use the **EndDoc** function.

If Print Manager was used to start the print job, calling the **AbortDoc** function erases the entire spool job--the printer receives nothing. If Print Manager was not used to start the print job, the data may have been sent to the printer before **AbortDoc** was called. In this case, the printer driver would have reset the printer (when possible) and closed the print job.

See Also

EndDoc, **SetAbortProc**, **StartDoc**

AddFontResource (2.x)

int AddFontResource(*lpszFilename***)**

LPCSTR *lpszFilename;* /* address of filename */

The **AddFontResource** function adds a font resource to the Windows font table. Any application can then use the font.

Parameter	Description
lpszFilename	Points to a character string that names the font resource file or that contains a handle of a loaded module. If this parameter points to a font resource filename, it must be a valid MS-DOS filename, including an extension, and the string must be null-terminated. The system passes this string to the **LoadLibrary** function if the font resource must be loaded.

Returns

The return value specifies the number of fonts added if the function is successful. Otherwise, it is zero.

Comments

Any application that adds or removes fonts from the Windows font table should send a **WM_FONTCHANGE** message to all top-level windows in the system by using the **SendMessage** function with the *hwnd* parameter set to 0xFFFF.

When font resources added by using **AddFontResource** are no longer needed, you should remove them by using the **RemoveFontResource** function.

Example

The following example uses the **AddFontResource** function to add a font resource from a file, notifies other applications by using the **SendMessage** function, then removes the font resource by using the **RemoveFontResource** function:

```
AddFontResource("fontres.fon");
SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0);
    .
    . /* Work with the font. */
    .
if (RemoveFontResource("fontres.fon")) {
    SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0);
    return TRUE;
}
else
    return FALSE;
```

See Also

LoadLibrary, **RemoveFontResource**, **SendMessage**

AnimatePalette (3.0)

void AnimatePalette(*hpal, iStart, cEntries, lppe***)**

```
HPALETTE hpal;                          /* handle of palette            */
UINT iStart;                            /* first palette entry to animate*/
UINT cEntries;                          /* number of entries in palette */
const PALETTEENTRY FAR* lppe;           /* address of color structure   */
```

The **AnimatePalette** function replaces entries in the specified logical palette. An application does not have to update the client area when it calls **AnimatePalette**, because Windows maps the new entries into the system palette immediately.

Parameter	Description
hpal	Identifies the logical palette.
iStart	Specifies the first entry in the palette to be animated.
cEntries	Specifies the number of entries in the palette to be animated.
lppe	Points to the first member of an array of **PALETTEENTRY** structures. These palette entries will replace the palette entries identified by the *iStart* and *cEntries* parameters.

Returns

This function does not return a value.

Comments

The **AnimatePalette** function can change an entry in a logical palette only when the PC_RESERVED flag is set in the corresponding **palPaletteEntry** member of the **LOGPALETTE** structure that defines the current logical palette.

Example

The following example initializes a **LOGPALETTE** structure and an array of **PALETTEENTRY** structures, uses the **CreatePalette** function to retrieve a handle of a logical palette, and then uses the **AnimatePalette** function to map the entries into the system palette:

```
#define NUMENTRIES 128
HPALETTE hpal;
PALETTEENTRY ape[NUMENTRIES];

plgpl = (LOGPALETTE*) LocalAlloc(LPTR,
    sizeof(LOGPALETTE) + cColors * sizeof(PALETTEENTRY));

plgpl->palNumEntries = cColors;
plgpl->palVersion = 0x300;

for (i = 0, red = 0, green = 127, blue = 127; i < NUMENTRIES;
        i++, red += 1, green += 1, blue += 1) {
    ape[i].peRed =
        plgpl->palPalEntry[i].peRed = LOBYTE(red);
    ape[i].peGreen =
        plgpl->palPalEntry[i].peGreen = LOBYTE(green);
    ape[i].peBlue =
        plgpl->palPalEntry[i].peBlue = LOBYTE(blue);
    ape[i].peFlags =
        plgpl->palPalEntry[i].peFlags = PC_RESERVED;
}
hpal = CreatePalette(plgpl);
LocalFree((HLOCAL) plgpl);
AnimatePalette(hpal, 0, NUMENTRIES, (PALETTEENTRY FAR*) &ape);
```

Arc (2.x)

BOOL Arc(*hdc, nLeftRect, nTopRect, nRightRect, nBottomRect, nXStartArc, nYStartArc, nXEndArc, nYEndArc***)**

```
HDC hdc;          /* handle of device context                          */
int nLeftRect;    /* x-coordinate upper-left corner bounding rectangle */
int nTopRect;     /* y-coordinate upper-left corner bounding rectangle */
int nRightRect;   /* x-coordinate lower-right corner bounding rectangle */
int nBottomRect;  /* y-coordinate lower-right corner bounding rectangle */
int nXStartArc;   /* x-coordinate arc starting point                   */
int nYStartArc;   /* y-coordinate arc starting point                   */
int nXEndArc;     /* x-coordinate arc ending point                     */
int nYEndArc;     /* y-coordinate arc ending point                     */
```

The **Arc** function draws an elliptical arc.

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle.
nXStartArc	Specifies the logical x-coordinate of the point that defines the arc's starting point. This point need not lie exactly on the arc.
nYStartArc	Specifies the logical y-coordinate of the point that defines the arc's starting point. This point need not lie exactly on the arc.
nXEndArc	Specifies the logical x-coordinate of the point that defines the arc's endpoint. This point need not lie exactly on the arc.
nYEndArc	Specifies the logical y-coordinate of the point that defines the arc's endpoint. This point need not lie exactly on the arc.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The arc drawn by using the **Arc** function is a segment of the ellipse defined by the specified bounding rectangle. The starting point of the arc is the point at which a ray drawn from the center of the bounding rectangle through the specified starting point intersects the ellipse. The end point of the arc is the point at which a ray drawn from the center of the bounding rectangle through the specified end point intersects the ellipse. The arc is drawn in a counterclockwise direction. Since an arc is not a closed figure, it is not filled.

Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.

Example

The following example uses a **RECT** structure to store the points defining the bounding rectangle and uses **POINT** structures to store the coordinates that specify the beginning and end of the arc:

```
HDC hdc;

RECT rc = { 10, 10, 180, 140 };
POINT ptStart = {  12,  12 };
POINT ptEnd = { 128, 135 };

Arc(hdc, rc.left, rc.top, rc.right, rc.bottom,
```

```
    ptStart.x, ptStart.y, ptEnd.x, ptEnd.y);
```

Chord, **POINT**, **RECT**

BitBlt (2.x)

BOOL BitBlt(*hdcDest, nXDest, nYDest, nWidth, nHeight, hdcSrc, nXSrc, nYSrc, dwRop***)**

```
HDC hdcDest;     /* handle of destination device context    */
int nXDest;      /* upper-left corner destination rectangle */
int nYDest;      /* upper-left corner destination rectangle */
int nWidth;      /* bitmap width                            */
int nHeight;     /* bitmap height                           */
HDC hdcSrc;      /* handle of source device context         */
int nXSrc;       /* upper-left corner source bitmap         */
int nYSrc;       /* upper-left corner source bitmap         */
DWORD dwRop;     /* raster operation for copy               */
```

The **BitBlt** function copies a bitmap from a specified device context to a destination device context.

Parameter	Description
hdcDest	Identifies the destination device context.
nXDest	Specifies the logical x-coordinate of the upper-left corner of the destination rectangle.
nYDest	Specifies the logical y-coordinate of the upper-left corner of the destination rectangle.
nWidth	Specifies the width, in logical units, of the destination rectangle and source bitmap.
nHeight	Specifies the height, in logical units, of the destination rectangle and source bitmap.
hdcSrc	Identifies the device context from which the bitmap will be copied. This parameter must be NULL if the *dwRop* parameter specifies a raster operation that does not include a source. This parameter can specify a memory device context.
nXSrc	Specifies the logical x-coordinate of the upper-left corner of the source bitmap.
nYSrc	Specifies the logical y-coordinate of the upper-left corner of the source bitmap.
dwRop	Specifies the raster operation to be performed. Raster operation codes define how the graphics device interface (**GDI**) combines colors in output operations that involve a current brush, a possible source bitmap, and a destination bitmap. This parameter can be one of the following:

Code	Description
BLACKNESS	Turns all output black.
DSTINVERT	Inverts the destination bitmap.
MERGECOPY	Combines the pattern and the source bitmap by using the Boolean AND operator.
MERGEPAINT	Combines the inverted source bitmap with the destination bitmap by using the Boolean OR operator.
NOTSRCCOPY	Copies the inverted source bitmap to the destination.
NOTSRCERASE	Inverts the result of combining the destination and source bitmaps by using the Boolean OR operator.
PATCOPY	Copies the pattern to the destination bitmap.
PATINVERT	Combines the destination bitmap with the pattern by using the Boolean XOR operator.
PATPAINT	Combines the inverted source bitmap with the pattern by using the Boolean OR operator. Combines the result of this operation with the destination bitmap by using the Boolean OR operator.
SRCAND	Combines pixels of the destination and source bitmaps by using the Boolean AND operator.
SRCCOPY	Copies the source bitmap to the destination bitmap.
SRCERASE	Inverts the destination bitmap and combines the result with the

	source bitmap by using the Boolean AND operator.
SRCINVERT	Combines pixels of the destination and source bitmaps by using the Boolean XOR operator.
SRCPAINT	Combines pixels of the destination and source bitmaps by using the Boolean OR operator.
WHITENESS	Turns all output white.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

An application that uses the **BitBlt** function to copy pixels from one window to another window or from a source rectangle in a window into a target rectangle in the same window should set the **CS_BYTEALIGNWINDOW** or **CS_BYTEALIGNCLIENT** flag when registering the window classes. By aligning the windows or client areas on byte boundaries, the application can ensure that the **BitBlt** operations occur on byte-aligned rectangles. **BitBlt** operations on byte-aligned rectangles are considerably faster than **BitBlt** operations on rectangles that are not byte-aligned.

GDI transforms the *nWidth* and *nHeight* parameters, once by using the destination device context, and once by using the source device context. If the resulting extents do not match, GDI uses the **StretchBlt** function to compress or stretch the source bitmap as necessary. If destination, source, and pattern bitmaps do not have the same color format, the **BitBlt** function converts the source and pattern bitmaps to match the destination. The foreground and background colors of the destination bitmap are used in the conversion.

When the **BitBlt** function converts a monochrome bitmap to color, it sets white bits (1) to the background color and black bits (0) to the foreground color. The foreground and background colors of the destination device context are used. To convert color to monochrome, **BitBlt** sets pixels that match the background color to white and sets all other pixels to black. **BitBlt** uses the foreground and background colors of the source (color) device context to convert from color to monochrome.

The foreground color is the current text color for the specified device context, and the background color is the current background color for the specified device context.

Not all devices support the **BitBlt** function. An application can determine whether a device supports **BitBlt** by calling the **GetDeviceCaps** function and specifying the **RASTERCAPS** index.

Example

The following example loads a bitmap, retrieves its dimensions, and displays it in a window:

```
HDC hdc, hdcMemory;
HBITMAP hbmpMyBitmap, hbmpOld;
BITMAP bm;

hbmpMyBitmap = LoadBitmap(hinst, "MyBitmap");
GetObject(hbmpMyBitmap, sizeof(BITMAP), &bm);

hdc = GetDC(hwnd);
hdcMemory = CreateCompatibleDC(hdc);
hbmpOld = SelectObject(hdcMemory, hbmpMyBitmap);

BitBlt(hdc, 0, 0, bm.bmWidth, bm.bmHeight, hdcMemory, 0, 0, SRCCOPY);
SelectObject(hdcMemory, hbmpOld);

DeleteDC(hdcMemory);
ReleaseDC(hwnd, hdc);
```

Chord (2.x)

BOOL Chord(*hdc, nLeftRect, nTopRect, nRightRect, nBottomRect, nXStartLine, nYStartLine, nXEndLine, nYEndLine***)**

```
HDC hdc;          /* handle of device context                          */
int nLeftRect;    /* x-coordinate upper-left corner bounding rectangle */
int nTopRect;     /* y-coordinate upper-left corner bounding rectangle */
int nRightRect;   /* x-coordinate lower-right corner bounding rectangle */
int nBottomRect;  /* y-coordinate lower-right corner bounding rectangle */
int nXStartLine;  /* x-coordinate line-segment starting point          */
int nYStartLine;  /* y-coordinate line-segment starting point          */
int nXEndLine;    /* x-coordinate line-segment ending point            */
int nYEndLine;    /* y-coordinate line-segment ending point            */
```

The **Chord** function draws a chord (a closed figure bounded by the intersection of an ellipse and a line segment).

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle.
nXStartLine	Specifies the logical x-coordinate of the starting point of the line segment.
nYStartLine	Specifies the logical y-coordinate of the starting point of the line segment.
nXEndLine	Specifies the logical x-coordinate of the ending point of the line segment.
nYEndLine	Specifies the logical y-coordinate of the ending point of the line segment.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The (*nLeftRect, nTopRect*) and (*nRightRect, nBottomRect*) parameter combinations specify the upper-left and lower-right corners, respectively, of a rectangle bounding the ellipse that is part of the chord. The (*nXStartLine, nYStartLine*) and (*nXEndLine, nYEndLine*) parameter combinations specify the endpoints of a line that intersects the ellipse. The chord is drawn by using the selected pen and is filled by using the selected brush.

The figure the **Chord** function draws extends up to but does not include the right and bottom coordinates. This means that the height of the figure is determined as follows:

nBottomRect - nTopRect

The width of the figure is determined similarly:

nRightRect - nLeftRect

Example

The following example uses a **RECT** structure to store the points defining the bounding rectangle and uses **POINT** structures to store the coordinates that specify the beginning and end of the chord:

```
HDC hdc;

RECT rc = { 10, 10, 180, 140 };
POINT ptStart = {  12,  12 };
POINT ptEnd = { 128, 135 };
```

```
Chord(hdc, rc.left, rc.top, rc.right, rc.bottom,
    ptStart.x, ptStart.y, ptEnd.x, ptEnd.y);
```

See Also
Arc, **POINT**, **RECT**

CloseMetaFile (2.x)

HMETAFILE CloseMetaFile(*hdc***)**

HDC *hdc;* /* handle of device context */

The **CloseMetaFile** function closes a metafile device context and creates a handle of a metafile. An application can use this handle to play the metafile.

Parameter	Description
hdc	Identifies the metafile device context to be closed.

Returns
The return value is the handle of the metafile if the function is successful. Otherwise, it is NULL.

Comments
If a metafile handle created by using the **CloseMetaFile** function is no longer needed, you should remove it (using the **DeleteMetaFile** function).

Example
The following example creates a device-context handle of a memory metafile, draws a line in the device context, retrieves a handle of the metafile, plays the metafile, and finally deletes the metafile.

```
HDC hdcMeta;
HMETAFILE hmf;

hdcMeta = CreateMetaFile(NULL);
MoveTo(hdcMeta, 10, 10);
LineTo(hdcMeta, 100, 100);
hmf = CloseMetaFile(hdcMeta);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);
```

See Also
CreateMetaFile, **DeleteMetaFile**, **PlayMetaFile**

CombineRgn (2.x)

int CombineRgn(*hrgnDest, hrgnSrc1, hrgnSrc2, fCombineMode***)**

```
HRGN hrgnDest;      /* handle of region to receive combined regions  */
HRGN hrgnSrc1;      /* handle of first source region                 */
HRGN hrgnSrc2;      /* handle of second source region                */
int fCombineMode;   /* mode for combining regions                    */
```

The **CombineRgn** function creates a new region by combining two existing regions.

Parameter	Description
hrgnDest	Identifies an existing region that will be replaced by the new region.
hrgnSrc1	Identifies an existing region.
hrgnSrc2	Identifies an existing region.
fCombineMode	Specifies the operation to use when combining the two source regions. This parameter can be any one of the following values:

Value	Meaning
RGN_AND	Uses overlapping areas of both regions (intersection).
RGN_COPY	Creates a copy of region 1 (identified by the *hrgnSrc1* parameter).
RGN_DIFF	Creates a region consisting of the areas of region 1 (identified by *hrgnSrc1*) that are not part of region 2 (identified by the *hrgnSrc2* parameter).
RGN_OR	Combines all of both regions (union).
RGN_XOR	Combines both regions but removes overlapping areas.

Returns

The return value specifies that the resulting region has overlapping borders (COMPLEXREGION), is empty (NULLREGION), or has no overlapping borders (SIMPLEREGION), if the function is successful. Otherwise, the return value is ERROR.

Comments

The size of a region is limited to 32,000 by 32,000 logical units or 64K of memory, whichever is smaller.

The **CombineRgn** function replaces the region identified by the *hrgnDest* parameter with the combined region. To use **CombineRgn** most efficiently, *hrgnDest* should be a trivial region, as shown in the following example.

Example

The following example creates two source regions and an empty destination region, uses the **CombineRgn** function to create a complex region, selects the region into a device context, and then uses the **PaintRgn** function to display the region:

```
HDC hdc;
HRGN hrgnDest, hrgnSrc1, hrgnSrc2;

hrgnDest = CreateRectRgn(0, 0, 0, 0);
hrgnSrc1 = CreateRectRgn(10, 10, 110, 110);
hrgnSrc2 = CreateRectRgn(90, 90, 200, 150);

CombineRgn(hrgnDest, hrgnSrc1, hrgnSrc2, RGN_OR);
SelectObject(hdc, hrgnDest);
PaintRgn(hdc, hrgnDest);
```

See Also

CreateRectRgn, **PaintRgn**

RGN_AND 1

Uses overlapping areas of both regions (intersection).

RGN_AND 1

RGN_COPY 5

Creates a copy of region 1 (identified by the *hrgnSrc1* parameter).

RGN_COPY 5

RGN_DIFF 4

Creates a region consisting of the areas of region 1 (identified by *hrgnSrc1*) that are not part of region 2 (identified by the *hrgnSrc2* parameter).

RGN_DIFF 4

RGN_OR 2

Combines all of both regions (union).

RGN_OR 2

RGN_XOR 3

Combines both regions but removes overlapping areas.

RGN_XOR 3

CopyMetaFile (2.x)

HMETAFILE CopyMetaFile(*hmfSrc, lpszFile***)**

HMETAFILE *hmfSrc;* /* handle of metafile to copy */
LPCSTR *lpszFile;* /* address of name of copied metafile */

The **CopyMetaFile** function copies a source metafile to a specified file and returns a handle of the new metafile.

Parameter	Description
hmfSrc	Identifies the source metafile to be copied.
lpszFile	Points to a null-terminated string that specifies the filename of the copied metafile. If this value is NULL, the source metafile is copied to a memory metafile.

Returns
The return value is the handle of the new metafile if the function is successful. Otherwise, it is NULL.

Example
The following example copies a metafile to a specified file, plays the copied metafile, retrieves a handle of the copied metafile, changes the position at which the metafile is played 200 logical units to the right, and then plays the metafile at the new location:

```
HANDLE hmf, hmfSource, hmfOld;
LPSTR lpszFile1 = "MFTest";

hmf = CopyMetaFile(hmfSource, lpszFile1);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);

hmfOld = GetMetaFile(lpszFile1);
SetWindowOrg(hdc, -200, 0);
PlayMetaFile(hdc, hmfOld);

DeleteMetaFile(hmfSource);
DeleteMetaFile(hmfOld);
```

See Also
GetMetaFile, **PlayMetaFile**, **SetWindowOrg**

CreateBitmap (2.x)

HBITMAP CreateBitmap(*nWidth, nHeight, cbPlanes, cbBits, lpvBits***)**

```
int nWidth;                 /* bitmap width                    */
int nHeight;                /* bitmap height                   */
UINT cbPlanes;              /* number of color planes          */
UINT cbBits;                /* number of bits per pixel        */
const void FAR* lpvBits;    /* address of array with bitmap bits */
```

The **CreateBitmap** function creates a device-dependent memory bitmap that has the specified width, height, and bit pattern.

Parameter	Description
nWidth	Specifies the width, in pixels, of the bitmap.
nHeight	Specifies the height, in pixels, of the bitmap.
cbPlanes	Specifies the number of color planes in the bitmap. The number of bits per plane is the product of the plane's width, height, and bits per pixel (*nWidth* ” *nHeight* ” *cbBits*).
cbBits	Specifies the number of color bits per display pixel.
lpvBits	Points to an array of short integers that contains the initial bitmap bit values. If this parameter is NULL, the new bitmap is left uninitialized.

Returns

The return value is the handle of the bitmap if the function is successful. Otherwise, it is NULL.

Comments

The bitmap created by the **CreateBitmap** function can be selected as the current bitmap for a memory device context by using the **SelectObject** function.

For a color bitmap, either the *cbPlanes* or *cbBits* parameter should be set to 1. If both of these parameters are set to 1, **CreateBitmap** creates a monochrome bitmap.

Although a bitmap cannot be copied directly to a display device, the **BitBlt** function can copy it from a memory device context (in which it is the current bitmap) to any compatible device context, including a screen device context.

When it has finished using a bitmap created by **CreateBitmap**, an application should select the bitmap out of the device context and then remove the bitmap by using the **DeleteObject** function.

Example

The following example uses the **CreateBitmap** function to create a bitmap with a zigzag pattern and then uses the **PatBlt** function to fill the client area with that pattern:

```
HDC hdc;
HBITMAP hbmp;
HBRUSH hbr, hbrPrevious;
RECT rc;

int aZigzag[] = { 0xFF, 0xF7, 0xEB, 0xDD, 0xBE, 0x7F, 0xFF, 0xFF };

hbmp = CreateBitmap(8, 8, 1, 1, aZigzag);
hbr = CreatePatternBrush(hbmp);

hdc = GetDC(hwnd);
UnrealizeObject(hbr);
hbrPrevious = SelectObject(hdc, hbr);
GetClientRect(hwnd, &rc);
```

```
PatBlt(hdc, rc.left, rc.top,
    rc.right - rc.left, rc.bottom - rc.top, PATCOPY);
SelectObject(hdc, hbrPrevious);
ReleaseDC(hwnd, hdc);

DeleteObject(hbr);
DeleteObject(hbmp);
```

See Also

BitBlt, **CreateBitmapIndirect**, **CreateCompatibleBitmap**, **CreateDIBitmap**, **CreateDiscardableBitmap**, **DeleteObject**, **SelectObject**

CreateBitmapIndirect (2.x)

HBITMAP CreateBitmapIndirect(*lpbm***)**

BITMAP FAR* *lpbm;* /* address of structure with bitmap information*/

The **CreateBitmapIndirect** function creates a bitmap that has the width, height, and bit pattern specified in a **BITMAP** structure.

Parameter	Description
lpbm	Points to a **BITMAP** structure that contains information about the bitmap.

Returns
The return value is the handle of the bitmap if the function is successful. Otherwise, it is NULL.

Comments
Large bitmaps cannot be displayed on a display device by copying them directly to the device context for that device. Instead, applications should create a memory device context that is compatible with the display device, select the bitmap as the current bitmap for the memory device context, and then use a function such as **BitBlt** or **StretchBlt** to copy it from the memory device context to the display device context. (The **PatBlt** function can copy the bitmap for the current brush directly to the display device context.)

When an application has finished using the bitmap created by the **CreateBitmapIndirect** function, it should select the bitmap out of the device context and then delete the bitmap by using the **DeleteObject** function.

If the **BITMAP** structure pointed to by the *lpbm* parameter has been filled in by using the **GetObject** function, the bits of the bitmap are not specified, and the bitmap is uninitialized. To initialize the bitmap, an application can use a function such as **BitBlt** or **SetDIBits** to copy the bits from the bitmap identified by the first parameter of **GetObject** to the bitmap created by **CreateBitmapIndirect**.

Example
The following example assigns values to the members of a **BITMAP** structure and then calls the **CreateBitmapIndirect** function to create a bitmap handle:

```
BITMAP bm;
HBITMAP hbm;

int aZigzag[] = { 0xFF, 0xF7, 0xEB, 0xDD, 0xBE, 0x7F, 0xFF, 0xFF };

bm.bmType = 0;
bm.bmWidth = 8;
bm.bmHeight = 8;
bm.bmWidthBytes = 2;
bm.bmPlanes = 1;
bm.bmBitsPixel = 1;
bm.bmBits = aZigzag;

hbm = CreateBitmapIndirect(&bm);
```

See Also
BitBlt, **CreateBitmap**, **CreateCompatibleBitmap**, **CreateDIBitmap**, **CreateDiscardableBitmap**, **DeleteObject**, **GetObject**, **BITMAP**

CreateBrushIndirect (2.x)

HBRUSH CreateBrushIndirect(*lplb***)**

LOGBRUSH FAR* *lplb;* /* address of structure with brush attributes */

The **CreateBrushIndirect** function creates a brush that has the style, color, and pattern specified in a **LOGBRUSH** structure. The brush can subsequently be selected as the current brush for any device.

Parameter	Description
lplb	Points to a **LOGBRUSH** structure that contains information about the brush.

Returns

The return value is the handle of the brush if the function is successful. Otherwise, it is NULL.

Comments

A brush created by using a monochrome (one plane, one bit per pixel) bitmap is drawn by using the current text and background colors. Pixels represented by a bit set to 0 are drawn with the current text color, and pixels represented by a bit set to 1 are drawn with the current background color.

When it has finished using a brush created by **CreateBrushIndirect**, an application should select the brush out of the device context in which it was used and then remove the brush by using the **DeleteObject** function.

Example

The following example creates a hatched brush with red diagonal hatch marks and uses that brush to fill a rectangle:

```
LOGBRUSH lb;
HBRUSH hbr, hbrOld;

lb.lbStyle = BS_HATCHED;
lb.lbColor = RGB(255, 0, 0);
lb.lbHatch = HS_BDIAGONAL;

hbr = CreateBrushIndirect(&lb);
hbrOld = SelectObject(hdc, hbr);
Rectangle(hdc, 0, 0, 100, 100);
```

See Also

CreateDIBPatternBrush, **CreatePatternBrush**, **CreateSolidBrush**, **DeleteObject**, **GetStockObject**, **SelectObject**, **LOGBRUSH**, **RGB**

CreateCompatibleBitmap (2.x)

HBITMAP CreateCompatibleBitmap(*hdc, nWidth, nHeight***)**

HDC *hdc;* /* handle of device context */
int *nWidth;* /* bitmap width */
int *nHeight;* /* bitmap height */

The **CreateCompatibleBitmap** function creates a bitmap that is compatible with the given device.

Parameter	Description
hdc	Identifies the device context.
nWidth	Specifies the width, in bits, of the bitmap.
nHeight	Specifies the height, in bits, of the bitmap.

Returns
The return value is the handle of the bitmap if the function is successful. Otherwise, it is NULL.

Comments
The bitmap created by the **CreateCompatibleBitmap** function has the same number of color planes or the same bits-per-pixel format as the given device. It can be selected as the current bitmap for any memory device that is compatible with the one identified by *hdc.*

If *hdc* identifies a memory device context, the bitmap returned has the same format as the currently selected bitmap in that device context. A memory device context is a memory object that represents a screen surface. It can be used to prepare images in memory before copying them to the screen surface of the compatible device.

When a memory device context is created, the graphics device interface (**GDI**) automatically selects a monochrome stock bitmap for it.

Since a color memory device context can have either color or monochrome bitmaps selected, the format of the bitmap returned by the **CreateCompatibleBitmap** function is not always the same; however, the format of a compatible bitmap for a non–memory device context is always in the format of the device.

When it has finished using a bitmap created by **CreateCompatibleBitmap**, an application should select the bitmap out of the device context and then remove the bitmap by using the **DeleteObject** function.

Example
The following example shows a function named DuplicateBitmap that accepts the handle of a bitmap, duplicates the bitmap, and returns a handle of the duplicate. This function uses the **CreateCompatibleDC** function to create source and destination device contexts and then uses the **GetObject** function to retrieve the dimensions of the source bitmap. The **CreateCompatibleBitmap** function uses these dimensions to create a new bitmap. When each bitmap has been selected into a device context, the **BitBlt** function copies the bits from the source bitmap to the new bitmap. (Although an application could use the **GetDIBits** and **SetDIBits** functions to duplicate a bitmap, the method illustrated in this example is much faster.)

```
HBITMAP PASCAL DuplicateBitmap(HBITMAP hbmpSrc)
{
    HBITMAP hbmpOldSrc, hbmpOldDest, hbmpNew;
    HDC     hdcSrc, hdcDest;
    BITMAP  bmp;

    hdcSrc = CreateCompatibleDC(NULL);
    hdcDest = CreateCompatibleDC(hdcSrc);

    GetObject(hbmpSrc, sizeof(BITMAP), &bmp);
```

```
    hbmpOldSrc = SelectObject(hdcSrc, hbmpSrc);

    hbmpNew = CreateCompatibleBitmap(hdcSrc, bmp.bmWidth,
        bmp.bmHeight);

    hbmpOldDest = SelectObject(hdcDest, hbmpNew);

    BitBlt(hdcDest, 0, 0, bmp.bmWidth, bmp.bmHeight, hdcSrc, 0, 0,
        SRCCOPY);

    SelectObject(hdcDest, hbmpOldDest);
    SelectObject(hdcSrc, hbmpOldSrc);

    DeleteDC(hdcDest);
    DeleteDC(hdcSrc);

    return hbmpNew;
}
```

CreateBitmap, **CreateBitmapIndirect**, **CreateDIBitmap**, **DeleteObject**

CreateCompatibleDC (2.x)

HDC CreateCompatibleDC(*hdc***)**

HDC *hdc;* /* handle of device context */

The **CreateCompatibleDC** function creates a memory device context that is compatible with the given device.

An application must select a bitmap into a memory device context to represent a screen surface. The device context can then be used to prepare images in memory before copying them to the screen surface of the compatible device.

Parameter	Description
hdc	Identifies the device context. If this parameter is NULL, the function creates a memory device context that is compatible with the system screen.

Returns

The return value is the handle of the new memory device context if the function is successful. Otherwise, it is NULL.

Comments

The **CreateCompatibleDC** function can be used only to create compatible device contexts for devices that support raster operations. To determine whether a device supports raster operations, an application can call the **GetDeviceCaps** function with the RC_BITBLT index.

GDI output functions can be used with a memory device context only if a bitmap has been created and selected into that context.

When it has finished using a device context created by **CreateCompatibleDC**, an application should free the device context by calling the **DeleteDC** function. All objects selected into the device context after it was created should be selected out and replaced with the original objects before the device context is removed.

Example

The following example loads a bitmap named Dog, uses the **CreateCompatibleDC** function to create a memory device context that is compatible with the screen, selects the bitmap into the memory device context, and then uses the **BitBlt** function to move the bitmap from the memory device context to the screen device context:

```
HDC hdc, hdcMemory;
HBITMAP hbmpMyBitmap, hbmpOld;
BITMAP bm;

hbmpMyBitmap = LoadBitmap(hinst, "MyBitmap");
GetObject(hbmpMyBitmap, sizeof(BITMAP), &bm);

hdc = GetDC(hwnd);
hdcMemory = CreateCompatibleDC(hdc);
hbmpOld = SelectObject(hdcMemory, hbmpMyBitmap);

BitBlt(hdc, 0, 0, bm.bmWidth, bm.bmHeight, hdcMemory, 0, 0, SRCCOPY);
SelectObject(hdcMemory, hbmpOld);

DeleteDC(hdcMemory);
ReleaseDC(hwnd, hdc);
```

DeleteDC, **GetDeviceCaps**

CreateDC (2.x)

#include <print.h>

HDC CreateDC(*lpszDriver, lpszDevice, lpszOutput, lpvInitData***)**

```
LPCSTR lpszDriver;          /* address of driver name          */
LPCSTR lpszDevice;          /* address of device name          */
LPCSTR lpszOutput;          /* address of filename or port name */
const void FAR* lpvInitData; /* address of initialization data  */
```

The **CreateDC** function creates a device context for the given device.

Parameter	Description
lpszDriver	Points to a null-terminated string that specifies the MS-DOS filename (without extension) of the device driver (for example, Epson).
lpszDevice	Points to a null-terminated string that specifies the name of the specific device to be supported (for example, Epson FX-80). This parameter is used if the module supports more than one device.
lpszOutput	Points to a null-terminated string that specifies the MS-DOS filename or device name for the physical output medium (file or output port).
lpvInitData	Points to a **DEVMODE** structure that contains device-specific initialization information for the device driver. The **ExtDeviceMode** function retrieves this structure already filled in for a given device. The *lpvInitData* parameter must be NULL if the device driver is to use the default initialization (if any) specified by the user through Windows Control Panel.

Returns

The return value is the handle of the device context for the specified device if the function is successful. Otherwise, it is NULL.

Comments

The PRINT.H header file is required if the **DEVMODE** structure is used.

Device contexts created by using the **CreateDC** function must be deleted by using the **DeleteDC** function. All objects selected into the device context after it was created should be selected out and replaced with the original objects before the device context is deleted.

MS-DOS device names follow MS-DOS conventions; an ending colon (:) is recommended, but optional. Windows strips the terminating colon so that a device name ending with a colon is mapped to the same port as the same name without a colon. The driver and port names must not contain leading or trailing spaces.

Example

The following example uses the **CreateDC** function to create a device context for a printer, using information returned by the **PrintDlg** function in a **PRINTDLG** structure:

```
PRINTDLG   pd;
HDC        hdc;
LPDEVNAMES lpDevNames;
LPSTR      lpszDriverName;
LPSTR      lpszDeviceName;
LPSTR      lpszPortName;

/*
 * PrintDlg displays the common dialog box for printing. The
 * PRINTDLG structure should be initialized with appropriate values.
 */
```

```
PrintDlg(&pd);
lpDevNames = (LPDEVNAMES) GlobalLock(pd.hDevNames);
lpszDriverName = (LPSTR) lpDevNames + lpDevNames->wDriverOffset;
lpszDeviceName = (LPSTR) lpDevNames + lpDevNames->wDeviceOffset;
lpszPortName   = (LPSTR) lpDevNames + lpDevNames->wOutputOffset;
GlobalUnlock(pd.hDevNames);
hdc = CreateDC(lpszDriverName, lpszDeviceName, lpszPortName, NULL);
```

CreateDIBitmap (3.0)

HBITMAP CreateDIBitmap(*hdc, lpbmih, dwInit, lpvBits, lpbmi, fnColorUse***)**

```
HDC hdc;                              /* handle of device context          */
BITMAPINFOHEADER FAR* lpbmih;         /* address of structure with header  */
DWORD dwInit;                         /* CBM_INIT to initialize bitmap     */
const void FAR* lpvBits;              /* address of array with bitmap values */
BITMAPINFO FAR* lpbmi;                /* address of structure with bitmap data */
UINT fnColorUse;                      /* RGB or palette indices            */
```

The **CreateDIBitmap** function creates a device-specific memory bitmap from a device-independent bitmap (DIB) specification and optionally sets bits in the bitmap.

Parameter	Description
hdc	Identifies the device context.
lpbmih	Points to a **BITMAPINFOHEADER** structure that describes the size and format of the device-independent bitmap.
dwInit	Specifies whether the memory bitmap is initialized. If this value is CBM_INIT, the function initializes the bitmap with the bits specified by the *lpvBits* and *lpbmi* parameters.
lpvBits	Points to a byte array that contains the initial bitmap values. The format of the bitmap values depends on the **biBitCount** member of the **BITMAPINFOHEADER** structure identified by the *lpbmi* parameter.
lpbmi	Points to a **BITMAPINFO** structure that describes the dimensions and color format of the *lpvBits* parameter. The **BITMAPINFO** structure contains a **BITMAPINFOHEADER** structure and an array of **RGBQUAD** structures specifying the colors in the bitmap.
fnColorUse	Specifies whether the **bmiColors** member of the **BITMAPINFO** structure contains explicit red, green, blue (**RGB**) values or indices into the currently realized logical palette. The *fnColorUse* parameter must be one of the following values:

Value	Meaning
DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the currently realized logical palette.
DIB_RGB_COLORS	The color table contains literal **RGB** values.

Returns

The return value is the handle of the bitmap if the function is successful. Otherwise, it is NULL.

When it has finished using a bitmap created by **CreateDIBitmap**, an application should select the bitmap out of the device context and then remove the bitmap by using the **DeleteObject** function.

Example

The following example initializes an array of bits and an array of **RGBQUAD** structures, allocates memory for the bitmap header and color table, fills in the required members of a **BITMAPINFOHEADER** structure, and calls the **CreateDIBitmap** function to create a handle of the bitmap:

```
HANDLE hloc;
PBITMAPINFO pbmi;
HBITMAP hbm;

BYTE aBits[] = { 0x00, 0x00, 0x00, 0x00,    /* bottom row */
                 0x01, 0x12, 0x22, 0x11,
                 0x01, 0x12, 0x22, 0x11,
                 0x02, 0x20, 0x00, 0x22,
                 0x02, 0x20, 0x20, 0x22,
                 0x02, 0x20, 0x00, 0x22,
```

```
                0x01, 0x12, 0x22, 0x11,
                0x01, 0x12, 0x22, 0x11 };  /* top row    */

RGBQUAD argbq[] = {{ 255, 0, 0, 0 },        /* blue       */
                  { 0, 255, 0, 0 },         /* green      */
                  { 0, 0, 255, 0 }};        /* red        */

hloc = LocalAlloc(LMEM_ZEROINIT | LMEM_MOVEABLE,
    sizeof(BITMAPINFOHEADER) + (sizeof(RGBQUAD) * 16));
pbmi = (PBITMAPINFO) LocalLock(hloc);

pbmi->bmiHeader.biSize = sizeof(BITMAPINFOHEADER);
pbmi->bmiHeader.biWidth = 8;
pbmi->bmiHeader.biHeight = 8;
pbmi->bmiHeader.biPlanes = 1;
pbmi->bmiHeader.biBitCount = 4;
pbmi->bmiHeader.biCompression = BI_RGB;

memcpy(pbmi->bmiColors, argbq, sizeof(RGBQUAD) * 3);

hbm = CreateDIBitmap(hdcLocal, (BITMAPINFOHEADER FAR*) pbmi, CBM_INIT,
    aBits, pbmi, DIB_RGB_COLORS);
LocalFree(hloc);
    .
    . /* Use the bitmap handle. */
    .
DeleteObject(hbm);
```

DIB_PAL_COLORS 1

The color table consists of an array of 16-bit indices into the currently realized logical palette.

DIB_PAL_COLORS 1

DIB_RGB_COLORS 0

The color table contains literal **RGB** values.

DIB_RGB_COLORS 0

CreateDIBPatternBrush (3.0)

HBRUSH CreateDIBPatternBrush(*hglbDIBPacked, fnColorSpec***)**

HGLOBAL *hglbDIBPacked;* /* handle of device-independent bitmap */
UINT *fnColorSpec;* /* type of color table */

The **CreateDIBPatternBrush** function creates a brush that has the pattern specified by a device-independent bitmap (DIB). The brush can subsequently be selected for any device that supports raster operations.

Parameter	Description
hglbDIBPacked	Identifies a global memory object containing a packed device-independent bitmap. A packed DIB consists of a **BITMAPINFO** structure immediately followed by the array of bytes that define the pixels of the bitmap.
fnColorSpec	Specifies whether the **bmiColors** member(s) of the **BITMAPINFO** structure contain explicit red, green, blue (**RGB**) values or indices into the currently realized logical palette. This parameter must be one of the following values:

Value	Meaning
DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the currently realized logical palette.
DIB_RGB_COLORS	The color table contains literal **RGB** values.

Returns
The return value is the handle of the brush if the function is successful. Otherwise, it is NULL.

Comments
To retrieve the handle identified by the *hglbDIBPacked* parameter, an application calls the **GlobalAlloc** function to allocate a global memory object and then fills the memory with the packed DIB.

Bitmaps used as fill patterns should be 8 pixels by 8 pixels. If such a bitmap is larger, Windows creates a fill pattern using only the bits corresponding to the first 8 rows and 8 columns of pixels in the upper-left corner of the bitmap.

When an application selects a two-color DIB pattern brush into a monochrome device context, Windows ignores the colors specified in the DIB and instead displays the pattern brush, using the current text and background colors of the device context. Pixels mapped to the first color (at offset 0 in the DIB color table) of the DIB are displayed using the text color, and pixels mapped to the second color (at offset 1 in the color table) are displayed using the background color.

When it has finished using a brush created by **CreateDIBPatternBrush**, an application should remove the brush by using the **DeleteObject** function.

Example
The following example retrieves a bitmap named DIBit from the application's resource file, uses the bitmap to create a pattern brush in a call to the **CreateDIBPatternBrush** function, selects the brush into a device context, and fills a rectangle by using the new brush:

```
HRSRC hrsrc;
HGLOBAL hglbl;
HBRUSH hbr, hbrOld;

hrsrc = FindResource(hinst, "DIBit", RT_BITMAP);
hglbl = LoadResource(hinst, hrsrc);
LockResource(hglbl);

hbr = CreateDIBPatternBrush(hglbl, DIB_RGB_COLORS);
```

```
hbrOld = SelectObject(hdc, hbr);
Rectangle(hdc, 10, 10, 100, 100);
UnlockResource(hglbl);
```

See Also

CreatePatternBrush, **DeleteObject**, **FindResource**, **GetDeviceCaps**, **GlobalAlloc**, **LoadResource**, **LockResource**, **SelectObject**, **SetBkColor**, **SetTextColor**, **UnlockResource**, **BITMAPINFO**

CreateDiscardableBitmap (2.x)

HBITMAP CreateDiscardableBitmap(*hdc, nWidth, nHeight***)**

```
HDC hdc;        /* handle of device context */
int nWidth;     /* bitmap width             */
int nHeight;    /* bitmap height            */
```

The **CreateDiscardableBitmap** function creates a discardable bitmap that is compatible with the given device. The bitmap has the same number of color planes or the same bits-per-pixel format as the device. An application can select this bitmap as the current bitmap for a memory device that is compatible with the one identified by the *hdc* parameter.

Parameter	Description
hdc	Identifies the device context.
nWidth	Specifies the width, in bits, of the bitmap.
nHeight	Specifies the height, in bits, of the bitmap.

Returns

The return value is the handle of the bitmap if the function is successful. Otherwise, it is NULL.

Comments

Windows can discard a bitmap created by this function only if an application has not selected it into a device context. If Windows discards the bitmap when it is not selected and the application later attempts to select it, the **SelectObject** function will return zero.

Applications should use the **DeleteObject** function to delete the handle returned by the **CreateDiscardableBitmap** function, even if Windows has discarded the bitmap.

See Also

CreateBitmap, **CreateBitmapIndirect**, **CreateDIBitmap**, **DeleteObject**

CreateEllipticRgn (2.x)

HRGN CreateEllipticRgn(*nLeftRect, nTopRect, nRightRect, nBottomRect***)**

```
int nLeftRect;      /* x-coordinate upper-left corner bounding rectangle  */
int nTopRect;       /* y-coordinate upper-left corner bounding rectangle  */
int nRightRect;     /* x-coordinate lower-right corner bounding rectangle */
int nBottomRect;    /* y-coordinate lower-right corner bounding rectangle */
```

The **CreateEllipticRgn** function creates an elliptical region.

Parameter	Description
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle of the ellipse.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle of the ellipse.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle of the ellipse.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle of the ellipse.

Returns

The return value is the handle of the region if the function is successful. Otherwise, it is NULL.

Comments

The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.

When it has finished using a region created by using the **CreateEllipticRgn** function, an application should remove it by using the **DeleteObject** function.

See Also

CreateEllipticRgnIndirect, **DeleteObject**, **PaintRgn**

CreateEllipticRgnIndirect (2.x)

HRGN CreateEllipticRgnIndirect(*lprc***)**

const RECT FAR* *lprc;* /* address of structure with bounding rectangle */

The **CreateEllipticRgnIndirect** function creates an elliptical region.

Parameter	Description
lprc	Points to a **RECT** structure that contains the logical coordinates of the upper-left and lower-right corners of the bounding rectangle of the ellipse.

Returns
The return value is the handle of the region if the function is successful. Otherwise, it is NULL.

Comments
The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.

When it has finished using a region created by **CreateEllipticRgnIndirect**, an application should remove the region by using the **DeleteObject** function.

Example
The following example assigns values to the members of a **RECT** structure, uses the **CreateEllipticRgnIndirect** function to create an elliptical region, selects the region into a device context, and then uses the **PaintRgn** function to display the region:

```
HDC hdc;
RECT rc;
HRGN hrgn;

SetRect(&rc, 10, 10, 200, 50);

hrgn = CreateEllipticRgnIndirect(&rc);
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);
```

CreateEllipticRgn, **DeleteObject**, **PaintRgn**, **RECT**

CreateFont (2.x)

HFONT CreateFont(*nHeight, nWidth, nEscapement, nOrientation, fnWeight, fbItalic, fbUnderline, fbStrikeOut, fbCharSet, fbOutputPrecision, fbClipPrecision, fbQuality, fbPitchAndFamily, lpszFace***)**

```
int nHeight;                /* font height                    */
int nWidth;                 /* character width                */
int nEscapement;            /* escapement of line of text     */
int nOrientation;           /* angle of base line and x-axis  */
int fnWeight;               /* font weight                    */
BYTE fbItalic;              /* flag for italic attribute      */
BYTE fbUnderline;           /* flag for underline attribute   */
BYTE fbStrikeOut;           /* flag for strikeout attribute   */
BYTE fbCharSet;             /* character set                  */
BYTE fbOutputPrecision;     /* output precision               */
BYTE fbClipPrecision;       /* clipping precision             */
BYTE fbQuality;             /* output quality                 */
BYTE fbPitchAndFamily;      /* pitch and family               */
LPCSTR lpszFace;            /* address of typeface name       */
```

The **CreateFont** function creates a logical font that has the specified characteristics. The logical font can subsequently be selected as the font for any device.

Parameter	Description
nHeight	Specifies the requested height, in logical units, for the font. If this parameter is greater than zero, it specifies the cell height of the font. If it is less than zero, it specifies the character height of the font. (Character height is the cell height minus the internal leading. Applications that specify font height in points typically use a negative number for this member.) If this parameter is zero, the font mapper uses a default height. The font mapper chooses the largest physical font that does not exceed the requested size (or the smallest font, if all the fonts exceed the requested size). The absolute value of the *nHeight* parameter must not exceed 16,384 after it is converted to device units.
nWidth	Specifies the average width, in logical units, of characters in the font. If this parameter is zero, the font mapper chooses a "closest match" default width for the specified font height. (The default width is chosen by matching the aspect ratio of the device against the digitization aspect ratio of the available fonts. The closest match is determined by the absolute value of the difference.)
nEscapement	Specifies the angle, in tenths of degrees, between the escapement vector and the x-axis of the screen surface. The escapement vector is the line through the origins of the first and last characters on a line. The angle is measured counterclockwise from the x-axis.
nOrientation	Specifies the angle, in tenths of degrees, between the base line of a character and the x-axis. The angle is measured in a counterclockwise direction from the x-axis for left-handed coordinate systems (that is, MM_TEXT, in which the y-direction is down) and in a clockwise direction from the x-axis for right-handed coordinate systems (in which the y-direction is up).
fnWeight	Specifies the font weight. This parameter can be one of the following values:

Constant	Value
FW_DONTCARE	0
FW_THIN	100
FW_EXTRALIGHT	200
FW_ULTRALIGHT	200

FW_LIGHT	300
FW_NORMAL	400
FW_REGULAR	400
FW_MEDIUM	500
FW_SEMIBOLD	600
FW_DEMIBOLD	600
FW_BOLD	700
FW_EXTRABOLD	800
FW_ULTRABOLD	800
FW_BLACK	900
FW_HEAVY	900

The appearance of the font depends on the typeface. Some fonts have only FW_NORMAL, FW_REGULAR, and FW_BOLD weights. If FW_DONTCARE is specified, a default weight is used.

fbItalic Specifies an italic font if set to nonzero.

fbUnderline Specifies an underlined font if set to nonzero.

fbStrikeOut Specifies a strikeout font if set to nonzero.

fbCharSet Specifies the character set of the font. The following values are predefined:

Constant	Value
ANSI_CHARSET	0
DEFAULT_CHARSET	1
SYMBOL_CHARSET	2
SHIFTJIS_CHARSET	128
OEM_CHARSET	255

The DEFAULT_CHARSET value is not used by the font mapper. An application can use this value to allow the name and size of a font to fully describe the logical font. If the specified font name does not exist, a font from any character set can be substituted for the specified font; to avoid unexpected results, applications should use the DEFAULT_CHARSET value sparingly.

The OEM character set is system-dependent.

Fonts with other character sets may exist in the system. If an application uses a font with an unknown character set, it should not attempt to translate or interpret strings that are to be rendered with that font.

fbOutputPrecision Specifies the requested output precision. The output precision defines how closely the output must match the requested font's height, width, character orientation, escapement, and pitch. This parameter can be one of the following values:

OUT_CHARACTER_PRECIS
OUT_DEFAULT_PRECIS
OUT_DEVICE_PRECIS
OUT_RASTER_PRECIS
OUT_STRING_PRECIS
OUT_STROKE_PRECIS
OUT_TT_PRECIS

Applications can use the OUT_DEVICE_PRECIS, OUT_RASTER_PRECIS, and OUT_TT_PRECIS values to control how the font mapper chooses a font when the system contains more than one font with a given name. For example, if a system contained a font named Symbol in raster and TrueType form, specifying

OUT_TT_PRECIS would force the font mapper to choose the TrueType version. (Specifying OUT_TT_PRECIS forces the font mapper to choose a TrueType font whenever the specified font name matches a device or raster font, even when there is no TrueType font of the same name.)

fbClipPrecision Specifies the requested clipping precision. The clipping precision defines how to clip characters that are partially outside the clipping region. This parameter can be one of the following values:

CLIP_CHARACTER_PRECIS
CLIP_DEFAULT_PRECIS
CLIP_ENCAPSULATE
CLIP_LH_ANGLES
CLIP_MASK
CLIP_STROKE_PRECIS
CLIP_TT_ALWAYS

To use an embedded read-only font, applications must specify CLIP_ENCAPSULATE.

To achieve consistent rotation of device, TrueType, and vector fonts, an application can use the OR operator to combine the CLIP_LH_ANGLES value with any of the other *fbClipPrecision* values. If the CLIP_LH_ANGLES bit is set, the rotation for all fonts is dependent on whether the orientation of the coordinate system is left-handed or right-handed. If CLIP_LH_ANGLES is not set, device fonts always rotate counterclockwise, but the rotation of other fonts is dependent on the orientation of the coordinate system. (For more information about the orientation of coordinate systems, see the description of the *nOrientation* parameter.)

fbQuality Specifies the output quality of the font, which defines how carefully the graphics device interface (**GDI**) must attempt to match the attributes of a logical font to those of a physical font. This parameter can be one of the following values:

Value	Meaning
DEFAULT_QUALITY	Appearance of the font does not matter.
DRAFT_QUALITY	Appearance of the font is less important than when the PROOF_QUALITY value is used. For **GDI** raster fonts, scaling is enabled. Bold, italic, underline, and strikeout fonts are synthesized if necessary.
PROOF_QUALITY	Character quality of the font is more important than exact matching of the logical-font attributes. For **GDI** raster fonts, scaling is disabled and the font closest in size is chosen. Bold, italic, underline, and strikeout fonts are synthesized if necessary.

fbPitchAndFamily Specifies the pitch and family of the font. The two low-order bits specify the pitch of the font and can be one of the following values:

DEFAULT_PITCH
FIXED_PITCH
VARIABLE_PITCH

Applications can set bit 2 (0x04) of the **lfPitchAndFamily** member to choose a TrueType font.

The four high-order bits specify the font family and can be one of the following values:

Value	Meaning
FF_DECORATIVE	Novelty fonts. Old English is an example.

	FF_DONTCARE	Don't care or don't know.
	FF_MODERN	Fonts with constant stroke width, with or without serifs. Pica, Elite, and Courier New are examples.
	FF_ROMAN	Fonts with variable stroke width and with serifs. Times New Roman and New Century Schoolbook are examples.
	FF_SCRIPT	Fonts designed to look like handwriting. Script and Cursive are examples.
	FF_SWISS	Fonts with variable stroke width and without serifs. MS Sans Serif is an example.
	An application can specify a value for the *fbPitchAndFamily* parameter by using the Boolean OR operator to join a pitch constant with a family constant.	
	Font families describe the look of a font in a general way. They are intended for specifying fonts when the exact typeface requested is not available.	
lpszFace	Points to a null-terminated string that specifies the typeface name of the font. The length of this string must not exceed LF_FACESIZE - 1. The **EnumFontFamilies** function can be used to enumerate the typeface names of all currently available fonts. If this parameter is NULL, **GDI** uses a device-dependent typeface.	

Returns

The return value is the handle of the logical font if the function is successful. Otherwise, it is NULL.

Comments

The **CreateFont** function creates the handle of a logical font. The font mapper uses this logical font to find the closest match from the fonts available in **GDI**'s pool of physical fonts.

Applications can use the default settings for most of these parameters when creating a logical font. The parameters that should always be given specific values are *nHeight* and *lpszFace.* If *nHeight* and *lpszFace* are not set by the application, the logical font that is created is device-dependent.

Fonts created by using the **CreateFont** function must be selected out of any device context in which they were used and then removed by using the **DeleteObject** function.

Example

The following example sets the mapping mode to MM_TWIPS and then uses the **CreateFont** function to create an 18-point logical font:

```
HFONT hfont, hfontOld;
int MapModePrevious, iPtSize = 18;
PSTR pszFace = "MS Serif";

MapModePrevious = SetMapMode(hdc, MM_TWIPS);
hfont = CreateFont(-iPtSize * 20, 0, 0, 0, 0, /* specify pt size    */
    0, 0, 0, 0, 0, 0, 0, 0, pszFace);         /* and face name only */

hfontOld = SelectObject(hdc, hfont);

TextOut(hdc, 100, -500, pszFace, strlen(pszFace));
SetMapMode(hdc, MapModePrevious);
SelectObject(hdc, hfontOld);
DeleteObject(hfont);
```

See Also

CreateFontIndirect, **DeleteObject**, **EnumFontFamilies**

CreateFontIndirect (2.x)

HFONT CreateFontIndirect(*lplf***)**

const LOGFONT FAR* *lplf;* /* address of struct. with font attributes */

The **CreateFontIndirect** function creates a logical font that has the characteristics given in the specified structure. The font can subsequently be selected as the current font for any device.

Parameter	Description
lplf	Points to a **LOGFONT** structure that defines the characteristics of the logical font.

Returns
The return value is the handle of the logical font if the function is successful. Otherwise, it is NULL.

Comments
The **CreateFontIndirect** function creates a logical font that has the characteristics specified in the **LOGFONT** structure. When the font is selected by using the **SelectObject** function, the graphics device interface (**GDI**) font mapper attempts to match the logical font with an existing physical font. If it cannot find an exact match for the logical font, the font mapper provides an alternative whose characteristics match as many of the requested characteristics as possible.

Fonts created by using the **CreateFontIndirect** function must be selected out of any device context in which they were used and then removed by using the **DeleteObject** function.

Example
The following example uses the **CreateFontIndirect** function to retrieve the handle of a logical font. The nPtSize and pszFace parameters are passed to the function containing this code. The **MulDiv** and **GetDeviceCaps** functions are used to convert the specified point size into the correct point size for the MM_TEXT mapping mode on the current device.

```
HFONT hfont, hfontOld;

PLOGFONT plf = (PLOGFONT) LocalAlloc(LPTR, sizeof(LOGFONT));

plf->lfHeight = -MulDiv(nPtSize, GetDeviceCaps(hdc, LOGPIXELSY), 72);
strcpy(plf->lfFaceName, pszFace);

hfont = CreateFontIndirect(plf);

hfontOld = SelectObject(hdc, hfont);

TextOut(hdc, 10, 50, pszFace, strlen(pszFace));

LocalFree((HLOCAL) plf);
SelectObject(hdc, hfontOld);
DeleteObject(hfont);
```

See Also
CreateFont, **DeleteObject**

CreateHatchBrush (2.x)

HBRUSH CreateHatchBrush(*fnStyle, clrref***)**

int *fnStyle;* /* hatch style of brush */
COLORREF *clrref;* /* color of brush */

The **CreateHatchBrush** function creates a brush that has the specified hatched pattern and color. The brush can subsequently be selected as the current brush for any device.

Parameter	Description
fnStyle	Specifies the hatch style of the brush. This parameter can be one of the following values:

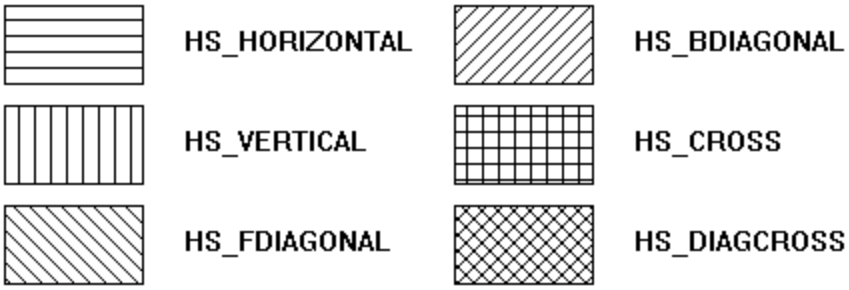
Value	Meaning
HS_BDIAGONAL	45-degree upward hatch (left to right)
HS_CROSS	Horizontal and vertical crosshatch
HS_DIAGCROSS	45-degree crosshatch
HS_FDIAGONAL	45-degree downward hatch (left to right)
HS_HORIZONTAL	Horizontal hatch
HS_VERTICAL	Vertical hatch

clrref	Specifies the foreground color of the brush (the color of the hatches).

Returns
The return value is the handle of the brush if the function is successful. Otherwise, it is NULL.

Comments
When an application has finished using the brush created by the **CreateHatchBrush** function, it should select the brush out of the device context and then delete it by using the **DeleteObject** function.

The following illustration shows how the various hatch brushes appear when used to fill a rectangle:



Example
The following example creates a hatched brush with green diagonal hatch marks and uses that brush to fill a rectangle:

```
HBRUSH hbr, hbrOld;

hbr = CreateHatchBrush(HS_FDIAGONAL, RGB(0, 255, 0));
hbrOld = SelectObject(hdc, hbr);
Rectangle(hdc, 0, 0, 100, 100);
```

See Also

CreateIC (2.x)

HDC CreateIC(*lpszDriver, lpszDevice, lpszOutput, lpvInitData***)**

LPCSTR *lpszDriver;* /* address of driver name */
LPCSTR *lpszDevice;* /* address of device name */
LPCSTR *lpszOutput;* /* address of filename or port name */
const void FAR* *lpvInitData;* /* address of initialization data */

The **CreateIC** function creates an information context for the specified device. The information context provides a fast way to get information about the device without creating a device context.

Parameter	Description
lpszDriver	Points to a null-terminated string that specifies the MS-DOS filename (without extension) of the device driver (for example, EPSON).
lpszDevice	Points to a null-terminated string that specifies the name of the specific device to be supported (for example, EPSON FX-80). This parameter is used if the module supports more than one device.
lpszOutput	Points to a null-terminated string that specifies the MS-DOS filename or device name for the physical output medium (file or port).
lpvInitData	Points to a **DEVMODE** structure that contains, initially, device-specific information necessary to initialize the device driver. The **ExtDeviceMode** function retrieves this structure filled in for a given device. The *lpvInitData* parameter must be NULL if the device driver is to use the default initialization information (if any) specified by the user through Windows Control Panel.

Returns
The return value is the handle of an information context for the given device if the function is successful. Otherwise, it is NULL.

Comments
The PRINT.H header file is required if the **DEVMODE** structure is used.

MS-DOS device names follow MS-DOS conventions; an ending colon (:) is recommended, but optional. Windows strips the terminating colon so that a device name ending with a colon is mapped to the same port as would be the same name without a colon.

The driver and port names must not contain leading or trailing spaces.

GDI output functions cannot be used with information contexts.

When it has finished using an information context created by **CreateIC**, an application should remove the information context by using the **DeleteDC** function.

Example
The following example uses the **CreateIC** function to create an information context for the display and then uses the **GetDCOrg** function to retrieve the origin for the information context:

```
HDC   hdcIC;
DWORD dwOrigin;

hdcIC = CreateIC("DISPLAY", NULL, NULL, NULL);
dwOrigin = GetDCOrg(hdcIC);

DeleteDC(hdcIC);
```

See Also
CreateDC, **DeleteDC**, **ExtDeviceMode**, **DEVMODE**

CreateMetaFile (2.x)

HDC CreateMetaFile(*lpszFile***)**

LPCSTR *lpszFile;* /* address of metafile name */

The **CreateMetaFile** function creates a metafile device context.

Parameter	Description
lpszFile	Points to a null-terminated string that specifies the MS-DOS filename of the metafile to create. If this parameter is NULL, a device context for a memory metafile is returned.

Returns
The return value is the handle of the metafile device context if the function is successful. Otherwise, it is NULL.

Comments
When it has finished using a metafile device context created by **CreateMetaFile**, an application should close it by using the **CloseMetaFile** function.

Example
The following example uses the **CreateMetaFile** function to create the handle of a device context for a memory metafile, draws a line in that device context, retrieves a handle of the metafile by calling the **CloseMetaFile** function, plays the metafile by using the **PlayMetaFile** function, and finally deletes the metafile by using the **DeleteMetaFile** function:

```
HDC hdcMeta;
HMETAFILE hmf;

hdcMeta = CreateMetaFile(NULL);
MoveTo(hdcMeta, 10, 10);
LineTo(hdcMeta, 100, 100);
hmf = CloseMetaFile(hdcMeta);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);
```

See Also
DeleteMetaFile

CreatePalette (3.0)

HPALETTE CreatePalette(*lplgpl***)**

const LOGPALETTE FAR* *lplgpl;* /* address of LOGPALETTE structure */

The **CreatePalette** function creates a logical color palette.

Parameter	Description
lplgpl	Points to a **LOGPALETTE** structure that contains information about the colors in the logical palette.

Returns

The return value is the handle of the logical palette if the function is successful. Otherwise, it is NULL.

Comments

When it has finished using a palette created by **CreatePalette**, an application should remove the palette by using the **DeleteObject** function.

Example

The following example initializes a **LOGPALETTE** structure and an array of **PALETTEENTRY** structures, and then uses the **CreatePalette** function to retrieve a handle of a logical palette:

```
#define NUMENTRIES 128
HPALETTE hpal;
PALETTEENTRY ape[NUMENTRIES];

plgpl = (LOGPALETTE*) LocalAlloc(LPTR,
    sizeof(LOGPALETTE) + cColors * sizeof(PALETTEENTRY));

plgpl->palNumEntries = cColors;
plgpl->palVersion = 0x300;

for (i = 0, red = 0, green = 127, blue = 127; i < NUMENTRIES;
        i++, red += 1, green += 1, blue += 1) {
    ape[i].peRed =
        plgpl->palPalEntry[i].peRed = LOBYTE(red);
    ape[i].peGreen =
        plgpl->palPalEntry[i].peGreen = LOBYTE(green);
    ape[i].peBlue =
        plgpl->palPalEntry[i].peBlue = LOBYTE(blue);
    ape[i].peFlags =
        plgpl->palPalEntry[i].peFlags = PC_RESERVED;
}
hpal = CreatePalette(plgpl);
LocalFree((HLOCAL) plgpl);
.
. /* Use the palette handle. */
.
DeleteObject(hpal);
```

See Also

DeleteObject

CreatePatternBrush (2.x)

HBRUSH CreatePatternBrush(*hbmp***)**

HBITMAP *hbmp;* /* handle of bitmap */

The **CreatePatternBrush** function creates a brush whose pattern is specified by a bitmap. The brush can subsequently be selected for any device that supports raster operations.

Parameter	Description
hbmp	Identifies the bitmap.

Returns
The return value is the handle of the brush if the function is successful. Otherwise, it is NULL.

Comments
The bitmap identified by the *hbmp* parameter is typically created by using the **CreateBitmap**, **CreateBitmapIndirect**, **CreateCompatibleBitmap**, or **LoadBitmap** function.

Bitmaps used as fill patterns should be 8 pixels by 8 pixels. If the bitmap is larger, Windows will use the bits corresponding to only the first 8 rows and 8 columns of pixels in the upper-left corner of the bitmap.

An application can use the **DeleteObject** function to remove a pattern brush. This does not affect the associated bitmap, which means the bitmap can be used to create any number of pattern brushes. In any case, when the brush is no longer needed, the application should remove it by using **DeleteObject**.

A brush created by using a monochrome bitmap (one color plane, one bit per pixel) is drawn using the current text and background colors. Pixels represented by a bit set to 0 are drawn with the current text color, and pixels represented by a bit set to 1 are drawn with the current background color.

Example
The following example loads a bitmap named Pattern, uses the bitmap to create a pattern brush in a call to the **CreatePatternBrush** function, selects the brush into a device context, and fills a rectangle by using the new brush:

```
HBITMAP hbmp;
HBRUSH hbr, hbrOld;

hbmp = LoadBitmap(hinst, "Pattern");
hbr = CreatePatternBrush(hbmp);
hbrOld = SelectObject(hdc, hbr);
Rectangle(hdc, 10, 10, 100, 100);
```

CreatePen (2.x)

HPEN CreatePen(*fnPenStyle, nWidth, clrref***)**

```
int fnPenStyle;      /* style of pen  */
int nWidth;          /* width of pen */
COLORREF clrref;     /* color of pen */
```

The **CreatePen** function creates a pen having the specified style, width, and color. The pen can subsequently be selected as the current pen for any device.

Parameter	Description
fnPenStyle	Specifies the pen style. This parameter can be one of the following values:

Value	Meaning
PS_SOLID	Creates a solid pen.
PS_DASH	Creates a dashed pen. (Valid only when the pen width is 1.)
PS_DOT	Creates a dotted pen. (Valid only when the pen width is 1.)
PS_DASHDOT	Creates a pen with alternating dashes and dots. (Valid only when the pen width is 1.)
PS_DASHDOTDOT	Creates a pen with alternating dashes and double dots. (Valid only when the pen width is 1.)
PS_NULL	Creates a null pen.
PS_INSIDEFRAME	Creates a pen that draws a line inside the frame of closed shapes produced by graphics device interface (**GDI**) output functions that specify a bounding rectangle (for example, the **Ellipse**, **Rectangle**, **RoundRect**, **Pie**, and **Chord** functions). When this style is used with GDI output functions that do not specify a bounding rectangle (for example, the **LineTo** function), the drawing area of the pen is not limited by a frame.

nWidth	Specifies the width, in logical units, of the pen. If this value is zero, the width in device units is always one pixel, regardless of the mapping mode.
clrref	Specifies the color of the pen.

Returns

The return value is the handle of the pen if the function is successful. Otherwise, it is NULL.

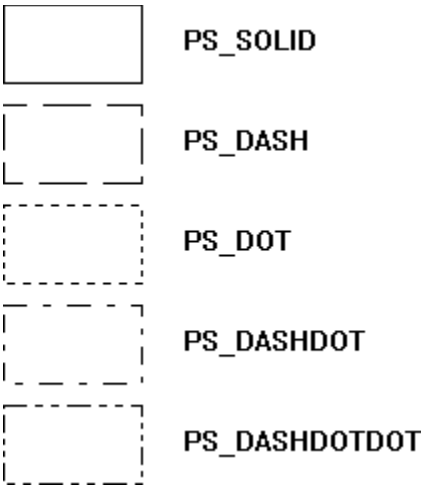
Comments

Pens whose width is greater than one pixel always have the **PS_NULL**, **PS_SOLID**, or **PS_INSIDEFRAME** style.

If a pen has the **PS_INSIDEFRAME** style and a color that does not match a color in the logical color table, the pen is drawn with a dithered color. The **PS_SOLID** pen style cannot be used to create a pen with a dithered color. The style PS_INSIDEFRAME is identical to PS_SOLID if the pen width is less than or equal to 1.

When it has finished using a pen created by **CreatePen**, an application should remove the pen by using the **DeleteObject** function.

The following illustration shows how the various system pens appear when used to draw a rectangle.



Example
The following example uses the **CreatePen** function to create a solid blue pen 6 units wide, selects the pen into a device context, and then uses the pen to draw a rectangle:

```
HPEN hpen, hpenOld;

hpen = CreatePen(PS_SOLID, 6, RGB(0, 0, 255));
hpenOld = SelectObject(hdc, hpen);

Rectangle(hdc, 10, 10, 100, 100);

SelectObject(hdc, hpenOld);
DeleteObject(hpen);
```

See Also
CreatePenIndirect, **DeleteObject**, **Ellipse**, **Rectangle**, **RoundRect**, **RGB**

PS_SOLID 0

Creates a solid pen.

PS_SOLID 0

PS_DASH 1

Creates a dashed pen. (Valid only when the pen width is 1.)

PS_DASH 1

PS_DOT 2

Creates a dotted pen. (Valid only when the pen width is 1.)

PS_DOT 2

PS_DASHDOT 3

Creates a pen with alternating dashes and dots. (Valid only when the pen width is 1.)

PS_DASHDOT 3

PS_DASHDOTDOT 4

Creates a pen with alternating dashes and double dots. (Valid only when the pen width is 1.)

PS_DASHDOTDOT 4

PS_NULL 5

Creates a null pen.

PS_NULL 5

PS_INSIDEFRAME 6

Creates a pen that draws a line inside the frame of closed shapes produced by graphics device interface (**GDI**) output functions that specify a bounding rectangle (for example, the **Ellipse**, **Rectangle**, **RoundRect**, **Pie**, and **Chord** functions). When this style is used with GDI output functions that do not specify a bounding rectangle (for example, the **LineTo** function), the drawing area of the pen is not limited by a frame.

PS_INSIDEFRAME 6

CreatePenIndirect (2.x)

HPEN CreatePenIndirect(*lplgpn***)**

LOGPEN FAR* *lplgpn;* /* address of structure with pen data */

The **CreatePenIndirect** function creates a pen that has the style, width, and color given in the specified structure.

Parameter	Description
lplgpn	Points to the **LOGPEN** structure that contains information about the pen.

Returns
The return value is the handle of the pen if the function is successful. Otherwise, it is NULL.

Comments
Pens whose width is greater than 1 pixel always have the **PS_NULL**, **PS_SOLID**, or **PS_INSIDEFRAME** style.

If a pen has the **PS_INSIDEFRAME** style and a color that does not match a color in the logical color table, the pen is drawn with a dithered color. The PS_INSIDEFRAME style is identical to **PS_SOLID** if the pen width is less than or equal to 1.

When it has finished using a pen created by **CreatePenIndirect**, an application should remove the pen by using the **DeleteObject** function.

Example
The following example fills a **LOGPEN** structure with values defining a solid red pen 10 logical units wide, uses the **CreatePenIndirect** function to create this pen, selects the pen into a device context, and then uses the pen to draw a rectangle:

```
LOGPEN lp;
HPEN hpen, hpenOld;

lp.lopnStyle = PS_SOLID;
lp.lopnWidth.x = 10;
lp.lopnWidth.y = 0;               /* y-dimension not used */
lp.lopnColor = RGB(255, 0, 0);

hpen = CreatePenIndirect(&lp);
hpenOld = SelectObject(hdc, hpen);
Rectangle(hdc, 10, 10, 100, 100);
```

See Also
CreatePen, **DeleteObject**, **LOGPEN**, **RGB**

CreatePolygonRgn (2.x)

HRGN CreatePolygonRgn(*lppt, cPoints, fnPolyFillMode***)**

const POINT FAR* *lppt;* /* address of array of points */
int *cPoints;* /* number of points in array */
int *fnPolyFillMode;* /* polygon-filling mode */

The **CreatePolygonRgn** function creates a polygonal region. The system closes the polygon automatically, if necessary, by drawing a line from the last vertex to the first.

Parameter	Description
lppt	Points to an array of **POINT** structures. Each structure specifies the x-coordinate and y-coordinate of one vertex of the polygon.
cPoints	Specifies the number of **POINT** structures in the array pointed to by the *lppt* parameter.
fnPolyFillMode	Specifies the polygon-filling mode. This value may be either ALTERNATE or WINDING.

Returns

The return value is the handle of the region if the function is successful. Otherwise, it is NULL.

Comments

The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.

When the polygon-filling mode is ALTERNATE, the system fills the area between odd-numbered and even-numbered polygon sides on each scan line. That is, the system fills the area between the first and second side, between the third and fourth side, and so on.

When the polygon-filling mode is WINDING, the system uses the direction in which a figure was drawn to determine whether to fill an area. Each line segment in a polygon is drawn in either a clockwise or a counterclockwise direction. Whenever an imaginary line drawn from an enclosed area to the outside of a figure passes through a clockwise line segment, the system increments a count (increases it by one); when the line passes through a counterclockwise line segment, the system decrements the count. The area is filled if the count is nonzero when the line reaches the outside of the figure.

When it has finished using a region created by **CreatePolygonRgn**, an application should remove the region by using the **DeleteObject** function.

Example

The following example fills an array of **POINT** structures with the coordinates of a five-pointed star, uses this array in a call to the **CreatePolygonRgn** function, selects the region into a device context, and then uses the **PaintRgn** function to display the region:

```
HDC hdc;
HRGN hrgn;
POINT apts[5] = {{ 200, 10  },
                 { 300, 200 },
                 { 100, 100 },
                 { 300, 100 },
                 { 100, 200 }};

hrgn = CreatePolygonRgn(apts,          /* array of points  */
    sizeof(apts) / sizeof(POINT),      /* number of points */
    ALTERNATE);                        /* alternate mode   */
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);
```

See Also

CreatePolyPolygonRgn, **DeleteObject**, **Polygon**, **SetPolyFillMode**, **POINT**

CreatePolyPolygonRgn (3.0)

HRGN CreatePolyPolygonRgn(*lppt, lpnPolyCount, cIntegers, fnPolyFillMode***)**

```
const POINT FAR* lppt;          /* address of structure of points   */
const int FAR* lpnPolyCount;    /* address of array of vertex data  */
int cIntegers;                  /* number of integers in array      */
int fnPolyFillMode;             /* polygon-filling mode             */
```

The **CreatePolyPolygonRgn** function creates a region consisting of a series of closed polygons. The polygons may be disjoint, or they may overlap.

Parameter	Description
lppt	Points to an array of **POINT** structures that define the vertices of the polygons. Each polygon must be explicitly closed, because the system does not close them automatically. The polygons are specified consecutively.
lpnPolyCount	Points to an array of integers. The first integer specifies the number of vertices in the first polygon in the array pointed to by the *lppt* parameter, the second integer specifies the number of vertices in the second polygon, and so on.
cIntegers	Specifies the total number of integers in the array pointed to by the *lpnPolyCount* parameter.
fnPolyFillMode	Specifies the polygon-filling mode. This value may be either ALTERNATE or WINDING.

Returns

The return value is the handle of the region if the function is successful. Otherwise, it is NULL.

Comments

The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.

When the polygon-filling mode is ALTERNATE, the system fills the area between odd-numbered and even-numbered polygon sides on each scan line. That is, the system fills the area between the first and second side, between the third and fourth side, and so on.

When the polygon-filling mode is WINDING, the system uses the direction in which a figure was drawn to determine whether to fill an area. Each line segment in a polygon is drawn in either a clockwise or a counterclockwise direction. Whenever an imaginary line drawn from an enclosed area to the outside of a figure passes through a clockwise line segment, the system increments a count (increases it by one); when the line passes through a counterclockwise line segment, the system decrements the count. The area is filled if the count is nonzero when the line reaches the outside of the figure.

When it has finished using a region created by **CreatePolyPolygonRgn**, an application should remove the region by using the **DeleteObject** function.

Example

The following example fills an array of **POINT** structures with the coordinates of a five-pointed star and a rectangle, uses this array in a call to the **CreatePolyPolygonRgn** function, selects the region into a device context, and then uses the **PaintRgn** function to display the region:

```
HDC hdc;
HRGN hrgn;
int aVertices[2] = { 6, 5 };
POINT apts[11] = {{ 200, 10  },
                  { 300, 200 },
                  { 100, 100 }, /* Star figure, manually closed */
                  { 300, 100 },
                  { 100, 200 },
                  { 200, 10  },
```

```
                    {  10, 150 },
                    { 350, 150 },
                    { 350, 170 }, /* Rectangle, manually closed */
                    {  10, 170 },
                    {  10, 150 }};

hrgn = CreatePolyPolygonRgn(apts,    /* array of points          */
    aVertices,                       /* array of vertices        */
    sizeof(aVertices) / sizeof(int), /* integers in vertex array */
    ALTERNATE);                      /* alternate mode           */
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);
```

See Also

CreatePolygonRgn, **DeleteObject**, **PolyPolygon**, **SetPolyFillMode**, **POINT**

CreateRectRgn (2.x)

HRGN CreateRectRgn(*nLeftRect, nTopRect, nRightRect, nBottomRect***)**

int *nLeftRect;* /* x-coordinate upper-left corner of region */
int *nTopRect;* /* y-coordinate upper-left corner of region */
int *nRightRect;* /* x-coordinate lower-right corner of region */
int *nBottomRect;* /* y-coordinate lower-right corner of region */

The **CreateRectRgn** function creates a rectangular region.

Parameter	Description
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the region.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the region.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the region.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the region.

Returns
The return value is the handle of a rectangular region if the function is successful. Otherwise, it is NULL.

Comments
The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.

When it has finished using a region created by **CreateRectRgn**, an application should remove the region by using the **DeleteObject** function.

Example
The following example uses the **CreateRectRgn** function to create a rectangular region, selects the region into a device context, and then uses the **PaintRgn** function to display the region:

```
HDC hdc;
HRGN hrgn;

hrgn = CreateRectRgn(10, 10, 110, 110);
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);
```

See Also
CreateRectRgnIndirect, **CreateRoundRectRgn**, **DeleteObject**, **PaintRgn**

CreateRectRgnIndirect (2.x)

HRGN CreateRectRgnIndirect(*lprc***)**

const RECT FAR* *lprc;* /* address of structure with region */

The **CreateRectRgnIndirect** function creates a rectangular region by using a **RECT** structure.

Parameter	Description
lprc	Points to a **RECT** structure that contains the logical coordinates of the upper-left and lower-right corners of the region.

Returns

The return value is the handle of the rectangular region if the function is successful. Otherwise, it is NULL.

Comments

The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.

When it has finished using a region created by **CreateRectRgnIndirect**, an application should remove the region by using the **DeleteObject** function.

Example

The following example assigns values to the members of a **RECT** structure, uses the **CreateRectRgnIndirect** function to create a rectangular region, selects the region into a device context, and then uses the **PaintRgn** function to display the region:

```
RECT rc;
HRGN hrgn;

SetRect(&rc, 10, 10, 200, 50);

hrgn = CreateRectRgnIndirect(&rc);
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);
```

See Also

CreateRectRgn, **CreateRoundRectRgn**, **DeleteObject**, **PaintRgn**, **RECT**

CreateRoundRectRgn (3.0)

HRGN CreateRoundRectRgn(*nLeftRect, nTopRect, nRightRect, nBottomRect, nWidthEllipse, nHeightEllipse***)**

int *nLeftRect;* /* x-coordinate upper-left corner of region */
int *nTopRect;* /* y-coordinate upper-left corner of region */
int *nRightRect;* /* x-coordinate lower-right corner of region */
int *nBottomRect;* /* y-coordinate lower-right corner of region */
int *nWidthEllipse;* /* height of ellipse for rounded corners */
int *nHeightEllipse;* /* width of ellipse for rounded corners */

The **CreateRoundRectRgn** function creates a rectangular region with rounded corners.

Parameter	Description
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the region.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the region.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the region.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the region.
nWidthEllipse	Specifies the width of the ellipse used to create the rounded corners.
nHeightEllipse	Specifies the height of the ellipse used to create the rounded corners.

Returns
The return value is the handle of the region if the function is successful. Otherwise, it is NULL.

Comments
The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.

When it has finished using a region created by **CreateRoundRectRgn**, an application should remove the region by using the **DeleteObject** function.

Example
The following example uses the **CreateRoundRectRgn** function to create a region, selects the region into a device context, and then uses the **PaintRgn** function to display the region:

```
HRGN hrgn;
int nEllipWidth = 10;
int nEllipHeight = 30;

hrgn = CreateRoundRectRgn(10, 10, 110, 110,
    nEllipWidth, nEllipHeight);
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);
```

See Also
CreateRectRgn, **CreateRectRgnIndirect**, **DeleteObject**, **PaintRgn**

CreateScalableFontResource (3.1)

BOOL CreateScalableFontResource(*fHidden, lpszResourceFile, lpszFontFile, lpszCurrentPath***)**

```
UINT fHidden;           /* flag for read-only embedded font      */
LPCSTR lpszResourceFile; /* address of filename of font resource */
LPCSTR lpszFontFile;    /* address of filename of scalable font  */
LPCSTR lpszCurrentPath; /* address of path to font file          */
```

The **CreateScalableFontResource** function creates a font resource file for the specified scalable font file.

Parameter	Description
fHidden	Specifies whether the font is a read-only embedded font. This parameter can be one of the following values:

Value	Meaning
0	The font has read-write permission.
1	The font has read-only permission and should be hidden from other applications in the system. When this flag is set, the font is not enumerated by the **EnumFonts** or **EnumFontFamilies** function.

lpszResourceFile	Points to a null-terminated string specifying the name of the font resource file that this function creates.
lpszFontFile	Points to a null-terminated string specifying the scalable font file this function uses to create the font resource file. This parameter must specify either the filename and extension or a full path and filename, including drive and filename extension.
lpszCurrentPath	Points to a null-terminated string specifying either the path to the scalable font file specified in the *lpszFontFile* parameter or NULL, if *lpszFontFile* specifies a full path.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

An application must use the **CreateScalableFontResource** function to create a font resource file before installing an embedded font. Font resource files for fonts with read-write permission should use the .FOT filename extension. Font resource files for read-only fonts should use a different extension (for example, .FOR) and should be hidden from other applications in the system by specifying 1 for the *fHidden* parameter. The font resource files can be installed by using the **AddFontResource** function.

When the *lpszFontFile* parameter specifies only a filename and extension, the *lpszCurrentPath* parameter must specify a path. When the *lpszFontFile* parameter specifies a full path, the *lpszCurrentPath* parameter must be NULL or a pointer to NULL.

When only a filename and extension is specified in the *lpszFontFile* parameter and a path is specified in the *lpszCurrentPath* parameter, the string in *lpszFontFile* is copied into the .FOT file as the .TTF file that belongs to this resource. When the **AddFontResource** function is called, the system assumes that the .TTF file has been copied into the SYSTEM directory (or into the main Windows directory in the case of a network installation). The .TTF file need not be in this directory when the **CreateScalableFontResource** function is called, because the *lpszCurrentPath* parameter contains the directory information. A resource created in this manner does not contain absolute path information and can be used in any Windows installation.

When a path is specified in the *lpszFontFile* parameter and NULL is specified in the *lpszCurrentPath* parameter, the string in *lpszFontFile* is copied into the .FOT file. In this case, when the **AddFontResource** function is called, the .TTF file must be at the location specified in the *lpszFontFile* parameter when the **CreateScalableFontResource** function was called; the *lpszCurrentPath* parameter is not needed. A resource created in this manner contains absolute references to paths and drives and

will not work if the .TTF file is moved to a different location.

The **CreateScalableFontResource** function supports only TrueType scalable fonts.

Example

The following example shows how to create a TrueType font file in the SYSTEM directory of the Windows startup directory:

```
CreateScalableFontResource(0, "c:\\windows\\system\\font.fot",
   "font.ttr", "c:\\windows\\system");

AddFontResource("c:\\windows\\system\\font.fot");
```

The following example shows how to create a TrueType font file in a specified directory:

```
CreateScalableFontResource(0, "c:\\windows\\system\\font.fot",
    "c:\\fontdir\\font.ttr", NULL);

AddFontResource("c:\\windows\\system\\font.fot");
```

The following example shows how to work with a standard embedded font:

```
HFONT hfont;

/* Extract .TTF file into C:\MYDIR\FONT.TTR. */

CreateScalableFontResource(0, "font.fot", "c:\\mydir\\font.ttr", NULL);

AddFontResource("font.fot");

hfont = CreateFont(..., CLIP_DEFAULT_PRECIS, ..., "FONT");
    .
    . /* Use the font. */
    .
DeleteObject(hfont);

RemoveFontResource("font.fot");
    .
    . /* Delete C:\MYDIR\FONT.FOT and C:\MYDIR\FONT.TTR. */
    .
```

The following example shows how to work with a read-only embedded font:

```
HFONT hfont;

/* Extract.TTF file into C:\MYDIR\FONT.TTR. */

CreateScalableFontResource(1, "font.for", "c:\\mydir\\font.ttr", NULL);

AddFontResource("font.for");

hfont = CreateFont(..., CLIP_EMBEDDED, ..., "FONT");
    .
    . /* Use the font. */
    .
DeleteObject(hfont);

RemoveFontResource("font.for");
    .
```

```
. /* Delete C:\MYDIR\FONT.FOR and C:\MYDIR\FONT.TTR. */
.
```

See Also

AddFontResource

CreateSolidBrush (2.x)

HBRUSH CreateSolidBrush(*clrref***)**

COLORREF *clrref;* /* brush color */

The **CreateSolidBrush** function creates a brush that has a specified solid color. The brush can subsequently be selected as the current brush for any device.

Parameter	Description
clrref	Specifies the color of the brush.

Returns
The return value is the handle of the brush if the function is successful. Otherwise, it is NULL.

Comments
When an application has finished using the brush created by **CreateSolidBrush**, it should select the brush out of the device context and then remove it by using the **DeleteObject** function.

Example
The following example uses the **CreateSolidBrush** function to create a green brush, selects the brush into a device context, and then uses the brush to fill a rectangle:

```
HBRUSH hbrOld;
HBRUSH hbr;

hbr = CreateSolidBrush(RGB(0, 255, 0));
hbrOld = SelectObject(hdc, hbr);
Rectangle(hdc, 10, 10, 100, 100);
```

See Also
CreateBrushIndirect, **CreateDIBPatternBrush**, **CreateHatchBrush**, **CreatePatternBrush**, **DeleteObject**, **RGB**

DeleteDC (2.x)

BOOL DeleteDC(*hdc***)**

HDC *hdc;* /* handle of device context */

The **DeleteDC** function deletes the given device context.

Parameter	Description
hdc	Identifies the device context.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
If the *hdc* parameter identifies the last device context for a given device, the device is notified and all storage and system resources used by the device are released.

An application must not delete a device context whose handle was retrieved by calling the **GetDC** function. Instead, the application must call the **ReleaseDC** function to free the device context.

An application should not call **DeleteDC** if the application has selected objects into the device context. Objects must be selected out of the device context before it is deleted.

Example
The following example uses the **CreateDC** function to create a device context for a printer and then calls the **DeleteDC** function when the device context is no longer needed:

```
/* Retrieves a device context for a printer. */

hdcPrinter = CreateDC(lpDriverName, lpDeviceName, lpOutput,
    lpInitData);
    .
    . /* Use the device context. */
    .

/* Delete the device context. */

DeleteDC(hdcPrinter);
```

See Also
CreateDC, **GetDC**, **ReleaseDC**

DeleteMetaFile (2.x)

BOOL DeleteMetaFile(*hmf*)

HMETAFILE *hmf;* /* handle of metafile */

The **DeleteMetaFile** function invalidates the given metafile handle.

Parameter	Description
hmf	Identifies the metafile to be deleted.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
The **DeleteMetaFile** function does not destroy a metafile that is saved on disk. After calling **DeleteMetaFile**, an application can retrieve a new handle of a disk-based metafile by calling the **GetMetaFile** function.

Example
The following example uses the **CreateMetaFile** function to create the handle of a memory metafile device context, draws a line in that device context, retrieves a handle of the metafile by calling the **CloseMetaFile** function, plays the metafile by using the **PlayMetaFile** function, and finally deletes the metafile by using **DeleteMetaFile**:

```
HDC hdcMeta;
HMETAFILE hmf;

hdcMeta = CreateMetaFile(NULL);
MoveTo(hdcMeta, 10, 10);
LineTo(hdcMeta, 100, 100);
hmf = CloseMetaFile(hdcMeta);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);
```

See Also
CreateMetaFile, **GetMetaFile**

DeleteObject (2.x)

BOOL DeleteObject(*hgdiobj***)**

HGDIOBJ *hgdiobj;* /* handle of object to delete */

The **DeleteObject** function deletes an object from memory by freeing all system storage associated with the object. (Objects include pens, brushes, fonts, bitmaps, regions, and palettes.)

Parameter	Description
hgdiobj	Identifies a pen, brush, font, bitmap, region, or palette.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
After the object is deleted, the handle given in the *hgdiobj* parameter is no longer valid.

An application should not delete an object that is currently selected into a device context.

When a pattern brush is deleted, the bitmap associated with the brush is not deleted. The bitmap must be deleted independently.

Example
The following example creates a pen, selects it into a device context, and uses the pen to draw a rectangle. To delete the pen, the original pen is selected back into the device context and the **DeleteObject** function is called.

```
HPEN hpen, hpenOld;

hpen = CreatePen(PS_SOLID, 6, RGB(0, 0, 255));
hpenOld = SelectObject(hdc, hpen);

Rectangle(hdc, 10, 10, 100, 100);

SelectObject(hdc, hpenOld);
DeleteObject(hpen);
```

See Also
SelectObject, **RGB**

Changes

DeviceCapabilities (3.0)

#include <print.h>

DWORD DeviceCapabilities(*lpszDevice, lpszPort, fwCapability, lpszOutput, lpdm***)**

```
LPSTR lpszDevice;     /* address of device-name string        */
LPSTR lpszPort;       /* address of port-name string          */
WORD fwCapability;    /* device capability to query           */
LPSTR lpszOutput;     /* address of the output                */
LPDEVMODE lpdm;       /* address of structure with device data */
```

The **DeviceCapabilities** function retrieves the capabilities of the printer device driver.

Parameter	Description
lpszDevice	Points to a null-terminated string that contains the name of the printer device, such as PCL/HP LaserJet.
lpszPort	Points to a null-terminated string that contains the name of the port to which the device is connected, such as LPT1.
fwCapability	Specifies the capabilities to query. This parameter can be one of the following values:

Value	Meaning
DC_BINNAMES	Copies an array containing a list of the names of the paper bins. This array is in the form **char** *PaperNames*[*cBinMax*][*cchBinName*] where *cchBinName* is 24. If the *lpszOutput* parameter is NULL, the return value is the number of bin entries required. Otherwise, the return value is the number of bins copied.
DC_BINS	Retrieves a list of available bins. The function copies the list to the *lpszOutput* parameter as a **WORD** array. If *lpszOutput* is NULL, the function returns the number of supported bins to allow the application the opportunity to allocate a buffer with the correct size. For more information about these bins, see the description of the **dmDefaultSource** member of the **DEVMODE** structure.
DC_COPIES	Returns the number of copies the device can print.
DC_DRIVER	Returns the version number of the printer driver.
DC_DUPLEX	Returns the level of duplex support. The function returns 1 if the printer is capable of duplex printing. Otherwise, the return value is zero.
DC_ENUMRESOLUTIONS	Returns a list of available resolutions. If *lpszOutput* is NULL, the function returns the number of available resolution configurations. Resolutions are represented by pairs of **LONG** integers representing the horizontal and vertical resolutions (specified in dots per inch).
DC_EXTRA	Returns the number of bytes required for the device-specific portion of the **DEVMODE** structure for the printer driver.
DC_FIELDS	Returns the **dmFields** member of the printer driver's **DEVMODE** structure. The **dmFields** member

indicates which fields in the device-independent portion of the structure are supported by the printer driver.

DC_FILEDEPENDENCIES — Returns a list of files that also need to be loaded when a driver is installed. If the *lpszOutput* parameter is NULL, the function returns the number of files. Otherwise, *lpszOutput* points to an array of filenames in the form **char[***chFileName***, 64]**. Each filename is a null-terminated string.

DC_MAXEXTENT — Returns a **POINT** structure containing the maximum paper size that the **dmPaperLength** and **dmPaperWidth** members of the printer driver's **DEVMODE** structure can specify.

DC_MINEXTENT — Returns a **POINT** structure containing the minimum paper size that the **dmPaperLength** and **dmPaperWidth** members of the printer driver's **DEVMODE** structure can specify.

DC_ORIENTATION — Returns the relationship between portrait and landscape orientations for a device, in terms of the number of degrees that portrait orientation is rotated counterclockwise to produce landscape orientation. The return value can be one of the following:

Value	Meaning
0	No landscape orientation.
90	Portrait is rotated 90 degrees to produce landscape. (For example, Hewlett-Packard PCL printers.)
270	Portrait is rotated 270 degrees to produce landscape. (For example, dot-matrix printers.)

DC_PAPERNAMES — Retrieves a list of supported paper names--for example, Letter or Legal. If the *lpszOutput* parameter is NULL, the function returns the number of paper sizes available. Otherwise, *lpszOutput* points to an array for the paper names in the form **char[***cPaperNames***, 64]**. Each paper name is a null-terminated string.

DC_PAPERS — Retrieves a list of supported paper sizes. The function copies the list to *lpszOutput* as a **WORD** array and returns the number of entries in the array. If *lpszOutput* is NULL, the function returns the number of supported paper sizes to allow the application the opportunity to allocate a buffer with the correct size. For more information on paper sizes, see the description of the **dmPaperSize** member of the **DEVMODE** structure.

DC_PAPERSIZE — Copies the dimensions of all supported paper sizes, in tenths of a millimeter, to an array of **POINT** structures pointed to by the *lpszOutput* parameter. The width (x-dimension) and length (y-dimension) of a paper size are returned as if the paper were in the DMORIENT_PORTRAIT orientation.

DC_SIZE — Returns the **dmSize** member of the printer driver's

DEVMODE structure.

DC_TRUETYPE — Retrieves the abilities of the driver to use TrueType fonts. The return value can be one or more of the following:

Value	Meaning
DCTT_BITMAP	Device is capable of printing TrueType fonts as graphics. (For example, dot-matrix and PCL printers.)
DCTT_DOWNLOAD	Device is capable of downloading TrueType fonts. (For example, PCL and PostScript printers.)
DCTT_SUBDEV	Device is capable of substituting device fonts for TrueType fonts. (For example, PostScript printers.)

For **DC_TRUETYPE**, the *lpszOutput* parameter should be NULL.

DC_VERSION — Returns the specification version to which the printer driver conforms.

lpszOutput — Points to an array of bytes. The format of the array depends on the setting of the *fwCapability* parameter. If *lpszOutput* is zero, **DeviceCapabilities** returns the number of bytes required for the output data.

lpdm — Points to a **DEVMODE** structure. If this parameter is NULL, **DeviceCapabilities** retrieves the current default initialization values for the specified printer driver. Otherwise, the function retrieves the values contained in the structure to which *lpdm* points.

Returns

The return value, if the function is successful, depends on the setting of the *fwCapability* parameter. The return value is -1 if the function fails.

Comments

This function is supplied by the printer driver. To use the **DeviceCapabilities** function, an application must retrieve the address of the function by calling the **LoadLibrary** and **GetProcAddress** functions, and it must include the PRINT.H file.

DeviceCapabilities is not supported by all printer drivers. If the **GetProcAddress** function returns NULL, **DeviceCapabilities** is not supported.

See Also

GetProcAddress, **LoadLibrary**

Changes

The following index values have been added for Windows version 3.1:

DC_COPIES
DC_ENUMRESOLUTIONS
DC_FILEDEPENDENCIES
DC_ORIENTATION
DC_PAPERNAMES
DC_TRUETYPE
DCTT_BITMAP
DCTT_DOWNLOAD
DCTT_SUBDEV

Corrections

Changed the type of the last argument *lpdm* from LPFNDEVMODE to LPDEVMODE.

DC_BINNAMES 12

Copies an array containing a list of the names of the paper bins. This array is in the form **char** *PaperNames*[*cBinMax*][*cchBinName*] where *cchBinName* is 24. If the *lpszOutput* parameter is NULL, the return value is the number of bin entries required. Otherwise, the return value is the number of bins copied.

DC_BINNAMES 12

DC_BINS 6

Retrieves a list of available bins. The function copies the list to the *lpszOutput* parameter as a **WORD** array. If *lpszOutput* is NULL, the function returns the number of supported bins to allow the application the opportunity to allocate a buffer with the correct size. For more information about these bins, see the description of the **dmDefaultSource** member of the **DEVMODE** structure.

DC_BINS 6

DC_COPIES 18

Returns the number of copies the device can print.

DC_COPIES 18

DC_DRIVER 11

Returns the version number of the printer driver.

DC_DUPLEX 7

Returns the level of duplex support. The function returns 1 if the printer is capable of duplex printing. Otherwise, the return value is zero.

DC_DUPLEX 7

DC_ENUMRESOLUTIONS 13

Returns a list of available resolutions. If *lpszOutput* is NULL, the function returns the number of available resolution configurations. Resolutions are represented by pairs of **LONG** integers representing the horizontal and vertical resolutions (specified in dots per inch).

DC_EXTRA 9

Returns the number of bytes required for the device-specific portion of the **DEVMODE** structure for the printer driver.

DC_EXTRA 9

DC_FIELDS 1

Returns the **dmFields** member of the printer driver's **DEVMODE** structure. The **dmFields** member indicates which fields in the device-independent portion of the structure are supported by the printer driver.

DC_FIELDS 1

DC_FILEDEPENDENCIES 14

Returns a list of files that also need to be loaded when a driver is installed. If the *lpszOutput* parameter is NULL, the function returns the number of files. Otherwise, *lpszOutput* points to an array of filenames in the form **char[***chFileName***, 64]**. Each filename is a null-terminated string.

DC_FILEDEPENDENCIES 14

DC_MAXEXTENT 5

Returns a **POINT** structure containing the maximum paper size that the **dmPaperLength** and **dmPaperWidth** members of the printer driver's **DEVMODE** structure can specify.

DC_MAXEXTENT 5

DC_MINEXTENT 4

Returns a **POINT** structure containing the minimum paper size that the **dmPaperLength** and **dmPaperWidth** members of the printer driver's **DEVMODE** structure can specify.

DC_MINEXTENT 4

DC_ORIENTATION 17

Returns the relationship between portrait and landscape orientations for a device, in terms of the number of degrees that portrait orientation is rotated counterclockwise to produce landscape orientation. The return value can be one of the following:

DC_PAPERNAMES 16

Retrieves a list of supported paper names--for example, Letter or Legal. If the *lpszOutput* parameter is NULL, the function returns the number of paper sizes available. Otherwise, *lpszOutput* points to an array for the paper names in the form **char[***cPaperNames***, 64]**. Each paper name is a null-terminated string.

DC_PAPERNAMES 16

DC_PAPERS 2

Retrieves a list of supported paper sizes. The function copies the list to *lpszOutput* as a **WORD** array and returns the number of entries in the array. If *lpszOutput* is NULL, the function returns the number of supported paper sizes to allow the application the opportunity to allocate a buffer with the correct size. For more information on paper sizes, see the description of the **dmPaperSize** member of the **DEVMODE** structure.

DC_PAPERSIZE 3

Copies the dimensions of all supported paper sizes, in tenths of a millimeter, to an array of **POINT** structures pointed to by the *lpszOutput* parameter. The width (x-dimension) and length (y-dimension) of a paper size are returned as if the paper were in the DMORIENT_PORTRAIT orientation.

DC_PAPERSIZE 3

DC_SIZE 8

Returns the **dmSize** member of the printer driver's **DEVMODE** structure.

DC_SIZE 8

DC_TRUETYPE 15

Retrieves the abilities of the driver to use TrueType fonts. The return value can be one or more of the following:

DC_TRUETYPE 15

For

DC_TRUETYPE, the *lpszOutput* parameter should be NULL.

DC_VERSION 10

Returns the specification version to which the printer driver conforms.

DC_VERSION 10

DeviceMode (2.x)

void DeviceMode(*hwnd, hModule, lpszDevice, lpszOutput***)**

```
HWND hwnd;          /* handle of window owning dialog box */
HANDLE hModule;     /* handle of printer-driver module    */
LPSTR lpszDevice;   /* address of string for device name  */
LPSTR lpszOutput;   /* address of string for output name  */
```

The **DeviceMode** function sets the current printing modes for a specified device by using a dialog box to prompt for those modes. An application calls **DeviceMode** to allow the user to change the printing modes of the corresponding device. **DeviceMode** copies the mode information to the environment block that is associated with the device and maintained by the graphics device interface (**GDI**).

The **ExtDeviceMode** function provides a superset of the functionality of the **DeviceMode** function; new applications should use **ExtDeviceMode** instead of **DeviceMode** whenever possible. (Applications can use the **DM_IN_PROMPT** constant with **ExtDeviceMode** to duplicate the functionality of **DeviceMode**.)

Parameter	Description
hwnd	Identifies the window that will own the dialog box.
hModule	Identifies the printer-driver module. The application should retrieve this handle by calling either the **GetModuleHandle** or **LoadLibrary** function.
lpszDevice	Points to a null-terminated string that specifies the name of the specific device to be supported (for example, Epson FX-80). The device name is the same as the name passed to the **CreateDC** function.
lpszOutput	Points to a null-terminated string that specifies the MS-DOS filename or device name for the physical output medium (file or output port). The output name is the same as the name passed to the **CreateDC** function.

Returns

This function does not return a value.

Comments

The **DeviceMode** function is part of the printer's device driver, not part of GDI. To call this function, an application must load the printer driver by calling the **LoadLibrary** function and retrieve the address of the function by using the **GetProcAddress** function. The application can then use the address to set up the printer.

DeviceMode is not supported by all printer drivers. If the **GetProcAddress** function returns NULL, **DeviceMode** is not supported.

See Also

CreateDC, **ExtDeviceMode**, **GetModuleHandle**, **LoadLibrary**

DPtoLP (2.x)

BOOL DPtoLP(*hdc, lppt, cPoints***)**

```
HDC hdc;            /* handle of device context      */
POINT FAR* lppt;    /* address of array with points */
int cPoints;        /* number of points in array     */
```

The **DPtoLP** function converts device coordinates (points) into logical coordinates.

Parameter	Description
hdc	Identifies the device context.
lppt	Points to an array of **POINT** structures. Each coordinate in each structure is mapped into the logical coordinate system for the current device context.
cPoints	Specifies the number of points in the array.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The conversion depends on the current mapping mode and the settings of the origins and extents for the device's window and viewport.

Example

The following example sets the mapping mode to MM_LOENGLISH, and then calls the **DPtoLP** function to convert the coordinates of a rectangle into logical coordinates:

```
RECT rc;

SetMapMode(hdc, MM_LOENGLISH);
SetRect(&rc, 100, 100, 200, 200);
DPtoLP(hdc, (LPPOINT) &rc, 2);
```

See Also

LPtoDP, **POINT**

Ellipse (2.x)

BOOL Ellipse(*hdc, nLeftRect, nTopRect, nRightRect, nBottomRect***)**

```
HDC hdc;          /* handle of device context                        */
int nLeftRect;    /* x-coordinate upper-left corner bounding rectangle  */
int nTopRect;     /* y-coordinate upper-left corner bounding rectangle  */
int nRightRect;   /* x-coordinate lower-right corner bounding rectangle */
int nBottomRect;  /* y-coordinate lower-right corner bounding rectangle */
```

The **Ellipse** function draws an ellipse. The center of the ellipse is the center of the specified bounding rectangle. The ellipse is drawn by using the current pen, and its interior is filled by using the current brush.

If either the width or the height of the bounding rectangle is zero, the function does not draw the ellipse.

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
The figure drawn by this function extends up to but does not include the right and bottom coordinates. This means that the height of the figure is determined as follows:

nBottomRect - nTopRect

Similarly, the width of the figure is determined as follows:

nRightRect - nLeftRect

Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.

Arc, **Chord**, **RECT**

EndDoc (3.1)

int EndDoc(*hdc***)**

HDC *hdc;* /* handle of device context */

The **EndDoc** function ends a print job. This function replaces the ENDDOC printer escape for Windows version 3.1.

Parameter	Description
hdc	Identifies the device context for the print job.

Returns
The return value is greater than or equal to zero if the function is successful. Otherwise, it is less than zero.

Comments
An application should call the **EndDoc** function immediately after finishing a successful print job. To terminate a print job because of an error or if the user chooses to cancel the job, an application should call the **AbortDoc** function.

Do not use the **EndDoc** function inside metafiles.

See Also
AbortDoc, **Escape**, **StartDoc**

EndPage (3.1)

int EndPage(*hdc***)**

HDC *hdc;* /* handle of device context */

The **EndPage** function signals the device that the application has finished writing to a page. This function is typically used to direct the driver to advance to a new page.

This function replaces the **NEWFRAME** printer escape for Windows 3.1. Unlike **NEWFRAME**, this function is always called after printing a page.

Parameter	Description
hdc	Identifies the device context for the print job.

Returns

The return value is greater than or equal to zero if the function is successful. Otherwise, it is an error value.

Errors

If the function fails, it returns one of the following error values:

Value	Meaning
SP_ERROR	General error.
SP_APPABORT	Job was terminated because the application's print-canceling function returned zero.
SP_USERABORT	User terminated the job by using Windows Print Manager (PRINTMAN.EXE).
SP_OUTOFDISK	Not enough disk space is currently available for spooling, and no more space will become available.
SP_OUTOFMEMORY	Not enough memory is available for spooling.

Comments

The **ResetDC** function can be used to change the device mode, if necessary, after calling the **EndPage** function.

See Also

Escape, **ResetDC**, **StartPage**

SP_ERROR (-1)

General error.

SP_ERROR (-1)

SP_APPABORT (-2)

Job was terminated because the application's print-canceling function returned zero.

SP_APPABORT (-2)

SP_USERABORT (-3)

User terminated the job by using Windows Print Manager (PRINTMAN.EXE).

SP_USERABORT (-3)

SP_OUTOFDISK (-4)

Not enough disk space is currently available for spooling, and no more space will become available.

SP_OUTOFDISK (-4)

SP_OUTOFMEMORY (-5)

Not enough memory is available for spooling.

SP_OUTOFMEMORY (-5)

EnumFontFamilies (3.1)

int EnumFontFamilies(*hdc, lpszFamily, fntenmprc, lParam***)**

HDC *hdc;* /* handle of device context */
LPCSTR *lpszFamily;* /* address of font-family name */
FONTENUMPROC *fntenmprc;* /* address of callback function */
LPARAM *lParam;* /* application-defined data */

The **EnumFontFamilies** function enumerates the fonts in a specified font family that are available on a given device. **EnumFontFamilies** continues until there are no more fonts or the callback function returns zero.

Parameter	Description
hdc	Identifies the device context.
lpszFamily	Points to a null-terminated string that specifies the family name of the desired fonts. If this parameter is NULL, the **EnumFontFamilies** function selects and enumerates one font from each available font family.
fntenmprc	Specifies the procedure-instance address of the application-defined callback function. The address must be created by the **MakeProcInstance** function. For more information about the callback function, see the description of the **EnumFontFamProc** callback function.
lParam	Specifies a 32-bit application-defined value that is passed to the callback function along with the font information.

Returns

The return value specifies the last value returned by the callback function, if the function is successful. This value depends on which font families are available for the given device.

Comments

The **EnumFontFamilies** function differs from the **EnumFonts** function in that it retrieves the style names associated with a TrueType font. Using **EnumFontFamilies**, an application can retrieve information about unusual font styles (for example, Outline) that cannot be enumerated by using the **EnumFonts** function. Applications should use **EnumFontFamilies** instead of **EnumFonts**.

For each font having the font name specified by the *lpszFamily* parameter, the **EnumFontFamilies** function retrieves information about that font and passes it to the function pointed to by the *fntenmprc* parameter. The application-supplied callback function can process the font information, as necessary.

Example

The following example uses the **MakeProcInstance** function to create a pointer to the callback function for the **EnumFontFamilies** function. The **FreeProcInstance** function is called when enumeration is complete. Because the second parameter is NULL, **EnumFontFamilies** enumerates one font from each family that is available in the given device context. The aFontCount variable points to an array that is used inside the callback function.

```
FONTENUMPROC lpEnumFamCallBack;
int aFontCount[] = { 0, 0, 0 };

lpEnumFamCallBack = (FONTENUMPROC) MakeProcInstance(
    (FARPROC) EnumFamCallBack, hAppInstance);
EnumFontFamilies(hdc, NULL, lpEnumFamCallBack, (LPARAM) aFontCount);
FreeProcInstance((FARPROC) lpEnumFamCallBack);
```

See Also

EnumFonts, **EnumFontFamProc**, **LOGFONT**, **TEXTMETRIC**

EnumFonts (2.x)

int EnumFonts(*hdc, lpszFace, fntenmprc, lParam***)**

```
HDC hdc;                    /* handle of device context      */
LPCSTR lpszFace;            /* address of font name          */
FONTENUMPROC fntenmprc;     /* address of callback function  */
LPARAM lParam;              /* application-defined data      */
```

The **EnumFonts** function enumerates the fonts available for a given device. This function is provided for backwards compatibility with earlier versions of Windows; current applications should use the **EnumFontFamilies** function.

EnumFonts continues until there are no more fonts or the callback function returns zero.

Parameter	Description
hdc	Identifies the device context.
lpszFace	Points to a null-terminated string that specifies the names of the requested fonts. If this parameter is NULL, the **EnumFonts** function randomly selects and enumerates one font from each available typeface.
fntenmprc	Specifies the procedure-instance address of the application-defined callback function. The address must be created by the **MakeProcInstance** function. For more information about the callback function, see the description of the **EnumFontsProc** callback function.
lParam	Specifies a 32-bit application-defined value that is passed to the callback function along with the font information.

Returns

The return value specifies the last value returned by the callback function and is defined by the user.

Comments

The **EnumFonts** function retrieves information about the specified font and passes it to the function pointed to by the *fntenmprc* parameter. The application-supplied callback function can process the font information, as necessary.

If the device is capable of text transformations (scaling, italicizing, and so on), only the base font will be enumerated. The user must know the device's text-transformation abilities to determine which additional fonts are available directly from the device. The graphics device interface (**GDI**) can simulate the bold, italic, underlined, and strikeout attributes for any GDI-based font.

The **EnumFonts** function enumerates fonts from the **GDI** internal table only. This does not include fonts that are generated by a device, such as fonts that are transformations of fonts from the internal table. The **GetDeviceCaps** function can be used to determine which transformations a device can perform. This information is available by using the TEXTCAPS index.

GDI can scale GDI-based raster fonts by one to five units horizontally and one to eight units vertically, unless PROOF_QUALITY is being used.

Example

The following example uses the **MakeProcInstance** function to create a pointer to the callback function for the **EnumFonts** function. The **FreeProcInstance** function is called when enumeration is complete. Because the second parameter is "Arial", **EnumFonts** enumerates the Arial fonts available in the given device context. The cArial variable is passed to the callback function.

```
FONTENUMPROC lpEnumFontsCallBack;
int cArial = 0;

lpEnumFontsCallBack = (FONTENUMPROC) MakeProcInstance(
    (FARPROC) EnumFontsCallBack, hAppInstance);
```

```
EnumFonts(hdc, "Arial", lpEnumFontsCallBack, (LPARAM) &cArial);
FreeProcInstance((FARPROC) lpEnumFontsCallBack);
```

See Also
EnumFontFamilies, **EnumFontsProc**

EnumMetaFile (2.x)

BOOL EnumMetaFile(*hdc, hmf, mfenmprc, lParam***)**

```
HDC hdc;                /* handle of device context      */
HLOCAL hmf;             /* handle of metafile            */
MFENUMPROC mfenmprc;    /* address of callback function  */
LPARAM lParam;          /* application-defined data      */
```

The **EnumMetaFile** function enumerates the metafile records in a given metafile. **EnumMetaFile** continues until there are no more graphics device interface (**GDI**) calls or the callback function returns zero.

Parameter	Description
hdc	Identifies the device context associated with the metafile.
hmf	Identifies the metafile. Note: The **HLOCAL** type for this parameter is incorrect in the WINDOWS.H file. The type of this parameter is actually **HMETAFILE**. Developers should cast this parameter to an **HLOCAL** type to avoid compiler warnings.
mfenmprc	Specifies the procedure-instance address of the application-supplied callback function. The address must be created by using the **MakeProcInstance** function. For more information about the callback function, see the description of the **EnumMetaFileProc** callback function.
lParam	Specifies a 32-bit application-defined value that is passed to the callback function along with the metafile information.

Returns

The return value is nonzero if the callback function enumerates all the **GDI** calls in a metafile. Otherwise, it is zero.

Comments

The **EnumMetaFile** function retrieves metafile records and passes them to a callback function. An application can modify the metafile record inside the callback function. The application can also use the **PlayMetaFileRecord** function inside the callback function; this is useful for very large metafiles, when using the **PlayMetaFile** function might be time-consuming.

Example

The following example creates a dashed green pen and passes it to the callback function for the **EnumMetaFile** function. If the first element in the array of object handles is a handle, that handle is replaced by the handle of the green pen before the **PlayMetaFileRecord** function is called. (For this example, it is assumed that the table of object handles contains only one handle and that it is the handle of a pen.)

```
MFENUMPROC lpEnumMetaProc;
HPEN hpenGreen;

lpEnumMetaProc = (MFENUMPROC) MakeProcInstance(
    (FARPROC) EnumMetaFileProc, hAppInstance);
hpenGreen = CreatePen(PS_DASH, 1, RGB(0, 255, 0));
EnumMetaFile(hdc, hmf, lpEnumMetaProc, (LPARAM) &hpenGreen);
FreeProcInstance((FARPROC) lpEnumMetaProc);
DeleteObject(hpenGreen);
    .
    .
    .
```

```
int FAR PASCAL EnumMetaFileProc(HDC hdc, HANDLETABLE FAR* lpHTable,
    METARECORD FAR* lpMFR, int cObj, BYTE FAR* lpClientData)
{
    if (lpHTable->objectHandle[0] != 0)
        lpHTable->objectHandle[0] = *(HPEN FAR *) lpClientData;
    PlayMetaFileRecord(hdc, lpHTable, lpMFR, cObj);

    return 1;
}
```

See Also

EnumMetaFileProc, **MakeProcInstance**, **PlayMetaFile**, **PlayMetaFileRecord**

EnumObjects (2.x)

int EnumObjects(*hdc, fnObjectType, goenmprc, lParam***)**

```
HDC hdc;                    /* handle of device context        */
int fnObjectType;           /* type of object                  */
GOBJENUMPROC goenmprc;      /* address of callback function    */
LPARAM lParam;              /* application-defined data        */
```

The **EnumObjects** function enumerates the pens and brushes available in the given device context. For each object of a given type, the callback function is called with the information for that object. **EnumObjects** continues until there are no more objects or the callback function returns zero.

Parameter	Description
hdc	Identifies the device context.
fnObjectType	Specifies the object type. This parameter can be one of the following values:

Value	Meaning
OBJ_BRUSH	Specifies a brush.
OBJ_PEN	Specifies a pen.

goenmprc	Specifies the procedure-instance address of the application-supplied callback function. The address must be created by the **MakeProcInstance** function. For more information about the callback function, see the description of the **EnumObjectsProc** callback function.
lParam	Specifies a 32-bit application-defined value that is passed to the callback function.

Returns

The return value specifies the last value returned by the callback function and is defined by the user.

Example

The following example retrieves the number of horizontally hatched brushes and fills **LOGBRUSH** structures with information about each of them:

```
#define MAXBRUSHES 50

GOBJENUMPROC lpProcCallback;
HGLOBAL hglbl;
LPBYTE lpbCountBrush;

lpProcCallback = (GOBJENUMPROC) MakeProcInstance(
    (FARPROC) Callback, hinst);

hglbl = GlobalAlloc(GMEM_FIXED, sizeof(LOGBRUSH)
    * MAXBRUSHES);
lpbCountBrush = (LPBYTE) GlobalLock(hglbl);
*lpbCountBrush = 0;
EnumObjects(hdc, OBJ_BRUSH, lpProcCallback,
    (LPARAM) lpbCountBrush);

FreeProcInstance((FARPROC) lpProcCallback);

int FAR PASCAL Callback(LPLOGBRUSH lpLogBrush, LPBYTE pbData)
{
    /*
     * The pbData parameter contains the number of horizontally
     * hatched brushes; the lpDest parameter is set to follow the
     * byte reserved for pbData and the LOGBRUSH structures that
```

```
     * have been filled with brush information.
     */

    LPLOGBRUSH lpDest =
        (LPLOGBRUSH) (pbData + 1 + (*pbData * sizeof(LOGBRUSH)));

    if (lpLogBrush->lbStyle ==
            BS_HATCHED && /* if horiz hatch */
            lpLogBrush->lbHatch == HS_HORIZONTAL) {
        *lpDest++ = *lpLogBrush; /* fills structure with brush info */
        (*pbData) ++;            /* increments brush count          */
        if (*pbData >= MAXBRUSHES)
            return 0;
    }

    return 1;
}
```

See Also

EnumObjectsProc, **FreeProcInstance**, **GlobalAlloc**, **GlobalLock**, **MakeProcInstance**, **LOGBRUSH**, **LOGPEN**

OBJ_BRUSH 2

Specifies a brush.

OBJ_BRUSH 2

OBJ_PEN 1

Specifies a pen.

OBJ_PEN 1

EqualRgn (2.x)

BOOL EqualRgn(*hrgnSrc1, hrgnSrc2***)**

HRGN *hrgnSrc1;* /* handle of first region to test for equality */
HRGN *hrgnSrc2;* /* handle of second region to test for equality */

The **EqualRgn** function determines whether two given regions are identical.

Parameter	Description
hrgnSrc1	Identifies the first region.
hrgnSrc2	Identifies the second region.

Returns
The return value is nonzero if the two regions are equal. Otherwise, it is zero.

Example
The following example uses the **EqualRgn** function to test the equality of a region against two other regions. In this case, hrgn2 is identical to hrgn1, but hrgn3 is not identical to hrgn1.

```
BOOL fEqual;
HRGN hrgn1, hrgn2, hrgn3;
LPSTR lpszEqual = "Regions are equal.";
LPSTR lpszNotEqual = "Regions are not equal.";

hrgn1 = CreateRectRgn(10, 10, 110, 110); /* 1 and 2 identical */
hrgn2 = CreateRectRgn(10, 10, 110, 110);
hrgn3 = CreateRectRgn(100, 100, 210, 210); /* same dimensions */

fEqual = EqualRgn(hrgn1, hrgn2);
if (fEqual)
    TextOut(hdc, 10, 10, lpszEqual, lstrlen(lpszEqual));
else
    TextOut(hdc, 10, 10, lpszNotEqual, lstrlen(lpszNotEqual));

fEqual = EqualRgn(hrgn1, hrgn3);
if (fEqual)
    TextOut(hdc, 10, 30, lpszEqual, lstrlen(lpszEqual));
else
    TextOut(hdc, 10, 30, lpszNotEqual, lstrlen(lpszNotEqual));

DeleteObject(hrgn1);
DeleteObject(hrgn2);
DeleteObject(hrgn3);
```

Changes

Escape (2.x)

int Escape(*hdc, nEscape, cbInput, lpszInData, lpvOutData***)**

```
HDC hdc;                /* handle of device context          */
int nEscape;            /* specifies escape function         */
int cbInput;            /* size of structure for input       */
LPCSTR lpszInData;      /* address of structure for input    */
void FAR* lpvOutData;   /* address of structure for output   */
```

The **Escape** function allows applications to access capabilities of a particular device that are not directly available through the graphics device interface (**GDI**). Escape calls made by an application are translated and sent to the driver.

Parameter	Description
hdc	Identifies the device context.
nEscape	Specifies the escape function to be performed.
cbInput	Specifies the number of bytes of data pointed to by the *lpszInData* parameter.
lpszInData	Points to the input structure required for the specified escape.
lpvOutData	Points to the structure that receives output from this escape. This parameter should be NULL if no data is returned.

Returns

The return value specifies the outcome of the function. It is greater than zero if the function is successful, except for the QUERYESCSUPPORT printer escape, which checks for implementation only. The return value is zero if the escape is not implemented. A return value less than zero indicates an error.

Errors

If the function fails, the return value is one of the following:

Value	Meaning
SP_ERROR	General error.
SP_OUTOFDISK	Not enough disk space is currently available for spooling, and no more space will become available.
SP_OUTOFMEMORY	Not enough memory is available for spooling.
SP_USERABORT	User terminated the job through Print Manager.

Changes

Windows version 3.1 introduces six new functions that supersede some printer escapes:

Function	Description
AbortDoc	Terminates a print job. Supersedes the **ABORTDOC** escape.
EndDoc	Ends a print job. Supersedes the **ENDDOC** escape.
EndPage	Ends a page. Supersedes the **NEWFRAME** escape. Unlike **NEWFRAME**, this function is always called after printing a page.
SetAbortProc	Sets the abort function for a print job. Supersedes the **SETABORTPROC** escape.
StartDoc	Starts a print job. Supersedes the **STARTDOC** escape.
StartPage	Prepares printer driver to receive data.

The **ResetDC** function is also new for Windows version 3.1. **ResetDC** updates a device context, allowing such new functionality as changing the paper orientation or paper bin within a single print job. This ability was not supported by an escape in previous versions of Windows.

For a complete list of the printer escapes under Windows version 3.0, and how support has changed for Windows 3.1, see the **Printer escapes** topic.

Printer escapes

Escape	Description
ABORTDOC	Superseded by the **AbortDoc** function in Windows version 3.1.
BANDINFO	Obsolete in Windows version 3.1. Because all printer drivers for Windows version 3.1 and later set the text flag in every band, this escape is useful only for older printer drivers.
BEGIN_PATH	No changes for Windows version 3.1. This escape is specific to PostScript printers.
CLIP_TO_PATH	No changes for Windows version 3.1. This escape is specific to PostScript printers.
DEVICEDATA	Superseded in Windows version 3.1. Applications should use the **PASSTHROUGH** escape to achieve the same functionality.
DRAFTMODE	Superseded in Windows version 3.1. Applications can achieve the same functionality by setting the *dmPrintQuality* member of the **DEVMODE** structure to DMRES_DRAFT and passing this structure to the **CreateDC** function.
DRAWPATTERNRECT	No changes for Windows version 3.1.
ENABLEDUPLEX	Superseded in Windows version 3.1. Applications can achieve the same functionality by setting the *dmDuplex* member of the **DEVMODE** structure and passing this structure to the **CreateDC** function.
ENABLEPAIRKERNING	No changes for Windows version 3.1.
ENABLERELATIVEWIDTHS	No changes for Windows version 3.1.
ENDDOC	Superseded by the **EndDoc** function in Windows version 3.1.
END_PATH	No changes for Windows version 3.1. This escape is specific to PostScript printers.
ENUMPAPERBINS	Superseded in Windows version 3.1. Applications can use the **DeviceCapabilities** function to achieve the same functionality.
ENUMPAPERMETRICS	Superseded in Windows version 3.1. Applications can use the **DeviceCapabilities** function to achieve the same functionality.
EPSPRINTING	No changes for Windows version 3.1. This escape is specific to PostScript printers.
EXT_DEVICE_CAPS	Superseded in Windows version 3.1. Applications can use the **GetDeviceCaps** function to achieve the same functionality. This escape is specific to PostScript printers.
EXTTEXTOUT	Superseded in Windows version 3.1. Applications can use the **ExtTextOut** function to achieve the same functionality. This escape is not supported by the version 3.1 PCL driver.
FLUSHOUTPUT	Removed for Windows version 3.1.
GETCOLORTABLE	Removed for Windows version 3.1.
GETEXTENDEDTEXTMETRICS	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows.
GETEXTENTTABLE	Superseded in Windows version 3.1. Applications can use the **GetCharWidth** function to achieve the same

	functionality. This escape is not supported by the version 3.1 PCL or PSCRIPT drivers.
GETFACENAME	No changes for Windows version 3.1. This escape is specific to PostScript printers.
GETPAIRKERNTABLE	No changes for Windows version 3.1.
GETPHYSPAGESIZE	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows.
GETPRINTINGOFFSET	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows.
GETSCALINGFACTOR	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows.
GETSETPAPERBINS	Superseded in Windows version 3.1. Applications can achieve the same functionality by calling the **DeviceCapabilities** function to find the number of paper bins, calling the **ExtDeviceMode** function to find the current bin, and then setting the *dmDefaultSource* member of the **DEVMODE** structure and passing this structure to the **CreateDC** function. **GETSETPAPERBINS** changes the paper bin only for the current device context. A new device context will use the system-default paper bin until the bin is explicitly changed for that device context.
GETSETPAPERMETRICS	Obsolete in Windows version 3.1. Applications can use the **DeviceCapabilities** and **ExtDeviceMode** functions to achieve the same functionality.
GETSETPAPERORIENT	Obsolete in Windows version 3.1. Applications can achieve the same functionality by setting the *dmOrientation* member of the **DEVMODE** structure and passing this structure to the **CreateDC** function. This escape is not supported by the Windows 3.1 PCL driver.
GETSETSCREENPARAMS	No changes for Windows version 3.1.
GETTECHNOLOGY	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows. This escape is not supported by the Windows 3.1 PCL driver.
GETTRACKKERNTABLE	No changes for Windows version 3.1.
GETVECTORBRUSHSIZE	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows.
GETVECTORPENSIZE	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows.
MFCOMMENT	No changes for Windows version 3.1.
NEWFRAME	No changes for Windows version 3.1. Applications should use the **StartPage** and **EndPage** functions instead of this escape. Support for this escape may change in future versions of Windows.
NEXTBAND	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows.
PASSTHROUGH	No changes for Windows version 3.1.
QUERYESCAPESUPPORT	No changes for Windows version 3.1.
RESTORE_CTM	No changes for Windows version 3.1. This escape is specific to PostScript printers.
SAVE_CTM	No changes for Windows version 3.1. This escape is

	specific to PostScript printers.
SELECTPAPERSOURCE	Obsolete in Windows version 3.1. Applications can achieve the same functionality by using the **DeviceCapabilities** function.
SETABORTPROC	Superseded in Windows version 3.1 by the **SetAbortProc** function.
SETALLJUSTVALUES	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows. This escape is not supported by the Windows 3.1 PCL driver.
SET_ARC_DIRECTION	No changes for Windows version 3.1. This escape is specific to PostScript printers.
SET_BACKGROUND_COLOR	No changes for Windows version 3.1. Applications should use the **SetBkColor** function instead of this escape. Support for this escape may change in future versions of Windows.
SET_BOUNDS	No changes for Windows version 3.1. This escape is specific to PostScript printers.
SETCOLORTABLE	No changes for Windows version 3.1. Support for this escape may change in future versions of Windows.
SETCOPYCOUNT	Superseded in Windows version 3.1. An application should call the **DeviceCapabilities** function, specifying **DC_COPIES** for the *nIndex* parameter, to find the maximum number of copies the device can make. Then the application can set the number of copies by passing to the **CreateDC** function a pointer to the **DEVMODE** structure.
SETKERNTRACK	No changes for Windows version 3.1.
SETLINECAP	No changes for Windows version 3.1. This escape is specific to PostScript printers.
SETLINEJOIN	No changes for Windows version 3.1. This escape is specific to PostScript printers.
SETMITERLIMIT	No changes for Windows version 3.1. This escape is specific to PostScript printers.
SET_POLY_MODE	No changes for Windows version 3.1. This escape is specific to PostScript printers.
SET_SCREEN_ANGLE	No changes for Windows version 3.1.
SET_SPREAD	No changes for Windows version 3.1.
STARTDOC	Superseded in Windows version 3.1. An application should call the **StartDoc** function instead of this escape.
TRANSFORM_CTM	No changes for Windows version 3.1. This escape is specific to PostScript printers.

ExcludeClipRect (2.x)

int ExcludeClipRect(*hdc, nLeftRect, nTopRect, nRightRect, nBottomRect***)**

```
HDC hdc;          /* handle of device context                    */
int nLeftRect;    /* x-coordinate top-left corner of rectangle   */
int nTopRect;     /* y-coordinate top-left corner of rectangle   */
int nRightRect;   /* x-coordinate bottom-right corner of rectangle */
int nBottomRect;  /* y-coordinate bottom-right corner of rectangle */
```

The **ExcludeClipRect** function creates a new clipping region that consists of the existing clipping region minus the specified rectangle.

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the rectangle.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the rectangle.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the rectangle.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the rectangle.

Returns

The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR (no region is created).

Comments

The width of the rectangle, specified by the absolute value of *nRightRect* - *nLeftRect,* must not exceed 32,767 units. This limit applies to the height of the rectangle as well.

Example

The following example uses the **ExcludeClipRect** function to create a clipping region in the shape of a frame that is 20 units wide. The frame is painted red when the **FillRect** function is used to paint the client area.

```
RECT rc;
HRGN hrgn;
HBRUSH hbrRed;

GetClientRect(hwnd, &rc);
hrgn = CreateRectRgn(10, 10, 110, 110);
SelectClipRgn(hdc, hrgn);

ExcludeClipRect(hdc, 30, 30, 90, 90);

hbrRed = CreateSolidBrush(RGB(255, 0, 0));
FillRect(hdc, &rc, hbrRed);

DeleteObject(hbrRed);
DeleteObject(hrgn);
```

See Also

CombineRgn

ExtDeviceMode (3.0)

#include <print.h>

int ExtDeviceMode(*hwnd, hDriver, lpdmOutput, lpszDevice, lpszPort, lpdmInput, lpszProfile, fwMode***)**

```
HWND hwnd;              /* handle of window                      */
HANDLE hDriver;         /* handle of driver                      */
LPDEVMODE lpdmOutput;   /* address of structure for driver output*/
LPSTR lpszDevice;       /* string for name of device             */
LPSTR lpszPort;         /* string for name of port               */
LPDEVMODE lpdmInput;    /* address of structure for driver input */
LPSTR lpszProfile;      /* string for profile filename           */
WORD fwMode;            /* operations mask                       */
```

The **ExtDeviceMode** function retrieves or modifies device initialization information for a given printer driver or displays a driver-supplied dialog box for configuring the printer driver. Printer drivers that support device initialization by applications export **ExtDeviceMode** so that applications can call it.

Parameter	Description
hwnd	Identifies a window. If the application calls the **ExtDeviceMode** function to display a dialog box, the specified window is the parent window of the dialog box.
hDriver	Identifies the device-driver module. The **GetModuleHandle** function or **LoadLibrary** function returns a module handle.
lpdmOutput	Points to a **DEVMODE** structure. The driver writes the initialization information supplied in the *lpdmInput* parameter to this structure.
lpszDevice	Points to a null-terminated string that contains the name of the printer device--for example, PCL/HP LaserJet.
lpszPort	Points to a null-terminated string that contains the name of the port to which the device is connected--for example, LPT1.
lpdmInput	Points to a **DEVMODE** structure that supplies initialization information to the printer driver.
lpszProfile	Points to a null-terminated string that contains the name of the initialization file, where initialization information is recorded and read from. If this parameter is NULL, WIN.INI is the default initialization file.
fwMode	Specifies a mask of values that determines the operations the function performs. If this parameter is zero, the **ExtDeviceMode** function returns the number of bytes required by the printer driver's **DEVMODE** structure. Otherwise, the *fwMode* parameter can be one or more of the following values (to change the print settings, the application must specify at least one input value and one output value):

Value	Meaning
DM_IN_BUFFER	Input value. Before prompting, copying, or updating, this value merges the printer driver's current print settings with the settings in the **DEVMODE** structure identified by the *lpdmInput* parameter. The structure is updated only for those members indicated by the application in the **dmFields** member. This value is also defined as DM_MODIFY.
DM_IN_PROMPT	Input value. This value presents the printer driver's Print Setup dialog box and then changes the settings in the printer's **DEVMODE** structure to values specified by the user. This value is also defined as DM_PROMPT.
DM_OUT_BUFFER	Output value. This value writes the printer driver's current print settings (including private data) to the **DEVMODE** structure identified by the *lpdmOutput* parameter. The calling

	application must allocate a buffer sufficiently large to contain the information. If this bit is clear, *lpdmOutput* can be NULL. This value is also defined as DM_COPY.
DM_OUT_DEFAULT	Output value. This value updates graphics device interface (**GDI**)'s current printer environment and the WIN.INI file, using the contents of the printer driver's **DEVMODE** structure. Avoid using this value, because it permanently changes the print settings for all applications. This value is also defined as DM_UPDATE.

Returns

If the *fwMode* parameter is zero, the return value is the size of the buffer required to contain the printer driver initialization data. (Note that this buffer can be larger than a **DEVMODE** structure, if the printer driver appends private data to the structure.) If the function displays the initialization dialog box, the return value is either **IDOK** or **IDCANCEL**, depending on which button the user selects. If the function does not display the dialog box and is successful, the return value is IDOK. The return value is less than zero if the function fails.

Comments

The **ExtDeviceMode** function is part of the printer's device driver and not part of GDI. To use this function, an application must retrieve the address of the function by calling the **LoadLibrary** and **GetProcAddress** functions, and it must include the header file PRINT.H. The application can then use the address to set up the printer.

ExtDeviceMode is not supported by all printer drivers. If the **GetProcAddress** function returns NULL, **ExtDeviceMode** is not supported.

To make changes to print settings that are local to the application, an application should call the **ExtDeviceMode** function, specifying the **DM_OUT_BUFFER** value; modify the returned **DEVMODE** structure; and then pass the modified **DEVMODE** structure back to **ExtDeviceMode**, specifying **DM_IN_BUFFER** and DM_OUT_BUFFER (combined by using the OR operator). The **DEVMODE** structure returned by this second call to **ExtDeviceMode** can be used as an argument in a call to the **CreateDC** function.

Any call to **ExtDeviceMode** must set either **DM_OUT_BUFFER** or DM_OUT_DEFAULT.

An application can set the *fwMode* parameter to **DM_OUT_BUFFER** to obtain a **DEVMODE** structure filled with the printer driver's initialization data. The application can then pass this structure to the **CreateDC** function to set a private environment for the printer device context.

See Also

CreateDC, **DeviceMode**, **GetModuleHandle**, **GetProcAddress**, **LoadLibrary**, **DEVMODE**

DM_IN_BUFFER DM_MODIFY

Input value. Before prompting, copying, or updating, this value merges the printer driver's current print settings with the settings in the **DEVMODE** structure identified by the *lpdmInput* parameter. The structure is updated only for those members indicated by the application in the **dmFields** member. This value is also defined as DM_MODIFY.

DM_IN_BUFFER DM_MODIFY

DM_IN_PROMPT DM_PROMPT

Input value. This value presents the printer driver's Print Setup dialog box and then changes the settings in the printer's **DEVMODE** structure to values specified by the user. This value is also defined as DM_PROMPT.

DM_IN_PROMPT DM_PROMPT

DM_OUT_BUFFER DM_COPY

Output value. This value writes the printer driver's current print settings (including private data) to the **DEVMODE** structure identified by the *lpdmOutput* parameter. The calling application must allocate a buffer sufficiently large to contain the information. If this bit is clear, *lpdmOutput* can be NULL. This value is also defined as DM_COPY.

DM_OUT_BUFFER DM_COPY

DM_OUT_DEFAULT DM_UPDATE

Output value. This value updates graphics device interface (**GDI**)'s current printer environment and the WIN.INI file, using the contents of the printer driver's **DEVMODE** structure. Avoid using this value, because it permanently changes the print settings for all applications. This value is also defined as DM_UPDATE.

DM_OUT_DEFAULT DM_UPDATE

ExtFloodFill (3.0)

BOOL ExtFloodFill(*hdc, nXStart, nYStart, clrref, fuFillType***)**

```
HDC hdc;            /* handle of device context          */
int nXStart;        /* x-coordinate where filling begins */
int nYStart;        /* y-coordinate where filling begins */
COLORREF clrref;    /* color of fill                     */
UINT fuFillType;    /* fill type                         */
```

The **ExtFloodFill** function fills an area of the screen surface by using the current brush. The type of flood fill specified determines which part of the screen is filled.

Parameter	Description
hdc	Identifies the device context.
nXStart	Specifies the logical x-coordinate at which to begin filling.
nYStart	Specifies the logical y-coordinate at which to begin filling.
clrref	Specifies the color of the boundary or area to be filled. The interpretation of this parameter depends on the value of the *fuFillType* parameter.
fuFillType	Specifies the type of flood fill to be performed. It must be one of the following values:

Value	Meaning
FLOODFILLBORDER	Fill area is bounded by the color specified by the *clrref* parameter. This style is identical to the filling performed by the **FloodFill** function.
FLOODFILLSURFACE	Fill area is defined by the color specified by the *clrref* parameter. Filling continues outward in all directions as long as the color is encountered. This style is useful for filling areas that have multicolored boundaries.

Returns

The return value is nonzero if the function is successful. It is zero if the filling cannot be completed, if the given point has the boundary color specified by the *clrref* parameter (if **FLOODFILLBORDER** was requested), if the given point does not have the color specified by *clrref* (if **FLOODFILLSURFACE** was requested), or if the point is outside the clipping region.

Comments

Only memory device contexts and devices that support raster-display technology support the **ExtFloodFill** function.

If the *fuFillType* parameter is the **FLOODFILLBORDER** value, the area is assumed to be completely bounded by the color specified by the *clrref* parameter. The **ExtFloodFill** function begins at the coordinates specified by the *nXStart* and *nYStart* parameters and fills in all directions to the color boundary.

If *fuFillType* is **FLOODFILLSURFACE**, **ExtFloodFill** begins at the coordinates specified by *nXStart* and *nYStart* and continues in all directions, filling all adjacent areas containing the color specified by *clrref.*

See Also

FloodFill, **GetDeviceCaps**

FLOODFILLBORDER 0

Fill area is bounded by the color specified by the *clrref* parameter. This style is identical to the filling performed by the **FloodFill** function.

FLOODFILLBORDER 0

FLOODFILLSURFACE 1

Fill area is defined by the color specified by the *clrref* parameter. Filling continues outward in all directions as long as the color is encountered. This style is useful for filling areas that have multicolored boundaries.

ExtTextOut (2.x)

BOOL ExtTextOut(*hdc, nXStart, nYStart, fuOptions, lprc, lpszString, cbString, lpDx***)**

```
HDC hdc;                    /* handle of device context                */
int nXStart;                /* x-coordinate of starting position       */
int nYStart;                /* y-coordinate of starting position       */
UINT fuOptions;             /* rectangle type                          */
const RECT FAR* lprc;       /* address of structure with rectangle     */
LPCSTR lpszString;          /* address of string                       */
UINT cbString;              /* number of bytes in string               */
int FAR* lpDx;              /* spacing between character cells         */
```

The **ExtTextOut** function writes a character string within a rectangular region, using the currently selected font. The rectangular region can be opaque (filled by using the current background color as set by the **SetBkColor** function), and it can be a clipping region.

Parameter	Description
hdc	Identifies the device context.
nXStart	Specifies the logical x-coordinate at which the string begins.
nYStart	Specifies the logical y-coordinate at which the string begins.
fuOptions	Specifies the rectangle type. This parameter can be one, both, or neither of the following values:

Value	Meaning
ETO_CLIPPED	Text is clipped to the rectangle.
ETO_OPAQUE	Current background color fills the rectangle. (An application can set and query the current background color by using the **SetBkColor** and **GetBkColor** functions.)

lprc	Points to a **RECT** structure that determines the dimensions of the rectangle.
lpszString	Points to the specified character string.
cbString	Specifies the number of bytes in the string.
lpDx	Points to an array of values that indicate the distance, in logical units, between origins of adjacent character cells. The *n*th element in the array specifies the number of logical units that separate the origin of the *n*th item in the string from the origin of item *n* + 1. If this parameter is NULL, **ExtTextOut** uses the default spacing between characters. Otherwise, the array contains the number of elements specified in the *cbString* parameter.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

If the *fuOptions* parameter is zero and the *lprc* parameter is NULL, the **ExtTextOut** function writes text to the device context without using a rectangular region.

By default, the current position is not used or updated by **ExtTextOut**. If an application needs to update the current position when it calls **ExtTextOut**, the application can call the **SetTextAlign** function with the *wFlags* parameter set to TA_UPDATECP. When this flag is set, Windows ignores the *nXStart* and *nYStart* parameters on subsequent calls to **ExtTextOut**, using the current position instead. When an application uses **TA_UPDATECP** to update the current position, **ExtTextOut** sets the current position either to the end of the previous line of text or to the position specified by the last element of the array pointed to by the *lpDX* parameter, whichever is greater.

Example

The following example uses the **ExtTextOut** function to clip text to a rectangular region defined by a

RECT structure:

```
RECT rc;

SetRect(&rc, 90, 190, 250, 220);

ExtTextOut(hdc, 100, 200,    /* x and y coordinates       */
    ETO_CLIPPED,             /* clips text to rectangle   */
    &rc,                     /* address of RECT structure */
    "Test of ExtTextOut function.", /* string to write    */
    28,                      /* characters in string      */
    (LPINT) NULL);           /* default character spacing */
```

GetBkColor, **SetBkColor**, **SetTextAlign**, **SetTextColor**, **TabbedTextOut**, **TextOut**, **RECT**

ETO_CLIPPED 0x0004

Text is clipped to the rectangle.

ETO_CLIPPED 0x0004

ETO_OPAQUE 0x0002

Current background color fills the rectangle. (An application can set and query the current background color by using the **SetBkColor** and **GetBkColor** functions.)

ETO_OPAQUE 0x0002

FillRgn (2.x)

BOOL FillRgn(*hdc, hrgn, hbr***)**

HDC *hdc;* /* handle of device context */
HRGN *hrgn;* /* handle of region */
HBRUSH *hbr;* /* handle of brush */

The **FillRgn** function fills the given region by using the specified brush.

Parameter	Description
hdc	Identifies the device context.
hrgn	Identifies the region to be filled. The coordinates for the given region are specified in device units.
hbr	Identifies the brush to be used to fill the region.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Example
The following example uses a blue brush to fill a rectangular region. Note that it is not necessary to select the brush into the device context before using it to fill the region.

```
HRGN hrgn;
HBRUSH hBrush;

hrgn = CreateRectRgn(10, 10, 110, 110);
SelectObject(hdc, hrgn);

hBrush = CreateSolidBrush(RGB(0, 0, 255));

FillRgn(hdc, hrgn, hBrush);

DeleteObject(hrgn);
```

See Also
CreateBrushIndirect, **CreateDIBPatternBrush**, **CreateHatchBrush**, **CreatePatternBrush**, **CreateSolidBrush**, **PaintRgn**

FloodFill (2.x)

BOOL FloodFill(*hdc, nXStart, nYStart, clrref***)**

```
HDC hdc;          /* handle of device context          */
int nXStart;      /* x-coordinate of starting position */
int nYStart;      /* y-coordinate of starting position */
COLORREF clrref;  /* color of fill boundary            */
```

The **FloodFill** function fills an area of the screen surface by using the current brush. The area is assumed to be bounded as specified by the *clrref* parameter. The **FloodFill** function begins at the point specified by the *nXStart* and *nYStart* parameters and continues in all directions to the color boundary.

Parameter	Description
hdc	Identifies the device context.
nXStart	Specifies the logical x-coordinate at which to begin filling.
nYStart	Specifies the logical y-coordinate at which to begin filling.
clrref	Specifies the color of the boundary.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero, indicating that the filling cannot be completed, that the given point has the boundary color specified by *clrref,* or that the point is outside the clipping region.

Comments

Only memory device contexts and devices that support raster-display technology support the **FloodFill** function.

See Also

ExtFloodFill, **GetDeviceCaps**

FrameRgn (2.x)

BOOL FrameRgn(*hdc, hrgn, hbr, nWidth, nHeight***)**

HDC *hdc;* /* handle of device context */
HRGN *hrgn;* /* handle of region */
HBRUSH *hbr;* /* handle of brush */
int *nWidth;* /* width of region frame */
int *nHeight;* /* height of region frame */

The **FrameRgn** function draws a border around the given region, using the specified brush.

Parameter	Description
hdc	Identifies the device context.
hrgn	Identifies the region to be enclosed in a border.
hbr	Identifies the brush to be used to draw the border.
nWidth	Specifies the width, in device units, of vertical brush strokes.
nHeight	Specifies the height, in device units, of horizontal brush strokes.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Example
The following example uses a blue brush to frame a rectangular region. Note that it is not necessary to select the brush or the region into the device context.

```
HRGN hrgn;
HBRUSH hBrush;
int Width = 5, Height = 2;

hrgn = CreateRectRgn(10, 10, 110, 110);
hBrush = CreateSolidBrush(RGB(0, 0, 255));

FrameRgn(hdc, hrgn, hBrush, Width, Height);

DeleteObject(hrgn);
DeleteObject(hBrush);
```

See Also
FillRgn, **PaintRgn**

GetAspectRatioFilter (2.x)

DWORD GetAspectRatioFilter(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetAspectRatioFilter** function retrieves the setting for the current aspect-ratio filter. The aspect ratio is the ratio formed by a device's pixel width and height. Information about a device's aspect ratio is used in the creation, selection, and display of fonts. Windows provides a special filter, the aspect-ratio filter, to select fonts designed for a particular aspect ratio from all of the available fonts. The filter uses the aspect ratio specified by the **SetMapperFlags** function.

Parameter	Description
hdc	Identifies the device context that contains the specified aspect ratio.

Returns

The low-order word of the return value contains the x-coordinate of the aspect ratio if the function is successful; the high-order word contains the y-coordinate.

See Also

SetMapperFlags

GetAspectRatioFilterEx (3.1)

BOOL GetAspectRatioFilterEx(*hdc, lpAspectRatio***)**

HDC *hdc;*
SIZE FAR* *lpAspectRatio;*

The **GetAspectRatioFilterEx** function retrieves the setting for the current aspect-ratio filter. The aspect ratio is the ratio formed by a device's pixel width and height. Information about a device's aspect ratio is used in the creation, selection, and displaying of fonts. Windows provides a special filter, the aspect-ratio filter, to select fonts designed for a particular aspect ratio from all of the available fonts. The filter uses the aspect ratio specified by the **SetMapperFlags** function.

Parameter	Description
hdc	Identifies the device context that contains the specified aspect ratio.
lpAspectRatio	Pointer to a **SIZE** structure where the current aspect ratio filter will be returned.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also
SetMapperFlags

GetBitmapBits (2.x)

LONG GetBitmapBits(*hbm, cbBuffer, lpvBits***)**

```
HBITMAP hbm;        /* handle of bitmap                  */
LONG cbBuffer;      /* number of bytes to copy to buffer */
void FAR* lpvBits;  /* address of buffer for bitmap bits */
```

The **GetBitmapBits** function copies the bits of the specified bitmap into a buffer.

Parameter	Description
hbm	Identifies the bitmap.
cbBuffer	Specifies the number of bytes to be copied.
lpvBits	Points to the buffer that is to receive the bitmap. The bitmap is an array of bytes. This array conforms to a structure in which horizontal scan lines are multiples of 16 bits.

Returns

The return value specifies the number of bytes in the bitmap if the function is successful. It is zero if there is an error.

Comments

An application can use the **GetObject** function to determine the number of bytes to copy into the buffer pointed to by the *lpvBits* parameter.

See Also

GetObject, **SetBitmapBits**

GetBitmapDimension (2.x)

DWORD GetBitmapDimension(*hbm***)**

HBITMAP *hbm;* /* handle of bitmap */

The **GetBitmapDimension** function returns the width and height of the specified bitmap. The height and width is assumed to have been set by the **SetBitmapDimension** function.

Parameter	Description
hbm	Identifies the bitmap.

Returns

The low-order word of the return value contains the bitmap width, in tenths of a millimeter, if the function is successful; the high-order word contains the height. If the bitmap width and height have not been set by using the **SetBitmapDimension** function, the return value is zero.

See Also

SetBitmapDimension

GetBitmapDimensionEx (2.x)

BOOL GetBitmapDimensionEx(*hBitmap, lpDimension***)**

HBITMAP *hBitmap;* /* handle of bitmap */
SIZE FAR* *lpDimension;* /* address of dimension structure */

The **GetBitmapDimensionEx** function returns the dimensions of the bitmap previously set by the **SetBitmapDimensionEx** function. If no dimensions have been set, a default of 0,0 will be returned.

Parameter	Description
hBitmap	Identifies the bitmap.
lpDimension	Points to a **SIZE** structure to which the dimensions are returned.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also
SetBitmapDimensionEx, **SIZE**

GetBkColor (2.x)

COLORREF GetBkColor(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetBkColor** function returns the current background color.

Parameter	Description
hdc	Identifies the device context.

Returns

The return value is an **RGB** (red, green, blue) color value if the function is successful.

Comments

If the background mode is **OPAQUE**, the system uses the background color to fill the gaps in styled lines, the gaps between hatched lines in brushes, and the background in character cells. The system also uses the background color when converting bitmaps between color and monochrome device contexts.

Example

The following example uses the **GetBkColor** function to determine whether the current background color is white. If it is, the **SetBkColor** function sets it to red.

```
DWORD dwBackColor;

dwBackColor = GetBkColor(hdc);
if (dwBackColor == RGB(255, 255, 255)) { /* if color is white */
    SetBkColor(hdc, RGB(255, 0, 0));     /* sets color to red */
    TextOut(hdc, 100, 200, "SetBkColor test.", 16);
}
```

See Also

GetBkMode, **SetBkColor**, **SetBkMode**, **RGB**

GetBkMode (2.x)

int GetBkMode(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetBkMode** function returns the background mode. The background mode defines whether the system removes existing background colors on the drawing surface before drawing text, hatched brushes, or any pen style that is not a solid line.

Parameter	Description
hdc	Identifies the device context.

Returns

The return value specifies the current background mode if the function is successful. It can be **OPAQUE**, **TRANSPARENT**, or TRANSPARENT1.

Example

The following example determines the current background mode by calling the **GetBkMode** function. If the mode is **OPAQUE**, the **SetBkMode** function sets it to TRANSPARENT.

```
int nBackMode;

nBackMode = GetBkMode(hdc);
if (nBackMode == OPAQUE) {
    TextOut(hdc, 90, 100, "This background mode is OPAQUE.", 31);
    SetBkMode(hdc, TRANSPARENT);
}
```

See Also

GetBkColor, **SetBkColor**, **SetBkMode**

GetBoundsRect (3.1)

UINT GetBoundsRect(*hdc, lprcBounds, flags***)**

```
HDC hdc;                    /* handle of device context                    */
RECT FAR* lprcBounds;       /* address of structure for bounding rectangle */
UINT flags;                 /* specifies whether to clear rectangle        */
```

The **GetBoundsRect** function returns the current accumulated bounding rectangle for the specified device context.

Parameter	Description
hdc	Identifies the device context to return the bounding rectangle for.
lprcBounds	Points to a buffer that will receive the current bounding rectangle. The rectangle is returned in logical coordinates.
flags	Specifies whether the bounding rectangle to be cleared after it is returned. This parameter can be DCB_RESET, to clear the rectangle. Otherwise, it should be zero.

Returns

The return value is DBC_SET if the bounding rectangle is not empty. Otherwise it is DCB_RESET.

See Also

SetBoundsRect

GetBrushOrg (2.x)

DWORD GetBrushOrg(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetBrushOrg** function retrieves the origin, in device coordinates, of the brush currently selected for the given device context.

Parameter	Description
hdc	Identifies the device context.

Returns

The low-order word of the return value contains the current x-coordinate of the brush, in device coordinates, if the function is successful; the high-order word contains the y-coordinate.

Comments

The initial brush origin is at the coordinates (0,0) in the client area. The return value specifies these coordinates in device units relative to the origin of the desktop window.

Example

The following example uses the **LOWORD** and **HIWORD** macros to extract the x- and y-coordinate of the current brush from the return value of the **GetBrushOrg** function:

```
DWORD dwBrOrg;
WORD wXBrOrg, wYBrOrg;

dwBrOrg = GetBrushOrg(hdc);
wXBrOrg = LOWORD(dwBrOrg);
wYBrOrg = HIWORD(dwBrOrg);
```

See Also

GetBrushOrgEx, **SelectObject**, **SetBrushOrg**, **HIWORD**, **LOWORD**

GetBrushOrgEx (3.1)

BOOL GetBrushOrgEx(*hDC, lpPoint***)**

```
HDC hDC;                /* handle of device context              */
POINT FAR* lpPoint;     /* address of structure for brush origin */
```

The **GetBrushOrgEx** function retrieves the current brush origin for the given device context.

Parameter	Description
hDC	Identifies the device context.
lpPoint	Points to a **POINT** structure to which the device coordinates of the brush origin are to be returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The initial brush origin is at the coordinate (0,0).

See Also

GetBrushOrg, **SetBrushOrg**

GetCharABCWidths (3.1)

BOOL GetCharABCWidths(*hdc, uFirstChar, uLastChar, lpabc***)**

```
HDC hdc;          /* handle of device context          */
UINT uFirstChar;  /* first character in range to query */
UINT uLastChar;   /* last character in range to query  */
LPABC lpabc;      /* address of ABC width structures   */
```

The **GetCharABCWidths** function retrieves the widths of consecutive characters in a specified range from the current TrueType font. The widths are returned in logical units. This function succeeds only with TrueType fonts.

Parameter	Description
hdc	Identifies the device context.
uFirstChar	Specifies the first character in the range of characters from the current font for which character widths are returned.
uLastChar	Specifies the last character in the range of characters from the current font for which character widths are returned.
lpabc	Points to an array of **ABC** structures that receive the character widths when the function returns. This array must contain at least as many **ABC** structures as there are characters in the range specified by the *uFirstChar* and *uLastChar* parameters.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The TrueType rasterizer provides **ABC** character spacing after a specific point size has been selected. "A" spacing is the distance that is added to the current position before placing the glyph. "B" spacing is the width of the black part of the glyph. "C" spacing is added to the current position to account for the white space to the right of the glyph. The total advanced width is given by A + B + C.

When the **GetCharABCWidths** function retrieves negative "A" or "C" widths for a character, that character includes underhangs or overhangs.

To convert the **ABC** widths to font design units, an application should create a font whose height (as specified in the **lfHeight** member of the **LOGFONT** structure) is equal to the value stored in the **ntmSizeEM** member of the **NEWTEXTMETRIC** structure. (The value of the **ntmSizeEM** member can be retrieved by calling the **EnumFontFamilies** function.)

The **ABC** widths of the default character are used for characters that are outside the range of the currently selected font.

To retrieve the widths of characters in non-TrueType fonts, applications should use the **GetCharWidth** function.

See Also

EnumFontFamilies, **GetCharWidth**, **ABC**, **OUTLINETEXTMETRIC**

GetCharWidth (2.x)

BOOL GetCharWidth(*hdc, uFirstChar, uLastChar, lpnWidths***)**

HDC *hdc;* /* handle of device context */
UINT *uFirstChar;* /* first character in range to query */
UINT *uLastChar;* /* last character in range to query */
int FAR* *lpnWidths;* /* address of buffer for widths */

The **GetCharWidth** function retrieves the widths of individual characters in a range of consecutive characters in the current font.

Parameter	Description
hdc	Identifies the device context.
uFirstChar	Specifies the first character in a group of consecutive characters in the current font.
uLastChar	Specifies the last character in a group of consecutive characters in the current font.
lpnWidths	Points to a buffer that receives the width values for a group of consecutive characters in the current font.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

If a character in the group of consecutive characters does not exist in a particular font, it will be assigned the width value of the default character.

Example

The following example uses the **GetCharWidth** function to retrieve the widths of the characters from "I" through "S" and displays the total number of widths retrieved in a message box:

```
HDC hdc;
WORD wTotalValues;
WORD wFirstChar, wLastChar;
int InfoBuffer[256];
char szMessage[30];

wFirstChar = (WORD) 'I';
wLastChar  = (WORD) 'S';

hdc = GetDC(hwnd);
if (GetCharWidth(hdc, wFirstChar, wLastChar, (int FAR*) InfoBuffer)) {
    wTotalValues = wLastChar - wFirstChar + 1;
    wsprintf(szMessage, "Total values received: %d", wTotalValues);
    MessageBox(hwnd, szMessage, "GetCharWidth", MB_OK);
}
else
    MessageBox(hwnd, "GetCharWidth was unsuccessful", "ERROR!",
        MB_OK);

ReleaseDC(hwnd, hdc);
```

GetCharABCWidths

GetClipBox (2.x)

int GetClipBox(*hdc, lprc***)**

```
HDC hdc;          /* handle of device context          */
RECT FAR* lprc;   /* address of structure with rectangle */
```

The **GetClipBox** function retrieves the dimensions of the smallest rectangle that completely contains the current clipping region.

Parameter	Description
hdc	Identifies the device context.
lprc	Points to the **RECT** structure that receives the logical coordinates of the rectangle.

Returns

The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.

See Also

GetBoundsRect, **GetRgnBox**, **GetTextExtent**, **SelectClipRgn**, **RECT**

GetCurrentPosition (2.x)

DWORD GetCurrentPosition(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetCurrentPosition** function retrieves the logical coordinates of the current position. The current position is set by using the **MoveTo** function.

Parameter	Description
hdc	Identifies the device context.

Returns

The low-order word of the return value contains the logical x-coordinate of the current position if the function is successful; the high-order word contains the logical y-coordinate.

See Also

GetCurrentPositionEx, **LineTo**, **MoveTo**

GetCurrentPositionEx (3.1)

BOOL GetCurrentPositionEx(*hdc, lpPoint***)**

HDC *hdc;*
POINT FAR* *lpPoint;*

The **GetCurrentPositionEx** function retrieves the current position in logical coordinates.

Parameter	Description
hdc	Identifies the device context to get the current position from.
lpPoint	Points to a **POINT** structure that gets filled with the current position.

Returns
The return value is nonzero if the function is successful, zero if there is an error.

See Also
GetCurrentPosition

GetDCOrg (2.x)

DWORD GetDCOrg(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetDCOrg** function retrieves the coordinates of the final translation origin for the device context. This origin specifies the offset used by Windows to translate device coordinates into client coordinates for points in an application's window. The final translation origin is relative to the physical origin of the screen.

Parameter	Description
hdc	Identifies the device context whose origin is to be retrieved.

Returns

The low-order word of the return value contains the x-coordinate of the final translation origin, in device coordinates, if the function is successful; the high-order word contains the y-coordinate.

Example

The following example uses the **CreateIC** function to create an information context for the screen and then retrieves the context's origin by using the **GetDCOrg** function:

```
HDC   hdcIC;
DWORD dwOrigin;

hdcIC = CreateIC("DISPLAY", NULL, NULL, NULL);
dwOrigin = GetDCOrg(hdcIC);

DeleteDC(hdcIC);
```

See Also

CreateIC

GetDeviceCaps (2.x)

int GetDeviceCaps(*hdc, iCapability***)**

HDC *hdc;* /* handle of device context */
int *iCapability;* /* index of capability to query */

The **GetDeviceCaps** function retrieves device-specific information about a given display device.

Parameter	Description
hdc	Identifies the device context.
iCapability	Specifies the type of information to be returned. It can be one of the following indices:

Index	Description
DRIVERVERSION	Version number of the device driver.
TECHNOLOGY	Device technology. It can be one of the following values:

Value	Meaning
DT_PLOTTER	Vector plotter
DT_RASDISPLAY	Raster display
DT_RASPRINTER	Raster printer
DT_RASCAMERA	Raster camera
DT_CHARSTREAM	Character stream
DT_METAFILE	Metafile
DT_DISPFILE	Display file

HORZSIZE	Width of the physical display, in millimeters.
VERTSIZE	Height of the physical display, in millimeters.
HORZRES	Width of the display, in pixels.
VERTRES	Height of the display, in raster lines.
LOGPIXELSX	Number of pixels per logical inch along the display width.
LOGPIXELSY	Number of pixels per logical inch along the display height.
BITSPIXEL	Number of adjacent color bits for each pixel.
PLANES	Number of color planes.
NUMBRUSHES	Number of device-specific brushes.
NUMPENS	Number of device-specific pens.
NUMMARKERS	Number of device-specific markers.
NUMFONTS	Number of device-specific fonts.
NUMCOLORS	Number of entries in the device's color table.
ASPECTX	Relative width of a device pixel used for line drawing.
ASPECTY	Relative height of a device pixel used for line drawing.
ASPECTXY	Diagonal width of a device pixel used for line drawing.
PDEVICESIZE	Size of the **PDEVICE** internal structure, in bytes.
CLIPCAPS	Clipping capabilities the device supports. It can be one of the following values:

Value	Meaning
CP_NONE	Output is not clipped.
CP_RECTANGLE	Output is clipped to rectangles.
CP_REGION	Output is clipped to regions.

SIZEPALETTE	Number of entries in the system palette. This index is valid only if the device driver sets the RC_PALETTE bit in the

RASTERCAPS index; it is available only if the driver is written for Windows 3.0 or later.

NUMRESERVED — Number of reserved entries in the system palette. This index is valid only if the device driver sets the RC_PALETTE bit in the RASTERCAPS index; it is available only if the driver is written for Windows 3.0 or later.

COLORRES — Color resolution of the device, in bits per pixel. This index is valid only if the device driver sets the RC_PALETTE bit in the RASTERCAPS index; it is available only if the driver is written for Windows 3.0 or later.

RASTERCAPS — Raster capabilities the device supports. It can be a combination of the following values:

Value	Meaning
RC_BANDING	Supports banding.
RC_BIGFONT	Supports fonts larger than 64K.
RC_BITBLT	Transfers bitmaps.
RC_BITMAP64	Supports bitmaps larger than 64K.
RC_DEVBITS	Supports device bitmaps.
RC_DI_BITMAP	Supports the **SetDIBits** and **GetDIBits** functions.
RC_DIBTODEV	Supports the **SetDIBitsToDevice** function.
RC_FLOODFILL	Performs flood fills.
RC_GDI20_OUTPUT	Supports Windows version 2.0 features.
RC_GDI20_STATE	Includes a state block in the device context.
RC_NONE	Supports no raster operations.
RC_OP_DX_OUTPUT	Supports dev opaque and DX array.
RC_PALETTE	Specifies a palette-based device.
RC_SAVEBITMAP	Saves bitmaps locally.
RC_SCALING	Supports scaling.
RC_STRETCHBLT	Supports the **StretchBlt** function.
RC_STRETCHDIB	Supports the **StretchDIBits** function.

CURVECAPS — Curve capabilities the device supports. It can be a combination of the following values:

Value	Meaning
CC_NONE	Supports curves.
CC_CIRCLES	Supports circles.
CC_PIE	Supports pie wedges.
CC_CHORD	Supports chords.
CC_ELLIPSES	Supports ellipses.
CC_WIDE	Supports wide borders.
CC_STYLED	Supports styled borders.
CC_WIDESTYLED	Supports wide, styled borders.
CC_INTERIORS	Supports interiors.

	CC_ROUNDRECT	Supports rectangles with rounded corners.
LINECAPS	Line capabilities the device supports. It can be a combination of the following values:	
	Value	**Meaning**
	LC_NONE	Supports no lines.
	LC_POLYLINE	Supports polylines.
	LC_MARKER	Supports markers.
	LC_POLYMARKER	Supports polymarkers.
	LC_WIDE	Supports wide lines.
	LC_STYLED	Supports styled lines.
	LC_WIDESTYLED	Supports wide, styled lines.
	LC_INTERIORS	Supports interiors.
POLYGONALCAPS	Polygonal capabilities the device supports. It can be a combination of the following values:	
	Value	**Meaning**
	PC_NONE	Supports no polygons.
	PC_POLYGON	Supports alternate fill polygons.
	PC_RECTANGLE	Supports rectangles.
	PC_WINDPOLYGON	Supports winding number fill polygons.
	PC_SCANLINE	Supports scan lines.
	PC_WIDE	Supports wide borders.
	PC_STYLED	Supports styled borders.
	PC_WIDESTYLED	Supports wide, styled borders.
	PC_INTERIORS	Supports interiors.
TEXTCAPS	Text capabilities the device supports. It can be a combination of the following values:	
	Value	**Meaning**
	TC_OP_CHARACTER	Supports character output precision, which indicates the device can place device fonts at any pixel location. This is required for any device with device fonts.
	TC_OP_STROKE	Supports stroke output precision, which indicates the device can omit any stroke of a device font.
	TC_CP_STROKE	Supports stroke clip precision, which indicates the device can clip device fonts to a pixel boundary.
	TC_CR_90	Supports 90-degree character rotation, which indicates the device can rotate characters only 90 degrees at a time.
	TC_CR_ANY	Supports character rotation at any degree, which indicates the device can rotate device fonts

	through any angle.
TC_SF_X_YINDEP	Supports scaling independent of x and y directions, which indicates the device can scale device fonts separately in x and y directions.
TC_SA_DOUBLE	Supports doubled characters for scaling, which indicates the device can double the size of device fonts.
TC_SA_INTEGER	Supports integer multiples for scaling, which indicates the device can scale the size of device fonts in any integer multiple.
TC_SA_CONTIN	Supports any multiples for exact scaling, which indicates the device can scale device fonts by any amount but still preserve the x and y ratios.
TC_EA_DOUBLE	Supports double-weight characters, which indicates the device can make device fonts bold. If this bit is not set for printer drivers, graphics device interface (**GDI**) attempts to create bold device fonts by printing them twice.
TC_IA_ABLE	Supports italics, which indicates the device can make device fonts italic. If this bit is not set, **GDI** assumes italics are not available.
TC_UA_ABLE	Supports underlining, which indicates the device can underline device fonts. If this bit is not set, **GDI** creates underlines for device fonts.
TC_SO_ABLE	Supports strikeouts, which indicates the device can strikeout device fonts. If this bit is not set, **GDI** creates strikeouts for device fonts.
TC_RA_ABLE	Supports raster fonts, which indicates that **GDI** should enumerate any raster or TrueType fonts available for this device in response to a call to the **EnumFonts** or **EnumFontFamilies** function. If this bit is not set, GDI-supplied raster or TrueType fonts are not enumerated when these functions are called.

TC_VA_ABLE	Supports vector fonts, which indicates that **GDI** should enumerate any vector fonts available for this device in response to a call to the **EnumFonts** or **EnumFontFamilies** function. This is significant for vector devices only (that is, for plotters). Display drivers (which must be able to use raster fonts) and raster printer drivers always enumerate vector fonts, because GDI rasterizes vector fonts before sending them to the driver.
TC_RESERVED	Reserved; must be zero.

Returns

The return value is the value of the requested capability if the function is successful.

Example

The following example uses the **GetDeviceCaps** function to determine whether a device supports raster capabilities and is palette-based. If so, the example calls the **GetSystemPaletteUse** function.

```
WORD nUse;

hdc = GetDC(hwnd);
if ((GetDeviceCaps(hdc, RASTERCAPS) & RC_PALETTE) == 0) {
    ReleaseDC(hwnd, hdc);
    break;
}
nUse = GetSystemPaletteUse(hdc);
ReleaseDC(hwnd, hdc);
```

LOGFONT

GetDIBits (3.0)

int GetDIBits(*hdc, hbmp, nStartScan, cScanLines, lpvBits, lpbmi, fuColorUse***)**

```
HDC hdc;                    /* handle of device context                    */
HBITMAP hbmp;               /* handle of bitmap                            */
UINT nStartScan;            /* first scan line to set in destination bitmap*/
UINT cScanLines;            /* number of scan lines to copy                */
void FAR* lpvBits;          /* address of array for bitmap bits            */
BITMAPINFO FAR* lpbmi;      /* address of structure with bitmap data       */
UINT fuColorUse;            /* type of color table                         */
```

The **GetDIBits** function retrieves the bits of the specified bitmap and copies them, in device-independent format, into the buffer pointed to by the *lpvBits* parameter. The *lpbmi* parameter retrieves the color format for the device-independent bits.

Parameter	Description
hdc	Identifies the device context.
hbmp	Identifies the bitmap.
nStartScan	Specifies the first scan line to be set in the bitmap received in the *lpvBits* parameter.
cScanLines	Specifies the number of lines to be copied.
lpvBits	Points to a buffer that will receive the bitmap bits in device-independent format.
lpbmi	Points to a **BITMAPINFO** structure that specifies the color format and dimension for the device-independent bitmap.
fuColorUse	Specifies whether the **bmiColors** members of the **BITMAPINFO** structure are to contain explicit **RGB** values or indices into the currently realized logical palette. The *fuColorUse* parameter must be one of the following values:

Value	Meaning
DIB_PAL_COLORS	Color table is to consist of an array of 16-bit indices into the currently realized logical palette.
DIB_RGB_COLORS	Color table is to contain literal **RGB** values.

Returns

The return value specifies the number of scan lines copied from the bitmap if the function is successful. Otherwise, it is zero.

Comments

If the *lpvBits* parameter is NULL, the **GetDIBits** function fills in the **BITMAPINFO** structure to which the *lpbmi* parameter points but does not retrieve bits from the bitmap.

The bitmap identified by the *hbmp* parameter must not be selected into a device context when the application calls this function.

The origin for device-independent bitmaps (DIBs) is the lower-left corner of the bitmap, not the upper-left corner, which is the origin when the mapping mode is MM_TEXT.

SetDIBits, **BITMAPINFO**

GetFontData (3.1)

DWORD GetFontData(*hdc, dwTable, dwOffset, lpvBuffer, cbData***)**

```
HDC hdc;            /* handle of device context        */
DWORD dwTable;      /* metric table to query           */
DWORD dwOffset;     /* offset into table being queried */
void FAR* lpvBuffer;/* address of buffer for font data */
DWORD cbData;       /* length of data to query         */
```

The **GetFontData** function retrieves font-metric information from a scalable font file. The information to retrieve is identified by specifying an offset into the font file and the length of the information to return.

Parameter	Description
hdc	Identifies the device context.
dwTable	Specifies the name of the metric table to be returned. This parameter can be one of the metric tables documented in the TrueType Font Files specification, published by Microsoft Corporation. If this parameter is zero, the information is retrieved starting at the beginning of the font file.
dwOffset	Specifies the offset from the beginning of the table at which to begin retrieving information. If this parameter is zero, the information is retrieved starting at the beginning of the table specified by the *dwTable* parameter. If this value is greater than or equal to the size of the table, **GetFontData** returns zero.
lpvBuffer	Points to a buffer that will receive the font information. If this value is NULL, the function returns the size of the buffer required for the font data specified in the *dwTable* parameter.
cbData	Specifies the length, in bytes, of the information to be retrieved. If this parameter is zero, **GetFontData** returns the size of the data specified in the *dwTable* parameter.

Returns

The return value specifies the number of bytes returned in the buffer pointed to by the *lpvBuffer* parameter, if the function is successful. Otherwise, it is -1.

Comments

An application can sometimes use the **GetFontData** function to save a TrueType font with a document. To do this, the application determines whether the font can be embedded and then retrieves the entire font file, specifying zero for the *dwTable, dwOffset,* and *cbData* parameters.

Applications can determine whether a font can be embedded by checking the **otmfsType** member of the **OUTLINETEXTMETRIC** structure. If bit 1 of **otmfsType** is set, embedding is not permitted for the font. If bit 1 is clear, the font can be embedded. If bit 2 is set, the embedding is read-only.

If an application attempts to use this function to retrieve information for a non-TrueType font, the **GetFontData** function returns -1.

Example

The following example retrieves an entire TrueType font file:

```
HGLOBAL hglb;
DWORD dwSize;
void FAR* lpvBuffer;

dwSize = GetFontData(hdc, NULL, 0L, NULL, 0L); /* get file size   */

hglb = GlobalAlloc(GPTR, dwSize);  /* allocate memory */
lpvBuffer = GlobalLock(hglb);
GetFontData(hdc, NULL, 0L, lpvBuffer, dwSize);  /* retrieve data   */
```

The following retrieves an entire TrueType font file 4K at a time:

```
#define BUFFER_SIZE  4096
BYTE Buffer[BUFFER_SIZE];
DWORD dwOffset;
DWORD dwSize;

dwOffset = 0L;
while(dwSize = GetFontData(hdc, NULL, dwOffset,
    Buffer, BUFFER_SIZE)) {
  .
  . /* process data in buffer */
  .
  dwOffset += dwSize;
}
```

The following example retrieves a TrueType font table:

```
HGLOBAL hglb;
DWORD dwSize;
void FAR* lpvBuffer;

LPSTR lpszTable;
DWORD dwTable;

lpszTable = "cmap";
dwTable   = *(LPDWORD) lpszTable;          /* construct DWORD type */

dwSize = GetFontData(hdc, dwTable, 0L, NULL, 0L); /* get table size */

hglb = GlobalAlloc(GPTR, dwSize);                /* allocate memory */
lpvBuffer = GlobalLock(hglb);
GetFontData(hdc, dwTable, 0L, lpvBuffer, dwSize);  /* retrieve data */
```

See Also
GetOutlineTextMetrics, **OUTLINETEXTMETRIC**

GetGlyphOutline (3.1)

DWORD GetGlyphOutline(*hdc, uChar, fuFormat, lpgm, cbBuffer, lpBuffer, lpmat2***)**

```
HDC hdc;                /* handle of device context                */
UINT uChar;             /* character to query                      */
UINT fuFormat;          /* format of data to return                */
LPGLYPHMETRICS lpgm;    /* address of structure with glyph metrics */
DWORD cbBuffer;         /* size of buffer for data                 */
void FAR* lpBuffer;     /* address of buffer for outline data      */
LPMAT2 lpmat2;          /* address of structure with transform matrix */
```

The **GetGlyphOutline** function retrieves the outline curve or bitmap for an outline character in the current font.

Parameter	Description
hdc	Identifies the device context.
uChar	Specifies the character for which information is to be returned.
fuFormat	Specifies the format in which the function is to return information. It can be one of the following values:

Value	Meaning
GGO_BITMAP	Returns the glyph bitmap. When the function returns, the buffer pointed to by the *lpBuffer* parameter contains a 1-bit-per-pixel bitmap whose rows start on doubleword boundaries.
GGO_NATIVE	Returns the curve data points in the rasterizer's native format, using device units. When this value is specified, any transformation specified in the *lpmat2* parameter is ignored.

When the value of this parameter is zero, the function fills in a **GLYPHMETRICS** structure but does not return glyph-outline data.

lpgm	Points to a **GLYPHMETRICS** structure that describes the placement of the glyph in the character cell.
cbBuffer	Specifies the size of the buffer into which the function copies information about the outline character. If this value is zero and the *fuFormat* parameter is either the **GGO_BITMAP** or **GGO_NATIVE** values, the function returns the required size of the buffer.
lpBuffer	Points to a buffer into which the function copies information about the outline character. If the *fuFormat* parameter specifies the **GGO_NATIVE** value, the information is copied in the form of **TTPOLYGONHEADER** and **TTPOLYCURVE** structures. If this value is NULL and the *fuFormat* parameter is either the **GGO_BITMAP** or GGO_NATIVE value, the function returns the required size of the buffer.
lpmat2	Points to a **MAT2** structure that contains a transformation matrix for the character. This parameter cannot be NULL, even when the **GGO_NATIVE** value is specified for the *fuFormat* parameter.

Returns

The return value is the size, in bytes, of the buffer required for the retrieved information if the *cbBuffer* parameter is zero or the *lpBuffer* parameter is NULL. Otherwise, it is a positive value if the function is successful, or -1 if there is an error.

Comments

An application can rotate characters retrieved in bitmap format by specifying a 2-by-2 transformation matrix in the structure pointed to by the *lpmat2* parameter.

A glyph outline is returned as a series of contours. Each contour is defined by a **TTPOLYGONHEADER** structure followed by as many **TTPOLYCURVE** structures as are required to describe it. All points are

returned as **POINTFX** structures and represent absolute positions, not relative moves. The starting point given by the **pfxStart** member of the **TTPOLYGONHEADER** structure is the point at which the outline for a contour begins. The **TTPOLYCURVE** structures that follow can be either polyline records or spline records. Polyline records are a series of points; lines drawn between the points describe the outline of the character. Spline records represent the quadratic curves used by TrueType (that is, quadratic b-splines).

For example, the **GetGlyphOutline** function retrieves the following information about the lowercase "i" in the Arial TrueType font:

```
dwrc = 88                       /* total size of native buffer     */

TTPOLYGONHEADER #1              /* contour for dot on i            */
  cb     = 44                   /* size for contour                */
  dwType = 24                   /* TT_POLYGON_TYPE                 */
  pfxStart = 1.000, 11.000

  TTPOLYCURVE #1
    wType  = TT_PRIM_LINE
    cpfx   = 3
    pfx[0] = 1.000, 12.000
    pfx[1] = 2.000, 12.000
    pfx[2] = 2.000, 11.000      /* automatically close to pfxStart */

TTPOLYGONHEADER #2              /* contour for body of i           */
  cb     = 44
  dwType = 24                   /* TT_POLYGON_TYPE                 */
  pfxStart = 1.000, 0.000

  TTPOLYCURVE #1
    wType  = TT_PRIM_LINE
    cpfx   = 3
    pfx[0] = 1.000, 9.000
    pfx[1] = 2.000, 9.000
    pfx[2] = 2.000, 0.000       /* automatically close to pfxStart */
```

See Also

GetOutlineTextMetrics, **GLYPHMETRICS**, **MAT2**, **OUTLINETEXTMETRIC**, **POINTFX**, **TTPOLYCURVE**, **TTPOLYGONHEADER**

GGO_BITMAP 1

Returns the glyph bitmap. When the function returns, the buffer pointed to by the *lpBuffer* parameter contains a 1-bit-per-pixel bitmap whose rows start on doubleword boundaries.

GGO_BITMAP 1

GGO_NATIVE 2

Returns the curve data points in the rasterizer's native format, using device units. When this value is specified, any transformation specified in the *lpmat2* parameter is ignored.

GetKerningPairs (3.1)

int GetKerningPairs(*hdc, cPairs, lpkrnpair***)**

```
HDC hdc;                          /* handle of device context              */
int cPairs;                       /* number of kerning pairs               */
KERNINGPAIR FAR* lpkrnpair;       /* pointer to structures for kerning pairs*/
```

The **GetKerningPairs** function retrieves the character kerning pairs for the font that is currently selected in the specified device context.

Parameter	Description
hdc	Identifies a device context. The **GetKerningPairs** function retrieves kerning pairs for the current font for this device context.
cPairs	Specifies the number of **KERNINGPAIR** structures pointed to by the *lpkrnpair* parameter. The function will not copy more kerning pairs than specified by *cPairs.*
lpkrnpair	Points to an array of **KERNINGPAIR** structures that receive the kerning pairs when the function returns. This array must contain at least as many structures as specified by the *cPairs* parameter. If this parameter is NULL, the function returns the total number of kerning pairs for the font.

Returns

The return value specifies the number of kerning pairs retrieved or the total number of kerning pairs in the font, if the function is successful. It is zero if the function fails or there are no kerning pairs for the font.

See Also

KERNINGPAIR

GetMapMode (2.x)

int GetMapMode(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetMapMode** function retrieves the current mapping mode.

Parameter	Description
hdc	Identifies the device context.

Returns
The return value specifies the mapping mode if the function is successful.

It can be one of the following values:

Value	Meaning
MM_ANISOTROPIC	Logical units are converted to arbitrary units with arbitrarily scaled axes. Setting the mapping mode to MM_ANISOTROPIC does not change the current window or viewport settings. To change the units, orientation, and scaling, an application should use the **SetWindowExt** and **SetViewportExt** functions.
MM_HIENGLISH	Each logical unit is converted to 0.001 inch. Positive x is to the right; positive y is up.
MM_HIMETRIC	Each logical unit is converted to 0.01 millimeter. Positive x is to the right; positive y is up.
MM_ISOTROPIC	Logical units are converted to arbitrary units with equally scaled axes; that is, one unit along the x-axis is equal to one unit along the y-axis. The **SetWindowExt** and **SetViewportExt** functions must be used to specify the desired units and the orientation of the axes. **GDI** makes adjustments as necessary to ensure that the x and y units remain the same size.
MM_LOENGLISH	Each logical unit is converted to 0.01 inch. Positive x is to the right; positive y is up.
MM_LOMETRIC	Each logical unit is converted to 0.1 millimeter. Positive x is to the right; positive y is up.
MM_TEXT	Each logical unit is converted to one device pixel. Positive x is to the right; positive y is down.
MM_TWIPS	Each logical unit is converted to 1/20 of a point. (Because a point is 1/72 inch, a twip is 1/1440 inch). Positive x is to the right; positive y is up.

Example
The following example uses the **GetMapMode** function to determine whether the current mapping mode is MM_TEXT:

```
if (GetMapMode(hdc) != MM_TEXT) {
    TextOut(hdc, 100, -200, "Mapping mode must be MM_TEXT", 28);
    return FALSE;
}
```

See Also
SetMapMode

GetMetaFile (2.x)

HMETAFILE GetMetaFile(*lpszFile***)**

LPCSTR *lpszFile;* /* address of metafile name */

The **GetMetaFile** function creates a handle of a specified metafile.

Parameter	Description
lpszFile	Points to the null-terminated string that specifies the MS-DOS filename of the metafile. The metafile is assumed to exist.

Returns
The return value is the handle of a metafile if the function is successful. Otherwise, it is NULL.

Example
The following example uses the **CopyMetaFile** function to copy a metafile to a specified file, plays the copied metafile, uses the **GetMetaFile** function to retrieve a handle to the copied metafile, uses the **SetWindowOrg** function to change the position at which the metafile is played 200 logical units to the right, and then plays the metafile at the new location:

```
HANDLE hmf, hmfSource, hmfOld;
LPSTR lpszFile1 = "MFTest";

hmf = CopyMetaFile(hmfSource, lpszFile1);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);

hmfOld = GetMetaFile(lpszFile1);
SetWindowOrg(hdc, -200, 0);
PlayMetaFile(hdc, hmfOld);

DeleteMetaFile(hmfSource);
DeleteMetaFile(hmfOld);
```

See Also
CopyMetaFile, **PlayMetaFile**, **SetWindowOrg**

GetMetaFileBits (2.x)

HGLOBAL GetMetaFileBits(*hmf***)**

HMETAFILE *hmf;* /* handle of metafile */

The **GetMetaFileBits** function returns a handle of the global memory object that contains the specified metafile as a collection of bits. The memory object can be used to determine the size of the metafile or to save the metafile as a file. The memory object should not be modified.

Parameter	Description
hmf	Identifies the memory metafile.

Returns

The return value is the handle of the global memory object that contains the metafile, if the function is successful. Otherwise, it is NULL.

Comments

The handle contained in the *hmf* parameter becomes invalid when the **GetMetaFileBits** function returns, so the returned global memory handle must be used to refer to the metafile.

When it no longer requires a global memory object that is associated with a metafile, an application should remove the object by using the **GlobalFree** function.

See Also

GlobalFree

GetNearestColor (2.x)

COLORREF GetNearestColor(*hdc, clrref***)**

```
HDC hdc;            /* handle of device context */
COLORREF clrref;    /* color to match           */
```

The **GetNearestColor** function retrieves the solid color that best matches a specified logical color; the given device must be able to represent this solid color.

Parameter	Description
hdc	Identifies the device context.
clrref	Specifies the color to be matched.

Returns

The return value specifies an **RGB** (red, green, blue) color value that defines the solid color closest to the *clrref* value that the device can represent.

See Also

GetNearestPaletteIndex

GetNearestPaletteIndex (3.0)

UINT GetNearestPaletteIndex(*hpal, clrref***)**

HPALETTE *hpal;* /* handle of palette */
COLORREF *clrref;* /* color to match */

The **GetNearestPaletteIndex** function retrieves the index of the logical-palette entry that best matches the specified color value.

Parameter	Description
hpal	Identifies the logical palette.
clrref	Specifies the color to be matched.

Returns

The return value is the index of the logical-palette entry whose corresponding color best matches the specified color.

Example

The following example uses the **GetNearestPaletteIndex** function to retrieve a color index from a palette. It then creates a brush with that retrieved color by using the **PALETTEINDEX** macro in a call to the **CreateSolidBrush** function.

```
WORD nColor;
HPALETTE hpal;
DWORD dwBrushColors[8][8];
HBRUSH hbr;
int x, y;
    .
    . /* Initialize the array of brush colors. */
    .
nColor = GetNearestPaletteIndex(hpal, dwBrushColors[x][y]);
hbr = CreateSolidBrush(PALETTEINDEX(nColor));

    .
    . /* Use the brush handle. */
    .
DeleteObject(hbr);
```

See Also

CreateSolidBrush, **GetNearestColor**, **GetPaletteEntries**, **GetSystemPaletteEntries**, **PALETTEINDEX**

GetObject (2.x)

int GetObject(*hgdiobj, cbBuffer, lpvObject***)**

```
HGDIOBJ hgdiobj;        /* handle of object                      */
int cbBuffer;           /* size of buffer for object information */
void FAR* lpvObject;    /* address of buffer for object information */
```

The **GetObject** function fills a buffer with information that defines a given object. The function retrieves a **LOGPEN**, **LOGBRUSH**, **LOGFONT**, or **BITMAP** structure, or an integer, depending on the specified object.

Parameter	Description
hgdiobj	Identifies a logical pen, brush, font, bitmap, or palette.
cbBuffer	Specifies the number of bytes to be copied to the buffer.
lpvObject	Points to the buffer that is to receive the information.

Returns

The return value specifies the number of bytes retrieved if the function is successful. Otherwise, it is zero.

Comments

The buffer pointed to by the *lpvObject* parameter must be sufficiently large to receive the information.

If the *hgdiobj* parameter identifies a bitmap, the **GetObject** function returns only the width, height, and color format information of the bitmap. The bits can be retrieved by using the **GetBitmapBits** function.

If *hgdiobj* identifies a logical palette, **GetObject** retrieves an integer that specifies the number of entries in the palette; the function does not retrieve the **LOGPALETTE** structure that defines the palette. To retrieve information about palette entries, an application can call the **GetPaletteEntries** function.

Example

The following example uses the **GetObject** function to fill a **LOGBRUSH** structure with the attributes of the current brush and then tests whether the brush style is BS_SOLID:

```
LOGBRUSH lb;

HBRUSH hbr;

GetObject(hbr, sizeof(LOGBRUSH), (LPSTR) &lb);
if (lb.lbStyle == BS_SOLID) {
    .
    .
    .
}
```

GetBitmapBits, **GetPaletteEntries**, **GetStockObject**, **BITMAP**, **LOGBRUSH**, **LOGFONT**, **LOGPALETTE**, **LOGPEN**

GetOutlineTextMetrics (3.1)

WORD GetOutlineTextMetrics(*hdc, cbData, lpotm***)**

```
HDC hdc;                                /* handle of device context          */
UINT cbData;                            /* size of buffer for information    */
OUTLINETEXTMETRIC FAR* lpotm;           /* address of structure for metrics  */
```

The **GetOutlineTextMetrics** function retrieves metric information for TrueType fonts.

Parameter	Description
hdc	Identifies the device context.
cbData	Specifies the size, in bytes, of the buffer to which information is returned.
lpotm	Points to an **OUTLINETEXTMETRIC** structure. If this parameter is NULL, the function returns the size of the buffer required for the retrieved metric information.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The **OUTLINETEXTMETRIC** structure contains most of the font metric information provided with the TrueType format, including a **TEXTMETRIC** structure. The last four members of the **OUTLINETEXTMETRIC** structure are pointers to strings. Applications should allocate space for these strings in addition to the space required for the other members. Because there is no system-imposed limit to the size of the strings, the simplest method for allocating memory is to retrieve the required size by specifying NULL for the *lpotm* parameter in the first call to the **GetOutlineTextMetrics** function.

See Also

GetTextMetrics, **OUTLINETEXTMETRIC**, **TEXTMETRIC**

GetPaletteEntries (3.0)

UINT GetPaletteEntries(*hpal, iStart, cEntries, lppe***)**

```
HPALETTE hpal;                  /* handle of palette                    */
UINT iStart;                    /* first palette entry to retrieve      */
UINT cEntries;                  /* number of entries to retrieve        */
PALETTEENTRY FAR* lppe;         /* address of structure for palette entries */
```

The **GetPaletteEntries** function retrieves a range of palette entries in a logical palette.

Parameter	Description
hpal	Identifies the logical palette.
iStart	Specifies the first logical-palette entry to be retrieved.
cEntries	Specifies the number of logical-palette entries to be retrieved.
lppe	Points to an array of **PALETTEENTRY** structures that will receive the palette entries. The array must contain at least as many structures as specified by the *cEntries* parameter.

Returns

The return value is the number of entries retrieved from the logical palette, if the function is successful. Otherwise, it is zero.

See Also

GetSystemPaletteEntries, **PALETTEENTRY**

GetPixel (2.x)

COLORREF GetPixel(*hdc, nXPos, nYPos***)**

```
HDC hdc;        /* handle of device context          */
int nXPos;      /* x-coordinate of pixel to retrieve */
int nYPos;      /* y-coordinate of pixel to retrieve */
```

The **GetPixel** function retrieves the **RGB** (red, green, blue) color value of the pixel at the specified coordinates. The point must be in the clipping region; if it is not, the function is ignored.

Parameter	Description
hdc	Identifies the device context.
nXPos	Specifies the logical x-coordinate of the point to be examined.
nYPos	Specifies the logical y-coordinate of the point to be examined.

Returns

The return value specifies an **RGB** color value for the color of the given point, if the function is successful. It is -1 if the coordinates do not specify a point in the clipping region.

Comments

Not all devices support the **GetPixel** function.

See Also

GetDeviceCaps, **SetPixel**

GetPolyFillMode (2.x)

int GetPolyFillMode(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetPolyFillMode** function retrieves the current polygon-filling mode.

Parameter	Description
hdc	Identifies the device context.

Returns

The return value specifies the polygon-filling mode, ALTERNATE or WINDING, if the function is successful.

Comments

When the polygon-filling mode is ALTERNATE, the system fills the area between odd-numbered and even-numbered polygon sides on each scan line. That is, the system fills the area between the first and second side, between the third and fourth side, and so on.

When the polygon-filling mode is WINDING, the system uses the direction in which a figure was drawn to determine whether to fill an area. Each line segment in a polygon is drawn in either a clockwise or a counterclockwise direction. Whenever an imaginary line drawn from an enclosed area to the outside of a figure passes through a clockwise line segment, a count is incremented. When the line passes through a counterclockwise line segment, the count is decremented. The area is filled if the count is nonzero when the line reaches the outside of the figure.

Example

The following example uses the **GetPolyFillMode** function to determine whether the current polygon-filling mode is ALTERNATE:

```
int nPolyFillMode;

nPolyFillMode = GetPolyFillMode(hdc);
if (nPolyFillMode == ALTERNATE) {
    .
    .
    .
}
```

See Also

SetPolyFillMode

GetRasterizerCaps (3.1)

BOOL GetRasterizerCaps(*lpraststat, cb***)**

```
RASTERIZER_STATUS FAR* lpraststat;      /* address of structure for status*/
int cb;                                 /* number of bytes in structure   */
```

The **GetRasterizerCaps** function returns flags indicating whether TrueType fonts are installed in the system.

Parameter	Description
lpraststat	Points to a **RASTERIZER_STATUS** structure that receives information about the rasterizer.
cb	Specifies the number of bytes that will be copied into the structure pointed to by the *lpraststat* parameter.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The **GetRasterizerCaps** function enables applications and printer drivers to determine whether TrueType is installed.

If the TT_AVAILABLE flag is set in the **wFlags** member of the **RASTERIZER_STATUS** structure, at least one TrueType font is installed. If the TT_ENABLED flag is set, TrueType is enabled for the system.

See Also

GetOutlineTextMetrics, **RASTERIZER_STATUS**

GetRgnBox (3.0)

int GetRgnBox(*hrgn, lprc***)**

HRGN *hrgn;* /* handle of region */
RECT FAR* *lprc;* /* address of structure with rectangle */

The **GetRgnBox** function retrieves the coordinates of the bounding rectangle of the given region.

Parameter	Description
hrgn	Identifies the region.
lprc	Points to a **RECT** structure that receives the coordinates of the bounding rectangle.

Returns

The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.

Example

The following example uses the **GetRgnBox** function to determine the type of a region:

```
RECT rc;
HRGN hrgn;
int RgnType;

RgnType = GetRgnBox(hrgn, &rc);

if (RgnType == COMPLEXREGION)
    TextOut(hdc, 10, 10, "COMPLEXREGION", 13);
else if (RgnType == SIMPLEREGION)
    TextOut(hdc, 10, 10, "SIMPLEREGION", 12);
else
    TextOut(hdc, 10, 10, "NULLREGION", 10);
```

See Also

RECT

GetROP2 (2.x)

int GetROP2(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetROP2** function retrieves the current drawing mode. The drawing mode specifies how the colors of the pen and the interior of filled objects are combined with the color already on the screen surface.

Parameter	Description
hdc	Identifies the device context.

Returns
The return value specifies the drawing mode if the function is successful.

Comments
The drawing mode is for raster devices only and does not apply to vector devices. It can be any of the following values:

Value	Meaning
R2_BLACK	Pixel is always black.
R2_WHITE	Pixel is always white.
R2_NOP	Pixel remains unchanged.
R2_NOT	Pixel is the inverse of the screen color.
R2_COPYPEN	Pixel is the pen color.
R2_NOTCOPYPEN	Pixel is the inverse of the pen color.
R2_MERGEPENNOT	Pixel is a combination of the pen color and the inverse of the screen color (final pixel = (~screen pixel) | pen).
R2_MASKPENNOT	Pixel is a combination of the colors common to both the pen and the inverse of the screen (final pixel = (~screen pixel) & pen).
R2_MERGENOTPEN	Pixel is a combination of the screen color and the inverse of the pen color (final pixel = (~pen) | screen pixel).
R2_MASKNOTPEN	Pixel is a combination of the colors common to both the screen and the inverse of the pen (final pixel = (~pen) & screen pixel).
R2_MERGEPEN	Pixel is a combination of the pen color and the screen color (final pixel = pen | screen pixel).
R2_NOTMERGEPEN	Pixel is the inverse of the R2_MERGEPEN color (final pixel = ~(pen | screen pixel)).
R2_MASKPEN	Pixel is a combination of the colors common to both the pen and the screen (final pixel = pen & screen pixel).
R2_NOTMASKPEN	Pixel is the inverse of the R2_MASKPEN color (final pixel = ~(pen & screen pixel)).
R2_XORPEN	Pixel is a combination of the colors that are in the pen and in the screen, but not in both (final pixel = pen ^ screen pixel).
R2_NOTXORPEN	Pixel is the inverse of the R2_XORPEN color (final pixel = ~(pen ^ screen pixel)).

Example
The following example uses the **GetROP2** function to test whether the current drawing mode is R2_COPYPEN:

```
int nROP;

nROP = GetROP2(hdc);
```

```
if (nROP == R2_COPYPEN)
    TextOut(hdc, 100, 100, "ROP is R2_COPYPEN.", 18);
```

See Also
GetDeviceCaps, **SetROP2**

GetStockObject (2.x)

HGDIOBJ GetStockObject(*fnObject***)**

int *fnObject;* /* type of stock object */

The **GetStockObject** function retrieves a handle of one of the predefined stock pens, brushes, or fonts.

Parameter	Description
fnObject	Specifies the type of stock object for which to retrieve a handle. This parameter can be one of the following values:

Value	Meaning
BLACK_BRUSH	Black brush.
DKGRAY_BRUSH	Dark-gray brush.
GRAY_BRUSH	Gray brush.
HOLLOW_BRUSH	Hollow brush.
LTGRAY_BRUSH	Light-gray brush.
NULL_BRUSH	Null brush.
WHITE_BRUSH	White brush.
BLACK_PEN	Black pen.
NULL_PEN	Null pen.
WHITE_PEN	White pen.
ANSI_FIXED_FONT	Windows fixed-pitch system font.
ANSI_VAR_FONT	Windows variable-pitch system font.
DEVICE_DEFAULT_FONT	Device-dependent font.
OEM_FIXED_FONT	OEM-dependent fixed font.
SYSTEM_FONT	System font. By default, Windows uses the system font to draw menus, dialog box controls, and other text. In Windows versions 3.0 and later, the system font is a variable-pitch font width; earlier versions of Windows use a fixed-pitch system font.
SYSTEM_FIXED_FONT	Fixed-pitch system font used in Windows versions earlier than 3.0. This object is available for compatibility with earlier versions of Windows.
DEFAULT_PALETTE	Default color palette. This palette consists of the static colors in the system palette.

Returns

The return value is the handle of the specified object if the function is successful. Otherwise, it is NULL.

Comments

The **DKGRAY_BRUSH**, **GRAY_BRUSH**, and **LTGRAY_BRUSH** objects should be used only in windows with the **CS_HREDRAW** and **CS_VREDRAW** class styles. Using a gray stock brush in any other style of window can lead to misalignment of brush patterns after a window is moved or sized. The origins of stock brushes cannot be adjusted.

Example

The following example retrieves the handle of a black brush by calling the **GetStockObject** function, selects the brush into the device context, and fills a rectangle by using the black brush:

```
HBRUSH hbr, hbrOld;

hbr = GetStockObject(BLACK_BRUSH);
```

```
hbrOld = SelectObject(hdc, hbr);
Rectangle(hdc, 10, 10, 100, 100);
```

DEFAULT_PALETTE 15

Default color palette. This palette consists of the static colors in the system palette.

DEFAULT_PALETTE 15

GetStretchBltMode (2.x)

int GetStretchBltMode(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetStretchBltMode** function retrieves the current bitmap-stretching mode. The bitmap-stretching mode defines how information is removed from bitmaps that were compressed by using the **StretchBlt** function.

Parameter	Description
hdc	Identifies the device context.

Returns

The return value specifies the current bitmap-stretching mode--STRETCH_ANDSCANS, **STRETCH_DELETESCANS**, or STRETCH_ORSCANS--if the function is successful.

Comments

The **STRETCH_ANDSCANS** and **STRETCH_ORSCANS** modes are typically used to preserve foreground pixels in monochrome bitmaps. The **STRETCH_DELETESCANS** mode is typically used to preserve color in color bitmaps.

Example

The following example uses the **GetStretchBltMode** function to determine whether the current bitmap-stretching mode is **STRETCH_DELETESCANS**; if so, it uses the **StretchBlt** function to display a compressed bitmap.

```
HDC hdcMem;

int nStretchMode;

nStretchMode = GetStretchBltMode(hdc);
if (nStretchMode == STRETCH_DELETESCANS) {
    StretchBlt(hdc, 50, 175, 32, 32, hdcMem, 0, 0, 64, 64,
        SRCCOPY);
        .
        .
        .
}
```

See Also

SetStretchBltMode, **StretchBlt**

GetSystemPaletteEntries (3.0)

UINT GetSystemPaletteEntries(*hdc, iStart, cEntries, lppe***)**

HDC *hdc;*	/* handle of device context	*/
UINT *iStart;*	/* first palette entry to retrieve	*/
UINT *cEntries;*	/* number of entries to retrieve	*/
PALETTEENTRY FAR* *lppe;*	/* address of structure for palette entries	*/

The **GetSystemPaletteEntries** function retrieves a range of palette entries from the system palette.

Parameter	Description
hdc	Identifies the device context.
iStart	Specifies the first system-palette entry to be retrieved.
cEntries	Specifies the number of system-palette entries to be retrieved.
lppe	Points to an array of **PALETTEENTRY** structures that receives the palette entries. The array must contain at least as many structures as specified by the *cEntries* parameter.

Returns

The return value is the number of entries retrieved from the system palette, if the function is successful. Otherwise, it is zero.

Example

The following example uses the **GetDeviceCaps** function to determine whether the specified device is palette-based. If the device supports palettes, the **GetSystemPaletteEntries** function is called, using **GetDeviceCaps** again, this time to determine the number of entries in the system palette.

```
PALETTEENTRY pe[MAXNUMBER];

hdc = GetDC(hwnd);
if (!(GetDeviceCaps(hdc, RASTERCAPS) & RC_PALETTE)) {
    ReleaseDC(hwnd, hdc);
    break;
}
GetSystemPaletteEntries(hdc, 0, GetDeviceCaps(hdc, SIZEPALETTE),
    pe);
ReleaseDC(hwnd, hdc);
```

See Also

GetDeviceCaps, **GetPaletteEntries**, **PALETTEENTRY**

GetSystemPaletteUse (3.0)

UINT GetSystemPaletteUse(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetSystemPaletteUse** function determines whether an application has access to the entire system palette.

Parameter	Description
hdc	Identifies the device context. This device context must support color palettes.

Returns

The return value specifies the current use of the system palette, if the function is successful. This parameter can be one of the following values:

Value	Meaning
SYSPAL_NOSTATIC	System palette contains no static colors except black and white.
SYSPAL_STATIC	System palette contains static colors that do not change when an application realizes its logical palette.

Comments

The system palette contains 20 default static colors that are not changed when an application realizes its logical palette. An application can gain access to most of these colors by calling the **SetSystemPaletteUse** function.

Example

The following example uses the **GetDeviceCaps** function to determine whether the specified device is palette-based. If the device supports palettes, the **GetSystemPaletteUse** function is called.

```
WORD nUse;

hdc = GetDC(hwnd);
if ((GetDeviceCaps(hdc, RASTERCAPS) & RC_PALETTE) == 0) {
    ReleaseDC(hwnd, hdc);
    break;
}
nUse = GetSystemPaletteUse(hdc);
ReleaseDC(hwnd, hdc);
```

See Also

GetDeviceCaps, **SetSystemPaletteUse**

SYSPAL_NOSTATIC 2

System palette contains no static colors except black and white.

SYSPAL_NOSTATIC 2

SYSPAL_STATIC 1

System palette contains static colors that do not change when an application realizes its logical palette.

SYSPAL_STATIC 1

GetTextCharacterExtra (2.x)

int GetTextCharacterExtra(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetTextCharacterExtra** function retrieves the current setting for the amount of intercharacter spacing. Graphics device interface (**GDI**) adds this spacing to each character, including break characters, when it writes a line of text to the device context.

Parameter	Description
hdc	Identifies the device context.

Returns
The return value specifies the amount of intercharacter spacing if the function is successful.

Comments
The default value for the amount of intercharacter spacing is zero.

See Also
SetTextCharacterExtra

GetTextAlign (2.x)

UINT GetTextAlign(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetTextAlign** function retrieves the status of the text-alignment flags for the given device context.

Parameter	Description
hdc	Identifies the device context.

Returns

The return value specifies the status of the text-alignment flags. This parameter can be one or more of the following values:

Value	Meaning
TA_BASELINE	Specifies alignment of the x-axis and the base line of the chosen font within the bounding rectangle.
TA_BOTTOM	Specifies alignment of the x-axis and the bottom of the bounding rectangle.
TA_CENTER	Specifies alignment of the y-axis and the center of the bounding rectangle.
TA_LEFT	Specifies alignment of the y-axis and the left side of the bounding rectangle.
TA_NOUPDATECP	Specifies that the current position is not updated.
TA_RIGHT	Specifies alignment of the y-axis and the right side of the bounding rectangle.
TA_TOP	Specifies alignment of the x-axis and the top of the bounding rectangle.
TA_UPDATECP	Specifies that the current position is updated.

Comments

The text-alignment flags retrieved by the **GetTextAlign** function are used by the **TextOut** and **ExtTextOut** functions. These flags determine how **TextOut** and **ExtTextOut** align a string of text in relation to the string's starting point.

The text-alignment flags are not necessarily single-bit flags and may be equal to zero. To test whether a flag is set, an application should follow three steps:

1 Apply the bitwise OR operator to the flag and its related flags.

Following are the groups of related flags:

- **TA_LEFT**, **TA_CENTER**, and **TA_RIGHT**
- **TA_BASELINE**, **TA_BOTTOM**, and **TA_TOP**
- **TA_NOUPDATECP** and **TA_UPDATECP**

2 Apply the bitwise AND operator to the result and the return value of the **GetTextAlign** function.

3 Test for the equality of this result and the flag.

Example

The following example uses the method described in the preceding Comments section to determine whether text is aligned at the right, left, or center of the bounding rectangle. If the **TA_RIGHT** flag is set, the **SetTextAlign** function is used to set the text alignment to the left side of the rectangle.

```
switch ((TA_LEFT | TA_CENTER | TA_RIGHT) & GetTextAlign(hdc)) {
    case TA_RIGHT:
        TextOut(hdc, 200, 100, "This is TA_RIGHT.", 17);
        SetTextAlign(hdc, TA_LEFT);
        TextOut(hdc, 200, 120, "This is TA_LEFT.", 16);
        break;
    case TA_LEFT:
        .
        .
```

```
        .
    case TA_CENTER:
        .
        .
        .
}
```

Specifies alignment of the x-axis and the top of the bounding rectangle.

TA_TOP 0x0000

TA_UPDATECP 0x0001

Specifies that the current position is updated.

TA_UPDATECP 0x0001

GetTextColor (2.x)

COLORREF GetTextColor(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetTextColor** function retrieves the current text color. The text color is the foreground color of characters drawn by using the graphics device interface (**GDI**) text-output functions.

Parameter	Description
hdc	Identifies the device context.

Returns

The return value specifies the current text color as a red, green, blue (**RGB**) color value, if the function is successful.

Example

The following example sets the text color to red if the **GetTextColor** function determines that the current text color is black:

```
DWORD dwColor;

dwColor = GetTextColor(hdc);
if (dwColor == RGB(0, 0, 0))     /* if current color is black */
    SetTextColor(hdc, RGB(255, 0, 0)); /* sets color to red  */
```

See Also

GetBkColor, **GetBkMode**, **SetBkMode**, **SetTextColor**, **RGB**

GetTextExtent (2.x)

DWORD GetTextExtent(*hdc, lpszString, cbString***)**

HDC *hdc;* /* handle of device context */
LPCSTR *lpszString;* /* address of string */
int *cbString;* /* number of bytes in string */

The **GetTextExtent** function computes the width and height of a line of text, using the current font to compute the dimensions.

Parameter	Description
hdc	Identifies the device context.
lpszString	Points to a character string.
cbString	Specifies the number of bytes in the string.

Returns
The low-order word of the return value contains the string width, in logical units, if the function is successful; the high-order word contains the string height.

Comments
The current clipping region does not affect the width and height returned by the **GetTextExtent** function.

Since some devices do not place characters in regular cell arrays (that is, they kern characters), the sum of the extents of the characters in a string may not be equal to the extent of the string.

Example
The following example retrieves the number of characters in a string by using the **lstrlen** function, calls the **GetTextExtent** function to retrieve the dimensions of the string, and then uses the **LOWORD** macro to determine the string width, in logical units:

```
DWORD dwExtent;
WORD wTextWidth;
LPSTR lpszJustified = "Text to be justified in this test.";

dwExtent = GetTextExtent(hdc, lpszJustified, lstrlen(lpszJustified));
wTextWidth = LOWORD(dwExtent);
```

See Also
GetTabbedTextExtent, **SetTextJustification**

GetTextExtentPoint (3.1)

BOOL GetTextExtentPoint(*hdc, lpszString, cbString, lpSize***)**

```
HDC hdc;              /* handle of device context          */
LPCSTR lpszString;    /* address of text string            */
int cbString;         /* number of bytes in string         */
SIZE FAR* lpSize;     /* address if structure for string size*/
```

The **GetTextExtentPoint** function computes the width and height of the specified text string. The **GetTextExtentPoint** function uses the currently selected font to compute the dimensions of the string. The width and height, in logical units, are computed without considering any clipping.

The **GetTextExtentPoint** function may be used as either a wide-character function (where text arguments must use Unicode) or an ANSI function (where text arguments must use characters from the Windows 3.*x* character set

Parameter	Description
hdc	Identifies the device context.
lpszString	Points to a text string.
cbString	Specifies the number of bytes in the text string.
lpSize	Points to a **SIZE** structure that will receive the dimensions of the string

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

Because some devices do not place characters in regular cell arrays--that is, because they carry out kerning--the sum of the extents of the characters in a string may not be equal to the extent of the string.

The calculated width takes into account the intercharacter spacing set by the **SetTextCharacterExtra** function.

See Also

SetTextCharacterExtra

GetTextFace (2.x)

int GetTextFace(*hdc, cbBuffer, lpszFace***)**

```
HDC hdc;          /* handle of device context       */
int cbBuffer;     /* size of buffer for face name   */
LPSTR lpszFace;   /* pointer to buffer for face name*/
```

The **GetTextFace** function copies the typeface name of the current font into a buffer. The typeface name is copied as a null-terminated string.

Parameter	Description
hdc	Identifies the device context.
cbBuffer	Specifies the buffer size, in bytes. If the typeface name is longer than the number of bytes specified by this parameter, the name is truncated.
lpszFace	Points to the buffer for the typeface name.

Returns

The return value specifies the number of bytes copied to the buffer, not including the terminating null character, if the function is successful. Otherwise, it is zero.

Example

The following example uses the **GetTextFace** function to retrieve the name of the current typeface, calls the **SetTextAlign** function so that the current position is updated when the **TextOut** function is called, and then writes some introductory text and the name of the typeface by calling **TextOut**:

```
int nFaceNameLen;
char aFaceName[80];

nFaceNameLen = GetTextFace(hdc, /* returns length of string */
    sizeof(aFaceName),       /* size of face-name buffer    */
    (LPSTR) aFaceName);      /* address of face-name buffer */

SetTextAlign(hdc,
    TA_UPDATECP);          /* updates current position       */
MoveTo(hdc, 100, 100);     /* sets current position          */
TextOut(hdc, 0, 0,         /* uses current position for text */
    "This is the current face name: ", 31);
TextOut(hdc, 0, 0, aFaceName, nFaceNameLen);
```

See Also

GetTextMetrics, **SetTextAlign**, **TextOut**

GetTextMetrics (2.x)

BOOL GetTextMetrics(*hdc, lptm***)**

HDC *hdc;* /* handle of device context */
TEXTMETRIC FAR* *lptm;* /* pointer to structure for font metrics */

The **GetTextMetrics** function retrieves the metrics for the current font.

Parameter	Description
hdc	Identifies the device context.
lptm	Points to the **TEXTMETRIC** structure that receives the metrics.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Example
The following example calls the **GetTextMetrics** function and then uses information in a **TEXTMETRIC** structure to determine how many break characters are in a string of text:

```
TEXTMETRIC tm;
int j, cBreakChars, cchString;
LPSTR lpszJustified = "Text to be justified in this test.";

GetTextMetrics(hdc, &tm);

cchString = lstrlen(lpszJustified);

for (cBreakChars = 0, j = 0; j < cchString; j++)
    if(*(lpszJustified + j) == (char) tm.tmBreakChar)
        cBreakChars++;
```

See Also
GetTextAlign, **GetTextExtent**, **GetTextFace**, **SetTextJustification**, **TEXTMETRIC**

GetViewportExt (2.x)

DWORD GetViewportExt(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetViewportExt** function retrieves the x- and y-extents of the device context's viewport.

Parameter	Description
hdc	Identifies the device context.

Returns

The low-order word of the return value contains the x-extent, in device units, if the function is successful; the high-order word contains the y-extent.

Example

The following example uses the **GetViewportExt** function and the **LOWORD** and **HIWORD** macros to retrieve the x- and y-extents for a device context:

```
HDC  hdc;
DWORD dw;
int xViewExt, yViewExt;

hdc = GetDC(hwnd);
dw  = GetViewportExt(hdc);
ReleaseDC(hwnd, hdc);
xViewExt = LOWORD(dw);
yViewExt = HIWORD(dw);
```

See Also

GetViewportExtEx, **SetViewportExt**

GetViewportExtEx (3.1)

BOOL GetViewportExtEx(*hdc, lpSize***)**

HDC *hdc;*
SIZE FAR* *lpSize;*

The **GetViewportExtEx** function retrieves the x- and y-extents of the device context's viewport.

Parameter	Description
hdc	Identifies the device context.
lpSize	Points to a **SIZE** structure. The x- and y-extents (in device units) are placed in this structure.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also
GetViewportExt, **SetViewportExt**, **SetViewportExtEx**

GetViewportOrg (2.x)

DWORD GetViewportOrg(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetViewportOrg** function retrieves the x- and y-coordinates of the origin of the viewport associated with the given device context.

Parameter	Description
hdc	Identifies the device context.

Returns

The low-order word of the return value contains the viewport origin's x-coordinate, in device coordinates, if the function is successful; the high-order word contains the y-coordinate of the viewport origin.

Example

The following example uses the **GetViewportOrg** function and the **LOWORD** and **HIWORD** macros to retrieve the x- and y-coordinates of the viewport origin:

```
HDC  hdc;
DWORD dw;
int xViewOrg, yViewOrg;

hdc = GetDC(hwnd);
dw  = GetViewportOrg(hdc);
ReleaseDC(hwnd, hdc);
xViewOrg = LOWORD(dw);
yViewOrg = HIWORD(dw);
```

See Also

GetViewportOrgEx, **GetWindowOrg**, **SetViewportOrg**

GetViewportOrgEx (3.1)

BOOL GetViewportOrgEx(*hdc, lpPoint***)**

HDC *hdc;*
POINT FAR* *lpPoint;*

The **GetViewportOrgEx** function retrieves the x- and y-coordinates of the origin of the viewport associated with the specified device context.

Parameter	Description
hdc	Identifies the device context.
lpPoint	Points to a **POINT** structure. The origin of the viewport (in device coordinates) is placed in this structure.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also
GetViewportOrg, **SetViewportOrg**, **SetViewportOrgEx**

GetWindowExt (2.x)

DWORD GetWindowExt(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetWindowExt** function retrieves the x- and y-extents of the window associated with the given device context.

Parameter	Description
hdc	Identifies the device context.

Returns

The return value specifies the x- and y-extents, in logical units, if the function is successful. The x-extent is in the low-order word; the y-extent is in the high-order word.

Example

The following example uses the **GetWindowExt** function and the **LOWORD** and **HIWORD** macros to retrieve the x- and y-extents of a window:

```
HDC  hdc;
DWORD dw;
int xWindExt, yWindExt;

hdc = GetDC(hwnd);
dw  = GetWindowExt(hdc);
ReleaseDC(hwnd, hdc);
xWindExt = LOWORD(dw);
yWindExt = HIWORD(dw);
```

See Also

GetWindowExtEx, **SetWindowExt**

GetWindowExtEx (3.1)

BOOL GetWindowExtEx(*hdc, lpSize***)**

HDC *hdc;*
SIZE FAR* *lpSize;*

This function retrieves the x- and y-extents of the window associated with the specified device context.

Parameter	Description
hdc	Identifies the device context.
lpSize	Points to a **SIZE** structure. The x- and y-extents (in logical units) are placed in this structure.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also
GetWindowExt, **SetWindowExt**, **SetWindowExtEx**

GetWindowOrg (2.x)

DWORD GetWindowOrg(*hdc***)**

HDC *hdc;* /* handle of device context */

The **GetWindowOrg** function retrieves the x- and y-coordinates of the origin of the window associated with the given device context.

Parameter	Description
hdc	Identifies the device context.

Returns

The low-order word of the return value contains the logical x-coordinate of the window's origin, if the function is successful; the high-order word contains the y-coordinate.

Example

The following example uses the **GetWindowOrg** function and the **LOWORD** and **HIWORD** macros to retrieve the x- and y-coordinates for the window origin:

```
HDC  hdc;
DWORD dw;
int xWindOrg, yWindOrg;

hdc = GetDC(hwnd);
dw  = GetWindowOrg(hdc);
ReleaseDC(hwnd, hdc);
xWindOrg = LOWORD(dw);
yWindOrg = HIWORD(dw);
```

See Also

GetViewportOrg, **GetWindowOrgEx**, **SetWindowOrg**

GetWindowOrgEx (3.1)

BOOL GetWindowOrgEx(*hdc, lpPoint***)**

HDC *hdc;*
POINT FAR* *lpPoint;*

The **GetWindowOrgEx** function retrieves the x- and y-coordinates of the origin of the window associated with the specified device context.

Parameter	Description
hdc	Identifies the device context.
lpPoint	Points to a **POINT** structure. The origin of the window (in logical coordinates) is placed in this structure.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also
GetWindowOrg, **SetWindowOrg**, **SetWindowOrgEx**

IntersectClipRect (2.x)

int IntersectClipRect(*hdc, nLeftRect, nTopRect, nRightRect, nBottomRect***)**

HDC *hdc;* /* handle of device context */
int *nLeftRect;* /* x-coordinate top-left corner of rectangle */
int *nTopRect;* /* y-coordinate top-left corner of rectangle */
int *nRightRect;* /* x-coordinate bottom-right corner of rectangle */
int *nBottomRect;* /* y-coordinate bottom-right corner of rectangle */

The **IntersectClipRect** function creates a new clipping region from the intersection of the current region and a specified rectangle.

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the rectangle.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the rectangle.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the rectangle.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the rectangle.

Returns

The return value specifies that the resulting region has overlapping borders (COMPLEXREGION), is empty (NULLREGION), or has no overlapping borders (SIMPLEREGION). Otherwise, the return value is ERROR.

Comments

An application uses the **IntersectClipRect** function to create a clipping region from the intersection of the current region and a specified rectangle. An application can also create a clipping region that is the intersection of two regions, by specifying **RGN_AND** in a call to the **CombineRgn** function and then making this combined region the clipping region by calling the **SelectClipRgn** function.

The width of the rectangle, specified by the absolute value of *nRightRect* - *nLeftRect,* must not exceed 32,767 units. This limit applies to the height of the rectangle as well.

Example

The following example creates a square clipping region and colors it red by using a red brush to fill the client area. The **IntersectClipRect** function is called with coordinates that overlap the region, and the client area is filled with a yellow brush. The only region colored yellow is the overlap between the region and the coordinates specified in the call to **IntersectClipRect**.

```
RECT rc;
HRGN hrgn;
HBRUSH hbrRed, hbrYellow;

GetClientRect(hwnd, &rc);
hrgn = CreateRectRgn(10, 10, 110, 110);
SelectClipRgn(hdc, hrgn);
hbrRed = CreateSolidBrush(RGB(255, 0, 0));
FillRect(hdc, &rc, hbrRed);

IntersectClipRect(hdc, 100, 100, 200, 200);

hbrYellow = CreateSolidBrush(RGB(255, 255, 0));
FillRect(hdc, &rc, hbrYellow);

DeleteObject(hbrRed);
DeleteObject(hbrYellow);
```

```
DeleteObject(hrgn);
```

See Also
CombineRgn, **SelectClipRgn**

InvertRgn (2.x)

BOOL InvertRgn(*hdc, hrgn***)**

HDC *hdc;* /* handle of device context */
HRGN *hrgn;* /* handle of region */

The **InvertRgn** function inverts the colors in a given region.

Parameter	Description
hdc	Identifies the device context.
hrgn	Identifies the region for which colors are to be inverted.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
On monochrome screens, the **InvertRgn** function makes white pixels black and black pixels white. On color screens, the inversion depends on how the colors are generated for the screen.

Example
The following example sets the device coordinates of and creates a rectangular region, selects the region into a device context, and then calls the **InvertRgn** function to display the region in inverted colors:

```
HRGN hrgn;

hrgn = CreateRectRgn(10, 10, 110, 110);
SelectObject(hdc, hrgn);
InvertRgn(hdc, hrgn);

DeleteObject(hrgn);
```

See Also
FillRgn, **PaintRgn**

IsGDIObject (3.1)

BOOL IsGDIObject(*hobj***)**

HGDIOBJ *hobj;* /* handle of a menu */

The **IsGDIObject** function determines whether the specified handle is not the handle of a graphics device interface (**GDI**) object.

Parameter	Description
hobj	Specifies a handle to test.

Returns

The return value is nonzero if the handle may be the handle of a **GDI** object. It is zero if the handle is not the handle of a GDI object.

Comments

An application cannot use **IsGDIObject** to guarantee that a given handle is to a **GDI** object. However, this function can be used to guarantee that a given handle is not to a GDI object.

GetObject

LineDDA (2.x)

void LineDDA(*nXStart, nYStart, nXEnd, nYEnd, lnddaprc, lParam***)**

```
int nXStart;                    /* x-coordinate of line beginning          */
int nYStart;                    /* y-coordinate of line beginning          */
int nXEnd;                      /* x-coordinate of line end                */
int nYEnd;                      /* y-coordinate of line end                */
LINEDDAPROC lnddaprc;           /* address of callback function            */
LPARAM lParam;                  /* address of application-defined data     */
```

The **LineDDA** function computes all successive points in a line specified by starting and ending coordinates. For each point on the line, the system calls an application-defined callback function, specifying the coordinates of that point.

Parameter	Description
nXStart	Specifies the logical x-coordinate of the first point.
nYStart	Specifies the logical y-coordinate of the first point.
nXEnd	Specifies the logical x-coordinate of the endpoint. This endpoint is not part of the line.
nYEnd	Specifies the logical y-coordinate of the endpoint. This endpoint is not part of the line.
lnddaprc	Specifies the procedure-instance address of the application-defined callback function. The address must have been created by using the **MakeProcInstance** function. For more information about the callback function, see the description of the **LineDDAProc** callback function.
lParam	Points to 32 bits of application-defined data that is passed to the callback function.

Returns

This function does not return a value.

Example

The following example uses the **LineDDA** function to draw a dot every two spaces between the beginning and ending points of a line:

```
/* Callback function */

void CALLBACK DrawDots(int xPos, int yPos, LPSTR lphdc)
{
    static short cSpaces = 1;

    if (cSpaces == 3) {

        /* Draw a black dot. */

        SetPixel(*(HDC FAR*) lphdc, xPos, yPos, 0);

        /* Initialize the space count. */

        cSpaces = 1;
    }
    else
        cSpaces++;
}
```

See Also

LineDDAProc, **MakeProcInstance**

LineTo (2.x)

BOOL LineTo(*hdc, xEnd, yEnd***)**

HDC *hdc;* /* handle of device context */
int *xEnd;* /* x-coordinate of line endpoint */
int *yEnd;* /* y-coordinate of line endpoint */

The **LineTo** function draws a line from the current position up to, but not including, the specified endpoint. The function uses the selected pen to draw the line and sets the current position to the coordinates (*xEnd,yEnd*).

Parameter	Description
hdc	Identifies the device context.
xEnd	Specifies the logical x-coordinate of the line's endpoint.
yEnd	Specifies the logical y-coordinate of the line's endpoint.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Example
The following example sets the current position by using the **MoveTo** function before calling the **LineTo** function. The example uses **POINT** structures to store the coordinates.

```
HDC hdc;

POINT ptStart = {  12,  12 };
POINT ptEnd = { 128, 135 };

MoveTo(hdc, ptStart.x, ptStart.y);
LineTo(hdc, ptEnd.x, ptEnd.y);
```

See Also
MoveTo, **POINT**

LPtoDP (2.x)

BOOL LPtoDP(*hdc, lppt, cPoints***)**

```
HDC hdc;                /* handle of device context      */
POINT FAR* lppt;        /* address of array with points */
int cPoints;            /* number of points in array     */
```

The **LPtoDP** function converts logical coordinates (points) into device coordinates.

Parameter	Description
hdc	Identifies the device context.
lppt	Points to an array of **POINT** structures. The coordinates in each structure are mapped to the device coordinates of the current device context.
cPoints	Specifies the number of points in the array.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The conversion depends on the current mapping mode and the settings of the origins and extents of the device's window and viewport.

The x- and y-coordinates of points are 2-byte signed integers in the range -32,768 through 32,767. In cases where the mapping mode would result in values larger than these limits, the system sets the values to -32,768 and 32,767, respectively.

Example

The following example sets the mapping mode to MM_LOENGLISH and then calls the **LPtoDP** function to convert the coordinates of a rectangle into device coordinates:

```
RECT rc;

SetMapMode(hdc, MM_LOENGLISH);
SetRect(&rc, 100, -100, 200, -200);
LPtoDP(hdc, (LPPOINT) &rc, 2);
```

See Also

DPtoLP, **POINT**

MoveTo (2.x)

DWORD MoveTo(*hdc, x, y***)**

HDC *hdc;* /* handle of device context */
int *x;* /* x-coordinate of new position */
int *y;* /* y-coordinate of new position */

The **MoveTo** function moves the current position to the specified coordinates.

Parameter	Description
hdc	Identifies the device context.
x	Specifies the logical x-coordinate of the new position.
y	Specifies the logical y-coordinate of the new position.

Returns

The low-order word of the return value contains the logical x-coordinate of the previous position, if the function is successful; the high-order word contains the logical y-coordinate.

Example

The following example uses the **MoveTo** function to set the current position and then calls the **LineTo** function. The example uses **POINT** structures to store the coordinates.

```
HDC hdc;

POINT ptStart = {  12,  12 };
POINT ptEnd = { 128, 135 };

MoveTo(hdc, ptStart.x, ptStart.y);
LineTo(hdc, ptEnd.x, ptEnd.y);
```

See Also

GetCurrentPosition, **LineTo**, **POINT**

MoveToEx (3.1)

BOOL MoveToEx(*hdc, x, y, lpPoint***)**

```
HDC hdc;                /* handle of device context                    */
int x;                  /* x-coordinate of new position                */
int y;                  /* y-coordinate of new position                */
POINT FAR* lpPoint;     /* pointer to structure for previous position  */
```

The **MoveToEx** function moves the current position to the point specified by the *x* and *y* parameters, optionally returning the previous position.

Parameter	Description
hdc	Identifies the device context.
x	Specifies the logical x-coordinate of the new position.
y	Specifies the logical y-coordinate of the new position.
lpPoint	Points to a **POINT** structure in which the previous current position will be stored. If this parameter is NULL, no previous position is returned.

Returns

The return value is nonzero if the call is successful. Otherwise, it is zero.

See Also

MoveTo, **POINT**

OffsetClipRgn (2.x)

int OffsetClipRgn(*hdc, nXOffset, nYOffset***)**

HDC *hdc;* /* device-context handle */
int *nXOffset;* /* offset along x-axis */
int *nYOffset;* /* offset along y-axis */

The **OffsetClipRgn** function moves the clipping region of the given device by the specified offsets.

Parameter	Description
hdc	Identifies the device context.
nXOffset	Specifies the number of logical units to move left or right.
nYOffset	Specifies the number of logical units to move up or down.

Returns

The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.

Example

The following example creates an elliptical region and selects it as the clipping region for a device context. The **OffsetClipRgn** function is called repeatedly to move the clipping region from left to right across the screen. Because only the new clipping region is redrawn each time the **Rectangle** function is called, the left side of each ellipse remains on the screen when the clipping region moves. When the loop has finished, a wide blue line with rounded ends stretches from one side of the client area to the other.

```
RECT rc;
HRGN hrgn;
HBRUSH hbr, hbrPrevious;
int i;

GetClientRect(hwnd, &rc);
hrgn = CreateEllipticRgn(0, 100, 100, 200);
SelectClipRgn(hdc, hrgn);
hbr = CreateSolidBrush(RGB(0, 0, 255));
hbrPrevious = SelectObject(hdc, hbr);

for (i = 0; i < rc.right - 100; i++) {
    OffsetClipRgn(hdc, 1, 0);
    Rectangle(hdc, rc.left, rc.top, rc.right, rc.bottom);
}

SelectObject(hdc, hbrPrevious);
DeleteObject(hbr);
DeleteObject(hrgn);
```

See Also

CreateEllipticRgn, **SelectClipRgn**

OffsetRgn (2.x)

int OffsetRgn(*hrgn, nXOffset, nYOffset***)**

HRGN *hrgn;* /* handle of region */
int *nXOffset;* /* offset along x-axis */
int *nYOffset;* /* offset along y-axis */

The **OffsetRgn** function moves the given region by the specified offsets.

Parameter	Description
hrgn	Identifies the region to be moved.
nXOffset	Specifies the number of logical units to move left or right.
nYOffset	Specifies the number of logical units to move up or down.

Returns

The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.

Comments

The coordinate values of a region must not be greater than 32,767 or less than -32,768. The *nXOffset* and *nYOffset* parameters must be carefully chosen to prevent invalid regions.

Example

The following example creates a rectangular region, uses the **OffsetRgn** function to move the region 50 positive units in the x- and y-directions, selects the offset region into the device context, and then fills it by using a blue brush:

```
HDC hdcLocal;
HRGN hrgn;
HBRUSH hbrBlue;
int RgnType;

hdcLocal = GetDC(hwnd);
hrgn = CreateRectRgn(100, 10, 210, 110);
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);

RgnType = OffsetRgn(hrgn, 50, 50);
SelectObject(hdc, hrgn);

if (RgnType == ERROR)
    TextOut(hdcLocal, 10, 135, "ERROR", 5);
else if (RgnType == SIMPLEREGION)
    TextOut(hdcLocal, 10, 135, "SIMPLEREGION", 12);
else if (RgnType == NULLREGION)
    TextOut(hdcLocal, 10, 135, "NULLREGION", 10);
else
    TextOut(hdcLocal, 10, 135, "Unrecognized value.", 19);

hbrBlue = CreateSolidBrush(RGB(0, 0, 255));
FillRgn(hdc, hrgn, hbrBlue);

DeleteObject(hrgn);
DeleteObject(hbrBlue);
ReleaseDC(hwnd, hdcLocal);
```

OffsetViewportOrg (2.x)

DWORD OffsetViewportOrg(*hdc, nXOffset, nYOffset***)**

```
HDC hdc;        /* handle of device context */
int nXOffset;   /* offset along x-axis      */
int nYOffset;   /* offset along y-axis      */
```

The **OffsetViewportOrg** function modifies the coordinates of the viewport origin relative to the coordinates of the current viewport origin.

Parameter	Description
hdc	Identifies the device context.
nXOffset	Specifies the value, in device units, to add to the x-coordinate of the current origin.
nYOffset	Specifies the value, in device units, to add to the y-coordinate of the current origin.

Returns

The low-order word of the return value contains the x-coordinate, in device units, of the previous viewport origin, if the function is successful; the high-order word contains the y-coordinate.

Comments

The viewport origin is the origin of the device coordinate system for a window. By changing the viewport origin, an application can change the way the graphics device interface (**GDI**) maps points from the logical coordinate system. GDI maps all points in the logical coordinate system to the viewport in the same way as it maps the origin.

To map points to the right, specify a negative value for the *nXOffset* parameter. Similarly, to map points down (in the MM_TEXT mapping mode), specify a negative value for the *nYOffset* parameter.

Example

The following example uses the **OffsetWindowOrg** and **OffsetViewportOrg** functions to reposition the output of the **PlayMetaFile** function on the screen:

```
HDC hdcMeta;
HANDLE hmf;

hdcMeta = CreateMetaFile((LPSTR) NULL);
    .
    . /* Record the metafile. */
    .

PlayMetaFile(hdc, hmf);

OffsetWindowOrg(hdc, -200, -200);
PlayMetaFile(hdc, hmf);   /* MM_TEXT screen output +200 x, +200 y */

OffsetViewportOrg(hdc, 0, -200);
PlayMetaFile(hdc, hmf);   /* outputs -200 y from last PlayMetaFile */

DeleteMetaFile(hmf);
```

See Also

GetViewportOrg, **OffsetWindowOrg**, **SetViewportOrg**

OffsetViewportOrgEx (3.1)

BOOL OffsetViewportOrgEx(*hdc, nX, nY, lpPoint***)**

```
HDC hdc;                /* handle of device context              */
int nX;                 /* device units to add to x-coordinate   */
int nY;                 /* device units to add to y-coordinate   */
POINT FAR* lpPoint;     /* address of POINT structure            */
```

The **OffsetViewportOrgEx** function modifies the viewport origin relative to the current values. The formulas are written as follows:

```
xNewVO = xOldVO + X
yNewVO = yOldVO + Y
```

The new origin is the sum of the current origin and the *nX* and *nY* values.

Parameter	Description
hdc	Identifies the device context.
nX	Specifies the number of device units to add to the current origin's x-coordinate.
nY	Specifies the number of device units to add to the current origin's y-coordinate.
lpPoint	Points to a **POINT** structure. The previous viewport origin (in device coordinates) is placed in this structure. If *lpPoint* is NULL, the previous viewport origin in not returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

OffsetWindowOrg (2.x)

DWORD OffsetWindowOrg(*hdc, nXOffset, nYOffset***)**

```
HDC hdc;        /* handle of device context */
int nXOffset;   /* offset along x-axis      */
int nYOffset;   /* offset along y-axis      */
```

The **OffsetWindowOrg** function modifies the window origin relative to the coordinates of the current window origin.

Parameter	Description
hdc	Identifies the device context.
nXOffset	Specifies the value, in logical units, to add to the x-coordinate of the current origin.
nYOffset	Specifies the value, in logical units, to add to y-coordinate of the current origin.

Returns

The low-order word of the return value contains the logical x-coordinate of the previous window origin, if the function is successful; the high-order word contains the logical y-coordinate.

Comments

The window origin is the origin of the logical coordinate system for a window. By changing the window origin, an application can change the way the graphics device interface (**GDI**) maps logical points to the physical coordinate system (the viewport). GDI maps all points in the logical coordinate system to the viewport in the same way as it maps the origin.

To map points to the right, specify a negative value for the *nXOffset* parameter. Similarly, to map points down (in the MM_TEXT mapping mode), specify a negative value for the *nYOffset* parameter.

Example

The following example uses the **OffsetWindowOrg** and **OffsetViewportOrg** functions to reposition the output of the **PlayMetaFile** function on the screen:

```
HDC hdcMeta;
HANDLE hmf;

hdcMeta = CreateMetaFile((LPSTR) NULL);
    .
    . /* Record the metafile. */
    .

PlayMetaFile(hdc, hmf);

OffsetWindowOrg(hdc, -200, -200);
PlayMetaFile(hdc, hmf);   /* MM_TEXT screen output +200 x, +200 y */

OffsetViewportOrg(hdc, 0, -200);
PlayMetaFile(hdc, hmf);   /* outputs -200 y from last PlayMetaFile */

DeleteMetaFile(hmf);
```

See Also

GetWindowOrg, **OffsetViewportOrg**, **SetWindowOrg**

OffsetWindowOrgEx (3.1)

BOOL OffsetWindowOrgEx(*hdc, nX, nY, lpPoint***)**

```
HDC hdc;                    /* handle of device context          */
int nX;                     /* logical units to add to x-coordinate */
int nY;                     /* logical units to add to y-coordinate */
POINT FAR* lpPoint;         /* address of POINT structure        */
```

The **OffsetWindowOrgEx** function modifies the viewport origin relative to the current values. The formulas are written as follows:

```
xNewWO = xOldWO + X
yNewWO = yOldWO + Y
```

The new origin is the sum of the current origin and the *nX* and *nY* values.

Parameter	Description
hdc	Identifies the device context.
nX	Specifies the number of logical units to add to the current origin's x-coordinate.
nY	Specifies the number of logical units to add to the current origin's y-coordinate.
lpPoint	Points to a **POINT** structure. The previous window origin (in logical coordinates) is placed in this structure. If *lpPoint* is NULL, the previous origin is not returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

PaintRgn (2.x)

BOOL PaintRgn(*hdc, hrgn***)**

HDC *hdc;* /* handle of device context */
HRGN *hrgn;* /* handle of region */

The **PaintRgn** function fills a region by using the current brush for the given device context.

Parameter	Description
hdc	Identifies the device context that contains the region to be filled.
hrgn	Identifies the region to be filled. The coordinates for the given region are specified in device units.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Example
The following example uses the current brush for a device context to fill an elliptical region:

```
HDC hdc;
HRGN hrgn;

hrgn = CreateEllipticRgn(10, 10, 110, 110);
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);

DeleteObject(hrgn);
```

Changes

PatBlt (2.x)

BOOL PatBlt(*hdc, nLeftRect, nTopRect, nwidth, nheight, fdwRop***)**

```
HDC hdc;          /* handle of device context                          */
int nLeftRect;    /* x-coordinate top-left corner destination rectangle */
int nTopRect;     /* y-coordinate top-left corner destination rectangle */
int nwidth;       /* width of destination rectangle                    */
int nheight;      /* height of destination rectangle                   */
DWORD fdwRop;     /* raster operation                                  */
```

The **PatBlt** function creates a bit pattern on the specified device. The pattern is a combination of the selected brush and the pattern already on the device. The specified raster-operation code defines how the patterns are combined.

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the rectangle that receives the pattern.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the rectangle that receives the pattern.
nwidth	Specifies the width, in logical units, of the rectangle that will receive the pattern.
nheight	Specifies the height, in logical units, of the rectangle that will receive the pattern.
fdwRop	Specifies the raster-operation code that determines how the graphics device interface (**GDI**) combines the colors in the output operation. This parameter can be one of the following values:

Value	Meaning
PATCOPY	Copies the pattern to the destination bitmap.
PATINVERT	Combines the destination bitmap with the pattern by using the Boolean XOR operator.
PATPAINT	Paints the destination bitmap.
DSTINVERT	Inverts the destination bitmap.
BLACKNESS	Turns all output black.
WHITENESS	Turns all output white.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The raster operations listed for this function are a limited subset of the full 256 ternary raster-operation codes; in particular, a raster-operation code that refers to a source cannot be used.

Not all devices support the **PatBlt** function. To determine whether a device supports **PatBlt**, an application can call the **GetDeviceCaps** function with the RASTERCAPS index.

Example

The following example uses the **CreateBitmap** function to create a bitmap with a zig-zag pattern, and then uses the **PatBlt** function to fill the client area with that pattern:

```
HDC hdc;
HBITMAP hbmp;
HBRUSH hbr, hbrPrevious;
RECT rc;
```

```
int aZigzag[] = { 0xFF, 0xF7, 0xEB, 0xDD, 0xBE, 0x7F, 0xFF, 0xFF };

hbmp = CreateBitmap(8, 8, 1, 1, aZigzag);
hbr = CreatePatternBrush(hbmp);

hdc = GetDC(hwnd);
UnrealizeObject(hbr);
hbrPrevious = SelectObject(hdc, hbr);
GetClientRect(hwnd, &rc);

PatBlt(hdc, rc.left, rc.top,
    rc.right - rc.left, rc.bottom - rc.top, PATCOPY);
SelectObject(hdc, hbrPrevious);
ReleaseDC(hwnd, hdc);

DeleteObject(hbr);
DeleteObject(hbmp);
```

See Also

GetDeviceCaps

Windows 3.1 corrections

The following raster operation has been added:

Value	Meaning
PATPAINT	Paints the destination bitmap.

Pie (2.x)

BOOL Pie(*hdc, nLeftRect, nTopRect, nRightRect, nBottomRect, nxStartArc, nyStartArc, nxEndArc, nyEndArc***)**

```
HDC hdc;          /* handle of device context                          */
int nLeftRect;    /* x-coordinate upper-left corner bounding rectangle */
int nTopRect;     /* y-coordinate upper-left corner bounding rectangle */
int nRightRect;   /* x-coordinate lower-right corner bounding rectangle */
int nBottomRect;  /* y-coordinate lower-right corner bounding rectangle */
int nxStartArc;   /* x-coordinate arc starting point                   */
int nyStartArc;   /* y-coordinate arc starting point                   */
int nxEndArc;     /* x-coordinate arc ending point                     */
int nyEndArc;     /* y-coordinate arc ending point                     */
```

The **Pie** function draws a pie-shaped wedge by drawing an elliptical arc whose center and two endpoints are joined by lines.

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle.
nxStartArc	Specifies the logical x-coordinate of the arc's starting point. This point does not have to lie exactly on the arc.
nyStartArc	Specifies the logical y-coordinate of the arc's starting point. This point does not have to lie exactly on the arc.
nxEndArc	Specifies the logical x-coordinate of the arc's endpoint. This point does not have to lie exactly on the arc.
nyEndArc	Specifies the logical y-coordinate of the arc's endpoint. This point does not have to lie exactly on the arc.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The center of the arc drawn by the **Pie** function is the center of the bounding rectangle specified by the *nLeftRect, nTopRect, nRightRect,* and *nBottomRect* parameters. The starting and ending points of the arc are specified by the *nxStartArc, nyStartArc, nxEndArc,* and *nyEndArc* parameters. The function draws the arc by using the selected pen, moving in a counterclockwise direction. It then draws two additional lines from each endpoint to the arc's center. Finally, it fills the pie-shaped area by using the current brush.

If *nxStartArc* equals *nxEndArc* and *nyStartArc* equals *nyEndArc,* the result is an ellipse with a single line from the center of the ellipse to the point (*nxStartArc,nyStartArc*) or (*nxEndArc,nyEndArc*).

The figure drawn by this function extends up to but does not include the right and bottom coordinates. This means that the height of the figure is *nBottomRect - nTopRect* and the width of the figure is *nRightRect - nLeftRect.*

Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.

Example

The following example uses a **RECT** structure to store the points that define the bounding rectangle and uses **POINT** structures to store the coordinates that specify the beginning and end of the wedge:

```
HDC hdc;

RECT rc = { 10, 10, 180, 140 };
POINT ptStart = {  12,  12 };
POINT ptEnd = { 128, 135 };

Pie(hdc, rc.left, rc.top, rc.right, rc.bottom,
    ptStart.x, ptStart.y, ptEnd.x, ptEnd.y);
```

See Also
Chord, **POINT**, **RECT**

PlayMetaFile (2.x)

BOOL PlayMetaFile(*hdc, hmf***)**

HDC *hdc;* /* handle of device context */
HMETAFILE *hmf;* /* handle of metafile */

The **PlayMetaFile** function plays the contents of the specified metafile on the given device. The metafile can be played any number of times.

Parameter	Description
hdc	Identifies the device context of the output device.
hmf	Identifies the metafile to be played.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Example
The following example uses the **CreateMetaFile** function to create a device-context handle of a memory metafile, draws a line in the device context, retrieves a metafile handle by calling the **CloseMetaFile** function, plays the metafile by using the **PlayMetaFile** function, and finally deletes the metafile by using the **DeleteMetaFile** function:

```
HDC hdcMeta;
HMETAFILE hmf;

hdcMeta = CreateMetaFile(NULL);
MoveTo(hdcMeta, 10, 10);
LineTo(hdcMeta, 100, 100);
hmf = CloseMetaFile(hdcMeta);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);
```

See Also
PlayMetaFileRecord

PlayMetaFileRecord (2.x)

void PlayMetaFileRecord(*hdc, lpht, lpmr, cHandles***)**

```
HDC hdc;                        /* handle of device context          */
HANDLETABLE FAR* lpht;          /* address of table of object handles */
METARECORD FAR* lpmr;           /* address of metafile record        */
UINT cHandles;                  /* number of handles in table        */
```

The **PlayMetaFileRecord** function plays a metafile record by executing the graphics device interface (**GDI**) function contained in the record.

Parameter	Description
hdc	Identifies the device context of the output device.
lpht	Points to a table of handles associated with the objects (pens, brushes, and so on) in the metafile.
lpmr	Points to the metafile record to be played.
cHandles	Specifies the number of handles in the handle table.

Returns

This function does not return a value.

Comments

An application typically uses this function in conjunction with the **EnumMetafile** function to modify and then play a metafile.

Example

The following example creates a dashed green pen and passes it to the callback function for the **EnumMetaFile** function. If the first element in the array of object handles contains a handle, that handle is replaced by the handle of the green pen before the **PlayMetaFileRecord** function is called. (For this example, it is assumed that the table of object handles contains only one handle and that it is a pen handle.)

```
MFENUMPROC lpEnumMetaProc;
HPEN hpenGreen;

lpEnumMetaProc = (MFENUMPROC) MakeProcInstance(
    (FARPROC) EnumMetaFileProc, hAppInstance);
hpenGreen = CreatePen(PS_DASH, 1, RGB(0, 255, 0));
EnumMetaFile(hdc, hmf, lpEnumMetaProc, (LPARAM) &hpenGreen);
FreeProcInstance((FARPROC) lpEnumMetaProc);
DeleteObject(hpenGreen);
    .
    .
    .

int FAR PASCAL EnumMetaFileProc(HDC hdc, HANDLETABLE FAR* lpHTable,
    METARECORD FAR* lpMFR, int cObj, BYTE FAR* lpClientData)
{
    if (lpHTable->objectHandle[0] != 0)
        lpHTable->objectHandle[0] = *(HPEN FAR *) lpClientData;
    PlayMetaFileRecord(hdc, lpHTable, lpMFR, cObj);

    return 1;
}
```

EnumMetafile, **PlayMetaFile**

Polygon (2.x)

BOOL Polygon(*hdc, lppt, cPoints***)**

HDC *hdc;*	/* handle of device context */
const POINT FAR* *lppt;*	/* address of array with points for vertices */
int *cPoints;*	/* number of points in array */

The **Polygon** function draws a polygon consisting of two or more points (vertices) connected by lines. The system closes the polygon automatically, if necessary, by drawing a line from the last vertex to the first. Polygons are surrounded by a frame drawn by using the current pen and filled by using the current brush.

Parameter	Description
hdc	Identifies the device context.
lppt	Points to an array of **POINT** structures that specify the vertices of the polygon. Each structure in the array specifies a vertex.
cPoints	Specifies the number of vertices in the array.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The current polygon-filling mode can be retrieved or set by using the **GetPolyFillMode** and **SetPolyFillMode** functions.

Example

The following example assigns values to an array of points and then calls the **Polygon** function:

```
HDC hdc;

POINT aPoints[3];

aPoints[0].x = 50;
aPoints[0].y = 10;
aPoints[1].x = 250;
aPoints[1].y = 50;
aPoints[2].x = 125;
aPoints[2].y = 130;

Polygon(hdc, aPoints, sizeof(aPoints) / sizeof(POINT));
```

See Also

GetPolyFillMode, **Polyline**, **PolyPolygon**, **SetPolyFillMode**, **POINT**

Polyline (2.x)

BOOL Polyline(*hdc, lppt, cPoints***)**

```
HDC hdc;                    /* handle of device context                 */
const POINT FAR* lppt;      /* address of array with points to connect */
int cPoints;                /* number of points in array                */
```

The **Polyline** function draws a set of line segments, connecting the specified points. The lines are drawn from the first point through subsequent points, using the current pen. Unlike the **LineTo** function, the **Polyline** function neither uses nor updates the current position.

Parameter	Description
hdc	Identifies the device context.
lppt	Points to an array of **POINT** structures. Each structure in the array specifies a point.
cPoints	Specifies the number of points in the array. This value must be at least 2.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Example
The following example assigns values to an array of points and then calls the **Polyline** function:

```
HDC hdc;

POINT aPoints[3];

aPoints[0].x = 50;
aPoints[0].y = 10;
aPoints[1].x = 250;
aPoints[1].y = 50;
aPoints[2].x = 125;
aPoints[2].y = 130;

Polyline(hdc, aPoints, sizeof(aPoints) / sizeof(POINT));
```

See Also
LineTo, **Polygon**, **POINT**

PolyPolygon (3.0)

BOOL PolyPolygon(*hdc, lppt, lpnPolyCounts, cPolygons***)**

HDC *hdc;*	/* handle of device context */
const POINT FAR* *lppt;*	/* address of array with vertices */
int FAR* *lpnPolyCounts;*	/* address of array with point counts */
int *cPolygons;*	/* number of polygons to draw */

The **PolyPolygon** function creates two or more polygons that are filled by using the current polygon-filling mode. The polygons may be disjoint or overlapping.

Parameter	Description
hdc	Identifies the device context.
lppt	Points to an array of **POINT** structures. Each structure in the array specifies a vertext of a polygon.
lpnPolyCounts	Points to an array of integers, each of which specifies the number of points in one of the polygons in the array pointed to by the *lppt* parameter.
cPolygons	Specifies the number of polygons to be drawn. This value must be at least 2.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

Each polygon specified in a call to the **PolyPolygon** function must be closed. Unlike polygons created by the **Polygon** function, the polygons created by **PolyPolygon** are not closed automatically.

The **PolyPolygon** function creates two or more polygons. To create a single polygon, an application should use the **Polygon** function.

The current polygon-filling mode can be retrieved or set by using the **GetPolyFillMode** and **SetPolyFillMode** functions.

Example

The following example draws two overlapping polygons by assigning values to an array of points and then calling the **PolyPolygon** function:

```
HDC hdc;

POINT aPolyPoints[8];
int aVertices[] = { 4, 4 };

aPolyPoints[0].x = 50;
aPolyPoints[0].y = 10;
aPolyPoints[1].x = 250;
aPolyPoints[1].y = 50;
aPolyPoints[2].x = 125;
aPolyPoints[2].y = 130;
aPolyPoints[3].x = 50;
aPolyPoints[3].y = 10;

aPolyPoints[4].x = 100;
aPolyPoints[4].y = 25;
aPolyPoints[5].x = 300;
aPolyPoints[5].y = 125;
aPolyPoints[6].x = 70;
aPolyPoints[6].y = 150;
aPolyPoints[7].x = 100;
```

```
aPolyPoints[7].y = 25;

PolyPolygon(hdc, aPolyPoints, aVertices,
    sizeof(aVertices) / sizeof(int));
```

PtInRegion (2.x)

BOOL PtInRegion(*hrgn, nXPos, nYPos***)**

HRGN *hrgn;* /* handle of region */
int *nXPos;* /* x-coordinate of point */
int *nYPos;* /* y-coordinate of point */

The **PtInRegion** function determines whether a specified point is in the given region.

Parameter	Description
hrgn	Identifies the region to be examined.
nXPos	Specifies the logical x-coordinate of the point.
nYPos	Specifies the logical y-coordinate of the point.

Returns
The return value is nonzero if the point is in the region. Otherwise, it is zero.

Example
The following example uses the **PtInRegion** function to determine whether the point (50, 50) is in the specified region and prints the result:

```
HRGN hrgn;
BOOL fPtIn;
LPSTR lpszInRegion = "Specified point is in region.";
LPSTR lpszNotInRegion = "Specified point is not in region.";

fPtIn = PtInRegion(hrgn, 50, 50);
if (!fPtIn)
    TextOut(hdc, 10, 10, lpszNotInRegion,
        lstrlen(lpszNotInRegion));
else
    TextOut(hdc, 10, 10, lpszInRegion, lstrlen(lpszInRegion));
```

See Also
RectInRegion

PtVisible (2.x)

BOOL PtVisible(*hdc, nXPos, nYPos***)**

HDC *hdc;* /* handle of device context */
int *nXPos;* /* x-coordinate of point to query */
int *nYPos;* /* y-coordinate of point to query */

The **PtVisible** function determines whether the specified point is within the clipping region of the given device context.

Parameter	Description
hdc	Identifies the device context.
nXPos	Specifies the logical x-coordinate of the point.
nYPos	Specifies the logical y-coordinate of the point.

Returns
The return is nonzero if the point is within the clipping region. Otherwise, it is zero.

Example
The following example creates a rectangular region, displays a message inside it, and selects the region as the clipping region. The **PtVisible** function is used to determine whether coordinates generated by a double-click are inside the region. If so, the message changes to "Thank you." If not, the **CombineRgn** function is used to create a clipping region that combines the first region with a new region that surrounds the specified coordinates, and the word "Missed!" is displayed at the coordinates.

```
HDC hdcLocal;
HRGN hrgnClick, hrgnMiss, hrgnCombine;
HBRUSH hbr;

hdcLocal = GetDC(hwnd);
hbr = GetStockObject(BLACK_BRUSH);

hrgnClick = CreateRectRgn(90, 95, 225, 120);
FrameRgn(hdcLocal, hrgnClick, hbr, 1, 1);
TextOut(hdcLocal, 100, 100, "Double-click here.", 18);
SelectClipRgn(hdcLocal, hrgnClick);

if (PtVisible(hdcLocal, XClick, YClick)) {
    PaintRgn(hdcLocal, hrgnClick);
    FrameRgn(hdcLocal, hrgnClick, hbr, 1, 1);
    TextOut(hdcLocal, 100, 100, "Thank you.", 10);
}
else if (XClick > 0) {
    hrgnMiss = CreateRectRgn(XClick - 5, YClick - 5, XClick + 60,
        YClick + 20);
    hrgnCombine = CreateRectRgn(0, 0, 0, 0);
    CombineRgn(hrgnCombine, hrgnClick, hrgnMiss, RGN_OR);
    SelectClipRgn(hdcLocal, hrgnCombine);
    FrameRgn(hdcLocal, hrgnCombine, hbr, 1, 1);
    TextOut(hdcLocal, XClick, YClick, "Missed!", 7);
}

InvalidateRect(hwnd, NULL, FALSE);

DeleteObject(hrgnClick);
DeleteObject(hrgnMiss);
```

```
DeleteObject(hrgnCombine);
ReleaseDC(hwnd, hdcLocal);
```

QueryAbort (3.1)

BOOL QueryAbort(*hdc, reserved***)**

```
HDC hdc;        /* device-context handle   */
int reserved;   /* reserved; must be zero */
```

The **QueryAbort** function calls the **AbortProc** callback function for a printing application and queries whether the printing should be terminated.

Parameter	Description
hdc	Identifies the device context.
reserved	Reserved; must be zero.

Returns

The return value is TRUE if printing should continue or if there is no abort procedure. It is FALSE if the print job should be terminated. The return value is supplied by the **AbortProc** callback function.

See Also

AbortDoc, **AbortProc**, **SetAbortProc**

Rectangle (2.x)

BOOL Rectangle(*hdc, nLeftRect, nTopRect, nRightRect, nBottomRect***)**

HDC *hdc;* /* handle of device context */
int *nLeftRect;* /* x-coordinate upper-left corner */
int *nTopRect;* /* y-coordinate upper-left corner */
int *nRightRect;* /* x-coordinate lower-right corner */
int *nBottomRect;* /* y-coordinate lower-right corner */

The **Rectangle** function draws a rectangle, using the current pen. The interior of the rectangle is filled by using the current brush.

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the rectangle.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the rectangle.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the rectangle.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the rectangle.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
The figure this function draws extends up to, but does not include, the right and bottom coordinates. This means that the height of the figure is *nBottomRect - nTopRect* and the width of the figure is *nRightRect - nLeftRect.*

Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.

Example
The following example uses a **RECT** structure to store the coordinates used by the **Rectangle** function:

```
HDC hdc;

RECT rc = { 10, 10, 180, 140 };
Rectangle(hdc, rc.left, rc.top,
    rc.right, rc.bottom);
```

See Also
PolyLine, **RoundRect**, **RECT**

RectInRegion (3.0)

BOOL RectInRegion(*hrgn, lprc***)**

HRGN *hrgn;* /* handle of region */
const RECT FAR* *lprc;* /* address of structure with rectangle */

The **RectInRegion** function determines whether any part of the specified rectangle is within the boundaries of the given region.

Parameter	Description
hrgn	Identifies the region.
lprc	Points to a **RECT** structure containing the coordinates of the rectangle.

Returns

The return value is nonzero if any part of the specified rectangle lies within the boundaries of the region. Otherwise, it is zero.

Example

The following example uses the **RectInRegion** function to determine whether a specified rectangle is in a region and prints the result:

```
HRGN hrgn;
RECT rc = { 100, 10, 130, 50 };
BOOL fRectIn;
LPSTR lpszOverlap = "Some overlap between rc and region.";
LPSTR lpszNoOverlap = "No common points in rc and region.";

fRectIn = RectInRegion(hrgn, &rc);
if (!fRectIn)
    TextOut(hdc, 10, 10, lpszNoOverlap, lstrlen(lpszNoOverlap));
else
    TextOut(hdc, 10, 10, lpszOverlap, lstrlen(lpszOverlap));
```

See Also

PtInRegion, **RECT**

RectVisible (2.x)

BOOL RectVisible(*hdc, lprc***)**

HDC *hdc;* /* handle of device context */
const RECT FAR* *lprc;* /* address of structure with rectangle */

The **RectVisible** function determines whether any part of the specified rectangle lies within the clipping region of the given device context.

Parameter	Description
hdc	Identifies the device context.
lprc	Points to a **RECT** structure that contains the logical coordinates of the specified rectangle.

Returns

The return value is nonzero if some portion of the rectangle is within the clipping region. Otherwise, it is zero.

Example

The following example paints a clipping region yellow by painting the client area. The **RectVisible** function is called to determine whether a specified rectangle overlaps the clipping region. If there is some overlap, the rectangle is filled by using a red brush. If there is no overlap, text is displayed inside the clipping region. In this case, the rectangle and the region do not overlap, even though they both specify 110 as a boundary on the y-axis, because regions are defined as including the pixels up to but not including the specified right and bottom coordinates.

```
RECT rc, rcVis;
HRGN hrgn;
HBRUSH hbrRed, hbrYellow;

GetClientRect(hwnd, &rc);
hrgn = CreateRectRgn(10, 10, 310, 110);
SelectClipRgn(hdc, hrgn);

hbrYellow = CreateSolidBrush(RGB(255, 255, 0));
FillRect(hdc, &rc, hbrYellow);

SetRect(&rcVis, 10, 110, 310, 300);
if (RectVisible(hdc, &rcVis)) {
    hbrRed = CreateSolidBrush(RGB(255, 0, 0));
    FillRect(hdc, &rcVis, hbrRed);
    DeleteObject(hbrRed);
}
else {
    SetBkColor(hdc, RGB(255, 255, 0));
    TextOut(hdc, 20, 50, "Rectangle outside clipping region.", 34);
}

DeleteObject(hbrYellow);
DeleteObject(hrgn);
```

See Also

CreateRectRgn, **PtVisible**, **SelectClipRgn**, **RECT**

RemoveFontResource (2.x)

BOOL RemoveFontResource(*lpszFile***)**

LPCSTR *lpszFile;* /* address of string for filename */

The **RemoveFontResource** function removes an added font resource from the specified file or from the Windows font table.

Parameter	Description
lpszFile	Points to a string that names the font resource file or contains a handle of a loaded module. If this parameter points to the font resource file, the string must be null-terminated and have the MS-DOS filename format. If the parameter contains a handle, the handle must be in the low-order word and the high-order word must be zero.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

Any application that adds or removes fonts from the Windows font table should send a **WM_FONTCHANGE** message to all top-level windows in the system by using the **SendMessage** function with the *hwnd* parameter set to 0xFFFF.

In some cases, the **RemoveFontResource** function may not remove the font resource immediately. If there are outstanding references to the resource, it remains loaded until the last logical font using it has been removed (deleted) by using the **DeleteObject** function.

Example

The following example uses the **AddFontResource** function to add a font resource from a file, notifies other applications by using the **SendMessage** function, then removes the font resource by calling the **RemoveFontResource** function:

```
AddFontResource("fontres.fon");
SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0);
    .
    . /* Work with the font. */
    .
if (RemoveFontResource("fontres.fon")) {
    SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0);
    return TRUE;
}
else
    return FALSE;
```

See Also

AddFontResource, **DeleteObject**, **SendMessage**

ResetDC (3.1)

#include <print.h>

HDC ResetDC(*hdc, lpdm***)**

HDC *hdc;* /* handle of device context */
const DEVMODE FAR* *lpdm;* /* address of DEVMODE structure*/

The **ResetDC** function updates the given device context, based on the information in the specified **DEVMODE** structure.

Parameter	Description
hdc	Identifies the device context to be updated.
lpdm	Points to a **DEVMODE** structure containing information about the new device context.

Returns

The return value is the handle of the original device context if the function is successful. Otherwise, it is NULL.

Comments

An application will typically use the **ResetDC** function when a window receives a **WM_DEVMODECHANGE** message. **ResetDC** can also be used to change the paper orientation or paper bins while printing a document.

The **ResetDC** function cannot be used to change the driver name, device name or the output port. When the user changes the port connection or device name, the application must delete the original device context and create a new device context with the new information.

Before calling **ResetDC**, the application must ensure that all objects (other than stock objects) that had been selected into the device context have been selected out.

See Also

DeviceCapabilities, **Escape**, **ExtDeviceMode**, **DEVMODE**, **WM_DEVMODECHANGE**

ResizePalette (3.0)

BOOL ResizePalette(*hpal, cEntries***)**

```
HPALETTE hpal;      /* handle of palette                        */
UINT cEntries;      /* number of palette entries after resizing */
```

The **ResizePalette** function changes the size of the given logical palette.

Parameter	Description
hpal	Identifies the palette to be changed.
cEntries	Specifies the number of entries in the palette after it has been resized.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

If an application calls the **ResizePalette** function to reduce the size of the palette, the entries remaining in the resized palette are unchanged. If the application calls **ResizePalette** to enlarge the palette, the additional palette entries are set to black (the red, green, and blue values are all zero) and the flags for all additional entries are set to zero.

RestoreDC (2.x)

BOOL RestoreDC(*hdc, nSavedDC***)**

HDC *hdc;* /* handle of device context */
int *nSavedDC;* /* integer identifying device context to restore */

The **RestoreDC** function restores the given device context to a previous state. The device context is restored by popping state information off a stack created by earlier calls to the **SaveDC** function.

Parameter	Description
hdc	Identifies the device context.
nSavedDC	Specifies the device context to be restored. This parameter can be a value returned by a previous **SaveDC** function. If the parameter is -1, the most recently saved device context is restored.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
The stack can contain the state information for several instances of the device context. If the context specified by the *nSavedDC* parameter is not at the top of the stack, **RestoreDC** deletes all state information between the instance specified by *nSavedDC* and the top of the stack.

Example
The following example uses the **GetMapMode** function to retrieve the mapping mode for the current device context, uses the **SaveDC** function to save the state of the device context, changes the mapping mode, restores the previous state of the device context by using the **RestoreDC** function, and retrieves the mapping mode again. The final mapping mode is the same as the mapping mode prior to the call to the **SaveDC** function.

```
HDC hdcLocal;
int MapMode;
char *aModes[] = {"ZERO", "MM_TEXT", "MM_LOMETRIC", "MM_HIMETRIC",
    "MM_LOENGLISH", "MM_HIENGLISH", "MM_TWIPS",
    "MM_ISOTROPIC", "MM_ANISOTROPIC" };

hdcLocal = GetDC(hwnd);
MapMode = GetMapMode(hdcLocal);
TextOut(hdc, 100, 100, (LPSTR) aModes[MapMode],
    lstrlen(aModes[MapMode]));

SaveDC(hdcLocal);

SetMapMode(hdcLocal, MM_LOENGLISH);
MapMode = GetMapMode(hdcLocal);
TextOut(hdc, 100, 120, (LPSTR) aModes[MapMode],
    lstrlen(aModes[MapMode]));

RestoreDC(hdcLocal, -1);

MapMode = GetMapMode(hdcLocal);
TextOut(hdc, 100, 140, (LPSTR) aModes[MapMode],
    lstrlen(aModes[MapMode]));

ReleaseDC(hwnd, hdcLocal);
```

See Also

SaveDC

RoundRect (2.x)

BOOL RoundRect(*hdc, nLeftRect, nTopRect, nRightRect, nBottomRect, nEllipseWidth, nEllipseHeight***)**

```
HDC hdc;            /* handle of device context            */
int nLeftRect;      /* x-coordinate upper-left corner      */
int nTopRect;       /* y-coordinate upper-left corner      */
int nRightRect;     /* x-coordinate lower-right corner     */
int nBottomRect;    /* y-coordinate lower-right corner     */
int nEllipseWidth;  /* width of ellipse for rounded corners */
int nEllipseHeight; /* height of ellipse for rounded corners */
```

The **RoundRect** function draws a rectangle with rounded corners, using the current pen. The interior of the rectangle is filled by using the current brush.

Parameter	Description
hdc	Identifies the device context.
nLeftRect	Specifies the logical x-coordinate of the upper-left corner of the rectangle.
nTopRect	Specifies the logical y-coordinate of the upper-left corner of the rectangle.
nRightRect	Specifies the logical x-coordinate of the lower-right corner of the rectangle.
nBottomRect	Specifies the logical y-coordinate of the lower-right corner of the rectangle.
nEllipseWidth	Specifies the width, in logical units, of the ellipse used to draw the rounded corners.
nEllipseHeight	Specifies the height, in logical units, of the ellipse used to draw the rounded corners.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The figure this function draws extends up to but does not include the right and bottom coordinates. This means that the height of the figure is *nBottomRect* - *nTopRect* and the width of the figure is *nRightRect* - *nLeftRect.*

Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.

Example

The following example uses a **RECT** structure to store the coordinates used by the **RoundRect** function:

```
HDC hdc;

RECT rc = { 10, 10, 180, 140 };
int iEllipseWidth, iEllipseHeight;

iEllipseWidth = 20;
iEllipseHeight = 40;

RoundRect(hdc, rc.left, rc.top, rc.right, rc.bottom,
    iEllipseWidth, iEllipseHeight);
```

See Also

Rectangle, **RECT**

SaveDC (2.x)

int SaveDC(*hdc***)**

HDC *hdc;* /* handle of device context */

The **SaveDC** function saves the current state of the given device context by copying state information (such as clipping region, selected objects, and mapping mode) to a context stack. The saved device context can later be restored by using the **RestoreDC** function.

Parameter	Description
hdc	Identifies the device context to be saved.

Returns

The return value is an integer identifying the saved device context if the function is successful. This integer can be used to restore the device context by calling the **RestoreDC** function. The return value is zero if an error occurs.

Comments

The **SaveDC** function can be used any number of times to save any number of device-context states.

Example

The following example uses the **GetMapMode** function to retrieve the mapping mode for the current device context, uses the **SaveDC** function to save the state of the device context, changes the mapping mode, restores the previous state of the device context by using the **RestoreDC** function, and retrieves the mapping mode again. The final mapping mode is the same as the mapping mode prior to the call to the **SaveDC** function.

```
HDC hdcLocal;
int MapMode;
char *aModes[] = {"ZERO", "MM_TEXT", "MM_LOMETRIC", "MM_HIMETRIC",
    "MM_LOENGLISH", "MM_HIENGLISH", "MM_TWIPS",
    "MM_ISOTROPIC", "MM_ANISOTROPIC" };

hdcLocal = GetDC(hwnd);
MapMode = GetMapMode(hdcLocal);
TextOut(hdc, 100, 100, (LPSTR) aModes[MapMode],
    lstrlen(aModes[MapMode]));

SaveDC(hdcLocal);

SetMapMode(hdcLocal, MM_LOENGLISH);
MapMode = GetMapMode(hdcLocal);
TextOut(hdc, 100, 120, (LPSTR) aModes[MapMode],
    lstrlen(aModes[MapMode]));

RestoreDC(hdcLocal, -1);

MapMode = GetMapMode(hdcLocal);
TextOut(hdc, 100, 140, (LPSTR) aModes[MapMode],
    lstrlen(aModes[MapMode]));

ReleaseDC(hwnd, hdcLocal);
```

RestoreDC

ScaleViewportExt (2.x)

DWORD ScaleViewportExt(*hdc, nXNum, nXDenom, nYNum, nYDenom***)**

```
HDC hdc;        /* handle of device context                          */
int nXNum;      /* amount by which current x-extent is multiplied    */
int nXDenom;    /* amount by which current x-extent is divided       */
int nYNum;      /* amount by which current y-extent is multiplied    */
int nYDenom;    /* amount by which current y-extent is divided       */
```

The **ScaleViewportExt** function modifies the viewport extents relative to the current values.

Parameter	Description
hdc	Identifies the device context.
nXNum	Specifies the amount by which to multiply the current x-extent.
nXDenom	Specifies the amount by which to divide the result of multiplying the current x-extent by the value of the *nXNum* parameter.
nYNum	Specifies the amount by which to multiply the current y-extent.
nYDenom	Specifies the amount by which to divide the result of multiplying the current y-extent by the value of the *nYNum* parameter.

Returns

The low-order word of the return value contains the x-extent, in device units, of the previous viewport if the function is successful; the high-order word contains the y-extent.

Comments

The new viewport extents are calculated by multiplying the current extents by the given numerator and then dividing by the given denominator, as shown in the following formulas:

```
nXNewVE = (nXOldVE * nXNum) / nXDenom
nYNewVE = (nYOldVE * nYNum) / nYDenom
```

Example

The following example draws a rectangle that is 4 logical units high and 4 logical units wide. It then calls the **ScaleViewportExt** function and draws a rectangle that is 8 units by 8 units. Because of the viewport scaling, the second rectangle is the same size as the first.

```
HDC  hdc;
RECT rc;

GetClientRect(hwnd, &rc);
hdc = GetDC(hwnd);
SetMapMode(hdc, MM_ANISOTROPIC);

SetWindowExt(hdc, 10, 10);
SetViewportExt(hdc, rc.right, rc.bottom);
Rectangle(hdc, 3, 3, 7, 7);

ScaleViewportExt(hdc, 1, 2, 1, 2);
Rectangle(hdc, 6, 6, 14, 14);

ReleaseDC(hwnd, hdc);
```

See Also

GetViewportExt

ScaleViewportExtEx (3.1)

BOOL ScaleViewportExtEx(*hdc, nXnum, nXdenom, nYnum, nYdenom, lpSize***)**

```
HDC hdc;          /* handle of device context                    */
int nXnum;        /* amount by which current x-extent is multiplied */
int nXdenom;      /* amount by which current x-extent is divided */
int nYnum;        /* amount by which current y-extent is multiplied */
int nYdenom;      /* amount by which current y-extent is divided */
SIZE FAR* lpSize; /* address of SIZE structure                   */
```

The **ScaleViewportExtEx** function modifies the viewport extents relative to the current values. The formulas are written as follows:

```
xNewVE = (xOldVE * Xnum) / Xdenom
yNewVE = (yOldVE * Ynum) / Ydenom
```

The new extent is calculated by multiplying the current extents by the given numerator and then dividing by the given denominator.

Parameter	Description
hdc	Identifies the device context.
nXnum	Specifies the amount by which to multiply the current x-extent.
nXdenom	Specifies the amount by which to divide the current x-extent.
nYnum	Specifies the amount by which to multiply the current y-extent.
nYdenom	Specifies the amount by which to divide the current y-extent.
lpSize	Points to a **SIZE** structure. The previous viewport extents, in device units, are placed in this structure. If *lpSize* is NULL, nothing is returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

ScaleWindowExt (2.x)

DWORD ScaleWindowExt(*hdc, nXNum, nXDenom, nYNum, nYDenom***)**

HDC *hdc;* /* handle of device context */
int *nXNum;* /* amount by which current x-extent is multiplied */
int *nXDenom;* /* amount by which current x-extent is divided */
int *nYNum;* /* amount by which current y-extent is multiplied */
int *nYDenom;* /* amount by which current y-extent is divided */

The **ScaleWindowExt** function modifies the window extents relative to the current values.

Parameter	Description
hdc	Identifies the device context.
nXNum	Specifies the amount by which to multiply the current x-extent.
nXDenom	Specifies the amount by which to divide the result of multiplying the current x-extent by the value of the *nXNum* parameter.
nYNum	Specifies the amount by which to multiply the current y-extent.
nYDenom	Specifies the amount by which to divide the result of multiplying the current y-extent by the value of the *nYNum* parameter.

Returns

The low-order word of the return value contains the x-extent, in logical units, of the previous window, if the function is successful; the high-order word contains the y-extent.

Comments

The new window extents are calculated by multiplying the current extents by the given numerator and then dividing by the given denominator, as shown in the following formulas:

```
nXNewWE = (nXOldWE * nXNum) / nXDenom
nYNewWE = (nYOldWE * nYNum) / nYDenom
```

Example

The following example draws a rectangle that is 4 logical units high and 4 logical units wide. It then calls the **ScaleWindowExt** function and draws a rectangle that is 8 units by 8 units. Because of the window scaling, the second rectangle is the same size as the first.

```
HDC  hdc;
RECT rc;

GetClientRect(hwnd, &rc);
hdc = GetDC(hwnd);
SetMapMode(hdc, MM_ANISOTROPIC);

SetWindowExt(hdc, 10, 10);
SetViewportExt(hdc, rc.right, rc.bottom);
Rectangle(hdc, 3, 3, 7, 7);

ScaleWindowExt(hdc, 2, 1, 2, 1);
Rectangle(hdc, 6, 6, 14, 14);

ReleaseDC(hwnd, hdc);
```

See Also

GetWindowExt

ScaleWindowExtEx (3.1)

BOOL ScaleWindowExtEx(*hdc, nXnum, nXdenom, nYnum, nYdenom, lpSize***)**

```
HDC hdc;          /* handle of device context                    */
int nXnum;        /* amount by which current x-extent is multiplied */
int nXdenom;      /* amount by which current x-extent is divided */
int nYnum;        /* amount by which current y-extent is multiplied */
int nYdenom;      /* amount by which current y-extent is divided */
SIZE FAR* lpSize; /* address of SIZE structure                   */
```

The **ScaleWindowExtEx** function modifies the window extents relative to the current values. The formulas are written as follows:

```
xNewWE = (xOldWE * Xnum) / Xdenom
yNewWE = (yOldWE * Ynum) / Ydenom
```

The new extent is calculated by multiplying the current extents by the given numerator and then dividing by the given denominator.

Parameter	Description
hdc	Identifies the device context.
nXnum	Specifies the amount by which to multiply the current x-extent.
nXdenom	Specifies the amount by which to divide the current x-extent.
nYnum	Specifies the amount by which to multiply the current y-extent.
nYdenom	Specifies the amount by which to divide the current y-extent.
lpSize	Points to a **SIZE** structure. The previous window extents, in logical units, are placed in this structure. If *lpSize* is NULL, nothing is returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

SelectClipRgn (2.x)

int SelectClipRgn(*hdc, hrgn***)**

HDC *hdc;* /* handle of device context */
HRGN *hrgn;* /* handle of region */

The **SelectClipRgn** function selects the given region as the current clipping region for the given device context.

Parameter	Description
hdc	Identifies the device context.
hrgn	Identifies the region to be selected. If this value is NULL, the entire client area is selected and output is still clipped to the window.

Returns

The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.

Comments

The **SelectClipRgn** function selects only a copy of the specified region. Because **SelectClipRgn** uses only a copy, the region can be selected for any number of other device contexts or it can be deleted.

The coordinates for the specified region should be specified in device units.

Some printer devices support text output at a higher resolution than graphics output in order to retain the precision needed to express text metrics. These devices report device units at the higher resolution--that is, text units. These devices then scale coordinates for graphics so that several reported device units map to only one graphics unit. Applications should always call the **SelectClipRgn** function using the text unit. Applications that must take the scaling of graphics objects in the graphics device interface (**GDI**) can use the **GETSCALINGFACTOR** printer escape to determine the scaling factor. This scaling factor affects clipping. If a region is used to clip graphics, GDI divides the coordinates by the scaling factor. (If the region is used to clip text, however, GDI makes no scaling adjustment.) A scaling factor of 1 causes the coordinates to be divided by 2; a scaling factor of 2 causes the coordinates to be divided by 4; and so on.

Example

The following example uses the **GetClipBox** function to determine the size of the current clipping region and the **GetTextExtent** function to determine the width of a line of text. If the text will not fit in the clipping region, the **SelectClipRgn** is used to make the region wide enough for the text. The output is clipped to the window regardless of the size of the region specified in the second parameter of **SelectClipRegion**.

```
HRGN hrgnClip;
RECT rcClip;
LPSTR lpszTest = "Test of clipping region.";
DWORD dwStringLen;
WORD wExtent;

GetClipBox(hdc, &rcClip);
dwStringLen = GetTextExtent(hdc, lpszTest, lstrlen(lpszTest));
wExtent = LOWORD(dwStringLen);
if (rcClip.right < 50 + wExtent) {
    hrgnClip = CreateRectRgn(50, 50, 50 + wExtent, 80);
    SelectClipRgn(hdc, hrgnClip);
}
```

```
TextOut(hdc, 50, 60, lpszTest, lstrlen(lpszTest));

DeleteObject(hrgnClip);
```

See Also
GetClipBox, **GetTextExtent**, **GETSCALINGFACTOR**

Changes

SelectObject (2.x)

HGDIOBJ SelectObject(*hdc, hgdiobj***)**

```
HDC hdc;            /* handle of device context */
HGDIOBJ hgdiobj;    /* handle of object         */
```

The **SelectObject** function selects an object into the given device context. The new object replaces the previous object of the same type.

Parameter	Description
hdc	Identifies the device context.
hgdiobj	Identifies the object to be selected. The object can be one of the following and must have been created by using one of the listed functions:

Object	Functions
Bitmap	**CreateBitmap**, **CreateBitmapIndirect**, **CreateCompatibleBitmap**, **CreateDIBitmap**
Brush	**CreateBrushIndirect**, **CreateDIBPatternBrush**, **CreateHatchBrush**, **CreatePatternBrush**, **CreateSolidBrush**
Font	**CreateFont**, **CreateFontIndirect**
Pen	**CreatePen**, **CreatePenIndirect**
Region	**CreateEllipticRgn**, **CreateEllipticRgnIndirect**, **CreatePolygonRgn**, **CreateRoundRectRgn**, **CreateRectRgn**, **CreateRectRgnIndirect**

Returns

The return value is the handle of the object being replaced, if the function is successful. Otherwise, it is NULL.

If the *hgdiobj* parameter identifies a region, this function performs the same task as the **SelectClipRgn** function and the return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty). If an error occurs, the return value is ERROR and the previously selected object of the specified type remains selected in the device context.

Comments

When an application uses the **SelectObject** function to select a font, pen, or brush, the system allocates space for that object in its data segment. Because data-segment space is limited, an application should use the **DeleteObject** function to remove each drawing object that it no longer requires. Before removing the object, the application should select it out of the device context. To do this, the application can select a different object of the same type back into the device context; typically, this different object is the original object for the device context.

When the *hdc* parameter identifies a metafile device context, the **SelectObject** function does not return the handle of the previously selected object. When the device context is a metafile, calling **SelectObject** with the *hgdiobj* parameter set to a value returned by a previous call to **SelectObject** can cause unpredictable results. Because metafiles perform their own object cleanup, an application need not reselect default objects when recording a metafile.

Memory device contexts are the only device contexts into which an application can select a bitmap. A bitmap can be selected into only one memory device context at a time. The format of the bitmap must either be monochrome or be compatible with the given device; if it is not, **SelectObject** returns an error.

Example

The following example creates a pen, uses the **SelectObject** function to select it into a device context, uses the pen to draw a rectangle, selects the previous pen back into the device context, and uses the

DeleteObject function to remove the pen that was just created:

```
HPEN hpen, hpenOld;

hpen = CreatePen(PS_SOLID, 6, RGB(0, 0, 255));
hpenOld = SelectObject(hdc, hpen);

Rectangle(hdc, 10, 10, 100, 100);

SelectObject(hdc, hpenOld);
DeleteObject(hpen);
```

See Also
DeleteObject, **SelectClipRgn**, **SelectPalette**

Changes

For Windows 3.1, the **SelectObject** function returns the same value whether or not it is used in a metafile. Under previous versions of Windows, the **SelectObject** function returned a nonzero value for success and zero for failure when it was used in a metafile.

SetAbortProc (3.1)

int SetAbortProc(*hdc, abrtprc***)**

HDC *hdc;* /* handle of device context */
ABORTPROC *abrtprc;* /* instance address of abort function */

The **SetAbortProc** function sets the application-defined procedure that allows a print job to be canceled during spooling. This function replaces the SETABORTPROC printer escape for Windows version 3.1.

Parameter	Description
hdc	Identifies the device context for the print job.
abrtprc	Specifies the procedure-instance address of the callback function. The address must have been created by using the **MakeProcInstance** function. For more information about the callback function, see the description of the **AbortProc** callback function.

Returns

The return value is greater than zero if the function is successful. Otherwise, it is less than zero.

See Also

AbortDoc, **AbortProc**, **Escape**

SetBitmapBits (2.x)

LONG SetBitmapBits(*hbmp, cBits, lpvBits***)**

```
HBITMAP hbmp;          /* handle of bitmap                  */
DWORD cBits;           /* number of bytes in bitmap array   */
const void FAR* lpvBits;  /* address of array with bitmap bits */
```

The **SetBitmapBits** function sets the bits of the given bitmap, to the specified bit values.

Parameter	Description
hbmp	Identifies the bitmap to be set.
cBits	Specifies the number of bytes pointed to by the *lpvBits* parameter.
lpvBits	Points to an array of bytes for the bitmap bits.

Returns

The return value is the number of bytes used in setting the bitmap bits, if the function is successful. Otherwise, the return value is zero.

See Also

GetBitmapBits

SetBitmapDimension (2.x)

DWORD SetBitmapDimension(*hbmp, nWidth, nHeight***)**

```
HBITMAP hbmp;       /* handle of bitmap */
int nWidth;         /* bitmap width     */
int nHeight;        /* bitmap height    */
```

The **SetBitmapDimension** function assigns a width and height to a bitmap, in 0.1-millimeter units. The graphics device interface (**GDI**) does not use these values except to return them when an application calls the **GetBitmapDimension** function.

Parameter	Description
hbmp	Identifies the bitmap.
nWidth	Specifies the bitmap width, in 0.1-millimeter units.
nHeight	Specifies the bitmap height, in 0.1-millimeter units.

Returns

The return value is the dimensions of the previous bitmap, in 0.1-millimeter units, if the function is successful. The low-order word contains the previous width; the high-order word contains the previous height.

See Also

GetBitmapDimension

SetBitmapDimensionEx (3.1)

BOOL SetBitmapDimensionEx(*hbm, nX, nY, lpSize***)**

```
HBITMAP hbm;        /* handle of bitmap                        */
int nX;             /* bitmap width                            */
int nY;             /* bitmap height                           */
SIZE FAR* lpSize;   /* address of structure for prev. dimensions */
```

The **SetBitmapDimensionEx** function assigns the preferred size to a bitmap, in 0.1-millimeter units. The graphics device interface (**GDI**) does not use these values, except to return them when an application calls the **GetBitmapDimensionEx** function.

Parameter	Description
hbm	Identifies the bitmap.
nX	Specifies the width of the bitmap, in 0.1-millimeter units.
nY	Specifies the height of the bitmap, in 0.1-millimeter units.
lpSize	Points to a **SIZE** structure. The previous bitmap dimensions are placed in this structure. If *lpSize* is NULL, nothing is returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also

GetBitmapDimensionEx, **SIZE**

SetBkColor (2.x)

COLORREF SetBkColor(*hdc, clrref***)**

HDC *hdc;* /* handle of device context */
COLORREF *clrref;* /* color specification */

The **SetBkColor** function sets the current background color to the specified color.

Parameter	Description
hdc	Identifies the device context.
clrref	Specifies the new background color.

Returns

The return value is the **RGB** value of the previous background color, if the function is successful. The return value is 0x80000000 if an error occurs.

Comments

If the background mode is **OPAQUE**, the system uses the background color to fill the gaps in styled lines, the gaps between hatched lines in brushes, and the background in character cells. The system also uses the background color when converting bitmaps between color and monochrome device contexts.

If the device cannot display the specified color, the system sets the background color to the nearest physical color.

Example

The following example uses the **GetBkColor** function to determine whether the current background color is white. If it is, the **SetBkColor** function sets it to red.

```
DWORD dwBackColor;

dwBackColor = GetBkColor(hdc);
if (dwBackColor == RGB(255, 255, 255)) { /* if color is white */
    SetBkColor(hdc, RGB(255, 0, 0));     /* sets color to red */
    TextOut(hdc, 100, 200, "SetBkColor test.", 16);
}
```

See Also

BitBlt, **GetBkColor**, **GetBkMode**, **SetBkMode**, **StretchBlt**, **RGB**

SetBkMode (2.x)

int SetBkMode(*hdc, fnBkMode***)**

HDC *hdc;* /* handle of device context */
int *fnBkMode;* /* background mode */

The **SetBkMode** function sets the specified background mode. The background mode defines whether the system removes existing background colors on the drawing surface before drawing text, hatched brushes, or any pen style that is not a solid line.

Parameter	Description
hdc	Identifies the device context.
fnBkMode	Specifies the background mode to be set. This parameter can be one of the following values:

Value	Meaning
OPAQUE	Background is filled with the current background color before the text, hatched brush, or pen is drawn. This is the default background mode.
TRANSPARENT	Background is not changed before drawing.

Returns
The return value is the previous background mode, if the function is successful.

Example
The following example determines the current background mode by calling the **GetBkMode** function. If the mode is **OPAQUE**, the **SetBkMode** function sets it to TRANSPARENT.

```
int nBackMode;

nBackMode = GetBkMode(hdc);
if (nBackMode == OPAQUE) {
    TextOut(hdc, 90, 100, "This background mode is OPAQUE.", 31);
    SetBkMode(hdc, TRANSPARENT);
}
```

See Also
GetBkColor, **GetBkMode**, **SetBkColor**

OPAQUE 2

Background is filled with the current background color before the text, hatched brush, or pen is drawn. This is the default background mode.

OPAQUE 2

TRANSPARENT 1

Background is not changed before drawing.

TRANSPARENT 1

SetBoundsRect (3.1)

UINT SetBoundsRect(*hdc, lprcBounds, flags***)**

```
HDC hdc;                        /* handle of device context          */
const RECT FAR* lprcBounds;     /* address of structure for rectangle */
UINT flags;                     /* specifies information to return   */
```

The **SetBoundsRect** function controls the accumulation of bounding-rectangle information for the specified device context.

Parameter	Description
hdc	Identifies the device context to accumulate bounding rectangles for.
lprcBounds	Points to a **RECT** structure that is used to set the bounding rectangle. Rectangle dimensions are given in logical coordinates. This parameter can be NULL.
flags	Specifies how the new rectangle will be combined with the accumulated rectangle. This parameter may be a combination of the following values:

Value	Meaning
DCB_ACCUMULATE	Add the rectangle specified by the *lprcBounds* parameter to the bounding rectangle (using a rectangle union operation).
DCB_DISABLE	Turn off bounds accumulation.
DCB_ENABLE	Turn on bounds accumulation. (The default setting for bounds accumulation is disabled.)

Returns

The return value is the current state of the bounding rectangle, if the function is successful. Like the *flags* parameter, the return value can be a combination of DCB_ values, as shown in the following list:

Value	Meaning
DCB_ACCUMULATE	The bounding rectangle is not empty. (This value will always be set.)
DCB_DISABLE	Bounds accumulation is off.
DCB_ENABLE	Bounds accumulation is on.

Comments

Windows can maintain a bounding rectangle for all drawing operations. This rectangle can be queried and reset by the application. The drawing bounds are useful for invalidating bitmap caches.

GetBoundsRect

Changes

SetBrushOrg (2.x)

DWORD SetBrushOrg(*hdc, nXOrg, nYOrg***)**

HDC *hdc;* /* handle of device context */
int *nXOrg;* /* x-coordinate of new origin */
int *nYOrg;* /* y-coordinate of new origin */

The **SetBrushOrg** function specifies the origin that **GDI** will assign to the next brush an application selects into the specified device context.

Parameter	Description
hdc	Identifies the device context.
nXOrg	Specifies the x-coordinate, in device units, of the new origin. This value must be in the range 0 through 7.
nYOrg	Specifies the y-coordinate, in device units, of the new origin. This value must be in the range 0 through 7.

Returns
The return value is the coordinates, in device units, of the previous origin, if the function is successful. The low-order word contains the x-coordinate; the high-order word contains the y-coordinate.

Comments
The default coordinates for the brush origin are (0, 0).

To alter the origin of a brush, an application should call the **UnrealizeObject** function, specifying the handle of the brush for which the origin will be set; call **SetBrushOrg**; and then call the **SelectObject** function to select the brush into the device context.

The **SetBrushOrg** function should not be used with stock objects.

Example
The following example uses the **SetBrushOrg** function to shift the brush origin vertically by 5 pixels:

```
HBRUSH hbr, hbrOld;
SetBkMode(hdc, TRANSPARENT);
hbr = CreateHatchBrush(HS_CROSS, RGB(0, 0, 0));

UnrealizeObject(hbr);
SetBrushOrg(hdc, 0, 0);
hbrOld = SelectObject(hdc, hbr);

Rectangle(hdc, 0, 0, 200, 200);

hbr = SelectObject(hdc, hbrOld);              /* deselects hbr */
UnrealizeObject(hbr);  /* resets origin next time hbr selected */
SetBrushOrg(hdc, 3, 5);
hbrOld = SelectObject(hdc, hbr);          /* selects hbr again */

Rectangle(hdc, 0, 0, 200, 200);

SelectObject(hdc, hbrOld);
DeleteObject(hbr);
```

See Also
GetBrushOrg, **SelectObject**, **UnrealizeObject**, **HIWORD**, **LOWORD**

Corrections

The function purpose statement was incorrect. **SetBrushOrg** does not alter the origin of the current brush in a device context; instead, it sets the origin for the next brush to be selected into the device context. The original purpose statement read as follows: "The SetBrushOrg function sets the origin of the current brush for the specified device context."

SetDIBits (3.0)

int SetDIBits(*hdc, hbmp, uStartScan, cScanLines, lpvBits, lpbmi, fuColorUse***)**

```
HDC hdc;                        /* handle of device context              */
HBITMAP hbmp;                   /* handle of bitmap                      */
UINT uStartScan;                /* starting scan line                    */
UINT cScanLines;                /* number of scan lines                  */
const void FAR* lpvBits;        /* address of array with bitmap bits     */
BITMAPINFO FAR* lpbmi;          /* address of structure with bitmap data */
UINT fuColorUse;                /* type of color indices to use          */
```

The **SetDIBits** function sets the bits of a bitmap to the values given in a device-independent bitmap (DIB) specification.

Parameter	Description
hdc	Identifies the device context.
hbmp	Identifies the bitmap to set the data in.
uStartScan	Specifies the zero-based scan number of the first scan line in the buffer pointed to by the *lpvBits* parameter.
cScanLines	Specifies the number of scan lines in the *lpvBits* buffer to copy into the bitmap identified by the *hbmp* parameter.
lpvBits	Points to the device-independent bitmap bits that are stored as an array of bytes. The format of the bitmap values depends on the **biBitCount** member of the **BITMAPINFOHEADER** structure, which is the first member of the **BITMAPINFO** structure pointed to by the *lpbmi* parameter.
lpbmi	Points to a **BITMAPINFO** structure that contains information about the device-independent bitmap.
fuColorUse	Specifies whether the **bmiColors** member of the **BITMAPINFO** structure contains explicit **RGB** values or indices into the currently realized logical palette. This parameter must be one of the following values:

Value	Meaning
DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the palette of the device context identified by the *hdc* parameter.
DIB_RGB_COLORS	The color table contains literal **RGB** values.

Returns

The return value is the number of scan lines copied, if the function is successful. Otherwise, it is zero.

Comments

The bitmap identified by the *hbmp* parameter must not be selected into a device context when the application calls this function.

To reduce the amount of memory required to set bits from a large device-independent bitmap on a device surface, an application can band the output by repeatedly calling the **SetDIBitsToDevice** function, placing a different portion of the entire bitmap into the *lpvBits* buffer each time. The values of the *uStartScan* and *cScanLines* parameters identify the portion of the entire bitmap that is contained in the *lpvBits* buffer.

The origin of a device-independent bitmap is the bottom-left corner of the bitmap, not the top-left corner, which is the origin when the mapping mode is MM_TEXT. **GDI** performs the necessary transformation to display the image correctly.

SetDIBitsToDevice (3.0)

int SetDIBitsToDevice(*hdc, XDest, YDest, cx, cy, XSrc, YSrc, uStartScan, cScanLines, lpvBits, lpbmi, fuColorUse***)**

```
HDC hdc;                    /* handle of device context                */
int XDest;                  /* x-coordinate origin of destination rect */
int YDest;                  /* y-coordinate origin of destination rect */
int cx;                     /* rectangle width                         */
int cy;                     /* rectangle height                        */
int XSrc;                   /* x-coordinate origin of source rect      */
int YSrc;                   /* y-coordinate origin of source rect      */
UINT uStartScan;            /* number of first scan line in array      */
UINT cScanLines;            /* number of scan lines                    */
void FAR* lpvBits;          /* address of array with DIB bits          */
BITMAPINFO FAR* lpbmi;      /* address of structure with bitmap info   */
UINT fuColorUse;            /* RGB or palette indices                  */
```

The **SetDIBitsToDevice** function sets bits from a device-independent bitmap (DIB) directly on a device surface. The device coordinates specified define a rectangle within the total bitmap. **SetDIBitsToDevice** sets the bits in this rectangle directly on the display surface of the output device associated with the given device context, at the specified logical coordinates.

Parameter	Description
hdc	Identifies the device context.
XDest	Specifies the logical x-coordinate of the origin of the destination rectangle.
YDest	Specifies the logical y-coordinate of the origin of the destination rectangle.
cx	Specifies the x-extent, in device units, of the rectangle in the bitmap.
cy	Specifies the y-extent, in device units, of the rectangle in the bitmap.
XSrc	Specifies the x-coordinate, in device units, of the source rectangle in the bitmap.
YSrc	Specifies the y-coordinate, in device units, of the source rectangle in the bitmap.
uStartScan	Specifies the scan-line number of the device-independent bitmap that is contained in the first scan line of the buffer pointed to by the *lpvBits* parameter.
cScanLines	Specifies the number of scan lines in the *lpvBits* buffer to copy to the device.
lpvBits	Points to the DIB bits that are stored as an array of bytes.
lpbmi	Points to a **BITMAPINFO** structure that contains information about the bitmap.
fuColorUse	Specifies whether the **bmiColors** member of the *lpbmi* parameter contains explicit **RGB** values or indices into the currently realized logical palette. This parameter must be one of the following values:

Value	Meaning
DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the currently realized logical palette.
DIB_RGB_COLORS	The color table contains literal **RGB** values.

Returns

The return value is the number of scan lines set, if the function is successful.

Comments

The origin of a device-independent bitmap is the bottom-left corner of the bitmap, not the top-left corner, which is the origin when the mapping mode is MM_TEXT. **GDI** performs the necessary transformation to display the image correctly.

To reduce the amount of memory required to set bits from a large device-independent bitmap on a device surface, an application can band the output by repeatedly calling **SetDIBitsToDevice**, placing a

different portion of the entire bitmap into the *lpvBits* buffer each time. The values of the *uStartScan* and *cScanLines* parameters identify the portion of the entire bitmap that is contained in the *lpvBits* buffer.

See Also
SetDIBits, **BITMAPCOREINFO**, **BITMAPINFO**

SetMapMode (2.x)

int SetMapMode(*hdc, fnMapMode***)**

HDC *hdc;* /* handle of device context */
int *fnMapMode;* /* mapping mode to set */

The **SetMapMode** function sets the mapping mode of the given device context. The mapping mode defines the unit of measure used to convert logical units to device units; it also defines the orientation of the device's x- and y-axes. **GDI** uses the mapping mode to convert logical coordinates into the appropriate device coordinates.

Parameter	Description
hdc	Identifies the device context.
fnMapMode	Specifies the new mapping mode. This parameter can be any one of the following values:

Value	Meaning
MM_ANISOTROPIC	Logical units are converted to arbitrary units with arbitrarily scaled axes. Setting the mapping mode to MM_ANISOTROPIC does not change the current window or viewport settings. To change the units, orientation, and scaling, an application should use the **SetWindowExt** and **SetViewportExt** functions.
MM_HIENGLISH	Each logical unit is converted to 0.001 inch. Positive x is to the right; positive y is up.
MM_HIMETRIC	Each logical unit is converted to 0.01 millimeter. Positive x is to the right; positive y is up.
MM_ISOTROPIC	Logical units are converted to arbitrary units with equally scaled axes; that is, one unit along the x-axis is equal to one unit along the y-axis. The **SetWindowExt** and **SetViewportExt** functions must be used to specify the desired units and the orientation of the axes. **GDI** makes adjustments as necessary to ensure that the x and y units remain the same size.
MM_LOENGLISH	Each logical unit is converted to 0.01 inch. Positive x is to the right; positive y is up.
MM_LOMETRIC	Each logical unit is converted to 0.1 millimeter. Positive x is to the right; positive y is up.
MM_TEXT	Each logical unit is converted to one device pixel. Positive x is to the right; positive y is down.
MM_TWIPS	Each logical unit is converted to 1/20 of a point. (Because a point is 1/72 inch, a twip is 1/1440 inch). Positive x is to the right; positive y is up.

Returns

The return value is the previous mapping mode, if the function is successful.

Comments

The MM_TEXT mode allows applications to work in device pixels, where one unit is equal to one pixel. The physical size of a pixel varies from device to device.

The MM_HIENGLISH, MM_HIMETRIC, MM_LOENGLISH, MM_LOMETRIC, and MM_TWIPS modes are useful for applications that must draw in physically meaningful units (such as inches or millimeters).

The MM_ISOTROPIC mode ensures a 1:1 aspect ratio, which is useful when it is important to preserve

the exact shape of an image.

The MM_ANISOTROPIC mode allows the x- and y-coordinates to be adjusted independently.

Example

The following example uses the **SetMapMode** function to set the mapping mode to MM_TWIPS and then uses the **CreateFont** function to create an 18-point logical font:

```
HFONT hfont, hfontOld;
int MapModePrevious, iPtSize = 18;
PSTR pszFace = "MS Serif";

MapModePrevious = SetMapMode(hdc, MM_TWIPS);
hfont = CreateFont(-iPtSize * 20, 0, 0, 0, 0, /* specify pt size    */
    0, 0, 0, 0, 0, 0, 0, pszFace);          /* and face name only */

hfontOld = SelectObject(hdc, hfont);

TextOut(hdc, 100, -500, pszFace, strlen(pszFace));
SetMapMode(hdc, MapModePrevious);
SelectObject(hdc, hfontOld);
DeleteObject(hfont);
```

See Also

GetMapMode, **SetViewportExt**, **SetWindowExt**

SetMapperFlags (2.x)

DWORD SetMapperFlags(*hdc, fdwMatch***)**

```
HDC hdc;          /* handle of device context */
DWORD fdwMatch;   /* mapper flag              */
```

The **SetMapperFlags** function changes the method used by the font mapper when it converts a logical font to a physical font. An application can use **SetMapperFlags** to cause the font mapper to attempt to choose only a physical font that exactly matches the aspect ratio of the specified device.

Parameter	Description
hdc	Identifies a device context.
fdwMatch	Specifies whether the font mapper attempts to match a font's aspect height and width to the device. When this value is ASPECT_FILTERING, the mapper selects only fonts whose x-aspect and y-aspect exactly match those of the specified device, and the remaining bits are ignored.

Returns

The return value is the previous value of the font-mapper flag, if the function is successful.

Comments

An application that uses only raster fonts can use the **SetMapperFlags** function to ensure that the font selected by the font mapper is attractive and readable on the specified device. Applications that use scalable (TrueType) fonts typically do not use **SetMapperFlags**.

If no physical font has an aspect ratio that matches the specifications in the logical font, **GDI** chooses a new aspect ratio and selects a font that matches this new aspect ratio.

SetMetaFileBits (2.x)

HGLOBAL SetMetaFileBits(*hmf***)**

HMETAFILE *hmf;* /* handle of metafile */

The **SetMetaFileBits** function creates a memory metafile from the data in the given global memory object.

Parameter	Description
hmf	Identifies the global memory object that contains the metafile data. The object must have been created by a previous call to the **GetMetaFileBits** function. Note that this global handle must be cast to an HMETAFILE type to avoid compiler warnings.

Returns

The return value is the handle of a memory metafile, if the function is successful. Otherwise, it is NULL.

Comments

After the **SetMetaFileBits** function returns, the metafile handle it returns must be used instead of the *hmf* handle to refer to the metafile. If **SetMetaFileBits** is successful, the application should not use or free the memory handle specified by the *hmf* parameter, because that handle is reused by Windows.

When the application no longer needs the metafile handle, it should free the handle by calling the **DeleteMetaFile** function.

See Also

GetMetaFileBits, **GlobalFree**, **SetMetaFileBitsBetter**

SetMetaFileBitsBetter (3.1)

HGLOBAL SetMetaFileBitsBetter(*hmf***)**

HMETAFILE *hmf;* /* handle of the metafile */

The **SetMetaFileBitsBetter** function creates a memory metafile from the data in the specified global-memory object.

Parameter	Description
hmf	Identifies the global-memory object that contains the metafile data. The object must have been created by a previous call to the **GetMetaFileBits** function. Note that this global handle must be cast to an HMETAFILE type to avoid compiler warnings.

Returns

The return value is the handle of a memory metafile, if the function is successful. Otherwise, the return value is NULL.

Comments

The global-memory handle returned by **SetMetaFileBitsBetter** is owned by **GDI**, not by the application. This enables applications that use metafiles to support object linking and embedding (OLE) to use metafiles that persist beyond the termination of the application. An OLE application should always use **SetMetaFileBitsBetter** instead of the **SetMetaFileBits** function.

After the **SetMetaFileBitsBetter** function returns, the metafile handle returned by the function should be used to refer to the metafile, instead of the handle identified by the *hmf* parameter.

See Also

GetMetaFileBits, **SetMetaFileBits**

SetPaletteEntries (3.0)

UINT SetPaletteEntries(*hpal, iStart, cEntries, lppe***)**

```
HPALETTE hpal;                          /* handle of palette          */
UINT iStart;                            /* index of first entry to set */
UINT cEntries;                          /* number of entries to set   */
const PALETTEENTRY FAR* lppe;           /* address of array of structures */
```

The **SetPaletteEntries** function sets **RGB** color values and flags in a range of entries in the given logical palette.

Parameter	Description
hpal	Identifies the logical palette.
iStart	Specifies the first logical-palette entry to be set.
cEntries	Specifies the number of logical-palette entries to be set.
lppe	Points to the first member of an array of **PALETTEENTRY** structures containing the **RGB** values and flags.

Returns

The return value is the number of entries set in the logical palette, if the function is successful. Otherwise, it is zero.

Comments

If the logical palette is selected into a device context when the application calls the **SetPaletteEntries** function, the changes will not take effect until the application calls the **RealizePalette** function.

See Also

RealizePalette, **PALETTEENTRY**

SetPixel (2.x)

COLORREF SetPixel(*hdc, nXPos, nYPos, clrref***)**

```
HDC hdc;          /* handle of device context    */
int nXPos;        /* x-coordinate of pixel to set */
int nYPos;        /* y-coordinate of pixel to set */
COLORREF clrref;  /* color of set pixel          */
```

The **SetPixel** function sets the pixel at the specified coordinates to the closest approximation of the given color. The point must be in the clipping region; if it is not, the function does nothing.

Parameter	Description
hdc	Identifies the device context.
nXPos	Specifies the logical x-coordinate of the point to be set.
nYPos	Specifies the logical y-coordinate of the point to be set.
clrref	Specifies the color to be used to paint the point.

Returns

The return value is the **RGB** value for the color the point is painted, if the function is successful. This value can be different from the specified value if an approximation of that color is used. The return value is -1 if the function fails (if the point is outside the clipping region).

Comments

Not all devices support the **SetPixel** function. To discover whether a device supports raster operations, an application can call the **GetDeviceCaps** function using the RC_BITBLT index.

See Also

GetDeviceCaps, **GetPixel**

SetPolyFillMode (2.x)

int SetPolyFillMode(*hdc, fnMode***)**

HDC *hdc;* /* handle of device context */
int *fnMode;* /* polygon-filling mode */

The **SetPolyFillMode** function sets the specified polygon-filling mode.

Parameter	Description
hdc	Identifies the device context.
fnMode	Specifies the new filling mode. This value may be either ALTERNATE or WINDING. The default mode is ALTERNATE.

Returns

The return value specifies the previous filling mode, if the function is successful. Otherwise, it is zero.

Comments

When the polygon-filling mode is ALTERNATE, the system fills the area between odd-numbered and even-numbered polygon sides on each scan line. That is, the system fills the area between the first and second side, between the third and fourth side, and so on.

When the polygon-filling mode is WINDING, the system uses the direction in which a figure was drawn to determine whether to fill an area. Each line segment in a polygon is drawn in either a clockwise or a counterclockwise direction. Whenever an imaginary line drawn from an enclosed area to the outside of a figure passes through a clockwise line segment, a count is incremented (increased by one); when the line passes through a counterclockwise line segment, the count is decremented (decreased by one). The area is filled if the count is nonzero when the line reaches the outside of the figure.

Example

The following example uses winding mode to draw the same figure twice. The figure is a rectangle that completely encloses a triangle. The first time the figure is drawn, both the rectangle and the triangle are drawn clockwise, and both the rectangle and the triangle are filled. The second time, the rectangle is drawn clockwise, but the triangle is drawn counterclockwise; the rectangle is filled, but the triangle is not. (If the figures had been drawn using alternate mode, the rectangle would have been filled and the triangle would not have been filled, in both cases.)

```
HBRUSH hbrGray, hbrPrevious;

/*
 * Define the points for a clockwise triangle in a clockwise
 * rectangle.
 */

POINT aPolyPoints[9] = {{  50,  60 }, { 250,  60 }, { 250, 260 },
    {  50, 260 }, {  50,  60 }, { 150,  80 },
    { 230, 240 }, {  70, 240 }, { 150,  80 }};

int aPolyCount[] = { 5, 4 };
int cValues, i;

hbrGray = GetStockObject(GRAY_BRUSH);
hbrPrevious = SelectObject(hdc, hbrGray);

cValues = sizeof(aPolyCount) / sizeof(int);

SetPolyFillMode(hdc, WINDING);     /* sets winding mode */
PolyPolygon(hdc, aPolyPoints, aPolyCount, cValues);
```

```
/* Define the triangle counter-clockwise */

aPolyPoints[6].x = 70;  aPolyPoints[6].y = 240;
aPolyPoints[7].x = 230; aPolyPoints[7].y = 240;

for (i = 0; i < sizeof(aPolyPoints) / sizeof(POINT); i++)
    aPolyPoints[i].x += 300;   /* moves figure 300 units right */

PolyPolygon(hdc, aPolyPoints, aPolyCount, cValues);

SelectObject(hdc, hbrPrevious);
```

See Also
GetPolyFillMode, **PolyPolygon**

SetRectRgn (2.x)

void SetRectRgn(*hrgn, nLeftRect, nTopRect, nRightRect, nBottomRect***)**

```
HRGN hrgn;          /* handle of region                          */
int nLeftRect;      /* x-coordinate top-left corner of rectangle */
int nTopRect;       /* y-coordinate top-left corner of rectangle */
int nRightRect;     /* x-coordinate bottom-right corner of rectangle */
int nBottomRect;    /* y-coordinate bottom-right corner of rectangle */
```

The **SetRectRgn** function changes the given region into a rectangular region with the specified coordinates.

Parameter	Description
hrgn	Identifies the region.
nLeftRect	Specifies the x-coordinate of the upper-left corner of the rectangular region.
nTopRect	Specifies the y-coordinate of the upper-left corner of the rectangular region.
nRightRect	Specifies the x-coordinate of the lower-right corner of the rectangular region.
nBottomRect	Specifies the y-coordinate of the lower-right corner of the rectangular region.

Returns
This function does not return a value.

Comments
Applications can use this function instead of the **CreateRectRgn** function to avoid allocating more memory from the **GDI** heap. Because the memory allocated for the *hrgn* parameter is reused, no new allocation is performed.

Example
The following example uses the **CreateRectRgn** function to create a rectangular region and then calls the **SetRectRgn** function to change the region coordinates:

```
HRGN hrgn;

hrgn = CreateRectRgn(10, 10, 30, 30);
PaintRgn(hdc, hrgn);

SetRectRgn(hrgn, 50, 50, 150, 200);
PaintRgn(hdc, hrgn);

DeleteObject(hrgn);
```

See Also
CreateRectRgn

SetROP2 (2.x)

int SetROP2(*hdc, fnDrawMode***)**

HDC *hdc;* /* handle of device context */
int *fnDrawMode;* /* new drawing mode */

The **SetROP2** function sets the current drawing mode. The drawing mode specifies how the colors of the pen and the interior of filled objects are combined with the color already on the screen surface.

Parameter	Description
hdc	Identifies the device context.
fnDrawMode	Specifies the new drawing mode. This parameter can be one of the following values:

Value	Meaning
R2_BLACK	Pixel is always black.
R2_WHITE	Pixel is always white.
R2_NOP	Pixel remains unchanged.
R2_NOT	Pixel is the inverse of the screen color.
R2_COPYPEN	Pixel is the pen color.
R2_NOTCOPYPEN	Pixel is the inverse of the pen color.
R2_MERGEPENNOT	Pixel is a combination of the pen color and the inverse of the screen color (final pixel = (~screen pixel) | pen).
R2_MASKPENNOT	Pixel is a combination of the colors common to both the pen and the inverse of the screen (final pixel = (~screen pixel) & pen).
R2_MERGENOTPEN	Pixel is a combination of the screen color and the inverse of the pen color (final pixel = (~pen) | screen pixel).
R2_MASKNOTPEN	Pixel is a combination of the colors common to both the screen and the inverse of the pen (final pixel = (~pen) & screen pixel).
R2_MERGEPEN	Pixel is a combination of the pen color and the screen color (final pixel = pen | screen pixel).
R2_NOTMERGEPEN	Pixel is the inverse of the R2_MERGEPEN color (final pixel = ~(pen | screen pixel)).
R2_MASKPEN	Pixel is a combination of the colors common to both the pen and the screen (final pixel = pen & screen pixel).
R2_NOTMASKPEN	Pixel is the inverse of the R2_MASKPEN color (final pixel = ~(pen & screen pixel)).
R2_XORPEN	Pixel is a combination of the colors that are in the pen and in the screen, but not in both (final pixel = pen ^ screen pixel).
R2_NOTXORPEN	Pixel is the inverse of the R2_XORPEN color (final pixel = ~(pen ^ screen pixel)).

Returns

The return value specifies the previous drawing mode, if the function is successful.

Comments

The drawing mode is for raster devices only; it does not apply to vector devices.

Drawing modes are binary raster-operation codes representing all possible Boolean combinations of two variables. These values are created by using the binary operations AND, OR, and XOR (exclusive OR) and the unary operation NOT.

See Also
GetDeviceCaps, **GetROP2**

SetStretchBltMode (2.x)

int SetStretchBltMode(*hdc, fnStretchMode***)**

HDC *hdc;* /* handle of device context */
int *fnStretchMode;* /* bitmap-stretching mode */

The **SetStretchBltMode** function sets the bitmap-stretching mode. The bitmap-stretching mode defines how information is removed from bitmaps that are compressed by using the **StretchBlt** function.

Parameter	Description
hdc	Identifies the device context.
fnStretchMode	Specifies the new bitmap-stretching mode. This parameter can be one of the following values:

Value	Meaning
STRETCH_ANDSCANS	Uses the AND operator to combine eliminated lines with the remaining lines. This mode preserves black pixels at the expense of colored or white pixels. It is the default mode.
STRETCH_DELETESCANS	Deletes the eliminated lines. Information in the eliminated lines is not preserved.
STRETCH_ORSCANS	Uses the OR operator to combine eliminated lines with the remaining lines. This mode preserves colored or white pixels at the expense of black pixels.

Returns
The return value is the previous stretching mode, if the function is successful. It can be **STRETCH_ANDSCANS**, **STRETCH_DELETESCANS**, or STRETCH_ORSCANS.

Comments
The **STRETCH_ANDSCANS** and **STRETCH_ORSCANS** modes are typically used to preserve foreground pixels in monochrome bitmaps. The **STRETCH_DELETESCANS** mode is typically used to preserve color in color bitmaps.

See Also
GetStretchBltMode, **StretchBlt**, **StretchDIBits**

STRETCH_ANDSCANS 1

Uses the AND operator to combine eliminated lines with the remaining lines. This mode preserves black pixels at the expense of colored or white pixels. It is the default mode.

STRETCH_DELETESCANS 3

Deletes the eliminated lines. Information in the eliminated lines is not preserved.

STRETCH_ORSCANS 2

Uses the OR operator to combine eliminated lines with the remaining lines. This mode preserves colored or white pixels at the expense of black pixels.

STRETCH_ORSCANS 2

SetSystemPaletteUse (3.0)

UINT SetSystemPaletteUse(*hdc, fuStatic***)**

HDC *hdc;* /* handle of device context */
UINT *fuStatic;* /* system-palette contents */

The **SetSystemPaletteUse** function sets the use of static colors in the system palette. The default system palette contains 20 static colors, which are not changed when an application realizes its logical palette. An application can use **SetSystemPaletteUse** to change this to two static colors (black and white).

Parameter	Description
hdc	Identifies the device context. This device context must support color palettes.
fuStatic	Specifies the new use of the system palette. This parameter can be either of the following values:

Value	Meaning
SYSPAL_NOSTATIC	System palette contains no static colors except black and white.
SYSPAL_STATIC	System palette contains static colors that will not change when an application realizes its logical palette.

Returns

The return value is the previous setting for the static colors in the system palette, if the function is successful. This setting is either **SYSPAL_NOSTATIC** or SYSPAL_STATIC.

Comments

An application must call this function only when its window is maximized and has the input focus.

If an application calls **SetSystemPaletteUse** with *fuStatic* set to **SYSPAL_NOSTATIC**, Windows continues to set aside two entries in the system palette for pure white and pure black, respectively.

After calling this function with *fuStatic* set to **SYSPAL_NOSTATIC**, an application must follow these steps:

1 Call the **UnrealizeObject** function to force the graphics device interface (**GDI**) to remap the logical palette completely when it is realized.

2 Realize the logical palette.

3 Call the **GetSysColor** function to save the current system-color settings.

4 Call the **SetSysColors** function to set the system colors to reasonable values using black and white. For example, adjacent or overlapping items (such as window frames and borders) should be set to black and white, respectively.

5 Send the **WM_SYSCOLORCHANGE** message to other top-level windows to allow them to be redrawn with the new system colors.

When the application's window loses focus or closes, the application must perform the following steps:

1 Call **SetSystemPaletteUse** with the *fuStatic* parameter set to SYSPAL_STATIC.

2 Call **UnrealizeObject** to force **GDI** to remap the logical palette completely when it is realized.

3 Realize the logical palette.

4 Restore the system colors to their previous values.

5 Send the **WM_SYSCOLORCHANGE** message.

See Also

GetSysColor, **SetSysColors**, **SetSystemPaletteUse**, **UnrealizeObject**

SetTextAlign (2.x)

UINT SetTextAlign(*hdc, fuAlign***)**

```
HDC hdc;        /* handle of device context */
UINT fuAlign;   /* text-alignment flags     */
```

The **SetTextAlign** function sets the text-alignment flags for the given device context.

Parameter	Description
hdc	Identifies the device context.
fuAlign	Specifies text-alignment flags. The flags specify the relationship between a point and a rectangle that bounds the text. The point can be either the current position or coordinates specified by a text-output function (such as the **ExtTextOut** function). The rectangle that bounds the text is defined by the adjacent character cells in the text string. The *fuAlign* parameter can be one or more flags from the following three categories. Choose only one flag from each category. The first category affects text alignment in the x-direction:

Value	Meaning
TA_CENTER	Aligns the point with the horizontal center of the bounding rectangle.
TA_LEFT	Aligns the point with the left side of the bounding rectangle. This is the default setting.
TA_RIGHT	Aligns the point with the right side of the bounding rectangle.

The second category affects text alignment in the y-direction:

Value	Meaning
TA_BASELINE	Aligns the point with the base line of the chosen font.
TA_BOTTOM	Aligns the point with the bottom of the bounding rectangle.
TA_TOP	Aligns the point with the top of the bounding rectangle. This is the default setting.

The third category determines whether the current position is updated when text is written:

Value	Meaning
TA_NOUPDATECP	Does not update the current position after each call to a text-output function. This is the default setting.
TA_UPDATECP	Updates the current x-position after each call to a text-output function. The new position is at the right side of the bounding rectangle for the text. When this flag is set, the coordinates specified in calls to the **TextOut** function are ignored.

Returns

The return value is the previous text-alignment settings, if the function is successful. The low-order byte contains the horizontal setting; the high-order byte contains the vertical setting. Otherwise, the return value is zero.

Comments

The text-alignment flags set by **SetTextAlign** are used by the **TextOut** and **ExtTextOut** functions.

Example

The following example uses the **GetTextFace** function to retrieve the name of the current typeface, calls **SetTextAlign** so that the current position is updated when the **TextOut** function is called, and then writes some introductory text and the name of the typeface by calling **TextOut**:

```
int nFaceNameLen;
char aFaceName[80];

nFaceNameLen = GetTextFace(hdc, /* returns length of string */
    sizeof(aFaceName),       /* size of face-name buffer    */
    (LPSTR) aFaceName);      /* address of face-name buffer */

SetTextAlign(hdc,
    TA_UPDATECP);          /* updates current position       */
MoveTo(hdc, 100, 100);     /* sets current position          */
TextOut(hdc, 0, 0,         /* uses current position for text */
    "This is the current face name: ", 31);
TextOut(hdc, 0, 0, aFaceName, nFaceNameLen);
```

See Also

ExtTextOut, **GetTextAlign**, **TextOut**

SetTextCharacterExtra (2.x)

int SetTextCharacterExtra(*hdc, nExtraSpace***)**

HDC *hdc;* /* handle of device context */
int *nExtraSpace;* /* extra character spacing */

The **SetTextCharacterExtra** function sets the amount of intercharacter spacing. The graphics device interface (**GDI**) adds this spacing to each character, including break characters, when it writes a line of text to the device context.

Parameter	Description
hdc	Identifies the device context.
nExtraSpace	Specifies the amount of extra space, in logical units, to be added to each character. If the current mapping mode is not MM_TEXT, this parameter is transformed and rounded to the nearest pixel.

Returns
The return value is the previous intercharacter spacing, if the function is successful.

Comments
The default value for the amount of intercharacter spacing is zero.

See Also
GetTextCharacterExtra

SetTextColor (2.x)

COLORREF SetTextColor(*hdc, clrref***)**

HDC *hdc;* /* handle of device context */
COLORREF *clrref;* /* new color for text */

The **SetTextColor** function sets the text color to the specified color. The system uses the text color when writing text to a device context and also when converting bitmaps between color and monochrome device contexts.

Parameter	Description
hdc	Identifies the device context.
clrref	Specifies the color of the text.

Returns
The return value is the **RGB** (red-green-blue) value for the previous text color, if the function is successful.

Comments
If the device cannot represent the specified color, the system sets the text color to the nearest physical color.

The background color for a character is specified by the **SetBkColor** and **SetBkMode** functions.

Example
The following example sets the text color to red if the **GetTextColor** function determines that the current text color is black. The text color is specified by using the **RGB** macro.

```
DWORD dwColor;

dwColor = GetTextColor(hdc);
if (dwColor == RGB(0, 0, 0))     /* if current color is black */
    SetTextColor(hdc, RGB(255, 0, 0)); /* sets color to red  */
```

See Also
GetTextColor, **BitBlt**, **SetBkColor**, **SetBkMode**, **RGB**

SetTextJustification (2.x)

int SetTextJustification(*hdc, nExtraSpace, cBreakChars***)**

```
HDC hdc;          /* handle of device context                  */
int nExtraSpace;  /* space to add to string                    */
int cBreakChars;  /* number of break characters in the string  */
```

The **SetTextJustification** function adds space to the break characters in a string. An application can use the **GetTextMetrics** function to retrieve a font's break character.

Parameter	Description
hdc	Identifies the device context.
nExtraSpace	Specifies the total extra space, in logical units, to be added to the line of text. If the current mapping mode is not MM_TEXT, the value given by this parameter is converted to the current mapping mode and rounded to the nearest device unit.
cBreakChars	Specifies the number of break characters in the line.

Returns

The return value is 1 if the function is successful. Otherwise, it is zero.

Comments

After the **SetTextJustification** function is called, a call to a text-output function (for example, **TextOut**) distributes the specified extra space evenly among the specified number of break characters. The break character is usually the space character (ASCII 32), but it may be defined by a font as some other character.

The **GetTextExtent** function is typically used with **SetTextJustification**. The **GetTextExtent** function computes the width of a given line before alignment. An application can determine how much space to specify in the *nExtraSpace* parameter by subtracting the value returned by **GetTextExtent** from the width of the string after alignment.

The **SetTextJustification** function can be used to align a line that contains multiple runs in different fonts. In this case, the line must be created piecemeal by aligning and writing each run separately.

Because rounding errors can occur during alignment, the system keeps a running error term that defines the current error. When aligning a line that contains multiple runs, **GetTextExtent** automatically uses this error term when it computes the extent of the next run, allowing the text-output function to blend the error into the new run. After each line has been aligned, this error term must be cleared to prevent it from being incorporated into the next line. The term can be cleared by calling **SetTextJustification** with the *nExtraSpace* parameter set to zero.

Example

The following example writes two lines of text inside a box; one of the lines is aligned, and the other is not. The **GetTextExtent** function determines the width of the unaligned string. The **GetTextMetrics** function determines the break character that is used by the current font; this information is then used to determine how many break characters the string contains. The **SetTextJustification** function specifies the total amount of extra space and the number of break characters to distribute it among. After writing a line of aligned text, **SetTextJustification** is called again, to set the error term to zero.

```
POINT aPoints[5];
int iLMargin = 10, iRMargin = 10, iBoxWidth;
int cchString;
LPSTR lpszJustified = "Text to be justified in this test.";
DWORD dwExtent;
WORD wTextWidth;
TEXTMETRIC tm;
int j, cBreakChars;
```

```
aPoints[0].x = 100; aPoints[0].y =  50;
aPoints[1].x = 600; aPoints[1].y =  50;
aPoints[2].x = 600; aPoints[2].y = 200;
aPoints[3].x = 100; aPoints[3].y = 200;
aPoints[4].x = 100; aPoints[4].y =  50;

Polyline(hdc, aPoints, sizeof(aPoints) / sizeof(POINT));

TextOut(hdc, 100 + iLMargin, 100, "Unjustified text.", 17);
cchString = lstrlen(lpszJustified);
dwExtent = GetTextExtent(hdc, lpszJustified, cchString);
wTextWidth = LOWORD(dwExtent);

iBoxWidth = aPoints[1].x - aPoints[0].x;
GetTextMetrics(hdc, &tm);

for (cBreakChars = 0, j = 0; j < cchString; j++)
    if (*(lpszJustified + j) == (char) tm.tmBreakChar)
        cBreakChars++;

SetTextJustification(hdc,
    iBoxWidth - wTextWidth - (iLMargin + iRMargin),
    cBreakChars);

TextOut(hdc, 100 + iLMargin, 150, lpszJustified, cchString);

SetTextJustification(hdc, 0, 0);     /* clears error term */
```

See Also

GetMapMode, **GetTextExtent**, **GetTextMetrics**, **SetMapMode**, **TextOut**

SetViewportExt (2.x)

DWORD SetViewportExt(*hdc, nXExtent, nYExtent***)**

```
HDC hdc;        /* handle of device context */
int nXExtent;   /* x-extent of viewport     */
int nYExtent;   /* y-extent of viewport     */
```

The **SetViewportExt** function sets the x- and y-extents of the viewport of the given device context. The viewport, along with the window, defines how points are converted from logical coordinates to device coordinates.

Parameter	Description
hdc	Identifies the device context.
nXExtent	Specifies the x-extent, in device units, of the viewport.
nYExtent	Specifies the y-extent, in device units, of the viewport.

Returns

The return value is the previous viewport extents, in device units, if the function is successful. The low-order word contains the previous x-extent; the high-order word contains the previous y-extent. Otherwise, the return value is zero.

Comments

When the following mapping modes are set, calls to the **SetWindowExt** and **SetViewportExt** functions are ignored:

MM_HIENGLISH
MM_HIMETRIC
MM_LOENGLISH
MM_LOMETRIC
MM_TEXT
MM_TWIPS

When the mapping mode is MM_ISOTROPIC, an application must call the **SetWindowExt** function before calling **SetViewportExt**.

The x- and y-extents of the viewport define how much the graphics device interface (**GDI**) must stretch or compress units in the logical coordinate system to fit units in the device coordinate system. For example, if the x-extent of the window is 2 and the x-extent of the viewport is 4, GDI converts two logical units (measured from the x-axis) into four device units. Similarly, if the y-extent of the window is 2 and the y-extent of the viewport is -1, GDI converts two logical units (measured from the y-axis) into one device unit.

The extents also define the relative orientation of the x- and y-axes in both coordinate systems. If the signs of matching window and viewport extents are the same, the axes have the same orientation. If the signs are different, the orientation is reversed. For example, if the y-extent of the window is 2 and the y-extent of the viewport is -1, **GDI** converts the positive y-axis in the logical coordinate system to the negative y-axis in the device coordinate system. If the x-extents are 2 and 4, GDI converts the positive x-axis in the logical coordinate system to the positive x-axis in the device coordinate system.

Example

The following example uses the **SetMapMode**, **SetWindowExt**, and **SetViewportExt** functions to create a client area that is 10 logical units wide and 10 logical units high, and then draws a rectangle that is 4 logical units wide and 4 logical units high:

```
HDC  hdc;
RECT rc;

GetClientRect(hwnd, &rc);
```

```
hdc = GetDC(hwnd);
SetMapMode(hdc, MM_ANISOTROPIC);
SetWindowExt(hdc, 10, 10);
SetViewportExt(hdc, rc.right, rc.bottom);
Rectangle(hdc, 3, 3, 7, 7);
ReleaseDC(hwnd, hdc);
```

See Also

GetViewportExt, SetViewportExtEx, SetWindowExt

SetViewportExtEx (3.1)

BOOL SetViewportExtEx(*hdc, nX, nY, lpSize***)**

```
HDC hdc;                /* handle of device context              */
int nX;                 /* x-extent of viewport                  */
int nY;                 /* y-extent of viewport                  */
SIZE FAR* lpSize;       /* address of struct. with prev. extents */
```

The **SetViewportExtEx** function sets the x- and y-extents of the viewport of the specified device context. The viewport, along with the window, defines how points are mapped from logical coordinates to device coordinates.

Parameter	Description
hdc	Identifies the device context.
nX	Specifies the x-extent of the viewport, in device units.
nY	Specifies the y-extent of the viewport, in device units.
lpSize	Points to a **SIZE** structure. The previous extents of the viewport, in device units, are placed in this structure. If *lpSize* is NULL, nothing is returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

When the following mapping modes are set, calls to the **SetWindowExtEx** and **SetViewportExtEx** functions are ignored:

MM_HIENGLISH
MM_HIMETRIC
MM_LOENGLISH
MM_LOMETRIC
MM_TEXT
MM_TWIPS

When MM_ISOTROPIC mode is set, an application must call the **SetWindowExtEx** function before it calls **SetViewportExtEx**.

See Also

SetViewportExt, **SetWindowExtEx**

SetViewportOrg (2.x)

DWORD SetViewportOrg(*hdc, nXOrigin, nYOrigin***)**

HDC *hdc;* /* handle of device context */
int *nXOrigin;* /* x-coordinate of new origin */
int *nYOrigin;* /* y-coordinate of new origin */

The **SetViewportOrg** function sets the viewport origin of the specified device context. The viewport, along with the window, defines how points are converted from logical coordinates to device coordinates.

Parameter	Description
hdc	Identifies the device context.
nXOrigin	Specifies the x-coordinate, in device coordinates, of the origin of the viewport. This value must be within the range of the device coordinate system.
nYOrigin	Specifies the y-coordinate, in device coordinates, of the origin of the viewport. This value must be within the range of the device coordinate system.

Returns
The return value is the coordinates of the previous viewport origin, in device units, if the function is successful. The low-order word contains the previous x-coordinate; the high-order word contains the previous y-coordinate. Otherwise, the return value is zero.

Comments
The viewport origin is the origin of the device coordinate system. The graphics device interface (**GDI**) converts points from the logical coordinate system to device coordinates. (An application can specify the origin of the logical coordinate system by using the **SetWindowOrg** function.) GDI converts all points in the logical coordinate system to device coordinates in the same way as it converts the origin.

Example
The following example uses the **SetViewportOrg** function to set the viewport origin to the center of the client area and then draws a rectangle centered over the origin:

```
HDC  hdc;
RECT rc;

GetClientRect(hwnd, &rc);
hdc = GetDC(hwnd);
SetViewportOrg(hdc, rc.right/2, rc.bottom/2);
Rectangle(hdc, -100, -100, 100, 100);
ReleaseDC(hwnd, hdc);
```

See Also
SetViewportOrgEx, **SetWindowOrg**

SetViewportOrgEx (3.1)

BOOL SetViewportOrgEx(*hdc, nX, nY, lpPoint***)**

```
HDC hdc;                /* handle of device context          */
int nX;                 /* x-coordinate of new origin        */
int nY;                 /* y-coordinate of new origin        */
POINT FAR* lpPoint;     /* address of struct. with prev. origin */
```

The **SetViewportOrgEx** function sets the viewport origin of the specified device context. The viewport, along with the window, defines how points are mapped from logical coordinates to device coordinates.

Parameter	Description
hdc	Identifies the device context.
nX	Specifies the x-coordinate, in device units, of the origin of the viewport.
nY	Specifies the y-coordinate, in device units, of the origin of the viewport.
lpPoint	Points to a **POINT** structure. The previous origin of the viewport, in device coordinates, is placed in this structure. If *lpPoint* is NULL, nothing is returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also

SetViewportOrg, **SetWindowOrgEx**

SetWindowExt (2.x)

DWORD SetWindowExt(*hdc, nXExtent, nYExtent***)**

```
HDC hdc;        /* handle of device context */
int nXExtent;   /* x-extent of window       */
int nYExtent;   /* y-extent of window       */
```

The **SetWindowExt** function sets the x- and y-extents of the window associated with the given device context. The window, along with the viewport, defines how logical coordinates are converted to device coordinates.

Parameter	Description
hdc	Identifies the device context.
nXExtent	Specifies the x-extent, in logical units, of the window.
nYExtent	Specifies the y-extent, in logical units, of the window.

Returns

The return value is the window's previous extents, in logical units, if the function is successful. The low-order word contains the previous x-extent; the high-order word contains the previous y-extent. Otherwise, the return value is zero.

Comments

When the following mapping modes are set, calls to the **SetWindowExt** and **SetViewportExt** functions are ignored:

MM_HIENGLISH
MM_HIMETRIC
MM_LOENGLISH
MM_LOMETRIC
MM_TEXT
MM_TWIPS

When MM_ISOTROPIC mode is set, an application must call the **SetWindowExt** function before calling **SetViewportExt**.

The x- and y-extents of the window define how much the graphics device interface (**GDI**) must stretch or compress units in the logical coordinate system to fit units in the device coordinate system. For example, if the x-extent of the window is 2 and the x-extent of the viewport is 4, GDI converts two logical units (measured from the x-axis) into four device units. Similarly, if the y-extent of the window is 2 and the y-extent of the viewport is -1, GDI converts two logical units (measured from the y-axis) into one device unit.

The extents also define the relative orientation of the x- and y-axes in both coordinate systems. If the signs of matching window and viewport extents are the same, the axes have the same orientation. If the signs are different, the orientation is reversed. For example, if the y-extent of the window is 2 and the y-extent of the viewport is -1, **GDI** converts the positive y-axis in the logical coordinate system to the negative y-axis in the device coordinate system. If the x-extents are 2 and 4, GDI converts the positive x-axis in the logical coordinate system to the positive x-axis in the device coordinate system.

Example

The following example uses the **SetMapMode**, **SetWindowExt**, and **SetViewportExt** functions to create a client area that is 10 logical units wide and 10 logical units high and then draws a rectangle that is 4 units wide and 4 units high:

```
HDC  hdc;
RECT rc;

GetClientRect(hwnd, &rc);
```

```
hdc = GetDC(hwnd);
SetMapMode(hdc, MM_ANISOTROPIC);
SetWindowExt(hdc, 10, 10);
SetViewportExt(hdc, rc.right, rc.bottom);
Rectangle(hdc, 3, 3, 7, 7);
ReleaseDC(hwnd, hdc);
```

See Also

GetWindowExt, **SetViewportExt**, **SetWindowExtEx**

SetWindowExtEx (3.1)

BOOL SetWindowExtEx(*hdc, nX, nY, lpSize***)**

```
HDC hdc;          /* handle of device context          */
int nX;           /* x-extent of window                */
int nY;           /* y-extent of window                */
SIZE FAR* lpSize; /* address of struct. for prev. extents */
```

The **SetWindowExtEx** function sets the x- and y-extents of the window associated with the specified device context. The window, along with the viewport, defines how points are mapped from logical coordinates to device coordinates.

Parameter	Description
hdc	Identifies the device context.
nX	Specifies the x-extent, in logical units, of the window.
nY	Specifies the y-extent, in logical units, of the window.
lpSize	Points to a **SIZE** structure. The previous extents of the window (in logical units) are placed in this structure. If *lpSize* is NULL nothing is returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

When the following mapping modes are set, calls to the **SetWindowExtEx** and **SetViewportExt** functions are ignored:

MM_HIENGLISH
MM_HIMETRIC
MM_LOENGLISH
MM_LOMETRIC
MM_TEXT
MM_TWIPS

When MM_ISOTROPIC mode is set, an application must call the **SetWindowExtEx** function before calling **SetViewportExt**.

See Also

SetViewportExtEx, **SetWindowExt**

SetWindowOrg (2.x)

DWORD SetWindowOrg(*hdc, nXOrigin, nYOrigin***)**

```
HDC hdc;        /* handle of device context                          */
int nXOrigin;   /* x-coordinate to map to upper-left window corner   */
int nYOrigin;   /* y-coordinate to map to upper-left window corner   */
```

The **SetWindowOrg** function sets the window origin for the given device context.

Parameter	Description
hdc	Identifies the device context.
nXOrigin	Specifies the logical x-coordinate to map to the upper-left corner of the window.
nYOrigin	Specifies the logical y-coordinate to map to the upper-left corner of the window.

Returns

The return value is the coordinates of the previous window origin, in logical units, if the function is successful. The low-order word contains the x-coordinate of the previous window origin; the high-order word contains the y-coordinate. Otherwise, the return value is zero.

Comments

The window origin is the origin of the logical coordinate system for a window. By changing the window origin, an application can change the way the graphics device interface (**GDI**) converts logical coordinates to device coordinates (the viewport). GDI converts logical coordinates to the device coordinates of the viewport in the same way as it converts the origin.

To convert points to the right, an application can specify a negative value for the *nXOrigin* parameter. Similarly, to convert points down (in the MM_TEXT mapping mode), the *nYOrigin* parameter can be negative.

Example

The following example uses the **CopyMetaFile** function to copy a metafile to a specified file, plays the copied metafile, uses the **GetMetaFile** function to retrieve a handle of the copied metafile, uses the **SetWindowOrg** function to change the position at which the metafile is played 200 logical units to the right, and then plays the metafile at the new location:

```
HANDLE hmf, hmfSource, hmfOld;
LPSTR lpszFile1 = "MFTest";

hmf = CopyMetaFile(hmfSource, lpszFile1);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);

hmfOld = GetMetaFile(lpszFile1);
SetWindowOrg(hdc, -200, 0);
PlayMetaFile(hdc, hmfOld);

DeleteMetaFile(hmfSource);
DeleteMetaFile(hmfOld);
```

See Also

CopyMetaFile, **GetMetaFile**, **GetWindowOrg**, **PlayMetaFile**, **SetViewportOrg**, **SetWindowOrgEx**

SetWindowOrgEx (3.1)

BOOL SetWindowOrgEx(*hdc, nX, nY, lpPoint***)**

```
HDC hdc;                    /* handle of device context          */
int nX;                     /* x-coordinate of window            */
int nY;                     /* y-coordinate of window            */
POINT FAR* lpPoint;         /* address of struct. for prev. origin */
```

The **SetWindowOrgEx** function sets the window origin of the specified device context. The window, along with the viewport, defines how points are mapped from logical coordinates to device coordinates.

Parameter	Description
hdc	Identifies the device context.
nX	Specifies the logical x-coordinate of the new origin of the window.
nY	Specifies the logical y-coordinate of the new origin of the window.
lpPoint	Points to a **POINT** structure. The previous origin of the window is placed in this structure. If *lpPoint* is NULL nothing is returned.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also

GetWindowOrg, **GetWindowOrgEx**, **SetViewportOrgEx**, **SetWindowOrg**

SpoolFile (3.1)

HANDLE SpoolFile(*lpszPrinter, lpszPort, lpszJob, lpszFile***)**

LPSTR *lpszPrinter;* /* printer name */
LPSTR *lpszPort;* /* port name */
LPSTR *lpszJob;* /* job name */
LPSTR *lpszFile;* /* file name */

The **SpoolFile** function puts a file into the spooler queue. This function is typically used by device drivers.

Parameter	Description
lpszPrinter	Points to a null-terminated string specifying the printer name--for example, "HP LasterJet IIP".
lpszPort	Points to a null-terminated string specifying the local name--for example, "LPT1:". This must be a local port.
lpszJob	Points to a null-terminated string specifying the name of the print job for the spooler. This string cannot be longer than 32 characters, including the null-terminating character.
lpszFile	Points to a null-terminated string specifying the path and filename of the file to put in the spooler queue. This file contains raw printer data.

Returns

The return value is the global handle that is passed to the spooler, if the function is successful. Otherwise, it is an error value, which can be one of the following:

SP_APPABORT
SP_ERROR
SP_NOTREPORTED
SP_OUTOFDISK
SP_OUTOFMEMORY
SP_USERABORT

Comments

Applications should ensure that the spooler is enabled before calling the **SpoolFile** function.

StartDoc (3.1)

int StartDoc(*hdc, lpdi***)**

```
HDC hdc;                    /* handle of device context        */
DOCINFO FAR* lpdi;          /* pointer to DOCINFO structure  */
```

The **StartDoc** function starts a print job. For Windows version 3.1, this function replaces the STARTDOC printer escape.

Parameter	Description
hdc	Identifies the device context for the print job.
lpdi	Points to a **DOCINFO** structure containing the name of the document file and the name of the output file.

Returns

The return value is positive if the function is successful. Otherwise, it is SP_ERROR.

Comments

Applications should call the **StartDoc** function immediately before beginning a print job. Using this function ensures that documents containing more than one page are not interspersed with other print jobs.

The **StartDoc** function should not be used inside metafiles.

See Also

EndDoc, **Escape**, **DOCINFO**

StartPage (3.1)

int StartPage(*hdc***)**

HDC *hdc;* /* handle of device context */

The **StartPage** function prepares the printer driver to accept data.

Parameter	Description
hdc	Identifies the device context for the print job.

Returns
The return value is greater than zero if the function is successful. It is less than or equal to zero if an error occurs.

Comments
The system disables the **ResetDC** function between calls to the **StartPage** and **EndPage** functions. This means that applications cannot change the device mode except at page boundaries.

See Also
EndPage, **Escape**, **ResetDC**

StretchBlt (2.x)

BOOL StretchBlt(*hdcDest, nXOriginDest, nYOriginDest, nWidthDest, nHeightDest, hdcSrc, nXOriginSrc, nYOriginSrc, nWidthSrc, nHeightSrc, fdwRop***)**

```
HDC hdcDest;        /* destination device-context handle                */
int nXOriginDest;   /* x-coordinate of origin of destination rectangle */
int nYOriginDest;   /* y-coordinate of origin of destination rectangle */
int nWidthDest;     /* width of destination rectangle                   */
int nHeightDest;    /* height of destination rectangle                  */
HDC hdcSrc;         /* source device-context handle                     */
int nXOriginSrc;    /* x-coordinate of origin of source rectangle       */
int nYOriginSrc;    /* y-coordinate of origin of source rectangle       */
int nWidthSrc;      /* width of source rectangle                        */
int nHeightSrc;     /* height of source rectangle                       */
DWORD fdwRop;       /* raster operation                                 */
```

The **StretchBlt** function copies a bitmap from a source rectangle into a destination rectangle, stretching or compressing the bitmap if necessary to fit the dimensions of the destination rectangle. The **StretchBlt** function uses the stretching mode of the destination device context (set by the **SetStretchBltMode** function) to determine how to stretch or compress the bitmap.

Parameter	Description
hdcDest	Identifies the device context to receive the bitmap.
nXOriginDest	Specifies the logical x-coordinate of the upper-left corner of the destination rectangle.
nYOriginDest	Specifies the logical y-coordinate of the upper-left corner of the destination rectangle.
nWidthDest	Specifies the width, in logical units, of the destination rectangle.
nHeightDest	Specifies the height, in logical units, of the destination rectangle.
hdcSrc	Identifies the device context that contains the source bitmap.
nXOriginSrc	Specifies the logical x-coordinate of the upper-left corner of the source rectangle.
nYOriginSrc	Specifies the logical y-coordinate of the upper-left corner of the source rectangle.
nWidthSrc	Specifies the width, in logical units, of the source rectangle.
nHeightSrc	Specifies the height, in logical units, of the source rectangle.
fdwRop	Specifies the raster operation to be performed. Raster-operation codes define how the graphics device interface (**GDI**) combines colors in output operations that involve a current brush, a possible source bitmap, and a destination bitmap. This parameter can be one of the following values:

Code	Description
BLACKNESS	Turns all output black.
DSTINVERT	Inverts the destination bitmap.
MERGECOPY	Combines the pattern and the source bitmap by using the Boolean AND operator.
MERGEPAINT	Combines the inverted source bitmap with the destination bitmap by using the Boolean OR operator.
NOTSRCCOPY	Copies the inverted source bitmap to the destination.
NOTSRCERASE	Inverts the result of combining the destination and source bitmaps by using the Boolean OR operator.
PATCOPY	Copies the pattern to the destination bitmap.
PATINVERT	Combines the destination bitmap with the pattern by using the Boolean XOR operator.
PATPAINT	Combines the inverted source bitmap with the pattern by using

	the Boolean OR operator. Combines the result of this operation with the destination bitmap by using the Boolean OR operator.
SRCAND	Combines pixels of the destination and source bitmaps by using the Boolean AND operator.
SRCCOPY	Copies the source bitmap to the destination bitmap.
SRCERASE	Inverts the destination bitmap and combines the result with the source bitmap by using the Boolean AND operator.
SRCINVERT	Combines pixels of the destination and source bitmaps by using the Boolean XOR operator.
SRCPAINT	Combines pixels of the destination and source bitmaps by using the Boolean OR operator.
WHITENESS	Turns all output white.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

The **StretchBlt** function stretches or compresses the source bitmap in memory and then copies the result to the destination. If a pattern is to be merged with the result, it is not merged until the stretched source bitmap is copied to the destination.

If a brush is used, it is the selected brush in the destination device context.

The destination coordinates are transformed according to the destination device context; the source coordinates are transformed according to the source device context.

If the destination, source, and pattern bitmaps do not have the same color format, **StretchBlt** converts the source and pattern bitmaps to match the destination bitmaps. The foreground and background colors of the destination device context are used in the conversion.

If **StretchBlt** must convert a monochrome bitmap to color, it sets white bits (1) to the background color and black bits (0) to the foreground color. To convert color to monochrome, it sets pixels that match the background color to white (1) and sets all other pixels to black (0). The foreground and background colors of the device context with color are used.

StretchBlt creates a mirror image of a bitmap if the signs of the *nWidthSrc* and *nWidthDest* or *nHeightSrc* and *nHeightDest* parameters differ. If *nWidthSrc* and *nWidthDest* have different signs, the function creates a mirror image of the bitmap along the x-axis. If *nHeightSrc* and *nHeightDest* have different signs, the function creates a mirror image of the bitmap along the y-axis.

Not all devices support the **StretchBlt** function. Applications can discover whether a device supports **StretchBlt** by calling the **GetDeviceCaps** function and specifying the RASTERCAPS index.

Example

The following example retrieves the handle of the desktop window and uses it to create a device context. After retrieving the dimensions of the desktop window, the example calls the **StretchBlt** function to copy the desktop bitmap into a smaller rectangle in the destination device context.

```
HWND hwndDesktop;
HDC hdcLocal;
RECT rc;

hwndDesktop = GetDesktopWindow();
hdcLocal = GetDC(hwndDesktop);
GetWindowRect(GetDesktopWindow(), &rc);

StretchBlt(hdc, 10, 10, 138, 106,
    hdcLocal, 0, 0, rc.right, rc.bottom, SRCCOPY);
```

```
ReleaseDC(hwndDesktop, hdcLocal);
```

See Also
BitBlt, **GetDeviceCaps**, **SetStretchBltMode**, **StretchDIBits**

StretchDIBits (3.0)

int StretchDIBits(*hdc, XDest, YDest, cxDest, cyDest, XSrc, YSrc, cxSrc, cySrc, lpvBits, lpbmi, fuColorUse, fdwRop***)**

```
HDC hdc;                        /* handle of device context                */
int XDest;                      /* x-coordinate of destination rectangle   */
int YDest;                      /* y-coordinate of destination rectangle   */
int cxDest;                     /* width of destination rectangle          */
int cyDest;                     /* height of destination rectangle         */
int XSrc;                       /* x-coordinate of source rectangle        */
int YSrc;                       /* y-coordinate of source rectangle        */
int cxSrc;                      /* width of source rectangle               */
int cySrc;                      /* height of source rectangle              */
const void FAR* lpvBits;        /* address of buffer with DIB bits         */
LPBITMAPINFO lpbmi;             /* address of structure with bitmap data   */
UINT fuColorUse;                /* RGB or palette indices                  */
DWORD fdwRop;                   /* raster operation                        */
```

The **StretchDIBits** function moves a device-independent bitmap (DIB) from a source rectangle into a destination rectangle, stretching or compressing the bitmap if necessary to fit the dimensions of the destination rectangle.

Parameter	Description
hdc	Identifies the destination device context for a screen surface or memory bitmap.
XDest	Specifies the logical x-coordinate of the destination rectangle.
YDest	Specifies the logical y-coordinate of the destination rectangle.
cxDest	Specifies the logical x-extent of the destination rectangle.
cyDest	Specifies the logical y-extent of the destination rectangle.
XSrc	Specifies the x-coordinate, in pixels, of the source rectangle in the DIB.
YSrc	Specifies the y-coordinate, in pixels, of the source rectangle in the DIB.
cxSrc	Specifies the width, in pixels, of the source rectangle in the DIB.
cySrc	Specifies the height, in pixels, of the source rectangle in the DIB.
lpvBits	Points to the DIB bits that are stored as an array of bytes.
lpbmi	Points to a **BITMAPINFO** structure that contains information about the DIB.
fuColorUse	Specifies whether the **bmiColors** member of the *lpbmi* parameter contains explicit **RGB** (red-green-blue) values or indices into the currently realized logical palette. The *fuColorUse* parameter can be one of the following values:

Value	Meaning
DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the currently realized logical palette.
DIB_RGB_COLORS	The color table contains literal **RGB** values.

fdwRop	Specifies the raster operation to be performed. Raster-operation codes define how the graphics device interface (**GDI**) combines colors in output operations that involve a current brush, a possible source bitmap, and a destination bitmap. For a list of raster-operation codes, see the description of the **BitBlt** function.

Returns

The return value is the number of scan lines copied, if the function is successful.

Comments

The **StretchDIBits** function uses the stretching mode of the destination device context (set by the **SetStretchBltMode** function) to determine how to stretch or compress the bitmap.

The origin of the coordinate system for a device-independent bitmap is the lower-left corner. The origin of the coordinates of the destination rectangle depends on the current mapping mode of the device context.

StretchDIBits creates a mirror image of a bitmap if the signs of the *cxSrc* and *cxDest* parameters or the *cySrc* and *cyDest* parameters differ. If *cxSrc* and *cxDest* have different signs, the function creates a mirror image of the bitmap along the x-axis. If *cySrc* and *cyDest* have different signs, the function creates a mirror image of the bitmap along the y-axis.

SetMapMode, **SetStretchBltMode**, **BITMAPINFO**

TextOut (2.x)

BOOL TextOut(*hdc, nXStart, nYStart, lpszString, cbString***)**

```
HDC hdc;            /* handle of device context          */
int nXStart;        /* x-coordinate of starting position */
int nYStart;        /* y-coordinate of starting position */
LPCSTR lpszString;  /* address of string                 */
int cbString;       /* number of bytes in string         */
```

The **TextOut** function writes a character string at the specified location, using the currently selected font.

Parameter	Description
hdc	Identifies the device context.
nXStart	Specifies the logical x-coordinate of the starting point of the string.
nYStart	Specifies the logical y-coordinate of the starting point of the string.
lpszString	Points to the character string to be drawn.
cbString	Specifies the number of bytes in the string.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

Character origins are at the upper-left corner of the character cell.

By default, the **TextOut** function does not use or update the current position. If an application must update the current position when calling **TextOut**, it can call the **SetTextAlign** function with the *wFlags* parameter set to TA_UPDATECP. When this flag is set, Windows ignores the *nXStart* and *nYStart* parameters on subsequent calls to the **TextOut** function, using the current position instead.

Example

The following example uses the **GetTextFace** function to retrieve the face name of the current font, calls **SetTextAlign** so that the current position is updated when the **TextOut** function is called, and then writes some introductory text and the face name by calling **TextOut**:

```
int nFaceNameLen;
char aFaceName[80];

nFaceNameLen = GetTextFace(hdc, /* returns length of string */
    sizeof(aFaceName),       /* size of face-name buffer    */
    (LPSTR) aFaceName);      /* address of face-name buffer */

SetTextAlign(hdc,
    TA_UPDATECP);          /* updates current position       */
MoveTo(hdc, 100, 100);     /* sets current position          */
TextOut(hdc, 0, 0,         /* uses current position for text */
    "This is the current face name: ", 31);
TextOut(hdc, 0, 0, aFaceName, nFaceNameLen);
```

See Also

ExtTextOut, **GetTextExtent**, **SetTextAlign**, **SetTextColor**, **TabbedTextOut**

UnrealizeObject (2.x)

BOOL UnrealizeObject(*hgdiobj***)**

HGDIOBJ *hgdiobj;* /* handle of brush or palette */

The **UnrealizeObject** function resets the origin of a brush or resets a logical palette. If the *hgdiobj* parameter identifies a brush, **UnrealizeObject** directs the system to reset the origin of the brush the next time it is selected. If the *hgdiobj* parameter identifies a logical palette, **UnrealizeObject** directs the system to realize the palette as though it had not previously been realized. The next time the application calls the **RealizePalette** function for the specified palette, the system completely remaps the logical palette to the system palette.

Parameter	Description
hgdiobj	Identifies the object to be reset.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
The **UnrealizeObject** function should not be used with stock objects.

The **UnrealizeObject** function must be called whenever a new brush origin is set (by using the **SetBrushOrg** function).

A brush identified by the *hgdiobj* parameter must not be the currently selected brush of any device context.

A palette identified by *hgdiobj* can be the currently selected palette of a device context.

Example
The following example uses the **SetBrushOrg** function to set the origin coordinates of the current brush to (3,5), uses the **SelectObject** function to remove that brush from the device context, uses the **UnrealizeObject** function to force the system to reset the origin of the specified brush, and then calls **SelectObject** again to select the brush into the device context with the new brush origin:

```
HBRUSH hbr, hbrOld;
SetBkMode(hdc, TRANSPARENT);
hbr = CreateHatchBrush(HS_CROSS, RGB(0, 0, 0));

UnrealizeObject(hbr);
SetBrushOrg(hdc, 0, 0);
hbrOld = SelectObject(hdc, hbr);

Rectangle(hdc, 0, 0, 200, 200);

hbr = SelectObject(hdc, hbrOld);              /* deselects hbr */
UnrealizeObject(hbr);  /* resets origin next time hbr selected */
SetBrushOrg(hdc, 3, 5);
hbrOld = SelectObject(hdc, hbr);          /* selects hbr again */

Rectangle(hdc, 0, 0, 200, 200);

SelectObject(hdc, hbrOld);
DeleteObject(hbr);
```

See Also
RealizePalette, **SelectObject**, **SetBrushOrg**

UpdateColors (3.0)

int UpdateColors(*hdc***)**

HDC *hdc;* /* handle of device context */

The **UpdateColors** function updates the client area of the given device context by matching the current colors in the client area, pixel by pixel, to the system palette. An inactive window with a realized logical palette may call **UpdateColors** as an alternative to redrawing its client area when the system palette changes.

Parameter	Description
hdc	Identifies the device context.

Returns

The return value is not used.

Comments

Using **UpdateColors** to update a client area is typically faster than redrawing the area. However, because **UpdateColors** performs the color translation based on the color of each pixel before the system palette changed, each call to this function results in the loss of some color accuracy.

GDI functions (3.1)

AbortDoc	Terminates a print job
AddFontResource	Adds a font to the font table
AnimatePalette	Replaces entries in a logical palette
Arc	Draws an arc
BitBlt	Copies a bitmap between device contexts
Chord	Draws a chord
CloseMetaFile	Closes a metafile DC and gets the handle
CombineRgn	Creates a region by combining two regions
CopyMetaFile	Copies a metafile
CreateBitmap	Creates a device-dependent memory bitmap
CreateBitmapIndirect	Creates a bitmap using **BITMAP** structure
CreateBrushIndirect	Creates a brush with the specified attributes
CreateCompatibleBitmap	Creates a bitmap compatible with the DC
CreateCompatibleDC	Creates a DC compatible with the specified DC
CreateDC	Creates a device context
CreateDIBitmap	Creates bitmap handle from DIB specification
CreateDIBPatternBrush	Creates a pattern brush from a DIB
CreateDiscardableBitmap	Creates discardable bitmap
CreateEllipticRgn	Creates an elliptical region
CreateEllipticRgnIndirect	Creates an elliptical region
CreateFont	Creates a logical font
CreateFontIndirect	Creates a font using a **LOGFONT** structure
CreateHatchBrush	Creates a hatched brush
CreateIC	Creates an information context
CreateMetaFile	Creates a metafile device context
CreatePalette	Creates a logical color palette
CreatePatternBrush	Creates a pattern brush from a bitmap
CreatePen	Creates a pen
CreatePenIndirect	Creates a pen using a **LOGPEN** structure
CreatePolygonRgn	Creates a polygonal region
CreatePolyPolygonRgn	Creates a region consisting of polygons
CreateRectRgn	Creates a rectangular region
CreateRectRgnIndirect	Creates a region using a **RECT** structure
CreateRoundRectRgn	Creates a rectangular region with round corners
CreateScalableFontResource	Creates a resource file with font info
CreateSolidBrush	Creates a solid brush with a specified color
DeleteDC	Deletes a device context
DeleteMetaFile	Invalidates a metafile handle
DeleteObject	Deletes an object from memory
DeviceCapabilities	Retrieves the capabilities of a device
DeviceMode	Displays a dialog box for printing modes
DPtoLP	Converts device points to logical points
Ellipse	Draws an ellipse
EndDoc	Ends a print job
EndPage	Ends a page
EnumFontFamilies	Retrieves fonts in a specified family
EnumFonts	Enumerates fonts on the specified device
EnumMetaFile	Enumerates metafile records
EnumObjects	Enumerates pens and brushes in a device context
EqualRgn	Compares two regions for equality
Escape	Allows access to capabilities device
Printer escapes	
ExcludeClipRect	Changes clipping region, excluding rectangle
ExtDeviceMode	Displays a dialog box for printing modes

ExtFloodFill	Fills an area with the current brush
ExtTextOut	Writes character string in rectangular region
FillRgn	Fills a region with the specified brush
FloodFill	Fills an area with the current brush
FrameRgn	Draws a border around a region
GetAspectRatioFilter	Retrieves setting of aspect-ratio filter
GetAspectRatioFilterEx	Retrieves setting of aspect-ratio filter
GetBitmapBits	Copies bitmap bits to a buffer
GetBitmapDimension	Retrieves the width and height of a bitmap
GetBitmapDimensionEx	Retrieves the width and height of a bitmap
GetBkColor	Retrieves the current background color
GetBkMode	Retrieves the background mode
GetBoundsRect	Returns current accumulated bounding rectangle
GetBrushOrg	Retrieves the origin of the current brush
GetBrushOrgEx	Retrieves the origin of the current brush
GetCharABCWidths	Retrieves the widths of TrueType characters
GetCharWidth	Retrieves the character widths
GetClipBox	Retrieves a rectangle for the clipping region
GetCurrentPosition	Retrieves the current position, in logical units
GetCurrentPositionEx	Retrieves the current position, in logical units
GetDCOrg	Retrieves translation origin for device context
GetDeviceCaps	Retrieves the device capabilities
GetDIBits	Copies the DIB bits into a buffer
GetFontData	Retrieves font metric data
GetGlyphOutline	Retrieves data for individual outline character
GetKerningPairs	Retrieves kerning pairs for the current font
GetMapMode	Retrieves the mapping mode
GetMetaFile	Creates a handle to a specified metafile
GetMetaFileBits	Creates a global memory object from a metafile
GetNearestColor	Retrieves the closest available color
GetNearestPaletteIndex	Retrieves the nearest match for a color
GetObject	Retrieves information about an object
GetOutlineTextMetrics	Retrieves metrics for TrueType fonts
GetPaletteEntries	Retrieves a range of palette entries
GetPixel	Retrieves **RGB** color value of specified pixel
GetPolyFillMode	Retrieves the current polygon-filling mode
GetRasterizerCaps	Retrieves status of TrueType fonts on system
GetRgnBox	Retrieves the bounding rectangle for a region
GetROP2	Retrieves the current drawing mode
GetStockObject	Retrieves handle of stock pen, brush, or font
GetStretchBltMode	Retrieves the current bitmap-stretching mode
GetSystemPaletteEntries	Retrieves entries from the system palette
GetSystemPaletteUse	Determines the use of an entire system palette
GetTextCharacterExtra	Retrieves the intercharacter spacing
GetTextAlign	Retrieves the text-alignment flags
GetTextColor	Retrieves the current text color
GetTextExtent	Determines dimensions of specified text string
GetTextExtentPoint	Retrieves dimensions of specified text string
GetTextFace	Retrieves the typeface name of the current font
GetTextMetrics	Retrieves the metrics for the current font
GetViewportExt	Retrieves the viewport extent
GetViewportExtEx	Retrieves the viewport extent
GetViewportOrg	Retrieves the viewport origin
GetViewportOrgEx	Retrieves the viewport origin
GetWindowExt	Retrieves the window extents
GetWindowExtEx	Retrieves the window extents

GetWindowOrg	Retrieves the window origin
GetWindowOrgEx	Retrieves the window origin
IntersectClipRect	Creates a clipping region from an intersection
InvertRgn	Inverts the colors in a region
IsGDIObject	Determines if a handle is not a **GDI** object
LineDDA	Computes successive points in a line
LineTo	Draws a line from the current position
LPtoDP	Converts logical points to device points
MoveTo	Moves the current position
MoveToEx	Moves the current position
OffsetClipRgn	Moves a clipping region
OffsetRgn	Moves a region by a specified offset
OffsetViewportOrg	Moves the viewport origin
OffsetViewportOrgEx	Moves the viewport origin
OffsetWindowOrg	Moves the window origin
OffsetWindowOrgEx	Moves the window origin
PaintRgn	Fills region with brush in given device context
PatBlt	Creates a bitmap pattern
Pie	Draws a pie-shaped wedge
PlayMetaFile	Plays a metafile
PlayMetaFileRecord	Plays a metafile record
Polygon	Draws a polygon
Polyline	Draws line segments to connect specified points
PolyPolygon	Draws a series of polygons
PtInRegion	Determines whether a point is in a region
PtVisible	Determines whether point is in clipping region
QueryAbort	Determines whether to terminate a print job
Rectangle	Draws a rectangle
RectInRegion	Determines whether rectangle overlaps region
RectVisible	Determines whether rectangle is in clip region
RemoveFontResource	Removes an added font resource
ResetDC	Updates a device context
ResizePalette	Changes the size of a logical palette
RestoreDC	Restores the device context
RoundRect	Draws a rectangle with rounded corners
SaveDC	Saves the current state of a device context
ScaleViewportExt	Scales the viewport extents
ScaleViewportExtEx	Scales the viewport extents
ScaleWindowExt	Scales the window extents
ScaleWindowExtEx	Scales the window extents
SelectClipRgn	Selects clipping region for device context
SelectObject	Selects an object into a device context
SetAbortProc	Sets the abort function for a print job
SetBitmapBits	Sets the bitmap bits from an array of bytes
SetBitmapDimension	Sets the width and height of a bitmap
SetBitmapDimensionEx	Sets the width and height of a bitmap
SetBkColor	Sets the current background color
SetBkMode	Sets the background mode
SetBoundsRect	Controls the bounding-rectangle accumulation
SetBrushOrg	Sets the origin of the current brush
SetDIBits	Sets the bits of a bitmap
SetDIBitsToDevice	Sets DIB bits to a device
SetMapMode	Sets the mapping mode
SetMapperFlags	Sets the font-mapper flag
SetMetaFileBits	Creates a memory object from the metafile
SetMetaFileBitsBetter	Creates a memory object from the metafile

SetPaletteEntries	Sets the colors and flags for a color palette
SetPixel	Sets a pixel to the specified color
SetPolyFillMode	Sets the polygon-filling mode
SetRectRgn	Changes a region into a specified rectangle
SetROP2	Sets the current drawing mode
SetStretchBltMode	Sets the bitmap-stretching mode
SetSystemPaletteUse	Sets the use of system-palette static colors
SetTextAlign	Sets the text-alignment flags
SetTextCharacterExtra	Sets the intercharacter spacing
SetTextColor	Sets the foreground color for text
SetTextJustification	Sets the alignment for text output
SetViewportExt	Sets the viewport extents
SetViewportExtEx	Sets the viewport extents
SetViewportOrg	Sets the viewport origin
SetViewportOrgEx	Sets the viewport origin
SetWindowExt	Sets the window extents
SetWindowExtEx	Sets the window extents
SetWindowOrg	Sets the window origin
SetWindowOrgEx	Sets the window origin
SpoolFile	Puts a file in the spooler queue
StartDoc	Starts a print job
StartPage	Prepares a printer driver to receive data
StretchBlt	Copies a bitmap, transforming it if required
StretchDIBits	Moves DIB from source to destination rectangle
TextOut	Writes character string at specified location
UnrealizeObject	Resets brush origins and realizes palettes
UpdateColors	Updates colors in the client area

DRV_CLOSE (3.1)

DRV_CLOSE

The DRV_CLOSE message is the first message sent by Windows to an installable driver after an application calls the **CloseDriver** function.

Parameter	Description
dwDriverIdentifier	Specifies the unique 32-bit identifier returned by the **OpenDriver** function.
hDriver	Identifies the instance of the installable driver that should be closed.
lParam1	Specifies driver-specific data.
lParam2	Specifies driver-specific data.

Returns

An installable driver returns nonzero if its **DriverProc** function successfully closes the driver. Otherwise, it returns zero.

Comments

The *lParam1* and *lParam2* parameters specify the same values as the *lParam1* and *lParam2* parameters for the **CloseDriver** function.

Each time a driver processes this message, it must decrement a private use-count variable. When the value of this variable is zero, Windows closes the driver.

See Also

DRV_OPEN

DRV_CONFIGURE (3.1)

DRV_CONFIGURE

The DRV_CONFIGURE message is sent to inform an installable driver that it should display its private configuration dialog box.

Parameter	Description
dwDriverIdentifier	Specifies a unique 32-bit value that identifies the installable driver.
hDriver	Identifies an instance of the installable driver.
lParam1	Specifies the handle of the parent window for the configuration dialog box. This handle is in the parameter's low-order word.
lParam2	Points to an optional **DRVCONFIGINFO** structure. An installable driver should verify that this pointer is valid before using it.

Returns

An installable driver returns nonzero if it processes this message. Otherwise, it returns zero.

Comments

An installable driver that supports the DRV_CONFIGURE message must provide its own dialog box template and dialog box procedure. It must also record the user's configuration requests in an appropriate file. (This may be the SYSTEM.INI file or some other file used by the driver for this purpose.)

See Also

DRV_QUERYCONFIGURE

DRV_DISABLE (3.1)

DRV_DISABLE

The DRV_DISABLE message is the second message sent by Windows to an installable driver after an application calls the **CloseDriver** function.

Parameter	Description
dwDriverIdentifier	Not used.
hDriver	Identifies an instance of the installable driver.
lParam1	Not used.
lParam2	Not used.

Returns

An installable driver returns zero if it processes this message.

See Also

DRV_CLOSE

DRV_ENABLE (3.1)

DRV_ENABLE

The DRV_ENABLE message is sent to an installable driver when it is loaded or reloaded or whenever Windows is reinstalled after switching to an MS-DOS application.

Parameter	Description
dwDriverIdentifier	Not used.
hDriver	Identifies an instance of the installable driver.
lParam1	Not used.
lParam2	Not used.

Returns

An installable driver returns zero if it processes this message.

Comments

When the **DriverProc** function receives this message, it should initialize all of the driver-specific structures with default values.

See Also

DRV_OPEN

DRV_EXITAPPLICATION (3.1)

DRV_EXITAPPLICATION

The DRV_EXITAPPLICATION message is sent to all installable drivers when an application exits.

Parameter	Description
dwDriverIdentifier	Specifies a unique 32-bit value that identifies the installable driver.
lParam1	Specifies the type of application exit. This parameter can be one of the following values:

Value	Meaning
DRVEA_NORMALEXIT	Set if the application terminated normally.
DRVEA_ABNORMALEXIT	Set if the application terminated abnormally (because of an application or system error).

lParam2	Not used.

Returns

The value returned by the application is ignored for this message.

See Also

DRV_EXITSESSION

DRV_EXITSESSION (3.1)

DRV_EXITSESSION

The DRV_EXITSESSION message is sent to all installable drivers when Windows prepares to exit.

Parameter	Description
dwDriverIdentifier	Specifies a unique 32-bit value that identifies the installable driver.
lParam1	Reserved.
lParam2	Reserved.

Returns

The value returned by the application is ignored for this message.

Comments

The user interface and all other drivers are still enabled when this message is sent.

See Also

DRV_EXITAPPLICATION

DRV_FREE (3.1)

DRV_FREE

The DRV_FREE message is the third message sent by Windows to an installable driver after an application calls the **CloseDriver** function.

Parameter	Description
dwDriverIdentifier	Not used.
hDriver	Identifies an instance of the installable driver.
lParam1	Not used.
lParam2	Not used.

Returns

An installable driver returns zero if it processes this message.

Comments

When an installable driver's **DriverProc** function receives this message, it should free the memory that was allocated for all driver-specific structures.

DRV_INSTALL (3.1)

DRV_INSTALL

The DRV_INSTALL message is sent to an installable driver during the driver initialization process.

Parameter	Description
dwDriverIdentifier	Specifies a unique 32-bit value that identifies the installable driver.
hDriver	Identifies an instance of the installable driver.
lParam1	Not used.
lParam2	Points to an optional **DRVCONFIGINFO** structure. An installable driver should verify that this pointer is valid before using it.

Returns

An installable driver returns nonzero if it processes this message. Otherwise, it returns zero.

Comments

When the driver receives this message, it creates an entry for the driver in the SYSTEM.INI file and performs other necessary configuration operations.

DRV_LOAD (3.1)

DRV_LOAD

The DRV_LOAD message is sent to an installable driver to notify the driver that it has been loaded.

Parameter	Description
dwDriverIdentifier	Not used.
hDriver	Identifies an instance of the installable driver.
lParam1	Not used.
lParam2	Not used.

Returns

An installable driver returns nonzero if its **DriverProc** function successfully loads the driver. Otherwise, it returns zero.

DRV_OPEN (3.1)

DRV_OPEN

The DRV_OPEN message is sent to an installable driver each time it is opened.

Parameter	Description
dwDriverIdentifier	Specifies a unique 32-bit value that identifies the installable driver.
hDriver	Identifies an instance of the installable driver.
lParam1	Points to a null-terminated string containing any ASCII characters that followed the driver name in the SYSTEM.INI file.
lParam2	Contains the data specified by the *lParam* parameter, the third argument in the **OpenDriver** function.

Returns

An installable driver returns nonzero if it processes this message. Otherwise, it returns zero.

Comments

If no characters follow the driver name in SYSTEM.INI, the *lParam1* parameter is a NULL pointer.

See Also

DRV_CLOSE

DRV_QUERYCONFIGURE (3.1)

DRV_QUERYCONFIGURE

The DRV_QUERYCONFIGURE message is sent to an installable driver to determine whether it can be configured by the user.

Parameter	Description
dwDriverIdentifier	Specifies a unique 32-bit value that identifies the installable driver.
hDriver	Identifies an instance of the installable driver.
lParam1	Not used.
lParam2	Not used.

Returns

An installable driver returns nonzero if it supports custom configuration and is capable of displaying a configuration dialog box. Otherwise, it returns zero.

See Also

DRV_CONFIGURE

DRV_POWER (3.1)

DRV_POWER

The DRV_POWER message is sent to an installable driver each time the power supply to the associated device is about to be turned on or off.

Parameter	Description
dwDriverIdentifier	Specifies a unique 32-bit value that identifies the installable driver.
hDriver	Identifies an instance of the installable driver.
lParam1	Not used.
lParam2	Not used.

Returns

An installable driver returns nonzero if it processes this message. Otherwise, it returns zero.

DRV_REMOVE (3.1)

DRV_REMOVE

The DRV_REMOVE message is sent by an application to an installable driver to notify the driver that it is about to be removed from the system.

Parameter	Description
dwDriverIdentifier	Specifies a unique 32-bit value that identifies the installable driver.
lParam1	Not used.
lParam2	Not used.

Returns

An installable driver returns nonzero if it processes this message. Otherwise, it returns zero.

Comments

When an installable driver receives this message, it should remove necessary entries from the SYSTEM.INI file.

DRV_USER (3.1)

DRV_USER

The DRV_USER message is a user-defined or driver-dependent message.

Parameter	Description
dwDriverIdentifier	This parameter is not predefined; the value is driver dependent.
hDriver	This parameter is not predefined; the value is driver dependent.
lParam1	This parameter is not predefined; the value is driver dependent.
lParam2	This parameter is not predefined; the value is driver dependent.

Returns

The return value is driver dependent.

Installable-driver messages (3.1)

DRV_CLOSE	Indicates that driver should free resources
DRV_CONFIGURE	Indicates that driver should display dialog
DRV_DISABLE	Indicates that driver should unhook interrupts
DRV_ENABLE	Indicates that driver has been loaded or reloaded
DRV_EXITAPPLICATION	Indicates an application is exiting
DRV_EXITSESSION	Informs drivers that Windows is exiting
DRV_FREE	Indicates that driver must free all resources
DRV_INSTALL	Indicates that driver has been installed
DRV_LOAD	Indicates that driver has been loaded.
DRV_OPEN	Indicates that driver will be opened
DRV_QUERYCONFIGURE	Queries driver configuration capabilities
DRV_POWER	Indicates that device power-source was en/disabled
DRV_REMOVE	Indicates that driver will be removed
DRV_USER	Indicates that a user-defined action occurred

_hread (3.1)

long _hread(*hf, hpvBuffer, cbBuffer***)**

```
HFILE hf;                   /* file handle                        */
void _huge* hpvBuffer;      /* address of buffer for read data */
long cbBuffer;              /* length of data buffer              */
```

The **_hread** function reads data from the specified file. This function supports huge memory objects (that is, objects larger than 64K, allocated using the **GlobalAlloc** function).

Parameter	Description
hf	Identifies the file to be read.
hpvBuffer	Points to a buffer that is to receive the data read from the file.
cbBuffer	Specifies the number of bytes to be read from the file.

Returns

The return value indicates the number of bytes that the function read from the file, if the function is successful. If the number of bytes read is less than the number specified in *cbBuffer,* the function reached the end of the file (EOF) before reading the specified number of bytes. The return value is -1L if the function fails.

Comments

MS-DOS error return values are not available when an application calls this function.

See Also

_lread, **hmemcpy**, **_hwrite**

_hwrite (3.1)

long _hwrite(*hf, hpvBuffer, cbBuffer***)**

```
HFILE hf;                       /* file handle                      */
const void _huge* hpvBuffer;    /* address of buffer for write data */
long cbBuffer;                  /* size of data                     */
```

The **_hwrite** function writes data to the specified file. This function supports huge memory objects (that is, objects larger than 64K, allocated using the **GlobalAlloc** function).

Parameter	Description
hf	Identifies the file to be written to.
hpvBuffer	Points to a buffer that contains the data to be written to the file.
cbBuffer	Specifies the number of bytes to be written to the file.

Returns

The return value indicates the number of bytes written to the file, if the function is successful. Otherwise, the return value is -1L.

Comments

MS-DOS error return values are not available when an application calls this function.

See Also

hmemcpy, **_hread**, **_lwrite**

_lclose (2.x)

HFILE _lclose(*hf*)

HFILE *hf;* /* handle of file to close */

The **_lclose** function closes the given file. As a result, the file is no longer available for reading or writing.

Parameter	Description
hf	Identifies the file to be closed. This handle is returned by the function that created or last opened the file.

Returns
The return value is zero if the function is successful. Otherwise, it is HFILE_ERROR.

Example
The following example copies a file to a temporary file, then closes both files:

```
int cbRead;
PBYTE pbBuf;

/* Allocate a buffer for file I/O. */

pbBuf = (PBYTE) LocalAlloc(LMEM_FIXED, 2048);

/* Copy the input file to the temporary file. */

do {
    cbRead = _lread(hfReadFile, pbBuf, 2048);
    _lwrite(hfTempFile, pbBuf, cbRead);
} while (cbRead != 0);

/* Free the buffer and close the files. */

LocalFree((HLOCAL) pbBuf);

_lclose(hfReadFile);
_lclose(hfTempFile);
```

See Also
_lopen, **OpenFile**

_lcreat (2.x)

HFILE _lcreat(*lpszFilename, fnAttribute***)**

```
LPCSTR lpszFilename;      /* address of file to open */
int fnAttribute;          /* file attributes         */
```

The **_lcreat** function creates or opens a specified file. If the file does not exist, the function creates a new file and opens it for writing. If the file does exist, the function truncates the file size to zero and opens it for reading and writing. When the function opens the file, the pointer is set to the beginning of the file.

Parameter	Description
lpszFilename	Points to a null-terminated string that names the file to be opened. The string must consist of characters from the Windows character set.
fnAttribute	Specifies the file attributes. This parameter must be one of the following values:

Value	Meaning
0	Normal; can be read or written without restriction.
1	Read-only; cannot be opened for writing.
2	Hidden; not found by directory search.
3	System; not found by directory search.

Returns

The return value is a file handle if the function is successful. Otherwise, it is HFILE_ERROR.

Comments

Use this function carefully. It is possible to open any file, even one that has already been opened by another function.

Example

The following example uses the **_lcreat** function to open a temporary file:

```
HFILE hfTempFile;
char szBuf[144];

/* Create a temporary file. */

GetTempFileName(0, "tst", 0, szBuf);

hfTempFile = _lcreat(szBuf, 0);

if (hfTempFile == HFILE_ERROR) {
    ErrorHandler();
}
```

_llseek (2.x)

LONG _llseek(*hf, lOffset, nOrigin***)**

```
HFILE hf;       /* file handle                */
LONG lOffset;   /* number of bytes to move */
int nOrigin;    /* position to move from      */
```

The **_llseek** function repositions the pointer in a previously opened file.

Parameter	Description
hf	Identifies the file.
lOffset	Specifies the number of bytes the pointer is to be moved.
nOrigin	Specifies the starting position and direction of the pointer. This parameter must be one of the following values:

Value	Meaning
0	Move the file pointer *lOffset* bytes from the beginning of the file.
1	Move the file pointer *lOffset* bytes from its current position.
2	Move the file pointer *lOffset* bytes from the end of the file.

Returns

The return value specifies the new offset, in bytes, of the pointer from the beginning of the file, if the function is successful. Otherwise, the return value is HFILE_ERROR.

Comments

When a file is initially opened, the file pointer is positioned at the beginning of the file. The **_llseek** function permits random access to a file's contents by moving the pointer an arbitrary amount without reading data.

Example

The following example uses the **_llseek** function to move the file pointer to the end of an existing file:

```
HFILE hfAppendFile;

/* Open the write file. */

hfAppendFile = _lopen("append.txt", WRITE);

/* Move to the end of the file. */

if (_llseek(hfAppendFile, 0L, 2) == -1) {
    ErrorHandler();
}
```

See Also

_lopen

_lopen (2.x)

HFILE _lopen(*lpszFilename, fnOpenMode***)**

LPCSTR *lpszFilename;* /* address of file to open */
int *fnOpenMode;* /* file access */

The _**lopen** function opens an existing file and sets the file pointer to the beginning of the file.

Parameter	Description
lpszFilename	Points to a null-terminated string that names the file to be opened. The string must consist of characters from the Windows character set.
fnOpenMode	Specifies the modes in which to open the file. This parameter consists of one access mode and an optional share mode.

Value	Access mode
READ	Opens the file for reading only.
READ_WRITE	Opens the file for reading and writing.
WRITE	Opens the file for writing only.

Value	Share mode (optional)
OF_SHARE_COMPAT	Opens the file in compatibility mode, allowing any process on a given machine to open the file any number of times. If the file has been opened by using any of the other sharing modes, _**lopen** fails.
OF_SHARE_DENY_NONE	Opens the file without denying other programs read or write access to the file. If the file has been opened in compatibility mode by any other program, _**lopen** fails.
OF_SHARE_DENY_READ	Opens the file and denies other programs read access to the file. If the file has been opened in compatibility mode or for read access by any other program, _**lopen** fails.
OF_SHARE_DENY_WRITE	Opens the file and denies other programs write access to the file. If the file has been opened in compatibility mode or for write access by any other program, _**lopen** fails.
OF_SHARE_EXCLUSIVE	Opens the file in exclusive mode, denying other programs both read and write access to the file. If the file has been opened in any other mode for read or write access, even by the current program, _**lopen** fails.

Returns
The return value is a file handle if the function is successful. Otherwise, it is HFILE_ERROR.

Example
The following example uses the _**lopen** function to open an input file:

```
HFILE hfReadFile;
/* Open the input file (read only). */

hfReadFile = _lopen("testfile", READ);

if (hfReadFile == HFILE_ERROR) {
    ErrorHandler();
```

```
}
```

See Also
OpenFile

_lread (2.x)

UINT _lread(*hf, hpvBuffer, cbBuffer***)**

HFILE *hf;* /* file handle */
void _huge* *hpvBuffer;* /* address of buffer for read data */
UINT *cbBuffer;* /* length of data buffer */

The **_lread** function reads data from the specified file.

Parameter	Description
hf	Identifies the file to be read.
hpvBuffer	Points to a buffer that is to receive the data read from the file.
cbBuffer	Specifies the number of bytes to be read from the file. This value cannot be greater than 0xFFFE (65,534).

Returns

The return value indicates the number of bytes that the function read from the file, if the function is successful. If the number of bytes read is less than the number specified in *cbBuffer,* the function reached the end of the file (EOF) before reading the specified number of bytes. The return value is HFILE_ERROR if the function fails.

Comments

MS-DOS error return values are not available when an application calls this function.

Example

The following example uses the **_lread** and **_lwrite** functions to copy data from one file to another:

```
HFILE hfReadFile;
int cbRead;
PBYTE pbBuf;

/* Allocate a buffer for file I/O. */

pbBuf = (PBYTE) LocalAlloc(LMEM_FIXED, 2048);

/* Copy the input file to the temporary file. */

do {
    cbRead = _lread(hfReadFile, pbBuf, 2048);
    _lwrite(hfTempFile, pbBuf, cbRead);
} while (cbRead != 0);

/* Free the buffer and close the files. */

LocalFree((HLOCAL) pbBuf);

_lclose(hfReadFile);
_lclose(hfTempFile);
```

See Also

_hread, **_lwrite**

_lwrite (2.x)

UINT _lwrite(*hf, hpvBuffer, cbBuffer***)**

```
HFILE hf;                          /* file handle                      */
const void _huge* hpvBuffer;       /* address of buffer for write data */
UINT cbBuffer;                     /* size of data                     */
```

The **_lwrite** function writes data to the specified file.

Parameter	Description
hf	Identifies the file to be written to.
hpvBuffer	Points to a buffer that contains the data to be written to the file.
cbBuffer	Specifies the number of bytes to be written to the file. If this parameter is zero, the file is expanded or truncated to the current file-pointer position. This value cannot be greater than 0xFFFE (65,534).

Returns

The return value indicates the number of bytes written to the file, if the function is successful. Otherwise, the return value is HFILE_ERROR.

Comments

The buffer specified by *hpvBuffer* cannot extend past the end of a segment.

MS-DOS error return values are not available when an application calls this function.

Example

The following example uses the **_lread** and **_lwrite** functions to copy data from one file to another:

```
int cbRead;
PBYTE pbBuf;

/* Allocate a buffer for file I/O. */

pbBuf = (PBYTE) LocalAlloc(LMEM_FIXED, 2048);

/* Copy the input file to the temporary file. */

do {
    cbRead = _lread(hfReadFile, pbBuf, 2048);
    _lwrite(hfTempFile, pbBuf, cbRead);
} while (cbRead != 0);

/* Free the buffer and close the files. */

LocalFree((HLOCAL) pbBuf);

_lclose(hfReadFile);
_lclose(hfTempFile);
```

See Also

_hwrite, **_lread**

AccessResource (2.x)

int AccessResource(*hinst, hrsrc***)**

```
HINSTANCE hinst;        /* handle of module with resource */
HRSRC hrsrc;            /* handle of resource             */
```

The **AccessResource** function opens the given executable file and moves the file pointer to the beginning of the given resource.

Parameter	Description
hinst	Identifies the instance of the module whose executable file contains the resource.
hrsrc	Identifies the desired resource. This handle should be created by using the **FindResource** function.

Returns

The return value is the handle of the resource file if the function is successful. Otherwise, it is -1.

Comments

The **AccessResource** function supplies an MS-DOS file handle that can be used in subsequent file-read calls to load the resource. The file is opened for reading only.

Applications that use this function must close the resource file by calling the **_lclose** function after reading the resource. **AccessResource** can exhaust available MS-DOS file handles and cause errors if the opened file is not closed after the resource is accessed.

In general, the **LoadResource** and **LockResource** functions are preferred. These functions will access the resource more quickly if several resources are being read, because Windows maintains a file-handle cache for accessing executable files. However, each call to **AccessResource** requires that a new handle be opened to the executable file.

You should not use **AccessResource** to access executable files that are installed in ROM on a ROM-based system, since there are no disk files associated with the executable file; in such a case, a file handle cannot be returned.

See Also

FindResource, **_lclose**, **LoadResource**, **LockResource**

AddAtom (2.x)

ATOM AddAtom(*lpszName***)**

LPCSTR *lpszName;* /* address of string to add */

The **AddAtom** function adds a character string to the local atom table and returns a unique value identifying the string.

Parameter	Description
lpszName	Points to the null-terminated character string to be added to the table.

Returns
The return value specifies the newly created atom if the function is successful. Otherwise, it is zero.

Comments
The **AddAtom** function stores no more than one copy of a given string in the atom table. If the string is already in the table, the function returns the existing atom value and increments (increases by one) the string's reference count.

The **MAKEINTATOM** macro can be used to convert a word value into a string that can be added to the atom table by using the **AddAtom** function.

The atom values returned by **AddAtom** are in the range 0xC000 through 0xFFFF.

Atoms are case-insensitive.

Example
The following example uses the **AddAtom** function to add the string "This is an atom" to the local atom table:

```
ATOM at;
char szMsg[80];

at = AddAtom("This is an atom");

if (at == 0)
    MessageBox(hwnd, "AddAtom failed", "", MB_ICONSTOP);
else {
    wsprintf(szMsg, "AddAtom returned %u", at);
    MessageBox(hwnd, szMsg, "", MB_OK);
}
```

See Also
DeleteAtom, **FindAtom**, **GetAtomName**, **MAKEINTATOM**

Changes

AllocDStoCSAlias (3.0)

UINT AllocDStoCSAlias(*uSelector***)**

UINT *uSelector;* /* data-segment selector */

The **AllocDStoCSAlias** function accepts a data-segment selector and returns a code-segment selector that can be used to execute code in the data segment.

Parameter	Description
uSelector	Specifies the data-segment selector.

Returns

The return value is the code-segment selector corresponding to the data-segment selector if the function is successful. Otherwise, it is zero.

Comments

The application must free the new selector by calling the **FreeSelector** function.

In protected mode, attempting to execute code directly in a data segment will cause a general-protection violation. **AllocDStoCSAlias** allows an application to execute code that the application had created in its own stack segment.

Windows does not track segment movements. Consequently, the data segment must be fixed and nondiscardable; otherwise, the data segment might move, invalidating the code-segment selector.

The **PrestoChangoSelector** function provides another method of obtaining a code selector corresponding to a data selector.

An application should not use this function unless it is absolutely necessary, since its use violates preferred Windows programming practices.

See Also

FreeSelector, **PrestoChangoSelector**

Correction

The previous description of this function indicated that the application should free the selector with the **FreeSelector** function. Applications should *not* free the selector.

AllocResource (2.x)

HGLOBAL AllocResource(*hinst, hrsrc, cbResource***)**

```
HINSTANCE hinst;        /* handle of module containing resource */
HRSRC hrsrc;            /* handle of resource                   */
DWORD cbResource;       /* size to allocate, or zero            */
```

The **AllocResource** function allocates uninitialized memory for the given resource.

Parameter	Description
hinst	Identifies the instance of the module whose executable file contains the resource.
hrsrc	Identifies the desired resource. This handle should have been created by using the **FindResource** function.
cbResource	Specifies the size, in bytes, of the memory object to allocate for the resource. If this parameter is zero, Windows allocates enough memory for the specified resource.

Returns

The return value is the handle of the global memory object if the function is successful.

See Also

FindResource, **LoadResource**

AllocSelector (3.0)

UINT AllocSelector(*uSelector***)**

UINT *uSelector;* /* selector to copy or zero */

The **AllocSelector** function allocates a new selector.

Do not use this function in an application unless it is absolutely necessary, since its use violates preferred Windows programming practices.

Parameter	Description
uSelector	Specifies the selector to return. If this parameter specifies a valid selector, the function returns a new selector that is an exact copy of the one specified here. If this parameter is zero, the function returns a new, uninitialized sector.

Returns

The return value is a selector that is either a copy of an existing selector, or a new, uninitialized selector. Otherwise, the return value is zero.

Comments

The application must free the new selector by calling the **FreeSelector** function.

An application can call **AllocSelector** to allocate a selector that it can pass to the **PrestoChangoSelector** function.

See Also

PrestoChangoSelector

AnsiToOem (2.x)

void AnsiToOem(*hpszWindows, hpszOem***)**

const char _huge* *hpszWindows;* /* address of string to translate */
char _huge* *hpszOem;* /* address of buffer for string */

The **AnsiToOem** function translates a string from the Windows character set into the specified OEM character set.

Parameter	Description
hpszWindows	Points to a null-terminated string of characters from the Windows character set.
hpszOem	Points to the location where the translated string is to be copied. To translate the string in place, this parameter can be the same as *hpszWindows.*

Returns
This function does not return a value.

Comments
The string to be translated can be greater than 64K in length.

Windows-to-OEM mappings are defined by the keyboard driver, where this function is implemented. Some keyboard drivers may have different mappings than others, depending on the machine environment, and some keyboard driver support loading different OEM character sets; for example, the standard U.S. keyboard driver for an IBM keyboard supports loadable code pages, with the default being code page 437 and the most common alternative being code page 850. (The Windows character set is sometimes referred to as code page 1007.)

The OEM character set must always be used when accessing string data created by MS-DOS or MS-DOS applications. For example, a word processor should convert OEM characters to Windows characters when importing documents from an MS-DOS word processor. When an application makes an MS-DOS call, including a C run-time function call, filenames must be in the OEM character set, whereas they must be presented to the user in Windows characters (because the Windows fonts use Windows characters).

Example
The following example is part of a dialog box in which a user would create a directory by typing a name in an edit control:

```
case IDOK:
    GetWindowText(GetDlgItem(hwndDlg, ID_EDITDIRNAME), szDirName,
        sizeof(szDirName));
    AnsiToOem(szDirName, szDirName);
    mkdir(szDirName);
    EndDialog(hwndDlg, 1);
    return TRUE;
```

See Also
AnsiToOemBuff, **OemToAnsi**

AnsiToOemBuff (3.0)

void AnsiToOemBuff(*lpszWindowsStr, lpszOemStr, cbWindowsStr***)**

```
LPCSTR lpszWindowsStr;      /* address of string to translate          */
LPSTR lpszOemStr;           /* address of buffer for translated string */
UINT cbWindowsStr;          /* length of string to translate           */
```

The **AnsiToOemBuff** function translates a string from the Windows character set into the specified OEM character set.

Parameter	Description
lpszWindowsStr	Points to a buffer containing one or more characters from the Windows character set.
lpszOemStr	Points to the location where the translated string is to be copied. To translate the string in place, this parameter can be the same as *lpszWindowsStr.*
cbWindowsStr	Specifies the number of bytes in the buffer identified by the *lpszWindowsStr* parameter. If *cbWindowsStr* is zero, the length is 64K (65,536).

Returns

This function does not return a value.

See Also

AnsiToOem, **OemToAnsi**

Catch (2.x)

int Catch(*lpCatchBuf***)**

int FAR* *lpCatchBuf;* /* address of buffer for array */

The **Catch** function captures the current execution environment and copies it to a buffer. The **Throw** function can use this buffer later to restore the execution environment. The execution environment includes the state of all system registers and the instruction counter.

Parameter	Description
lpCatchBuf	Points to a memory buffer large enough to contain a **CATCHBUF** array.

Returns

The **Catch** function returns immediately with a return value of zero. When the **Throw** function is called, it returns again, this time with the return value specified in the *nErrorReturn* parameter of the **Throw** function.

Comments

The **Catch** function is similar to the C run-time function **setjmp**.

Example

The following example calls the **Catch** function to save the current execution environment before calling a recursive sort function. The first return value from **Catch** is zero. If the doSort function calls the **Throw** function, execution will again return to the **Catch** function. This time, **Catch** will return the STACKOVERFLOW error passed by the doSort function. The doSort function is recursive--that is, it calls itself. It maintains a variable, wStackCheck, that is used to check to see how much stack space has been used. If more then 3K of the stack has been used, doSort calls **Throw** to drop out of all the nested function calls back into the function that called **Catch**.

```
#define STACKOVERFLOW 1

UINT uStackCheck;
CATCHBUF catchbuf;

{
    int iReturn;
    char szBuf[80];

    if ((iReturn = Catch((int FAR*) catchbuf)) != 0) {
        .
        . /* Error processing goes here. */
        .
    }
    else {
        uStackCheck = 0;       /* initializes stack-usage count */
        doSort(1, 100);        /* calls sorting function        */
    }
    break;
}

void doSort(int sLeft, int sRight)
{
    int sLast;

    /*
     * Determine whether more than 3K of the stack has been
     * used, and if so, call Throw to drop back into the
```

```
     * original calling application.
     *
     * The stack is incremented by the size of the two parameters,
     * the two local variables, and the return value (2 for a near
     * function call).
     */

    uStackCheck += (sizeof(int) * 4) + 2;

    if (uStackCheck > (3 * 1024))
        Throw((int FAR*) catchbuf, STACKOVERFLOW);
    .
    . /* A sorting algorithm goes here. */
    .

    doSort(sLeft, sLast - 1);   /* note recursive call          */
    uStackCheck -= 10;          /* updates stack-check variable */
}
```

See Also

Throw

CloseSound (2.x)

void CloseSound(void)

This function is obsolete. Use the multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

CountVoiceNotes (2.x)

int CountVoiceNotes(*nvoice***)**

int *nvoice;* /* sound queue to be counted */

This function is obsolete. Use the multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

DebugBreak (3.0)

void DebugBreak(void)

The **DebugBreak** function causes a breakpoint exception to occur in the caller. This allows the calling process to signal the debugger, forcing it to take some action. If the process is not being debugged, the system invokes the default breakpoint exception handler. This may cause the calling process to terminate.

Returns

This function does not return a value.

Comments

This function is the only way to break into a **WEP** (Windows exit procedure) in a dynamic-link library.

For more information about using the debugging functions with Microsoft debugging tools, see Tools

Example

The following example uses the **DebugBreak** function to signal the debugger immediately before the application handles the **WM_DESTROY** message:

```
case WM_DESTROY:

    DebugBreak();
    PostQuitMessage(0);
    break;
```

See Also

WEP

DebugOutput (3.1)

void FAR _cdecl DebugOutput(*flags, lpszFmt, ...***)**

UINT *flags;* /* type of message */
LPCSTR *lpszFmt;* /* address of formatting string */

The **DebugOutput** function sends a message to the debugging terminal. Applications can apply the formatting codes to the message string and use filters and options to control the message category.

Parameter	Description
flags	Specifies the type of message to be sent to the debugging terminal. This parameter can be one of the following values:

Value	Meaning
DBF_TRACE	The message reports that no error has occurred and supplies information that may be useful during debugging. Example: "t Kernel: LoadResource(14AE of GDI)"
DBF_WARNING	The message reports a situation that may or may not be an error, depending on the circumstances. Example: "wn Kernel: GlobalWire(17BE of GDI) (try GlobalLock)"
DBF_ERROR	The message reports an error resulting from a failed call to a Windows function. The application continues to run. Example: "err Kernel: LocalShrink(15EA of GDI) (invalid local heap)"
DBF_FATAL	The message reports an error that will terminate the application. Example: "fatl User: SetDeskWallpaper(16CA of USER)"

lpszFmt	Points to a formatting string identical to the formatting strings used by the Windows function **wsprintf**. This string must be less than 160 characters long. Any additional formatting can be done by supplying additional parameters following *lpszFmt.*
. . .	Specifies zero or more optional arguments. The number and type of arguments depends on the corresponding format-control character sequences specified in the *lpszFmt* parameter.

Returns
This function does not return a value.

Comments
The messages sent by the **DebugOutput** function are affected by the system debugging options and trace-filter flags that are set and retrieved by using the **GetWinDebugInfo** and **SetWinDebugInfo** functions. These options and flags are stored in a **WINDEBUGINFO** structure.

Unlike most other Windows functions, **DebugOutput** uses the C calling convention (**_cdecl**), rather than the Pascal calling convention. As a result, the caller must pop arguments off the stack. Also, arguments must be pushed on the stack from right to left. In C-language modules, the C compiler performs this task.

See Also
GetWinDebugInfo, **OutputDebugString**, **SetWinDebugInfo**, **wsprintf**, **WINDEBUGINFO**

DBF_TRACE 0x0000

The message reports that no error has occurred and supplies information that may be useful during debugging. Example: "t Kernel: LoadResource(14AE of GDI)"

DBF_TRACE 0x0000

DBF_WARNING 0x4000

The message reports a situation that may or may not be an error, depending on the circumstances. Example: "wn Kernel: GlobalWire(17BE of GDI) (try GlobalLock)"

DBF_WARNING 0x4000

DBF_ERROR 0x8000

The message reports an error resulting from a failed call to a Windows function. The application continues to run. Example: "err Kernel: LocalShrink(15EA of GDI) (invalid local heap)"

DBF_ERROR 0x8000

DBF_FATAL 0xc000

The message reports an error that will terminate the application. Example: "fatl User: SetDeskWallpaper(16CA of USER)"

DBF_FATAL 0xc000

DeleteAtom (2.x)

ATOM DeleteAtom(*atm***)**

ATOM *atm;* /* atom to delete */

The **DeleteAtom** function decrements (decreases by one) the reference count of a local atom by one. If the atom's reference count is reduced to zero, the string associated with the atom is removed from the local atom table.

An atom's reference count specifies the number of times the atom has been added to the atom table. The **AddAtom** function increments (increases by one) the count on each call. **DeleteAtom** decrements the count on each call and removes the string only if the atom's reference count is reduced to zero.

Parameter	Description
atm	Identifies the atom and character string to be deleted.

Returns
The return value is zero if the function is successful. Otherwise, it is equal to the *atm* parameter.

Comments
The only way to ensure that an atom has been deleted from the atom table is to call this function repeatedly until it fails. When the count is decremented to zero, the next call to the **FindAtom** or **DeleteAtom** function will fail.

DeleteAtom has no effect on integer atoms (atoms created by using the **MAKEINTATOM** macro). The function always returns zero for integer atoms.

Example
The following example uses the **DeleteAtom** function to decrement the reference count for the specified atom:

```
ATOM at;

at = DeleteAtom(atTest);

if (at == NULL)
    MessageBox(hwnd, "atom count decremented",
        "DeleteAtom", MB_OK);
else
    MessageBox(hwnd, "atom count could not be decremented",
        "DeleteAtom", MB_ICONEXCLAMATION);
```

See Also
AddAtom, **FindAtom**, **GlobalDeleteAtom**

DirectedYield (3.1)

void DirectedYield(*htask***)**

HTASK *htask;*

The **DirectedYield** function puts the current task to sleep and awakens the given task.

Parameter	Description
htask	Specifies the task to be executed.

Returns
This function does not return a value.

Comments
When relinquishing control to other applications (that is, when exiting hard mode), a Windows-based debugger should call **DirectedYield**, identifying the handle of the task being debugged. This ensures that the debugged application runs next and that messages received during debugging are processed by the appropriate windows.

The Windows scheduler executes a task only when there is an event waiting for it, such as a paint message, or a message posted in the message queue.

If an application uses **DirectedYield** for a task with no events scheduled, the task will not be executed. Instead, Windows searches the task queue. In some cases, however, you may want the application to force a specific task to be scheduled. The application can do this by calling the **PostAppMessage** function, specifying a WM_NULL message identifier. Then, when the application calls **DirectedYield**, the scheduler will run the task regardless of the task's event status.

DirectedYield starts the task identified by *htask* at the location where it left off. Typically, debuggers should use **TaskSwitch** instead of **DirectedYield**, because **TaskSwitch** can start a task at any address.

DirectedYield returns when the current task is reawakened. This occurs when the task identified by *htask* waits for messages or uses the **Yield** or **DirectedYield** function. Execution will continue as before the task switch.

DirectedYield is located in KRNL286.EXE and KRNL386.EXE and is available in Windows versions 3.0 and 3.1.

See Also
PostAppMessage, **TaskSwitch**, **TaskGetCSIP**, **TaskSetCSIP**, **Yield**

DOS3Call (3.0)

DOS3Call

The **DOS3Call** function allows an application to call an MS-DOS Interrupt 21h function. **DOS3Call** can be called only from assembly-language routines. It is exported from KRNL286.EXE and KRNL386.EXE and is not defined in any Windows header or include files.

Parameters

Registers must be set up as required by the desired Interrupt 21h function before the application calls the **DOS3Call** function.

Returns

The register contents are preserved as they are returned by the Interrupt 21h function.

Comments

Applications should use this function instead of a directly coded MS-DOS Interrupt 21h function. The **DOS3Call** function runs somewhat faster than the equivalent MS-DOS Interrupt 21h function running in Windows.

Example

The following example shows how to prototype the **DOS3Call** function in C:

```
extern void FAR PASCAL DOS3Call(void);
```

To declare the **DOS3Call** function in an assembly-language routine, an application could use the following line:

```
extrn DOS3CALL: far
```

If the application includes CMACROS.INC, the function is declared as follows:

```
extrnFP DOS3Call
```

The following example is a typical use of the **DOS3Call** function:

```
extrn DOS3CALL: far
                .
                .
                .
        ; set registers

        mov     ah, DOSFUNC    ;DOSFUNC = Int 21h function number
        cCall   DOS3Call
```

FatalAppExit (3.0)

void FatalAppExit(*fuAction, lpszMessageText***)**

```
UINT fuAction;                  /* must be zero                    */
LPCSTR lpszMessageText;         /* string to display in message box */
```

The **FatalAppExit** function displays a message box and terminates the application when the message box is closed. If the user is running the debugging version of the Windows operating system, the message box gives the user the opportunity to terminate the application or to cancel the message box and return to the caller.

Parameter	Description
fuAction	Reserved; must be zero.
lpszMessageText	Points to a null-terminated string that is displayed in the message box. The message is displayed on a single line. To accommodate low-resolution screens, the string should contain no more than 35 characters.

Returns

This function does not return a value.

Comments

An application should call the **FatalAppExit** function only when it is incapable of terminating any other way. **FatalAppExit** may not always free an application's memory or close its files, and it may cause a general failure of Windows. An application that encounters an unexpected error should terminate by freeing all its memory and returning from its main message loop.

See Also

FatalExit, **TerminateApp**

FatalExit (2.x)

void FatalExit(*nErrCode***)**

int *nErrCode;* /* error value to display */

The **FatalExit** function sends the current state of Windows to the debugger and prompts for instructions on how to proceed.

An application should call this function for debugging purposes only; it should not call the function in a retail version of the application. Calling this function in the retail version will terminate the application.

Parameter	Description
nErrCode	Specifies the error value to be displayed.

Returns
This function does not return a value.

Comments
The displayed information includes an error value followed by a symbolic stack trace, showing the flow of execution up to the point of the call.

The **FatalExit** function prompts the user to respond to an Abort, Break, or Ignore message. Windows processes the response as follows:

Response	Description
A (Abort)	Terminate immediately.
B (Break)	Enter the debugger.
I (Ignore)	Return to the caller.

You can specify any combination of error values for the *nErrCode* parameter, since the meaning of the values is unique to your application. However, the error value -1 must always be reserved for the stack-overflow message. When this value is specified, Windows automatically displays a stack-overflow message.

See Also
FatalAppExit

FindAtom (2.x)

ATOM FindAtom(*lpszString***)**

LPCSTR *lpszString;* /* address of string to find */

The **FindAtom** function searches the local atom table for the specified character string and retrieves the atom associated with that string.

Parameter	Description
lpszString	Points to the null-terminated character string to search for.

Returns

The return value identifies the atom associated with the given string if the function is successful. Otherwise (if the string is not in the table), the return value is zero.

Example

The following example uses the **FindAtom** function to retrieve the atom for the string "This is an atom":

```
ATOM at;
char szMsg[80];

if ((at = FindAtom("This is an atom")) == 0)
    MessageBox(hwnd, "could not find atom",
        "FindAtom", MB_ICONEXCLAMATION);
else {
    wsprintf(szMsg, "atom = %u", at);
    MessageBox(hwnd, szMsg, "FindAtom", MB_OK);
}
```

See Also

AddAtom, **DeleteAtom**

FindResource (2.x)

HRSRC FindResource(*hinst, lpszName, lpszType***)**

```
HINSTANCE hinst;        /* handle of module containing resource */
LPCSTR lpszName;        /* address of resource name             */
LPCSTR lpszType;        /* address of resource type             */
```

The **FindResource** function determines the location of a resource in the specified resource file.

Parameter	Description
hinst	Identifies the instance of the module whose executable file contains the resource.
lpszName	Specifies the name of the resource. For details, see the following Comments section.
lpszType	Specifies the resource type. For details, see the following Comments section. For predefined resource types, this parameter should be one of the following values:

Value	Meaning
RT_ACCELERATOR	Accelerator table
RT_BITMAP	Bitmap resource
RT_CURSOR	Cursor resource
RT_DIALOG	Dialog box
RT_FONT	Font resource
RT_FONTDIR	Font directory resource
RT_ICON	Icon resource
RT_MENU	Menu resource
RT_RCDATA	User-defined resource (raw data)
RT_STRING	String resource

Returns

The return value is the handle of the named resource if the function is successful. Otherwise, it is NULL.

Comments

If the high-order word of the *lpszName* or *lpszType* parameter is zero, the low-order word specifies the integer identifier of the name or type of the given resource. Otherwise, the parameters are long pointers to null-terminated strings. If the first character of the string is a pound sign (#), the remaining characters represent a decimal number that specifies the integer identifier of the resource's name or type. For example, the string #258 represents the integer ID 258.

To reduce the amount of memory required for the resources used by an application, the application should refer to the resources by integer identifier instead of by name.

An application must not call the **FindResource** and **LoadResource** functions to load cursor, icon, and string resources. Instead, it must load these resources by calling the **LoadCursor**, **LoadIcon**, and **LoadString** functions, respectively.

Although the application can call the **FindResource** and **LoadResource** functions to load other predefined resource types, it should load the corresponding resources by calling the **LoadAccelerators**, **LoadBitmap**, and **LoadMenu** functions.

FreeLibrary (2.x)

void FreeLibrary(*hinst***)**

HINSTANCE *hinst;* /* handle of loaded library module */

The **FreeLibrary** function decrements (decreases by one) the reference count of the loaded library module. When the reference count reaches zero, the memory occupied by the module is freed.

Parameter	Description
hinst	Identifies the loaded library module.

Returns
This function does not return a value.

Comments
A dynamic-link library (DLL) must not call the **FreeLibrary** function within its **WEP** function (Windows exit procedure).

The reference count for a library module is incremented (increased by one) each time an application calls the **LoadLibrary** function for the library module.

Example
The following example uses the **LoadLibrary** function to load TOOLHELP.DLL and the **FreeLibrary** function to free it:

```
HINSTANCE hinstToolHelp = LoadLibrary("TOOLHELP.DLL");

if ((UINT) hinstToolHelp > 32) {
        .
        . /* use GetProcAddress to use TOOLHELP functions */
        .
}
else {
    ErrorHandler();
}

if ((UINT) hinstToolHelp > 32)
   FreeLibrary(hinstToolHelp); /* free TOOLHELP.DLL      */
```

See Also
GetProcAddress, **LoadLibrary**, **WEP**

FreeModule (3.0)

BOOL FreeModule(*hinst***)**

HINSTANCE *hinst;* /* handle of loaded module */

The **FreeModule** function decrements (decreases by one) the reference count of the loaded module. When the reference count reaches zero, the memory occupied by the module is freed.

Parameter	Description
hinst	Identifies the loaded module.

Returns

The return value is zero if the reference count is decremented to zero and the module's memory is freed. Otherwise, the return value is nonzero.

Comments

The reference count for a module is incremented (increased by one) each time an application calls the **LoadModule** function for the module.

See Also

LoadModule

FreeProcInstance (2.x)

void FreeProcInstance(*lpProc***)**

FARPROC *lpProc;* /* instance address of function to free */

The **FreeProcInstance** function frees the specified function from the data segment bound to it by the **MakeProcInstance** function.

Parameter	Description
lpProc	Points to the procedure-instance address of the function to be freed. It must be created by using the **MakeProcInstance** function.

Returns

This function does not return a value.

Comments

After a procedure instance has been freed, attempts to call the function using the freed procedure-instance address will result in an unrecoverable error.

See Also

MakeProcInstance

FreeResource (2.x)

BOOL FreeResource(*hglbResource***)**

HGLOBAL *hglbResource;* /* handle of loaded resource */

The **FreeResource** function decrements (decreases by one) the reference count of a loaded resource. When the reference count reaches zero, the memory occupied by the resource is freed.

Parameter	Description
hglbResource	Identifies the data associated with the resource. The handle is assumed to have been created by using the **LoadResource** function.

Returns

The return value is zero if the function is successful. Otherwise, it is nonzero, indicating that the function has failed and the resource has not been freed.

Comments

The reference count for a resource is incremented (increased by one) each time an application calls the **LoadResource** function for the resource.

See Also

LoadResource

FreeSelector (3.0)

UINT FreeSelector(*uSelector***)**

UINT *uSelector;* /* selector to be freed */

The **FreeSelector** function frees a selector originally allocated by the **AllocSelector** or **AllocDStoCSAlias** function. After the application calls this function, the selector is invalid and must not be used.

An application should not use this function unless it is absolutely necessary, since its use violates preferred Windows programming practices.

Parameter	Description
uSelector	Specifies the selector to be freed.

Returns

The return value is zero if the function is successful. Otherwise, it is the selector specified by the *uSelector* parameter.

Comments

The limit for the selector specified by the *uSelector* parameter must not be larger than 64K. If the limit of the selector exceeds 64K, the **FreeSelector** function may free selectors that are still required by the program.

See Also

AllocDStoCSAlias, **AllocSelector**

GetAtomHandle (2.x)

HLOCAL GetAtomHandle(*atm***)**

ATOM *atm;* /* atom to retrieve handle of */

The **GetAtomHandle** function retrieves a handle of the specified atom.

This function is only provided for compatibility with Windows, versions 1.*x* and 2.*x.* It should not be used with Windows 3.0 and later.

Parameter	Description
atm	Specifies an atom whose handle is to be retrieved.

Returns
The return value is a handle of the specified atom if the function is successful.

See Also
GetAtomName, **GlobalGetAtomName**

GetAtomName (2.x)

UINT GetAtomName(*atm, lpszBuffer, cbBuffer***)**

```
ATOM atm;          /* atom identifying character string */
LPSTR lpszBuffer;  /* address of buffer for atom string */
int cbBuffer;      /* size of buffer                    */
```

The **GetAtomName** function retrieves a copy of the character string associated with the specified local atom.

Parameter	Description
atm	Specifies the local atom that identifies the character string to be retrieved.
lpszBuffer	Points to the buffer for the character string.
cbBuffer	Specifies the maximum size, in bytes, of the buffer.

Returns
The return value specifies the number of bytes copied to the buffer, if the function is successful.

Comments
The string returned for an integer atom (an atom created by the **MAKEINTATOM** macro) will be a null-terminated string, where the first character is a pound sign (#) and the remaining characters make up the **UINT** used in **MAKEINTATOM**.

Example
The following example uses the **GetAtomName** function to retrieve the character string associated with a local atom:

```
char szBuf[80];

GetAtomName(atTest, szBuf, sizeof(szBuf));

MessageBox(hwnd, szBuf, "GetAtomName", MB_OK);
```

See Also
AddAtom, **DeleteAtom**, **FindAtom**, **MAKEINTATOM**

GetCodeHandle (2.x)

HGLOBAL GetCodeHandle(*lpProc***)**

FARPROC *lpProc;* /* instance address of function */

The **GetCodeHandle** function determines which code segment contains the specified function.

Parameter	Description
lpProc	Points to the procedure-instance address of the function for which to return the code segment. Typically, this address is returned by the **MakeProcInstance** function.

Returns

The return value identifies the code segment that contains the function if the **GetCodeHandle** function is successful. Otherwise, it is NULL.

Comments

If the code segment that contains the function is already loaded, the **GetCodeHandle** function marks the segment as recently used. If the code segment is not loaded, **GetCodeHandle** attempts to load it. Thus, an application can use this function to attempt to preload one or more segments necessary to perform a particular task.

See Also

MakeProcInstance

GetCodeInfo (3.0)

void GetCodeInfo(*lpProc, lpSegInfo***)**

```
FARPROC lpProc;          /* function address or module handle          */
SEGINFO FAR* lpSegInfo;  /* address of structure for segment information */
```

The **GetCodeInfo** function retrieves a pointer to a structure containing information about a code segment.

Parameter	Description
lpProc	Specifies the procedure-instance address of the function (typically, returned by the **MakeProcInstance** function) in the segment for which information is to be retrieved, or it specifies a module handle (typically, returned by the **GetModuleHandle** function) and segment number.
lpSegInfo	Points to a **SEGINFO** structure that will be filled with information about the code segment.

Returns

This function does not return a value.

See Also

GetModuleHandle, **MakeProcInstance**

GetCurrentPDB (3.0)

UINT GetCurrentPDB(void)

The **GetCurrentPDB** function returns the selector address of the current MS-DOS program database (PDB), also known as the program segment prefix (PSP).

Returns

The return value is the selector address of the current PDB if the function is successful.

Example

The following example uses the **GetCurrentPDB** function to list the current command tail:

```
typedef struct {
    WORD pspInt20;            /* Int 20h instruction             */
    WORD pspNextParagraph;    /* segment addr. of next paragraph */
    BYTE res1;                /* reserved                        */
    BYTE pspDispatcher[5];    /* long call to MS-DOS             */
    DWORD pspTerminateVector; /* termination address (Int 22h)   */
    DWORD pspControlCVector;  /* addr of CTRL+C (Int 23h)        */
    DWORD pspCritErrorVector; /* addr of Crit-Error (Int 24h)    */
    WORD res2[11];            /* reserved                        */
    WORD pspEnvironment;      /* segment address of environment  */
    WORD res3[23];            /* reserved                        */
    BYTE pspFCB_1[16];        /* default FCB #1                  */
    BYTE pspFCB_2[16];        /* default FCB #2                  */
    DWORD res4;               /* reserved                        */
    BYTE pspCommandTail[128]; /* command tail (also default DTA) */
} PSP, FAR* LPSP;

    LPSP lpsp = (LPSP) MAKELP(GetCurrentPDB(), 0);

    MessageBox(NULL, lpsp->pspCommandTail, "PDB Command Tail", MB_OK);
```

GetCurrentTask (2.x)

HTASK GetCurrentTask(void)

The **GetCurrentTask** function retrieves the handle of the current (running) task.

Returns
The return value is a handle of the current task if the function is successful. Otherwise, it is NULL.

GetDOSEnvironment (3.0)

LPSTR GetDOSEnvironment(void)

The **GetDOSEnvironment** function returns a far pointer to the environment string of the current (running) task.

Returns

The return value is a far pointer to the current environment string.

Comments

Unlike an application, a dynamic-link library (DLL) does not have a copy of the environment string. As a result, the library must call this function to retrieve the environment string.

Example

The following example uses the **GetDOSEnvironment** function to return a pointer to the environment, and then lists the environment settings:

```
LPSTR lpszEnv;

lpszEnv = GetDOSEnvironment();
while (*lpszEnv != '\0') {
    .
    . /* process the environment string */
    .

    /* Move to the next environment string */

    lpszEnv += lstrlen(lpszEnv) + 1;
}
```

GetDriveType (3.0)

UINT GetDriveType(*DriveNumber***)**

int *DriveNumber;* /* 0 = A, 1 = B, and so on */

The **GetDriveType** function determines whether a disk drive is removable, fixed, or remote.

Parameter	Description
DriveNumber	Specifies the drive for which the type is to be determined (0 = drive A, 1 = drive B, 2 = drive C, and so on).

Returns

The return value is DRIVE_REMOVABLE (disk can be removed from the drive), DRIVE_FIXED (disk cannot be removed from the drive), or DRIVE_REMOTE (drive is a remote, or network, drive), if the function is successful. Otherwise, the return value is zero.

Example

The following example uses the **GetDriveType** function to determine the drive type for all possible disk drives (letters A through Z):

```
int  iDrive;
WORD wReturn;
char szMsg[80];

for (iDrive = 0, wReturn = 0;
        (iDrive < 26) && (wReturn != 1); iDrive++) {

    wReturn = GetDriveType(iDrive);

    sprintf(szMsg, "drive %c: ", iDrive + 'A');

    switch (wReturn) {
        case 0:
            strcat(szMsg, "undetermined");
            break;

        case DRIVE_REMOVABLE:
            strcat(szMsg, "removable");
            break;

        case DRIVE_FIXED:
            strcat(szMsg, "fixed");
            break;

        case DRIVE_REMOTE:
            strcat(szMsg, "remote (network)");
            break;
    }
    TextOut(hdc, 10, 15 * iDrive, szMsg, strlen(szMsg));
}
```

GetFreeSpace (3.0)

DWORD GetFreeSpace(*fuFlags***)**

UINT *fuFlags;* /* ignored in Windows 3.1*/

The **GetFreeSpace** function scans the global heap and returns the number of bytes of memory currently available.

Parameter	Description
fuFlags	This parameter is ignored in Windows 3.1.

Returns
The return value is the amount of available memory, in bytes.

Comments
The amount of memory specified by the return value is not necessarily contiguous; the **GlobalCompact** function returns the number of bytes in the largest block of free global memory.

In standard mode, the value returned represents the number of bytes in the global heap that are not used and that are not reserved for code.

In 386-enhanced mode, the return value is an estimate of the amount of memory available to an application. It does not account for memory held in reserve for non-Windows applications.

See Also
GlobalCompact

GetInstanceData (2.x)

int GetInstanceData(*hinst, npbData, cbData***)**

```
HINSTANCE hinst;        /* handle of previous instance          */
BYTE* npbData;          /* address of current instance data buffer */
int cbData;             /* number of bytes to transfer          */
```

The **GetInstanceData** function copies data from a previous instance of an application into the data area of the current instance.

Parameter	Description
hinst	Identifies a previous instance of the application.
npbData	Points to a buffer in the current instance.
cbData	Specifies the number of bytes to be copied.

Returns

The return value specifies the number of bytes copied if the function is successful. Otherwise, it is zero.

GetKBCodePage (3.0)

int GetKBCodePage(void)

The **GetKBCodePage** function returns the current Windows code page.

Returns

The return value specifies the code page currently loaded by Windows, if the function is successful. It can be one of the following values:

Value	Meaning
437	Default (United States, used by most countries: indicates that there is no OEMANSI.BIN in the Windows directory)
850	International (OEMANSI.BIN = XLAT850.BIN)
860	Portugal (OEMANSI.BIN = XLAT860.BIN)
861	Iceland (OEMANSI.BIN = XLAT861.BIN)
863	French Canadian (OEMANSI.BIN = XLAT863.BIN)
865	Norway/Denmark (OEMANSI.BIN = XLAT865.BIN)

Comments

The keyboard driver provides the **GetKBCodePage** function. An application using this function must include the following information in its module-definition (.DEF) file:

```
IMPORTS
    KEYBOARD.GETKBCODEPAGE
```

If the OEMANSI.BIN file is in the Windows directory, Windows reads it and overwrites the OEM/ANSI translation tables in the keyboard driver.

When the user selects a language from the Setup program and the language does not use the default code page (437), Setup copies the appropriate file (such as XLAT850.BIN) to OEMANSI.BIN in the Windows system directory. If the language uses the default code page, Setup deletes OEMANSI.BIN, if it exists, from the Windows system directory.

Example

The following example uses the **GetKBCodePage** function to display the current code page:

```
char szBuf[80];
int i, cp, subtype, f_keys, len;

char *apszKeyboards[] = {
    "IBM PX/XT",
    "Olivetti ICO",
    "IBM AT",
    "IBM Enhanced",
    "Nokia 1050",
    "Nokia 9140",
    "Standard Japanese",
    };

cp = GetKBCodePage();

if ((i = GetKeyboardType(0)) == 0 || i > 7) {
    MessageBox(NULL, "invalid keyboard type",
        "GetKeyboardType", MB_ICONSTOP);
    break;
```

```
}

subtype = GetKeyboardType(1);
f_keys = GetKeyboardType(2);

len = wsprintf(szBuf, "%s keyboard, subtype %d\n",
    apszKeyboards[i - 1], subtype);
len = wsprintf(szBuf + len, " %d function keys, code page %d",
    f_keys, cp);

MessageBox(NULL, szBuf, "Keyboard Information", MB_OK);
```

See Also

GetKeyboardType

GetKeyboardType (3.0)

int GetKeyboardType(*fnKeybInfo***)**

int *fnKeybInfo;* /* specifies type of information to retrieve */

The **GetKeyboardType** function retrieves information about the current keyboard.

Parameter	Description
fnKeybInfo	Determines the type of keyboard information to be retrieved. This parameter can be one of the following values:

Value	Meaning
0	Retrieves the keyboard type.
1	Retrieves the keyboard subtype.
2	Retrieves the number of function keys on the keyboard.

Returns

The return value specifies the requested information if the function is successful. Otherwise, it is zero.

Comments

The subtype is an OEM-dependent value. The subtype may be one of the following values:

Value	Meaning
1	IBM PC/XT, or compatible (83-key) keyboard
2	Olivetti "ICO" (102-key) keyboard
3	IBM AT (84-key) or similar keyboard
4	IBM Enhanced (101- or 102-key) keyboard
5	Nokia 1050 and similar keyboards
6	Nokia 9140 and similar keyboards
7	Japanese keyboard

The keyboard driver provides the **GetKeyboardType** function. An application using this function must include the following information in its module-definition (.DEF) file:

```
IMPORTS
    KEYBOARD.GETKEYBOARDTYPE
```

The application can also determine the number of function keys on a keyboard from the keyboard type. The number of function keys for each keyboard type follows:

Type	Number of function keys
1	10
2	12 (sometimes 18)
3	10
4	12
5	10
6	24
7	This value is hardware-dependent and must be specified by the OEM.

Example

The following example uses the **GetKeyboardType** function to display information about the current keyboard:

```
char szBuf[80];
int i, cp, subtype, f_keys, len;
```

```
char *apszKeyboards[] = {
    "IBM PX/XT",
    "Olivetti ICO",
    "IBM AT",
    "IBM Enhanced",
    "Nokia 1050",
    "Nokia 9140",
    "Standard Japanese",
    };

cp = GetKBCodePage();

if ((i = GetKeyboardType(0)) == 0 || i > 7) {
    MessageBox(NULL, "invalid keyboard type",
        "GetKeyboardType", MB_ICONSTOP);
    break;
}

subtype = GetKeyboardType(1);
f_keys = GetKeyboardType(2);

len = wsprintf(szBuf, "%s keyboard, subtype %d\n",
    apszKeyboards[i - 1], subtype);
len = wsprintf(szBuf + len, " %d function keys, code page %d",
    f_keys, cp);

MessageBox(NULL, szBuf, "Keyboard Information", MB_OK);
```

GetKeyNameText (3.0)

int GetKeyNameText(*lParam, lpszBuffer, cbMaxKey***)**

```
LONG lParam;        /* 32-bit parameter of keyboard message  */
LPSTR lpszBuffer;   /* address of a buffer for key name      */
int cbMaxKey;       /* specifies maximum key string length   */
```

The **GetKeyNameText** function retrieves a string that represents the name of a key.

Parameter	Description
lParam	Specifies the 32-bit parameter of the keyboard message (such as **WM_KEYDOWN**) to be processed. The **GetKeyNameText** function interprets the following portions of *lParam:*

Bits	Meaning
16-23	Character scan code.
24	Extended bit. Distinguishes some keys on an enhanced keyboard.
25	"Don't care" bit. The application calling this function sets this bit to indicate that the function should not distinguish between left and right CTRL and SHIFT keys, for example.

lpszBuffer	Points to a buffer that will receive the key name.
cbMaxKey	Specifies the maximum length, in bytes, of the key name, not including the terminating null character (this parameter should one less than the size of the buffer pointed to by the *lpszBuffer* parameter).

Returns

The return value is the length, in bytes, of the string copied to the specified buffer, if the function is successful. Otherwise, it is zero.

Comments

The format of the key-name string depends on the current keyboard driver. This driver maintains a list of names in the form of character strings for keys with names longer than a single character. The key name is translated, according to the layout of the currently installed keyboard, into the principal language supported by the keyboard driver.

Correction

The previous documentation incorrectly listed bit 21 of *lparam* as the extended bit and bit 22 as the "don't care" bit.

GetModuleFileName (2.x)

int GetModuleFileName(*hinst, lpszFilename, cbFileName***)**

HINSTANCE *hinst;* /* handle of module */
LPSTR *lpszFilename;* /* address of buffer for filename */
int *cbFileName;* /* maximum number of bytes to copy */

The **GetModuleFileName** function retrieves the full path and filename of the executable file from which the specified module was loaded.

Parameter	Description
hinst	Identifies the module or the instance of the module.
lpszFilename	Points to the buffer that is to receive the null-terminated filename.
cbFileName	Specifies the maximum number of bytes to copy, including the terminating null character. The filename is truncated if it is longer than *cbFileName.* This parameter should be set to the length of the filename buffer.

Returns
The return value specifies the length, in bytes, of the string copied to the specified buffer, if the function is successful. Otherwise, it is zero.

Example
The following example retrieves an application's filename by using the instance handle passed to the application in the **WinMain** function:

```
int PASCAL WinMain(HINSTANCE hinst, HINSTANCE hPrevInst,
    LPSTR lpCmdLine, int nCmdShow)
{
    char szModuleName[260];

    GetModuleFileName(hinst, szModuleName, sizeof(szModuleName));
```

See Also
GetModuleHandle

GetModuleHandle (2.x)

HMODULE GetModuleHandle(*lpszModuleName***)**

LPCSTR *lpszModuleName;* /* address of name of module */

The **GetModuleHandle** function retrieves the handle of the specified module.

Parameter	Description
lpszModuleName	Points to a null-terminated string that specifies the name of the module.

Returns

The return value is the handle of the module if the function is successful. Otherwise, it is NULL.

See Also

GetModuleFileName

GetModuleUsage (2.x)

int GetModuleUsage(*hinst***)**

HINSTANCE *hinst;* /* handle of module */

The **GetModuleUsage** function retrieves the reference count of a specified module.

Parameter	Description
hinst	Identifies the module or an instance of the module.

Returns
The return value specifies the reference count of the module if the function is successful.

Comments
Windows increments (increases by one) a module's reference count each time an application calls the **LoadModule** function. The count is decremented (decreased by one) when an application calls the **FreeModule** function.

See Also
FreeModule, **LoadModule**

GetNumTasks (2.x)

UINT GetNumTasks(void)

The **GetNumTasks** function retrieves the number of currently running tasks.

Returns
The return value specifies the number of current tasks.

GetPrivateProfileInt (3.0)

UINT GetPrivateProfileInt(*lpszSection, lpszEntry, default, lpszFilename***)**

```
LPCSTR lpszSection;     /* address of section                */
LPCSTR lpszEntry;       /* address of entry                  */
int default;            /* return value if entry not found   */
LPCSTR lpszFilename;    /* address of initialization filename */
```

The **GetPrivateProfileInt** function retrieves the value of an integer from an entry within a specified section of a specified initialization file.

Parameter	Description
lpszSection	Points to a null-terminated string containing the section heading in the initialization file.
lpszEntry	Points to the null-terminated string containing the entry whose value is to be retrieved.
default	Specifies the default value to return if the entry cannot be found in the initialization file. This value must be a positive integer in the range 0 through 32,767 (0x0000 through 0x7FFF).
lpszFilename	Points to a null-terminated string that names the initialization file. If this parameter does not contain a full path, Windows searches for the file in the Windows directory.

Returns

The return value is the integer value of the specified entry if the function is successful. It is the value of the *default* parameter if the function does not find the entry. The return value is zero if the value that corresponds to the specified entry is not an integer.

Comments

The function searches the file for an entry that matches the name specified by the *lpszEntry* parameter under the section heading specified by the *lpszSection* parameter. An integer entry in the initialization file must have the following form:

[*section*]
entry=value
.
.
.

If the value that corresponds to the entry consists of digits followed by nonnumeric characters, the function returns the value of the digits. For example, the function would return 102 for the line "Entry=102abc".

The **GetPrivateProfileInt** function is not case-dependent, so the strings in the *lpszSection* and *lpszEntry* parameters may contain a combination of uppercase and lowercase letters.

GetPrivateProfileInt supports hexadecimal notation. When **GetPrivateProfileInt** is used to retrieve a negative integer, the value should be cast to an **int**.

An application can use the **GetProfileInt** function to retrieve an integer value from the WIN.INI file.

Example

The following example uses the **GetPrivateProfileInt** function to retrieve the last line number by reading the LastLine entry from the [MyApp] section of TESTCODE.INI:

```
WORD wInt;
char szMsg[144];

wInt = GetPrivateProfileInt("MyApp", "LastLine",
    0, "testcode.ini");
```

```
sprintf(szMsg, "last line was %d", wInt);
MessageBox(hwnd, szMsg, "GetPrivateProfileInt", MB_OK);
```

See Also
GetPrivateProfileString, **GetProfileInt**

Windows 3.1 changes

The **GetPrivateProfileInt** function supports hexadecimal notation. When the **GetPrivateProfileInt** function is used to retrieve a negative integer, the value should be cast to an **int**.

GetPrivateProfileString (3.0)

int GetPrivateProfileString(*lpszSection, lpszEntry, lpszDefault, lpszReturnBuffer, cbReturnBuffer, lpszFilename***)**

```
LPCSTR lpszSection;      /* address of section                */
LPCSTR lpszEntry;        /* address of entry                  */
LPCSTR lpszDefault;      /* address of default string         */
LPSTR lpszReturnBuffer;  /* address of destination buffer     */
int cbReturnBuffer;      /* size of destination buffer        */
LPCSTR lpszFilename;     /* address of initialization filename */
```

The **GetPrivateProfileString** function retrieves a character string from the specified section in the specified initialization file.

Parameter	Description
lpszSection	Points to a null-terminated string that specifies the section containing the entry.
lpszEntry	Points to the null-terminated string containing the entry whose associated string is to be retrieved. If this value is NULL, all entries in the section specified by the *lpszSection* parameter are copied to the buffer specified by the *lpszReturnBuffer* parameter. For more information, see the following Comments section.
lpszDefault	Points to a null-terminated string that specifies the default value for the given entry if the entry cannot be found in the initialization file. This parameter must never be NULL.
lpszReturnBuffer	Points to the buffer that receives the character string.
cbReturnBuffer	Specifies the size, in bytes, of the buffer pointed to by the *lpszReturnBuffer* parameter.
lpszFilename	Points to a null-terminated string that names the initialization file. If this parameter does not contain a full path, Windows searches for the file in the Windows directory.

Returns

The return value specifies the number of bytes copied to the specified buffer, not including the terminating null character.

Comments

The function searches the file for an entry that matches the name specified by the *lpszEntry* parameter under the section heading specified by the *lpszSection* parameter. If the entry is found, its corresponding string is copied to the buffer. If the entry does not exist, the default character string specified by the *lpszDefault* parameter is copied. A string entry in the initialization file must have the following form:

```
[section]
entry=string
    .
    .
    .
```

If *lpszEntry* is NULL, the **GetPrivateProfileString** function copies all entries in the specified section to the supplied buffer. Each string will be null-terminated, with the final string ending with two zero-termination characters. If the supplied destination buffer is too small to hold all the strings, the last string will be truncated and followed with two zero-termination characters.

If the string associated with *lpszEntry* is enclosed in single or double quotation marks, the marks are discarded when **GetPrivateProfileString** returns the string.

GetPrivateProfileString is not case-dependent, so the strings in *lpszSection* and *lpszEntry* may contain a combination of uppercase and lowercase letters.

An application can use the **GetProfileString** function to retrieve a string from the WIN.INI file.

The *lpszDefault* parameter must point to a valid string, even if the string is empty (its first character is zero).

Example

The following example uses the **GetPrivateProfileString** function to determine the last file saved by the [MyApp] application by reading the LastFile entry in TESTCODE.INI:

```
char szMsg[144], szBuf[80];

GetPrivateProfileString("MyApp", "LastFile",
    "", szBuf, sizeof(szBuf), "testcode.ini");

sprintf(szMsg, "last file was %s", szBuf);
MessageBox(hwnd, szMsg, "GetPrivateProfileString", MB_OK);
```

See Also

GetProfileString, **WritePrivateProfileString**

GetProcAddress (2.x)

FARPROC GetProcAddress(*hinst, lpszProcName***)**

HINSTANCE *hinst;* /* handle of module */
LPCSTR *lpszProcName;* /* address of function */

The **GetProcAddress** function retrieves the address of the given module function.

Parameter	Description
hinst	Identifies the module that contains the function.
lpszProcName	Points to a null-terminated string containing the function name, or specifies the ordinal value of the function. If it is an ordinal value, the value must be in the low-order word and the high-order word must be zero.

Returns

The return value is the address of the module function's entry point if the **GetProcAddress** function is successful. Otherwise, it is NULL.

If the *lpszProcName* parameter is an ordinal value and a function with the specified ordinal does not exist in the module, **GetProcAddress** can still return a non-NULL value. In cases where the function may not exist, specify the function by name rather than ordinal value.

Comments

Use the **GetProcAddress** function to retrieve addresses of exported functions in dynamic-link libraries (DLLs). The **MakeProcInstance** function can be used to access functions within different instances of the current module.

The spelling of the function name (pointed to by the *lpszProcName* parameter) must be identical to the spelling as it appears in the **EXPORTS** section of the source DLL's module-definition (.DEF) file.

Example

The following example uses the **GetProcAddress** function to retrieve the address of the **TimerCount** function in TOOLHELP.DLL:

```
char szBuf[80];
TIMERINFO timerinfo;
HINSTANCE hinstToolHelp;
BOOL (FAR *lpfnTimerCount) (TIMERINFO FAR*);

/* Turn off the "File not found" error box. */

SetErrorMode(SEM_NOOPENFILEERRORBOX);

/* Load the TOOLHELP.DLL library module. */

hinstToolHelp = LoadLibrary("TOOLHELP.DLL");

if (hinstToolHelp > HINSTANCE_ERROR) {    /* loaded successfully */

    /* Retrieve the address of the TimerCount function. */

    (FARPROC) lpfnTimerCount =
        GetProcAddress(hinstToolHelp, "TimerCount");

    if (lpfnTimerCount != NULL) {

        /* Call the TimerCount function. */
```

```
        timerinfo.dwSize = sizeof(TIMERINFO);

        if ((*lpfnTimerCount) ((TIMERINFO FAR *) &timerinfo)) {
            sprintf(szBuf, "task: %lu seconds\nVM: %lu seconds",
                timerinfo.dwmsSinceStart / 1000,
                timerinfo.dwmsThisVM / 1000);
        }
        else {
            strcpy(szBuf, "TimerCount failed");
        }
    }
    else {
        strcpy(szBuf, "GetProcAddress failed");
    }

    /* Free the TOOLHELP.DLL library module. */

    FreeLibrary(hinstToolHelp);
}
else {
    strcpy(szBuf, "LoadLibrary failed");
}

MessageBox(NULL, szBuf, "Library Functions", MB_ICONHAND);
```

MakeProcInstance

GetProfileInt (2.x)

UINT GetProfileInt(*lpszSection, lpszEntry, default***)**

```
LPCSTR lpszSection;     /* address of section                */
LPCSTR lpszEntry;       /* address of entry                  */
int default;            /* return value if entry is not found */
```

The **GetProfileInt** function retrieves the value of an integer from an entry within a specified section of the WIN.INI initialization file.

Parameter	Description
lpszSection	Points to a null-terminated string that specifies the section containing the entry.
lpszEntry	Points to the null-terminated string containing the entry whose value is to be retrieved.
default	Specifies the default value to return if the entry cannot be found. This value can be an unsigned value in the range 0 through 65,536 or a signed value in the range -32,768 through 32,768. Hexadecimal notation is accepted for both positive and negative values.

Returns

The return value is the integer value of the string following the specified entry, if the function is successful. The return value is the value of the *default* parameter if the function does not find the entry. The return value is zero if the value that corresponds to the specified entry is not an integer.

Comments

The **GetProfileInt** function is not case-dependent, so the strings in the *lpszSection* and *lpszEntry* parameters may contain a combination of uppercase and lowercase letters.

GetProfileInt supports hexadecimal notation. When the function is used to retrieve a negative integer, the value should be cast to an **int**.

An integer entry in the WIN.INI file must have the following form:

[*section*]
entry=value
.
.
.

If the value that corresponds to the entry consists of digits followed by nonnumeric characters, the function returns the value of the digits. For example, the function would return 102 for the line "Entry=102abc".

An application can use the **GetPrivateProfileInt** function to retrieve an integer from a specified file.

Example

The following example uses the **GetProfileInt** function to retrieve the screen-save timeout time from the WIN.INI file:

```
WORD wTimeOut;
char szMsg[80];

wTimeOut = GetProfileInt("windows",
    "ScreenSaveTimeOut", 0);

sprintf(szMsg, "timeout time is %d", wTimeOut);
MessageBox(hwnd, szMsg, "GetProfileInt", MB_OK);
```

See Also

GetPrivateProfileInt, **GetProfileString**

Windows 3.1 changes

The **GetProfileInt** function supports hexadecimal notation. When the **GetProfileInt** function is used to retrieve a negative integer, the value should be cast to an **int**.

GetProfileString (2.x)

int GetProfileString(*lpszSection, lpszEntry, lpszDefault, lpszReturnBuffer, cbReturnBuffer***)**

LPCSTR *lpszSection;* /* address of section */
LPCSTR *lpszEntry;* /* address of entry */
LPCSTR *lpszDefault;* /* address of default string */
LPSTR *lpszReturnBuffer;* /* address of destination buffer */
int *cbReturnBuffer;* /* size of destination buffer */

The **GetProfileString** function retrieves the string associated with an entry within the specified section in the WIN.INI initialization file.

Parameter	Description
lpszSection	Points to a null-terminated string that specifies the section containing the entry.
lpszEntry	Points to the null-terminated string containing the entry whose associated string is to be retrieved. If this value is NULL, all entries in the section specified by the *lpszSection* parameter are copied to the buffer specified by the *lpszReturnBuffer* parameter. For more information, see the following Comments section.
lpszDefault	Points to the default value for the given entry if the entry cannot be found in the initialization file. This parameter must never be NULL.
lpszReturnBuffer	Points to the buffer that will receive the character string.
cbReturnBuffer	Specifies the size, in bytes, of the buffer pointed to by the *lpszReturnBuffer* parameter.

Returns
The return value is the number of bytes copied to the buffer, not including the terminating zero, if the function is successful.

Comments
If the *lpszEntry* parameter is NULL, the **GetProfileString** function copies all entries in the specified section to the supplied buffer. Each string will be null-terminated, with the final string terminating with two null characters. If the supplied destination buffer is too small to hold all the strings, the last string will be truncated and followed by two terminating null characters.

If the string associated with *lpszEntry* is enclosed in single or double quotation marks, the marks are discarded when **GetProfileString** returns the string.

GetProfileString is not case-dependent, so the strings in the *lpszSection* and *lpszEntry* parameters may contain a combination of uppercase and lowercase letters.

A string entry in the WIN.INI file must have the following form:

[*section*]
entry=string
.
.
.

An application can use the **GetPrivateProfileString** function to retrieve a string from a specified file.

The *lpszDefault* parameter must point to a valid string, even if the string is empty (its first character is zero).

Example
The following example uses the **GetProfileString** function to list all the entries and strings in the [windows] section of the WIN.INI file:

```
int c, cc;
```

```
PSTR pszBuf, pszKey;
char szMsg[80], szVal[80];

/* Allocate a buffer for the entries. */

pszBuf = (PSTR) LocalAlloc(LMEM_FIXED, 1024);

/* Retrieve all the entries in the [windows] section. */

GetProfileString("windows", NULL, "", pszBuf, 1024);

 /*
  *  Retrieve the string for each entry, until
  *  reaching the double null character.
  */

for (pszKey = pszBuf, c = 0;
        *pszKey != '\0'; pszKey += strlen(pszKey) + 1) {

    /* Retrieve the value for each entry in the buffer. */

    GetProfileString("windows", pszKey, "not found",
        szVal, sizeof(szVal));

    cc = sprintf(szMsg, "%s = %s", pszKey, szVal);
    TextOut(hdc, 10, 15 * c++, szMsg, cc);
}

LocalFree((HANDLE) pszBuf);
```

GetPrivateProfileString, WriteProfileString

GetSelectorBase (3.1)

DWORD GetSelectorBase(*uSelector***)**

UINT *uSelector;*

The **GetSelectorBase** function retrieves the base address of a selector.

Parameter	Description
uSelector	Specifies the selector whose base address is retrieved.

Returns
This function returns the base address of the specified selector.

See Also
GetSelectorLimit, **SetSelectorBase**, **SetSelectorLimit**

GetSelectorLimit (3.1)

DWORD GetSelectorLimit(*uSelector***)**

UINT *uSelector;*

The **GetSelectorLimit** function retrieves the limit of a selector.

Parameter	Description
uSelector	Specifies the selector whose limit is being retrieved.

Returns
This function returns the limit of the specified selector.

See Also
GetSelectorBase, **SetSelectorBase**, **SetSelectorLimit**

GetSystemDirectory (3.0)

UINT GetSystemDirectory(*lpszSysPath, cbSysPath***)**

LPSTR *lpszSysPath;* /* address of buffer for system directory */
UINT *cbSysPath;* /* size of directory buffer */

The **GetSystemDirectory** function retrieves the path of the Windows system directory. The system directory contains such files as Windows libraries, drivers, and font files.

Parameter	Description
lpszSysPath	Points to the buffer that is to receive the null-terminated string containing the path of the system directory.
cbSysPath	Specifies the maximum size, in bytes, of the buffer. This value should be set to at least 144 to allow sufficient room in the buffer for the path.

Returns

The return value is the length, in bytes, of the string copied to the *lpszSysPath* parameter, not including the terminating null character. If the return value is greater than the size specified in the *cbSysPath* parameter, the return value is the size of the buffer required to hold the path. The return value is zero if the function fails.

Comments

Applications should *not* create files in the system directory. If the user is running a shared version of Windows, the application will not have write access to the system directory. Applications should create files only in the directory returned by the **GetWindowsDirectory** function.

The path that this function retrieves does not end with a backslash unless the system directory is the root directory. For example, if the system directory is named WINDOWS\SYSTEM on drive C, the path of the system directory retrieved by this function is C:\WINDOWS\SYSTEM.

A similar function, **GetSystemDir**, is intended for use by MS-DOS applications that set up Windows applications. Windows applications should use **GetSystemDirectory**, not **GetSystemDir**.

Example

The following example uses the **GetSystemDirectory** function to determine the path of the Windows system directory:

```
WORD wReturn;
char szBuf[144];

wReturn = GetSystemDirectory((LPSTR) szBuf, sizeof(szBuf));

if (wReturn == 0)
    MessageBox(hwnd, "function failed",
        "GetSystemDirectory", MB_ICONEXCLAMATION);

else if (wReturn > sizeof(szBuf))
    MessageBox(hwnd, "buffer is too small",
        "GetSystemDirectory", MB_ICONEXCLAMATION);

else
    MessageBox(hwnd, szBuf, "GetSystemDirectory", MB_OK);
```

See Also

GetWindowsDirectory

GetTempDrive (2.x)

BYTE GetTempDrive(*chDriveLetter***)**

char *chDriveLetter;* /* ignored */

The **GetTempDrive** function returns a letter that specifies a disk drive the application can use for temporary files.

Parameter	Description
chDriveLetter	This parameter is ignored.

Returns

The return value specifies a disk drive for temporary files if the function is successful. If at least one hard disk drive is available, the function returns the letter of the first hard disk drive (usually C). If no hard disk drives are available, the function returns the letter of the current drive.

Example

The following example uses the **GetTempDrive** function to determine a suitable disk drive for temporary files:

```
char szMsg[80];
BYTE bTempDrive;

bTempDrive = GetTempDrive(0);

sprintf(szMsg, "temporary drive: %c", bTempDrive);

MessageBox(hwnd, szMsg, "GetTempDrive", MB_OK);
```

See Also

GetTempFileName

GetTempFileName (2.x)

int GetTempFileName(*bDriveLetter, lpszPrefixString, uUnique, lpszTempFileName***)**

```
BYTE bDriveLetter;      /* suggested drive                    */
LPCSTR lpszPrefixString; /* address of filename prefix         */
UINT uUnique;           /* number to use as prefix            */
LPSTR lpszTempFileName; /* address of buffer for created filename */
```

The **GetTempFileName** function creates a temporary filename of the following form:

*drive:******path******prefixuuuu.***TMP**

The following list describes the filename syntax:

Element	Description
drive	Drive letter specified by the *bDriveLetter* parameter
path	Path of the temporary file (either the Windows directory or the directory specified in the TEMP environment variable)
prefix	All the letters (up to the first three) of the string pointed to by the *lpszPrefixString* parameter
uuuu	Hexadecimal value of the number specified by the *uUnique* parameter

Parameter	Description
bDriveLetter	Specifies the suggested drive for the temporary filename. If this parameter is zero, Windows uses the current default drive.
lpszPrefixString	Points to a null-terminated string to be used as the temporary filename prefix. This string must consist of characters in the OEM-defined character set.
uUnique	Specifies an unsigned short integer. If this parameter is nonzero, it will be appended to the temporary filename. If the parameter is zero, Windows uses the current system time to create a number to append to the filename.
lpszTempFileName	Points to the buffer that will receive the temporary filename. This string consists of characters in the OEM-defined character set. This buffer should be at least 144 bytes in length to allow sufficient room for the path.

Returns

The return value specifies a unique numeric value used in the temporary filename. If the *uUnique* parameter is nonzero, the return value specifies this same number.

Comments

Temporary files created with this function are *not* automatically deleted when Windows shuts down.

To avoid problems resulting from converting an OEM character string to a Windows string, an application should call the **_lopen** function to create the temporary file.

The **GetTempFileName** function uses the suggested drive letter for creating the temporary filename, except in the following cases:

- If a hard disk is present, **GetTempFileName** always uses the drive letter of the first hard disk.
- If, however, a TEMP environment variable is defined and its value begins with a drive letter, that drive letter is used.

If the TF_FORCEDRIVE bit of the *bDriveLetter* parameter is set, the preceding exceptions do not apply. The temporary filename will always be created in the current directory of the drive specified by *bDriveLetter,* regardless of the presence of a hard disk or the TEMP environment variable.

If the *uUnique* parameter is zero, **GetTempFileName** attempts to form a unique number based on the current system time. If a file with the resulting filename exists, the number is increased by one and the test for existence is repeated. This continues until a unique filename is found; **GetTempFileName** then

creates a file by that name and closes it. No attempt is made to create and open the file when *uUnique* is nonzero.

Example

The following example uses the **GetTempFileName** function to create a unique temporary filename on the first available hard disk:

```
HFILE hfTempFile;
char szBuf[144];

/* Create a temporary file. */

GetTempFileName(0, "tst", 0, szBuf);

hfTempFile = _lcreat(szBuf, 0);

if (hfTempFile == HFILE_ERROR) {
    ErrorHandler();
}
```

GetTempDrive, **_lopen**

GetThresholdEvent (2.x)

int FAR* GetThresholdEvent(void)

This function is obsolete. Use the Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

GetThresholdStatus (2.x)

int GetThresholdStatus(void)

This function is obsolete. Use the Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

GetVersion (2.x)

DWORD GetVersion(void)

The **GetVersion** function retrieves the current version numbers of the Windows and MS-DOS operation systems.

Returns
The return value specifies the major and minor version numbers of Windows and of MS-DOS.

Comments
The low-order word of the return value contains the version of Windows, if the function is successful. The high-order byte contains the minor version (revision) number as a two-digit decimal number. For example, in Windows 3.1, the minor version number is 10. The low-order byte contains the major version number.

The high-order word contains the version of MS-DOS, if the function is successful. The high-order byte contains the major version; the low-order byte contains the minor version (revision) number.

Example
The following example uses the **GetVersion** function to display the Windows and MS-DOS version numbers:

```
int len;
char szBuf[80];
DWORD dwVersion;

dwVersion = GetVersion();

len = sprintf(szBuf, "Windows version %d.%d\n",
    LOBYTE(LOWORD(dwVersion)),
    HIBYTE(LOWORD(dwVersion)));

sprintf(szBuf + len, "MS-DOS version %d.%d",
    HIBYTE(HIWORD(dwVersion)),
    LOBYTE(HIWORD(dwVersion)));

MessageBox(NULL, szBuf, "GetVersion", MB_ICONINFORMATION);
```

Note that the major and minor version information is reversed between the Windows version and MS-DOS version.

Win 3.1 correction

The return value is a **DWORD**, not a WORD. The high-order word contains the DOS version.

GetWinDebugInfo (3.1)

BOOL GetWinDebugInfo(*lpwdi, flags***)**

```
WINDEBUGINFO FAR* lpwdi;        /* address of WINDEBUGINFO structure   */
UINT flags;                     /* flags for returned information      */
```

The **GetWinDebugInfo** function retrieves current system-debugging information for the debugging version of the Windows 3.1 operating system.

Parameter	Description
lpwdi	Points to a **WINDEBUGINFO** structure that is filled with debugging information.
flags	Specifies which members of the **WINDEBUGINFO** structure should be filled in. This parameter can be one or more of the following values:

Value	Meaning
WDI_OPTIONS	Fill in the **dwOptions** member of **WINDEBUGINFO**.
WDI_FILTER	Fill in the **dwFilter** member of **WINDEBUGINFO**.
WDI_ALLOCBREAK	Fill in the **achAllocModule**, **dwAllocBreak**, and **dwAllocCount** members of **WINDEBUGINFO**.

Returns

The return value is nonzero if the function is successful. It is zero if the pointer specified in the *lpwdi* parameter is invalid or if the function is not called in the debugging version of Windows 3.1.

Comments

The **flags** member of the returned **WINDEBUGINFO** structure is set to the values supplied in the *flags* parameter of this function.

See Also

SetWinDebugInfo, **WINDEBUGINFO**

WDI_OPTIONS 0x0001

Fill in the **dwOptions** member of **WINDEBUGINFO**.

WDI_OPTIONS 0x0001

WDI_FILTER 0x0002

Fill in the **dwFilter** member of **WINDEBUGINFO**.

WDI_FILTER 0x0002

WDI_ALLOCBREAK 0x0004

Fill in the **achAllocModule**, **dwAllocBreak**, and **dwAllocCount** members of **WINDEBUGINFO**.

WDI_ALLOCBREAK 0x0004

GetWindowsDirectory (3.0)

UINT GetWindowsDirectory(*lpszSysPath, cbSysPath***)**

LPSTR *lpszSysPath;* /* address of buffer for Windows directory*/
UINT *cbSysPath;* /* size of directory buffer */

The **GetWindowsDirectory** function retrieves the path of the Windows directory. The Windows directory contains such files as Windows applications, initialization files, and help files.

Parameter	Description
lpszSysPath	Points to the buffer that will receive the null-terminated string containing the path.
cbSysPath	Specifies the maximum size, in bytes, of the buffer. This value should be set to at least 144 to allow sufficient room in the buffer for the path.

Returns

The return value is the length, in bytes, of the string copied to the *lpszSysPath* parameter, not including the terminating null character. If the return value is greater than the number specified in the *cbSysPath* parameter, it is the size of the buffer required to hold the path. The return value is zero if the function fails.

Comments

The Windows directory is the *only* directory where an application should create files. If the user is running a shared version of Windows, the Windows directory is the only directory guaranteed private to the user.

The path this function retrieves does not end with a backslash unless the Windows directory is the root directory. For example, if the Windows directory is named WINDOWS on drive C, the path retrieved by this function is C:\WINDOWS. If Windows is installed in the root directory of drive C, the path retrieved is C:\.

A similar function, **GetWindowsDir**, is intended for use by MS-DOS applications that set up Windows applications. Windows applications should use **GetWindowsDirectory**, not **GetWindowsDir**.

Example

The following example uses the **GetWindowsDirectory** function to determine the path of the Windows directory:

```
WORD wReturn;
char szBuf[144];

wReturn = GetWindowsDirectory((LPSTR)szBuf, sizeof(szBuf));

if (wReturn == 0)
    MessageBox(hwnd, "function failed",
        "GetWindowsDirectory", MB_ICONEXCLAMATION);

else if (wReturn > sizeof(szBuf))
    MessageBox(hwnd, "buffer is too small",
        "GetWindowsDirectory", MB_ICONEXCLAMATION);

else
    MessageBox(hwnd, szBuf, "GetWindowsDirectory", MB_OK);
```

See Also

GetSystemDirectory

GetWinFlags (3.0)

DWORD GetWinFlags(void)

The **GetWinFlags** function retrieves the current Windows system and memory configuration.

Returns
The return value specifies the current system and memory configuration.

Comments
The configuration returned by **GetWinFlags** can be a combination of the following values:

Value	Meaning
WF_80x87	System contains an Intel math coprocessor.
WF_CPU286	System CPU is an 80286.
WF_CPU386	System CPU is an 80386.
WF_CPU486	System CPU is an i486.
WF_ENHANCED	Windows is running in 386-enhanced mode. The **WF_PMODE** flag is always set when **WF_ENHANCED** is set.
WF_PAGING	Windows is running on a system with paged memory.
WF_PMODE	Windows is running in protected mode. In Windows 3.1, this flag is always set.
WF_STANDARD	Windows is running in standard mode. The **WF_PMODE** flag is always set when **WF_STANDARD** is set.
WF_WIN286	Same as WF_STANDARD.
WF_WIN386	Same as WF_ENHANCED.

Example
The following example uses the **GetWinFlags** function to display information about the current Windows system configuration:

```
int len;
char szBuf[80];
DWORD dwFlags;

dwFlags = GetWinFlags();

len = sprintf(szBuf, "system %s a coprocessor",
    (dwFlags & WF_80x87) ? "contains" : "does not contain");
TextOut(hdc, 10, 15, szBuf, len);

len = sprintf(szBuf, "processor is an %s",
    (dwFlags & WF_CPU286) ? "80286" :
    (dwFlags & WF_CPU386) ? "80386" :
    (dwFlags & WF_CPU486) ? "i486" : "unknown");
TextOut(hdc, 10, 30, szBuf, len);

len = sprintf(szBuf, "running in %s mode",
    (dwFlags & WF_ENHANCED) ? "enhanced" : "standard");
TextOut(hdc, 10, 45, szBuf, len);

len = sprintf(szBuf, "%s WLO",
    (dwFlags & WF_WLO) ? "using" : "not using");
TextOut(hdc, 10, 60, szBuf, len);
```

WF_80x87 0x0400

System contains an Intel math coprocessor.

WF_80x87 0x0400

WF_CPU286 0x0002

System CPU is an 80286.

WF_CPU286 0x0002

WF_CPU386 0x0004

System CPU is an 80386.

WF_CPU386 0x0004

WF_CPU486 0x0008

System CPU is an i486.

WF_CPU486 0x0008

WF_ENHANCED 0x0020

Windows is running in 386-enhanced mode. The **WF_PMODE** flag is always set when WF_ENHANCED is set.

WF_ENHANCED 0x0020

WF_PAGING 0x0800

Windows is running on a system with paged memory.

WF_PAGING 0x0800

WF_PMODE 0x0001

Windows is running in protected mode. In Windows 3.1, this flag is always set.

WF_PMODE 0x0001

WF_STANDARD 0x0010

Windows is running in standard mode. The **WF_PMODE** flag is always set when WF_STANDARD is set.

WF_STANDARD 0x0010

WF_WIN286 0x0010

Same as WF_STANDARD.

WF_WIN286 0x0010

WF_WIN386 0x0020

Same as WF_ENHANCED.

WF_WIN386 0x0020

GlobalAlloc (2.x)

HGLOBAL GlobalAlloc(*fuAlloc, cbAlloc***)**

UINT *fuAlloc;* /* how to allocate object */
DWORD *cbAlloc;* /* size of object */

The **GlobalAlloc** function allocates the specified number of bytes from the global heap.

Parameter	Description
fuAlloc	Specifies how to allocate memory. This parameter can be a combination of the following values:

Value	Meaning
GHND	Combines the **GMEM_MOVEABLE** and **GMEM_ZEROINIT** flags.
GMEM_DDESHARE	Allocates sharable memory. This flag is used for dynamic data exchange (DDE) only. This flag is equivalent to GMEM_SHARE.
GMEM_DISCARDABLE	Allocates discardable memory. This flag can only be used with the **GMEM_MOVEABLE** flag.
GMEM_FIXED	Allocates fixed memory. The **GMEM_FIXED** and **GMEM_MOVEABLE** flags cannot be combined.
GMEM_LOWER	Same as GMEM_NOT_BANKED. This flag is ignored in Windows 3.1.
GMEM_MOVEABLE	Allocates movable memory. The **GMEM_FIXED** and **GMEM_MOVEABLE** flags cannot be combined.
GMEM_NOCOMPACT	Does not compact or discard memory to satisfy the allocation request.
GMEM_NODISCARD	Does not discard memory to satisfy the allocation request.
GMEM_NOT_BANKED	Allocates non-banked memory (memory is not within the memory provided by expanded memory). This flag cannot be used with the **GMEM_NOTIFY** flag. This flag is ignored in Windows 3.1.
GMEM_NOTIFY	Calls the notification routine if the memory object is discarded.
GMEM_SHARE	Allocates memory that can be shared with other applications. This flag is equivalent to GMEM_DDESHARE.
GMEM_ZEROINIT	Initializes memory contents to zero.
GPTR	Combines the **GMEM_FIXED** and **GMEM_ZEROINIT** flags.

cbAlloc	Specifies the number of bytes to be allocated.

Returns

The return value is the handle of the newly allocated global memory object, if the function is successful. Otherwise, it is NULL.

Comments

To convert the handle returned by the **GlobalAlloc** function into a pointer, an application should use the **GlobalLock** function.

If this function is successful, it allocates at least the amount requested. If the amount allocated is greater than the amount requested, the application can use the entire amount. To determine the size of a global

memory object, an application can use the **GlobalSize** function.

To free a global memory object, an application should use the **GlobalFree** function. To change the size or attributes of an allocated memory object, an application can use the **GlobalReAlloc** function.

The largest memory object that an application can allocate on an 80286 processor is 1 megabyte less 80 bytes. The largest block on an 80386 processor is 16 megabytes less 64K.

If the *cbAlloc* parameter is zero, the **GlobalAlloc** function returns a handle of a memory object that is marked as discarded.

Example

The following example uses the **GlobalAlloc** and **GlobalLock** functions to allocate memory, and then calls the **GlobalUnlock** and **GlobalFree** functions to free it.

```
HGLOBAL hglb;
void FAR* lpvBuffer;

hglb = GlobalAlloc(GPTR, 1024);
lpvBuffer = GlobalLock(hglb);
    .
    .
    .
GlobalUnlock(hglb);
GlobalFree(hglb);
```

See Also

GlobalFree, **GlobalLock**, **GlobalNotify**, **GlobalReAlloc**, **GlobalSize**, **GlobalUnlock**, **LocalAlloc**

GHND (**GMEM_MOVEABLE** | **GMEM_ZEROINIT**)

Combines the **GMEM_MOVEABLE** and **GMEM_ZEROINIT** flags.

GHND (GMEM_MOVEABLE | GMEM_ZEROINIT)

GMEM_DDESHARE 0x2000

Allocates sharable memory. This flag is used for dynamic data exchange (DDE) only. This flag is equivalent to GMEM_SHARE.

GMEM_DDESHARE 0x2000

GMEM_DISCARDABLE 0x0100

Allocates discardable memory. This flag can only be used with the **GMEM_MOVEABLE** flag.

GMEM_DISCARDABLE 0x0100

GMEM_FIXED 0x0000

Allocates fixed memory. The GMEM_FIXED and **GMEM_MOVEABLE** flags cannot be combined.

GMEM_FIXED 0x0000

GMEM_LOWER **GMEM_NOT_BANKED**

Same as GMEM_NOT_BANKED. This flag is ignored in Windows 3.1.

GMEM_LOWER GMEM_NOT_BANKED

GMEM_MOVEABLE 0x0002

Allocates movable memory. The **GMEM_FIXED** and GMEM_MOVEABLE flags cannot be combined.

GMEM_MOVEABLE 0x0002

GMEM_NOCOMPACT 0x0010

Does not compact or discard memory to satisfy the allocation request.

GMEM_NOCOMPACT 0x0010

GMEM_NODISCARD 0x0020

Does not discard memory to satisfy the allocation request.

GMEM_NODISCARD 0x0020

GMEM_NOT_BANKED 0x1000

Allocates non-banked memory (memory is not within the memory provided by expanded memory). This flag cannot be used with the **GMEM_NOTIFY** flag. This flag is ignored in Windows 3.1.

GMEM_NOT_BANKED 0x1000

GMEM_NOTIFY 0x4000

Calls the notification routine if the memory object is discarded.

GMEM_NOTIFY 0x4000

GMEM_SHARE 0x2000

Allocates memory that can be shared with other applications. This flag is equivalent to GMEM_DDESHARE.

GMEM_SHARE 0x2000

GMEM_ZEROINIT 0x0040

Initializes memory contents to zero.

GMEM_ZEROINIT 0x0040

GPTR (**GMEM_FIXED** | **GMEM_ZEROINIT**)

Combines the **GMEM_FIXED** and **GMEM_ZEROINIT** flags.

```
GPTR    (GMEM_FIXED | GMEM_ZEROINIT)
```

GlobalCompact (2.x)

DWORD GlobalCompact(*dwMinFree***)**

DWORD *dwMinFree;* /* amount of memory requested */

The **GlobalCompact** function rearranges memory currently allocated to the global heap so that the specified amount of memory is free. If the function cannot free the requested amount of memory, it frees as much as possible.

Parameter	Description
dwMinFree	Specifies the number of contiguous free bytes desired. If this parameter is zero, the function does not discard memory, but the return value is valid.

Returns

The return value specifies the number of bytes in the largest free global memory object in the global heap. If the *dwMinFree* parameter is zero, the return value specifies the number of bytes in the largest free object that Windows can generate if it removes all discardable objects.

Comments

If an application passes the return value to the **GlobalAlloc** function, the **GMEM_NOCOMPACT** or **GMEM_NODISCARD** flag should not be used.

This function always rearranges movable memory objects before checking for free memory. Then it checks the memory currently allocated to the global heap for the number of contiguous free bytes specified by the *dwMinFree* parameter. If the specified amount of memory is not available, the function discards unlocked discardable objects, until the requested space is generated (if possible).

This function is not very useful in most enhanced-mode configurations, which rely on virtual memory. In such an environment, an application can discover how much memory is available by requesting the memory and checking the error value.

See Also

GlobalAlloc

GlobalDosAlloc (3.0)

DWORD GlobalDosAlloc(*cbAlloc***)**

DWORD *cbAlloc;* /* number of bytes to allocate */

The **GlobalDosAlloc** function allocates global memory that can be accessed by MS-DOS running in real mode. The memory is guaranteed to exist in the first megabyte of linear address space.

An application should not use this function unless it is absolutely necessary, because the memory pool from which the object is allocated is a scarce system resource.

Parameter	Description
cbAlloc	Specifies the number of bytes to be allocated.

Returns

The return value contains a paragraph-segment value in its high-order word and a selector in its low-order word. An application can use the paragraph-segment value to access memory in real mode and the selector to access memory in protected mode. If Windows cannot allocate a block of memory of the requested size, the return value is zero.

Comments

Memory allocated by using the **GlobalDosAlloc** function does not need to be locked by using the **GlobalLock** function.

See Also

GlobalDosFree

GlobalDosFree (3.0)

UINT GlobalDosFree(*uSelector***)**

UINT *uSelector;* /* memory to free */

The **GlobalDosFree** function frees a global memory object previously allocated by the **GlobalDosAlloc** function.

Parameter	Description
uSelector	Identifies the memory object to be freed.

Returns
The return value is zero if the function is successful. Otherwise, it is equal to the *uSelector* parameter.

See Also
GlobalDosAlloc

GlobalFix (3.0)

void GlobalFix(*hglb***)**

HGLOBAL *hglb;* /* handle of object to fix */

The **GlobalFix** function prevents the given global memory object from moving in linear memory.

This function interferes with effective Windows memory management and can result in linear-address fragmentation. Few applications need to fix memory in linear address space.

Parameter	Description
hglb	Identifies the global memory object to be fixed in linear memory.

Returns

This function does not return a value.

Comments

The object is locked into linear memory at its current address, and its lock count is incremented (increased by one). Locked memory is not subject to moving or discarding except when the memory object is being reallocated by the **GlobalReAlloc** function. The object remains locked in memory until its lock count is decreased to zero.

Each time an application calls the **GlobalFix** function for a memory object, it must eventually call the **GlobalUnfix** function, which decrements (decreases by one) the lock count for the object. Other functions also can affect the lock count of a memory object. For a list of these functions, see the description of the **GlobalFlags** function.

See Also

GlobalFlags, **GlobalReAlloc**, **GlobalUnfix**

GlobalFlags (2.x)

UINT GlobalFlags(*hglb***)**

HGLOBAL *hglb;* /* handle of global memory object */

The **GlobalFlags** function returns information about the given global memory object.

Parameter	Description
hglb	Identifies the global memory object.

Returns
The return value specifies the memory-allocation flag and the lock count for the memory object, if the function is successful.

Comments
When an application masks out the lock count in the low-order byte of the return value, the return value contains one of the following allocation flags:

Value	Meaning
GMEM_DISCARDABLE	Object can be discarded.
GMEM_DISCARDED	Object has been discarded.

The low-order byte of the return value contains the lock count of the object. Use the GMEM_LOCKCOUNT mask to retrieve the lock count from the return value.

The following functions can affect the lock count of a global memory object:

Increments lock count	Decrements lock count
GlobalFix	**GlobalUnfix**
GlobalLock	**GlobalUnlock**

See Also
GlobalFix, **GlobalLock**, **GlobalUnfix**, **GlobalUnlock**

GlobalFree (2.x)

HGLOBAL GlobalFree(*hglb***)**

HGLOBAL *hglb;* /* handle of object to free */

The **GlobalFree** function frees the given global memory object (if the object is not locked) and invalidates its handle.

Parameter	Description
hglb	Identifies the global memory object to be freed.

Returns

The return value is NULL if the function is successful. Otherwise, it is equal to the *hglb* parameter.

Comments

The **GlobalFree** function cannot be used to free a locked memory object--that is, a memory object with a lock count greater than zero. For a list of the functions that affect the lock count, see the description of the **GlobalFlags** function.

Once freed, the handle of the memory object must not be used again. Attempting to free the same memory object more than once can cause Windows to terminate abnormally.

Example

The following code fragment uses the **GlobalAlloc** and **GlobalLock** functions to allocate memory, and then calls the **GlobalUnlock** and **GlobalFree** functions to free it.

```
HGLOBAL hglb;
void FAR* lpvBuffer;

hglb = GlobalAlloc(GPTR, 1024);
lpvBuffer = GlobalLock(hglb);
    .
    .
    .
GlobalUnlock(hglb);
GlobalFree(hglb);
```

See Also

GlobalDiscard, **GlobalFlags**, **GlobalLock**, **GlobalUnlock**

GlobalHandle (2.x)

DWORD GlobalHandle(*uGlobalSel***)**

UINT *uGlobalSel;* /* selector of global memory object */

The **GlobalHandle** function retrieves the handle of the specified global memory object.

Parameter	Description
uGlobalSel	Specifies the selector of a global memory object.

Returns

The low-order word of the return value contains the handle of the global memory object, and the high-order word contains the selector of the memory object, if the function is successful. The return value is NULL if no handle exists for the memory object.

GlobalLock (2.x)

void FAR* GlobalLock(*hglb***)**

HGLOBAL *hglb;* /* handle of memory object to lock */

The **GlobalLock** function returns a pointer to the given global memory object. **GlobalLock** increments (increases by one) the lock count of movable objects and locks the memory. Locked memory will not be moved or discarded unless the memory object is reallocated by the **GlobalReAlloc** function. The object remains locked in memory until its lock count is decreased to zero.

Parameter	Description
hglb	Identifies the global memory object to be locked.

Returns

The return value points to the first byte of memory in the global object, if the function is successful. It is NULL if the object has been discarded or an error occurs.

Comments

Each time an application calls the **GlobalLock** function for an object, it must eventually call the **GlobalUnlock** function for the object.

This function will return NULL if an application attempts to lock a memory object with a zero-byte size.

If **GlobalLock** incremented the lock count for the object, **GlobalUnlock** decrements the lock count for the object. Other functions can also affect the lock count of a memory object. For a list of these functions, see the description of the **GetGlobalFlags** function.

Discarded objects always have a lock count of zero.

Example

The following example uses the **GlobalAlloc** and **GlobalLock** functions to allocate memory, and then calls the **GlobalUnlock** and **GlobalFree** functions to free it.

```
HGLOBAL hglb;
void FAR* lpvBuffer;

hglb = GlobalAlloc(GPTR, 1024);
lpvBuffer = GlobalLock(hglb);
    .
    .
    .
GlobalUnlock(hglb);
GlobalFree(hglb);
```

See Also

GlobalAlloc, **GlobalFlags**, **GlobalFree**, **GlobalLock**, **GlobalReAlloc**, **GlobalUnlock**

GlobalLRUNewest (2.x)

HGLOBAL GlobalLRUNewest(*hglb***)**

HGLOBAL *hglb;* /* handle of memory object to move */

The **GlobalLRUNewest** function moves a global memory object to the newest least-recently-used (LRU) position in memory. This greatly reduces the likelihood that the object will be discarded soon, but does not prevent the object from eventually being discarded.

Parameter	Description
hglb	Identifies the global memory object to be moved.

Returns
The return value is NULL if the *hglb* parameter is not a valid handle.

Comments
The **GlobalLRUNewest** function is useful only if the given object is discardable.

See Also
GlobalLRUOldest

GlobalLRUOldest (2.x)

HGLOBAL GlobalLRUOldest(*hglb***)**

HGLOBAL *hglb;* /* handle of memory object to move */

The **GlobalLRUOldest** function moves a global memory object to the oldest least-recently-used (LRU) position in memory. This makes the memory object the next candidate for discarding.

Parameter	Description
hglb	Identifies the global memory object to be moved.

Returns
The return value is NULL if the *hglb* parameter does not identify a valid handle.

Comments
The **GlobalLRUOldest** function is useful only if the *hglb* parameter is discardable.

See Also
GlobalLRUNewest

GlobalNotify (2.x)

void GlobalNotify(*lpNotifyProc***)**

GNOTIFYPROC *lpNotifyProc;* /* instance address of callback function */

The **GlobalNotify** function installs a notification procedure for the current task. A notification procedure is a library-defined callback function that the system calls whenever a global memory object allocated with the **GMEM_NOTIFY** flag is about to be discarded.

Parameter	Description
lpNotifyProc	Specifies the address of the current task's notification procedure. For more information, see the description of the **NotifyProc** callback function.

Returns

This function does not return a value.

Comments

An application must not call the **GlobalNotify** function more than once per instance.

The system does not call the notification procedure when discarding memory that belongs to a dynamic-link library (DLL).

If the object is discarded, the application must use the **GMEM_NOTIFY** flag when it calls the **GlobalRealloc** function to recreate the object. Otherwise, the application will not be notified when the object is discarded again.

If the notification procedure returns a nonzero value, Windows discards the global memory object. If the procedure returns zero, the block is not discarded.

The address of the **NotifyProc** callback function (specified in the *lpNotifyProc* parameter) must be in a fixed code segment of a dynamic-link library.

See Also

GlobalReAlloc, **NotifyProc**

GlobalPageLock (3.0)

UINT GlobalPageLock(*hglb***)**

HGLOBAL *hglb;* /* selector of global memory to lock */

The **GlobalPageLock** function increments (increases by one) the page-lock count for the memory associated with the given global selector. As long as its page-lock count is nonzero, the data that the selector references is guaranteed to remain in memory at the same physical address.

Parameter	Description
hglb	Specifies the selector of the memory to be page-locked.

Returns

The return value specifies the page-lock count after the function has incremented it. If the function fails, the return value is zero.

Comments

Because using this function violates preferred Windows programming practices, an application should not use it unless absolutely necessary. The function is intended to be used for dynamically allocated data that must be accessed at interrupt time. For this reason, it must be called only from a dynamic-link library (DLL).

The **GlobalPageLock** function increments the page-lock count for the block of memory, and the **GlobalPageUnlock** function decrements (decreases by one) the page-lock count. Page-locking operations can be nested, but each page-locking must be balanced by a corresponding unlocking.

See Also

GlobalPageUnlock

GlobalPageUnlock (3.0)

UINT GlobalPageUnlock(*hglb***)**

HGLOBAL *hglb;* /* selector of global memory to unlock */

The **GlobalPageLock** function decrements (decreases by one) the page-lock count for the memory associated with the specified global selector. When the page-lock count reaches zero, the data that the selector references is no longer guaranteed to remain in memory at the same physical address.

Parameter	Description
hglb	Specifies the selector of the memory to be page-unlocked.

Returns

The return value specifies the page-lock count after the function has decremented it. If the function fails, the return value is zero.

Comments

Because using this function violates preferred Windows programming practices, an application should not use it unless absolutely necessary. The function is intended to be used for dynamically allocated data that must be accessed at interrupt time. For this reason, it must only be called from a dynamic-link library (DLL).

The **GlobalPageLock** function increments the page-lock count for the block of memory, and the **GlobalPageUnlock** function decrements the page-lock count. Page-locking operations can be nested, but each page-locking must be balanced by a corresponding unlocking.

See Also

GlobalPageLock

GlobalReAlloc (2.x)

HGLOBAL GlobalReAlloc(*hglb, cbNewSize, fuAlloc***)**

```
HGLOBAL hglb;       /* handle of memory object to reallocate  */
DWORD cbNewSize;    /* new size of object                     */
UINT fuAlloc;       /* how object is reallocated              */
```

The **GlobalReAlloc** function changes the size or attributes of the given global memory object.

Parameter	Description
hglb	Identifies the global memory object to be reallocated.
cbNewSize	Specifies the new size of the memory object.
fuAlloc	Specifies how to reallocate the global object. If this parameter includes GMEM_MODIFY, the **GlobalReAlloc** function ignores the *cbNewSize* parameter.

Value	Meaning
GMEM_DISCARDABLE	Causes a previously movable object to become discardable. This flag can be used only with GMEM_MODIFY.
GMEM_MODIFY	Modifies the object's memory flags. This flag can be used with **GMEM_DISCARDABLE** and GMEM_MOVEABLE.
GMEM_MOVEABLE	Causes a previously movable and discardable object to be discarded, if the *cbNewSize* parameter is zero and the object's lock count is zero. If *cbNewSize* is zero and the object is not movable and discardable, this flag causes the **GlobalReAlloc** function to fail. If the *cbNewSize* parameter is nonzero and the object identified by the *hglb* parameter is fixed, this flag allows the reallocated object to be moved to a new fixed location. If a movable object is locked, this flag allows the object to be moved to a new locked location without invalidating the handle. This may occur even if the object is currently locked by a previous call to the **GlobalLock** function. If this flag is used with GMEM_MODIFY, the **GlobalReAlloc** function changes a fixed memory object to a movable memory object.
GMEM_NODISCARD	Prevents memory from being discarded to satisfy the allocation request. This flag cannot be used with GMEM_MODIFY.
GMEM_ZEROINIT	Causes the additional memory to be initialized to zero if the object is growing. This flag cannot be used with GMEM_MODIFY.

Returns

The return value is the handle of the reallocated global memory if the function is successful. It is NULL if the object cannot be reallocated as specified.

Comments

If **GlobalReAlloc** reallocates a movable object, the return value is a handle to the memory. To access the memory, an application must use the **GlobalLock** function to convert the handle to a pointer.

To free a global memory object, an application should use the **GlobalFree** function.

The **GMEM_ZEROINIT** flag will cause applications to fail if it is used as shown in the following sequence:

```
hMem = GlobalAlloc(GMEM_ZEROINIT | (other flags), dwSize1);
            .
            .
            .
hMem = GlobalReAlloc(hMem, dwSize2, GMEM_ZEROINIT | (other flags));

/* where dwSize2 > dwSize1. */
            .
            .
            .
hMem = GlobalReAlloc(hMem, dwSize3, GMEM_ZEROINIT | (other flags));

/* where dwSize3 < dwSize2. */
            .
            .
            .
hMem = GlobalReAlloc(hMem, dwSize4, GMEM_ZEROINIT | (other flags));

/* GMEM_ZEROINIT fails when dwSize4 > dwSize3. */
```

In the last step of the preceding example, the memory between dwSize3 and the internal allocation boundary is not set to zero. After the last step, the contents of the buffer equal its contents prior to the call to **GlobalReAlloc** that specified dwSize3.

See Also
GlobalAlloc, **GlobalDiscard**, **GlobalFree**, **GlobalLock**

GlobalSize (2.x)

DWORD GlobalSize(*hglb***)**

HGLOBAL *hglb;* /* handle of memory object to return size of */

The **GlobalSize** function retrieves the current size, in bytes, of the given global memory object.

Parameter	Description
hglb	Identifies the global memory object.

Returns

The return value specifies the size, in bytes, of the memory object. It is zero if the specified handle is not valid or if the object has been discarded.

Comments

The size of a memory object is sometimes larger than the size requested at the time the memory was allocated.

An application should call the **GlobalFlags** function prior to calling the **GlobalSize** function, to verify that the specified memory object was not discarded. If the memory object has been discarded, the return value for **GlobalSize** is meaningless.

See Also

GlobalAlloc, **GlobalFlags**

GlobalUnfix (3.0)

void GlobalUnfix(*hglb***)**

HGLOBAL *hglb;* /* handle of global memory to unlock */

The **GlobalUnfix** function cancels the effects of the **GlobalFix** function and allows a global memory object to be moved in linear memory.

Parameter	Description
hglb	Identifies the global memory object to be unlocked.

Returns
This function does not return a value.

Comments
This function interferes with effective Windows memory management and can result in linear-address fragmentation. Few applications need to fix memory in linear address space.

Each time an application calls the **GlobalFix** function for an object, it must eventually call the **GlobalUnfix** function for the object.

GlobalUnfix decrements (decreases by one) the object's lock count and returns the new lock count in the CX register. The object is completely unlocked and subject to moving or discarding if the lock count is decremented to zero. Other functions also can affect the lock count of a memory object. For a list of these functions, see the description of the **GlobalFlags** function.

See Also
GlobalFix, **GlobalFlags**

GlobalUnlock (2.x)

BOOL GlobalUnlock(*hglb***)**

HGLOBAL *hglb;* /* handle of global memory to unlock */

The **GlobalUnlock** function unlocks the given global memory object. This function has no effect on fixed memory.

Parameter	Description
hglb	Identifies the global memory object to be unlocked.

Returns
The return value is zero if the object's lock count was decremented (decreased by one) to zero. Otherwise, the return value is nonzero.

Comments
With movable or discardable memory, this function decrements the object's lock count. The object is completely unlocked and subject to moving or discarding if the lock count is decreased to zero.

This function returns nonzero if the given memory object is not movable. An application should not rely on the return value to determine the number of times it must subsequently call the **GlobalUnlock** function for the memory object.

Other functions can also affect the lock count of a memory object. For a list of the functions that affect the lock count, see the description of the **GlobalFlags** function.

Each time an application calls **GlobalLock** for an object, it must eventually call the **GlobalUnlock** function for the object.

Example
The following example uses the **GlobalAlloc** and **GlobalLock** functions to allocate memory, and then calls the **GlobalUnlock** and **GlobalFree** functions to free it.

```
HGLOBAL hglb;
void FAR* lpvBuffer;

hglb = GlobalAlloc(GPTR, 1024);
lpvBuffer = GlobalLock(hglb);
    .
    .
    .
GlobalUnlock(hglb);
GlobalFree(hglb);
```

See Also
GlobalAlloc, **GlobalFlags**, **GlobalFree**, **GlobalLock**, **GlobalUnlock**, **UnlockResource**

GlobalUnWire (2.x)

BOOL GlobalUnWire(*hglb***)**

HGLOBAL *hglb;*

This function should not be used in Windows 3.1.

See Also
GlobalUnlock

GlobalWire (2.x)

void FAR* GlobalWire(*hglb***)**

HGLOBAL *hglb;*

This function should not be used in Windows 3.1.

See Also
GlobalLock

hmemcpy (3.1)

void hmemcpy(*hpvDest, hpvSource, cbCopy***)**

```
void _huge* hpvDest;              /* address of destination buffer */
const void _huge* hpvSource;      /* address of source buffer      */
long cbCopy;                      /* number of bytes to copy       */
```

The **hmemcpy** function copies bytes from a source buffer to a destination buffer. This function supports huge memory objects (that is, objects larger than 64K, allocated using the **GlobalAlloc** function).

Parameter	Description
hpvDest	Points to a buffer that receives the copied bytes.
hpvSource	Points to a buffer that contains the bytes to be copied.
cbCopy	Specifies the number of bytes to be copied.

Returns

This function does not return a value.

Comments

The result of the **hmemcpy** function is undefined if the buffers identified by *hpvDest* and *hpvSource* overlap.

See Also

_hread, **_hwrite**, **lstrcpy**

InitAtomTable (2.x)

BOOL InitAtomTable(*cTableEntries***)**

int *cTableEntries;* /* size of atom table */

The **InitAtomTable** function initializes the local atom hash table and sets it to the specified size.

An application need not use this function to use a local atom table. The default size of the local and global atom hash tables is 37 table entries. If an application uses **InitAtomTable**, however, it should call the function before any other atom-management function.

Parameter	Description
cTableEntries	Specifies the size, in table entries, of the atom hash table. This value should be a prime number.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

If an application uses a large number of local atoms, it can increase the size of the local atom table, reducing the time required to add an atom to the local atom table or to find an atom in the table. However, this increases the amount of memory required to maintain the table.

The size of the global atom table cannot be changed from its default size of 37 entries.

Example

The following example uses the **InitAtomTable** function to change the size of the local atom table to 73:

```
BOOL fSuccess;

fSuccess = InitAtomTable(73);

if (fSuccess)
    MessageBox(hwnd, "table initialization succeeded",
        "InitAtomTable", MB_OK);
else
    MessageBox(hwnd, "table initialization failed",
        "InitAtomTable", MB_ICONEXCLAMATION);
```

IsBadCodePtr (3.1)

BOOL IsBadCodePtr(*lpfn***)**

FARPROC *lpfn;* /* pointer to test */

The **IsBadCodePtr** function determines whether a pointer to executable code is valid.

Parameter	Description
lpfn	Points to a function.

Returns

The return value is nonzero if the pointer is bad (that is, if it does not point to executable code). The return value is zero if the pointer is good.

See Also

IsBadHugeReadPtr, **IsBadHugeWritePtr**, **IsBadReadPtr**, **IsBadStringPtr**, **IsBadWritePtr**

IsBadHugeReadPtr (3.1)

BOOL IsBadHugeReadPtr(*lp, cb***)**

```
const void _huge* lp;      /* pointer to test              */
DWORD cb;                  /* number of allocated bytes    */
```

The **IsBadHugeReadPtr** function determines whether a huge pointer to readable memory is valid.

Parameter	Description
lp	Points to the beginning of a block of allocated memory. The data object may reside anywhere in memory and may exceed 64K in size.
cb	Specifies the number of bytes of memory that were allocated.

Returns

The return value is nonzero if the pointer is bad (that is, if it does not point to readable memory of the specified size). The return value is zero if the pointer is good.

See Also

IsBadCodePtr, **IsBadHugeWritePtr**, **IsBadReadPtr**, **IsBadStringPtr**, **IsBadWritePtr**

IsBadHugeWritePtr (3.1)

BOOL IsBadHugeWritePtr(*lp, cb***)**

```
void _huge* lp;      /* pointer to test              */
DWORD cb;            /* number of allocated bytes    */
```

The **IsBadHugeWritePtr** function determines whether a huge pointer to writable memory is valid.

Parameter	Description
lp	Points to the beginning of a block of allocated memory. The data object may reside anywhere in memory and may exceed 64K in size.
cb	Specifies the number of bytes of memory that were allocated.

Returns

The return value is nonzero if the pointer is bad (that is, if it does not point to writable memory of the specified size). The return value is zero if the pointer is good.

See Also

IsBadCodePtr, **IsBadHugeReadPtr**, **IsBadReadPtr**, **IsBadStringPtr**, **IsBadWritePtr**

IsBadReadPtr (3.1)

BOOL IsBadReadPtr(*lp, cb***)**

```
const void FAR* lp;     /* pointer to test              */
UINT cb;                /* number of allocated bytes    */
```

The **IsBadReadPtr** function determines whether a pointer to readable memory is valid.

Parameter	Description
lp	Points to the beginning of a block of allocated memory.
cb	Specifies the number of bytes of memory that were allocated.

Returns

The return value is nonzero if the pointer is bad (that is, if it does not point to readable memory of the specified size). The return value is zero if the pointer is good.

See Also

IsBadCodePtr, **IsBadHugeReadPtr**, **IsBadHugeWritePtr**, **IsBadStringPtr**, **IsBadWritePtr**

IsBadStringPtr (3.1)

BOOL IsBadStringPtr(*lpsz, cchMax***)**

```
const void FAR* lpsz;      /* pointer to test            */
UINT cchMax;               /* maximum size of string     */
```

The **IsBadStringPtr** function determines whether a pointer to a string is valid.

Parameter	Description
lpsz	Points to a null-terminated string.
cchMax	Specifies the maximum size of the string, in bytes.

Returns

The return value is nonzero if the pointer is bad (that is, if it does not point to a string of the specified size). The return value is zero if the pointer is good.

See Also

IsBadCodePtr, **IsBadHugeReadPtr**, **IsBadHugeWritePtr**, **IsBadReadPtr**, **IsBadWritePtr**

IsBadWritePtr (3.1)

BOOL IsBadWritePtr(*lp, cb***)**

```
void FAR* lp;       /* pointer to test              */
UINT cb;            /* number of allocated bytes    */
```

The **IsBadWritePtr** function determines whether a pointer to writable memory is valid.

Parameter	Description
lp	Points to the beginning of a block of allocated memory.
cb	Specifies the number of bytes of memory that were allocated.

Returns

The return value is nonzero if the pointer is bad (that is, if it does not point to writable memory of the specified size). The return value is zero if the pointer is good.

See Also

IsBadCodePtr, **IsBadHugeReadPtr**, **IsBadHugeWritePtr**, **IsBadReadPtr**, **IsBadStringPtr**

IsDBCSLeadByte (3.1)

BOOL IsDBCSLeadByte(*bTestChar***)**

BYTE *bTestChar;* /* character to test */

The **IsDBCSLeadByte** function determines whether a character is a lead byte, the first byte of a character in a double-byte character set (DBCS).

Parameter	Description
bTestChar	Specifies the character to be tested.

Returns
The return value is nonzero if the character is a DBCS lead byte. Otherwise, it is zero.

Comments
The language driver for the current language (the language the user selected at setup or by using Control Panel) determines whether the character is in the set. If no language driver is selected, Windows uses an internal function.

Each double-byte character set has a unique set of lead-byte values. By itself, a lead byte has no character value; together, the lead byte and the following byte represent a single character. The second, or following, byte is called a trailing byte.

See Also
GetKeyboardType

IsTask (3.1)

BOOL IsTask(*htask***)**

HTASK *htask;* /* handle of task */

The **IsTask** function determines whether the given task handle is valid.

Parameter	Description
htask	Identifies a task.

Returns

The return value is nonzero if the task handle is valid. Otherwise, it is zero.

LimitEmsPages (2.x)

void LimitEmsPages(*cAppKB***)**

DWORD *cAppKB;* /* amount of expanded memory available to application */

In Windows version 3.1, this function is obsolete and does nothing.

LoadLibrary (2.x)

HINSTANCE LoadLibrary(*lpszLibFileName***)**

LPCSTR *lpszLibFileName;* /* address of name of library file */

The **LoadLibrary** function loads the specified library module.

Parameter	Description
lpszLibFileName	Points to a null-terminated string that names the library file to be loaded. If the string does not contain a path, Windows searches for the library in this order:

1 The current directory.

2 The Windows directory (the directory containing WIN.COM); the **GetWindowsDirectory** function retrieves the path of this directory.

3 The Windows system directory (the directory containing such system files as GDI.EXE); the **GetSystemDirectory** function retrieves the path of this directory.

4 The directory containing the executable file for the current task; the **GetModuleFileName** function retrieves the path of this directory.

5 The directories listed in the PATH environment variable.

6 The list of directories mapped in a network.

Returns

The return value is the instance handle of the loaded library module if the function is successful. Otherwise, it is an error value less than HINSTANCE_ERROR.

Errors

If the function fails, it returns one of the following error values:

Value	Meaning
0	System was out of memory, executable file was corrupt, or relocations were invalid.
2	File was not found.
3	Path was not found.
5	Attempt was made to dynamically link to a task, or there was a sharing or network-protection error.
6	Library required separate data segments for each task.
8	There was insufficient memory to start the application.
10	Windows version was incorrect.
11	Executable file was invalid. Either it was not a Windows application or there was an error in the .EXE image.
12	Application was designed for a different operating system.
13	Application was designed for MS-DOS 4.0.
14	Type of executable file was unknown.
15	Attempt was made to load a real-mode application (developed for an earlier version of Windows).
16	Attempt was made to load a second instance of an executable file containing multiple data segments that were not marked read-only.
19	Attempt was made to load a compressed executable file. The file must be decompressed before it can be loaded.
20	Dynamic-link library (DLL) file was invalid. One of the DLLs required to run this application

was corrupt.

21 Application requires Microsoft Windows 32-bit extensions.

Comments

If the module has been loaded, **LoadLibrary** increments (increases by one) the module's reference count. If the module has not been loaded, the function loads it from the specified file.

LoadLibrary increments the reference count for a library module each time an application calls the function. When it has finished using the module, the application should use the **FreeLibrary** function to decrement (decrease by one) the reference count.

An application can use the **GetProcAddress** function to access functions in a library that was loaded using **LoadLibrary**.

Example

The following example uses the **LoadLibrary** function to load the Tool Helper Library TOOLHELP.DLL and the **FreeLibrary** function to free it:

```
HINSTANCE hinstToolHelp = LoadLibrary("TOOLHELP.DLL");

if ((UINT) hinstToolHelp > 32) {
        .
        . /* use GetProcAddress to use TOOLHELP functions */
        .
}
else {
    ErrorHandler();
}

if ((UINT) hinstToolHelp > 32)
   FreeLibrary(hinstToolHelp); /* free TOOLHELP.DLL      */
```

See Also

FreeLibrary, **GetProcAddress**

LoadModule (3.0)

HINSTANCE LoadModule(*lpszModuleName, lpvParameterBlock***)**

LPCSTR *lpszModuleName;* /* address of filename to load */
LPVOID *lpvParameterBlock;* /* address of parameter block for new module */

The **LoadModule** function loads and executes a Windows application or creates a new instance of an existing Windows application.

Parameter	Description
lpszModuleName	Points to a null-terminated string that contains the complete filename (including the file extension) of the application to be run. If the string does not contain a path, Windows searches for the executable file in this order:

1 The current directory.

2 The Windows directory (the directory containing WIN.COM), whose path the **GetWindowsDirectory** function retrieves.

3 The Windows system directory (the directory containing such system files as GDI.EXE), whose path the **GetSystemDirectory** function retrieves.

4 The directory containing the executable file for the current task; the **GetModuleFileName** function obtains the path of this directory.

5 The directories listed in the PATH environment variable.

6 The list of directories mapped in a network.

lpvParameterBlock Points to an application-defined LOADPARMS structure that defines the new application's parameter block. The LOADPARMS structure has the following form:

```
struct _LOADPARMS {
    WORD      segEnv;         /* child environment  */
    LPSTR     lpszCmdLine;    /* child command tail */
    UINT FAR* lpShow;         /* how to show child  */
    UINT FAR* lpReserved;     /* must be NULL       */
} LOADPARMS;
```

Member	Description
segEnv	Specifies whether the child application receives a copy of the parent application's environment or a new environment created by the parent application. If this member is zero, the child application receives an exact duplicate of the parent application's environment block. If the member is nonzero, the value entered must be the segment address of a memory object containing a copy of the new environment for the child application.
lpszCommandLine	Points to a null-terminated string that specifies the command line (excluding the child application name). This string must not exceed 120 characters. If there is no command line, this member must point to a zero-length string (it cannot be set to NULL).
lpShow	Points to an array containing two 16-bit values. The first value must always be set to two. The second value specifies how the application window is to be shown. For

	a list of the acceptable values, see the description of the *nCmdShow* parameter of the **ShowWindow** function.
lpReserved	Reserved; must be NULL.

Returns

The return value is the instance handle of the loaded module if the function is successful. If the function fails, it returns an error value less than HINSTANCE_ERROR.

Errors

If the function fails, it returns one of the following error values:

Value	Meaning
0	System was out of memory, executable file was corrupt, or relocations were invalid.
2	File was not found.
3	Path was not found.
5	Attempt was made to dynamically link to a task, or there was a sharing or network-protection error.
6	Library required separate data segments for each task.
8	There was insufficient memory to start the application.
10	Windows version was incorrect.
11	Executable file was invalid. Either it was not a Windows application or there was an error in the .EXE image.
12	Application was designed for a different operating system.
13	Application was designed for MS-DOS 4.0.
14	Type of executable file was unknown.
15	Attempt was made to load a real-mode application (developed for an earlier version of Windows).
16	Attempt was made to load a second instance of an executable file containing multiple data segments that were not marked read-only.
19	Attempt was made to load a compressed executable file. The file must be decompressed before it can be loaded.
20	Dynamic-link library (DLL) file was invalid. One of the DLLs required to run this application was corrupt.
21	Application requires Microsoft Windows 32-bit extensions.

Comments

The **WinExec** function provides an alternative method for executing an application.

Example

The following example uses the **LoadModule** function to run an executable file named DRAW.EXE:

```
struct LOADPARMS {
    WORD    segEnv;                 /* child environment  */
    LPSTR   lpszCmdLine;            /* child command tail */
    LPWORD  lpwShow;                /* how to show child  */
    LPWORD  lpwReserved;            /* must be NULL       */
};

char szMsg[80];
HINSTANCE hinstMod;
struct LOADPARMS parms;
WORD awShow[2] = { 2, SW_SHOWMINIMIZED };

parms.segEnv = 0;               /* child inherits environment */
```

```
parms.lpszCmdLine = (LPSTR) "";     /* no command line        */
parms.lpwShow = (LPWORD) awShow;    /* shows child as an icon */
parms.lpwReserved = (LPWORD) NULL;  /* must be NULL           */

hinstMod = LoadModule("draw.exe", &parms);

if ((UINT) hinstMod < 32) {
    sprintf(szMsg, "LoadModule failed; error code = %d",
        hinstMod);
    MessageBox(hwnd, szMsg, "Error", MB_ICONSTOP);
}
else {
    sprintf(szMsg, "LoadModule returned %d", hinstMod);
    MessageBox(hwnd, szMsg, "", MB_OK);
}
```

See Also

FreeModule, **GetModuleFileName**, **GetSystemDirectory**, **GetWindowsDirectory**, **ShowWindow**, **WinExec**

LoadResource (2.x)

HGLOBAL LoadResource(*hinst, hrsrc***)**

```
HINSTANCE hinst;        /* handle of file containing resource */
HRSRC hrsrc;            /* handle of resource                 */
```

The **LoadResource** function loads the specified resource in global memory.

Parameter	Description
hinst	Identifies an instance of the module whose executable file contains the resource to be loaded.
hrsrc	Identifies the resource to be loaded. This handle must have been created by using the **FindResource** function.

Returns

The return value is the instance handle of the global memory object containing the data associated with the resource. It is NULL if no such resource exists.

Comments

When finished with a resource, an application should free the global memory associated with it by using the **FreeResource** function.

If the specified resource has been loaded, this function simply increments the reference count for the resource.

The resource is not loaded until the **LockResource** function is called to translate the handle returned by **LoadResource** into a far pointer to the resource data.

See Also

FindResource, **FreeResource**, **LockResource**

LocalAlloc (2.x)

HLOCAL LocalAlloc(*fuAllocFlags, fuAlloc***)**

```
UINT fuAllocFlags;      /* allocation attributes          */
UINT fuAlloc;           /* number of bytes to allocate */
```

The **LocalAlloc** function allocates the specified number of bytes from the local heap.

Parameter	Description
fuAllocFlags	Specifies how to allocate memory. This parameter can be a combination of the following values:

Value	Meaning
LHND	Combines the **LMEM_MOVEABLE** and **LMEM_ZEROINIT** flags.
LMEM_DISCARDABLE	Allocates discardable memory.
LMEM_FIXED	Allocates fixed memory. The **LMEM_FIXED** and **LMEM_MOVEABLE** flags cannot be combined.
LMEM_MOVEABLE	Allocates movable memory. The **LMEM_FIXED** and **LMEM_MOVEABLE** flags cannot be combined.
LMEM_NOCOMPACT	Does not compact or discard memory to satisfy the allocation request.
LMEM_NODISCARD	Does not discard memory to satisfy the allocation request.
LMEM_ZEROINIT	Initializes memory contents to zero.
LPTR	Combines the **LMEM_FIXED** and **LMEM_ZEROINIT** flags.
NONZEROLHND	Same as the **LMEM_MOVEABLE** flag.
NONZEROLPTR	Same as the **LMEM_FIXED** flag.

fuAlloc	Specifies the number of bytes to be allocated.

Returns

The return value is the instance handle of the newly allocated local memory object, if the function is successful. Otherwise, it is NULL.

Comments

If **LocalAlloc** allocates movable memory, the return value is a local handle of the memory. To access the memory, an application must use the **LocalLock** function to convert the handle to a pointer.

If **LocalAlloc** allocates fixed memory, the return value is a pointer to the memory. To access the memory, an application can simply cast the return value to a pointer.

Fixed memory will be slightly faster than movable memory. If memory will be allocated and freed without an intervening local allocation or reallocation, then the memory should be allocated as fixed.

If this function is successful, it allocates at least the amount requested. If the amount allocated is greater than the amount requested, the application can use the entire amount. To determine the size of a local memory object, an application can use the **LocalSize** function.

To free a local memory object, an application should use the **LocalFree** function. To change the size or attributes of an allocated memory object, an application can use the **LocalReAlloc** function.

See Also

LocalFree, **LocalLock**, **LocalReAlloc**, **LocalSize**, **LocalUnlock**

LHND (**LMEM_MOVEABLE** | **LMEM_ZEROINIT**)

Combines the **LMEM_MOVEABLE** and **LMEM_ZEROINIT** flags.

LHND (LMEM_MOVEABLE | LMEM_ZEROINIT)

LMEM_DISCARDABLE 0x0F00

Allocates discardable memory.

LMEM_DISCARDABLE 0x0F00

LMEM_FIXED 0x0000

Allocates fixed memory. The LMEM_FIXED and **LMEM_MOVEABLE** flags cannot be combined.

LMEM_FIXED 0x0000

LMEM_MOVEABLE 0x0002

Allocates movable memory. The **LMEM_FIXED** and LMEM_MOVEABLE flags cannot be combined.

LMEM_MOVEABLE 0x0002

LMEM_NOCOMPACT 0x0010

Does not compact or discard memory to satisfy the allocation request.

LMEM_NOCOMPACT 0x0010

LMEM_NODISCARD 0x0020

Does not discard memory to satisfy the allocation request.

LMEM_NODISCARD 0x0020

LMEM_ZEROINIT 0x0040

Initializes memory contents to zero.

LMEM_ZEROINIT 0x0040

LPTR (**LMEM_FIXED** | **LMEM_ZEROINIT**)

Combines the **LMEM_FIXED** and **LMEM_ZEROINIT** flags.

LPTR (LMEM_FIXED | LMEM_ZEROINIT)

NONZEROLHND (**LMEM_MOVEABLE**)

Same as the **LMEM_MOVEABLE** flag.

NONZEROLHND (LMEM_MOVEABLE)

NONZEROLPTR (**LMEM_FIXED**)

Same as the **LMEM_FIXED** flag.

NONZEROLPTR (LMEM_FIXED)

LocalCompact (2.x)

UINT LocalCompact(*uMinFree***)**

UINT *uMinFree;* /* amount of memory requested */

The **LocalCompact** function rearranges the local heap so that the specified amount of memory is free.

Parameter	Description
uMinFree	Specifies the number of contiguous free bytes requested. If this parameter is zero, the function does not compact memory, but the return value is valid.

Returns

The return value specifies the number of bytes in the largest free local memory object. If the *uMinFree* parameter is zero, the return value specifies the number of bytes in the largest free object that Windows can generate if it removes all discardable objects.

Comments

The function first checks the local heap for the specified number of contiguous free bytes. If the bytes do not exist, the function compacts local memory by moving all unlocked, movable objects into high memory. If this does not generate the requested amount of space, the function discards movable and discardable objects that are not locked, until the requested amount of space is generated (if possible).

See Also

LocalAlloc, **LocalLock**

LocalFlags (2.x)

UINT LocalFlags(*hloc***)**

HLOCAL *hloc;* /* handle of local memory object */

The **LocalFlags** function retrieves information about the given local memory object.

Parameter	Description
hloc	Identifies the local memory object.

Returns
The low-order byte of the return value contains the lock count of the object; the high-order byte contains either **LMEM_DISCARDABLE** (object has been marked as discardable) or LMEM_DISCARDED (object has been discarded).

Comments
To retrieve the lock count from the return value, use the LMEM_LOCKCOUNT mask.

See Also
LocalAlloc, **LocalLock**, **LocalReAlloc**, **LocalUnlock**

LocalFree (2.x)

HLOCAL LocalFree(*hloc***)**

HLOCAL *hloc;* /* handle of local memory object */

The **LocalFree** function frees the given local memory object (if the object is not locked) and invalidates its handle.

Parameter	Description
hloc	Identifies the local memory object to be freed.

Returns
The return value is NULL if the function is successful. Otherwise, it is equal to the *hloc* parameter.

Comments
An application cannot use the **LocalFree** function to free a locked memory object--that is, a memory object with a lock count greater than zero.

After freeing the handle of the memory object, an application cannot use the handle again. An attempt to free the same memory object more than once can cause Windows to terminate abnormally.

See Also
LocalFlags, **LocalLock**

LocalHandle (2.x)

HLOCAL LocalHandle(*pvMem***)**

void NEAR* *pvMem;* /* address of local memory object */

The **LocalHandle** function retrieves the handle of the specified local memory object.

Parameter	Description
pvMem	Specifies the address of the local memory object.

Returns

The return value is the handle of the specified local memory object if the function is successful. It is NULL if the specified address has no handle.

See Also

LocalAlloc

LocalInit (2.x)

BOOL LocalInit(*uSegment, uStartAddr, uEndAddr***)**

```
UINT uSegment;      /* segment to contain local heap */
UINT uStartAddr;    /* starting address for heap     */
UINT uEndAddr;      /* ending address for heap       */
```

The **LocalInit** function initializes a local heap in the specified segment.

Parameter	Description
uSegment	Identifies the segment that is to contain the local heap.
uStartAddr	Specifies the starting address of the local heap within the segment.
uEndAddr	Specifies the ending address of the local heap within the segment.

Returns
The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments
The first 16 bytes of the segment containing a local heap must be reserved for use by the system.

See Also
GlobalLock, **LocalAlloc**, **LocalReAlloc**

Windows 3.1 changes

Removed the discussion of movable data segments (LockData etc.), since this is irrelevant in 3.1. Data segments may or may not move, but Windows maintains their selectors.

LocalLock (2.x)

void NEAR* LocalLock(*hloc***)**

HLOCAL *hloc;* /* handle of local memory object */

The **LocalLock** function retrieves a pointer to the given local memory object. **LocalLock** increments (increases by one) the lock count of movable objects and locks the memory.

Parameter	Description
hloc	Identifies the local memory object to be locked.

Returns

The return value points to the first byte of memory in the local object, if the function is successful. It is NULL if the object has been discarded or an error occurs.

Comments

Each time an application calls **LocalLock** for an object, it must eventually call **LocalUnlock** for the object.

This function will return NULL if an application attempts to lock a memory object with a size of 0 bytes.

The **LocalUnlock** function decrements (decreases by one) the lock count for the object if **LocalLock** incremented the count. Other functions can also affect the lock count of a memory object.

Locked memory will not be moved or discarded unless the memory object is reallocated by the **LocalReAlloc** function. The object remains locked in memory until its lock count is decreased to zero.

Discarded objects always have a lock count of zero.

See Also

LocalFlags, **LocalReAlloc**, **LocalUnlock**

LocalReAlloc (2.x)

HLOCAL LocalReAlloc(*hloc, fuNewSize, fuFlags***)**

```
HLOCAL hloc;        /* handle of local memory object  */
UINT fuNewSize;     /* new size of object             */
UINT fuFlags;       /* new allocation attributes      */
```

The **LocalReAlloc** function changes the size or attributes of the given local memory object.

Parameter	Description
hloc	Identifies the local memory object to be reallocated.
fuNewSize	Specifies the new size of the local memory object.
fuFlags	Specifies how to reallocate the local memory object. If this parameter includes the LMEM_MODIFY and **LMEM_DISCARDABLE** flags, **LocalReAlloc** ignores the *fuNewSize* parameter. The *fuFlags* parameter can be a combination of the following values.

Value	Meaning
LMEM_DISCARDABLE	Causes a previously movable object to become discardable. This flag can be used only with LMEM_MODIFY.
LMEM_MODIFY	Modifies the object's memory flags. This flag can be used only with LMEM_DISCARDABLE.
LMEM_MOVEABLE	If *fuNewSize* is zero, this flag causes a previously fixed object to be freed or a previously movable object to be discarded (if the object's lock count is zero). This flag cannot be used with LMEM_MODIFY. If *fuNewSize* is nonzero and the object identified by the *hloc* parameter is fixed, this flag allows the reallocated object to be moved to a new fixed location.
LMEM_NOCOMPACT	Prevents memory from being compacted or discarded to satisfy the allocation request. This flag cannot be used with LMEM_MODIFY.
LMEM_ZEROINIT	If the object is growing, this flag causes the additional memory contents to be initialized to zero. This flag cannot be used with LMEM_MODIFY.

Returns

The return value is the handle of the reallocated local memory object, if the function is successful. Otherwise, it is NULL.

Comments

If **LocalReAlloc** reallocates a movable object, the return value is a local handle of the memory. To access the memory, an application must use the **LocalLock** function to convert the handle to a pointer.

If **LocalReAlloc** reallocates a fixed object, the return value is a pointer to the memory. To access the memory, an application can simply cast the return value to a pointer.

To free a local memory object, an application should use the **LocalFree** function.

See Also

LocalAlloc, **LocalDiscard**, **LocalFree**, **LocalLock**

LocalShrink (2.x)

UINT LocalShrink(*hloc, cbNewSize***)**

```
HLOCAL hloc;        /* segment containing local heap  */
UINT cbNewSize;     /* new size of local heap         */
```

The **LocalShrink** function shrinks the local heap in the given segment.

Parameter	Description
hloc	Identifies the segment that contains the local heap. If this parameter is zero, the function shrinks the heap in the current data segment.
cbNewSize	Specifies the new size, in bytes, of the local heap.

Returns

The return value specifies the new size of the local heap if the function is successful.

Comments

Windows will not shrink the portion of the data segment that contains the stack and the static variables.

Use the **GlobalSize** function to determine the new size of the data segment.

See Also

GlobalSize

LocalSize (2.x)

UINT LocalSize(*hloc***)**

HLOCAL *hloc;* /* handle of local memory object */

The **LocalSize** function returns the current size, in bytes, of the given local memory object.

Parameter	Description
hloc	Identifies the local memory object.

Returns

The return value specifies the size, in bytes, of the memory object, if the function is successful. It is zero if the specified handle is invalid or if the object has been discarded.

Comments

The size of a memory object sometimes is larger than the size requested when the memory was allocated.

To verify that the memory object has not been discarded, an application should call the **LocalFlags** function prior to calling the **LocalSize** function. If the memory object has been discarded, the return value for **LocalSize** is meaningless.

See Also

LocalAlloc, **LocalFlags**

LocalUnlock (2.x)

BOOL LocalUnlock(*hloc***)**

HLOCAL *hloc;* /* handle of local memory object */

The **LocalUnlock** function unlocks the given local memory object. This function has no effect on fixed memory.

Parameter	Description
hloc	Identifies the local memory object to be unlocked.

Returns
The return value is zero if the function is successful. Otherwise, it is nonzero.

Comments
With discardable memory, this function decrements (decreases by one) the object's lock count. The object is completely unlocked, and subject to discarding, if the lock count is decreased to zero.

See Also
LocalLock

LockResource (2.x)

void FAR* LockResource(*hglb***)**

HGLOBAL *hglb;* /* handle of resource */

The **LockResource** function locks the given resource. The resource is locked in memory and its reference count is incremented (increased by one). The locked resource is not subject to discarding.

Parameter	Description
hglb	Identifies the resource to be locked. This handle must have been created by using the **LoadResource** function.

Returns

The return value points to the first byte of the loaded resource if the function is successful. Otherwise, it is NULL.

Comments

The resource remains locked in memory until its reference count is decreased to zero by calls to the **FreeResource** function.

If the resource identified by the *hglb* parameter has been discarded, the resource-handler function (if any) associated with the resource is called before the **LockResource** function returns. The resource-handler function can recalculate and reload the resource if necessary. After the resource-handler function returns, **LockResource** makes another attempt to lock the resource and returns with the result.

Using the handle returned by the **FindResource** function for the *hglb* parameter causes an error.

Use the **UnlockResource** macro to unlock a resource that was locked by **LockResource**.

See Also

FindResource, **FreeResource**, **SetResourceHandler**

LockSegment (2.x)

HGLOBAL LockSegment(*uSegment***)**

UINT *uSegment;* /* segment to lock */

The **LockSegment** function locks the specified discardable segment. The segment is locked into memory at the given address and its lock count is incremented (increased by one).

Parameter	Description
uSegment	Specifies the segment address of the segment to be locked. If this parameter is -1, the **LockSegment** function locks the current data segment.

Returns

The return value specifies the data segment if the function is successful. It is NULL if the segment has been discarded or an error occurs.

Comments

Locked memory is not subject to discarding except when a portion of the segment is being reallocated by the **GlobalReAlloc** function. The segment remains locked in memory until its lock count is decreased to zero by the **UnlockSegment** function.

Each time an application calls **LockSegment** for a segment, it must eventually call **UnlockSegment** for the segment. The **UnlockSegment** function decrements the lock count for the segment. Other functions also can affect the lock count of a memory object. For a list of these functions, see the description of the **GlobalFlags** function.

See Also

GlobalFlags, **GlobalReAlloc**, **LockData**, **UnlockSegment**

LogError (3.1)

void LogError(*uErr, lpvInfo***)**

UINT *uErr;* /* error type */
void FAR* *lpvInfo;* /* address of error information */

The **LogError** function identifies the most recent system error. An application's interrupt callback function typically calls **LogError** to return error information to the user.

Parameter	Description
uErr	Specifies the type of error that occurred. The *lpvInfo* parameter may point to more information about the error, depending on the value of *uErr.* This parameter may be one or more of the following values:

Value	Meaning
ERR_ALLOCRES	**AllocResource** failed.
ERR_BADINDEX	Bad index to **GetClassLong**, **GetClassWord**, **GetWindowLong**, **GetWindowWord**, **SetClassLong**, **SetClassWord**, **SetWindowLong**, or **SetWindowWord**.
ERR_BYTE	Invalid 8-bit parameter.
ERR_CREATEDC	**CreateCompatibleDC**, **CreateDC**, or **CreateIC** failed.
ERR_CREATEDLG	Could not create dialog box because **LoadMenu** failed.
ERR_CREATEDLG2	Could not create dialog box because **CreateWindow** failed.
ERR_CREATEMENU	Could not create menu.
ERR_CREATEMETA	**CreateMetaFile** failed.
ERR_CREATEWND	Could not create window because the class was not found.
ERR_DCBUSY	Device context (DC) cache is full.
ERR_DELOBJSELECTED	Program is trying to delete a bitmap that is selected into the DC.
ERR_DWORD	Invalid 32-bit parameter.
ERR_GALLOC	**GlobalAlloc** failed.
ERR_GLOCK	**GlobalLock** failed.
ERR_GREALLOC	**GlobalReAlloc** failed.
ERR_LALLOC	**LocalAlloc** failed.
ERR_LLOCK	**LocalLock** failed.
ERR_LOADMENU	**LoadMenu** failed.
ERR_LOADMODULE	**LoadModule** failed.
ERR_LOADSTR	**LoadString** failed.
ERR_LOCKRES	**LockResource** failed.
ERR_LREALLOC	**LocalReAlloc** failed.
ERR_NESTEDBEGINPAINT	Program contains nested **BeginPaint** calls.
ERR_REGISTERCLASS	**RegisterClass** failed because the class is already registered.
ERR_SELBITMAP	Program is trying to select a bitmap that is already selected.

	ERR_SIZE_MASK	Identifies which 2 bits of *uErr* specify the size of the invalid parameter.
	ERR_STRUCEXTRA	Program is using unallocated space.
	ERR_WARNING	A non-fatal error occurred.
	ERR_WORD	Invalid 16-bit parameter.
lpvInfo	Points to more information about the error. The value of *lpvInfo* depends on the value of *uErr.* If the value of (*uErr* & **ERR_SIZE_MASK**) is 0, *lpvInfo* is undefined. Currently, no *uErr* code has defined meanings for *lpvInfo.*	

Returns
This function does not return a value.

Comments
The errors identified by **LogError** may be trapped by the callback function that **NotifyRegister** installs.

Error values whose low 12 bits are less than 0x07FF are reserved for use by Windows.

See Also
LogParamError, **NotifyRegister**

LogParamError (3.1)

void LogParamError(*uErr, lpfn, lpvParam***)**

```
UINT uErr;          /* error type                        */
FARPROC lpfn;       /* address where error occurred      */
void FAR* lpvParam; /* address of more error information */
```

The **LogParamError** function identifies the most recent parameter validation error. An application's interrupt callback function typically calls **LogParamError** to return information about an invalid parameter to the user.

Parameter	Description
uErr	Specifies the type of parameter validation error that occurred. The *lpvParam* parameter may point to more information about the error, depending on the value of *uErr.* This parameter may be one or more of the following values:

Value	Meaning
ERR_BAD_ATOM	Invalid atom.
ERR_BAD_CID	Invalid communications identifier (CID).
ERR_BAD_COORDS	Invalid x,y coordinates.
ERR_BAD_DFLAGS	Invalid 32-bit flags.
ERR_BAD_DINDEX	Invalid 32-bit index or index out-of-range.
ERR_BAD_DVALUE	Invalid 32-bit signed or unsigned value.
ERR_BAD_FLAGS	Invalid bit flags.
ERR_BAD_FUNC_PTR	Invalid function pointer.
ERR_BAD_GDI_OBJECT	Invalid graphics device interface (GDI) object.
ERR_BAD_GLOBAL_HANDLE	Invalid global handle.
ERR_BAD_HANDLE	Invalid generic handle.
ERR_BAD_HBITMAP	Invalid bitmap handle.
ERR_BAD_HBRUSH	Invalid brush handle.
ERR_BAD_HCURSOR	Invalid cursor handle.
ERR_BAD_HDC	Invalid device context (DC) handle.
ERR_BAD_HDRVR	Invalid driver handle.
ERR_BAD_HDWP	Invalid handle of a window-position structure.
ERR_BAD_HFILE	Invalid file handle.
ERR_BAD_HFONT	Invalid font handle.
ERR_BAD_HICON	Invalid icon handle.
ERR_BAD_HINSTANCE	Invalid instance handle.
ERR_BAD_HMENU	Invalid menu handle.
ERR_BAD_HMETAFILE	Invalid metafile handle.
ERR_BAD_HMODULE	Invalid module handle.
ERR_BAD_HPALETTE	Invalid palette handle.
ERR_BAD_HPEN	Invalid pen handle.
ERR_BAD_HRGN	Invalid region handle.
ERR_BAD_HWND	Invalid window handle.
ERR_BAD_INDEX	Invalid index or index out-of-range.
ERR_BAD_LOCAL_HANDLE	Invalid local handle.
ERR_BAD_PTR	Invalid pointer.

ERR_BAD_SELECTOR	Invalid selector.
ERR_BAD_STRING_PTR	Invalid zero-terminated string pointer.
ERR_BAD_VALUE	Invalid 16-bit signed or unsigned value.
ERR_BYTE	Invalid 8-bit parameter.
ERR_DWORD	Invalid 32-bit parameter.
ERR_PARAM	A parameter validation error occurred. This flag is always set.
ERR_SIZE_MASK	Identifies which 2 bits of *uErr* specify the size of the invalid parameter.
ERR_WARNING	An invalid parameter was detected, but the error is not serious enough to cause the function to fail. The invalid parameter is reported, but the call runs as usual.
ERR_WORD	Invalid 16-bit parameter.

lpfn Specifies the address at which the parameter error occurred. This value is NULL if the address is unknown.

lpvParam Points to more information about the error. The value of *lpvParam* depends on the value of *uErr.* If the value of (*uErr* & **ERR_SIZE_MASK**) is 0, *lpvParam* is undefined. Currently, no *uErr* code has defined meanings for *lpvParam.*

Returns
This function does not return a value.

Comments
The errors identified by **LogParamError** may be trapped by the callback function that **NotifyRegister** installs.

Error values whose low 12 bits are less than 0x07FF are reserved for use by Windows.

The size of the value passed in *lpvParam* is determined by the values of the bits selected by **ERR_SIZE_MASK**, as follows:

```
switch (err & ERR_SIZE_MASK)
{
case ERR_BYTE:          /* 8-bit invalid parameter */
    b = LOBYTE(param);
    break;

case ERR_WORD:          /* 16-bit invalid parameter */
    w = LOWORD(param);
    break;

case ERR_DWORD:         /* 32-bit invalid parameter */
    l = (DWORD)param;
    break:

default:                /* invalid parameter value is unknown */
    break;
}
```

ERR_WORD 0x2000

Invalid 16-bit parameter.

ERR_WORD 0x2000

lstrcat (2.x)

LPSTR lstrcat(*lpszString1*, *lpszString2***)**

LPSTR *lpszString1;* /* address of buffer for concatenated strings */
LPCSTR *lpszString2;* /* address of string to add to string1 */

The **lstrcat** function appends one string to another.

Parameter	Description
lpszString1	Points to a byte array containing a null-terminated string. The byte array containing the string must be large enough to contain both strings.
lpszString2	Points to the null-terminated string to be appended to the string specified in the *lpszString1* parameter.

Returns
The return value points to *lpszString1* if the function is successful.

Comments
Both strings must be less than 64K in size.

Example
The following example uses the **lstrcat** function to append a test string to a buffer:

```
char szBuf[80] = { "the test string is " };

lstrcat(szBuf, lpsz);
MessageBox(hwnd, szBuf, "lstrcat", MB_OK);
```

See Also
lstrcpy

lstrcpy (2.x)

LPSTR lstrcpy(*lpszString1, lpszString2***)**

```
LPSTR lpszString1;      /* address of buffer          */
LPCSTR lpszString2;     /* address of string to copy  */
```

The **lstrcpy** function copies a string to a buffer.

Parameter	Description
lpszString1	Points to a buffer that will receive the contents of the string pointed to by the *lpszString2* parameter. The buffer must be large enough to contain the string, including the terminating null character.
lpszString2	Points to the null-terminated string to be copied.

Returns

The return value is a pointer to *lpszString1* if the function is successful. Otherwise, it is NULL.

Comments

This function can be used to copy a double-byte character set (DBCS) string.

Both strings must be less than 64K in size.

See Also

lstrcat, **lstrcpyn**, **lstrlen**

lstrcpyn (3.1)

LPSTR lstrcpyn(*lpszString1, lpszString2, cChars***)**

```
LPSTR lpszString1;      /* address of buffer              */
LPCSTR lpszString2;     /* address of string to copy from */
int cChars;             /* number of characters to copy   */
```

The **lstrcpyn** function copies a specified number of characters in a string to a buffer.

Parameter	Description
lpszString1	Points to a buffer that will receive characters from the string pointed to by the *lpszString2* parameter.
lpszString2	Points to the null-terminated string to copy from.
cChars	Specifies the number of characters to copy from the string pointed to by the *lpszString2* parameter.

Returns

The return value is a pointer to *lpszString1* if the function is successful. Otherwise, it is NULL.

See Also

lstrcpy

lstrlen (2.x)

int lstrlen(*lpszString***)**

LPCSTR *lpszString;* /* address of string to count */

The **lstrlen** function returns the length, in bytes, of the specified string (not including the terminating null character).

Parameter	Description
lpszString	Points to a null-terminated string. This string must be less than 64K in size.

Returns

The return value specifies the length, in bytes, of the string pointed to by the *lpszString* parameter. There is no error return.

See Also

lstrcpy

MakeProcInstance (2.x)

FARPROC MakeProcInstance(*lpProc, hinst***)**

```
FARPROC lpProc;         /* address of function          */
HINSTANCE hinst;        /* instance to bind to function */
```

The **MakeProcInstance** function returns the address of the prolog code for an exported function. The prolog code binds an instance data segment to an exported function. When the function is called, it has access to variables and data in that instance data segment.

Parameter	Description
lpProc	Specifies the address of an exported function.
hinst	Identifies the instance associated with the desired data segment.

Returns

The return value points to the prolog code for the specified exported function, if **MakeProcInstance** is successful. Otherwise, it is NULL.

Comments

The **MakeProcInstance** function is used to retrieve a calling address for a function that must be called by Windows, such as an About procedure. This function must be used only to access functions from instances of the current module. If the address specified in the *lpProc* parameter identifies a procedure in a dynamic-link library, **MakeProcInstance** returns the same address specified in *lpProc.*

After **MakeProcInstance** has been called for a particular function, all calls to that function should be made through the retrieved address.

The **FreeProcInstance** function frees the function from the data segment bound to it by the **MakeProcInstance** function.

MakeProcInstance will create more than one procedure instance. To avoid wasting memory, an application should not call **MakeProcInstance** more than once using the same function and instance handle.

If you are using a recent version of a Windows compiler, you may not have to use the **MakeProcInstance** function. Consult your compiler manual for specific information on function prolog and epilog code.

See Also

FreeProcInstance, **GetProcAddress**

MapVirtualKey (3.0)

UINT MapVirtualKey(*uKeyCode, fuMapType***)**

UINT *uKeyCode;* /* virtual-key code or scan code */
UINT *fuMapType;* /* translation to perform */

The **MapVirtualKey** function translates (maps) a virtual-key code into a scan code or ASCII value, or it translates a scan code into a virtual-key code.

Parameter	Description
uKeyCode	Specifies the virtual-key code or scan code for a key. How this parameter is interpreted depends on the value of the *fuMapType* parameter.
fuMapType	Specifies the translation to perform. If this parameter is 0, the *uKeyCode* parameter is a virtual-key code and is translated into its corresponding scan code. If *fuMapType* is 1, *uKeyCode* is a scan code and is translated to a virtual-key code. If *fuMapType* is 2, *uKeyCode* is a virtual-key code and is translated to an unshifted ASCII value. Other values are reserved.

Returns

The return value depends on the value of the *uKeyCode* and *fuMapType* parameters. For more information, see the description of the *fuMapType* parameter.

See Also

OemKeyScan, **VkKeyScan**

MulDiv (3.0)

int MulDiv(*nMultiplicand, nMultiplier, nDivisor***)**

```
int nMultiplicand;    /* 16-bit signed multiplicand */
int nMultiplier;      /* 16-bit signed multiplier   */
int nDivisor;         /* 16-bit signed divisor      */
```

The **MulDiv** function multiplies two 16-bit values and then divides the 32-bit result by a third 16-bit value. The return value is the 16-bit result of the division, rounded up or down to the nearest integer.

Parameter	Description
nMultiplicand	Specifies the multiplicand.
nMultiplier	Specifies the multiplier.
nDivisor	Specifies the number by which the result of the multiplication (*nMultiplicand* * *nMultiplier*) is to be divided.

Returns

The return value is the result of the multiplication and division if the function is successful. The return value is -32,768 if either an overflow occurs or the *nDivisor* parameter is 0.

See Also

CreateFontIndirect, **GetDeviceCaps**

NetBIOSCall (3.0)

The **NetBIOSCall** function allows an application to issue the NETBIOS Interrupt 5Ch. This function can be called only from assembly-language routines. It is exported from KRNL286.EXE and KRNL386.EXE and is not defined in any Windows header files.

Parameters

Registers must be set up as required by Interrupt 5Ch before the application calls the **NetBIOSCall** function.

Returns

The register contents are preserved as they are returned by Interrupt 5Ch.

Comments

Applications should use this function instead of directly issuing a NETBIOS Interrupt 5Ch.

Example

To use this function, an application should declare it in an assembly-language routine, as follows:

```
extrn NETBIOSCALL: far
```

If the application includes CMACROS.INC, the function is declared as follows:

```
externFP NetBIOSCall
```

Following is an example of how to use the **NetBIOSCall** function:

```
extrn NETBIOSCALL: far
                .
                .
                .
        ;set registers

        cCall NetBIOSCall
```

OemKeyScan (3.0)

DWORD OemKeyScan(*uOemChar***)**

UINT *uOemChar;* /* OEM ASCII character */

The **OemKeyScan** function translates (maps) OEM ASCII codes 0 through 0xFF to their corresponding OEM scan codes and shift states.

Parameter	Description
uOemChar	Specifies the ASCII value of the OEM character.

Returns

The low-order word of the return value contains the scan code of the specified OEM character; the high-order word contains flags that indicate the shift state: If bit 1 is set, a SHIFT key is pressed; if bit 2 is set, a CTRL key is pressed. Both the low-order and high-order words of the return value contain -1 if the character is not defined in the OEM character tables.

Comments

The **OemKeyScan** function does not translate characters that require CTRL+ALT or dead keys. Characters not translated by this function must be copied by simulating input, using the ALT+ keypad mechanism. For this to work, the NUM LOCK key must be off.

This function calls the **VkKeyScan** function in recent versions of the keyboard device drivers.

OemKeyScan allows an application to send OEM text to another application by simulating keyboard input. It is used specifically for this purpose by Windows in 386 enhanced mode.

See Also

VkKeyScan

OemToAnsi (2.x)

void OemToAnsi(*hpszOemStr, hpszWindowsStr***)**

```
const char _huge* hpszOemStr;      /* address of string to translate       */
char _huge* hpszWindowsStr;        /* address of translated string buffer */
```

The **OemToAnsi** function translates a string from the OEM-defined character set into the Windows character set.

Parameter	Description
hpszOemStr	Points to a null-terminated string of characters from the OEM-defined character set.
hpszWindowsStr	Points to the location where the translated string is to be copied. To translate the string in place, the *hpszWindowsStr* parameter can be the same as the *hpszOemStr* parameter.

Returns

This function does not return a value.

See Also

AnsiToOem, **OemToAnsiBuff**

OemToAnsiBuff (2.x)

void OemToAnsiBuff(*lpszOemStr, lpszWindowsStr, cbOemStr***)**

```
LPCSTR lpszOemStr;      /* address of OEM character string     */
LPSTR lpszWindowsStr;   /* address of buffer for Windows string */
UINT cbOemStr;          /* length of OEM string                */
```

The **OemToAnsiBuff** function translates a string from the OEM-defined character set into the Windows character set.

Parameter	Description
lpszOemStr	Points to a buffer containing one or more characters from the OEM-defined character set.
lpszWindowsStr	Points to the location where the translated string is to be copied. To translate the string in place, the *lpszWindowsStr* parameter can be the same as the *lpszOemStr* parameter.
cbOemStr	Specifies the length, in bytes, of the buffer pointed to by *lpszOemStr.* If *cbOemStr* is 0, the length is 64K.

Returns

This function does not return a value.

See Also

AnsiToOem, **OemToAnsi**

OpenFile (2.x)

HFILE OpenFile(*lpszFileName, lpOpenBuff, fuMode***)**

```
LPCSTR lpszFileName;          /* address of filename                  */
OFSTRUCT FAR* lpOpenBuff;     /* address of buffer for file information */
UINT fuMode;                  /* action and attributes                */
```

The **OpenFile** function creates, opens, reopens, or deletes a file.

Parameter	Description
lpszFileName	Points to a null-terminated string that names the file to be opened. The string must consist of characters from the Windows character set and cannot contain wildcards.
lpOpenBuff	Points to the **OFSTRUCT** structure that will receive information about the file when the file is first opened. The structure can be used in subsequent calls to the **OpenFile** function to refer to the open file.
fuMode	Specifies the action to take and the attributes for the file. This parameter can be a combination of the following values:

Value	Meaning
OF_CANCEL	Adds a Cancel button to the **OF_PROMPT** dialog box. Pressing the Cancel button directs **OpenFile** to return a file-not-found error message.
OF_CREATE	Creates a new file. If the file already exists, it is truncated to zero length. When this flag is specified, the sharing flags are ignored. If a file must be shared it should be closed after it is created and then reopened with the appropriate sharing flags.
OF_DELETE	Deletes the file.
OF_EXIST	Opens the file, and then closes it. This value is used to test for file existence. Using this value does not change the file date.
OF_PARSE	Fills the **OFSTRUCT** structure but carries out no other action.
OF_PROMPT	Displays a dialog box if the requested file does not exist. The dialog box informs the user that Windows cannot find the file and prompts the user to insert the file in drive A.
OF_READ	Opens the file for reading only.
OF_READWRITE	Opens the file for reading and writing.
OF_REOPEN	Opens the file using information in the reopen buffer.
OF_SEARCH	Windows searches in directories even when the file name includes a full path.
OF_SHARE_COMPAT	Opens the file with compatibility mode, allowing any program on a given machine to open the file any number of times. **OpenFile** fails if the file has been opened with any of the other sharing modes.
OF_SHARE_DENY_NONE	Opens the file without denying other programs read or write access to the file. **OpenFile** fails if the file has been opened in compatibility mode by any other program.

OF_SHARE_DENY_READ	Opens the file and denies other programs read access to the file. **OpenFile** fails if the file has been opened in compatibility mode or for read access by any other program.
OF_SHARE_DENY_WRITE	Opens the file and denies other programs write access to the file. **OpenFile** fails if the file has been opened in compatibility or for write access by any other program.
OF_SHARE_EXCLUSIVE	Opens the file with exclusive mode, denying other programs both read and write access to the file. **OpenFile** fails if the file has been opened in any other mode for read or write access, even by the current program.
OF_VERIFY	Compares the time and date in the OF_STRUCT with the time and date of the specified file. The function returns HFILE_ERROR if the dates and times do not agree.
OF_WRITE	Opens the file for writing only.

Returns

The return value is an MS-DOS file handle if the function is successful. (This handle is not necessarily valid; for example, if the *fuMode* parameter is **OF_EXIST**, the handle does not identify an open file, and if the *fuMode* parameter is **OF_DELETE**, the handle is invalid.) The return value is HFILE_ERROR if an error occurs.

Comments

If the *lpszFileName* parameter specifies a filename and extension only (or if the **OF_SEARCH** flag is specified), the **OpenFile** function searches for a matching file in the following directories (in this order):

1 The current directory.

2 The Windows directory (the directory containing WIN.COM), whose path the **GetWindowsDirectory** function retrieves.

3 The Windows system directory (the directory containing such system files as GDI.EXE), whose path the **GetSystemDirectory** function retrieves.

4 The directory containing the executable file for the current task; the **GetModuleFileName** function obtains the path of this directory.

5 The directories listed in the PATH environment variable.

6 The list of directories mapped in a network.

To close the file after use, the application should call the **_lclose** function.

See Also

GetSystemDirectory, **GetWindowsDirectory**, **OFSTRUCT**

OF_CANCEL 0x0800

Adds a Cancel button to the **OF_PROMPT** dialog box. Pressing the Cancel button directs **OpenFile** to return a file-not-found error message.

OF_CANCEL 0x0800

OF_CREATE 0x1000

Creates a new file. If the file already exists, it is truncated to zero length. When this flag is specified, the sharing flags are ignored. If a file must be shared it should be closed after it is created and then reopened with the appropriate sharing flags.

OF_CREATE 0x1000

OF_DELETE 0x0200

Deletes the file.

OF_DELETE 0x0200

OF_EXIST 0x4000

Opens the file, and then closes it. This value is used to test for file existence. Using this value does not change the file date.

OF_EXIST 0x4000

OF_PARSE 0x0100

Fills the **OFSTRUCT** structure but carries out no other action.

OF_PARSE 0x0100

OF_PROMPT 0x2000

Displays a dialog box if the requested file does not exist. The dialog box informs the user that Windows cannot find the file and prompts the user to insert the file in drive A.

OF_PROMPT 0x2000

OF_READ 0x0000

Opens the file for reading only.

OF_READ 0x0000

OF_READWRITE 0x0002

Opens the file for reading and writing.

OF_READWRITE 0x0002

OF_REOPEN 0x8000

Opens the file using information in the reopen buffer.

OF_REOPEN 0x8000

OF_SEARCH 0x0400

Windows searches in directories even when the file name includes a full path.

OF_SEARCH 0x0400

OF_SHARE_COMPAT 0x0000

Opens the file with compatibility mode, allowing any program on a given machine to open the file any number of times. **OpenFile** fails if the file has been opened with any of the other sharing modes.

OF_SHARE_COMPAT 0x0000

OF_SHARE_DENY_NONE 0x0040

Opens the file without denying other programs read or write access to the file. **OpenFile** fails if the file has been opened in compatibility mode by any other program.

OF_SHARE_DENY_NONE 0x0040

OF_SHARE_DENY_READ 0x0030

Opens the file and denies other programs read access to the file. **OpenFile** fails if the file has been opened in compatibility mode or for read access by any other program.

OF_SHARE_DENY_READ 0x0030

OF_SHARE_DENY_WRITE 0x0020

Opens the file and denies other programs write access to the file. **OpenFile** fails if the file has been opened in compatibility or for write access by any other program.

OF_SHARE_DENY_WRITE 0x0020

OF_SHARE_EXCLUSIVE 0x0010

Opens the file with exclusive mode, denying other programs both read and write access to the file. **OpenFile** fails if the file has been opened in any other mode for read or write access, even by the current program.

OF_SHARE_EXCLUSIVE 0x0010

OF_VERIFY 0x0400

Compares the time and date in the OF_STRUCT with the time and date of the specified file. The function returns HFILE_ERROR if the dates and times do not agree.

OF_VERIFY 0x0400

OF_WRITE 0x0001

Opens the file for writing only.

OF_WRITE 0x0001

OpenSound (2.x)

int OpenSound(void)

This function is obsolete. Use the Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

OutputDebugString (3.0)

void OutputDebugString(*lpszOutputString***)**

LPCSTR *lpszOutputString;* /* address of string to display */

The **OutputDebugString** function displays the specified character string on the debugging terminal if a debugger is running.

Parameter	Description
lpszOutputString	Points to a null-terminated string to be displayed.

Returns
This function does not return a value.

Comments
This function preserves all registers.

Example
The following example uses the **OutputDebugString** function to display information on the debugging terminal:

```
OutputDebugString("\n\rcalling ValidateCodeSegments");

ValidateCodeSegments();

OutputDebugString("\n\rdone");
```

See Also
DebugOutput

Correction

The previous description of this function indicated that it worked only with the debugging version of Windows. **OutputDebugString** works with both the debugging and retail version of Windows.

PrestoChangoSelector (3.0)

UINT PrestoChangoSelector(*uSourceSelector, uDestSelector***)**

```
UINT uSourceSelector;     /* selector to convert                        */
UINT uDestSelector;       /* converted selector (allocated by AllocSelector)  */
```

The **PrestoChangoSelector** function generates a code selector that corresponds to a given data selector, or it generates a data selector that corresponds to a given code selector.

An application should not use this function unless it is absolutely necessary, because its use violates preferred Windows programming practices.

Parameter	Description
uSourceSelector	Specifies the selector to be converted.
uDestSelector	Specifies a selector previously allocated by the **AllocSelector** function. This previously allocated selector receives the converted selector.

Returns

The return value is the copied and converted selector if the function is successful. Otherwise, it is zero.

Comments

Windows does not track changes to the source selector. Consequently, before any memory can be moved, the application should use the converted destination selector immediately after it is returned by this function.

The **PrestoChangoSelector** function modifies the destination selector to have the same properties as the source selector, but with the opposite code or data attribute. This function changes only the attributes of the selector, not the value of the selector.

This function was named **ChangeSelector** in the Windows 3.0 documentation.

See Also

AllocDStoCSAlias, **AllocSelector**

ProfClear (3.0)

void ProfClear(void)

The **ProfClear** function discards all Microsoft Windows Profiler samples currently in the sampling buffer.

Returns
This function does not return a value.

Example
The following example uses the **ProfClear** function to clear the Profiler sampling buffer before changing the sampling rate:

```
ProfClear();                /* clears existing buffer */
ProfSampRate(5, 1);         /* changes sampling rate  */
```

ProfFinish (3.0)

void ProfFinish(void)

The **ProfFinish** function stops Microsoft Windows Profiler sampling and flushes the output buffer to disk.

Returns
This function does not return a value.

Comments
If Profiler is running in 386 enhanced mode, the **ProfFinish** function also frees the buffer for system use.

Example
The following example uses the **ProfFinish** function to stop sampling and flush the output buffer during **WM_DESTROY** message processing:

```
case WM_DESTROY:
    ProfFinish();
    PostQuitMessage(0);
    break;
```

ProfFlush (3.0)

void ProfFlush(void)

The **ProfFlush** function flushes the Microsoft Windows Profiler sampling buffer to disk.

Returns
This function does not return a value.

Comments
Excessive use of the **ProfFlush** function can seriously impair application performance. An application should not use **ProfFlush** when MS-DOS may be unstable (inside an interrupt handler, for example).

Example
The following example uses the **ProfFlush** function to flush the Profiler buffer before changing the buffer size:

```
ProfFlush();                /* flushes existing buffer */
ProfSetup(1024, 0);         /* uses a 1024K buffer     */
```

ProfInsChk (3.0)

int ProfInsChk(void)

The **ProfInsChk** function determines whether Microsoft Windows Profiler is installed.

Returns

The return value is 1 if Profiler is installed for a mode other than 386 enhanced mode, or it is 2 if Profiler is installed for 386 enhanced mode. Otherwise, the return value is 0, indicating that Profiler is not installed.

Example

The following example uses the **ProfInsChk** function to determine whether the Profiler is installed:

```
int ick;
char szMsg[80];

if ((ick = ProfInsChk()) == 0)
    MessageBox(hwnd, "Profiler is not installed!",
        "ProfInsChk", MB_ICONSTOP);
else {
    strcpy(szMsg, "Profiler is installed");
    if (ick == 2) {
        strcat(szMsg, " in 386 enhanced mode");
        ProfSetup(128, 0);      /* uses a 128K buffer */
    }
    MessageBox(hwnd, szMsg, "ProfInsChk", MB_OK);
}
```

ProfSampRate (3.0)

void ProfSampRate(*nRate286, nRate386***)**

int *nRate286;* /* sample rate for non-386 enhanced mode */
int *nRate386;* /* sample rate for 386 enhanced mode */

The **ProfSampRate** function sets the Microsoft Windows Profiler code-sampling rate.

Parameter	Description
nRate286	Specifies the sampling rate if the application is not running in 386 enhanced mode. The *nRate286* parameter can be one of the following values:

Value	Sampling rate
1	122.070 microseconds
2	244.141 microseconds
3	488.281 microseconds
4	976.562 microseconds
5	1.953125 milliseconds
6	3.90625 milliseconds
7	7.8125 milliseconds
8	15.625 milliseconds
9	31.25 milliseconds
10	62.5 milliseconds
11	125 milliseconds
12	250 milliseconds
13	500 milliseconds

nRate386	Specifies the sampling rate, in milliseconds if the application is running in 386 enhanced mode. This value is in the range 1 through 1000.

Returns

This function does not return a value.

Comments

Only the rate parameter appropriate to the current mode is used; the other parameter is ignored.

The default rate is 2 milliseconds in 386 enhanced mode; in any other mode, the value is 5, which specifies a rate of 1.953125 milliseconds.

Example

The following example uses the **ProfSampRate** function to change the Profiler sampling rate to 1 millisecond in 386 enhanced mode:

```
ProfClear();                /* clears existing buffer */
ProfSampRate(5, 1);         /* changes sampling rate  */
```

ProfSetup (3.0)

void ProfSetup(*nBufferKB, nSamplesKB***)**

int *nBufferKB;* /* size of output buffer */
int *nSamplesKB;* /* amount of sample data written to disk */

The **ProfSetup** function specifies the size of the Microsoft Windows Profiler output buffer and how much sampling data Profiler is to write to the disk.

Profiler ignores the **ProfSetup** function when running with Windows in any mode other than 386 enhanced mode.

Parameter	Description
nBufferKB	Specifies the size, in kilobytes, of the output buffer. This value is in the range 1 through 1064. The default value is 64.
nSamplesKB	Specifies the amount, in kilobytes, of sampling data Profiler writes to the disk. A value of zero (the default value) specifies unlimited sampling data.

Returns
This function does not return a value.

Comments
Do not call the **ProfSetup** function after calling **ProfStart**. To resize memory after **ProfStart** has been called, first call the **ProfStop** function.

Example
The following example uses the **ProfSetup** function to set the output buffer size to 128K if Profiler is installed in 386 enhanced mode:

```
int ick;
char szMsg[80];

if ((ick = ProfInsChk()) == 0)
    MessageBox(hwnd, "Profiler is not installed!",
        "ProfInsChk", MB_ICONSTOP);
else {
    strcpy(szMsg, "Profiler is installed");
    if (ick == 2) {
        strcat(szMsg, " in 386 enhanced mode");
        ProfSetup(128, 0);      /* uses a 128K buffer */
    }
    MessageBox(hwnd, szMsg, "ProfInsChk", MB_OK);
}
```

See Also
ProfStart, **ProfStop**

ProfStart (3.0)

void ProfStart(void)

The **ProfStart** function starts Microsoft Windows Profiler sampling.

Returns
This function does not return a value.

Example
The following example uses the **ProfStart** and **ProfStop** functions to sample during the message-queue dispatch process:

```
/* Acquire and dispatch messages until WM_QUIT is received. */

while (GetMessage(&msg, /* message structure                  */
        (HWND) NULL,    /* handle of window receiving message */
        0,              /* lowest message to examine          */
        0))             /* highest message to examine         */
    {
    ProfStart();

    TranslateMessage(&msg); /* translates virtual-key codes   */
    DispatchMessage(&msg);  /* dispatches message to window   */

    ProfStop();
}
```

See Also
ProfStop

ProfStop (3.0)

void ProfStop(void)

The **ProfStop** function stops Microsoft Windows Profiler sampling.

Returns
This function does not return a value.

Example
The following example uses the **ProfStart** and **ProfStop** functions to sample during the message-queue dispatch process:

```
/* Acquire and dispatch messages until WM_QUIT is received. */

while (GetMessage(&msg, /* message structure                  */
        (HWND) NULL,    /* handle of window receiving message */
        0,              /* lowest message to examine          */
        0))             /* highest message to examine         */
    {
    ProfStart();

    TranslateMessage(&msg); /* translates virtual-key codes   */
    DispatchMessage(&msg);  /* dispatches message to window   */

    ProfStop();
}
```

See Also
ProfStart

SetErrorMode (2.x)

UINT SetErrorMode(*fuErrorMode***)**

UINT *fuErrorMode;* /* specifies the error-mode flag */

The **SetErrorMode** function controls whether Windows handles MS-DOS Interrupt 24h errors or allows the calling application to handle them.

Parameter	Description
fuErrorMode	Specifies the error-mode flag. The flag can be a combination of the following values:

Value	Meaning
SEM_FAILCRITICALERRORS	Windows does not display the critical-error-handler message box and returns the error to the calling application.
SEM_NOGPFAULTERRORBOX	Windows does not display the general-protection-fault message box. This flag should be set *only* by debugging applications that handle GP faults themselves.
SEM_NOOPENFILEERRORBOX	Windows does not display a message box when it fails to find a file.

Returns

The return value is the previous state of the error-mode flag, if the function is successful.

Example

The following example uses the **SetErrorMode** function to turn off the file-not-found message box (the application handles this error itself):

```
/* Turn off the "File not found" error box. */

SetErrorMode(SEM_NOOPENFILEERRORBOX);

/* Load the TOOLHELP.DLL library module. */

hinstToolHelp = LoadLibrary("TOOLHELP.DLL");

if (hinstToolHelp > HINSTANCE_ERROR) {    /* loaded successfully */

    .
    . /* Use the DLL here. */
    .

}
else {
    strcpy(szBuf, "LoadLibrary failed");
}

MessageBox(NULL, szBuf, "Library Functions", MB_ICONHAND);
```

SEM_FAILCRITICALERRORS 0x0001

Windows does not display the critical-error-handler message box and returns the error to the calling application.

SEM_FAILCRITICALERRORS 0x0001

SEM_NOGPFAULTERRORBOX 0x0002

Windows does not display the general-protection-fault message box. This flag should be set *only* by debugging applications that handle GP faults themselves.

SEM_NOGPFAULTERRORBOX 0x0002

SEM_NOOPENFILEERRORBOX 0x8000

Windows does not display a message box when it fails to find a file.

SEM_NOOPENFILEERRORBOX 0x8000

SetHandleCount (3.0)

UINT SetHandleCount(*cHandles***)**

UINT *cHandles;* /* number of file handles needed */

The **SetHandleCount** function changes the number of file handles available to a task.

Parameter	Description
cHandles	Specifies the number of file handles the application requires. This count cannot be greater than 255.

Returns

The return value is the number of file handles available to the application, if the function is successful. This number may be less than the number of handles specified.

Comments

By default, the maximum number of file handles available to a task is 20.

Example

The following example uses the **SetHandleCount** function to set the number of available file handles to 30:

```
UINT cHandles;
char szBuf[80];

cHandles = SetHandleCount(30);

sprintf(szBuf, "%d handles available", cHandles);
MessageBox(hwnd, szBuf, "SetHandleCount", MB_OK);
```

SetResourceHandler (2.x)

RSRCHDLRPROC SetResourceHandler(*hinst, lpszType, lpLoadProc***)**

```
HINSTANCE hinst;          /* handle of application instance          */
LPCSTR lpszType;          /* address of resource-type identifier     */
RSRCHDLRPROC lpLoadProc;  /* callback procedure-instance address     */
```

The **SetResourceHandler** function installs a callback function that loads resources.

Parameter	Description
hinst	Identifies the instance of the module whose executable file contains the resource.
lpszType	Points to a null-terminated string that specifies a resource type. For predefined resource types, the high-order word should be zero and the low-order word should indicate the resource type.
lpLoadProc	Specifies the procedure-instance address of the application-supplied callback function. For more information, see the description of the **LoadProc** callback function.

Returns

The return value is a pointer to the previously installed resource handler, if the function is successful. If no resource handler has been explicitly installed, the return value is a pointer to the default resource handler.

Comments

An application may find this function useful for handling its own resource types, but the use of this function is not required.

The address passed as the *lpLoadProc* parameter must be created by using the **MakeProcInstance** function.

See Also

FindResource, **LoadProc**, **LockResource**, **MakeProcInstance**

Correction

The second parameter points to a null-terminated string that specifies the resource type. Previous documentation stated that it pointed to a short integer.

SetSelectorBase (3.1)

UINT SetSelectorBase(*selector, dwBase***)**

UINT *selector;* /* selector to modify */
DWORD *dwBase;* /* new base */

The **SetSelectorBase** function sets the base address of a selector.

Parameter	Description
selector	Specifies the selector value to modify.
dwBase	Specifies the new base value. This value is the starting linear address that *selector* will reference.

Returns
The return value is the selector value, if the function is successful. If an error occurred, the return value is zero.

Comments
Because this function is selector-based, it will not exist in the Win32 API.

See Also
GetSelectorBase, **GetSelectorLimit**, **SetSelectorLimit**

SetSelectorLimit (3.1)

UINT SetSelectorLimit(*selector, dwLimit***)**

UINT *selector;* /* selector to modify */
DWORD *dwLimit;* /* new limit */

The **SetSelectorLimit** function sets the limit of a selector.

Parameter	Description
selector	Specifies the selector to modify.
dwLimit	Specifies the new limit value for *selector.* On a 80286, this value must be less than 0x10000.

Returns
The return value is always zero.

Comments
Because this function is selector-based, it will not exist in the Win32 API.

See Also
GetSelectorBase, **GetSelectorLimit**, **SetSelectorBase**

SetSoundNoise (2.x)

int SetSoundNoise(*fnSource, nDuration***)**

int *fnSource;* /* source of noise */
int *nDuration;* /* duration of noise */

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about audio functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

SetSwapAreaSize (2.x)

LONG SetSwapAreaSize(*cCodeParagraphs***)**

UINT *cCodeParagraphs;* /* number of paragraphs for code */

The **SetSwapAreaSize** function sets the amount of memory that an application uses for its code segments.

Parameter	Description
cCodeParagraphs	Specifies the number of 16-byte paragraphs requested by the application for use as code segments. If this parameter is zero, the return value specifies the current size of the code-segment space.

Returns

The return value is the amount of space available for the code segment, if the function is successful. The low-order word specifies the number of paragraphs obtained for use as a code-segment space (or the current size if the *cCodeParagraphs* parameter is zero); the high-order word specifies the maximum size available.

Comments

If *cCodeParagraphs* specifies a size larger than is available, this function sets the size to the available amount. The maximum amount of memory available is one half the space remaining after Windows is loaded.

Calling this function can improve an application's performance by preventing Windows from swapping code segments to the hard disk. However, increasing the code-segment space reduces the amount of memory available for data objects and can reduce the performance of other applications.

See Also

GetNumTasks, **GlobalAlloc**

SetVoiceAccent (2.x)

int SetVoiceAccent(*nVoice, nTempo, nVolume, fnMode, nPitch***)**

```
int nVoice;     /* voice queue                          */
int nTempo;     /* number of quarter notes per minute*/
int nVolume;    /* volume level                         */
int fnMode;     /* how notes are to be played           */
int nPitch;     /* pitch                                */
```

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

SetVoiceEnvelope (2.x)

int SetVoiceEnvelope(*nVoice, nShape, nRepeat***)**

```
int nVoice;     /* voice queue                          */
int nShape;     /* index into an OEM wave-shape table*/
int nRepeat;    /* repetition count                     */
```

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

SetVoiceNote (2.x)

int SetVoiceNote(*voice, value, length, cdots***)**

```
int voice;      /* voice queue      */
int value;      /* note             */
int length;     /* length of note   */
int cdots;      /* duration of note */
```

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

SetVoiceQueueSize (2.x)

int SetVoiceQueueSize(*nVoice, cbQueue***)**

int *nVoice;* /* voice queue */
int *cbQueue;* /* size of queue */

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

SetVoiceSound (2.x)

int SetVoiceSound(*nVoice, dwFrequency, nDuration***)**

```
int nVoice;          /* voice queue       */
DWORD dwFrequency;   /* frequency         */
int nDuration;       /* duration of sound */
```

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

SetVoiceThreshold (2.x)

int SetVoiceThreshold(*voice, cNotesThreshold***)**

int *voice;* /* voice queue */
int *cNotesThreshold;* /* threshold level */

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

SetWinDebugInfo (3.1)

BOOL SetWinDebugInfo(*lpwdi***)**

const WINDEBUGINFO FAR* *lpwdi;* /* address of WINDEBUGINFO structure */

The **SetWinDebugInfo** function sets current system-debugging information for the debugging version of the Windows 3.1 operating system.

Parameter	Description
lpwdi	Points to a **WINDEBUGINFO** structure that specifies the type of debugging information to be set.

Returns

The return value is nonzero if the function is successful. It is zero if the pointer specified in the *lpwdi* parameter is invalid, the **flags** member of the **WINDEBUGINFO** structure is invalid, or the function is not called in the debugging version of Windows 3.1.

Comments

The **flags** member of the **WINDEBUGINFO** structure specifies which debugging information should be set. Applications need initialize only those members of the **WINDEBUGINFO** structure that correspond to the flags set in the **flags** member.

Changes to debugging information made by calling **SetWinDebugInfo** apply only until you exit the system or restart your computer.

See Also

GetWinDebugInfo, **WINDEBUGINFO**

SizeofResource (2.x)

DWORD SizeofResource(*hinst, hrsrc***)**

```
HINSTANCE hinst;        /* handle of module with resource */
HRSRC hrsrc;            /* handle of resource             */
```

The **SizeofResource** function returns the size, in bytes, of the given resource.

Parameter	Description
hinst	Identifies the instance of the module whose executable file contains the resource.
hrsrc	Identifies the resource. This handle must have been created by using the **FindResource** function.

Returns

The return value specifies the number of bytes in the resource, if the function is successful. It is zero if the resource cannot be found.

Comments

The value returned may be larger than the resource due to alignment. An application should not rely upon this value for the exact size of a resource.

See Also

AccessResource, **FindResource**

Windows 3.1 changes

The return value is now a **DWORD** instead of a WORD.

StartSound (2.x)

int StartSound(void)

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

StopSound (2.x)

int StopSound(void)

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

SwapRecording (3.0)

void SwapRecording(*fuFlag***)**

UINT *fuFlag;* /* whether to start or stop swap recording */

The **SwapRecording** function starts or stops recording data about memory swapping. Because this function can be used only in real mode, it cannot be used with Windows 3.1.

SwitchStackBack (3.0)

void SwitchStackBack(void)

The **SwitchStackBack** function restores the stack of the current task, canceling the effect of the **SwitchStackTo** function.

Returns
This function does not return a value.

Comments
SwitchStackBack preserves the contents of the AX:DX registers when it returns.

See Also
SwitchStackTo

SwitchStackTo (3.0)

void SwitchStackTo(*uStackSegment, uStackPointer, uStackTop***)**

```
UINT uStackSegment;     /* new stack data segment     */
UINT uStackPointer;     /* offset of beginning of stack */
UINT uStackTop;         /* offset of top of stack     */
```

The **SwitchStackTo** function changes the stack of the current task to the specified data segment.

Parameter	Description
uStackSegment	Specifies the data segment to contain the stack.
uStackPointer	Specifies the offset to the beginning of the stack in the data segment.
uStackTop	Specifies the offset to the top of the stack from the beginning of the stack.

Returns

This function does not return a value.

Comments

Dynamic-link libraries (DLLs) do not have private stacks; instead, a DLL uses the stack of the task that calls the library. As a result, a DLL function fails if it treats the contents of the data-segment (DS) and stack-segment (SS) registers as equal. A task can call **SwitchStackTo** before calling a function in a DLL that treats the SS and DS registers as equal. When the DLL function returns, the task must then call the **SwitchStackBack** function to redirect its stack to its own data segment.

A DLL can also call **SwitchStackTo** before calling a function that assumes SS and DS to be equal and then call **SwitchStackBack** before returning to the task that called the DLL function.

Calls to **SwitchStackTo** and **SwitchStackBack** cannot be nested. That is, after calling **SwitchStackTo**, an application must call **SwitchStackBack** before calling **SwitchStackTo** again.

See Also

SwitchStackBack

SyncAllVoices (2.x)

int SyncAllVoices(void)

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

Throw (2.x)

void Throw(*lpCatchBuf, nErrorReturn***)**

const int FAR* *lpCatchBuf;* /* address of CATCHBUF saved by Catch */
int *nErrorReturn;* /* value to return from Catch function */

The **Throw** function restores the execution environment to the values saved in the specified array. Execution then transfers to the **Catch** function that copied the environment to the array.

Parameter	Description
lpCatchBuf	Points to a **CATCHBUF** array that contains the execution environment. This array must have been set by a previous call to the **Catch** function.
nErrorReturn	Specifies the value to be returned to the **Catch** function. The meaning of the value is determined by the application. The value should be nonzero, so that the call to the **Catch** function can distinguish between a return from **Catch** (which returns zero) and a return from **Throw**.

Returns

This function does not return a value.

Comments

The **Throw** function is similar to the C run-time function **longjmp**.

The function that calls **Catch** must free any resources allocated between the time **Catch** was called and the time **Throw** was called.

Do not use the **Throw** function across messages. For example, if an application calls **Catch** while processing a **WM_CREATE** message and then calls **Throw** while processing a **WM_PAINT** message, the application will terminate.

Example

The following example calls the **Catch** function to save the current execution environment before calling a recursive sort function. The first return from **Catch** is zero. If the doSort function calls the **Throw** function, execution will again return to the **Catch** function. This time, **Catch** returns the STACKOVERFLOW error passed by the doSort function. The doSort function is recursive--that is, it calls itself. It maintains a variable, wStackCheck, that is used to check the amount of stack space used. If more than 3K of the stack has been used, doSort calls **Throw** to drop out of all the nested function calls back into the function that called **Catch**.

```
#define STACKOVERFLOW 1

UINT uStackCheck;
CATCHBUF catchbuf;

{
    int iReturn;
    char szBuf[80];

    if ((iReturn = Catch((int FAR*) catchbuf)) != 0) {
        .
        . /* Error processing goes here. */
        .
    }
    else {
        uStackCheck = 0;       /* initializes stack-usage count */
        doSort(1, 100);        /* calls sorting function        */
    }
```

```
    break;
}

void doSort(int sLeft, int sRight)
{
    int sLast;

    /*
     * Determine whether more than 3K of the stack has been
     * used, and if so, call Throw to drop back into the
     * original calling application.
     *
     * The stack is incremented by the size of the two parameters,
     * the two local variables, and the return value (2 for a near
     * function call).
     */

    uStackCheck += (sizeof(int) * 4) + 2;

    if (uStackCheck > (3 * 1024))
        Throw((int FAR*) catchbuf, STACKOVERFLOW);
    .
    . /* A sorting algorithm goes here. */
    .

    doSort(sLeft, sLast - 1);   /* note recursive call          */
    uStackCheck -= 10;          /* updates stack-check variable */
}
```

Catch

ToAscii (3.0)

int ToAscii(*uVirtKey, uScanCode, lpbKeyState, lpdwTransKey, fuState***)**

```
UINT uVirtKey;                  /* virtual-key code                */
UINT uScanCode;                 /* scan code                       */
BYTE FAR* lpbKeyState;          /* address of key-state array      */
DWORD FAR* lpdwTransKey;        /* 32-bit buffer for translated key */
UINT fuState;                   /* active-menu flag                */
```

The **ToAscii** function translates the specified virtual-key code and keyboard state to the corresponding Windows character or characters.

Parameter	Description
uVirtKey	Specifies the virtual-key code to be translated.
uScanCode	Specifies the hardware scan code of the key to be translated. The high-order bit of this value is set if the key is not pressed (is up).
lpbKeyState	Points to a 256-byte array that contains the current keyboard state. Each element (byte) in the array contains the state of one key. If the high-order bit of a byte is set, the key is pressed (is down).
lpdwTransKey	Points to a doubleword buffer to receive the translated Windows character or characters.
fuState	Specifies whether a menu is active. This parameter must be 1 if a menu is active, or zero otherwise.

Returns

The return value is a negative value if the specified key is a dead key. Otherwise, it is one of the following values:

Value	Meaning
2	Two characters were copied to the buffer. This is usually an accent and a dead-key character, when the dead key cannot be translated otherwise.
1	One Windows character was copied to the buffer.
0	The specified virtual key has no translation for the current state of the keyboard.

Comments

If a previous dead key is stored in the keyboard driver, the parameters supplied to the **ToAscii** function might not be sufficient to translate the virtual-key code.

Typically, **ToAscii** performs the translation based on the virtual-key code. In some cases, however, the *uScanCode* parameter may be used to distinguish between a key press and a key release. The scan code is used for translating ALT+*number* key combinations.

See Also

OemKeyScan, **VkKeyScan**

UnlockSegment (2.x)

void UnlockSegment(*uSegment***)**

UINT *uSegment;* /* specifies segment to unlock */

The **UnlockSegment** function unlocks the specified discardable memory segment. The function decrements (decreases by one) the segment's lock count. The segment is completely unlocked and subject to discarding when the lock count reaches zero.

Parameter	Description
uSegment	Specifies the segment address of the segment to be unlocked. If this parameter is -1, the **UnlockSegment** function unlocks the current data segment.

Returns

The return value is the lock count for the segment, if the function is successful. This function returns its result in the CX register. When the CX register contains zero, the segment is completely unlocked.

The value returned when the function is called in C should be ignored, because the return value can be checked only in assembly language.

Comments

An application should not rely on the return value to determine the number of times it must subsequently call **UnlockSegment** for the segment.

Other functions also can affect the lock count of a memory object. For a list of these functions, see the description of the **GlobalFlags** function.

Each time an application calls **LockSegment** for a segment, it must eventually call **UnlockSegment** for the segment.

See Also

GlobalFlags, **LockSegment**, **UnlockData**

ValidateCodeSegments (3.0)

void ValidateCodeSegments(void)

The **ValidateCodeSegments** function tests all code segments for random memory overwrites. The function works only in real mode (for Windows versions earlier than 3.1) and only with the debugging version of Windows.

Returns
This function does not return a value.

Comments
Because code segments are not writeable in protected mode (standard or enhanced), this function does nothing in Windows 3.1.

See Also
ValidateFreeSpaces

ValidateFreeSpaces (2.x)

void ValidateFreeSpaces(void)

The **ValidateFreeSpaces** function checks free segments in memory for valid contents. This function is available only in the debugging version of Windows.

Returns
This function does not return a value.

Comments
In the debugging version of Windows, the kernel fills all the bytes in free segments with the hexadecimal value 0x0CC. This function begins checking for valid contents in the free segment with the lowest address; it continues checking until it finds an invalid byte or until it has determined that all free space contains valid contents. Before calling this function, put the following lines in the WIN.INI file:

```
[KERNEL]
EnableFreeChecking=1
EnableHeapChecking=1
```

Windows sends debugging information to the debugging terminal if an invalid byte is encountered, and then it performs a fatal exit.

The [**KERNEL**] entries in WIN.INI cause automatic checking of free memory. Before returning a memory object to the application in response to a call to the **GlobalAlloc** function, Windows checks that memory to make sure it is filled with 0x0CC. Before a call to the **GlobalCompact** function, all free memory is checked. Note that using this function slows Windows systemwide by about twenty percent.

See Also
GlobalAlloc, **GlobalCompact**, **ValidateCodeSegments**

VkKeyScan (2.x)

UINT VkKeyScan(*uChar***)**

UINT *uChar;* /* character to translate */

The **VkKeyScan** function translates a Windows character to the corresponding virtual-key code and shift state for the current keyboard.

Parameter	Description
uChar	Specifies the character to be translated to a virtual-key code.

Returns

The return value is the virtual-key code and shift state, if the function is successful. The low-order byte contains the virtual-key code; the high-order byte contains the shift state, which can be one of the following:

Value	Meaning
1	Character is shifted.
2	Character is a control character.
3-5	Shift-key combination that is not used for characters.
6	Character is generated by the CTRL+ALT key combination.
7	Character is generated by the SHIFT+CTRL+ALT key combination.

If no key is found that translates to the passed Windows code, the return value is -1.

Comments

Translations for the numeric keypad (VK_NUMPAD0 through VK_DIVIDE) are ignored. This function is intended to force a translation for the main keyboard only.

Applications that send characters by using the **WM_KEYUP** and **WM_KEYDOWN** messages use this function.

See Also

OemKeyScan

WaitSoundState (2.x)

int WaitSoundState(*fnState***)**

int *fnState;* /* state to wait for*/

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference.*

WinExec (3.0)

UINT WinExec(*lpszCmdLine, fuCmdShow***)**

LPCSTR *lpszCmdLine;* /* address of command line */
UINT *fuCmdShow;* /* window state of new app. */

The **WinExec** function runs the specified application.

Parameter	Description
lpszCmdLine	Points to a null-terminated Windows character string that contains the command line (filename plus optional parameters) for the application to be run. If the string does not contain a path, Windows searches the directories in this order:

1 The current directory.

2 The Windows directory (the directory containing WIN.COM); the **GetWindowsDirectory** function retrieves the path of this directory.

3 The Windows system directory (the directory containing such system files as GDI.EXE); the **GetSystemDirectory** function retrieves the path of this directory.

4 The directory containing the executable file for the current task; the **GetModuleFileName** function retrieves the path of this directory.

5 The directories listed in the PATH environment variable.

6 The directories mapped in a network.

fuCmdShow	Specifies how a Windows application window is to be shown. See the description of the **ShowWindow** function for a list of the acceptable values for the *fuCmdShow* parameter. For a non-Windows application, the program-information file (PIF), if any, for the application determines the window state.

Returns

The return value identifies the instance of the loaded module, if the function is successful. Otherwise, the return value is an error value less than 32.

Errors

The error value may be one of the following:

Value	Meaning
0	System was out of memory, executable file was corrupt, or relocations were invalid.
2	File was not found.
3	Path was not found.
5	Attempt was made to dynamically link to a task, or there was a sharing or network-protection error.
6	Library required separate data segments for each task.
8	There was insufficient memory to start the application.
10	Windows version was incorrect.
11	Executable file was invalid. Either it was not a Windows application or there was an error in the .EXE image.
12	Application was designed for a different operating system.
13	Application was designed for MS-DOS 4.0.
14	Type of executable file was unknown.
15	Attempt was made to load a real-mode application (developed for an earlier version of Windows).

16 Attempt was made to load a second instance of an executable file containing multiple data segments that were not marked read-only.

19 Attempt was made to load a compressed executable file. The file must be decompressed before it can be loaded.

20 Dynamic-link library (DLL) file was invalid. One of the DLLs required to run this application was corrupt.

21 Application requires Microsoft Windows 32-bit extensions.

Comments

The **LoadModule** function provides an alternative method for running an application.

Example

The following example uses the **WinExec** function to run DRAW.EXE:

```
WORD wReturn;
char szMsg[80];

wReturn = WinExec("draw", SW_SHOW);

if (wReturn < 32) {
    sprintf(szMsg, "WinExec failed; error code = %d", wReturn);
    MessageBox(hwnd, szMsg, "Error", MB_ICONSTOP);
}
else {
    sprintf(szMsg, "WinExec returned %d", wReturn);
    MessageBox(hwnd, szMsg, "", MB_OK);
}
```

See Also

GetModuleFileName, **GetSystemDirectory**, **GetWindowsDirectory**, **LoadModule**, **ShowWindow**

WritePrivateProfileString (3.0)

BOOL WritePrivateProfileString(*lpszSection, lpszEntry, lpszString, lpszFilename***)**

```
LPCSTR lpszSection;      /* address of section                */
LPCSTR lpszEntry;        /* address of entry                  */
LPCSTR lpszString;       /* address of string to add          */
LPCSTR lpszFilename;     /* address of initialization filename */
```

The **WritePrivateProfileString** function copies a character string into the specified section of the specified initialization file.

Parameter	Description
lpszSection	Points to a null-terminated string that specifies the section to which the string will be copied. If the section does not exist, it is created. The name of the section is case-independent; the string may be any combination of uppercase and lowercase letters.
lpszEntry	Points to the null-terminated string containing the entry to be associated with the string. If the entry does not exist in the specified section, it is created. If this parameter is NULL, the entire section, including all entries within the section, is deleted.
lpszString	Points to the null-terminated string to be written to the file. If this parameter is NULL, the entry specified by the *lpszEntry* parameter is deleted.
lpszFilename	Points to a null-terminated string that names the initialization file.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

To improve performance, Windows keeps a cached version of the most-recently accessed initialization file. If that filename is specified and the other three parameters are NULL, Windows flushes the cache.

Sections in the initialization file have the following form:

[*section***]**
*entry***=***string*
.
.
.

If *lpszFilename* does not contain a fully qualified path and filename for the file, **WritePrivateProfileString** searches the Windows directory for the file. If the file does not exist, this function creates the file in the Windows directory.

If *lpszFilename* contains a fully qualified path and filename and the file does not exist, this function creates the file. The specified directory must already exist.

An application should use a private (application-specific) initialization file to record information that affects only that application. This improves the performance of both the application and Windows itself by reducing the amount of information that Windows must read when it accesses the initialization file. The exception to this is that device drivers should use the SYSTEM.INI file, to reduce the number of initialization files Windows must open and read during the startup process.

An application can use the **WriteProfileString** function to add a string to the WIN.INI file.

Example

The following example uses the **WritePrivateProfileString** function to add the string "testcode.c" to the LastFile entry in the [MyApp] section of the TESTCODE.INI initialization file:

```
BOOL fSuccess;
```

```
DebugBreak();

fSuccess = WritePrivateProfileString("MyApp",
    "LastFile", "testcode.c", "testcode.ini");

if (fSuccess)
    MessageBox(hwnd, "String added successfully",
            "WritePrivateProfileString", MB_OK);
else
    MessageBox(hwnd, "String could not be added",
            "WritePrivateProfileString", MB_ICONSTOP);
```

See Also

WriteProfileString

Correction

The Windows 3.0 documentation stated that this function would fail if the *lpszFilename* parameter specified a full path and the file did not exist. In fact, Windows will create the specified file. The directory where the file is to be created must exist, however; Windows will not create the directory.

WriteProfileString (2.x)

BOOL WriteProfileString(*lpszSection, lpszEntry, lpszString***)**

LPCSTR *lpszSection;* /* address of section */
LPCSTR *lpszEntry;* /* address of entry */
LPCSTR *lpszString;* /* address of string to write */

The **WriteProfileString** function copies a string into the specified section of the Windows initialization file, WIN.INI.

Parameter	Description
lpszSection	Points to a null-terminated string that specifies the section to which the string is to be copied. If the section does not exist, it is created. The name of the section is case-independent; the string may be any combination of uppercase and lowercase letters.
lpszEntry	Points to the null-terminated string containing the entry to be associated with the string. If the entry does not exist in the specified section, it is created. If this parameter is NULL, the entire section, including all entries within the section, is deleted.
lpszString	Points to the null-terminated string to be written to the file. If this parameter is NULL, the entry specified by the *lpszEntry* parameter is deleted.

Returns

The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

Windows keeps a cached version of WIN.INI to improve performance. If all three parameters are NULL, Windows flushes the cache.

Sections in the WIN.INI initialization file have the following form:

[*section***]**
*entry***=***string*
.
.
.

Example

The following example calls the **GetWindowRect** function to retrieve the dimensions of the current window, converts the dimensions of a string, and writes the string to WIN.INI by using the **WriteProfileString** function. The next time the application is run, it could call the **GetProfileString** function to read the string, convert it to numbers, and pass the numbers as parameters to the **CreateWindow** function, thereby creating the window again with the same dimensions it had when the application terminated.

```
RECT rect;
BOOL fSuccess;
char szBuf[20];

GetWindowRect(hwnd, &rect);

sprintf(szBuf, "%u %u %u %u",
    rect.left, rect.right - rect.left,
    rect.top, rect.bottom - rect.top);

fSuccess = WriteProfileString("MySection",
        "Window dimensions", szBuf);
```

```
if (fSuccess)
    MessageBox(hwnd, "String added successfully",
            "WriteProfileString", MB_OK);
else
    MessageBox(hwnd, "String could not be added",
            "WriteProfileString", MB_ICONSTOP);
```

wsprintf (3.0)

int _cdecl wsprintf(*lpszOutput, lpszFormat,* **...)**

LPSTR *lpszOutput;* /* address of string for output */
LPSTR *lpszFormat;* /* address of format-control string */

The **wsprintf** function formats and stores a series of characters and values in a buffer. Each argument (if any) is converted according to the corresponding format specified in the format string.

Parameter	Description
lpszOutput	Points to a null-terminated string to receive the string formatted as specified in the *lpszFormat* parameter.
lpszFormat	Points to a null-terminated string that contains the format-control string. In addition to the standard ASCII characters, a format specification for each argument appears in this string. For more information about the format specification, see the following Comments section.
. . .	Specifies zero or more optional arguments. The number and type of the optional arguments depend on the corresponding format-control character sequences specified in the *lpszFormat* parameter.

Returns

The return value is the number of bytes stored in the *lpszOutput* string, not counting the terminating null character, if the function is successful.

Comments

The largest buffer that **wsprintf** can create is 1K.

Unlike most Windows functions, **wsprintf** uses the C calling convention (**_cdecl**) rather than the Pascal calling convention. As a result, the calling function must pop arguments off the stack. Also, arguments must be pushed on the stack from right to left. In C-language modules, the C compiler performs this task. (The **wvsprintf** function uses the Pascal calling convention.)

The format-control string contains format specifications that determine the output format for the arguments that follow the *lpszFormat* parameter. Format specifications always begin with a percent sign (**%**). If a percent sign is followed by a character that has no meaning as a format field, the character is not formatted. For example, **%%** produces a single percent-sign character.

The format-control string is read from left to right. When the first format specification is encountered, it causes the value of the first argument after the format-control string to be converted according to the format specification. The second format specification causes the second argument to be converted, and so on. If there are more arguments than there are format specifications, the extra arguments are ignored. The results are undefined if there are not enough arguments for all of the format specifications.

A format specification has the following form:

%[**-**][*#*][**0**][*width*][**.***precision*]*type*

Each field of the format specification is a single character or number signifying a particular format option. The *type* characters, for example, determine whether the associated argument is interpreted as a character, a string, or a number. The simplest format specification contains only the percent sign and a *type* character (for example, **%s**). The optional fields (in brackets) control other aspects of the formatting. Following are the optional and required fields and their meanings:

Field	Meaning
-	Pad the output value with blanks or zeros to the right to fill the field width, aligning the output value to the left. If this field is omitted, the output value is padded to the left, aligning it to the right.
#	Prefix hexadecimal values with 0x (lowercase) or 0X (uppercase).

0 Pad the output value with zeros to fill the field width. If this field is omitted, the output value is padded with blank spaces.

width Convert the specified minimum number of characters. The *width* field is a nonnegative integer. The width specification never causes a value to be truncated; if the number of characters in the output value is greater than the specified width, or if the *width* field is not present, all characters of the value are printed, subject to the value of the *precision* field.

precision Convert the specified minimum number of digits. If there are fewer digits in the argument than the specified value, the output value is padded on the left with zeros. The value is not truncated when the number of digits exceeds the specified precision. If the specified precision is zero or omitted entirely, or if the period (**.**) appears without a number following it, the precision is set to 1.

For strings, convert the specified maximum number of characters.

type Format the corresponding argument as a character, a string, or a number. This field may be any of the following character sequences:

Sequence	Meaning
c	Insert a single character argument. The **wsprintf** function ignores character arguments with a numeric value of zero.
d, **i**	Insert a signed decimal integer argument.
ld, **li**	Insert a long signed decimal integer argument.
u	Insert an unsigned integer argument.
lu	Insert a long unsigned integer argument.
lx, **lX**	Insert a long unsigned hexadecimal integer argument in lowercase or uppercase.
s	Insert a string.

wvsprintf

Yield (2.x)

void Yield(void)

The **Yield** function stops the current task and starts any waiting task.

Returns
This function does not return a value.

Comments
The **Yield** function should be used only when the application is guaranteed not to receive any messages.

Applications that contain windows should use a **DispatchMessage**, **PeekMessage**, or **TranslateMessage** loop rather than call the **Yield** function directly. The message-loop functions handle message synchronization properly and yield at the appropriate times.

See Also
DirectedYield, **DispatchMessage**, **PeekMessage**, **TranslateMessage**

Kernel functions (3.1)

_hread	Reads from a file
_hwrite	Writes to a file
_lclose	Closes an open file
_lcreat	Creates or opens a file
_llseek	Repositions the file pointer
_lopen	Opens a file
_lread	Reads from a file
_lwrite	Writes to a file
AccessResource	Opens a resource file and locates a resource
AddAtom	Adds a string to the local atom table
AllocDStoCSAlias	Translates a data segment to a code segment
AllocResource	Allocates memory for a resource
AllocSelector	Allocates a new selector
AnsiToOem	Translates a Windows string to an OEM string
AnsiToOemBuff	Translates a Windows string to an OEM string
Catch	Captures the current execution environment
CloseSound	Not used in Windows 3.1
CountVoiceNotes	Not used in Windows 3.1
DebugBreak	Causes a breakpoint exception
DebugOutput	Sends messages to the debugging terminal
DeleteAtom	Decrements the reference count of a local atom
DirectedYield	Forces execution of a specified task to continue
DOS3Call	Issues a DOS Int 21h function request
FatalAppExit	Terminates an application
FatalExit	Displays debug info after breakpoint exception
FindAtom	Retrieves string atom from local atom table
FindResource	Locates a resource in a resource file
FreeLibrary	Unloads a library module instance
FreeModule	Unloads a module instance
FreeProcInstance	Frees a function instance
FreeResource	Unloads a resource instance
FreeSelector	Frees an allocated selector
GetAtomHandle	Retrieves an atom handle
GetAtomName	Retrieves a local atom string
GetCodeHandle	Determines the location of a function
GetCodeInfo	Retrieves code-segment information
GetCurrentPDB	Returns the selector address of the current PDB
GetCurrentTask	Returns the current task handle
GetDOSEnvironment	Returns a far pointer to the current environment
GetDriveType	Determines the drive type
GetFreeSpace	Returns number of free bytes in global heap
GetInstanceData	Copies data from previous instance to current one
GetKBCodePage	Returns the current code page
GetKeyboardType	Retrieves keyboard information
GetKeyNameText	Retrieves a string representing the key name
GetModuleFileName	Returns the filename for a module handle
GetModuleHandle	Returns a module handle for a named module
GetModuleUsage	Returns the reference count for a module
GetNumTasks	Returns the current number of tasks
GetPrivateProfileInt	Retrieves integer value from initialization file
GetPrivateProfileString	Retrieves a string from an initialization file
GetProcAddress	Returns the address of an exported DLL function
GetProfileInt	Retrieves an integer value from WIN.INI
GetProfileString	Retrieves a string from WIN.INI
GetSelectorBase	Retrieves the base address of a selector

GetSelectorLimit	Retrieves the limit of a selector
GetSystemDirectory	Returns the Windows system directory
GetTempDrive	Returns a disk drive letter for temporary files
GetTempFileName	Creates a temporary filename
GetThresholdEvent	Not used in Windows 3.1
GetThresholdStatus	Not used in Windows 3.1
GetVersion	Returns the current DOS and Windows versions
GetWinDebugInfo	Retrieves current system-debugging information
GetWindowsDirectory	Returns the Windows directory
GetWinFlags	Returns the current system configuration flags
GlobalAlloc	Allocates memory from the global heap
GlobalCompact	Generates free global memory by compacting
GlobalDosAlloc	Allocates memory available to DOS in real mode
GlobalDosFree	Frees global memory allocated by GlobalDosAlloc
GlobalFix	Locks a global memory object in linear memory
GlobalFlags	Returns information about a global memory object
GlobalFree	Frees a global memory object
GlobalHandle	Retrieves a handle for a specified selector
GlobalLock	Locks global memory object and returns pointer
GlobalLRUNewest	Moves global memory object to newest LRU position
GlobalLRUOldest	Moves global memory object to oldest LRU position
GlobalNotify	Installs a notification procedure
GlobalPageLock	Increments global memory page-lock count
GlobalPageUnlock	Decrements global memory page-lock count
GlobalReAlloc	Changes size/attributes of global memory object
GlobalSize	Returns the size of a global memory object
GlobalUnfix	Unlocks a global memory object in linear memory
GlobalUnlock	Unlocks a global memory object
GlobalUnWire	Not used in Windows 3.1
GlobalWire	Not used in Windows 3.1
hmemcpy	Copies bytes from source to destination buffer
InitAtomTable	Sets the size of the local atom table
IsBadCodePtr	Determines whether a code pointer is valid
IsBadHugeReadPtr	Determines whether a huge read pointer is valid
IsBadHugeWritePtr	Determines whether a huge write pointer is valid
IsBadReadPtr	Determines whether a read pointer is valid
IsBadStringPtr	Determines whether a string pointer is valid
IsBadWritePtr	Determines whether a write pointer is valid
IsDBCSLeadByte	Determines whether character is DBCS lead byte
IsTask	Determines whether a task handle is valid
LimitEmsPages	Not used in Windows 3.1
LoadLibrary	Loads the specified library module
LoadModule	Loads and executes a program
LoadResource	Loads the specified resource in global memory
LocalAlloc	Allocates memory from the local heap
LocalCompact	Generates free local memory by compacting
LocalFlags	Returns local memory object information
LocalFree	Frees a local memory object
LocalHandle	Returns the handle of a local memory object
LocalInit	Initializes a local heap
LocalLock	Locks local memory object and returns pointer
LocalReAlloc	Changes size or attributes of local memory object
LocalShrink	Shrinks the specified local heap
LocalSize	Returns the size of a local memory object
LocalUnlock	Unlocks a local memory object
LockResource	Returns the address of a resource

LockSegment	Locks a discardable memory segment
LogError	Identifies an error message
LogParamError	Identifies a parameter validation error
lstrcat	Appends one string to another
lstrcpy	Copies a string to a buffer
lstrcpyn	Copies characters in a string to a buffer
lstrlen	Returns the number of characters in a string
MakeProcInstance	Returns address of prolog code for function
MapVirtualKey	Translates a virtual-key code or scan code
MulDiv	Multiplies two values and divides the result
NetBIOSCall	Issues a NETBIOS Interrupt 5Ch call
OemKeyScan	Maps OEM ASCII to scan codes
OemToAnsi	Translates an OEM string to a Windows string
OemToAnsiBuff	Translates an OEM string to a Windows string
OpenFile	Creates, opens, reopens, or deletes a file
OpenSound	Not used in Windows 3.1
OutputDebugString	Sends a character string to the debugger
PrestoChangoSelector	Converts code or data selector
ProfClear	Discards all buffered Profiler samples
ProfFinish	Stops Profiler sampling and flushes buffer
ProfFlush	Flushes the Profiler sampling buffer to a disk
ProfInsChk	Determines whether Profiler is installed
ProfSampRate	Sets the Profiler sampling rate
ProfSetup	Sets the Profiler buffer size and sample quantity
ProfStart	Starts Profiler sampling
ProfStop	Stops Profiler sampling
SetErrorMode	Controls Interrupt 24h error handling
SetHandleCount	Changes the number of available file handles
SetResourceHandler	Installs a load-resource callback function
SetSelectorBase	Sets the base of an existing selector
SetSelectorLimit	Sets the limit of a selector
SetSoundNoise	Not used in Windows 3.1
SetSwapAreaSize	Sets the amount of memory used for code segments
SetVoiceAccent	Not used in Windows 3.1
SetVoiceEnvelope	Not used in Windows 3.1
SetVoiceNote	Not used in Windows 3.1
SetVoiceQueueSize	Not used in Windows 3.1
SetVoiceSound	Not used in Windows 3.1
SetVoiceThreshold	Not used in Windows 3.1
SetWinDebugInfo	Sets the current system-debugging information
SizeofResource	Returns the size of a resource
StartSound	Not used in Windows 3.1
StopSound	Not used in Windows 3.1
SwapRecording	Starts or stops recording of memory swapping
SwitchStackBack	Restores the current task stack
SwitchStackTo	Changes the location of the stack
SyncAllVoices	Not used in Windows 3.1
Throw	Restores the execution environment
ToAscii	Translates virtual-key code to Windows character
UnlockSegment	Unlocks a discardable memory segment
ValidateCodeSegments	Tests for memory overwrites
ValidateFreeSpaces	Checks free memory for valid contents
VkKeyScan	Translates Windows character to virtual-key code
WaitSoundState	Not used in Windows 3.1
WinExec	Runs a program
WritePrivateProfileString	Writes a string to an initialization file

WriteProfileString	Writes a string to WIN.INI
wsprintf	Formats a string
Yield	Stops the current task

CopyLZFile (3.1)

#include lzexpand.h

LONG CopyLZFile(*hfSource, hfDest***)**

HFILE *hfSource;* /* handle of source file */
HFILE *hfDest;* /* handle of destination file */

The **CopyLZFile** function copies a source file to a destination file. If the source file is compressed, this function creates a decompressed destination file. If the source file is not compressed, this function duplicates the original file.

Parameter	Description
hfSource	Identifies the source file.
hfDest	Identifies the destination file.

Returns

The return value specifies the size, in bytes, of the destination file if the function is successful. Otherwise, it is an error value less than zero; it may be one of the following:

Value	Meaning
LZERROR_BADINHANDLE	The handle identifying the source file was not valid.
LZERROR_BADOUTHANDLE	The handle identifying the destination file was not valid.
LZERROR_BADVALUE	The input parameter is out of the allowable range.
LZERROR_GLOBALLOC	There is insufficient memory for the required buffers.
LZERROR_GLOBLOCK	The handle identifying the internal data structures is invalid.
LZERROR_READ	The source file format was not valid.
LZERROR_UNKNOWNALG	The source file was compressed with an unrecognized compression algorithm.
LZERROR_WRITE	There is insufficient space for the output file.

Comments

This function is identical to the **LZCopy** function.

The **CopyLZFile** function is designed for copying or decompressing multiple files, or both. To allocate required buffers, an application should call the **LZStart** function prior to calling **CopyLZFile**. To free these buffers, an application should call the **LZDone** function after copying the files.

If the function is successful, the file identified by *hfDest* is decompressed.

If the source or destination file is opened by using a C run-time function (rather than by using the **_lopen** or **OpenFile** function), it must be opened in binary mode.

Example

The following example uses the **CopyLZFile** function to create copies of four text files:

```
#define STRICT

#include <windows.h>
#include <lzexpand.h>

#define NUM_FILES   4

char *szSrc[NUM_FILES] =
    {"readme.txt", "data.txt", "update.txt", "list.txt"};
char *szDest[NUM_FILES] =
    {"readme.bak", "data.bak", "update.bak", "list.bak"};
```

```
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile;
int i;

/* Allocate internal buffers for the CopyLZFile function. */

LZStart();

/* Open, copy, and then close the files. */

for (i = 0; i < NUM_FILES; i++) {
    hfSrcFile = LZOpenFile(szSrc[i], &ofStrSrc, OF_READ);
    hfDstFile = LZOpenFile(szDest[i], &ofStrDest, OF_CREATE);
    CopyLZFile(hfSrcFile, hfDstFile);
    LZClose(hfSrcFile);
    LZClose(hfDstFile);
}

LZDone(); /* free the internal buffers */
```

See Also

_lopen, **LZCopy**, **LZDone**, **LZStart**, **OpenFile**

GetExpandedName (3.1)

#include lzexpand.h

int GetExpandedName(*lpszSource, lpszBuffer***)**

LPCSTR *lpszSource;* /* specifies name of compressed file */
LPSTR *lpszBuffer;* /* points to buffer receiving original filename */

The **GetExpandedName** function retrieves the original name of a compressed file if the file was compressed with the COMPRESS.EXE utility and the ***/r*** option was specified.

Parameter	Description
lpszSource	Points to a string that specifies the name of a compressed file.
lpszBuffer	Points to a buffer that receives the name of the compressed file.

Returns

The return value is TRUE if the function is successful. Otherwise, it is an error value that is less than zero, and it may be **LZERROR_BADINHANDLE**, which means that the handle identifying the source file was not valid.

Example

The following example uses the **GetExpandedName** function to retrieve the original filename of a compressed file:

```
char szSrc[] = {"readme.cmp"};
char szFileName[128];
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile, hfCompFile;
int cbRead;
BYTE abBuf[512];

/* Open the compressed source file. */

hfSrcFile = OpenFile(szSrc, &ofStrSrc, OF_READ);

/*
 * Initialize internal data structures for the decompression
 * operation.
 */

hfCompFile = LZInit(hfSrcFile);

/* Retrieve the original name for the compressed file. */

GetExpandedName(szSrc, szFileName);

/* Create the destination file using the original name. */

hfDstFile = LZOpenFile(szFileName, &ofStrDest, OF_CREATE);

/* Copy the compressed source file to the destination file. */

do {
    if ((cbRead = LZRead(hfCompFile, abBuf, sizeof(abBuf))) > 0)
        _lwrite(hfDstFile, abBuf, cbRead);
    else {
```

```
        .
        . /* handle error condition */
        .
    }
} while (cbRead == sizeof(abBuf));

/* Close the files. */

LZClose(hfSrcFile);
LZClose(hfDstFile);
```

Comments

This function retrieves the original filename from the header of the compressed file. If the source file is not compressed, the filename to which *lpszSource* points is copied to the buffer to which *lpszBuffer* points.

If the ***l*r** option was not set when the file was compressed, the string in the buffer to which *lpszBuffer* points is invalid.

LZClose (3.1)

#include lzexpand.h

void LZClose(*hf*)

HFILE *hf;* /* handle of file to be closed */

The **LZClose** function closes a file that was opened by the **LZOpenFile** or **OpenFile** function.

Parameter	Description
hf	Identifies the source file.

Returns
This function does not return a value.

Comments
If the file was compressed by Microsoft File Compression Utility (COMPRESS.EXE) and opened by the **LZOpenFile** function, **LZClose** frees any global heap space that was required to expand the file.

Example
The following example uses **LZClose** to close a file opened by **LZOpenFile**:

```
char szSrc[] = {"readme.txt"};
char szDst[] = {"readme.bak"};
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile;

/* Open the source file. */

hfSrcFile = LZOpenFile(szSrc, &ofStrSrc, OF_READ);

/* Create the destination file. */

hfDstFile = LZOpenFile(szDst, &ofStrDest, OF_CREATE);

/* Copy the source file to the destination file. */

LZCopy(hfSrcFile, hfDstFile);

/* Close the files. */

LZClose(hfSrcFile);
LZClose(hfDstFile);
```

See Also
OpenFile, **LZOpenFile**

LZCopy (3.1)

#include lzexpand.h

LONG LZCopy(*hfSource, hfDest***)**

HFILE *hfSource;* /* handle of source file */
HFILE *hfDest;* /* handle of destination file */

The **LZCopy** function copies a source file to a destination file. If the source file was compressed by Microsoft File Compression Utility (COMPRESS.EXE), this function creates a decompressed destination file. If the source file was not compressed, this function duplicates the original file.

Parameter	Description
hfSource	Identifies the source file. (This handle is returned by the **LZOpenFile** function when a compressed file is opened.)
hfDest	Identifies the destination file.

Returns

The return value is the size, in bytes, of the destination file if the function is successful. Otherwise, it is an error value that is less than zero and may be one of the following:

Value	Meaning
LZERROR_BADINHANDLE	The handle identifying the source file was not valid.
LZERROR_BADOUTHANDLE	The handle identifying the destination file was not valid.
LZERROR_BADVALUE	The input parameter is out of the allowable range.
LZERROR_GLOBALLOC	There is insufficient memory for the required buffers.
LZERROR_GLOBLOCK	The handle identifying the internal data structures is invalid.
LZERROR_READ	The source file format was not valid.
LZERROR_UNKNOWNALG	The source file was compressed with an unrecognized compression algorithm.
LZERROR_WRITE	There is insufficient space for the output file.

Comments

This function is identical to the **CopyLZFile** function.

If the function is successful, the file identified by *hfDest* is uncompressed.

If the source or destination file is opened by a C run-time function (rather than the **_lopen** or **OpenFile** function), it must be opened in binary mode.

Example

The following example uses the **LZCopy** function to copy a file:

```
char szSrc[] = {"readme.txt"};
char szDst[] = {"readme.bak"};
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile;

/* Open the source file. */

hfSrcFile = LZOpenFile(szSrc, &ofStrSrc, OF_READ);

/* Create the destination file. */

hfDstFile = LZOpenFile(szDst, &ofStrDest, OF_CREATE);
```

```
/* Copy the source file to the destination file. */

LZCopy(hfSrcFile, hfDstFile);

/* Close the files. */

LZClose(hfSrcFile);
LZClose(hfDstFile);
```

See Also

CopyLZFile, **_lopen**, **LZOpenFile**, **OpenFile**

LZERROR_BADINHANDLE (-1)

The handle identifying the source file was not valid.

LZERROR_BADINHANDLE (-1)

LZERROR_BADOUTHANDLE (-2)

The handle identifying the destination file was not valid.

LZERROR_BADOUTHANDLE (-2)

LZERROR_BADVALUE (-7)

The input parameter is out of the allowable range.

LZERROR_BADVALUE (-7)

LZERROR_GLOBALLOC (-5)

There is insufficient memory for the required buffers.

LZERROR_GLOBALLOC (-5)

LZERROR_GLOBLOCK (-6)

The handle identifying the internal data structures is invalid.

LZERROR_GLOBLOCK (-6)

LZERROR_READ (-3)

The source file format was not valid.

LZERROR_READ (-3)

LZERROR_UNKNOWNALG (-8)

The source file was compressed with an unrecognized compression algorithm.

LZERROR_UNKNOWNALG (-8)

LZERROR_WRITE (-4)

There is insufficient space for the output file.

LZERROR_WRITE (-4)

LZDone (3.1)

#include lzexpand.h

void LZDone(void)

The **LZDone** function frees buffers that the **LZStart** function allocated for multiple-file copy operations.

Returns

This function does not return a value.

Comments

Applications that copy multiple files should call **LZStart** before copying the files with the **CopyLZFile** function. **LZStart** allocates buffers for the file copy operations.

Example

The following example uses **LZDone** to free buffers allocated by **LZStart**:

```
#define NUM_FILES   4

char *szSrc[NUM_FILES] =
    {"readme.txt", "data.txt", "update.txt", "list.txt"};
char *szDest[NUM_FILES] =
    {"readme.bak", "data.bak", "update.bak", "list.bak"};
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile;
int i;

/* Allocate internal buffers for the CopyLZFile function. */

LZStart();

/* Open, copy, and then close the files. */

for (i = 0; i < NUM_FILES; i++) {
    hfSrcFile = LZOpenFile(szSrc[i], &ofStrSrc, OF_READ);
    hfDstFile = LZOpenFile(szDest[i], &ofStrDest, OF_CREATE);
    CopyLZFile(hfSrcFile, hfDstFile);
    LZClose(hfSrcFile);
    LZClose(hfDstFile);
}

LZDone(); /* free the internal buffers */
```

See Also

CopyLZFile, **LZCopy**, **LZStart**

LZInit (3.1)

#include lzexpand.h

HFILE LZInit(*hfSrc***)**

HFILE *hfSrc;* /* handle of source file */

The **LZInit** function allocates memory for, creates, and initializes the internal data structures that are required to decompress files.

Parameter	Description
hfSrc	Identifies the source file.

Returns

The return value is the original file handle if the function is successful and the file is not compressed. If the function is successful and the file is compressed, the return value is a new file handle. If the function fails, the return value is an error value that is less than zero and may be one of the following:

Value	Meaning
LZERROR_BADINHANDLE	The handle identifying the source file is invalid.
LZERROR_GLOBALLOC	There is insufficient memory for the required internal data structures. This value is returned when an application attempts to open more than 16 files.
LZERROR_GLOBLOCK	The handle identifying global memory is invalid. (The internal call to the **GlobalLock** function failed.)
LZERROR_READ	The source file format is invalid.
LZERROR_UNKNOWNALG	The file was compressed with an unrecognized compression algorithm.

Comments

A maximum of 16 compressed files can be open at any given time.

Example

The following example uses **LZInit** to initialize the internal structures that are required to decompress a file:

```
char szSrc[] = {"readme.cmp"};
char szFileName[128];
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile, hfCompFile;
int cbRead;
BYTE abBuf[512];

/* Open the compressed source file. */

hfSrcFile = OpenFile(szSrc, &ofStrSrc, OF_READ);

/*
 * Initialize internal data structures for the decompression
 * operation.
 */

hfCompFile = LZInit(hfSrcFile);

/* Retrieve the original name for the compressed file. */
```

```
GetExpandedName(szSrc, szFileName);

/* Create the destination file using the original name. */

hfDstFile = LZOpenFile(szFileName, &ofStrDest, OF_CREATE);

/* Copy the compressed source file to the destination file. */

do {
    if ((cbRead = LZRead(hfCompFile, abBuf, sizeof(abBuf))) > 0)
        _lwrite(hfDstFile, abBuf, cbRead);
    else {
        .
        . /* handle error condition */
        .
    }
} while (cbRead == sizeof(abBuf));

/* Close the files. */

LZClose(hfSrcFile);
LZClose(hfDstFile);
```

LZOpenFile (3.1)

#include lzexpand.h

HFILE LZOpenFile(*lpszFile, lpof, style***)**

```
LPCSTR lpszFile;          /* address of filename              */
OFSTRUCT FAR* lpof;       /* address of structure for file info*/
UINT style;               /* action to be taken               */
```

The **LZOpenFile** function creates, opens, reopens, or deletes the file specified by the string to which *lpszFile* points.

Parameter	Description
lpszFile	Points to a string that specifies the name of a file.
lpof	Points to the **OFSTRUCT** structure that is to receive information about the file when the file is opened. The structure can be used in subsequent calls to **LZOpenFile** to refer to the open file. The **szPathName** member of this structure contains characters from the OEM character set.
style	Specifies the action to be taken. These styles can be combined by using the bitwise OR operator:

Value	Meaning
OF_CANCEL	Adds a Cancel button to the **OF_PROMPT** dialog box. Choosing the Cancel button directs **LZOpenFile** to return a file-not-found error message.
OF_CREATE	Directs **LZOpenFile** to create a new file. If the file already exists, it is truncated to zero length.
OF_DELETE	Deletes the file.
OF_EXIST	Opens the file, and then closes it. This action is used to test for file existence.
OF_PARSE	Fills the **OFSTRUCT** structure, but carries out no other action.
OF_PROMPT	Displays a dialog box if the requested file does not exist. The dialog box informs the user that Windows cannot find the file and prompts the user to insert the disk containing the file in drive A.
OF_READ	Opens the file for reading only.
OF_READWRITE	Opens the file for reading and writing.
OF_REOPEN	Opens the file using information in the reopen buffer.
OF_SHARE_DENY_NONE	Opens the file without denying other programs read access or write access to the file. **LZOpenFile** fails if the file has been opened in compatibility mode by any other program.
OF_SHARE_DENY_READ	Opens the file and denies other programs read access to the file. **LZOpenFile** fails if the file has been opened in compatibility mode or for read access by any other program.
OF_SHARE_DENY_WRITE	Opens the file and denies other programs write access to the file. **LZOpenFile** fails if the file has been opened in compatibility mode or for write access by any other program.

OF_SHARE_EXCLUSIVE	Opens the file in exclusive mode, denying other programs both read access and write access to the file. **LZOpenFile** fails if the file has been opened in any other mode for read access or write access, even by the current program.
OF_WRITE	Opens the file for writing only.

Returns

The return value is a handle identifying the file if the function is successful and the value specified by *style* is not OF_READ. If the file is compressed and opened with *style* set to the **OF_READ** value, the return value is a special file handle. If the function fails, the return value is -1.

Comments

If *style* is **OF_READ** (or OF_READ and any of the OF_SHARE_ flags) and the file is compressed, **LZOpenFile** calls the **LZInit** function, which performs the required initialization for the decompression operations.

Example

The following example uses **LZOpenFile** to open a source file and create a destination file into which the source file can be copied:

```
char szSrc[] = {"readme.txt"};
char szDst[] = {"readme.bak"};
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile;

/* Open the source file. */

hfSrcFile = LZOpenFile(szSrc, &ofStrSrc, OF_READ);

/* Create the destination file. */

hfDstFile = LZOpenFile(szDst, &ofStrDest, OF_CREATE);

/* Copy the source file to the destination file. */

LZCopy(hfSrcFile, hfDstFile);

/* Close the files. */

LZClose(hfSrcFile);
LZClose(hfDstFile);
```

See Also

LZInit

LZRead (3.1)

#include lzexpand.h

int LZRead(*hf, lpvBuf, cb***)**

HFILE *hf;* /* handle of the file */
void FAR* *lpvBuf;* /* address of buffer for file data */
int *cb;* /* number of bytes to read */

The **LZRead** function reads into a buffer bytes from a file.

Parameter	Description
hf	Identifies the source file.
lpvBuf	Points to a buffer that is to receive the bytes read from the file.
cb	Specifies the maximum number of bytes to be read.

Returns

The return value is the actual number of bytes read if the function is successful. Otherwise, it is an error value that is less than zero and may be any of the following:

Value	Meaning
LZERROR_BADINHANDLE	The handle identifying the source file was invalid.
LZERROR_BADVALUE	The *cb* parameter specified a negative value.
LZERROR_GLOBLOCK	The handle identifying required initialization data is invalid.
LZERROR_READ	The format of the source file was invalid.
LZERROR_UNKNOWNALG	The file was compressed with an unrecognized compression algorithm.

Comments

If the file is not compressed, **LZRead** calls the **_lread** function, which performs the read operation.

If the file is compressed, **LZRead** emulates **_lread** on an expanded image of the file and copies the bytes of data into the buffer to which *lpvBuf* points.

If the source file was compressed by Microsoft File Compression Utility (COMPRESS.EXE), the **LZOpenFile**, **LZSeek**, and **LZRead** functions can be called instead of the **OpenFile**, **_llseek**, and **_lread** functions.

Example

The following example uses **LZRead** to copy and decompress a compressed file:

```
char szSrc[] = {"readme.cmp"};
char szFileName[128];
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile, hfCompFile;
int cbRead;
BYTE abBuf[512];

/* Open the compressed source file. */

hfSrcFile = OpenFile(szSrc, &ofStrSrc, OF_READ);

/*
 * Initialize internal data structures for the decompression
 * operation.
 */
```

```
hfCompFile = LZInit(hfSrcFile);

/* Retrieve the original name for the compressed file. */

GetExpandedName(szSrc, szFileName);

/* Create the destination file using the original name. */

hfDstFile = LZOpenFile(szFileName, &ofStrDest, OF_CREATE);

/* Copy the compressed source file to the destination file. */

do {
    if ((cbRead = LZRead(hfCompFile, abBuf, sizeof(abBuf))) > 0)
        _lwrite(hfDstFile, abBuf, cbRead);
    else {
        .
        . /* handle error condition */
        .
    }
} while (cbRead == sizeof(abBuf));

/* Close the files. */

LZClose(hfSrcFile);
LZClose(hfDstFile);
```

See Also

_llseek, **_lread**, **LZOpenFile**, **LZRead**, **LZSeek**

LZSeek (3.1)

#include lzexpand.h

LONG LZSeek(*hf, lOffset, nOrigin***)**

```
HFILE hf;       /* handle of file              */
LONG lOffset;   /* number of bytes to move     */
int nOrigin;    /* original position           */
```

The **LZSeek** function moves a file pointer from its original position to a new position.

Parameter	Description
hf	Identifies the source file.
lOffset	Specifies the number of bytes by which the file pointer should be moved.
nOrigin	Specifies the starting position of the pointer. This parameter must be one of the following values:

Value	Meaning
0	Move the file pointer *lOffset* bytes from the beginning of the file.
1	Move the file pointer *lOffset* bytes from the current position.
2	Move the file pointer *lOffset* bytes from the end of the file.

Returns

The return value is the offset from the beginning of the file to the new pointer position, if the function is successful. Otherwise, it is an error value that is less than zero and may be one of the following:

Value	Meaning
LZERROR_BADINHANDLE	The handle identifying the source file was invalid.
LZERROR_BADVALUE	One of the parameters exceeds the range of valid values.
LZERROR_GLOBLOCK	The handle identifying the initialization data is invalid.

Comments

If the file is not compressed, **LZSeek** calls the **_llseek** function and moves the file pointer by the specified offset.

If the file is compressed, **LZSeek** emulates **_llseek** on an expanded image of the file.

See Also

_llseek

LZStart (3.1)

#include lzexpand.h

int LZStart(void)

The **LZStart** function allocates the buffers that the **CopyLZFile** function uses to copy a source file to a destination file.

Returns

The return value is nonzero if the function is successful. Otherwise, it is LZERROR_GLOBALLOC.

Comments

Applications that copy (or copy and decompress) multiple consecutive files should call the **LZStart**, **CopyLZFile**, and **LZDone** functions. Applications that copy a single file should call the **LZCopy** function.

Example

The following example uses **LZStart** to allocate buffers used by **CopyLZFile**:

```
#define NUM_FILES   4

char *szSrc[NUM_FILES] =
    {"readme.txt", "data.txt", "update.txt", "list.txt"};
char *szDest[NUM_FILES] =
    {"readme.bak", "data.bak", "update.bak", "list.bak"};
OFSTRUCT ofStrSrc;
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile;
int i;

/* Allocate internal buffers for the CopyLZFile function. */

LZStart();

/* Open, copy, and then close the files. */

for (i = 0; i < NUM_FILES; i++) {
    hfSrcFile = LZOpenFile(szSrc[i], &ofStrSrc, OF_READ);
    hfDstFile = LZOpenFile(szDest[i], &ofStrDest, OF_CREATE);
    CopyLZFile(hfSrcFile, hfDstFile);
    LZClose(hfSrcFile);
    LZClose(hfDstFile);
}

LZDone(); /* free the internal buffers */
```

See Also

Lempel-Ziv Encoding functions

CopyLZFile	Copies files and decompresses them if compressed
GetExpandedName	Retrieves the original filename of a compressed file
LZClose	Closes a file
LZCopy	Copies a file and decompresses it if compressed
LZDone	Frees buffers allocated by the LZStart function
LZInit	Initializes structures needed for decompression
LZOpenFile	Opens a file (both compressed and uncompressed)
LZRead	Reads a specified number of bytes from a compressed file
LZSeek	Repositions a pointer in a file
LZStart	Allocates buffers for the CopyLZFile function

DECLARE_HANDLE (3.1)

DECLARE_HANDLE(*name***)**

The **DECLARE_HANDLE** macro creates a data type that can be used to define 16-bit handles.

Parameter	Description
name	Specifies the name of the new data type.

Comments

The **DECLARE_HANDLE** macro is defined in WINDOWS.H as follows:

```
#define DECLARE_HANDLE(name) struct name##__ { int unused; }; \
                             typedef const struct name##__ NEAR* name
```

See Also

DECLARE_HANDLE32

DECLARE_HANDLE32 (3.1)

#include ddeml.h

DECLARE_HANDLE32(*name***)**

The **DECLARE_HANDLE32** macro creates a data type that can be used to define 32-bit handles.

Parameter	Description
name	Specifies the name of the new data type.

Parameter	Description
name	Specifies the name of the variable for which a pointer is created.

Comments

The **DECLARE_HANDLE32** macro is defined in DDEML.H as follows:

```
#define DECLARE_HANDLE32(name) struct name##__ { int unused; }; \
                               typedef const struct name##__ _far* name
```

See Also

DECLARE_HANDLE

FIELDOFFSET (3.1)

int FIELDOFFSET(*type, field***)**

The **FIELDOFFSET** macro computes the address offset of the specified member in the structure specified by the *type* parameter.

Parameter	Description
type	Specifies the name of the structure.
field	Specifies the name of the member defined within the given structure.

Returns

The return value is the address offset of the given structure member.

Comments

The **FIELDOFFSET** macro is defined in WINDOWS.H as follows:

```
#define FIELDOFFSET(type, field)    ((int)(&((type NEAR*)1)->field)-1)
```

GetBValue (3.1)

BYTE GetBValue(*rgb***)**

DWORD *rgb;* /* RGB color value */

The **GetBValue** macro extracts the intensity value of the blue color field from the 32-bit integer value specified by the *rgb* parameter.

Parameter	Description
rgb	Specifies the **RGB** color value.

Returns
The return value specifies the intensity of the blue color field.

Comments
The **GetBValue** macro is defined in WINDOWS.H as follows:

```
#define GetBValue(rgb)  ((BYTE)((rgb)>>16))
```

See Also
GetGValue, **GetRValue**, **RGB**

GetGValue (3.1)

BYTE GetGValue(*rgb***)**

DWORD *rgb;* /* RGB color value */

The **GetGValue** macro extracts the intensity value of the green color field from the 32-bit integer value specified by the *rgb* parameter.

Parameter	Description
rgb	Specifies the **RGB** color value.

Returns
The return value specifies the intensity of the green color field.

Comments
The **GetGValue** macro is defined in WINDOWS.H as follows:

```
#define GetGValue(rgb)  ((BYTE)(((WORD)(rgb)) >> 8))
```

See Also
GetBValue, **GetRValue**, **RGB**

GetRValue (3.1)

BYTE GetRValue(*rgb***)**

DWORD *rgb;* /* RGB color value */

The **GetRValue** macro extracts the intensity value of the red color field from the 32-bit integer value specified by the *rgb* parameter.

Parameter	Description
rgb	Specifies the **RGB** color value.

Returns
The return value specifies the intensity of the red color field.

Comments
The **GetRValue** macro is defined in WINDOWS.H as follows:

```
#define GetRValue(rgb)  ((BYTE)(rgb))
```

See Also
GetBValue, **GetGValue**, **RGB**

GlobalDiscard (2.x)

HGLOBAL GlobalDiscard(*hglb***)**

HGLOBAL *hglb;* /* handle of object to discard */

The **GlobalDiscard** macro discards the given global memory object. The lock count of the memory object must be zero.

Parameter	Description
hglb	Identifies the global memory object to be discarded.

Returns
The return value is a handle of the discarded object if the macro is successful. Otherwise, it is NULL.

Comments
The **GlobalDiscard** macro discards only global objects that an application allocated with the **GMEM_DISCARDABLE** and **GMEM_MOVEABLE** flags set. The macro fails if an application attempts to discard a fixed or locked object.

Although **GlobalDiscard** removes the global memory object from memory, the object's handle remains valid. An application can subsequently pass the handle to the **GlobalReAlloc** function to allocate another global memory object identified by the same handle.

The **GlobalDiscard** macro is defined in WINDOWS.H as follows:

```
#define GlobalDiscard(h)  GlobalReAlloc(h, 0L, GMEM_MOVEABLE)
```

See Also
GlobalFree, **GlobalReAlloc**

HIBYTE (2.x)

BYTE HIBYTE(*wInteger***)**

UINT *uVal;* /* value from which high byte is retrieved */

The **HIBYTE** macro retrieves the high-order byte from the integer value specified by the *wInteger* parameter.

Parameter	Description
uVal	Specifies the value to be converted.

Returns
The return value specifies the high-order byte of the given value.

Comments
The **HIBYTE** macro is defined in WINDOWS.H as follows:

```
#define HIBYTE(w)   ((BYTE)(((UINT)(w) >> 8) & 0xFF))
```

HIWORD (2.x)

WORD HIWORD(*dwInteger***)**

DWORD *dwInteger;* /* value from which high word is retrieved */

The **HIWORD** macro retrieves the high-order word from the 32-bit integer value specified by the *dwInteger* parameter.

Parameter	Description
dwInteger	Specifies the value to be converted.

Returns

The return value specifies the high-order word of the given 32-bit integer value.

Comments

The **HIWORD** macro is defined in WINDOWS.H as follows:

```
#define HIWORD(l)  ((WORD)((((DWORD)(l)) >> 16) & 0xFFFF))
```

LOBYTE (2.x)

BYTE LOBYTE(*uVal***)**

UINT *uVal;* /* value from which low byte is retrieved */

The **LOBYTE** macro extracts the low-order byte from the 16-bit integer value specified by the *uVal* parameter.

Parameter	Description
uVal	Specifies the value to be converted.

Returns
The return value specifies the low-order byte of the value.

Comments
The **LOBYTE** macro is defined in WINDOWS.H as follows:

```
#define LOBYTE(w)   ((BYTE)(w))
```

See Also
LOWORD

LocalDiscard (2.x)

HLOCAL LocalDiscard(*hloc***)**

HLOCAL *hloc;* /* handle of object to discard */

The **LocalDiscard** macro discards the given local memory object. The lock count of the memory object must be zero.

Parameter	Description
hloc	Identifies the local memory object to be discarded.

Returns
The return value is equal to the *hloc* parameter if the macro is successful. Otherwise, it is NULL.

Comments
Although the **LocalDiscard** macro removes the local memory object from memory, the object's handle remains valid. An application can subsequently pass the handle to the **LocalReAlloc** function to allocate another local memory object identified by the same handle.

The **LocalLock** function increments (increases by one) a memory object's lock count. The **LocalUnlock** function decrements (decreases by one) the lock count.

The **LocalDiscard** macro is defined in WINDOWS.H as follows:

```
#define LocalDiscard(h)   LocalReAlloc(h, 0, LMEM_MOVEABLE)
```

See Also
LocalLock, **LocalReAlloc**, **LocalUnlock**

LockData (2.x)

HANDLE LockData(*dummy***)**

The **LockData** macro locks the current data segment in memory. It is intended to be used in modules that have movable data segments.

Parameter	Description
dummy	This parameter is ignored.

Returns
The return value identifies the locked data segment if the function is successful. Otherwise, it is NULL.

Comments
The **LockData** macro is defined in WINDOWS.H as follows:

```
#define LockData(dummy)  LockSegment((UINT)-1)
```

See Also
LockSegment

LOWORD (2.x)

WORD LOWORD(*dwVal***)**

DWORD *dwVal;* /* value from which low word is retrieved */

The **LOWORD** macro extracts the low-order word from the 32-bit integer value specified by the *dwVal* parameter.

Parameter	Description
dwVal	Specifies the value to be converted.

Returns
The return value specifies the low-order word of the 32-bit integer value.

Comments
The **LOWORD** macro is defined in WINDOWS.H as follows:

```
#define LOWORD(l)   ((WORD)(DWORD)(l))
```

See Also
LOBYTE

MAKEINTATOM (2.x)

LPCSTR MAKEINTATOM(*wInteger***)**

WORD *wInteger;* /* integer to make into atom */

The **MAKEINTATOM** macro creates an integer atom that represents a character string of decimal digits.

Integer atoms created by this macro can be added to the atom table using the **AddAtom** function.

Parameter	Description
wInteger	Specifies the numeric value to be made into an integer atom.

Returns
The return value is a pointer to the atom created for the given integer.

Comments
Although the return value of the **MAKEINTATOM** macro is cast as an **LPCSTR**, the return value cannot be used as a string pointer, except when it is passed to atom-management functions that require an **LPCSTR** parameter.

The **DeleteAtom** function always succeeds for integer atoms, even though it does nothing. The string returned by the **GetAtomName** function for an integer atom will be a null-terminated string where the first character is a pound sign (#) and the remaining characters are the word used in the **MAKEINTATOM** macro.

The **MAKEINTATOM** macro is defined in WINDOWS.H as follows:

```
#define MAKEINTATOM(i)  ((LPCSTR)MAKELP(NULL, (i)))
```

Example
The following example uses the **MAKEINTATOM** macro to convert the number 32,565 into an integer atom. The atom is then added to the local atom table by the **AddAtom** function:

```
ATOM at;
char szMsg[80];
LPCSTR lpszAtom;

lpszAtom = MAKEINTATOM(32565);
at = AddAtom(lpszAtom);

if (at == 0)
    MessageBox(hwnd, "AddAtom failed", "", MB_ICONSTOP);
else {
    wsprintf(szMsg, "AddAtom returned %u", at);
    MessageBox(hwnd, szMsg, "", MB_OK);
}
```

See Also
AddAtom, **DeleteAtom**, **GetAtomName**

MAKEINTRESOURCE (2.x)

LPCSTR MAKEINTRESOURCE(*idResource***)**

WORD *idResource;* /* resource identifier to convert */

The **MAKEINTRESOURCE** macro converts an integer resource identifier into a value compatible with Windows resource-management functions. This macro is used in place of a string containing the name of the resource.

Parameter	Description
idResource	Specifies the integer resource identifier to be converted.

Returns

The return value contains the *idResource* parameter in the low-order word and zero in the high-order word.

Comments

The **MAKEINTRESOURCE** macro is defined in WINDOWS.H as follows:

```
#define MAKEINTRESOURCE(i)  ((LPCSTR)MAKELP(NULL, (i)))
```

See Also

MAKELP

MAKELONG (2.x)

DWORD MAKELONG(*uLow, uHigh***)**

UINT *uLow;* /* low-order word of long value */
UINT *uHigh;* /* high-order word of long value */

The **MAKELONG** macro creates an unsigned long integer by concatenating two integer values, specified by the *uLow* and *uHigh* parameters.

Parameter	Description
uLow	Specifies the low-order word of the new long value.
uHigh	Specifies the high-order word of the new long value.

Returns
The return value specifies an unsigned long-integer value.

Comments
The **MAKELONG** macro is defined in WINDOWS.H as follows:

```
#define MAKELONG(low, high) \
     ((LONG)(((WORD)(low)) | (((DWORD)((WORD)(high))) << 16)))
```

MAKELP (3.1)

void FAR* MAKELP(*wSel, wOff***)**

WORD *wSel;* /* selector */
WORD *wOff;* /* offset */

The **MAKELP** macro combines a segment selector and an address offset to create a long (32-bit) pointer to a memory address.

Parameter	Description
wSel	Specifies a segment selector.
wOff	Specifies an offset from the beginning of the given segment to the desired byte.

Returns
The return value is a long pointer to an unspecified data type.

Comments
The **MAKELP** macro is defined in WINDOWS.H as follows:

```
#define MAKELP(sel, off)    ((void FAR*)MAKELONG((off), (sel)))
```

See Also
MAKELONG

MAKELPARAM (3.1)

LPARAM MAKELPARAM(*wLow, wHigh***)**

WORD *wLow;* /* low-order word */
WORD *wHigh;* /* high-order word */

The **MAKELPARAM** macro creates an unsigned long integer for use as an *lParam* parameter in a message. The macro concatenates two integer values, specified by the *wLow* and *wHigh* parameters.

Parameter	Description
wLow	Specifies the low-order word of the new long value.
wHigh	Specifies the high-order word of the new long value.

Returns
The return value specifies an unsigned long-integer value.

Comments
The **MAKELPARAM** macro is defined in WINDOWS.H as follows:

```
#define MAKELPARAM(low, high)   ((LPARAM)MAKELONG(low, high))
```

See Also
MAKELONG, **MAKELRESULT**

MAKELRESULT (3.1)

LRESULT MAKELRESULT(*wLow, wHigh***)**

WORD *wLow;* /* low-order word */
WORD *wHigh;* /* high-order word */

The **MAKELRESULT** macro creates an unsigned long integer for use as a return value from a window procedure. The macro concatenates two integer values, specified by the *wLow* and *wHigh* parameters.

Parameter	Description
wLow	Specifies the low-order word of the new long value.
wHigh	Specifies the high-order word of the new long value.

Returns
The return value specifies an unsigned long-integer value.

Comments
The **MAKELRESULT** macro is defined in WINDOWS.H as follows:

```
#define MAKELRESULT(low, high)  ((LRESULT)MAKELONG(low, high))
```

See Also
MAKELONG, **MAKELPARAM**

MAKEPOINT (2.x)

POINT MAKEPOINT(*lval***)**

DWORD *lval;* /* coordinates of a point */

The **MAKEPOINT** macro converts a long value that contains the x- and y-coordinates of a point into a **POINT** structure. This macro is useful for converting the long value returned by the **GetMessagePos** function into a **POINT** structure and for converting the *lParam* value passed with mouse messages into a **POINT** structure containing the mouse coordinates.

Parameter	Description
lval	Specifies the coordinates of a point. The x-coordinate is in the low-order word, and the y-coordinate is in the high-order word.

Returns
The return value is a pointer to a **POINT** structure.

Comments
The **MAKEPOINT** macro is defined in WINDOWS.H as follows:

```
#define MAKEPOINT(l)   (*((POINT FAR*)&(l)))
```

The **MAKEPOINT** macro is not compatible with the Windows 32-bit application programming interface (API).

See Also
GetMessagePos, **POINT**

max (2.x)

int max(*value1, value2***)**

The **max** macro compares two values and returns the value of the larger one. The data type can be any numerical data type, signed or unsigned. The type of the arguments and the return value is the same.

Parameter	Description
value1	Specifies the first of two values.
value2	Specifies the second of two values.

Returns
The return value is *value1* or *value2,* whichever is greater.

Comments
The **max** macro is defined in WINDOWS.H as follows:

```
#define max(a, b)  (((a) > (b)) ? (a) : (b))
```

See Also
min

min (2.x)

int min(*value1, value2***)**

The **min** macro compares two values and returns the value of the smaller one. The data type can be any numerical data type, signed or unsigned. The type of the arguments and the return value is the same.

Parameter	Description
value1	Specifies the first of two values.
value2	Specifies the second of two values.

Returns
The return value is *value1* or *value2,* whichever is smaller.

Comments
The **min** macro is defined in WINDOWS.H as follows:

```
#define min(a, b)  (((a) < (b)) ? (a) : (b))
```

See Also
max

OFFSETOF (3.1)

WORD OFFSETOF(*lp*)

void FAR* *lp;* /* long pointer */

The **OFFSETOF** macro retrieves the address offset of the specified long pointer.

Parameter	Description
lp	Specifies a long pointer.

Returns
The return value is the offset address.

Comments
The **OFFSETOF** macro is defined in WINDOWS.H as follows:

```
#define OFFSETOF(lp)        LOWORD(lp)
```

See Also
LOWORD, **SELECTOROF**

PALETTEINDEX (3.0)

COLORREF PALETTEINDEX(*wPaletteIndex***)**

WORD *wPaletteIndex;* /* index to palette entry */

The **PALETTEINDEX** macro accepts an index to a logical-color palette entry and returns a value consisting of 1 in the high-order byte and the palette-entry index in the low-order byte. This is called a palette-entry specifier. An application using a color palette can pass this specifier instead of an explicit **RGB** value to functions that expect a color. This allows the function to use the color in the specified palette entry.

Parameter	Description
wPaletteIndex	Specifies an index to the palette entry containing the color to be used for a graphics operation.

Returns

The return value is a logical-palette index specifier. When using a logical palette, an application can use this specifier in place of an explicit **RGB** value for graphics-device interface (GDI) functions that require a color.

Comments

The **PALETTEINDEX** macro is defined in WINDOWS.H as follows:

```
#define PALETTEINDEX(i)  ((COLORREF)(0x01000000L | (DWORD)(WORD)(i)))
```

See Also

PALETTERGB, **RGB**

PALETTERGB (3.0)

COLORREF PALETTERGB(*cRed, cGreen, cBlue***)**

BYTE *cRed;* /* red component of palette-relative RGB */
BYTE *cGreen;* /* green component of palette-relative RGB */
BYTE *cBlue;* /* blue component of palette-relative RGB */

The **PALETTERGB** macro accepts three values representing relative intensities of red, green, and blue and returns a value consisting of 2 in the high-order byte and an **RGB** value in the three low-order bytes. This is called a palette-relative RGB specifier. An application using a color palette can pass this specifier instead of an explicit RGB value to functions that expect a color.

For output devices that support logical palettes, Windows matches a palette-relative **RGB** value to the nearest color in the logical palette of the device context as though the application had specified an index to that palette entry. If an output device does not support a system palette, then Windows uses the palette-relative RGB as though it were a conventional RGB doubleword returned by the **RGB** macro.

Parameter	Description
cRed	Specifies the intensity of the red color field.
cGreen	Specifies the intensity of the green color field.
cBlue	Specifies the intensity of the blue color field.

Returns
The return value specifies a palette-relative **RGB** value.

Comments
The **PALETTERGB** macro is defined in WINDOWS.H as follows:

```
#define PALETTERGB(r,g,b)    (0x02000000L | RGB(r,g,b))
```

See Also
PALETTEINDEX, **RGB**

RGB (2.x)

COLORREF RGB(*cRed, cGreen, cBlue***)**

BYTE *cRed;* /* red component of color */
BYTE *cGreen;* /* green component of color */
BYTE *cBlue;* /* blue component of color */

The **RGB** macro selects an RGB color based on the parameters supplied and the color capabilities of the output device.

Parameter	Description
cRed	Specifies the intensity of the red color field.
cGreen	Specifies the intensity of the green color field.
cBlue	Specifies the intensity of the blue color field.

Returns
The return value specifies the resultant RGB color.

Comments
The intensity for each argument can range from 0 through 255. If all three intensities are specified as zero, the result is black. If all three intensities are specified as 255, the result is white.

Comments
The **RGB** macro is defined in WINDOWS.H as follows:

```
#define RGB(r,g,b)    ((COLORREF)(((BYTE)(r)|((WORD)(g)<<8))| \
     (((DWORD)(BYTE)(b))<<16)))
```

See Also
GetBValue, **GetGValue**, **GetRValue**, **PALETTEINDEX**, **PALETTERGB**

SELECTOROF (3.1)

WORD SELECTOROF(*lp*)

void FAR* *lp;* /* long pointer */

The **SELECTOROF** macro retrieves the segment selector from the specified long pointer.

Parameter	Description
lp	Specifies a long pointer.

Returns
The return value is the segment selector.

Comments
The **SELECTOROF** macro is defined in WINDOWS.H as follows:

```
#define SELECTOROF(lp)      HIWORD(lp)
```

See Also
HIWORD, **OFFSETOF**

UnlockData (2.x)

HANDLE UnlockData(*dummy***)**

The **UnlockData** macro unlocks the current data segment. It is intended to be used by modules that have movable data segments.

Parameter	Description
dummy	This parameter is ignored.

Returns
The return value specifies the outcome of the **UnlockSegment** function. It is zero if the segment's lock count was decreased to zero. Otherwise, the return value is nonzero.

Comments
The **UnlockData** macro is defined in WINDOWS.H as follows:

```
#define UnlockData(dummy)    UnlockSegment((UINT)-1)
```

See Also
LockData, **UnlockSegment**

UnlockResource (2.x)

BOOL UnlockResource(*hglblResData***)**

HGLOBAL *hglblResData;* /* handle of memory object to unlock */

The **UnlockResource** macro unlocks the resource specified by the *hglblResData* parameter and decreases the reference count of the resource by one.

Parameter	Description
hglblResData	Identifies the global memory object to be unlocked.

Returns
The return value is zero if the object's reference count is decreased to zero. Otherwise, it is nonzero.

Comments
The **UnlockResource** macro is defined in WINDOWS.H as follows:

```
#define UnlockResource(h)   GlobalUnlock(h)
```

See Also
GlobalUnlock

Windows macros (3.1)

DECLARE_HANDLE	Creates a 32-bit handle data type
DECLARE_HANDLE32	Creates a 16-bit handle data type
FIELDOFFSET	Computes the address offset of a structure member
GetBValue	Retrieves the blue color field of an **RGB** value
GetGValue	Retrieves the green color field of an **RGB** value
GetRValue	Retrieves the red color field of an **RGB** value
GlobalDiscard	Discards a global memory object
HIBYTE	Retrieves the high-order byte of an integer
HIWORD	Retrieves the high-order word of a 32-bit integer
LOBYTE	Retrieves the low-order byte of a 16-bit integer
LocalDiscard	Discards a local memory object
LockData	Locks the current data segment in memory
LOWORD	Retrieves the low-order word of a 32-bit integer
MAKEINTATOM	Creates an integer atom
MAKEINTRESOURCE	Converts a resource identifier into a string
MAKELONG	Creates a 32-bit integer from two 16-bit integers
MAKELP	Creates a long pointer to a memory address
MAKELPARAM	Creates unsigned long-integer message parameter
MAKELRESULT	Creates unsigned long-integer message result
MAKEPOINT	Converts a long value into a **POINT** structure
max	Returns the larger of two values
min	Returns the smaller of two values
OFFSETOF	Retrieves the address offset of a long pointer
PALETTEINDEX	Returns a logical-palette index specifier
PALETTERGB	Returns a palette-relative **RGB** specifier
RGB	Creates an **RGB** value from three colors
SELECTOROF	Retrieves the segment selector from a long pointer
UnlockData	Unlocks the current data segment
UnlockResource	Unlocks a resource and decreases its reference count

MS Windows (3.1)

New 3.1 API

Microsoft Windows
Software Development Kit

Version 3.1

Windows function groups (3.1)

32-bit Memory Manager Functions

GetWinMem32Version	Retrieves the version of the 32-bit memory API
Global16PointerAlloc	Converts a 16:32 pointer to a 16:16 pointer alias
Global16PointerFree	Frees a 16:16 pointer alias
Global32Alloc	Allocates a USE32 memory object
Global32CodeAlias	Creates a USE32 alias selector for 32-bit object
Global32CodeAliasFree	Frees a USE32 code-segment alias selector
Global32Free	Frees a USE32 memory object
Global32Realloc	Changes the size of a USE32 memory object

Alphabetical functions

Caret Functions (3.1)

CreateCaret	Creates a new shape for the system caret
DestroyCaret	Destroys the current caret shape
GetCaretBlinkTime	Retrieves the caret blink rate
GetCaretPos	Retrieves the current caret position
HideCaret	Removes the caret from the screen
SetCaretBlinkTime	Sets the caret blink rate
SetCaretPos	Sets the caret position
ShowCaret	Shows (unhides) the caret on the screen

Clipboard Functions (3.1)

The clipboard provides a mechanism that makes it possible for applications to pass data handles to other applications. Clipboard functions carry out data interchange between Windows applications.

ChangeClipboardChain	Removes window from clipboard-viewer chain
CloseClipboard	Closes the clipboard
CountClipboardFormats	Retrieves the number of clipboard formats
EmptyClipboard	Empties the clipboard and frees data handles
EnumClipboardFormats	Returns the available clipboard formats
GetClipboardData	Retrieves a handle to clipboard data
GetClipboardFormatName	Retrieves the registered clipboard-format name
GetClipboardOwner	Retrieves clipboard-owner window handle
GetClipboardViewer	Retrieves first clipboard-viewer window handle
GetPriorityClipboardFormat	Retrieves first clipboard format in priority list
IsClipboardFormatAvailable	Determines whether format data is available
OpenClipboard	Opens the clipboard
RegisterClipboardFormat	Registers a new clipboard format
SetClipboardData	Sets the data in the clipboard
SetClipboardViewer	Adds a window to the clipboard-viewer chain

Cursor Functions (3.1)

ClipCursor	Confines the cursor to a specified rectangle
CreateCursor	Creates a cursor with specified dimensions
DestroyCursor	Destroys a cursor created by CreateCursor or LoadCursor
GetCursorPos	Retrieves the current cursor position in screen coordinates
LoadCursor	Loads a cursor resource
SetCursor	Changes the mouse cursor
SetCursorPos	Sets the mouse-cursor position in screen coordinates
ShowCursor	Shows or hides the mouse cursor

Dialog-Box Functions (3.1)

CheckDlgButton	Changes a check mark by a dialog box button
CheckRadioButton	Adds a check mark to a radio button
CreateDialog	Creates a modeless dialog box
CreateDialogIndirect	Creates modeless dialog box from memory template
CreateDialogIndirectParam	Creates modeless dialog box from memory template
CreateDialogParam	Creates a modeless dialog box
DefDlgProc	Provides default window message processing
DialogBox	Creates a modal dialog box
DialogBoxIndirect	Creates modal dialog box from memory template
DialogBoxIndirectParam	Creates modal dialog box from memory template
DialogBoxParam	Creates a modal dialog box
DlgDirList	Fills a directory list box
DlgDirListComboBox	Fills a directory list box
DlgDirSelect	Retrieves a selection from a directory list box
DlgDirSelectEx	Retrieves a selection from a directory list box
DlgDirSelectComboBox	Retrieves a selection from a directory list box
DlgDirSelectComboBoxEx	Retrieves a selection from a directory list box
EndDialog	Hides a modal dialog box
GetDialogBaseUnits	Returns dialog base units
GetDlgCtrlID	Returns the handle of a child window
GetDlgItem	Retrieves the handle of a dialog box control
GetDlgItemInt	Translates control text into an integer
GetDlgItemText	Retrieves control text or title
GetNextDlgGroupItem	Returns handle of previous or next group control
GetNextDlgTabItem	Returns the next or previous **WS_TABSTOP** control
IsDialogMessage	Determines if message is for modeless dialog box
IsDlgButtonChecked	Determines the state of a button
MapDialogRect	Maps dialog box units to pixels
SendDlgItemMessage	Sends a message to a dialog box control
SetDlgItemInt	Converts an integer to a dialog box string
SetDlgItemText	Sets title or text of a control

Display and Movement Functions (3.1)

ArrangeIconicWindows	Arranges minimized child windows
BeginDeferWindowPos	Creates a window-position structure
BringWindowToTop	Uncovers an overlapped window
CloseWindow	Minimizes (but does not destroy) a window
DeferWindowPos	Updates a window-position structure
EndDeferWindowPos	Updates the position and size of multiple windows
GetClientRect	Retrieves a window's client coordinates
GetWindowRect	Retrieves a window's screen coordinates
GetWindowText	Copies window title or control text to a buffer
GetWindowTextLength	Returns length of window title or control text
IsIconic	Determines whether a window is minimized
IsWindowVisible	Determines the visibility state of a window
IsZoomed	Determines whether a window is maximized
MoveWindow	Changes the position and dimensions of a window
OpenIcon	Activates and displays a minimized window
SetWindowPos	Sets a window's size, position, and z-order
SetWindowText	Sets control text or window title
ShowOwnedPopups	Shows or hides pop-up windows
ShowWindow	Sets a window's visibility state

Error Functions (3.1)

FlashWindow	Flashes a window once
MessageBeep	Generates a beep sound
MessageBox	Creates and displays a message-box window

Hardware Functions (3.1)

EnableHardwareInput	Controls mouse and keyboard input queuing
GetAsyncKeyState	Determines the key state
GetInputState	Determines mouse, keyboard and timer queuing status
GetKeyboardState	Copies virtual-keyboard keys status to a buffer
GetKeyNameText	Retrieves the string representing the name of a key
GetKeyState	Retrieves the virtual-key state
GetKBCodePage	Returns the current Windows code page
OemKeyScan	Translates OEM ASCII to scan codes
SetKeyboardState	Sets the Windows keyboard-state table
MapVirtualKey	Translates a virtual-key code or scan code
VkKeyScan	Translates a Windows character to a virtual-key code

Hook Functions (3.1)

CallMsgFilter	Passes a message to a message-filter function
DefHookProc	Calls the next function in a hook-function chain
SetWindowsHook	Installs an application-defined hook function
SetWindowsHookEx	Installs an application-defined hook function
UnhookWindowsHook	Removes an application-defined hook function

Icon Functions (3.1)

ArrangeIconicWindows	Arranges minimized child windows
CopyIcon	Copies an icon
CreateIcon	Creates an icon with the specified dimensions
DestroyIcon	Destroys an icon created by CreateIcon or LoadIcon
DrawIcon	Draws an icon in the specified device context
IsIconic	Determines whether a window is minimized
LoadIcon	Loads an icon resource
OpenIcon	Activates and displays a minimized window

Information Functions (3.1)

AnyPopup	Indicates whether pop-up or overlapped window exists
ChildWindowFromPoint	Determines which child window contains a point
EnumChildWindows	Enumerates child windows
EnumTaskWindows	Enumerates windows associated with task on screen
EnumWindows	Enumerates parent windows
FindWindow	Returns window handle for class name and window name
GetNextWindow	Returns handle of window in window manager's list
GetParent	Returns parent window handle
GetTopWindow	Returns handle for top-level child of given window
GetWindow	Returns handle of window with specified relationship
GetWindowTask	Returns the task handle associated with a window
IsChild	Determines whether a window is a child
IsWindow	Determines whether a window handle is valid
SetParent	Changes a child's parent window
WindowFromPoint	Returns the handle of window containing a point

Input Functions (3.1)

EnableWindow	Enables or disables input to a window or control
GetActiveWindow	Retrieves the handle of the active window
GetCapture	Returns the handle for the mouse-capture window
GetCurrentTime	Retrieves the elapsed time since Windows started
GetDoubleClickTime	Retrieves mouse double-click time
GetFocus	Returns handle of window with input focus
GetTickCount	Retrieves the amount of time Windows has been running
IsWindowEnabled	Determines whether a window accepts user input
KillTimer	Removes a timer
ReleaseCapture	Releases the mouse capture
SetActiveWindow	Makes a top-level window active
SetCapture	Sets the mouse capture to a window
SetDoubleClickTime	Sets the mouse double-click time
SetFocus	Sets the input focus to a window
SetSysModalWindow	Makes a window the system-modal window
SetTimer	Installs a system timer
SwapMouseButton	Reverses the meaning of mouse buttons

Installable-Driver Functions (3.1)

CloseDriver	Closes an installable driver
DefDriverProc	Default processing of installable-driver messages
DriverProc	Processes installable-driver messages
GetDriverModuleHandle	Returns an installable-driver instance handle
GetDriverInfo	Retrieves installable-driver data
GetNextDriver	Enumerates installable-driver instances
OpenDriver	Opens an installable driver
SendDriverMessage	Sends a message to an installable driver

Menu Functions (3.1)

A menu is an input tool in a Windows application that offers users one or more items, which they can select with the mouse or keyboard. An item in a menu bar can display a pop-up menu, and any item in a pop-up menu can display another pop-up menu. In addition, a pop-up menu can appear anywhere on the screen.

AppendMenu	Appends a new item to the end of a menu
CheckMenuItem	Changes a check mark by a menu item
CreateMenu	Creates a menu
CreatePopupMenu	Creates an empty pop-up window
DeleteMenu	Deletes an item from a menu
DestroyMenu	Destroys a menu
DrawMenuBar	Redraws the menu bar of a window
EnableMenuItem	Enables, disables, or grays a menu item
GetMenu	Returns a menu handle for the specified window
GetMenuCheckMarkDimensions	Retrieves default check mark bitmap dimensions
GetMenuItemCount	Retrieves the number of items in a menu
GetMenuItemID	Returns the handle of a menu item
GetMenuState	Retrieves status flags for a menu item
GetMenuString	Copies a menu-item label into a buffer
GetSubMenu	Returns a pop-up menu handle
GetSystemMenu	Provides access to the System menu
HiliteMenuItem	Changes highlighting of top-level menu item
InsertMenu	Inserts a new item in a menu
LoadMenuIndirect	Returns a menu handle for a menu template
ModifyMenu	Changes an existing menu item
RemoveMenu	Deletes a menu item and pop-up menu
SetMenu	Sets the menu for a window
SetMenuItemBitmaps	Associates bitmaps with a menu item
TrackPopupMenu	Displays and tracks a pop-up menu

Message functions (3.1)

CallWindowProc	Passes message information to a window procedure
DispatchMessage	Dispatches a message to a window
GetMessage	Retrieves a message from the message queue
GetMessagePos	Retrieves the cursor position for the last message
GetMessageTime	Retrieves the time for the last message
InSendMessage	Determines whether window is processing SendMessage
PeekMessage	Checks an application's message queue
PostAppMessage	Posts a message to an application (task)
PostMessage	Places a message in a window's message queue
PostQuitMessage	Informs Windows that an application is exiting
ReplyMessage	Replies to a message sent through SendMessage
SendMessage	Sends a message to a window
SetMessageQueue	Creates a new message queue
TranslateAccelerator	Processes accelerator keys for menu commands
TranslateMDISysAccel	Processes MDI keyboard accelerators
TranslateMessage	Translates virtual-key messages
WaitMessage	Suspends an application and yields control

Network functions (3.1)

WNetAddConnection	Adds a network connection
WNetCancelConnection	Removes a network connection
WNetGetConnection	Lists the network connection

Painting Functions (3.1)

BeginPaint	Prepares a window for painting
DrawFocusRect	Draws a rectangle in the focus style
DrawIcon	Draws an icon in the specified device context
EndPaint	Marks the end of painting in the specified window
ExcludeUpdateRgn	Excludes an updated region from a clipping region
FrameRect	Draws a window border with the specified brush
GetDC	Returns a window device-context handle
GetUpdateRect	Retrieves window update-region dimensions
GetUpdateRgn	Retrieves the window update region
GetWindowDC	Retrieves the window device context
GrayString	Draws gray text at the specified location
InvalidateRect	Adds a rectangle to a window's update region
InvalidateRgn	Adds a region to a window's update region
InvertRect	Inverts a rectangular area
ReleaseDC	Frees a device context
UpdateWindow	Updates a window's client area
ValidateRect	Removes a rectangle from a window's update region
ValidateRgn	Removes a region from a window's update region

Property Functions (3.1)

EnumProps	Enumerates property-list entries
GetProp	Returns a data handle from a window property list
RemoveProp	Removes a property-list entry
SetProp	Adds or changes a property-list entry

Scrolling Functions (3.1)

GetScrollPos	Retrieves the current scroll-bar thumb position
GetScrollRange	Retrieves the minimum and maximum scroll-bar positions
ScrollDC	Scrolls a rectangle of bits horizontally and vertically
ScrollWindow	Scrolls the contents of a window's client area
ScrollWindowEx	Scrolls the contents of a window's client area
SetScrollPos	Sets the scroll-bar thumb position
SetScrollRange	Sets minimum and maximum scroll-bar positions
ShowScrollBar	Shows or hides a scroll bar

System Functions (3.1)

GetSysColor	Retrieves the display-element color
GetSystemMetrics	Retrieves the system metrics
GetTickCount	Retrieves the amount of time Windows has been running
SetSysColors	Sets one or more system colors

Window-Creation Functions (3.1)

AdjustWindowRect	Computes the required size of a window rectangle
AdjustWindowRectEx	Computes the required size of a window rectangle
CreateWindow	Creates an overlapped, pop-up, or child window
CreateWindowEx	Creates an overlapped, pop-up, or child window
DefDlgProc	Provides default window message processing
DefFrameProc	Provides default MDI frame window message processing
DefMDIChildProc	Provides default MDI child window message processing
DefWindowProc	Calls the default window procedure
DestroyWindow	Destroys a window
GetClassInfo	Returns window class information
GetClassLong	Retrieves a long value from extra class memory window class
GetClassName	Retrieves class name of a window
GetClassWord	Retrieves a word value from extra class memory window class memory word
GetLastActivePopup	Determines most recently active pop-up window
GetWindowLong	Retrieves a long value from extra window memory
GetWindowWord	Retrieves a word value from extra window memory
RegisterClass	Registers a window class
SetClassLong	Sets a long value in extra class memory
SetClassWord	Sets a word value in extra class memory
SetWindowLong	Sets a long value in extra window memory
SetWindowWord	Sets a word value in extra window memory
UnregisterClass	Frees a window class

New 3.1 user functions

CallNextHookEx	Passes hook information down the hook chain
CloseDriver	Closes an installable driver
CopyCursor	Copies a cursor
CopyIcon	Copies an icon
DefDriverProc	Provides default processing of installable-driver messages
EnableCommNotification	Enables or disables **WM_COMMNOTIFY** posting
EnableScrollBar	Enables or disables scroll-bar arrows
GetClipCursor	Retrieves screen coordinates for cursor-confining rectangle
GetCursor	Returns current cursor handle
GetDCEx	Returns the handle of a device context
GetDriverInfo	Retrieves installable-driver data
GetDriverModuleHandle	Returns an installable-driver instance handle
GetFreeSystemResources	Returns percentage of free system resource space
GetMessageExtraInfo	Retrieves information about a hardware message
GetNextDriver	Enumerates installable-driver instances
GetOpenClipboardWindow	Returns handle to window that opened clipboard
GetQueueStatus	Determines queued message type
GetSystemDebugState	Returns system-state information to a debugger
GetTimerResolution	Retrieves the timer resolution
GetWindowPlacement	Retrieves window show state and min/max positions
IsMenu	Determines whether a menu handle is valid
LockInput	Locks input to all tasks except the current one
LockWindowUpdate	Disables or reenables drawing in a window
MapWindowPoints	Converts points to another coordinate system
OpenDriver	Opens an installable driver
QuerySendMessage	Determines whether message originated in task
RedrawWindow	Updates rectangle or region in window's client area
ScrollWindowEx	Scrolls the contents of a window's client area
SendDriverMessage	Sends a message to an installable driver
SetWindowPlacement	Sets window show state and min/max position
SetWindowsHookEx	Installs an application defined hook function
SubtractRect	Creates a rectangle from the difference of two
SystemParametersInfo	Queries or sets system-wide parameters
UnhookWindowsHookEx	Removes a function from the hook chain
WNetAddConnection	Adds a network connection
WNetCancelConnection	Removes a network connection
WNetGetConnection	Lists a network connection

Bitmap Functions (3.1)

BitBlt	Copies a bitmap between device contexts
CreateBitmap	Creates a device-dependent memory bitmap
CreateBitmapIndirect	Creates a bitmap using a **BITMAP** structure
CreateCompatibleBitmap	Creates a bitmap compatible with a device context
CreateDIBitmap	Creates a bitmap handle from DIB specification
CreateDiscardableBitmap	Creates a discardable bitmap
GetBitmapBits	Copies bitmap bits into a buffer
GetBitmapDimension	Retrieves the width and height of a bitmap
GetBitmapDimensionEx	Retrieves the width and height of a bitmap
GetDIBits	Copies DIB bits into a buffer
GetPixel	Retrieves the **RGB** color of a specified pixel
LoadBitmap	Loads a bitmap resource
PatBlt	Creates a bit pattern on a device
SetBitmapBits	Sets bitmap bits from an array of bytes
SetBitmapDimension	Sets the width and height of bitmap
SetBitmapDimensionEx	Sets the width and height of bitmap
SetDIBits	Sets the bits of a bitmap
SetDIBitsToDevice	Sets DIB bits to a device
SetPixel	Sets a pixel to a specified color
StretchBlt	Sets the bitmap-stretching mode
StretchDIBits	Moves DIB from source to destination rectangle

Clipping Functions (3.1)

ExcludeClipRect	Creates new clipping region, excluding rectangle
GetClipBox	Retrieves a rectangle for the clipping region
IntersectClipRect	Creates a clipping region from an intersection
OffsetClipRgn	Moves a clipping region
PtVisible	Queries whether a point is within the clipping region
RectVisible	Queries whether a rectangle is within the clipping region
SelectClipRgn	Selects a clipping region for the device context

Coordinate Functions (3.1)

ChildWindowFromPoint	Determines which child window contains a point
ClientToScreen	Converts client point to screen coordinates
DPtoLP	Converts device points to logical coordinates
GetCurrentPosition	Retrieves position in logical coordinates
GetCurrentPositionEx	Retrieves position in logical coordinates
LPtoDP	Converts logical points to device coordinates
MapWindowPoints	Converts points to another coordinate system
ScreenToClient	Converts screen points to client coordinates
WindowFromPoint	Returns the handle of a window containing a point

Device-Context Functions (3.1)

CreateCompatibleDC	Creates a DC compatible with a specified device
CreateDC	Creates a device context
CreateIC	Creates an information context
DeleteDC	Deletes a device context
GetDC	Retrieves the handle of a device context
GetDCEx	Retrieves the handle of a device context
GetDCOrg	Retrieves the translation origin for a device context
ResetDC	Updates a device context
RestoreDC	Restores a device context
ReleaseDC	Frees a device context
SaveDC	Saves the current state of a device context

Drawing-Attribute Functions (3.1)

GetBkColor	Retrieves the current background color
GetBkMode	Retrieves the background mode
GetPolyFillMode	Retrieves the current polygon-filling mode
GetROP2	Retrieves the current drawing mode
GetStretchBltMode	Retrieves the current bitmap-stretching mode
GetTextColor	Retrieves the current text color
SetBkColor	Sets the background color
SetBkMode	Sets the background mode
SetPolyFillMode	Sets the polygon-filling mode
SetROP2	Sets the drawing mode
SetStretchBltMode	Sets the bitmap-stretching mode
SetTextColor	Sets the foreground color of text

Drawing-Tool Functions (3.1)

CreateBrushIndirect	Creates a brush with the specified attributes
CreateDIBPatternBrush	Creates a pattern brush from a DIB
CreateHatchBrush	Creates a hatched brush
CreatePatternBrush	Creates a pattern brush from a bitmap
CreatePen	Creates a pen with the specified attributes
CreatePenIndirect	Creates a pen using a **LOGPEN** structure
CreateSolidBrush	Creates a solid brush with a specified color
DeleteObject	Deletes an object from memory
EnumObjects	Enumerates the pens and brushes in a device context
GetBrushOrg	Retrieves the origin of the current brush
GetObject	Retrieves information about an object
GetStockObject	Retrieves the handle of a stock pen, brush, or font
IsGDIObject	Determines if handle is not handle of **GDI** object
SelectObject	Selects an object into a device context
SetBrushOrg	Sets the origin of the current brush
UnrealizeObject	Resets brush origins or logical palettes

Ellipse and Polygon Functions (3.1)

Chord	Draws a chord
DrawFocusRect	Draws a rectangle in the focus style
Ellipse	Draws an ellipse
Pie	Draws a pie-shaped wedge
Polygon	Draws a polygon
PolyPolygon	Draws a series of polygons
Rectangle	Draws a rectangle
RoundRect	Draws a rectangle with rounded corners

Font Functions (3.1)

AddFontResource	Adds a font resource to the font table
CreateFont	Creates a logical font
CreateFontIndirect	Creates a font using the **LOGFONT** structure
CreateScalableFontResource	Creates a resource file with font information
EnumFontFamilies	Enumerates fonts in a specified family
EnumFonts	Enumerates fonts on a specified device
GetAspectRatioFilter	Retrieves the current aspect-ratio filter
GetAspectRatioFilterEx	Retrieves the current aspect-ratio filter
GetCharABCWidths	Retrieves the widths of consecutive characters
GetCharWidth	Retrieves character widths
GetFontData	Retrieves font-metric information
GetGlyphOutline	Retrieves data for individual outline character
GetKerningPairs	Retrieves kerning pairs for the current font
GetOutlineTextMetrics	Retrieves metrics for TrueType fonts
GetRasterizerCaps	Retrieves status of TrueType fonts on system
RemoveFontResource	Removes an added font resource
SetMapperFlags	Sets the font-mapper flag

Line-Output Functions (3.1)

Arc	Draws an arc
LineDDA	Computes successive points in a line
LineTo	Draws a line from the current position
MoveTo	Moves the current position
MoveToEx	Moves the current position
Polyline	Draws line segments to connect specified points

Mapping Functions (3.1)

GetMapMode	Retrieves the mapping mode
GetViewportExt	Retrieves viewport extents
GetViewportExtEx	Retrieves viewport extents
GetViewportOrg	Retrieves the viewport origin
GetViewportOrgEx	Retrieves the viewport origin
GetWindowExt	Retrieves the window extents
GetWindowExtEx	Retrieves the window extents
GetWindowOrg	Retrieves the window origin
GetWindowOrgEx	Retrieves the window origin
OffsetViewportOrg	Moves the viewport origin
OffsetViewportOrgEx	Moves the viewport origin
OffsetWindowOrg	Moves the window origin
OffsetWindowOrgEx	Moves the window origin
ScaleViewportExt	Scales the viewport extents
ScaleViewportExtEx	Scales the viewport extents
ScaleWindowExt	Scales the window extents
ScaleWindowExtEx	Scales the window extents
SetMapMode	Sets the mapping mode
SetViewportExt	Sets the viewport extents
SetViewportExtEx	Sets the viewport extents
SetViewportOrg	Sets the viewport origin
SetViewportOrgEx	Sets the viewport origin
SetWindowExt	Sets the window extents
SetWindowExtEx	Sets the window extents
SetWindowOrg	Sets the window origin
SetWindowOrgEx	Sets the window origin

Metafile Functions (3.1)

CloseMetaFile	Closes a metafile device context and creates a handle
CopyMetaFile	Copies a source metafile to a file
CreateMetaFile	Creates a metafile device context
DeleteMetaFile	Invalidates a metafile handle
EnumMetaFile	Enumerates the metafile records in a metafile
GetMetaFile	Creates a handle to a metafile
GetMetaFileBits	Creates a memory object from a metafile
PlayMetaFile	Plays a metafile
PlayMetaFileRecord	Plays a metafile record
SetMetaFileBits	Creates a memory object from a metafile
SetMetaFileBitsBetter	Creates a memory object from a metafile

Palette Functions (3.1)

AnimatePalette	Replaces entries in a logical palette
CreatePalette	Creates a logical color palette
GetNearestColor	Retrieves the closest available color
GetNearestPaletteIndex	Retrieves the nearest match for a color
GetPaletteEntries	Retrieves a range of palette entries
GetSystemPaletteEntries	Retrieves entries from the system palette
GetSystemPaletteUse	Determines access to the entire system palette
RealizePalette	Maps entries from logical to system palette
ResizePalette	Changes the size of a logical palette
SelectPalette	Selects a palette into a device context
SetPaletteEntries	Sets colors and flags for a logical palette
SetSystemPaletteUse	Sets the use of static colors in the system palette

Printer-Control Functions (3.1)

AbortDoc	Terminates a print job
DeviceCapabilities	Retrieves the capabilities of a device
DeviceMode	Displays a dialog box for the printing modes
EndDoc	Ends a print job
EndPage	Ends a page
Escape	Allows access to device capabilities
ExtDeviceMode	Displays a dialog box for the printing modes
GetDeviceCaps	Retrieves the device capabilities
SetAbortProc	Sets the abort function for a print job
SpoolFile	Puts a file in the spooler queue
StartDoc	Starts a print job
StartPage	Prepares the printer driver to accept data
QueryAbort	Queries whether to terminate a print job

Rectangle Functions (3.1)

CopyRect	Copies the dimensions of a rectangle
EqualRect	Determines whether two rectangles are equal
FrameRect	Draws a window border with the specified brush
FillRect	Fills a rectangle with the specified brush
GetBoundsRect	Returns current accumulated bounding rectangle
InflateRect	Changes rectangle dimensions
IntersectRect	Calculates the intersection of two rectangles
InvertRect	Inverts a rectangular area
IsRectEmpty	Determines whether a rectangle is empty
OffsetRect	Moves a rectangle by the specified offsets
PtInRect	Determines whether a point is in a rectangle
SetBoundsRect	Controls bounding-rectangle accumulation
SetRect	Sets rectangle coordinates
SetRectEmpty	Creates an empty rectangle
SubtractRect	Creates rectangle from difference of two others
UnionRect	Creates the union of two rectangles

Region Functions (3.1)

CombineRgn	Creates a region by combining two regions
CreateEllipticRgn	Creates an elliptical region
CreateEllipticRgnIndirect	Creates an elliptical region
CreatePolygonRgn	Creates a polygonal region
CreatePolyPolygonRgn	Creates a region consisting of polygons
CreateRectRgn	Creates a rectangular region
CreateRectRgnIndirect	Creates a region using a **RECT** structure
CreateRoundRectRgn	Creates a rectangular region with round corners
EqualRgn	Compares two regions for equality
FillRgn	Fills a region with the specified brush
FrameRgn	Draws a border around a region
GetRgnBox	Retrieves the bounding rectangle for a region
InvertRgn	Inverts the colors in a region
OffsetRgn	Moves a region by the specified offsets
PaintRgn	Fills region with brush in device context
PtInRegion	Queries whether a point is in a region
RectInRegion	Queries whether a rectangle overlaps a region
SetRectRgn	Changes a region into the specified rectangle

Text Functions (3.1)

DrawText	
ExtTextOut	Writes a character string in a rectangular region
GetTabbedTextExtent	Determines the dimensions of a tabbed string
GetTextAlign	Retrieves the status of text-alignment flags
GetTextCharacterExtra	Retrieves the intercharacter spacing
GetTextExtent	Computes the dimensions of a string
GetTextExtentPoint	Computes the dimensions of a string
GetTextFace	Retrieves the typeface name of the current font
GetTextMetrics	Retrieves the metrics for the current font
SetTextAlign	Sets text-alignment flags for the device context
SetTextCharacterExtra	Sets the intercharacter spacing
SetTextJustification	Sets the justification for text output
TabbedTextOut	Writes a tabbed character string
TextOut	Writes a character string at the specified location

TrueType Functions (3.1)

CreateScalableFontResource	Creates a resource file with font information
GetCharABCWidths	Retrieves the widths of consecutive characters
GetFontData	Retrieves font-metric information
GetGlyphOutline	Retrieves data for individual outline character
GetKerningPairs	Retrieves kerning pairs for the current font
GetOutlineTextMetrics	Retrieves metric information for TrueType fonts
GetRasterizerCaps	Retrieves status of TrueType fonts on system

Pen Functions (3.1)

CreatePen	Creates a pen with the specified attributes
CreatePenIndirect	Creates a pen using a **LOGPEN** structure
GetStockObject	Retrieves the handle of a stock pen, brush, or font
LineTo	Draws a line from the current position

Brush Functions (3.1)

CreateBrushIndirect	Creates a brush with the specified attributes
CreateHatchBrush	Creates a hatched brush
CreatePatternBrush	Creates a pattern brush from a bitmap
CreateSolidBrush	Creates a solid brush with a specified color
GetBrushOrg	Retrieves the origin of the current brush
GetBrushOrgEx	Retrieves the origin of the current brush
GetStockObject	Retrieves the handle of a stock pen, brush, or font
SetBrushOrg	Sets the origin of the current brush

New 3.1 GDI functions

AbortDoc	Terminates a print job
CreateScalableFontResource	Creates a resource file with font information
EndDoc	Ends a print job
EndPage	Ends a page
EnumFontFamilies	Enumerates fonts in a specified family
GetAspectRatioFilterEx	Retrieves the current aspect-ratio filter
GetBoundsRect	Returns current accumulated bounding rectangle
GetBrushOrgEx	Retrieves the origin of the current brush
GetCharABCWidths	Retrieves the widths of consecutive characters
GetCurrentPositionEx	Retrieves the current position in logical units
GetFontData	Retrieves font-metric information
GetGlyphOutline	Retrieves data for individual outline character
GetKerningPairs	Retrieves kerning pairs for the current font
GetOutlineTextMetrics	Retrieves metrics for TrueType fonts
GetRasterizerCaps	Retrieves status of TrueType fonts on system
GetTextExtentPoint	Computes the dimensions of a string
GetViewportExtEx	Retrieves the viewport extents
GetViewportOrgEx	Retrieves the viewport origin
GetWindowExtEx	Retrieves the window extents
GetWindowOrgEx	Retrieves the window origin
IsGDIObject	Determines whether handle is not a **GDI** object
MoveToEx	Moves the current position
OffsetViewportOrgEx	Moves the viewport origin
OffsetWindowOrgEx	Moves the window origin
QueryAbort	Queries whether to terminate a print job
ResetDC	Updates a device context
ScaleViewportExtEx	Scales the viewport extents
ScaleWindowExtEx	Scales the window extents
SetAbortProc	Sets the abort function for a print job
SetBitmapDimensionEx	Sets the width and height of a bitmap
SetBoundsRect	Controls bounding-rectangle accumulation
SetMetaFileBitsBetter	Creates a memory object from a metafile
SetViewportExtEx	Sets the viewport extents
SetViewportOrgEx	Sets the viewport origin
SetWindowExtEx	Sets the window extents
SetWindowOrgEx	Sets the window origin
SpoolFile	Puts a file in the spooler queue
StartDoc	Starts a print job
StartPage	Prepares a printer driver to accept data

Application Execution Functions (3.1)

LoadModule	Loads and executes Windows application
WinExec	Runs the specified application
WinHelp	Invokes Windows Help

Atom-management Functions (3.1)

Atom-management functions create and manipulate atoms. Atoms are integers that uniquely identify character strings. They are useful in applications that use many character strings and in applications that need to conserve memory. Windows stores atoms in atom tables. A local atom table is allocated in an application's data segment; it cannot be accessed by other applications. The global atom table can be shared and is useful in applications that use dynamic data exchange (DDE).

AddAtom	Adds a string to the local atom table
DeleteAtom	Decrements the reference count of a local atom
FindAtom	Retrieves a string atom from a local atom table
GetAtomHandle	Retrieves an atom handle
GetAtomName	Retrieves a local atom string
GlobalAddAtom	Adds a string to the system atom table
GlobalDeleteAtom	Decrements the reference count of a global atom
GlobalFindAtom	Retrieves a string atom from a global atom table
GlobalGetAtomName	Retrieves a global atom string
InitAtomTable	Sets the size of the local atom hash table

Communication Functions (3.1)

BuildCommDCB	Translates a device-definition string to a **DCB**
ClearCommBreak	Restores character transmission
CloseComm	Closes a communications device
EnableCommNotification	Enables or disables **WM_COMMNOTIFY** posting
EscapeCommFunction	Passes an extended function to a device
FlushComm	Flushes a transmission or receiving queue
GetCommError	Retrieves the communications-device status
GetCommEventMask	Retrieves the device event word
GetCommState	Retrieves the device control block
OpenComm	Opens a communications device
ReadComm	Reads from a communications device
SetCommBreak	Suspends character transmission
SetCommEventMask	Enables events in a device event word
SetCommState	Sets the communications-device state
TransmitCommChar	Places a character in the transmission queue
UngetCommChar	Puts a character back in the receiving queue
WriteComm	Writes to a communications device

Debugging Functions (3.1)

DebugBreak	Causes a breakpoint exception
DebugOutput	Sends messages to the debugging terminal
DirectedYield	Forces execution of a specified task
FatalAppExit	Terminates an application
FatalExit	Sends current state of Windows to the debugger
GetSystemDebugState	Returns system-state information to a debugger
GetWinDebugInfo	Retrieves current system-debugging information
LockInput	Locks input to all tasks except the current one
LogError	Identifies the most recent system error
LogParamError	Identifies a parameter validation error
OutputDebugString	Sends a character string to the debugger
QuerySendMessage	Determines whether a message originated in a task
SetWinDebugInfo	Sets the current system-debugging information
ValidateCodeSegments	Tests for random memory overwrites
ValidateFreeSpaces	Checks free memory for valid contents

File I/O Functions (3.1)

GetDriveType	Determines the drive type
GetSystemDirectory	Returns the path of the Windows system directory
GetTempDrive	Returns a disk drive letter for temporary files
GetTempFileName	Creates a temporary filename
GetWindowsDirectory	Returns the path of the Windows directory
_hread	Reads data from a file
_hwrite	Writes data to a file
_lclose	Closes an open file
_lcreat	Creates or opens a file
_llseek	Repositions the file pointer
_lopen	Opens an existing file
_lread	Reads data from a file
_lwrite	Writes data to a file
hmemcpy	Copies bytes from source to destination buffer
OpenFile	Creates, opens, reopens, or deletes a file
SetHandleCount	Changes the number of available file handles

Initialization-File Functions (3.1)

Initialization-file functions obtain information from and copy information to a Windows or private (application-specific) initialization file. The Windows initialization file (WIN.INI) is a special ASCII file that contains entry-value pairs representing run-time options for applications.

An application should use a private initialization file to record information that affects it alone. This improves the performance of the application and Windows by reducing the amount of information that Windows must read when it accesses the initialization file. An application should record information in WIN.INI only if the information affects the Windows environment or other applications and should send the **WM_WININICHANGE** message to all top-level windows.

The WININI.WRI and SYSINI.WRI files supplied with the retail version of Windows describe the contents of the WIN.INI and SYSTEM.INI files, respectively.

GetPrivateProfileInt	Retrieves integer value from initialization file
GetPrivateProfileString	Retrieves a string from an initialization file
GetProfileInt	Retrieves an integer value from WIN.INI
GetProfileString	Retrieves a string from WIN.INI
WritePrivateProfileString	Writes a string to an initialization file
WriteProfileString	Writes a string to WIN.INI

Memory-Management Functions (3.1)

Memory-management functions manage system memory. There are two categories of memory-management functions: those that manage global memory and those that manage local memory. Global memory is all memory in the system that has not been allocated by an application or reserved by the system. Local memory is the memory in the data segment of a Windows application.

GetFreeSpace	Returns the number of free bytes in the global heap
GetFreeSystemResources	Returns the percentage of free system-resource space
GetSelectorBase	Retrieves the base address of a selector
GetSelectorLimit	Retrieves the limit of a selector
GetWinFlags	Returns the current system configuration flags
GlobalAlloc	Allocates memory from the global heap
GlobalCompact	Generates free global memory by compacting
GlobalDosAlloc	Allocates memory available to MS-DOS in real mode
GlobalDosFree	Frees global memory allocated by GlobalDosAlloc
GlobalFlags	Returns information about a global memory object
GlobalFree	Frees a global memory object
GlobalHandle	Retrieves the handle for a specified selector
GlobalLock	Locks global memory object and returns pointer
GlobalLRUNewest	Moves global memory object to newest LRU position
GlobalLRUOldest	Moves global memory object to oldest LRU position
GlobalNotify	Installs a notification procedure
GlobalReAlloc	Changes size or attributes of global memory object
GlobalSize	Returns the size of a global memory object
GlobalUnlock	Unlocks a global memory object
GlobalUnwire	Not used in Windows 3.1
GlobalWire	Not used in Windows 3.1
LimitEMSPages	Not used in Windows 3.1
LocalAlloc	Allocates memory from the local heap
LocalCompact	Generates free local memory by compacting
LocalFlags	Returns local memory object information
LocalFree	Frees a local memory object
LocalHandle	Returns the handle of a local memory object
LocalInit	Initializes the specified local heap
LocalLock	Locks local memory object and returns pointer
LocalReAlloc	Changes size or attributes of local memory object
LocalShrink	Shrinks the specified local heap
LocalSize	Returns the size of a local memory object
LocalUnlock	Unlocks a local memory object
LockSegment	Locks a discardable memory segment
SetSelectorBase	Sets the base address of a selector
SetSelectorLimit	Sets the limit of a selector
SetSwapAreaSize	Sets the amount of memory used for code segments
SwitchStackBack	Restores the current task stack
SwitchStackTo	Changes the location of the current task stack
UnLockSegment	Unlocks a discardable memory segment

Module-Management Functions (3.1)

Module-management functions alter and retrieve information about Windows modules, which are loadable, executable units of code and data.

FreeLibrary	Frees a loaded library module
FreeModule	Frees a loaded module
FreeProcInstance	Frees a function instance
GetCodeHandle	Determines the location of a function
GetInstanceData	Copies data from previous instance to current one
GetModuleFileName	Returns the filename for a module
GetModuleHandle	Retrieves a handle for the specified module
GetModuleUsage	Retrieves the reference count of a module
GetProcAddress	Returns the address of an exported DLL function
GetVersion	Returns the current MS-DOS and Windows versions
LoadLibrary	Loads the specified library module
MakeProcInstance	Returns address of prolog code for function

Optimization-Tool Functions (3.1)

ProfClear	Discards all buffered Profiler samples
ProfFinish	Stops Profiler sampling and flushes the buffer
ProfFlush	Flushes the Profiler sampling buffer to a disk
ProfInsChk	Determines whether Profiler is installed
ProfSampRate	Sets the Profiler code-sampling rate
ProfSetup	Sets the Profiler buffer size and sample quantity
ProfStart	Starts Profiler sampling
ProfStop	Stops Profiler sampling
SwapRecording	Starts or stops recording of memory swapping

Pointer-Validation Functions (3.1)

IsBadCodePtr	Determines whether a code pointer is valid
IsBadHugeReadPtr	Determines whether a huge read pointer is valid
IsBadHugeWritePtr	Determines whether a huge write pointer is valid
IsBadReadPtr	Determines whether a read pointer is valid
IsBadStringPtr	Determines whether a string pointer is valid
IsBadWritePtr	Determines whether a write pointer is valid

Resource-Management Functions (3.1)

Resource-management functions find and load application resources from a Windows executable file. A resource can be a cursor, icon, bitmap, string, or font.

AccessResource	Opens an executable file and locates a resource
AllocResource	Allocates memory for a resource
FindResource	Locates a resource in a resource file
FreeResource	Frees a loaded resource
LoadAccelerators	Loads an accelerator table
LoadBitmap	Loads a bitmap resource
LoadCursor	Loads a cursor resource
LoadIcon	Loads an icon resource
LoadMenu	Loads a menu resource
LoadResource	Loads the specified resource in global memory
LoadString	Loads a string resource
LockResource	Locks a resource in memory
SetResourceHandler	Installs a callback function that loads resources
SizeofResource	Returns the size of a resource

Segment Functions (3.1)

Segment functions allocate, free, and convert selectors; lock and unlock memory objects referenced by selectors; and retrieve information about segments.

An application should not use these functions unless it is absolutely necessary. Use of these functions violates preferred Windows programming practices.

AllocDStoCSAlias	Translates a data segment to a code segment
AllocSelector	Allocates a new selector
FreeSelector	Frees an allocated selector
GetCodeInfo	Retrieves code-segment information
GlobalFix	Locks a global memory object in linear memory
GlobalPageLock	Increments the global memory page-lock count
GlobalPageUnlock	Decrements the global memory page-lock count
GlobalUnfix	Unlocks a global memory object in linear memory
LockSegment	Locks a discardable memory segment
PrestoChangoSelector	Converts a code or data selector
UnlockSegment	Unlocks a discardable memory segment

String-Manipulation Functions (3.1)

String-manipulation functions translate strings from one character set to another, determine and convert the case of strings, determine whether a character is alphabetic or alphanumeric, find adjacent characters in a string, and perform other string manipulations.

AnsiLower	Converts a string to lowercase
AnsiLowerBuff	Converts a buffer string to lowercase
AnsiNext	Moves to the next character in a string
AnsiPrev	Moves to the previous character in a string
AnsiToOem	Translates a Windows string to an OEM string
AnsiToOemBuff	Translates a Windows string to an OEM string
AnsiUpper	Converts a string to uppercase
AnsiUpperBuff	Converts a buffer string to uppercase
IsCharAlpha	Determines whether a character is alphabetic
IsCharAlphaNumeric	Determines whether a character is alphanumeric
IsCharLower	Determines whether a character is lowercase
IsCharUpper	Determines whether a character is uppercase
lstrcat	Appends one string to another
lstrcmp	Compares two character strings
lstrcmpi	Compares two character strings
lstrcpy	Copies a string to a buffer
lstrcpyn	Copies characters from a string to a buffer
lstrlen	Returns the length, in bytes, of a string
OemToAnsi	Translates an OEM string to a Windows string
OemToAnsiBuff	Translates an OEM string to a Windows string
ToAscii	Translates virtual-key code to Windows character
wsprintf	Formats and stores a string in a buffer
wvsprintf	Formats and stores a string in a buffer

Task Functions (3.1)

Task functions alter the execution status of tasks, return information associated with a task, and retrieve information about the environment in which the task is being executed. A task is a single Windows application call.

Catch	Captures the current execution environment
ExitWindows	Restarts or terminates Windows
GetCurrentPDB	Returns the selector address of the current PDB
GetCurrentTask	Returns the current task handle
GetDOSEnvironment	Returns a far pointer to the current environment
GetNumTasks	Retrieves the current number of tasks
IsTask	Determines whether a task handle is valid
SetErrorMode	Controls Interrupt 24h error handling
Throw	Restores the execution environment
Yield	Stops the current task

New 3.1 kernel functions

_hread	Reads data from a file
_hwrite	Writes data to a file
DebugOutput	Sends messages to the debugging terminal
DirectedYield	Forces execution to continue with specified task
GetSelectorBase	Retrieves the base address of a selector
GetSelectorLimit	Retreives the limit of a selector
GetWinDebugInfo	Queries current system-debugging information
hmemcpy	Copies bytes from source to destination buffer
IsBadCodePtr	Determines whether a code pointer is valid
IsBadHugeReadPtr	Determines whether huge read pointer is valid
IsBadHugeWritePtr	Determines whether a huge write pointer is valid
IsBadReadPtr	Determines whether a read pointer is valid
IsBadStringPtr	Determines whether a string pointer is valid
IsBadWritePtr	Determines whether a write pointer is valid
IsDBCSLeadByte	Determines whether character is DBCS lead byte
IsTask	Determines whether a task handle is valid
LogError	Identifies a system error
LogParamError	Identifies a parameter validation error
SetSelectorBase	Sets the base address of a selector
SetSelectorLimit	Sets the limit of a selector
SetWinDebugInfo	Sets the current system-debugging information

OLE function groups (3.1)

Document Functions
Link Functions
Object-creation Functions
Object-management Functions
Server Functions (Client)
Server Functions (Server)

Document Functions (3.1)

OleEnumObjects	Enumerates objects in a document
OleRegisterClientDoc	Registers a document with the library
OleRegisterServerDoc	Registers a document with the server library
OleRename	Informs the library that an object is renamed
OleRenameClientDoc	Informs the library that a document is renamed
OleRenameServerDoc	Informs the library that a document is renamed
OleRevertClientDoc	Informs library that document reverted to saved state
OleRevertServerDoc	Informs library that document is reset to saved state
OleRevokeClientDoc	Informs the library that a document is not open
OleRevokeServerDoc	Revokes the specified document
OleSavedClientDoc	Informs library that a document has been saved
OleSavedServerDoc	Informs library that a document has been saved

Link Functions (3.1)

OleGetLinkUpdateOptions	Retrieves update options for an object
OleQueryLinkFromClip	Retrieves link data for clipboard object
OleQueryOutOfDate	Determines whether an object is out-of-date
OleSetLinkUpdateOptions	Sets link-update options for an object
OleUpdate	Updates the specified object

Object-creation Functions (3.1)

OleClone	Makes a copy of an object
OleCopyFromLink	Makes an embedded copy of a linked object
OleCreate	Creates an object of a specified class
OleCreateFromClip	Creates an object from the clipboard
OleCreateFromFile	Creates an object from a file
OleCreateFromTemplate	Creates an object from a template
OleCreateInvisible	Creates an object without displaying it
OleCreateLinkFromClip	Creates a link to an object from the clipboard
OleCreateLinkFromFile	Creates a link to an object in a file
OleLoadFromStream	Loads an object from the containing document
OleObjectConvert	Creates a new object using a specified protocol
OleQueryCreateFromClip	Retrieves protocol data for clipboard object

Object-management Functions (3.1)

OleActivate	Opens an object for an operation
OleCopyToClipboard	Puts the specified object on the clipboard
OleDelete	Deletes an object
OleDraw	Draws an object into a device context
OleEnumFormats	Enumerates data formats for an object
OleEqual	Compares two objects for equality
OleGetData	Retrieves data from an object in a specified format
OleQueryBounds	Retrieves the bounding rectangle for an object
OleQueryClientVersion	Retrieves the version number of a client library
OleQueryName	Retrieves the name of an object
OleQueryProtocol	Determines whether an object supports a protocol
OleQuerySize	Retrieves the size of an object
OleQueryType	Determines if object is linked, embedded, or static
OleRelease	Releases an object from memory
OleSaveToStream	Saves an object to the stream
OleSetBounds	Sets the bounding rectangle for an object
OleSetColorScheme	Specifies the client's recommended object colors
OleSetData	Sends data in the specified format to the server
OleSetHostNames	Sets the client name and object name for server
OleSetTargetDevice	Specifies the target device for an object

Server Functions (Client) (3.1)

OleClose	Closes the specified open object
OleExecute	Sends DDE execute commands to a server
OleLockServer	Keeps an open server application in memory
OleQueryOpen	Determines whether an object is open
OleQueryReleaseError	Determines the status of a released operation
OleQueryReleaseMethod	Determines which operation released
OleQueryReleaseStatus	Determines whether an operation released
OleReconnect	Reconnects to an open linked object
OleRequestData	Retrieves data from a server in a specified format
OleUnlockServer	Releases a server locked with OleLockServer

Server Functions (Server) (3.1)

OleBlockServer	Queues incoming requests for the server
OleQueryServerVersion	Retrieves the version number of the server library
OleRegisterServer	Registers the specified server
OleRevokeObject	Revokes access to an object
OleRevokeServer	Revokes the specified server
OleUnblockServer	Processes requests from a queue

Alphabetized Windows functions (3.1)

_hread	Reads from a file
_hwrite	Writes to a file
_lclose	Closes an open file
_lcreat	Creates or opens a file
_llseek	Repositions the file pointer
_lopen	Opens a file
_lread	Reads from a file
_lwrite	Writes to a file
AbortDoc	Terminates a print job
AccessResource	Opens a resource file and locates a resource
AddAtom	Adds a string to the local atom table
AddFontResource	Adds a font to the font table
AdjustWindowRect	Computes the required size of a window rectangle
AdjustWindowRectEx	Computes the required size of a window rectangle
AllocDiskSpace	Creates a file to consume space on a disk partition.
AllocDStoCSAlias	Translates a data segment to a code segment
AllocFileHandles	Allocates up to 256 file handles
AllocGDIMem	Allocates all available memory in the **GDI** heap.
AllocMem	Allocates all available memory.
AllocResource	Allocates memory for a resource
AllocSelector	Allocates a new selector
AllocUserMem	Allocates all available memory in the User heap.
AnimatePalette	Replaces entries in a logical palette
AnsiLower	Converts a string to lower case
AnsiLowerBuff	Converts a string buffer to lower case
AnsiNext	Moves to the next character in a string
AnsiPrev	Move to the previous character in a string
AnsiToOem	Translates a Windows string to an OEM string
AnsiToOemBuff	Translates a Windows string to an OEM string
AnsiUpper	Converst a string to upper case
AnsiUpperBuff	Converts a string buffer to upper case
AnyPopup	Indicates if pop-up or overlapped window exists
AppendMenu	Appends a new item to a menu
Arc	Draws an arc
ArrangeIconicWindows	Arranges minimized child windows
BeginDeferWindowPos	Creates a window-position structure
BeginPaint	Prepares a window for painting
BitBlt	Copies a bitmap between device contexts
BringWindowToTop	Uncovers an overlapped window
BuildCommDCB	Translates a device definition string to a **DCB**
CallMsgFilter	Passes a message to a message-filter function
CallNextHookEx	Passes hook information down the hook chain
CallWindowProc	Passes a message to a window procedure
Catch	Captures the current execution environment
ChangeClipboardChain	Removes a window from the clipboard-viewer chain
ChangeMenu	Obsolete
CheckDlgButton	Changes a check mark by a dialog button
CheckMenuItem	Changes a check mark by a menu item
CheckRadioButton	Places a check mark by a radio button
ChildWindowFromPoint	Determines the window containing a point
ChooseColor	Creates a color-selection dialog box
ChooseFont	Creates a font-selection dialog box
Chord	Draws a chord
ClassFirst	Retrieves information about first class in class list

ClassNext	Retrieves information about next class in class list
ClearCommBreak	Restores character transmission
ClientToScreen	Converts client point to screen coordinates
ClipCursor	Confines the cursor to a specified rectangle
CloseClipboard	Closes the clipboard
CloseComm	Closes a communications device
CloseDriver	Closes an installable driver
CloseMetaFile	Closes metafile dc and gets handle
CloseSound	Obsolete
CloseWindow	Minimizes a window
CombineRgn	Creates a region by combining two regions
CommDlgExtendedError	Retrieves Error Data
CopyCursor	Copies a cursor
CopyIcon	Copies an icon
CopyLZFile	Copies a file and decompresss it if compressed
CopyMetaFile	Copies a metafile
CopyRect	Copies the dimensions of a rectangle
CountClipboardFormats	Returns the number of clipboard formats
CountVoiceNotes	Obsolete
CreateBitmap	Creates device-dependent memory bitmap
CreateBitmapIndirect	Creates bitmap using **BITMAP** structure
CreateBrushIndirect	Creates a brush with specified attributes
CreateCaret	Creates a new shape for the system caret
CreateCompatibleBitmap	Creates bitmap compatible with DC
CreateCompatibleDC	Creates a DC compatible with specified DC
CreateCursor	Creates a cursor with specified dimensions
CreateDC	Creates a device context
CreateDialog	Creates a modeless dialog box
CreateDialogIndirect	Creates modeless dialog box from memory template
CreateDialogIndirectParam	Creates modeless dialog box from memory template
CreateDialogParam	Creates a modeless dialog box
CreateDIBitmap	Creates bitmap handle from DIB spec
CreateDIBPatternBrush	Creates a pattern brush from a DIB
CreateDiscardableBitmap	Creates discardable bitmap
CreateEllipticRgn	Creates an elliptical region
CreateEllipticRgnIndirect	Creates an elliptical region
CreateFont	Creates a logical font
CreateFontIndirect	Creates a font using **LOGFONT** structure
CreateHatchBrush	Creates a hatched brush
CreateIC	Creates an information context
CreateIcon	Creates an icon with the specified dimensions
CreateMenu	Creates a menu
CreateMetaFile	Creates a metafile device context
CreatePalette	Creates a logical color palette
CreatePatternBrush	Creates a pattern brush from a bitmap
CreatePen	Creates a pen
CreatePenIndirect	Creates a pen using a **LOGPEN** structure
CreatePolygonRgn	Creates a polygonal region
CreatePolyPolygonRgn	Creates a region consisting of polygons
CreatePopupMenu	Creates a pop-up window
CreateRectRgn	Creates a rectangular region
CreateRectRgnIndirect	Creates a region using a **RECT** structure
CreateRoundRectRgn	Creates a rectangular region with round corners
CreateScalableFontResource	Creates resource file with font info
CreateSolidBrush	Creates a solid brush with a specified color
CreateWindow	Creates a window

CreateWindowEx	Creates a window
DdeAbandonTransaction	Abandons an asynchronous transaction
DdeAccessData	Accesses a DDE global memory object
DdeAddData	Adds data to a DDE global memory object
DdeClientTransaction	Begins a DDE data transaction
DdeCmpStringHandles	Compares two DDE string handles
DdeConnect	Establishes a conversation with a server
DdeConnectList	Establishes multiple DDE conversations
DdeCreateDataHandle	Creates a DDE data handle
DdeCreateStringHandle	Creates a DDE string handle
DdeDisconnect	Terminates a DDE conversation
DdeDisconnectList	Destroys a DDE conversation list
DdeEnableCallback	Enables or disables one or more DDE conversations
DdeFreeDataHandle	Frees a global memory object
DdeFreeStringHandle	Frees a DDE string handle
DdeGetData	Copies data from a global memory object to a buffer
DdeGetLastError	Returns an error code set by a DDEML function
DdeInitialize	Registers an application with the DDEML
DdeKeepStringHandle	Increments the usage count for a string handle
DdeNameService	Registers or unregisters a service name
DdePostAdvise	Prompts a server to send advise data to a client
DdeQueryConvInfo	Retrieves information about a DDE conversation
DdeQueryNextServer	Obtains the next handle in a conversation list
DdeQueryString	Copies string-handle text to a buffer
DdeReconnect	Reestablishes a conversation with a server
DdeSetUserHandle	Associates a user-defined handle with a transaction
DdeUnaccessData	Frees a DDE global memory object
DdeUninitialize	Frees an application's DDEML resources
DebugBreak	Causes a breakpoint exception
DebugOutput	sends messages to the debugging terminal
DefDlgProc	Provides default window message processing
DefDriverProc	Calls the default installable-driver procedure
DeferWindowPos	Updates a multiple window position structure
DefFrameProc	Default MDI frame window message processing
DefHookProc	Calls the next function in a hook-function chain
DefMDIChildProc	Default MDI child window message processing
DefScreenSaverProc	Calls default screen-saver window procedure
DefWindowProc	Calls the default window procedure
DeleteAtom	Decrements a local atom's reference count
DeleteDC	Deletes a device context
DeleteMenu	Deletes an item from a menu
DeleteMetaFile	Invalidates a metafile handle
DeleteObject	Deletes an object from memory
DestroyCaret	Destroys the current caret
DestroyCursor	Destroys a cursor
DestroyIcon	Destroys an icon
DestroyMenu	Destroys a menu
DestroyWindow	Destroys a window
DeviceCapabilities	Retrieves the capabilities of a device
DeviceMode	Displays dialog box for printing modes
DialogBox	Creates a modal dialog box
DialogBoxIndirect	Creates modal dialog box from template in memory
DialogBoxIndirectParam	Creates modal dialog box from template in memory
DialogBoxParam	Creates a modal dialog box
DirectedYield	Forces execution to continue at a specified task
DispatchMessage	Dispatches a message to a window

DlgChangePassword	Changes password for screen saver
DlgDirList	Fills a directory list box
DlgDirListComboBox	Fills a directory list box
DlgDirSelect	Retrieves a selection from a directory list box
DlgDirSelectComboBox	Retrieves a selction from a directory list box
DlgDirSelectComboBoxEx	Retrieves selection from dir. list box
DlgDirSelectEx	Retrieves a selection from a directory list box
DlgGetPassword	Retrieves password for screen saver
DlgInvalidPassword	Warns of invalid screen saver password
DOS3Call	Issues a DOS Int 21h function request
DPtoLP	Converts device points to logical points
DragAcceptFiles	Registers whether a windows accepts dropped files
DragFinish	Releases memory allocated for dropping files
DragQueryFile	Retrieves filename of dropped file
DragQueryPoint	Retrieves mouse position at file drop
DrawFocusRect	Draws a rectangle in the focus style
DrawIcon	Draws an icon in the specified device context
DrawMenuBar	Redraws the menu bar
DrawText	Draws formatted text in a rectangle
Ellipse	Draws an ellipse
EmptyClipboard	Empties the clipboard and frees data handles
EnableCommNotification	Enables/disables **WM_COMMNOTIFY** posting to window
EnableHardwareInput	Controls mouse and keyboard input queuing
EnableMenuItem	Enabls, disables, or grays a menu item
EnableScrollBar	Enables or disables scroll-bar arrows
EnableWindow	Sets the window-enable state
EndDeferWindowPos	Updates position and size of multiple windows
EndDialog	Hides a modal dialog box
EndDoc	Ends a print job
EndPage	Ends a page
EndPaint	Marks end of painting in the specified window
EnumChildWindows	Passes child-window handles to callback function
EnumClipboardFormats	Returns available clipboard formats
EnumFontFamilies	Retrieves fonts in a specified family
EnumFonts	Enumerates fonts on specified device
EnumMetaFile	Enumerates metafile records
EnumObjects	Enumerates pens and brushes in a device context
EnumProps	Passes property-list entries to callback
EnumTaskWindows	Passes task's window handles to callback
EnumWindows	Passes parent-window handles to a callback
EqualRect	Determines whether two rectangles are equal
EqualRgn	Compares two regions for equality
Escape	Allows access to device facilities
EscapeCommFunction	Passes an extended function to a device
ExcludeClipRect	Changes clipping region, excluding rectangle
ExcludeUpdateRgn	Excludes an updated region from clipping region
ExitWindows	Restarts or terminates Windows
ExitWindowsExec	Terminates Windows, runs MS-DOS app
ExtDeviceMode	Displays dialog box for printing modes
ExtFloodFill	Fills area with current brush
ExtractIcon	Retrieves handle of icon from executable file
ExtTextOut	Writes a character string in rectangular region
FatalAppExit	Terminates an application
FatalExit	Displays debug info., causes breakpoint exception
FillRect	Fills a rectangle with the specified brush
FillRgn	Fills a region with a brush

FindAtom	Retrieves a string atom from the local atom table
FindExecutable	Retrieves name and handle of program for a file
FindResource	Locates a resource in a resource file
FindText	Creates a find-text dialog box
FindWindow	Returns window handle for class and window name
FlashWindow	Flashes a window once
FloodFill	Fills area with current brush
FlushComm	Flushes a transmit or receive queue
FrameRect	Draws a window border with a specified brush
FrameRgn	Draws a border around a region
FreeAllGDIMem	Frees memory allocated by AllocGDIMem.
FreeAllMem	Frees memory allocated by AllocMem.
FreeAllUserMem	Frees memory allocated by AllocUserMem.
FreeLibrary	Unloads a library module instance
FreeModule	Unloads a module instance
FreeProcInstance	Frees a function instance
FreeResource	Unloads a resource instance
FreeSelector	Fress an allocated selector
GetActiveWindow	Retrieves the handle of the active window
GetAspectRatioFilter	Retrieves setting of aspect-ratio filter
GetAspectRatioFilterEx	Retrieves current aspect-ratio filter
GetAsyncKeyState	Determines key state
GetAtomHandle	Retrieves an atom handle
GetAtomName	Retrieves a local atom string
GetBitmapBits	Copies bitmap bits to a buffer
GetBitmapDimension	Retrieves width and height of bitmap
GetBitmapDimensionEx	Retrieves width and height of bitmap
GetBkColor	Retrieves the current background color
GetBkMode	Retrieves the background mode
GetBoundsRect	Returns current accumulated bounding rectangle
GetBrushOrg	Retrieves the origin of the current brush
GetBrushOrgEx	Retrieves the origin of the current brush
GetCapture	Returns the handle for the mouse-capture window
GetCaretBlinkTime	Returns the caret blink rate
GetCaretPos	Returns the current caret position
GetCharABCWidths	Retrieves widths of TrueType characters
GetCharWidth	Retrieves character widths
GetClassInfo	Returns window class information
GetClassLong	Returns window-class data
GetClassName	Returns window class name
GetClassWord	Returns window class memory word
GetClientRect	Returns window client area coordinates
GetClipboardData	Returns a handle to clipboard data
GetClipboardFormatName	Returns registered clipboard format name
GetClipboardOwner	Returns clipboard owner window handle
GetClipboardViewer	Returns first clipboard viewer window handle
GetClipBox	Retrieves rectangle for clipping region
GetClipCursor	Returns cursor-confining rectangle coordinates
GetCodeHandle	Determines the location of a function
GetCodeInfo	Retrieves code-segment information
GetCommError	Returns communications-device status
GetCommEventMask	Retrieves the device event mask
GetCommState	Reads communications device status
GetCurrentPDB	Returns the selector address of the current PDB
GetCurrentPosition	Retrieves current position
GetCurrentPositionEx	Retrieves position in logical units

GetCurrentTask	Returns current task handle
GetCurrentTime	Returns elapsed time since Windows started
GetCursor	Returns current cursor handle
GetCursorPos	Returns current cursor position
GetDC	Returns window device-context handle
GetDCEx	Retrieves the handle of a device context
GetDCOrg	Retrieves translation origin for device context
GetDesktopWindow	Returns desktop window handle
GetDeviceCaps	Retrieves device capabilities
GetDialogBaseUnits	Returns dialog base units
GetDIBits	Copies DIB bits into a buffer
GetDlgCtrlID	Returns child window ID
GetDlgItem	Returns handle of a dialog control
GetDlgItemInt	Translates dialog text into an integer
GetDlgItemText	Retrieves dialog control text
GetDOSEnvironment	Returns a far pointer to the current environment
GetDoubleClickTime	Returns mouse double click time
GetDriverInfo	Retrieves installable-driver data
GetDriverModuleHandle	Retrieves an installable-driver instance handle
GetDriveType	Determines drive type
GetExpandedName	Retrieves original filename for a compressed file
GetFileResource	Copies a resource into a buffer
GetFileResourceSize	Returns the size of a resource
GetFileTitle	Retrieves a filename
GetFileVersionInfo	Returns version information about a file
GetFileVersionInfoSize	Returns the size of a file's version information
GetFocus	Returns current focus window handle
GetFontData	Retrieves font metric data
GetFreeFileHandles	Returns the number of free file handles
GetFreeSpace	Returns number of free bytes in the global heap
GetFreeSystemResources	Returns percentage of free system resource space
GetGlyphOutline	Retrieves data for individual outline character
GetInputState	Returns mouse, keyboard and timer queue status
GetInstanceData	Copy previous instance data into current instance
GetKBCodePage	Returns the current code page
GetKerningPairs	Retrieves kerning pairs for current font
GetKeyboardState	Returns virtual-keyboard keys status
GetKeyboardType	Retrieves keyboard information
GetKeyNameText	Retrieves string representing the name of a key
GetKeyState	Returns specified virtual key state
GetLastActivePopup	Determines most recently active pop-up window
GetMapMode	Retrieves mapping mode
GetMenu	Returns menu handle for the specified window
GetMenuCheckMarkDimensions	Returns default check mark bitmap dimensions
GetMenuItemCount	Returns the number of items in a menu
GetMenuItemID	Returns a menu-item identifier
GetMenuState	Returns status flags for the specified menu item
GetMenuString	Copies a menu-itme label into a buffer
GetMessage	Retrieves a message from the message queue
GetMessageExtraInfo	Retrieves information about a hardware message
GetMessagePos	Returns cursor position for last message
GetMessageTime	Returns the time for the last message
GetMetaFile	Creates handle to a metafile
GetMetaFileBits	Creates memory block from metafile
GetModuleFileName	Returns the file name for a module handle
GetModuleHandle	Returns a module handle for a named module

GetModuleUsage	Returns the reference count for a module
GetNearestColor	Retrieves closest available color
GetNearestPaletteIndex	Retrieves nearest match for a color
GetNextDlgGroupItem	Returns handle of previous or next group control
GetNextDlgTabItem	Returns the next or previous **WS_TABSTOP** control
GetNextDriver	Enumerates installable-driver instances
GetNextWindow	Returns next or previous window-manager window
GetNumTasks	Returns the current number of tasks
GetObject	Retrieves infOrmation about an object
GetOpenClipboardWindow	Returns handle to window that opened clipboard
GetOpenFileName	Creates an open-filename dialog box
GetOutlineTextMetrics	Retrieves metrics for TrueType fonts
GetPaletteEntries	Retrieves range of palette entries
GetParent	Returns parent window handle
GetPixel	Retrieves **RGB** color of specified pixel
GetPolyFillMode	Retrieves the current polygon-filling mode
GetPriorityClipboardFormat	Returns first clipboard format
GetPrivateProfileInt	Retrieves integer value from .ini file
GetPrivateProfileString	Retrieves a string from an initialization file
GetProcAddress	Returns the address of an exported DLL function
GetProfileInt	Retrieves an integer value from WIN.INI
GetProfileString	Retrieves a string from WIN.INI
GetProp	Returns data handle from a window property list
GetQueueStatus	Determines queued message type
GetRasterizerCaps	Retrieves status of TrueType on system
GetRgnBox	Retrieves bounding rectangle for region
GetROP2	Retrieves the current drawing mode
GetSaveFileName	Creates a save-filename dialog box
GetScrollPos	Returns current scroll-bar thumb position
GetScrollRange	Returns minimum and maximum scroll-bar positions
GetSelectorBase	Retrieves the base address of a selector
GetSelectorLimit	Retreives the limit of a selector
GetStockObject	Retrieves handle of a stock pen, brush, or font
GetStretchBltMode	Retrieves the current bitmap-stretching mode
GetSubMenu	Returns pop-up menu handle
GetSysColor	Returns display-element color
GetSysModalWindow	Returns system-model window handle
GetSystemDebugState	Returns system-state information to a debugger
GetSystemDir	Returns the Windows system subdirectory
GetSystemDirectory	Returns the Windows system directory
GetSystemMenu	Provides access to the System menu
GetSystemMetrics	Retrieves the system metrics
GetSystemPaletteEntries	Retrieves entries from system palette
GetSystemPaletteUse	Determines use of entire system palette
GetTabbedTextExtent	Determines dimensions of tabbed string
GetTempDrive	Returns a disk drive letter for temporary files
GetTempFileName	Creates a temporary filename
GetTextAlign	Retrieves text-alignment flags
GetTextCharacterExtra	Retrieves intercharacter spacing
GetTextColor	Retrieves the current text color
GetTextExtent	Determines dimensions of a string
GetTextExtentPoint	Retrieves dimensions of string
GetTextFace	Retrieves typeface name of the current font
GetTextMetrics	Retrieves the metrics for the current font
GetThresholdEvent	Obsolete
GetThresholdStatus	Obsolete

GetTickCount	Returns amount of time Windows has been running
GetTimerResolution	Retrieves the timer resolution
GetTopWindow	Returns handle for top child of given window
GetUpdateRect	Returns window update region dimensions
GetUpdateRgn	Returns window update region
GetVersion	Returns the current Dos and Windows versions
GetViewportExt	Retrieves viewport extent
GetViewportExtEx	Retrieves viewport extent
GetViewportOrg	Retrieves viewport origin
GetViewportOrgEx	Retrieves viewport origin
GetWinDebugInfo	Queries current system-debugging information
GetWindow	Returns specified window handle
GetWindowDC	Returns window device context
GetWindowExt	Retrieves window extents
GetWindowExtEx	Retrieves window extents
GetWindowLong	Returns long value from extra window memory
GetWindowOrg	Retrieves window origin
GetWindowOrgEx	Retrieves window origin
GetWindowPlacement	Returns window show state and min/max position
GetWindowRect	Retrieves a window's coordinates
GetWindowsDir	Returns the Windows directory
GetWindowsDirectory	Returns the Windows directory
GetWindowTask	Returns the task associated with a window
GetWindowText	Copies window title-bar text to a buffer
GetWindowTextLength	Returns length of window title bar text
GetWindowWord	Returns a word value from extra window memory
GetWinFlags	Returns system configuration flags
GetWinMem32Version	Retrieves version of the 32-bit memory API
Global16PointerAlloc	Converts 16:32 pointer to 16:16
Global16PointerFree	Frees a 16:16 pointer alias
Global32Alloc	Allocates a USE32 memory object
Global32CodeAlias	Creates USE32 alias selector for 32-bit object
Global32CodeAliasFree	Frees a USE32 code-segment alias selector
Global32Free	Frees a USE32 memory object
Global32Realloc	Changes size of a USE32 memory object
GlobalAddAtom	Adds a string to the system atom table
GlobalAlloc	Allocates memory from the global heap
GlobalCompact	Generates free global memory by compacting
GlobalDeleteAtom	Decrements a global atom's reference count
GlobalDosAlloc	Allocates memory available to DOS in real mode
GlobalDosFree	Frees global memory allocated by GlobalDosAlloc
GlobalEntryHandle	Retrieves information about global memory object
GlobalEntryModule	Retrieves information about specific memory object
GlobalFindAtom	Retrieves string atom from the global atom table
GlobalFirst	Retrieves information about first global memory object
GlobalFix	Locks a global memory block in linear memory
GlobalFlags	Returns information about a global memory object
GlobalFree	Frees a global memory object
GlobalGetAtomName	Retrieves a global atom string
GlobalHandle	Returns a handle for a specified selector
GlobalHandleToSel	Converts a global handle to a selector
GlobalInfo	Retrieves information about the global heap
GlobalLock	Locks global memory object and returns a pointer
GlobalLRUNewest	Moves global memory block to newest LRU position
GlobalLRUOldest	Moves global memory block to oldest LRU position
GlobalNext	Retrieves information about next global memory object

GlobalNotify	Installs a notification procedure
GlobalPageLock	Increments global memory page-lock count
GlobalPageUnlock	Decrements global memory page-lock count
GlobalReAlloc	Changes size/attributes of global memory object
GlobalSize	Returns the size of a global memory object
GlobalUnfix	Unlocks a global-memory block in linear memory
GlobalUnlock	Unlocks a global memory object
GlobalUnWire	Should not be used
GlobalWire	Should not be used
GrayString	Draws gray text at the specified location
HelpMessageFilterHookFunction	Posts screen saver help message
HideCaret	Removes the caret from the screen
HiliteMenuItem	Changes highlight of top-level menu item
hmemcpy	Copies bytes
InflateRect	Changes rectangle dimensions
InitAtomTable	Sets the size of the local atom table
InSendMessage	Determines if a window is processing SendMessage
InsertMenu	Inserts a new item in a menu
InterruptRegister	Installs function to handle system interrupts
InterruptUnRegister	Removes function that processed system interrupts
IntersectClipRect	Creates clipping region from intersection
IntersectRect	Calculates a rectangle intersection
InvalidateRect	Adds a rectangle to the update region
InvalidateRgn	Adds a region to the update region
InvertRect	Inverts a rectangular region
InvertRgn	Inverts the colors in a region
IsBadCodePtr	Determines whether a code pointer is valid
IsBadHugeReadPtr	Determines if a huge read pointer is valid
IsBadHugeWritePtr	Determines if a huge write pointer is valid
IsBadReadPtr	Determines whether a read pointer is valid
IsBadStringPtr	Determines whether a string pointer is valid
IsBadWritePtr	Determines whether a write pointer is valid
IsCharAlpha	Determines if a character is alphabetical
IsCharAlphaNumeric	Determines is a character is alphanumeric
IsCharLower	Determines if a character is lower case
IsCharUpper	Determines if a character is upper case
IsChild	Determines if a window is a child
IsClipboardFormatAvailable	Determines if specified format data is available
IsDBCSLeadByte	Determines if a character is a DBCS lead byte
IsDialogMessage	Determines if a message is for a dialog box
IsDlgButtonChecked	Determines the state of a button control
IsGDIObject	Determines if handle is not **GDI** object
IsIconic	Determines if a window is minimized
IsMenu	Determines if a menu handle is valid
IsRectEmpty	Determines whether rectangle is empty
IsTask	Determines whether a task handle is valid
IsWindow	Determines if a window handle is valid
IsWindowEnabled	Determines if a window accepts user input
IsWindowVisible	Determines visibility state of a window
IsZoomed	Determines if a window is maximized
KillTimer	Removes a timer
LimitEmsPages	Obsolete
LineDDA	Computes successive points in a line
LineTo	Draws a line from the current position
LoadAccelerators	Loads an accelerator table
LoadBitmap	Loads a bitmap resource

LoadCursor	Loads a cursor resource
LoadIcon	Loads an icon resource
LoadLibrary	Returns a handle to a library module
LoadMenu	Loads a menu resource
LoadMenuIndirect	Obtains a menu handle for a menu template
LoadModule	Loads and executes a program
LoadResource	Returns a handle to a resource
LoadString	Loads a string resource
LocalAlloc	Allocate memory from the local heap
LocalCompact	Generates free local memory by compacting
LocalFirst	Retrieves information about first local memory object
LocalFlags	Returns local memory object information
LocalFree	Frees a local memory object
LocalHandle	Returns the handle of a local memory object
LocalInfo	Fills structure with information about local heap
LocalInit	Initializes a local heap
LocalLock	Locks a local memory object and returns a pointer
LocalNext	Retrieves information about next local memory object
LocalReAlloc	Changes local memory size or attributes
LocalShrink	Shrinks the specified local heap
LocalSize	Returns the size of a local memory object
LocalUnlock	Unlocks a local memory object
LockInput	Locks input to all tasks except the current one
LockResource	Returns the address of a resource
LockSegment	Locks a discardable memory segment
LockWindowUpdate	Disables or reenables drawing in a window
LogError	Identifies an error message
LogParamError	Identifies a parameter validation error
LPtoDP	Converts logical points to device points
lstrcat	Appends one string to another
lstrcmp	Compares two character strings
lstrcmpi	Compares two character strings
lstrcpy	Copies a string to a buffer
lstrlen	Returns the number of characters in a string
LZClose	Closes a file
LZCopy	Copies a file and expands it if compressed
LZDone	Frees buffers allocated by LZStart
LZInit	Initializes data structures needed for decompression
LZOpenFile	Opens a file (both compressed and uncompressed)
LZRead	Reads a specified number of bytes from a compressed file
LZSeek	Repositions pointer in file
LZStart	Allocates buffers for CopyLZFile function
MakeProcInstance	Returns the address of prolog code for a function
MapDialogRect	Maps dialog box units to pixels
MapVirtualKey	Translates a virual-key code or scan code
MapWindowPoints	Converts points to another coordinate system
MemManInfo	Retrieves information about the memory manager
MemoryRead	Reads memory from an arbitrary global heap object
MemoryWrite	Writes memory to an arbitrary global heap object
MessageBeep	Generates a beep
MessageBox	Creates a message-box window
ModifyMenu	Changes an existing menu item
ModuleFindHandle	Retrieves information about a module
ModuleFindName	Retrieves information about a module
ModuleFirst	Retrieves information about first module
ModuleNext	Retrieves information about next module

MoveTo	Moves the current position
MoveToEx	Moves the current position
MoveWindow	Changes the position and dimensions of a window
MulDiv	Multiplies two values and divides the result
NetBIOSCall	Issues a NETBIOS Interrupt 5Ch
NotifyRegister	Installs a notification callback function
NotifyUnRegister	Removes a notification callback function
OemKeyScan	Maps OEM ASCII to scan codes
OemToAnsi	Translates an OEM string to a Windows string
OemToAnsiBuff	Translates an OEM string to a Windows string
OffsetClipRgn	Moves a clipping region
OffsetRect	Moves a rectangle by an offset
OffsetRgn	Moves a region by a specified offset
OffsetViewportOrg	Moves viewport origin
OffsetViewportOrgEx	Moves viewport origin
OffsetWindowOrg	Moves window origin
OffsetWindowOrgEx	Moves window origin
OleActivate	Activates an object
OleBlockServer	Queues incoming requests for the server
OleClone	Makes a copy of an object
OleClose	Closes specified object
OleCopyFromLink	Makes an embedded copy of a linked object
OleCopyToClipboard	Puts the specified object on the clipboard
OleCreate	Creates an object of a specified class
OleCreateFromClip	Creates an object from the clipboard
OleCreateFromFile	Creates an object from a file
OleCreateFromTemplate	Creates an object from a template
OleCreateInvisible	Creates an object without displaying it
OleCreateLinkFromClip	Creates link to object from the clipboard
OleCreateLinkFromFile	Creates link to object in a file
OleDelete	Deletes an object
OleDraw	Draws an object into a device context
OleEnumFormats	Enumerates data formats for an object
OleEnumObjects	Enumerates objects in a document
OleEqual	Compares two objects for equality
OleExecute	Sends DDE execute commands to a server
OleGetData	Retrieves data for an object in a specified format
OleGetLinkUpdateOptions	Retrieves update options for an object
OleIsDcMeta	Identifies metafile device context
OleLoadFromStream	Loads an object from containing document
OleLockServer	Keeps server in memory
OleObjectConvert	Creates a new object using a specified protocol
OleQueryBounds	Retrieves bounding rectangle for object
OleQueryClientVersion	Retrieves version of client library
OleQueryCreateFromClip	Retrieves create data for clipboard object
OleQueryLinkFromClip	Retrieves link data for clipboard object
OleQueryName	Retrieves the name of an object
OleQueryOpen	Determines whether an object is open
OleQueryOutOfDate	Determines whether an object is out-of-date
OleQueryProtocol	Determines if an object supports a protocol
OleQueryReleaseError	Determines status of released operation
OleQueryReleaseMethod	Determines which operation released
OleQueryReleaseStatus	Determines whether an operation released
OleQueryServerVersion	Retrieves version of server library
OleQuerySize	Retrieves the size of an object
OleQueryType	Determines if object is linked, embedded, or static

OleReconnect	Reconnects to an open linked object
OleRegisterClientDoc	Registers a document with the library
OleRegisterServer	Registers the specified server
OleRegisterServerDoc	Registers document with server library
OleRelease	Releases an object from memory
OleRename	Informs library an object is renamed
OleRenameClientDoc	Informs library a document is renamed
OleRenameServerDoc	Informs library a document is renamed
OleRequestData	Retrieves data from a server in a specified format
OleRevertClientDoc	Informs library a doc reverted to saved state
OleRevertServerDoc	Informs library a doc is reset to saved state
OleRevokeClientDoc	Informs library a document is not open
OleRevokeObject	Revokes access to an object
OleRevokeServer	Revokes the specified server
OleRevokeServerDoc	Revokes the specified document
OleSavedClientDoc	Informs library a doc has been saved
OleSavedServerDoc	Informs library a doc has been saved
OleSaveToStream	Saves an object to the stream
OleSetBounds	Sets bounding rectangle for object
OleSetColorScheme	Specifies client's recommended object colors
OleSetData	Sends data in specified format to server
OleSetHostNames	Sets client name and object name for server
OleSetLinkUpdateOptions	Sets update options for an object
OleSetTargetDevice	Sets target device for an object
OleUnblockServer	Processes requests from queue
OleUnlockServer	Releases server locked with OleLockServer
OleUpdate	Updates an object
OpenClipboard	Opens the clipboard
OpenComm	Opens a communications device
OpenDriver	Opens an installable driver
OpenFile	Creates, opens, reopens or deletes a file
OpenIcon	Activates a minimized window
OpenSound	Obsolete
OutputDebugString	Sends a character string to the debugger
PaintRgn	Fills region with brush in device context
PatBlt	Creates a bitmap pattern
PeekMessage	Checks message queue
Pie	Draws a pie-shaped wedge
PlayMetaFile	Plays a metafile
PlayMetaFileRecord	Plays a metafile record
Polygon	Draws a polygon
Polyline	Draws line segments to connect specified points
PolyPolygon	Draws a series of polygons
PostAppMessage	Posts a message to an application
PostMessage	Places a message in a window's message queue
PostQuitMessage	Tells Windows that an application is terminating
PrestoChangoSelector	Generates code selector from data
PrintDlg	Creates a print-text dialog box
ProfClear	Discards all buffered Profiler samples
ProfFinish	Stops profile sampling and flushes profile buffer
ProfFlush	Flushes the Profiler sampling buffer to disk
ProfInsChk	Determines whether Profiler is installed
ProfSampRate	Sets the Profiler sampling rate
ProfSetup	Sets Profiler buffer size and sample quantity
ProfStart	Starts profile sampling
ProfStop	Stops profile sampling

PtInRect	Determines if a point is in a rectangle
PtInRegion	Queries whether a point is in a region
PtVisible	Queries whether point is within clipping region
QueryAbort	Queries whether to terminate a print job
QuerySendMessage	Determines if a message originated within a task
ReadComm	Reads from a communications device
RealizePalette	Maps entries from logical to system palette
Rectangle	Draws a rectangle
RectInRegion	Queries whether rectangle overlaps region
RectVisible	Queries whether rectangle is in clip region
RedrawWindow	Updates a client rectangle or region
RegCloseKey	Closes a key
RegCreateKey	Creates a key
RegDeleteKey	Deletes a key
RegEnumKey	Enumerates subkeys of specified key
RegisterClass	Registers a window class
RegisterClipboardFormat	Registers a new clipboard format
RegisterDialogClasses	Registers dialog classes for screen-savers
RegisterWindowMessage	Defines a new unique window message
RegOpenKey	Opens a key
RegQueryValue	Retrieves text string for specified key
RegSetValue	Associates a text string with a specified key
ReleaseCapture	Releases mouse capture
ReleaseDC	Frees a device context
RemoveFontResource	Removes font resource
RemoveMenu	Deletes a menu item and pop-up menu
RemoveProp	Removes a property-list entry
ReplaceText	Creates a replace-text dialog box
ReplyMessage	Replies to a SendMessage
ResetDC	Updates a device context
ResizePalette	Changes the size of a logical palette
RestoreDC	Restores device context
RoundRect	Draws a rectangle with rounded corners
SaveDC	Saves current state of device context
ScaleViewportExt	Scales viewport extents
ScaleViewportExtEx	Scales viewport extents
ScaleWindowExt	Scales window extents
ScaleWindowExtEx	Scales window extents
ScreenSaverConfigureDialog	Processes input to screensaver config. dialog
ScreenSaverProc	Processes input to a screen-saver window
ScreenToClient	Converts screen point to client coordinates
ScrollDC	Scrolls a rectangle horizontally and vertically
ScrollWindow	Scrolls a window's client area
ScrollWindowEx	Scrolls a window's client area
SelectClipRgn	Selects clipping region for device context
SelectObject	Selects object into a device context
SelectPalette	Selects a palette into a device context
SendDlgItemMessage	Sends a message to a dialog box control
SendDriverMessage	Sends a message to an installable driver
SendMessage	Sends a message to a window
SetAbortProc	Sets the abort function for a print job
SetActiveWindow	Makes a top-level window active
SetBitmapBits	Sets bitmap bits from array of bytes
SetBitmapDimension	Sets width and height of bitmap
SetBitmapDimensionEx	Sets width and height of bitmap
SetBkColor	Sets the current background color

SetBkMode	Sets the background mode
SetBoundsRect	Controls bounding-rectangle accumulation
SetBrushOrg	Sets the origin of the current brush
SetCapture	Sets the mouse capture to a window
SetCaretBlinkTime	Sets caret blink rate
SetCaretPos	Sets the caret position
SetClassLong	Sets a long value in extra class memory
SetClassWord	Sets a word value in extra class memory
SetClipboardData	Sets the data in the clipboard
SetClipboardViewer	Adds a window to the clipboard-viewer chain
SetCommBreak	Suspends character transmission
SetCommEventMask	Enables events in a device event mask
SetCommState	Sets communications-device state
SetCursor	Changes the mouse cursor
SetCursorPos	Sets mouse-cursor position in screen coordinates
SetDIBits	Sets the bits of a bitmap
SetDIBitsToDevice	Sets DIB bits to device
SetDlgItemInt	Converts an integer to a dialog text string
SetDlgItemText	Sets dialog title or item text
SetDoubleClickTime	Sets the mouse double-click time
SetErrorMode	Controls Interrupt 24h Error Handling
SetFocus	Sets the input focus to a window
SetHandleCount	Changes the number of available file handles
SetKeyboardState	Sets the keyboard state table
SetMapMode	Sets mapping mode
SetMapperFlags	Sets font-mapper flag
SetMenu	Sets the menu for a window
SetMenuItemBitmaps	Associates bitmaps with a menu item
SetMessageQueue	Creates a new message queue
SetMetaFileBits	Creates memory block from metafile
SetMetaFileBitsBetter	Creates memory block from metafile
SetPaletteEntries	Sets colors and flags for a color palette
SetParent	Changes a child's paren window
SetPixel	Sets pixel to specified color
SetPolyFillMode	Sets the polygon-filling mode
SetProp	Adds or changes a property-list entry
SetRect	Sets a rectangle's dimensions
SetRectEmpty	Creates an empty rectangle
SetRectRgn	Changes a region into specified rectangle
SetResourceHandler	Installs a load-resource callback function
SetROP2	Sets the current drawing mode
SetScrollPos	Sets scroll-bar thumb position
SetScrollRange	Sets minimum and maximum scroll-bar positions
SetSelectorBase	Sets the base and limit of a selector
SetSelectorLimit	Sets the limit of a selector
SetSoundNoise	Obsolete
SetStretchBltMode	Sets the bitmap-stretching mode
SetSwapAreaSize	Sets the amount of memory used for code segments
SetSysColors	Sets one or more system colors
SetSysModalWindow	Makes a window the system-modal window
SetSystemPaletteUse	Use of system palette static colors
SetTextAlign	Sets text-alignment flags
SetTextCharacterExtra	Sets intercharacter spacing
SetTextColor	Sets the foreground color of text
SetTextJustification	Sets alignment for text output
SetTimer	Installs a system timer

SetViewportExt	Sets viewport extents
SetViewportExtEx	Sets viewport extents
SetViewportOrg	Sets viewport origin
SetViewportOrgEx	Sets viewport origin
SetVoiceAccent	Obsolete
SetVoiceEnvelope	Obsolete
SetVoiceNote	Obsolete
SetVoiceQueueSize	Obsolete
SetVoiceSound	Obsolete
SetVoiceThreshold	Obsolete
SetWinDebugInfo	Sets current system-debugging information
SetWindowExt	Sets window extents
SetWindowExtEx	Sets window extents
SetWindowLong	Sets a long value in extra window memory
SetWindowOrg	Sets the window origin
SetWindowOrgEx	Sets the window origin
SetWindowPlacement	Sets window show state and min/max position
SetWindowPos	Sets a windows size, position, and order
SetWindowsHook	Installs a hook function
SetWindowsHookEx	Installs a hook function
SetWindowText	Sets text in a caption title or control window
SetWindowWord	Sets a word value in extra window memory
ShellExecute	Opens or prints specified file
ShowCaret	Shows (unhides) the caret
ShowCursor	Shows or hides the mouse cursor
ShowOwnedPopups	Shows or hides pop-up windows
ShowScrollBar	Shows or hides a scroll bar
ShowWindow	Sets window visibility state
SizeofResource	Returns the size of a resource
SpoolFile	Puts a file in the spooler queue
StackTraceCSIPFirst	Retrieves information about a stack frame
StackTraceFirst	Retrieves information about the first stack frame
StackTraceNext	Retrieves information about the next stack frame
StartDoc	Starts a print job
StartPage	Prepares printer driver to receive data
StartSound	Obsolete
StopSound	Obsolete
StretchBlt	Copies a bitmap, transforming if required
StretchDIBits	Moves DIB from source to destination rectangle
SubtractRect	Creates rect from difference of two rects
SwapMouseButton	Reverses the meaning of the mouse buttons
SwapRecording	Starts or stops memory swap recording
SwitchStackBack	Restores the current-task stack
SwitchStackTo	Changes the location of the stack
SyncAllVoices	Obsolete
SystemHeapInfo	Retrieves information about the **USER** heap
SystemParametersInfo	Queries or sets systemwide parameters
TabbedTextOut	Writes a tabbed character string
TaskFindHandle	Retrieves information about a task
TaskFirst	Retrieves information about first task in task queue
TaskGetCSIP	Returns the next CS:IP value of a task.
TaskNext	Retrieves information about next task in the task queue
TaskSetCSIP	Sets the CS:IP of a sleeping task.
TaskSwitch	Switches to a specific address within a new task
TerminateApp	Terminates an application
TextOut	Writes a character string at specified location

Throw	Restores the execution environment
TimerCount	Retrieves execution times
ToAscii	Translates virtual-key code to Windows character
TrackPopupMenu	Displays and tracks a pop-up menu
TranslateAccelerator	Processes menu command keyboard accelerators
TranslateMDISysAccel	Processes MDI keyboard accelerators
TranslateMessage	Translates virtual-key messages
TransmitCommChar	Places a character in the transmit queue
UnAllocDiskSpace	Deletes the file created by AllocDiskSpace.
UnAllocFileHandles	Frees file handles allocated by AllocFileHandles.
UngetCommChar	Puts a character back in the receive queue
UnhookWindowsHook	Removes a filter function
UnhookWindowsHookEx	Removes a function from the hook chain
UnionRect	Creates the union of two rectangles
UnlockSegment	Unlocks a discardable memory segment
UnrealizeObject	Resets brush origins and realizes palettes
UnregisterClass	Removes a window class
UpdateColors	Updates colors in client area
UpdateWindow	Updates a window's client area
ValidateCodeSegments	Test for memory overwrites
ValidateFreeSpaces	Checks free memory for valid contents
ValidateRect	Removes a rectangle from the update region
ValidateRgn	Removes a region from the update region
VerFindFile	Determines where to install a file
VerInstallFile	Installs a file
VerLanguageName	Converts a binary language identifier into a string
VerQueryValue	Returns version information about a block
VkKeyScan	Translates Windows character to virtual-key code
WaitMessage	Suspends an application and yields control
WaitSoundState	Obsolete
WindowFromPoint	Returns window containing a point
WinExec	Runs a program
WinHelp	Invokes Windows Help
WNetAddConnection	Adds network connections
WNetCancelConnection	Removes network connections
WNetGetConnection	Lists network connections
WriteComm	Writes to a communications device
WritePrivateProfileString	Writes a string to an initialization file
WriteProfileString	Writes a string to WIN.INI
wsprintf	Formats a string
wvsprintf	Formats a string
XTYP_ADVDATA	Passes advise data to a client
XTYP_ADVREQ	Prompts a server to send advise data to a client
XTYP_ADVSTART	Requests an advise loop
XTYP_ADVSTOP	Ends an advise loop
XTYP_CONNECT	Requests a DDE conversation
XTYP_CONNECT_CONFIRM	Confirms a DDE conversation
XTYP_DISCONNECT	Terminates a DDE conversation
XTYP_ERROR	Notifies a DDEML application of a critical error
XTYP_EXECUTE	Executes a server command
XTYP_MONITOR	Informs a DDE monitor application of a DDE event
XTYP_POKE	Sends unsolicited data to a server
XTYP_REGISTER	Registers a service name
XTYP_REQUEST	Requests data from a server
XTYP_UNREGISTER	Unregisters a service name
XTYP_WILDCONNECT	Requests multiple DDE conversation

XTYP_XACT_COMPLETE	Confirms completion of asynchronous transaction
Yield	Stops the current task

Message groups (3.1)

Button messages

BM_GETCHECK	Retrieves the button check state
BM_GETSTATE	Determines the state of a button or check box
BM_SETCHECK	Sets the button check state
BM_SETSTATE	Sets the highlighting state of a button
BM_SETSTYLE	Sets the style of a button

Clipboard messages

WM_ASKCBFORMATNAME	Retrieves the name of the clipboard format
WM_CHANGECBCHAIN	Notifies clipboard viewer of removal from chain
WM_COPY	Copies a selection to the clipboard
WM_CUT	Deletes a selection and copies it to the clipboard
WM_DESTROYCLIPBOARD	Notifies owner that the clipboard was emptied
WM_DRAWCLIPBOARD	Indicates the clipboard's contents have changed
WM_HSCROLLCLIPBOARD	Prompts owner to scroll clipboard contents
WM_PAINTCLIPBOARD	Prompts owner to display clipboard contents
WM_PASTE	Inserts clipboard data into an edit control
WM_RENDERALLFORMATS	Notifies owner to render all clipboard formats
WM_RENDERFORMAT	Notifies owner to render clipboard data
WM_SIZECLIPBOARD	Indicates a change in the chipboard's size
WM_VSCROLLCLIPBOARD	Prompts owner to scroll clipboard contents

Combo box messages

CB_ADDSTRING	Adds a string to the list box of a combo box
CB_DELETESTRING	Deletes list-box string in a combo box
CB_DIR	Adds file names to the list box of a combo box
CB_FINDSTRING	Finds a string in the list box of a combo box
CB_GETCOUNT	Gets the number of list-box items in a combo box
CB_GETCURSEL	Gets index of selected list-box item in combo box
CB_GETDROPPEDCONTROLRECT	Gets rectangle of combo-box drop-down list box
CB_GETDROPPEDSTATE	Determines if a combo box's list box is visible
CB_GETEDITSEL	Gets position of selection in edit control
CB_GETEXTENDEDUI	Determines if combo box has extended interface
CB_GETITEMDATA	Retrieves a value associated with an item
CB_GETITEMHEIGHT	Retrieves the height of items in a combo box
CB_GETLBTEXT	Gets a string from the list box of a combo box
CB_GETLBTEXTLEN	Gets length of a list-box string in a combo box
CB_INSERTSTRING	Inserts a string into the list box of a combo box
CB_LIMITTEXT	Limits amount of edit-control text in a combo box
CB_RESETCONTENT	Removes all items from list box of a combo box
CB_SELECTSTRING	Selects a string in the list box of a combo box
CB_SETCURSEL	Selects a string in the list box of a combo box
CB_SETEDITSEL	Sets the edit-control selection of a combo box
CB_SETEXTENDEDUI	Sets the default or extended user interface
CB_SETITEMDATA	Sets the value associated with an item
CB_SETITEMHEIGHT	Sets the height of items in a combo box
CB_SHOWDROPDOWN	Shows or hides the list box of a combo box

DDE messages

WM_DDE_ACK	Acknowledges the receipt of a DDE transaction
WM_DDE_ADVISE	Starts an advise loop with a DDE server
WM_DDE_DATA	Passes a data item to a DDE client
WM_DDE_EXECUTE	Passes a command to a DDE server
WM_DDE_INITIATE	Initiates a DDE conversation
WM_DDE_POKE	Send unsolicited data to a server
WM_DDE_REQUEST	Requests a data item from a DDE server
WM_DDE_TERMINATE	Terminates a DDE conversation
WM_DDE_UNADVISE	Ends a DDE advise loop

Edit-control messages

EM_CANUNDO	Determines if edit-control operation can be undone
EM_EMPTYUNDOBUFFER	Resets (clears) the edit-control undo flag
EM_FMTLINES	Sets soft line-break characters on or off
EM_GETFIRSTVISIBLELINE	Gets index of top line in an edit control
EM_GETHANDLE	Gets the handle of the memory for an MLE
EM_GETLINE	Retrieves a line from an MLE
EM_GETLINECOUNT	Retrieves number of lines in an MLE
EM_GETMODIFY	Checks whether edit-control contents have changed
EM_GETRECT	Gets the coordinates of an edit-control rectangle
EM_GETSEL	Gets position of current edit-contol selection
EM_LIMITTEXT	Limits amount of text in an edit control
EM_LINEFROMCHAR	Retrieves a line number from a character index
EM_LINEINDEX	Retrieves the character index of an MLE line
EM_LINELENGTH	Retrieves the length of a line in an MLE
EM_LINESCROLL	Scrolls text in an MLE
EM_REPLACESEL	Replaces current selection in an edit control
EM_SETHANDLE	Sets the memory handle for an MLE
EM_SETMODIFY	Sets or clears edit-control modification flag
EM_SETPASSWORDCHAR	Sets or removes edit-control password character
EM_SETREADONLY	Sets the read-only state of an edit control
EM_SETRECT	Sets the formatting rectangle of an MLE
EM_SETRECTNP	Sets the formatting rectangle of an MLE
EM_SETSEL	Selects text within an edit control
EM_SETTABSTOPS	Sets the tab stops in an MLE
EM_SETWORDBREAKPROC	Provides custom word breaks in edit controls
EM_UNDO	Undoes the last operation in an edit control

List box messages

LB_ADDSTRING	Adds a string to a list box
LB_DELETESTRING	Deletes a string in a list box
LB_DIR	Adds file names to a list box
LB_FINDSTRING	Finds a string in a list box
LB_GETCARETINDEX	Gets index of list-box item with focus rectangle
LB_GETCOUNT	Gets the number of items in a list box
LB_GETCURSEL	Gets index of selected item in a list box
LB_GETHORIZONTALEXTENT	Gets the horizontal extent of a list box
LB_GETITEMDATA	Retrieves value associated with a list-box item
LB_GETITEMHEIGHT	Retrieves the height of items in a list box
LB_GETITEMRECT	Retrieves the bounding rectangle for an item
LB_GETSEL	Retrieves the selection state of an item
LB_GETSELCOUNT	Retrieves a count of selected list-box items
LB_GETSELITEMS	Lists item numbers of selected list-box items
LB_GETTEXT	Gets a string from a list box
LB_GETTEXTLEN	Gets the length of a string in a list box
LB_GETTOPINDEX	Retrieves index of first visible list-box item
LB_INSERTSTRING	Inserts a string into a list box
LB_RESETCONTENT	Removes all items from a list box
LB_SELECTSTRING	Selects a string in a list box
LB_SELITEMRANGE	Selects consecutive items in a list box
LB_SETCARETINDEX	Sets the focus rectangle in a list box
LB_SETCOLUMNWIDTH	Sets the width of columns in a list box
LB_SETCURSEL	Selects a string in a list box
LB_SETHORIZONTALEXTENT	Sets the horizontal extent of a list box
LB_SETITEMDATA	Associates a value with a list-box item
LB_SETITEMHEIGHT	Sets the height of items in a list box
LB_SETSEL	Selects a string in a multi-selection list box
LB_SETTABSTOPS	Sets tab stops in a list box
LB_SETTOPINDEX	Ensures that a list-box item is visible

New 3.1 messages

CB_FINDSTRINGEXACT	Finds a string in the list box of a combo box
CB_GETDROPPEDCONTROLRECT	Gets rectangle of combo-box drop-down list box
CB_GETDROPPEDSTATE	Determines if a combo box's list box is visible
CB_GETEXTENDEDUI	Selects the default or extended user interface
CB_GETITEMHEIGHT	Retrieves the height of items in a combo box
CB_SETEXTENDEDUI	Sets the default or extended user interface
CB_SETITEMHEIGHT	Sets the height of items in a combo box
EM_GETFIRSTVISIBLELINE	Gets index of top line in an edit control
EM_GETPASSWORDCHAR	Retrieves edit-control password character
EM_GETWORDBREAKPROC	Retrieves edit-control wordwrap function
EM_SETREADONLY	Sets the read-only state of an edit control
EM_SETWORDBREAKPROC	Provides custom word breaks in edit controls
LB_FINDSTRINGEXACT	Finds a string in a list box
LB_GETCARETINDEX	Gets index of list-box item with focus rectangle
LB_GETITEMHEIGHT	Retrieves the height of items in a list box
LB_SETCARETINDEX	Sets the focus rectangle in a list box
LB_SETITEMHEIGHT	Sets the height of items in a list box
STM_GETICON	Gets icon handle associated with an icon control
STM_SETICON	Associates an icon handle with an icon control
WM_CHOOSEFONT_GETLOGFONT	Retrieves **LOGFONT** for Font Dialog
WM_COMMNOTIFY	Notifies a window about the status of its queues
WM_DROPFILES	Indicates that a file has been dropped
WM_PALETTEISCHANGING	Indicates that the palette is changing
WM_POWER	Indicates the system is entering suspended mode
WM_QUEUESYNC	Delimits CBT messages
WM_SYSTEMERROR	Indicates a system error has occurred
WM_WINDOWPOSCHANGED	Notifies window of size or position change
WM_WINDOWPOSCHANGING	Notifies window of new size or position

BM_GETCHECK (2.x)

```
BM_GETCHECK
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a BM_GETCHECK message to retrieve the check state of a button.

Parameters

This message has no parameters.

Returns

The return value from a button created with the **BS_AUTOCHECKBOX**, **BS_AUTORADIOBUTTON**, BS_AUTO3STATE, **BS_CHECKBOX**, **BS_RADIOBUTTON**, or BS_3STATE style may be one of the following values:

Value	Meaning
0	Button state is unchecked.
1	Button state is checked.
2	Button state is indeterminate (applies only if the button has the BS_3STATE or BS_AUTO3STATE style).

If the button has any other style, the return value is 0.

Example

This example determines if the ID_MYCHECKBOX control is currently checked:

```
int checked;

checked = (int) SendDlgItemMessage(hwndDlg, ID_MYCHECKBOX,
    BM_GETCHECK, 0, 0);
```

See Also

BM_GETSTATE, **BM_SETCHECK**, **SendDlgItemMessage**

BM_GETSTATE (2.x)

```
BM_GETSTATE
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a BM_GETSTATE message to retrieve the state of a button.

Parameters

This message has no parameters.

Returns

The return value specifies the current state of the button. You can use the following masks to extract information about the state:

Mask	Description
0x0003	Specifies the check state (radio buttons and check boxes only). A value of 0 indicates the button is unchecked. A value of 1 indicates the button is checked. A radio button is checked when it contains a dot; a check box is checked when it contains an X. A value of 2 indicates the check state is indeterminate (3-state check boxes only). The state of a 3-state check box is indeterminate when it is grayed.
0x0004	Specifies the highlight state. A nonzero value indicates that the button is highlighted. A button is highlighted when the user presses and holds the left mouse button. The highlighting is removed when the user releases the mouse button.
0x0008	Specifies the focus state. A nonzero value indicates that the button has the focus.

Example

This example determines whether a button currently has the focus:

```
#define BFFOCUS 0x0008

DWORD dwResult;

dwResult = SendDlgItemMessage(hdlg, ID_MYBUTTON, BM_GETSTATE, 0, 0);
if (dwResult & BFFOCUS)

    /* button has the focus */
```

See Also

BM_GETCHECK, **BM_SETSTATE**

BM_SETCHECK (2.x)

```
BM_SETCHECK
wParam = (WPARAM) fCheck; /* check state            */
lParam = 0L;              /* not used, must be zero */
```

An application sends a BM_SETCHECK message to set the check state of a button.

Parameter	Description
fCheck	Value of *wParam.* Specifies the check state. This parameter can be one of the following values:

Value	Meaning
0	Set the button state to unchecked.
1	Set the button state to checked.
2	Set the button state to indeterminate. This value can be used only if the button has the BS_3STATE or BS_AUTO3STATE style.

Returns
The return value is always zero.

Comments
The BM_SETCHECK message has no effect on push buttons.

Example
This example places a dot inside a radio button:

```
SendDlgItemMessage(hdlg, ID_MYRADIOBUTTON, BM_SETCHECK, TRUE, 0);
```

See Also
BM_GETCHECK, **BM_SETSTATE**

BM_SETSTATE (2.x)

```
BM_SETSTATE
wParam = (WPARAM) fState;   /* highlight state        */
lParam = 0L;                /* not used, must be zero */
```

An application sends a BM_SETSTATE message to set the highlight state of a button.

Parameter	Description
fState	Value of *wParam.* Specifies whether the button is to be highlighted. A nonzero value highlights the button. A zero value removes any highlighting.

Returns
The return value is always zero.

Comments
Highlighting affects the exterior of a button. It has no effect on the check state of a radio button or check box.

A button is automatically highlighted when the user presses and holds the left mouse button. The highlighting is removed when the user releases the mouse button.

Example
This example highlights and then removes highlighting from a push button, simulating the visual effect of a user clicking the button:

```
SendDlgItemMessage(hdlg, ID_MYPUSHBUTTON, BM_SETSTATE, TRUE, 0);

    /*
     * Perform some action; then remove the highlighting,
     * thereby returning it to its normal state.
     */

SendDlgItemMessage(hdlg, ID_MYPUSHBUTTON, BM_SETSTATE, FALSE, 0);
```

See Also
BM_GETSTATE, **BM_SETCHECK**

BM_SETSTYLE (2.x)

```
BM_SETSTYLE
wParam =  (WPARAM) LOWORD(dwStyle); /* style       */
lParam =  MAKELPARAM(fRedraw, 0);   /* redraw flag */
```

An application sends a BM_SETSTYLE message to change the style of a button.

Parameter	Description
dwStyle	Value of *wParam.* Specifies the button style. For a list of possible buttons styles, see the **Button styles** topic.
fRedraw	Value of the low-order word of *lParam.* Specifies whether the button is to be redrawn. A value of TRUE redraws the button. A value of FALSE does not redraw the button.

Returns

The return value is always zero.

Comments

Unlike **BM_SETCHECK** and **BM_SETSTATE**, BM_SETSTYLE does not have a corresponding message to retrieve the current style. Use the **GetWindowLong** function with the **GWL_STYLE** offset to retrieve the complete button style. The low word of the complete button style is the button-specific style.

An application should not attempt to change a button's type (for example, changing a radio button to a check box).

Example

This example sends a BM_SETSTYLE message to make a button become the default push button:

```
SendDlgItemMessage(hdlg, ID_MYPUSHBUTTON, BM_SETSTYLE,
    (WPARAM) BS_DEFPUSHBUTTON, TRUE);
```

See Also

GetWindowLong

CB_ADDSTRING (3.0)

```
CB_ADDSTRING
wParam = 0;                          /* not used, must be zero   */
lParam = (LPARAM) (LPCSTR) lpsz;     /* address of string to add */
```

An application sends a CB_ADDSTRING message to add a string to the list box of a combo box. If the combo box does not have the **CBS_SORT** style, the string is added to the end of the list. Otherwise, the string is inserted into the list and the list is sorted.

Parameter	Description
lpsz	Value of *lParam.* Points to the null-terminated string to be added. If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the value of the *lpsz* parameter is stored rather than the string it would otherwise point to.

Returns

The return value is the zero-based index to the string in the list box of the combo box. The return value is CB_ERR if an error occurs; the return value is CB_ERRSPACE if insufficient space is available to store the new string.

Comments

If an owner-drawn combo box was created with the **CBS_SORT** style but not the **CBS_HASSTRINGS** style, the **WM_COMPAREITEM** message is sent one or more times to the owner of the combo box so that the new item can be properly placed in the list.

To insert a string into a specific location within the list, use the **CB_INSERTSTRING** message.

Example

This example adds the string "my string" to the list box of a combo box:

```
DWORD dwIndex;

dwIndex = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_ADDSTRING, 0, (LPARAM) ((LPSTR) "my string"));
```

See Also

CB_INSERTSTRING, **WM_COMPAREITEM**, **CB_DIR**

CB_DELETESTRING (3.0)

```
CB_DELETESTRING
wParam = (WPARAM) index;  /* item to delete         */
lParam = 0L;              /* not used, must be zero */
```

An application sends a CB_DELETESTRING message to delete a string in the list box of a combo box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the string to delete.

Returns

The return value is a count of the strings remaining in the list. The return value is CB_ERR if the *index* parameter specifies an index greater than the number of items in the list.

Comments

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, a **WM_DELETEITEM** message is sent to the owner of the combo box so that the application can free any additional data associated with the item.

Example

This example deletes the first string in a combo box:

```
DWORD dwRemaining;

dwRemaining = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_DELETESTRING, 0, 0);
```

See Also

WM_DELETEITEM, **CB_RESETCONTENT**

CB_DIR (3.0)

```
CB_DIR
wParam = (WPARAM) (UINT) uAttrs;          /* file attributes     */
lParam = (LPARAM) (LPCSTR) lpszFileSpec; /* address of filename */
```

An application sends a CB_DIR message to add a list of filenames to the list box of a combo box.

Parameter	Description
uAttrs	Value of *wParam.* Specifies the attributes of the files to be added to the list box. It can be any combination of the following values:

Value	Meaning
DDL_READWRITE	File can be read from or written to.
DDL_READONLY	File can be read from but not written to.
DDL_HIDDEN	File is hidden and does not appear in a directory listing.
DDL_SYSTEM	File is a system file.
DDL_DIRECTORY	The name pointed to by the *lpszFileSpec* parameter specifies a directory.
DDL_ARCHIVE	File has been archived.
DDL_DRIVES	All drives that match the name specified by the *lpszFileSpec* parameter are included. If the **DDL_DRIVES** flag is set, the **DDL_EXCLUSIVE** flag is set automatically. Therefore, to create a directory listing that includes drives and files, the developer must send this message twice: once with the DDL_DRIVES flag set and once with the flags for the rest of the list.
DDL_EXCLUSIVE	Exclusive flag. If the exclusive flag is set, only files of the specified type are listed. Otherwise, files of the specified type are listed in addition to files that do not match the specified type.

lpszFileSpec	Value of *lParam.* Points to the null-terminated string that specifies the filename to add to the list. If the filename contains any wildcards (for example, *.*), all files that match and have the attributes specified by the *uAttrs* parameter will be added to the list.

Returns

The return value is the zero-based index of the last filename added to the list. The return value is CB_ERR if an error occurs. The return value is CB_ERRSPACE if insufficient space is available to store the new strings.

Example

This example adds the names of all available drives to a combo box:

```
DWORD dwIndexLastItem;

dwIndexLastItem = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX, CB_DIR,
    0x4000 | 0x8000, (LPARAM) ((LPSTR) "*"));
```

See Also

DlgDirList, **DlgDirListComboBox**, **CB_ADDSTRING**, **CB_INSERTSTRING**

CB_FINDSTRING (3.0)

```
CB_FINDSTRING
wParam = (WPARAM) indexStart;        /* item before start of search */
lParam = (LPARAM) (LPCSTR) lpszFind; /* address of prefix string    */
```

An application sends a CB_FINDSTRING message to search the list box of a combo box for an item that begins with the characters in a specified string.

Parameter	Description
indexStart	Value of *wParam.* Specifies the zero-based index of the item before the first item to be searched. When the search reaches the bottom of the list box, it continues from the top of the list box back to the item specified by the *indexStart* parameter. If *indexStart* is -1, the entire list box is searched from the beginning.
lpszFind	Value of *lParam.* Points to the null-terminated string that contains the prefix to search for. The search is not case-sensitive, so this string can contain any combination of uppercase and lowercase letters.

Returns

The return value is the zero-based index of the matching item, or it is CB_ERR if the search was unsuccessful.

Comments

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the action taken by the CB_FINDSTRING message depends on whether the **CBS_SORT** style is used. If the CBS_SORT style is used, **WM_COMPAREITEM** messages are sent to the owner of the combo box to determine which item matches the specified string. Otherwise, CB_FINDSTRING attempts to match the doubleword value against the value of the *lpszFind* parameter.

Example

This example searches for the string "my string" in a combo box and copies it, if found, to the szBuf buffer:

```
char szBuf[20];
DWORD dwIndex;

dwIndex = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_FINDSTRING, 0, (LPARAM) ((LPSTR) "my string"));
if (dwIndex != CB_ERR)
    SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
        CB_GETLBTEXT, (WPARAM) dwIndex, (LPARAM) ((LPSTR) szBuf));
```

See Also

CB_FINDSTRINGEXACT, **CB_SELECTSTRING**, **WM_COMPAREITEM**

CB_FINDSTRINGEXACT (3.1)

```
CB_FINDSTRINGEXACT
wParam = (WPARAM) indexStart;        /* item before start of search */
lParam = (LPARAM) (LPCSTR) lpszFind; /* address of prefix string    */
```

An application sends a CB_FINDSTRINGEXACT message to find the first list box string (in a combo box) that matches the string specified in the *lpszFind* parameter.

Parameter	Description
indexStart	Value of *wParam.* Specifies the zero-based index of the item before the first item to be searched. When the search reaches the bottom of the list box, it continues from the top of the list box back to the item specified by the *indexStart* parameter. If *indexStart* is -1, the entire list box is searched from the beginning.
lpszFind	Value of *lParam.* Points to the null-terminated string to search for. This string can contain a complete filename, including the extension. The search is not case-sensitive, so this string can contain any combination of uppercase and lowercase letters.

Returns

The return value is the zero-based index of the matching item, or it is CB_ERR if the search was unsuccessful.

Comments

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the action taken by the CB_FINDSTRINGEXACT message depends on whether the **CBS_SORT** style is used. If the CBS_SORT style is used, **WM_COMPAREITEM** messages are sent to the owner of the combo box to determine which item matches the specified string. Otherwise, CB_FINDSTRINGEXACT attempts to match the doubleword value against the value of the *lpszFind* parameter.

Example

This example searches for the string "my string" in a combo box and copies it, if found, to the *szBuf* buffer:

```
char szBuf[20];
DWORD dwIndex;

dwIndex = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_FINDSTRINGEXACT, 0, (LPARAM) ((LPSTR) "my string"));
if (dwIndex != CB_ERR)
    SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
        CB_GETLBTEXT, (WPARAM) dwIndex, (LPARAM) ((LPSTR) szBuf));
```

See Also

CB_FINDSTRING, **CB_SELECTSTRING**, **WM_COMPAREITEM**

CB_GETCOUNT (3.0)

```
CB_GETCOUNT
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a CB_GETCOUNT message to retrieve the number of items in the list box of a combo box.

Parameters

This message has no parameters.

Returns

The return value is the number of items in the list box.

Comments

The returned count is one greater than the index value of the last item (the index is zero-based).

Example

This example retrieves the number of items in a combo box:

```
WORD cListItems;

cListItems = (WORD) SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_GETCOUNT, 0, 0);
```

CB_GETCURSEL (3.0)

```
CB_GETCURSEL
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a CB_GETCURSEL message to retrieve the index of the currently selected item, if any, in the list box of a combo box.

Parameters

This message has no parameters.

Returns

The return value is the zero-based index of the currently selected item, or it is CB_ERR if no item is selected.

Example

This example retrieves the index of the currently selected string in the list box of a combo box and then retrieves that string:

```
char szBuf[20];
DWORD dwIndex;

dwIndex = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX, CB_GETCURSEL, 0, 0);
if (dwIndex != CB_ERR)
    SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
        CB_GETLBTEXT, (WPARAM) dwIndex, (LPARAM) ((LPSTR) szBuf));
```

See Also

CB_SELECTSTRING, CB_SETCURSEL

CB_GETDROPPEDCONTROLRECT (3.1)

```
CB_GETDROPPEDCONTROLRECT
wParam = 0;                              /* not used, must be zero    */
lParam = (LPARAM) (RECT FAR*) lprc;      /* address of RECT structure */
```

An application sends a CB_GETDROPPEDCONTROLRECT message to retrieve the screen coordinates of the visible (dropped-down) list box of a combo box.

Parameter	Description
lprc	Value of *lParam.* Points to the **RECT** structure that is to receive the coordinates.

Returns

The return value is always CB_OKAY.

Example

This example retrieves the bounding rectangle of the list box of a combo box:

```
RECT rcl;

SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_GETDROPPEDCONTROLRECT, 0, (DWORD) ((LPRECT) &rcl));
```

CB_GETDROPPEDSTATE (3.1)

```
CB_GETDROPPEDSTATE
wParam = 0;     /* not used, must be zero */
lParam = 0L;    /* not used, must be zero */
```

An application sends a CB_GETDROPPEDSTATE message to determine whether the list box of a combo box is visible (dropped down).

Parameters

This message has no parameters.

Returns

The return value is nonzero if the list box is visible; otherwise, it is zero.

Example

This example determines whether the list box of a combo box is visible:

```
BOOL fDropped;

fDropped = (BOOL) SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_GETDROPPEDSTATE, 0, 0L);
```

See Also

CB_SHOWDROPDOWN

CB_GETEDITSEL (2.x)

```
CB_GETEDITSEL
wParam = 0;     /* not used, must be zero */
lParam = 0L;    /* not used, must be zero */
```

An application sends a CB_GETEDITSEL message to retrieve the starting and ending character positions of the current selection in the edit control of a combo box.

Parameters

This message has no parameters.

Returns

The return value is a doubleword value that contains the starting position in the low-order word and the position of the first nonselected character after the end of the selection in the high-order word.

Example

This example retrieves the selection positions of the edit control of a combo box, and converts them into starting and ending positions:

```
DWORD dwResult;
WORD wStart, wEnd;

dwResult = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
        CB_GETEDITSEL, 0, 0);
wStart = LOWORD(dwResult);
wEnd   = HIWORD(dwResult);
```

See Also

CB_SETEDITSEL

CB_GETEXTENDEDUI (3.1)

```
CB_GETEXTENDEDUI
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a CB_GETEXTENDEDUI message to determine whether a combo box has the default user interface or the extended user interface.

Parameters

This message has no parameters.

Returns

The return value is nonzero if the combo box has the extended user interface; otherwise, it is zero.

Comments

The extended user interface differs from the default user interface in the following ways:

- Clicking the static control displays the list box (**CBS_DROPDOWNLIST** style only).
- Pressing the DOWN ARROW key displays the list box (F4 is disabled).
- Scrolling in the static control is disabled when the item list is not visible (arrow keys are disabled).

Example

This example determines whether a combo box has the extended user interface:

```
BOOL fExtended;

fExtended = (BOOL) SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_GETEXTENDEDUI, 0, 0L);
```

See Also

CB_SETEXTENDEDUI

CB_GETITEMDATA (3.0)

```
CB_GETITEMDATA
wParam = (WPARAM) index;  /* item index             */
lParam = 0L;              /* not used, must be zero */
```

An application sends a CB_GETITEMDATA message to a combo box to retrieve the application-supplied doubleword value associated with the specified item in the combo box. (This is the value in the *lParam* parameter of a **CB_SETITEMDATA** message.)

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item.

Returns

The return value is the doubleword value associated with the item, or it is CB_ERR if an error occurs.

See Also

CB_SETITEMDATA

CB_GETITEMHEIGHT (3.1)

```
CB_GETITEMHEIGHT
wParam = (WPARAM) index;  /* item index             */
lParam = 0L;              /* not used, must be zero */
```

An application sends a CB_GETITEMHEIGHT message to retrieve the height of list items in a combo box.

Parameter	Description
index	Value of *wParam.* Specifies the component of the combo box whose height is to be retrieved. If the *index* parameter is -1, the height of the edit-control (or static-text) portion of the combo box is retrieved. If the combo box has the **CBS_OWNERDRAWVARIABLE** style, *index* specifies the zero-based index of the list item whose height is to be retrieved. Otherwise, *index* should be set to zero.

Returns

The return value is the height, in pixels, of the list items in a combo box. The return value is the height of the item specified by the *index* parameter if the combo box has the **CBS_OWNERDRAWVARIABLE** style. The return value is the height of the edit-control (or static-text) portion of the combo box if *index* is -1. The return value is CB_ERR if an error occurred.

Example

This example sends a CB_GETITEMHEIGHT message to retrieve the height of the list items in a combo box:

```
LRESULT lrHeight;

lrHeight = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_GETITEMHEIGHT, 0, 0L);
```

See Also

CB_SETITEMHEIGHT, **WM_MEASUREITEM**

CB_GETLBTEXT (3.0)

```
CB_GETLBTEXT
wParam = (WPARAM) index;                /* item index        */
lParam = (LPARAM) (LPCSTR) lpszBuffer;  /* address of buffer */
```

An application sends a CB_GETLBTEXT message to retrieve a string from the list box of a combo box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the string to retrieve.
lpszBuffer	Value of *lParam.* Points to the buffer that receives the string. The buffer must have sufficient space for the string and a terminating null character. A **CB_GETLBTEXTLEN** message can be sent before the CB_GETLBTEXT message to retrieve the length, in bytes, of the string.

Returns

The return value is the length of the string, in bytes, excluding the terminating null character. If the *index* parameter does not specify a valid index, the return value is CB_ERR.

Comments

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the buffer pointed to by the *lpszBuffer* parameter of the message receives the doubleword value associated with the item.

Example

This example retrieves the length of the first item in the list box of a combo box, allocates sufficient memory for the string, and sends a CB_GETLBTEXT message to retrieve the string:

```
DWORD cbItemString;
PSTR psz;

cbItemString = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_GETLBTEXTLEN, 0, 0);
if (cbItemString != CB_ERR) {
    psz = (PSTR) LocalAlloc(LMEM_FIXED, (WORD) cbItemString);
    SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
        CB_GETLBTEXT, 0, (LPARAM) ((LPSTR) psz));
}
```

See Also

CB_GETLBTEXTLEN

CB_GETLBTEXTLEN (3.0)

```
CB_GETLBTEXTLEN
wParam = (WPARAM) index;  /* item index             */
lParam = 0L;              /* not used, must be zero */
```

An application sends a CB_GETLBTEXTLEN message to retrieve the length of a string in the list box of a combo box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the string.

Returns

The return value is the length of the string, in bytes, excluding the terminating null character. If the *index* parameter does not specify a valid index, the return value is CB_ERR.

Example

This example retrieves the length of the first item in the list box of a combo box:

```
DWORD cbItemString;

cbItemString = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_GETLBTEXTLEN, 0, 0);
```

See Also

CB_GETLBTEXT

CB_INSERTSTRING (3.0)

```
CB_INSERTSTRING
wParam = (WPARAM) index;            /* item index                  */
lParam = (LPARAM) (LPCSTR) lpsz;    /* address of string to insert */
```

An application sends a CB_INSERTSTRING message to insert a string into the list box of a combo box. Unlike the **CB_ADDSTRING** message, the CB_INSERTSTRING message does not cause a list with the **CBS_SORT** style to be sorted.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the position at which to insert the string. If this parameter is -1, the string is added to the end of the list.
lpsz	Value of *lParam.* Points to the null-terminated string that is to be inserted. If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the value of the *lpsz* parameter is stored rather than the string it would otherwise point to.

Returns

The return value is the index of the position at which the string was inserted. The return value is CB_ERR if an error occurs. The return value is CB_ERRSPACE if insufficient space is available to store the new string.

Example

This example inserts the string "my string" into the third position in the list box of a combo box:

```
SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_INSERTSTRING, 2, (LPARAM) ((LPSTR) "my string"));
```

See Also

CB_ADDSTRING, **CB_DIR**

CB_LIMITTEXT (3.0)

```
CB_LIMITTEXT
wParam = (WPARAM) cchLimit;    /* maximum number of characters */
lParam = 0L;                   /* not used, must be zero       */
```

An application sends a CB_LIMITTEXT message to limit the length of the text that the user may type in the edit control of a combo box.

Parameter	Description
cchLimit	Value of *wParam.* Specifies the length, in bytes, of the text the user can enter. If this parameter is zero, the text length is set to 65,535 bytes.

Returns

The return value is 1 if the message is successful. If this message is sent to a combo box with the style **CBS_DROPDOWNLIST**, the return value is CB_ERR.

Comments

If the combo box does not have the style **CBS_AUTOHSCROLL**, setting the text limit to be larger than the size of the edit control has no effect.

The CB_LIMITTEXT message limits only the text the user can enter. It has no effect on any text already in the edit control when the message is sent, nor does it affect the length of the text copied to the edit control when a string in the list box is selected.

Example

This example limits the text of the edit control of a combo box to five characters:

```
SendDlgItemMessage(hdlg, ID_MYCOMBOBOX, CB_LIMITTEXT, 5, 0);
```

CB_RESETCONTENT (3.0)

```
CB_RESETCONTENT
wParam = 0;     /* not used, must be zero */
lParam = 0L;    /* not used, must be zero */
```

An application sends a CB_RESETCONTENT message to remove all items from the list box and edit control of a combo box.

Parameters

This message has no parameters.

Returns

The return value is always CB_OKAY.

Comments

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the owner of the combo box receives a **WM_DELETEITEM** message for each item in the combo box.

Example

This example removes all items from the list box and edit control of a combo box:

```
SendDlgItemMessage(hdlg, ID_MYCOMBOBOX, CB_RESETCONTENT, 0, 0);
```

See Also

CB_DELETESTRING, **WM_DELETEITEM**

CB_SELECTSTRING (3.0)

```
CB_SELECTSTRING
wParam = (WPARAM) indexStart;          /* item before first selection */
lParam = (LPARAM) (LPCSTR) lpszSelect; /* address of prefix string    */
```

An application sends a CB_SELECTSTRING message to search the list box of a combo box for an item that begins with the characters in a specified string. If a matching item is found, the item is selected and copied to the edit control.

Parameter	Description
indexStart	Value of *wParam.* Specifies the zero-based index of the item before the first item to be searched. When the search reaches the bottom of the list box, it continues from the top of the list box back to the item specified by the *indexStart* parameter. If *indexStart* is -1, the entire list box is searched from the beginning.
lpszSelect	Value of *lParam.* Points to the null-terminated string that contains the prefix to search for. The search is not case-sensitive, so this string can contain any combination of uppercase and lowercase letters.

Returns

The return value is the index of the selected item if the string was found. The return value is CB_ERR and the current selection is not changed if the search was unsuccessful.

Comments

A string is selected only if its initial characters (from the starting point) match the characters in the prefix string.

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the action taken by the CB_SELECTSTRING message depends on whether the **CBS_SORT** style is used. If the CBS_SORT style is used, **WM_COMPAREITEM** messages are sent to the owner of the combo box to determine which item matches the specified string. Otherwise, CB_SELECTSTRING attempts to match the doubleword value against the value of the *lpszFind* parameter.

Example

This example searches the entire list box of a combo box for the string "my string" and, if the string is found, selects it:

```
DWORD dwIndexFoundString;

dwIndexFoundString = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_SELECTSTRING, -1, (LPARAM) ((LPSTR) "my string"));
```

See Also

CB_FINDSTRING, **CB_FINDSTRINGEXACT**, **CB_SETCURSEL**, **WM_COMPAREITEM**

CB_SETCURSEL (3.0)

```
CB_SETCURSEL
wParam = (WPARAM) index;  /* item index             */
lParam = 0L;              /* not used, must be zero */
```

An application sends a CB_SETCURSEL message to select a string in the list box of a combo box. If necessary, the list box scrolls the string into view (if the list box is visible). The text in the edit control of the combo box is changed to reflect the new selection. Any previous selection in the list box is removed.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the string to select. If the *index* parameter is -1, any current selection in the list box is removed and the edit control is cleared.

Returns

The return value is the index of the item selected if the message is successful. The return value is CB_ERR if the *index* parameter is greater than the number of items in the list or if *index* is set to -1 (which clears the selection).

Example

This example retrieves the number of items in the list box of a combo box and sends a CB_SETCURSEL message to select the last item in the list:

```
WORD cListItems;

cListItems = (WPARAM) SendDlgItemMessage(hdlg,
    ID_MYCOMBOBOX, CB_GETCOUNT, 0, 0);
SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_SETCURSEL,
    cListItems - 1,   /* zero-based index, so subtract one from total */
    0);
```

See Also

CB_GETCURSEL, **CB_SELECTSTRING**

CB_SETEDITSEL (3.0)

```
CB_SETEDITSEL
wParam = 0;                                  /* not used, must be zero  */
lParam = MAKELPARAM((ichStart), (ichEnd);  /* start and end positions */
```

An application sends a CB_SETEDITSEL message to select characters in the edit control of a combo box.

Parameter	Description
ichStart	Value of the low-order word of *lParam.* Specifies the starting position. If this parameter is set to -1, the selection, if any, is removed.
ichEnd	Value of the high-order word of *lParam.* Specifies the ending position. If this parameter is set to -1, all text from the starting position to the last character in the edit control is selected.

Returns

The return value is nonzero if the message is successful. It is CB_ERR if the message is sent to a combo box with the **CBS_DROPDOWNLIST** style.

Comments

The positions are zero-based. To select the first character of the edit control, you specify a starting position of zero. The ending position is for the character just after the last character to select. For example, to select the first four characters of the edit control, you would use a starting position of 0 and an ending position of 4.

Example

This example selects the first four characters of the edit control of a combo box:

```
SendDlgItemMessage(hdlg, ID_MYCOMBOBOX,
    CB_SETEDITSEL, 0, MAKELONG(0, 4));
```

See Also

CB_GETEDITSEL

CB_SETEXTENDEDUI (3.1)

```
CB_SETEXTENDEDUI
wParam = (WPARAM) (BOOL) fExtended;      /* extended UI flag       */
lParam = 0L;                             /* not used, must be zero */
```

An application sends a CB_SETEXTENDEDUI message to select either the default user interface or the extended user interface for a combo box that has the **CBS_DROPDOWN** or **CBS_DROPDOWNLIST** style.

Parameter	Description
fExtended	Value of *wParam.* Specifies whether the combo box should use the extended user interface or the default user interface. A value of TRUE selects the extended user interface; a value of FALSE selects the standard user interface.

Returns

The return value is CB_OKAY if the operation is successful, or it is CB_ERR if an error occurred.

Comments

The extended user interface differs from the default user interface in the following ways:

- Clicking the static control displays the list box (**CBS_DROPDOWNLIST** style only).
- Pressing the DOWN ARROW key displays the list box (F4 is disabled).
- Scrolling in the static control is disabled when the item list is not visible (the arrow keys are disabled).

Example

This example selects the extended user interface for a combo box:

```
SendDlgItemMessage(hdlg, ID_MYCOMBOBOX, CB_SETEXTENDEDUI,
    TRUE, 0L);
```

See Also

CB_GETEXTENDEDUI

CB_SETITEMDATA (3.0)

```
CB_SETITEMDATA
wParam = (WPARAM) index;            /* item index */
lParam = (LPARAM) (DWORD) dwData;   /* item data  */
```

An application sends a CB_SETITEMDATA message to set the doubleword value associated with the specified item in a combo box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index to the item.
dwData	Value of *lParam.* Specifies the new value to be associated with the item.

Returns

The return value is CB_ERR if an error occurs.

See Also

CB_GETITEMDATA

CB_SETITEMHEIGHT (3.1)

```
CB_SETITEMHEIGHT
wParam = (WPARAM) index;        /* item index  */
lParam = (LPARAM) (int) height; /* item height */
```

An application sends a CB_SETITEMHEIGHT message to set the height of list items in a combo box or the height of the edit-control (or static-text) portion of a combo box.

Parameter	Description
index	Value of *wParam.* Specifies whether the height of list items or the height of the edit-control (or static-text) portion of the combo box is set. If the combo box has the **CBS_OWNERDRAWVARIABLE** style, the *index* parameter specifies the zero-based index of the list item whose height is to be set; otherwise, *index* must be zero and the height of all list items will be set. If *index* is -1, the height of the edit-control or static-text portion of the combo box is to be set.
height	Value of the low-order word of *lParam.* Specifies the height, in pixels, of the combo box component identified by *index.*

Returns

The return value is CB_ERR if the index or height is invalid.

Comments

The height of the edit-control (or static-text) portion of the combo box is set independently of the height of the list items. An application must ensure that the height of the edit-control (or static-text) portion isn't smaller than the height of a particular list box item.

Example

This example sends a CB_SETITEMHEIGHT message to set the height of list items in a combo box:

```
LPARAM lrHeight;

SendDlgItemMessage(hdlg, ID_MYCOMBOBOX, CB_SETITEMHEIGHT,
    0, lrHeight);
```

See Also

CB_GETITEMHEIGHT, **WM_MEASUREITEM**

CB_SHOWDROPDOWN (3.0)

```
CB_SHOWDROPDOWN
wParam = (WPARAM) (BOOL) fShow;      /* the show/hide flag     */
lParam = 0L;                         /* not used, must be zero */
```

An application sends a CB_SHOWDROPDOWN message to show or hide the list box of a combo box that has the **CBS_DROPDOWN** or **CBS_DROPDOWNLIST** style.

Parameter	Description
fShow	Value of *wParam.* Specifies whether the drop-down list box is to be shown or hidden. A value of TRUE shows the list box. A value of FALSE hides the list box.

Returns
The return value is always nonzero.

Comments
This message has no effect on a combo box created with the **CBS_SIMPLE** style.

Example
This example shows the list box of a combo box:

```
SendDlgItemMessage(hdlg, ID_MYCOMBOBOX, CB_SHOWDROPDOWN, TRUE, 0);
```

See Also
CB_GETDROPPEDSTATE

DM_GETDEFID

```
DM_GETDEFID
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a DM_GETDEFID message to get the identifier of the default push button for a dialog box.

Parameters

This message has no parameters.

Returns

The return value is a doubleword value. If the default push button has an identifier value, the high-order word contains DC_HASDEFID and the low-order word contains the identifier value. The return value is zero if the default push button does not have an identifier value.

Example

This example gets the identifier of the default push button of a dialog box:

```
DWORD dwResult;
WORD idDefPushButton;

dwResult = SendMessage(hdlg, DM_GETDEFID, 0, 0);
if (HIWORD(dwResult) == DC_HASDEFID)
    idDefPushButton = LOWORD(dwResult);
```

See Also

DM_SETDEFID

DM_SETDEFID (2.x)

```
DM_SETDEFID
wIDPushBtn = wParam; /* identifier of new default push button */
```

An application sends a DM_SETDEFID message to change the identifier of the default push button for a dialog box.

Parameter	Description
wIDPushBtn	Value of *wParam.* Specifies the identifier of the push button that will become the default.

Returns

The return value is always nonzero.

See Also

DM_GETDEFID

EM_CANUNDO (2.x)

```
EM_CANUNDO
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_CANUNDO message to determine whether an edit-control operation can be undone.

Parameters

This message has no parameters.

Returns

The return value is nonzero if the last edit operation can be undone, or it is zero if the last edit operation cannot be undone.

Example

This example sends an EM_CANUNDO message to determine whether the last edit-control operation can be undone and, if so, sends an **EM_UNDO** message to undo the last operation:

```
if (SendDlgItemMessage(hdlg, ID_MYEDITCONTROL, EM_CANUNDO, 0, 0))
    SendDlgItemMessage(hdlg, ID_MYEDITCONTROL, EM_UNDO, 0, 0);
```

See Also

EM_EMPTYUNDOBUFFER, **EM_UNDO**

EM_EMPTYUNDOBUFFER (3.0)

```
EM_EMPTYUNDOBUFFER
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_EMPTYUNDOBUFFER message to reset (clear) the undo flag of an edit control. The undo flag is set whenever an operation within the edit control can be undone.

Parameters

This message has no parameters.

Returns
This message does not return a value.

Comments
The undo flag is automatically cleared whenever the edit control receives a **WM_SETTEXT** or **EM_SETHANDLE** message.

Example
This example resets the undo flag of an edit control:

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL, EM_EMPTYUNDOBUFFER, 0, 0);
```

See Also
EM_CANUNDO, **EM_UNDO**

EM_FMTLINES (2.x)

```
EM_FMTLINES
wParam = (WPARAM) (BOOL) fAddEOL;   /* line break flag        */
lParam = 0L;                        /* not used, must be zero */
```

An application sends an EM_FMTLINES message to set the inclusion of soft line break characters on or off within a multiline edit control. A soft line break consists of two carriage returns and a linefeed inserted at the end of a line that is broken because of wordwrapping.

This message is processed only by multiline edit controls.

Parameter	Description
fAddEOL	Value of *wParam.* Specifies whether soft line break characters are to be inserted. A value of TRUE inserts the characters; a value of FALSE removes them.

Returns

The return value is identical to the *fAddEOL* parameter.

Comments

This message affects only the buffer returned by the **EM_GETHANDLE** message and the text returned by the **WM_GETTEXT** message. It has no effect on the display of the text within the edit control.

A line that ends with a hard line break is not affected by the EM_FMTLINES message. A hard line break consists of one carriage return and a linefeed.

Example

This example sends an EM_FMTLINES message to turn off soft line breaks, then allocates a buffer for the text, and then retrieves the text by sending a **WM_GETTEXT** message:

```
WPARAM cbText;
HGLOBAL hmem;
LPSTR lpstr;

SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_FMTLINES, FALSE, 0);

cbText = (WPARAM) SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    WM_GETTEXTLENGTH, 0, 0);
cbText++;       /* make room for the terminating null character */
hmem = (HGLOBAL) GlobalAlloc(GMEM_MOVEABLE, (DWORD) cbText);
lpstr = GlobalLock(hmem);
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    WM_GETTEXT, cbText, (LPARAM) lpstr);
```

See Also

EM_GETWORDBREAKPROC, **EM_SETWORDBREAKPROC**

EM_GETFIRSTVISIBLELINE (3.1)

```
EM_GETFIRSTVISIBLELINE
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_GETFIRSTVISIBLELINE message to determine the topmost visible line in an edit control.

Parameters

This message has no parameters.

Returns

The return value is the zero-based index of the topmost visible line. For single-line edit controls, the return value is zero.

Example

This example gets the index of the topmost visible line in an edit control:

```
int FirstVis;

FirstVis = (int) SendDlgItemMessage(hdlg, IDD_EDIT,
    EM_GETFIRSTVISIBLELINE, 0, 0L);
```

EM_GETHANDLE (2.x)

```
EM_GETHANDLE
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_GETHANDLE message to retrieve a handle to the memory currently allocated for a multiline edit control. The handle is a local memory handle and can be used by any of the functions that take a local memory handle as a parameter.

This message is processed only by multiline edit controls.

Parameters

This message has no parameters.

Returns

The return value is a local memory handle identifying the buffer that holds the contents of the edit control. If an error occurs, such as sending the message to a single-line edit control, the return value is zero.

Comments

An application can send this message to a multiline edit control in a dialog box only if it created the dialog box with the **DS_LOCALEDIT** style flag set. If the DS_LOCALEDIT style is not set, the return value is still nonzero, but the return value will not be meaningful.

Example

This example sends an EM_GETHANDLE message to a multiline edit control and calls the **LocalSize** function to determine the current size of the edit control using the handle returned by the EM_GETHANDLE message:

```
HANDLE hmemMle;
WORD cbMle;

hmemMle = (HLOCAL) SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_GETHANDLE, 0, 0);
cbMle = LocalSize(hmemMle);
```

See Also

EM_SETHANDLE

EM_GETLINE (2.x)

```
EM_GETLINE
wParam = (WPARAM) line;          /* line number to retrieve    */
lParam = (LPARAM) (LPSTR) lpch; /* address of buffer for line */
```

An application sends an EM_GETLINE message to retrieve a line of text from an edit control.

Parameter	Description
line	Value of *wParam.* Specifies the line number of the line to retrieve from a multiline edit control. Line numbers are zero-based; a value of zero specifies the first line. This parameter is ignored by a single-line edit control.
lpch	Value of *lParam.* Points to the buffer that receives a copy of the line. The first word of the buffer specifies the maximum number of bytes that can be copied to the buffer.

Returns

The return value is the number of bytes actually copied. The return value is zero if the line number specified by the *line* parameter is greater than the number of lines in the edit control.

Comments

The copied line does not contain a terminating null character.

Example

This example sets the maximum size of the buffer, sends an EM_GETLINE message to get the first line of the multiline edit control, and adds a terminating null character to the end of the retrieved line:

```
unsigned char szBuf[128];
WORD cbText;

*(WORD *) szBuf = sizeof(szBuf) - 1; /* sets the buffer size   */
cbText = (WORD) SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_GETLINE,
    0,                           /* line number               */
    (DWORD) (LPSTR) szBuf);      /* buffer address            */
szBuf[cbText] = '\0';            /* terminating null character */
```

See Also

EM_LINELENGTH, **WM_GETTEXT**

EM_GETLINECOUNT (2.x)

```
EM_GETLINECOUNT
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_GETLINECOUNT message to retrieve the number of lines in a multiline edit control.

This message is processed only by multiline edit controls.

Parameters

This message has no parameters.

Returns

The return value is an integer containing the number of lines in the multiline edit control. If no text is in the edit control, the return value is 1.

Example

This example sends an EM_GETLINECOUNT message to retrieve the number of lines in a multiline edit control and then sends an **EM_LINESCROLL** message to scroll the edit control so that the last line is displayed at the top of the edit control.

```
int cLines;

cLines = (int) SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_GETLINECOUNT, 0, 0);
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_LINESCROLL, 0, MAKELONG(cLines - 1, 0));
```

EM_GETMODIFY (2.x)

```
EM_GETMODIFY
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_GETMODIFY message to determine whether the contents of an edit control have been modified.

Parameters

This message has no parameters.

Returns

The return value is nonzero if the edit-control contents have been modified, or it is zero if the contents have remained unchanged.

Comments

Windows maintains an internal flag indicating whether the contents of the edit control have been changed. This flag is cleared when the edit control is first created; or an **EM_SETMODIFY** message can be sent to clear the flag.

Example

This example sends an EM_GETMODIFY message to determine whether the edit control has been modified and, if it has, retrieves the current contents of the edit control and clears the modification flag by sending an **EM_SETMODIFY** message:

```
char szBuf[128];

if (SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
        EM_GETMODIFY, 0, 0)) {
    SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
        WM_GETTEXT, sizeof(szBuf), (LPARAM) ((LPSTR) szBuf));
    SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
        EM_SETMODIFY, FALSE, 0);
}
```

See Also

EM_SETMODIFY

EM_GETPASSWORDCHAR (3.1)

```
EM_GETPASSWORDCHAR
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_GETPASSWORDCHAR message to retrieve the password character displayed in an edit control when the user enters text.

Parameters

This message has no parameters.

Returns

The return value specifies the character to be displayed in place of the character typed by the user. The return value is NULL if no password character exists.

Comments

If the edit control is created with the **ES_PASSWORD** style, the default password character is set to an asterisk (*).

See Also

EM_SETPASSWORDCHAR

EM_GETRECT (2.x)

```
EM_GETRECT
wParam = 0;                          /* not used, must be zero    */
lParam = (LPARAM) (RECT FAR*) lprc; /* address of RECT structure */
```

An application sends an EM_GETRECT message to retrieve the formatting rectangle of an edit control. The formatting rectangle is the limiting rectangle of the text. The limiting rectangle is independent of the size of the edit-control window.

Parameter	Description
lprc	Value of *lParam.* Points to the **RECT** structure that receives the formatting rectangle.

Returns
The return value is not a meaningful value.

Comments
The formatting rectangle of a multiline edit control can be modified by the **EM_SETRECT** and **EM_SETRECTNP** messages.

Example
This example sends an EM_GETRECT message to retrieve the formatting rectangle of an edit control:

```
RECT rcl;

SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_GETRECT, 0, (DWORD) ((LPRECT) &rcl));
```

See Also
EM_SETRECT, **EM_SETRECTNP**, **RECT**

EM_GETSEL (2.x)

```
EM_GETSEL
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_GETSEL message to get the starting and ending character positions of the current selection in an edit control.

Parameters

This message has no parameters.

Returns

The return value is a doubleword value that contains the starting position in the low-order word and the position of the first nonselected character after the end of the selection in the high-order word.

Example

This example gets the selection positions of an edit control and converts them into starting and ending positions:

```
DWORD dwResult;
WORD wStart, wEnd;

dwResult = SendDlgItemMessage(hdlg, ID_MYCOMBOBOX, EM_GETSEL, 0, 0);
wStart = LOWORD(dwResult);
wEnd   = HIWORD(dwResult);
```

See Also

EM_REPLACESEL, **EM_SETSEL**

EM_GETWORDBREAKPROC (3.1)

```
EM_GETWORDBREAKPROC
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends the EM_GETWORDBREAKPROC message to an edit control to retrieve the current wordwrap function.

Parameters

This message has no parameters.

Returns

The return value specifies the procedure-instance address of the application-defined wordwrap function. The return value is NULL if no wordwrap function exists.

Comments

A wordwrap function scans a text buffer (which contains text to be sent to the display), looking for the first word that does not fit on the current display line. The wordwrap function places this word at the beginning of the next line on the display. A wordwrap function defines at what point Windows should break a line of text for multiline edit controls, usually at a space character that separates two words.

See Also

EM_FMTLINES, **EM_SETWORDBREAKPROC**, **MakeProcInstance**, **WordBreakProc**

EM_LIMITTEXT (2.x)

```
EM_LIMITTEXT
wParam = (WPARAM) cchMax;    /* text length            */
lParam = 0L;                 /* not used, must be zero */
```

An application sends an EM_LIMITTEXT message to limit the length of the text the user can enter into an edit control.

Parameter	Description
cchMax	Value of *wParam.* Specifies the length, in bytes, of the text the user can enter. If this parameter is zero, the text length is set to 65,535 bytes.

Returns

This message does not return a value.

Comments

The EM_LIMITTEXT message limits only the text the user can enter. It has no effect on any text already in the edit control when the message is sent, nor does it affect the length of text copied to the edit control by the **WM_SETTEXT** message.

If an application uses the **WM_SETTEXT** message to place more text into an edit control than is specified in the EM_LIMITTEXT message, the user can edit the entire contents of the edit control.

EM_LINEFROMCHAR (2.x)

```
EM_LINEFROMCHAR
wParam = (WPARAM) ich;     /* character index        */
lParam = 0L;               /* not used, must be zero */
```

An application sends an EM_LINEFROMCHAR message to retrieve the line number of the line that contains the specified character index. A character index is the number of characters from the beginning of the edit control.

This message is processed only by multiline edit controls.

Parameter	Description
ich	Value of *wParam.* Specifies the character index of the character contained in the line whose number is to be retrieved. If the *ich* parameter is -1, either the line number of the current line (the line containing the caret) is retrieved or, if there is a selection, the line number of the line containing the beginning of the selection is retrieved.

Returns

The return value is the zero-based line number of the line containing the character index specified by *ich.*

Example

This example sends an EM_LINEFROMCHAR message to retrieve the line number of the current line in a multiline edit control:

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_LINEFROMCHAR, -1, 0);
```

See Also

EM_LINEINDEX

EM_LINEINDEX (2.x)

```
EM_LINEINDEX
wParam = (WPARAM) line;    /* line number            */
lParam = 0L;               /* not used, must be zero */
```

An application sends an EM_LINEINDEX message to retrieve the character index of a line within a multiline edit control. The character index is the number of characters from the beginning of the edit control to the specified line.

This message is processed only by multiline edit controls.

Parameter	Description
line	Value of *wParam.* Specifies the zero-based line number. A value of -1 specifies the current line number (the line that contains the caret).

Returns

The return value is the character index of the line specified in the *line* parameter, or it is -1 if the specified line number is greater than the number of lines in the edit control.

Example

This example uses the **EM_GETLINECOUNT** message to retrieve the number of lines in an edit control and then uses EM_LINEINDEX to retrieve the character index for the last line in the edit control:

```
WPARAM cLines, index;

cLines = (WPARAM) SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_GETLINECOUNT, 0, 0);
index = (WPARAM) SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_LINEINDEX, cLines - 1, 0);
```

See Also

EM_LINEFROMCHAR

EM_LINELENGTH (2.x)

```
EM_LINELENGTH
wParam = (WPARAM) ich;     /* character index        */
lParam = 0L;               /* not used, must be zero */
```

An application sends an EM_LINELENGTH message to retrieve the length of a line in an edit control.

Parameter	Description
ich	Value of *wParam.* Specifies the character index of a character in the line whose length is to be retrieved when EM_LINELENGTH is sent to a multiline edit control. If this parameter is -1, the message returns the number of unselected characters on lines containing selected characters. For example, if the selection extended from the fourth character of one line through the eighth character from the end of the next line, the return value would be 10 (three characters on the first line and seven on the next). When EM_LINELENGTH is sent to a single-line edit control, this parameter is ignored.

Returns

The return value is the length, in bytes, of the line specified by the *ich* parameter when an EM_LINELENGTH message is sent to a multiline edit control. The return value is the length, in bytes, of the text in the edit control when an EM_LINELENGTH message is sent to a single-line edit control.

Comments

Use the **EM_LINEINDEX** message to retrieve a character index for a given line number within a multiline edit control.

Example

This example sends an **EM_LINEINDEX** message to retrieve the length of the first line in a multiline edit control (or the entire text of a single-line edit control):

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_LINELENGTH, 0, 0);
```

See Also

EM_GETLINE

EM_LINESCROLL (2.x)

```
EM_LINESCROLL
wParam = 0;                      /* not used, must be zero         */
lParam = MAKELPARAM(dv, dh);     /* lines and characters to scroll */
```

An application sends an EM_LINESCROLL message to scroll the text of a multiline edit control.

This message is processed only by multiline edit controls.

Parameter	Description
dv	Value of the low-order word of *lParam.* Specifies the number of lines to scroll vertically.
dh	Value of the high-order word of *lParam.* Specifies the number of character positions to scroll horizontally. This value is ignored if the edit control has either the **ES_RIGHT** or **ES_CENTER** style.

Returns

The return value is nonzero if the message is sent to a multiline edit control, or it is zero if the message is sent to a single-line edit control.

Comments

The edit control does not scroll vertically past the last line of text in the edit control. If the current line plus the number of lines specified by the *dv* parameter exceeds the total number of lines in the edit control, the value is adjusted so that the last line of the edit control is scrolled to the top of the edit-control window.

The EM_LINESCROLL message can be used to scroll horizontally past the last character of any line.

Example

This example sends an EM_LINESCROLL message to scroll the text in a multiline edit control vertically by five lines:

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_LINESCROLL, 0, MAKELONG(5, 0));
```

EM_REPLACESEL (2.x)

```
EM_REPLACESEL
wParam = 0;                                  /* not used, must be zero */
lParam = (LPARAM) (LPCSTR) lpszReplace;      /* address of new string  */
```

An application sends an EM_REPLACESEL message to replace the current selection in an edit control with the text specified by the *lpszReplace* parameter.

Parameter	Description
lpszReplace	Value of *lParam.* Points to a null-terminated string containing the replacement text.

Returns
This message does not return a value.

Comments
Use the EM_REPLACESEL message when you want to replace only a portion of the text in an edit control. If you want to replace all of the text, use the **WM_SETTEXT** message.

If there is no current selection, the replacement text is inserted at the current cursor location.

Example
This example sets the selection to the beginning of the edit control and inserts the string "C:\":

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETSEL, 0, MAKELONG(0, 0));
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_REPLACESEL, 0, (LPARAM) ((LPSTR) "C:\\"));
```

See Also
EM_GETSEL, **EM_SETSEL**

EM_SETHANDLE (2.x)

```
EM_SETHANDLE
wParam = (WPARAM) (HLOCAL) hloc; /* handle of local memory object */
lParam = 0L;                     /* not used, must be zero        */
```

An application sends an EM_SETHANDLE message to set the handle to the local memory that will be used by a multiline edit control.

This message is processed only by multiline edit controls.

Parameter	Description
hloc	Value of *wParam.* Identifies the local memory. This handle must have been created by a previous call to the **LocalAlloc** function using the **LMEM_MOVEABLE** flag. The memory should contain a null-terminated string, or the first byte of the allocated memory should be set to zero.

Returns

This message does not return a value.

Comments

Before an application sets a new memory handle, it should send an **EM_GETHANDLE** message to retrieve the handle to the current memory buffer and should free that memory by using the **LocalFree** function.

Sending an EM_SETHANDLE message clears the undo buffer (**EM_CANUNDO** returns zero) and the internal modification flag (**EM_GETMODIFY** returns zero). The edit-control window is redrawn.

An application can send this message to a multiline edit control in a dialog box only if it has created the dialog box with the **DS_LOCALEDIT** style flag set.

Example

This example frees the current memory for the edit control, allocates new memory, and reads up to BUF_SIZE bytes of a file into the allocated memory. It then sends an EM_SETHANDLE message to set the handle of the edit control to the new memory, effectively placing up to BUF_SIZE bytes of the file into the edit control.

```
#define BUF_SIZE 4 * 1024

HFILE hf;
OFSTRUCT of;
HLOCAL hlocOldMem, hlocNewMem;
PSTR pBuf;
int cbRead;

/* Get the handle to the old memory and free it. */

hlocOldMem = (HLOCAL) SendDlgItemMessage(hdlg,
    ID_MYEDITCONTROL, EM_GETHANDLE, 0, 0);
LocalFree(hlocOldMem);

/* Allocate new memory and read the file into it. */

hlocNewMem = LocalAlloc(LMEM_MOVEABLE, BUF_SIZE);
pBuf = LocalLock(hlocNewMem);
of.cBytes = sizeof(OFSTRUCT);
hf = OpenFile("test.txt", &of, OF_READ);
cbRead = _lread(hf, pBuf, BUF_SIZE);
pBuf[cbRead] = '\0';    /* add terminating null character */
```

```
_lclose(hf);

/* Adjust the buffer for the amount actually read in. */

LocalReAlloc(hlocNewMem, cbRead, 0);

/* Set the handle to the new buffer. */

LocalUnlock(hlocNewMem);
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETHANDLE, (WPARAM) hlocNewMem, 0);
```

See Also

EM_GETHANDLE, LocalAlloc, LocalFree

EM_SETMODIFY (2.x)

```
EM_SETMODIFY
wParam = (WPARAM) (UINT) fModified;     /* modification flag      */
lParam = 0L;                            /* not used, must be zero */
```

An application sends an EM_SETMODIFY message to set or clear the modification flag for an edit control. The modification flag indicates whether the text within the edit control has been modified. It is automatically set whenever the user changes the text. An **EM_GETMODIFY** message can be sent to retrieve the value of the modification flag.

Parameter	Description
fModified	Value of *wParam.* Specifies the new value for the modification flag. A value of TRUE indicates the text has been modified, and a value of FALSE indicates it has not been modified.

Returns

This message does not return a value.

Example

This example sends an EM_SETMODIFY message to clear the modification flag:

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL, EM_SETMODIFY, FALSE, 0);
```

See Also

EM_GETMODIFY

EM_SETPASSWORDCHAR (3.0)

```
EM_SETPASSWORDCHAR
wParam = (WPARAM) (UINT) ch;     /* character to display   */
lParam = 0L;                     /* not used, must be zero */
```

An application sends an EM_SETPASSWORDCHAR message to set or remove a password character displayed in an edit control when the user types text. When a password character is set, that character is displayed for each character the user types.

This message has no effect on a multiline edit control.

Parameter	Description
ch	Value of *wParam.* Specifies the character to be displayed in place of the character typed by the user. If the *ch* parameter is zero, the actual characters typed by the user are displayed.

Returns

The return value is nonzero if the message is sent to an edit control.

Comments

When the EM_SETPASSWORDCHAR message is received by an edit control, the edit control redraws all visible characters by using the character specified by the *ch* parameter.

If the edit control is created with the **ES_PASSWORD** style, the default password character is set to an asterisk (*). This style is removed if an EM_SETPASSWORDCHAR message is sent with the *wParam* parameter set to zero.

Example

This example sends an EM_SETPASSWORDCHAR message to set the password character of an edit control to a question mark:

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETPASSWORDCHAR, (WORD) '?', 0);
```

See Also

EM_GETPASSWORDCHAR

EM_SETREADONLY (3.1)

```
EM_SETREADONLY
wParam = (WPARAM) (BOOL) fReadOnly;      /* read-only flag          */
lParam = 0L;                             /* not used, must be zero */
```

An application sends an EM_SETREADONLY message to set the read-only state of an edit control.

Parameter	Description
fReadOnly	Value of *wParam.* Specifies whether to set or remove the read-only state of the edit control. A value of TRUE sets the state to read-only; a value of FALSE sets the state to read/write.

Returns

The return value is nonzero if the operation is successful, or it is zero if an error occurs.

Comments

When the state of an edit control is set to read-only, the user cannot change the text within the edit control.

EM_SETREADONLY does not have a corresponding message to retrieve the current style. Calling the **GetWindowLong** function with the **GWL_STYLE** offset retrieves the full control style.

Example

This example sets the state of an edit control to read-only:

```
SendDlgItemMessage(hdlg, IDD_EDIT, EM_SETREADONLY,
    TRUE, 0L);
```

See Also

GetWindowLong

EM_SETRECT (2.x)

```
EM_SETRECT
wParam = 0;                              /* not used, must be zero */
lParam = (LPARAM) (const RECT FAR*) lprc; /* address of RECT    */
```

An application sends an EM_SETRECT message to set the formatting rectangle of a multiline edit control. The formatting rectangle is the limiting rectangle of the text. The limiting rectangle is independent of the size of the edit-control window. When the edit control is first created, the formatting rectangle is the same as the client area of the edit-control window. By using the EM_SETRECT message, an application can make the formatting rectangle larger or smaller than the edit-control window.

This message is processed only by multiline edit controls.

Parameter	Description
lprc	Value of *lParam.* Points to a **RECT** structure that specifies the new dimensions of the rectangle.

Returns

This message does not return a value.

Comments

The EM_SETRECT message causes the text of the edit control to be redrawn. To change the size of the formatting rectangle without redrawing the text, use the **EM_SETRECTNP** message.

If the edit control does not have a horizontal scroll bar, and the formatting rectangle is set to be larger than the edit-control window, lines of text exceeding the width of the edit-control window (but smaller than the width of the formatting rectangle) are clipped instead of wrapped.

If the edit control contains a border, the formatting rectangle is reduced by the size of the border. If you are adjusting the rectangle returned by an **EM_GETRECT** message, you must remove the size of the border before using the rectangle with the EM_SETRECT message.

Example

This example retrieves the current formatting rectangle for a multiline edit control, removes the border width dimensions, and sets the right border to 32767 so that all text sent to the edit control is clipped rather than wrapped if it exceeds the width of the edit-control window. The example then sends an EM_SETRECT message to set the new formatting rectangle.

```
RECT rect;

SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_GETRECT, 0, (LPARAM) (RECT FAR*) &rect);
rect.left = 0;             /* remove border width  */
rect.right = 32767;        /* clip all lines       */
rect.bottom += rect.top;   /* remove border height */
rect.top = 0;              /* remove border height */
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETRECT, 0, (LPARAM) (RECT FAR*) &rect);
```

See Also

EM_GETRECT, **EM_SETRECTNP**, **RECT**

EM_SETRECTNP (2.x)

```
EM_SETRECTNP
wParam = 0;                          /* not used, must be zero    */
lParam = (LPARAM) (const RECT FAR*) lprc; /* address of RECT      */
```

An application sends an EM_SETRECTNP message to set the formatting rectangle of a multiline edit control. The formatting rectangle is the limiting rectangle of the text. The limiting rectangle is independent of the size of the edit-control window. When the edit control is first created, the formatting rectangle is the same as the client area of the edit-control window. By using the EM_SETRECTNP message, an application can make the formatting rectangle larger or smaller than the edit-control window.

The EM_SETRECTNP message is identical to the **EM_SETRECT** message, except that the edit-control window is not redrawn.

This message is processed only by multiline edit controls.

Parameter	Description
lprc	Value of *lParam.* Points to a **RECT** structure that specifies the new dimensions of the rectangle.

Returns

This message does not return a value.

See Also

EM_GETRECT, **EM_SETRECT**, **RECT**

EM_SETSEL (2.x)

```
EM_SETSEL
wParam = (WPARAM) (UINT) fScroll;          /* flag for caret scrolling */
lParam = MAKELPARAM(ichStart, ichEnd);     /* start and end positions  */
```

An application sends an EM_SETSEL message to select a range of characters in an edit control.

Parameter	Description
fScroll	Value of *wParam.* When this parameter is zero, the caret is scrolled into view. When this parameter is one, the caret is not scrolled into view.
ichStart	Value of the low-order word of *lParam.* Specifies the starting position.
ichEnd	Value of the high-order word of *lParam.* Specifies the ending position.

Returns

The return value is nonzero if the message is sent to an edit control.

Comments

If the *ichStart* parameter is 0 and the *ichEnd* parameter is -1, all the text in the edit control is selected. If *ichStart* is -1, any current selection is removed. The caret is placed at the end of the selection indicated by the greater of the two values *ichEnd* and *ichStart.*

Example

This example sends an EM_SETSEL message to select the entire contents of an edit control. It then sends a **WM_CUT** message to copy the contents of the edit control to the clipboard and then to delete the contents of the edit control.

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETSEL, 0, MAKELONG(0, -1));
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    WM_CUT, 0, 0);
```

See Also

EM_GETSEL, **EM_REPLACESEL**

Windows 3.1 changes

The meaning of the *wParam* parameter has changed. The *wParam* parameter specifies whether or not to scroll the caret.

EM_SETTABSTOPS (3.0)

```
EM_SETTABSTOPS
wParam = (WPARAM) cTabs;                        /* number of tab stops */
lParam = (LPARAM) (const int FAR*) lpTabs;      /* tab-stop array      */
```

An application sends an EM_SETTABSTOPS message to set the tab stops in a multiline edit control (MLE). When text is copied to an MLE, any tab character in the text causes space to be generated up to the next tab stop.

This message is processed only by MLEs.

Parameter	Description
cTabs	Value of *wParam.* Specifies the number of tab stops contained in the *lpTabs* parameter. If this parameter is 0, the *lpTabs* parameter is ignored and default tab stops are set at every 32 dialog box units. If this parameter is 1, tab stops are set at every *n* dialog box units, where *n* is the distance pointed to by the *lpTabs* parameter. If the *cTabs* parameter is greater than 1, *lpTabs* points to an array of tab stops.
lpTabs	Low and high-order words of *lParam.* Points to an array of unsigned integers specifying the tab stops, in dialog box units. If the *cTabs* parameter is 1, *lpTabs* points to an unsigned integer containing the distance between all tab stops, in dialog units.

Returns

The return value is nonzero if the tabs were set; otherwise, the return value is zero.

Comments

The EM_SETTABSTOPS message does not automatically redraw the edit-control window. If the application is changing the tab stops for text already in the edit control, it should call the **InvalidateRect** function to redraw the edit-control window.

Example

This example sends an EM_SETTABSTOPS message to set tab stops at every 64 dialog box units. It then calls **InvalidateRect** to redraw the edit-control window.

```
WORD wTabSpacing = 64;

SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETTABSTOPS, 1, (LPARAM) (int far*) &wTabSpacing);
InvalidateRect(GetDlgItem(hdlg, ID_MYEDITCONTROL),
    NULL, TRUE);
```

See Also

GetDialogBaseUnits

EM_SETWORDBREAKPROC (3.1)

```
EM_SETWORDBREAKPROC
wParam = 0;                                  /* not used, must be zero */
lParam = (LPARAM) (EDITWORDBREAKPROC) ewbprc; /* address of function */
```

An application sends the EM_SETWORDBREAKPROC message to an edit control to replace the default wordwrap function with an application-defined wordwrap function.

Parameter	Description
ewbprc	Value of *lParam.* Specifies the procedure-instance address of the application-defined wordwrap function. The **MakeProcInstance** function must be used to create the address. For more information, see the description of the **WordBreakProc** callback function.

Returns

This message does not return a value.

Comments

A wordwrap function scans a text buffer (which contains text to be sent to the display), looking for the first word that does not fit on the current display line. The wordwrap function places this word at the beginning of the next line on the display.

A wordwrap function defines the point at which Windows should break a line of text for multiline edit controls, usually at a space character that separates two words. Either a multiline or a single-line edit control might call this function when the user presses arrow keys in combination with the CTRL key to move the cursor to the next word or previous word. The default wordwrap function breaks a line of text at a space character. The application-defined function may define wordwrap to occur at a hyphen or a character other than the space character.

EM_FMTLINES, **EM_GETWORDBREAKPROC**, **MakeProcInstance**, **WordBreakProc**

EM_UNDO (2.x)

```
EM_UNDO
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an EM_UNDO message to undo the last edit-control operation.

Parameters

This message has no parameters.

Returns

The return value is always nonzero for a single-line edit control. For a multiline edit control, the return value is nonzero if the undo operation is successful or zero if the undo operation fails.

Comments

An undo operation can also be undone. For example, you can restore deleted text with the first EM_UNDO message and remove the text again with a second EM_UNDO message as long as there is no intervening edit-control operation.

Example

This example undoes the last edit-control operation:

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL, EM_UNDO, 0, 0);
```

See Also

EM_CANUNDO, **EM_EMPTYUNDOBUFFER**, **WM_UNDO**

LB_ADDSTRING (2.x)

```
LB_ADDSTRING
wParam = 0;                        /* not used, must be zero   */
lParam = (LPARAM) (LPCSTR) lpsz; /* address of string to add */
```

An application sends an LB_ADDSTRING message to add a string to a list box. If the list box does not have the **CBS_SORT** style, the string is added to the end of the list. Otherwise, the string is inserted into the list and the list is sorted.

Parameter	Description
lpsz	Value of *lParam.* Points to the null-terminated string that is to be added. If the list box was created with an owner-drawn style but without the **LBS_HASSTRINGS** style, the value of the *lpsz* parameter is stored rather than the string it would otherwise point to.

Returns

The return value is the zero-based index to the string in the list box. The return value is LB_ERR if an error occurs; the return value is LB_ERRSPACE if insufficient space is available to store the new string.

Comments

If an owner-drawn list box was created with the **LBS_SORT** style but not the **LBS_HASSTRINGS** style, the **WM_COMPAREITEM** message is sent one or more times to the owner of the list box so the new item can be properly placed in the list box.

Example

This example adds the string "my string" to a list box:

```
DWORD dwIndex;

dwIndex = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_ADDSTRING, 0, (LPARAM) ((LPSTR) "my string"));
```

See Also

LB_DIR, **LB_INSERTSTRING**, **WM_COMPAREITEM**

LB_DELETESTRING (2.x)

```
LB_DELETESTRING
wParam = (WPARAM) index;     /* index of string to delete */
lParam = 0L;                 /* not used, must be zero    */
```

An application sends an LB_DELETESTRING message to delete a string in a list box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the string to delete.

Returns

The return value is a count of the strings remaining in the list. The return value is LB_ERR if the *index* parameter specifies an index greater than the number of items in the list.

Comments

If the list box was created with an owner-drawn style but without the **LBS_HASSTRINGS** style, a **WM_DELETEITEM** message is sent to the owner of the list box so that the application can free any additional data associated with the item.

Example

This example deletes the first string in a list box:

```
DWORD dwRemaining;

dwRemaining = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_DELETESTRING, 0, 0);
```

See Also

LB_RESETCONTENT, **WM_DELETEITEM**

LB_DIR (2.x)

```
LB_DIR
wParam = (WPARAM) (UINT) uAttrs;         /* file attributes           */
lParam = (LPARAM) (LPCSTR) lpszFileSpec; /* filename string's address */
```

An application sends an LB_DIR message to add a list of filenames to a list box.

Parameter	Description
uAttrs	Value of *wParam.* Specifies the attributes of the files to be added to the list box. It can be any combination of the following values:

Value	Meaning
DDL_READWRITE	File can be read from or written to.
DDL_READONLY	File can be read from but not written to.
DDL_HIDDEN	File is hidden and does not appear in a directory listing.
DDL_SYSTEM	File is a system file.
DDL_DIRECTORY	The name pointed to by the *lpszFileSpec* parameter specifies a directory.
DDL_ARCHIVE	File has been archived.
DDL_DRIVES	All drives that match the name specified by the *lpszFileSpec* parameter are included. If the **DDL_DRIVES** flag is set, the **DDL_EXCLUSIVE** flag is set automatically. Therefore, to create a directory listing that includes drives and files, the developer must send this message twice: once with the DDL_DRIVES flag set and once with the flags for the rest of the list.
DDL_EXCLUSIVE	Exclusive flag. If the exclusive flag is set, only files of the specified type are listed. Otherwise, files of the specified type are listed in addition to files that do not match the specified type.

lpszFileSpec	Value of *lParam.* Points to the null-terminated string that specifies the filename to add to the list. If the filename contains wildcards (for example, *.*), all files that match and have the attributes specified by the *uAttrs* parameter are added to the list.

Returns

The return value is the zero-based index of the last filename added to the list. The return value is LB_ERR if an error occurs; the return value is LB_ERRSPACE if insufficient space is available to store the new strings.

Example

This example adds the names of all available drives to a list box:

```
DWORD dwIndexLastItem;

dwIndexLastItem = SendDlgItemMessage(hdlg, ID_MYLISTBOX, LB_DIR,
    0x4000 | 0x8000, (LPARAM) ((LPSTR) "*"));
```

See Also

DlgDirList, **LB_ADDSTRING**, **LB_INSERTSTRING**

LB_FINDSTRING (3.0)

```
LB_FINDSTRING
wParam = (WPARAM) indexStart;        /* item before start of search */
lParam = (LPARAM) (LPCSTR) lpszFind; /* address of search string    */
```

An application sends an LB_FINDSTRING message to search a list box for an item that begins with the characters in a specified string.

Parameter	Description
indexStart	Value of *wParam.* Specifies the zero-based index of the item before the first item to be searched. When the search reaches the bottom of the list box, it continues from the top of the list box back to the item specified by the *indexStart* parameter. If *indexStart* is -1, the entire list box is searched from the beginning.
lpszFind	Value of *lParam.* Points to the null-terminated string that contains the prefix to search for. The search is not case-sensitive, so this string can contain any combination of uppercase and lowercase letters.

Returns

The return value is the index of the matching item, or it is LB_ERR if the search was unsuccessful.

Comments

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the action taken by the LB_FINDSTRING message depends on whether the **CBS_SORT** style is used. If the CBS_SORT style is used, **WM_COMPAREITEM** messages are sent to the owner of the combo box to determine which item matches the specified string. Otherwise, LB_FINDSTRING attempts to match the doubleword value against the value of the *lpszFind* parameter.

Example

This example searches for the string "my string" in a list box and copies it, if found, to the szBuf buffer:

```
char szBuf[20];
DWORD dwIndex;

dwIndex = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_FINDSTRING, 0, (LPARAM) ((LPSTR) "my string"));
if (dwIndex != LB_ERR)
    SendDlgItemMessage(hdlg, ID_MYLISTBOX,
        LB_GETTEXT, (WPARAM) dwIndex, (LPARAM) ((LPSTR) szBuf));
```

See Also

LB_FINDSTRINGEXACT, **LB_SELECTSTRING**, **WM_COMPAREITEM**

LB_FINDSTRINGEXACT (3.1)

```
LB_FINDSTRINGEXACT
wParam = (WPARAM) indexStart;        /* item before start of search */
lParam = (LPARAM) (LPCSTR) lpszFind; /* address of search string    */
```

An application sends an LB_FINDSTRINGEXACT message to find the first list box string that matches the string specified in the *lpszFind* parameter.

Parameter	Description
indexStart	Value of *wParam.* Specifies the zero-based index of the item before the first item to be searched. When the search reaches the bottom of the list box, it continues from the top of the list box back to the item specified by the *indexStart* parameter. If *indexStart* is -1, the entire list box is searched from the beginning.
lpszFind	Value of *lParam.* Points to the null-terminated string to search for. This string can contain a complete filename, including the extension. The search is not case-sensitive, so the string can contain any combination of uppercase and lowercase letters.

Returns

The return value is the index of the matching item, or it is LB_ERR if the search was unsuccessful.

Comments

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the action taken by the LB_FINDSTRINGEXACT message depends on whether the **CBS_SORT** style is used. If the CBS_SORT style is used, **WM_COMPAREITEM** messages are sent to the owner of the combo box to determine which item matches the specified string. Otherwise, LB_FINDSTRINGEXACT attempts to match the doubleword value against the value of the *lpszFind* parameter.

Example

This example searches for the string "my string" in a list box and copies it, if found, to the *szBuf* buffer:

```
char szBuf[20];
DWORD dwIndex;

dwIndex = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_FINDSTRINGEXACT, 0, (LPARAM) ((LPSTR) "my string"));
if (dwIndex != LB_ERR)
    SendDlgItemMessage(hdlg, ID_MYLISTBOX,
        LB_GETTEXT, (WPARAM) dwIndex, (LPARAM) ((LPSTR) szBuf));
```

See Also

LB_FINDSTRING, **LB_SELECTSTRING**, **WM_COMPAREITEM**

LB_GETCARETINDEX (3.1)

```
LB_GETCARETINDEX
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an LB_GETCARETINDEX message to determine the index of the item that has the focus rectangle in a multiple-selection list box. The item may or may not be selected.

Parameters

This message has no parameters.

Returns

The return value is the zero-based index of the item that has the focus rectangle in a list box. If the list box is a single-selection list box, the return value is the index of the item that is selected, if any.

Example

This example sends an LB_GETCARETINDEX message to retrieve the index of the item that has the focus rectangle in the list box:

```
LRESULT lrIndex;

lrIndex = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_GETCARETINDEX, 0, 0L);
```

See Also

LB_SETCARETINDEX

LB_GETCOUNT (2.x)

```
LB_GETCOUNT
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an LB_GETCOUNT message to retrieve the number of items in a list box.

Parameters

This message has no parameters.

Returns

The return value is the number of items in the list box, or it is LB_ERR if an error occurs.

Comments

The returned count is one greater than the index value of the last item (the index is zero-based).

Example

This example retrieves the number of items in a list box:

```
DWORD cListItems;

cListItems = SendDlgItemMessage(hdlg, ID_MYLISTBOX, LB_GETCOUNT, 0, 0);
```

LB_GETCURSEL (2.x)

```
LB_GETCURSEL
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an LB_GETCURSEL message to retrieve the index of the currently selected item, if any, in a single-selection list box.

Parameters

This message has no parameters.

Returns

The return value is the zero-based index of the currently selected item. It is LB_ERR if no item is currently selected.

Comments

An application should use the **LB_GETCARETINDEX** to retrieve the index of the item that has the focus rectangle in a multiple-selection list box.

The LB_GETCURSEL message cannot be sent to a multiple-selection list box.

Example

This example retrieves the index of the currently selected string in a list box and then retrieves that string:

```
char szBuf[20];
DWORD dwIndex;

dwIndex = SendDlgItemMessage(hdlg, ID_MYLISTBOX, LB_GETCURSEL, 0, 0);
if (dwIndex != LB_ERR)
    SendDlgItemMessage(hdlg, ID_MYLISTBOX,
        LB_GETTEXT, (WPARAM) dwIndex, (LPARAM) ((LPSTR) szBuf));
```

See Also

LB_GETSEL, **LB_SETCURSEL**, **LB_SELECTSTRING**

LB_GETHORIZONTALEXTENT (3.0)

```
LB_GETHORIZONTALEXTENT
wParam = 0;     /* not used, must be zero */
lParam = 0L;    /* not used, must be zero */
```

An application sends the LB_GETHORIZONTALEXTENT message to retrieve from a list box the width, in pixels, by which the list box can be scrolled horizontally if the list box has a horizontal scroll bar.

Parameters

This message has no parameters.

Returns

The return value is the scrollable width of the list box, in pixels.

Comments

To respond to the LB_GETHORIZONTALEXTENT message, the list box must have been defined with the **WS_HSCROLL** style.

This message is not useful for multicolumn listboxes.

Example

This example gets the horizontal extent of a list box:

```
SendDlgItemMessage(hDlg, ID_MYLISTBOX,
    LB_GETHORIZONTALEXTENT, 0, 0L);
```

See Also

LB_SETHORIZONTALEXTENT

LB_GETITEMDATA (3.0)

```
LB_GETITEMDATA
wParam = (WPARAM) index;     /* item index              */
lParam = 0L;                 /* not used, must be zero */
```

An application sends the LB_GETITEMDATA message to retrieve the application-supplied doubleword value associated with the specified item in a list box. (This is the value of the *lParam* parameter of an **LB_SETITEMDATA** message.)

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item.

Returns

The return value is the doubleword value associated with the item, or it is LB_ERR if an error occurs.

Example

This example retrieves the value associated with an item in a list box. The value is the handle of a global memory object.

```
HGLOBAL hglbData;
LPSTR   lpLBData;
HWND    hListBox;
WPARAM  nIndex;

if ((hglbData = (HGLOBAL) LOWORD(SendMessage(hListBox, LB_GETITEMDATA,
        nIndex, 0)))) {
    if ((lpLBData = GlobalLock(hglbData))) {
        .
        . /* Access or manipulate the data */
        .

        GlobalUnlock(hglbData);
    }
}
```

See Also

LB_SETITEMDATA

LB_GETITEMHEIGHT (3.1)

```
LB_GETITEMHEIGHT
wParam = (WPARAM) index;    /* item index             */
lParam = 0L;                /* not used, must be zero */
```

An application sends an LB_GETITEMHEIGHT message to determine the height of items in a list box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item in the list box. This parameter is used only if the list box has the **LBS_OWNERDRAWVARIABLE** style; otherwise, it should be set to zero.

Returns

The return value is the height, in pixels, of the items in the list box. The return value is the height of the item specified by the *index* parameter if the list box has the **LBS_OWNERDRAWVARIABLE** style. The return value is LB_ERR if an error occurs.

Example

This example sends an LB_GETITEMHEIGHT message to retrieve the height of the items in a list box:

```
LRESULT lrHeight;

lrHeight = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_GETITEMHEIGHT, 0, 0L);
```

See Also

LB_GETITEMRECT, **LB_SETITEMHEIGHT**, **WM_MEASUREITEM**

LB_GETITEMRECT (3.0)

```
LB_GETITEMRECT
wParam = (WPARAM) index;            /* item index                */
lParam = (LPARAM) (RECT FAR*) lprc; /* address of RECT structure */
```

An application sends an LB_GETITEMRECT message to retrieve the dimensions of the rectangle that bounds an item as it is currently displayed in the list box window.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item.
lprc	Value of *lParam.* Specifies a long pointer to a **RECT** structure that receives the client coordinates for the item in the list box.

Returns

The return value is LB_ERR if an error occurs.

See Also

LB_GETITEMHEIGHT, **LB_SETITEMHEIGHT**, **WM_MEASUREITEM**, **RECT**

LB_GETSEL (2.x)

```
LB_GETSEL
wParam = (WPARAM) index;     /* item index              */
lParam = 0L;                 /* not used, must be zero */
```

An application sends an LB_GETSEL message to retrieve the selection state of an item.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item.

Returns

The return value is a positive number if an item is selected; otherwise, it is zero. The return value is LB_ERR if an error occurs.

See Also

LB_GETCURSEL, **LB_SELECTSTRING**, **LB_SELITEMRANGE**, **LB_SETSEL**

LB_GETSELCOUNT (3.0)

```
LB_GETSELCOUNT
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an LB_GETSELCOUNT message to retrieve the total number of selected items in a multiple-selection list box.

Parameters

This message has no parameters.

Returns

The return value is the count of selected items in a list box. The return value is LB_ERR if the list box is a single-selection list box.

See Also

LB_GETSELITEMS

LB_GETSELITEMS (3.0)

```
LB_GETSELITEMS
wParam = (WPARAM) cItems;              /* maximum number of items */
lParam = (LPARAM) (int FAR*) lpItems; /* address of buffer       */
```

An application sends an LB_GETSELITEMS message to fill a buffer with an array of integers that specify the item numbers of selected items in a multiple-selection list box.

Parameter	Description
cItems	Value of *wParam.* Specifies the maximum number of selected items whose item numbers are to be placed in the buffer.
lpItems	Value of *lParam.* Specifies a long pointer to a buffer large enough for the number of integers specified by the *cItems* parameter.

Returns

The return value is the actual number of items placed in the buffer. The return value is LB_ERR if the list box is a single-selection list box.

See Also

LB_GETSELCOUNT

LB_GETTEXT (2.x)

```
LB_GETTEXT
wParam = (WPARAM) index;                /* item index        */
lParam = (LPARAM) (LPCSTR) lpszBuffer; /* address of buffer */
```

An application sends an LB_GETTEXT message to retrieve a string from a list box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the string to retrieve.
lpszBuffer	Value of *lParam.* Points to the buffer that receives the string. The buffer must have sufficient space for the string and a terminating null character. An **LB_GETTEXTLEN** message can be sent before the LB_GETTEXT message to retrieve the length, in bytes, of the string.

Returns

The return value is the length of the string, in bytes, excluding the terminating null character. The return value is LB_ERR if the *index* parameter does not specify a valid index.

Comments

If the list box was created with an owner-drawn style but without the **LBS_HASSTRINGS** style, the buffer pointed to by the *lpszBuffer* parameter receives the doubleword value associated with the item.

Example

This example retrieves the length of the first item in the list box, allocates sufficient memory for the string, and then sends an LB_GETTEXT message to retrieve the string:

```
DWORD cbItemString;
PSTR psz;

cbItemString = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_GETTEXTLEN, 0, 0);
if (cbItemString != LB_ERR) {
    psz = (PSTR) LocalAlloc(LMEM_FIXED, (WORD) cbItemString);
    SendDlgItemMessage(hdlg, ID_MYLISTBOX,
        LB_GETTEXT, 0, (LPARAM) ((LPSTR) psz));
}
```

See Also

LB_GETTEXTLEN

LB_GETTEXTLEN (2.x)

```
LB_GETTEXTLEN
wParam = (WPARAM) index;     /* item index             */
lParam = 0L;                 /* not used, must be zero */
```

An application sends an LB_GETTEXTLEN message to retrieve the length of a string in a list box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the string.

Returns

The return value is the length of the string, in bytes, excluding the terminating null character. The return value is LB_ERR if the *index* parameter does not specify a valid index.

Example

This example retrieves the length of the first item in the list box:

```
DWORD cbItemString;

cbItemString = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_GETTEXTLEN, 0, 0);
```

See Also

LB_GETTEXT

LB_GETTOPINDEX (3.0)

```
LB_GETTOPINDEX
wParam = 0;     /* not used, must be zero */
lParam = 0L;    /* not used, must be zero */
```

An application sends an LB_GETTOPINDEX message to retrieve the index of the first visible item in a list box. Initially, the item with index 0 is at the top of the list box, but if the list box is scrolled, another item may be at the top.

Parameters

This message has no parameters.

Returns

The return value is the zero-based index of the first visible item in a list box.

See Also

LB_SETTOPINDEX

LB_INSERTSTRING (2.x)

```
LB_INSERTSTRING
wParam = (WPARAM) index;            /* item index                   */
lParam = (LPARAM) (LPCSTR) lpsz;    /* address of string to insert */
```

An application sends an LB_INSERTSTRING message to insert a string into a list box. Unlike the **LB_ADDSTRING** message, the LB_INSERTSTRING message does not cause a list with the **LBS_SORT** style to be sorted.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the position at which to insert the string. If this parameter is -1, the string is added to the end of the list.
lpsz	Value of *lParam.* Points to the null-terminated string that is to be inserted. If the list was created with an owner-drawn style but without the **LBS_HASSTRINGS** style, the value of the *lpsz* parameter is stored rather than the string it would otherwise point to.

Returns

The return value is the index of the position at which the string was inserted. The return value is LB_ERR if an error occurs. The return value is LB_ERRSPACE if insufficient space is available to store the new string.

Example

This example inserts the string "my string" into the third position of the list box:

```
SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_INSERTSTRING, 2, (LPARAM) ((LPSTR) "my string"));
```

See Also

LB_ADDSTRING, **LB_DIR**

LB_RESETCONTENT (2.x)

```
LB_RESETCONTENT
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an LB_RESETCONTENT message to remove all items from a list box.

Parameters

This message has no parameters.

Returns

This message does not return a value.

Comments

If the list box was created with an owner-drawn style but without the **LBS_HASSTRINGS** style, the owner of the list box receives a **WM_DELETEITEM** message for each item in the list box.

Example

This example removes all items from a list box:

```
SendDlgItemMessage(hdlg, ID_MYLISTBOX, LB_RESETCONTENT, 0, 0);
```

See Also

LB_DELETESTRING, **WM_DELETEITEM**

LB_SELECTSTRING (2.x)

```
LB_SELECTSTRING
wParam = (WPARAM) indexStart;        /* item before start of search */
lParam = (LPARAM) (LPCSTR) lpszFind; /* address of search string    */
```

An application sends an LB_SELECTSTRING message to search a list box for an item that begins with the characters in a specified string. If a matching item is found, the item is selected.

Parameter	Description
indexStart	Value of *wParam.* Specifies the zero-based index of the item before the first item to be searched. When the search reaches the bottom of the list box, it continues from the top of the list box back to the item specified by the *indexStart* parameter. If *indexStart* is -1, the entire list box is searched from the beginning.
lpszFind	Value of *lParam.* Points to the null-terminated string that contains the prefix to search for. The search is not case-sensitive, so this string can contain any combination of uppercase and lowercase letters.

Returns

The return value is the index of the selected item if the search was successful. The return value is LB_ERR if the search was unsuccessful and the current selection is not changed.

Comments

The list box is scrolled, if necessary, to bring the selected item into view.

An item is selected only if its initial characters (from the starting point) match the characters in the string specified by the *lpszFind* parameter.

If the combo box was created with an owner-drawn style but without the **CBS_HASSTRINGS** style, the action taken by the LB_SELECTSTRING message depends on whether the **CBS_SORT** style is used. If the CBS_SORT style is used, **WM_COMPAREITEM** messages are sent to the owner of the combo box to determine which item matches the specified string. Otherwise, LB_SELECTSTRING attempts to match the doubleword value against the value of the *lpszFind* parameter.

Example

This example searches the entire list box for an item that matches the string "my string" and, if the item is found, selects it:

```
DWORD dwIndexFoundString;

dwIndexFoundString = SendDlgItemMessage(hdlg, ID_MYLISTBOX,
    LB_SELECTSTRING, -1, (LPARAM) ((LPSTR) "my string"));
```

See Also

LB_FINDSTRING, **LB_FINDSTRINGEXACT**, **LB_SELITEMRANGE**, **LB_SETCURSEL**, **LB_SETSEL**, **WM_COMPAREITEM**

LB_SELITEMRANGE (3.0)

```
LB_SELITEMRANGE
wParam = (WPARAM) (BOOL) fSelect;   /* selection flag       */
lParam = MAKELPARAM(wFirst, wLast); /* first and last items */
```

An application sends an LB_SELITEMRANGE message to select one or more consecutive items in a multiple-selection list box.

Parameter	Description
fSelect	Value of *wParam.* Specifies how to set the selection. If the *fSelect* parameter is nonzero, the string is selected and highlighted; if *fSelect* is zero, the highlight is removed and the string is no longer selected.
wFirst	Value of the low-order word of *lParam.* Specifies the zero-based index of the first item to set.
wLast	Value of the high-order word of *lParam.* Specifies the zero-based index of the last item to set.

Returns
The return value is LB_ERR if an error occurs.

Comments
This message should be used only with multiple-selection list boxes.

See Also
LB_SELECTSTRING, **LB_SETSEL**

LB_SETCARETINDEX (3.1)

```
LB_SETCARETINDEX
wParam = (WPARAM) index;          /* item index               */
lParam = MAKELPARAM(fScroll, 0); /* flag for scrolling item */
```

An application sends an LB_SETCARETINDEX message to set the focus rectangle to the item at the specified index in a multiple-selection list box. If the item is not visible, it is scrolled into view.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item to receive the focus rectangle in the list box.
fScroll	Value of *lParam.* If this value is zero, the item is scrolled until it is fully visible. If this value is nonzero, the item is scrolled until it is at least partially visible.

Returns

The return value is LB_ERR if an error occurs.

Example

This example sends an LB_SETCARETINDEX message to set the focus rectangle to an item in a list box:

```
WPARAM wIndex;

wIndex = 0;     /* set index to first item */

SendDlgItemMessage(hdlg, ID_MYLISTBOX, LB_SETCARETINDEX,
    wIndex, 0L);
```

See Also

LB_GETCARETINDEX

Windows 3.1 Changes

In previous versions of Windows, the *lParam* was not used.

LB_SETCOLUMNWIDTH (3.0)

```
LB_SETCOLUMNWIDTH
wParam = (WPARAM) cxColumn;      /* column width           */
lParam = 0L;                     /* not used, must be zero */
```

An application sends an LB_SETCOLUMNWIDTH message to a multiple-column list box (created with the **LBS_MULTICOLUMN** style) to set the width, in pixels, of all columns in the list box.

Parameter	Description
cxColumn	Value of *wParam.* Specifies the width, in pixels, of all columns.

Returns
This message does not return a value.

Example
This example sets the width of the columns in a multiple-column list box:

```
WPARAM wColWidth;

wColWidth = 100;    /* set column width to 100 pixels */

SendDlgItemMessage(hDlg, ID_MYLISTBOX, LB_SETCOLUMNWIDTH,
    wColWidth, 0L);
```

See Also
LB_SETHORIZONTALEXTENT

LB_SETCURSEL (2.x)

```
LB_SETCURSEL
wParam = (WPARAM) index;     /* item index             */
lParam = 0L;                 /* not used, must be zero */
```

An application sends an LB_SETCURSEL message to select a string and scroll it into view, if necessary. When the new string is selected, the list box removes the highlight from the previously selected string.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the string that is selected. If the *index* parameter is -1, the list box is set to have no selection.

Returns

The return value is LB_ERR if an error occurs. The return value will be LB_ERR even though no error has occurred if the *index* parameter is -1.

Comments

This message should be used only with single-selection list boxes. It cannot be used to set or remove a selection in a multiple-selection list box.

See Also

LB_GETCURSEL, **LB_SELECTSTRING**, **LB_SETSEL**

LB_SETHORIZONTALEXTENT (3.0)

```
LB_SETHORIZONTALEXTENT
wParam = (WPARAM) cxExtent; /* horizontal scroll width */
lParam = 0L;                /* not used, must be zero  */
```

An application sends the LB_SETHORIZONTALEXTENT message to set the width, in pixels, by which a list box can be scrolled horizontally. If the size of the list box is smaller than this value, the horizontal scroll bar horizontally scrolls items in the list box. If the size of the list box is equal to or greater than this value, the horizontal scroll bar is hidden.

Parameter	Description
cxExtent	Value of *wParam.* Specifies the number of pixels by which the list box can be scrolled.

Returns

This message does not return a value.

Comments

To respond to the LB_SETHORIZONTALEXTENT message, the list box must have been defined with the **WS_HSCROLL** style.

By default, the horizontal extent of a list box is zero. Windows does not display the scroll bar unless the horizontal extent is set to a value greater than the width, in pixels, of the client area of the list box.

This message is not useful for multicolumn listboxes. Multicolumn listboxes should instead use the **LB_SETCOLUMNWIDTH** message.

Example

This example sets the horizontal extent of a list box based on the width of the string about to be added to the list box. The horizontal extent is set if the string is wider than the widest string in the list box and is wider than the client area of the list box.

```
DWORD dwStringExt;
HDC hdcLB;
PSTR pszString;
TEXTMETRIC tm;
WORD wLongest;
WORD wLBWidth;

dwStringExt = GetTextExtent(hdcLB, (LPSTR) pszString,
    strlen(pszString)) + tm.tmAveCharWidth;

if ((LOWORD(dwStringExt) > wLongest) &&
        (LOWORD(dwStringExt) > wLBWidth)) {
    SendDlgItemMessage(hDlg, ID_MYLISTBOX, LB_SETHORIZONTALEXTENT,
        LOWORD(dwStringExt), 0L);
    wLongest = LOWORD(dwStringExt);
}

SendDlgItemMessage(hDlg, ID_MYLISTBOX, LB_ADDSTRING, 0,
    (LPARAM) ((LPCSTR) pszString));
```

See Also

LB_GETHORIZONTALEXTENT, **LB_SETCOLUMNWIDTH**

LB_SETITEMDATA (3.0)

```
LB_SETITEMDATA
wParam = (WPARAM) index;    /* item index                    */
lParam = (LPARAM) dwData;   /* value to associate with item */
```

An application sends the LB_SETITEMDATA message to set a doubleword value associated with the specified item in a list box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item.
dwData	Value of *lParam.* Specifies the value to be associated with the item.

Returns

The return value is LB_ERR if an error occurs.

Example

This example associates a handle of a 64-byte memory object with each item in a list box:

```
HGLOBAL hglbData;
LPSTR   lpLBData;
HWND    hListBox;
WPARAM  nIndex;

case WM_INITDIALOG:

    if ((hglbData = GlobalAlloc(GMEM_MOVEABLE, 64))) {
        if ((lpLBData = GlobalLock(hglbData))) {
            .
            . /* Store the data in the memory object. */
            .
            GlobalUnlock(hglbData);
        }
    }
    SendMessage(hListBox, LB_SETITEMDATA, nIndex,
        MAKELONG(hglbData, 0));
```

See Also

LB_GETITEMDATA

LB_SETITEMHEIGHT (3.1)

```
LB_SETITEMHEIGHT
wParam = (WPARAM) index;        /* item index */
lParam = MAKELPARAM(cyItem, 0); /* item height */
```

An application sends an LB_SETITEMHEIGHT message to set the height of items in a list box. If the list box has the **LBS_OWNERDRAWVARIABLE** style, this message sets the height of the item specified by the *wParam* parameter. Otherwise, this message sets the height of all items in the list box.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item in the list box. This parameter is used only if the list box has the **LBS_OWNERDRAWVARIABLE** style; otherwise, it should be set to zero.
cyItem	Value of the low-order word of *lParam.* Specifies the height, in pixels, of the item.

Returns

The return value is LB_ERR if the index or height is invalid.

Example

This example sends an LB_SETITEMHEIGHT message to set the height of the items in a list box:

```
LPARAM lpmHeight;

SendDlgItemMessage(hdlg, ID_MYLISTBOX, LB_SETITEMHEIGHT,
    0, lpmHeight);
```

See Also

LB_GETITEMHEIGHT, **LB_GETITEMRECT**, **WM_MEASUREITEM**

LB_SETSEL (2.x)

```
LB_SETSEL
wParam = (WPARAM) (BOOL) fSelect;   /* selection flag */
lParam = MAKELPARAM(index, 0);      /* item index     */
```

An application sends an LB_SETSEL message to select a string in a multiple-selection list box.

Parameter	Description
fSelect	Value of *wParam.* Specifies how to set the selection. If the *fSelect* parameter is TRUE, the string is selected and highlighted; if *fSelect* is FALSE, the highlight is removed and the string is no longer selected.
index	Value of the low-order word of *lParam.* Specifies the zero-based index of the string to set. If the *index* parameter is -1, the selection is added to or removed from all strings, depending on the value of *fSelect.*

Returns

The return value is LB_ERR if an error occurs.

Comments

This message should be used only with multiple-selection list boxes.

See Also

LB_GETSEL, **LB_SETCURSEL**, **LB_SELECTSTRING**, **LB_SELITEMRANGE**

LB_SETTABSTOPS (3.0)

```
LB_SETTABSTOPS
wParam = (WPARAM) cTabs;              /* number of tab stops       */
lParam = (LPARAM) (int FAR*) lpTabs; /* address of tab-stop array */
```

An application sends an LB_SETTABSTOPS message to set the tab-stop positions in a list box.

Parameter	Description
cTabs	Value of *wParam.* Specifies the number of tab stops in the list box.
lpTabs	Value of *lParam.* Points to the first member of an array of integers containing the tab stops, in dialog box units. The tab stops must be sorted in increasing order; back tabs are not allowed.

Returns

The return value is nonzero if all the tabs were set; otherwise, the return value is zero.

Comments

To respond to the LB_SETTABSTOPS message, the list box must have been created with the **LBS_USETABSTOPS** style.

If the *cTabs* parameter is zero and the *lpTabs* parameter is NULL, the default tab stop is two dialog box units.

If *cTabs* is 1, the list box will have tab stops separated by the distance specified by *lpTabs.*

If *lpTabs* points to more than a single value, a tab stop will be set for each value in *lpTabs,* up to the number specified by *cTabs.*

A dialog box unit is a horizontal or vertical distance. One horizontal dialog box unit is equal to one-fourth of the current dialog box base width unit. The dialog box base units are computed based on the height and width of the current system font. The **GetDialogBaseUnits** function returns the current dialog box base units, in pixels.

LB_SETTOPINDEX (3.0)

```
LB_SETTOPINDEX
wParam = (WPARAM) index;        /* item index             */
lParam = 0L;                    /* not used, must be zero */
```

An application sends an LB_SETTOPINDEX message to ensure that a particular item in a list box is visible.

Parameter	Description
index	Value of *wParam.* Specifies the zero-based index of the item in the list box.

Returns

The return value is LB_ERR if an error occurs.

Comments

The system scrolls the list box so that either the specified item appears at the top of the list box or the maximum scroll range has been reached.

Example

This example searches for an item in a list box that matches the string "my string" and, if a match is found, ensures that the item is visible:

```
int iIndex;

iIndex = (int) SendMessage(hMyListbox, LB_FINDSTRING, -1,
    (LPARAM) (LPSTR) "my string");

if (iIndex != LB_ERR)
  SendMessage(hMyListbox, LB_SETTOPINDEX, (WPARAM) iIndex, 0);
```

See Also

LB_GETTOPINDEX

STM_GETICON (3.1)

```
STM_GETICON
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends an STM_GETICON message to retrieve the handle of the icon associated with an icon resource.

Parameters

This message has no parameters.

Returns

The return value is the icon handle if the operation is successful, or it is zero if the icon has no associated icon resource or if an error occurred.

Example

This example gets the handle of the icon associated with an icon resource:

```
HICON hicon;

hicon = (HICON) SendDlgItemMessage(hdlg, IDD_ICON,
    STM_GETICON, 0, 0L);
```

See Also

STM_SETICON

STM_SETICON (3.1)

```
STM_SETICON
wParam = (WPARAM) (HICON) hicon;     /* handle of the icon     */
lParam = 0L;                         /* not used, must be zero */
```

An application sends an STM_SETICON message to associate an icon with an icon resource.

Parameter	Description
hicon	Value of *wParam.* Identifies the icon to associate with the icon resource.

Returns

The return value is the handle of the icon that was previously associated with the icon resource, or it is zero if an error occurred.

Example

This example associates the system-defined question-mark icon with an icon resource:

```
HICON hicon, hiconOld;

hicon = LoadIcon(NULL, IDI_QUESTION);
hiconOld = (HICON) SendDlgItemMessage(hdlg, IDD_ICON,
    STM_SETICON, (WPARAM) hicon, 0);
```

See Also

STM_GETICON, **LoadIcon**

WM_ACTIVATE (2.x)

```
WM_ACTIVATE
fActive = wParam;                    /* activation flag */
fMinimized = (BOOL) HIWORD(lParam); /* minimized flag  */
hwnd = (HWND) LOWORD(lParam);        /* window handle   */
```

The WM_ACTIVATE message is sent when a window is being activated or deactivated. This message is sent first to the window procedure of the main window being deactivated and then to the window procedure of the main window being activated.

Parameter	Description
fActive	Value of *wParam.* Specifies whether the window is being activated or deactivated. It can be one of the following values:

Value	Description
WA_INACTIVE	The window is being deactivated.
WA_ACTIVE	The window is being activated through some method other than a mouse click (for example, by use of the keyboard interface to select the window).
WA_CLICKACTIVE	The window is being activated by a mouse click.

fMinimized	Value of the high-order word of *lParam.* Specifies the minimized state of the window being activated or deactivated. A nonzero value indicates the window is minimized.
hwnd	Value of the low-order word of *lParam.* Identifies the window being activated or deactivated. This handle can be NULL.

Returns
An application should return zero if it processes this message.

Comments
If the window is activated with a mouse click, it also receives a **WM_MOUSEACTIVATE** message.

Example
This example sets the input focus while processing the WM_ACTIVATE message:

```
case WM_ACTIVATE:

    if (wParam && !HIWORD(lParam))
        SetFocus(hwnd);
    break;
```

See Also
WM_MOUSEACTIVATE, **WM_NCACTIVATE**, **DefWindowProc**, **SetFocus**

WM_ACTIVATEAPP (2.x)

```
WM_ACTIVATEAPP
fActive = (BOOL) wParam;        /* the activation/deactivation flag */
htask = (HTASK) LOWORD(lParam); /* task handle                      */
```

The WM_ACTIVATEAPP message is sent when a window is about to be activated and that window belongs to a different task than the active window. The message is sent to all top-level windows of the task being activated and to all top-level windows of the task being deactivated.

Parameter	Description
fActive	Value of *wParam.* Specifies whether the window is being activated or deactivated. A nonzero value means the window is being activated. A zero value means the window is being deactivated.
htask	Value of the low-order word of *lParam.* Specifies a task handle. If the *fActive* parameter is nonzero, the handle identifies the task that owns the window being deactivated. If *fActive* is zero, the handle identifies the task that owns the window being activated.

Returns

An application should return zero if it processes this message.

See Also

WM_ACTIVATE

WM_ASKCBFORMATNAME (2.x)

```
WM_ASKCBFORMATNAME
wParam = (WPARAM) cbMax;            /* maximum bytes to copy  */
lParam = (LPARAM) lpszFormatName;   /* address of format name */
```

A clipboard viewer application sends a WM_ASKCBFORMATNAME message to the clipboard owner when the clipboard contains the data handle of the CF_OWNERDISPLAY format (that is, when the clipboard owner should display the clipboard contents).

Parameter	Description
cbMax	Value of *wParam.* Specifies the maximum number of bytes to copy.
lpszFormatName	Value of *lParam.* Points to the buffer where the copy of the format name is to be stored.

Returns

An application should return zero if it processes this message.

Comments

The clipboard owner should copy the name of the CF_OWNERDISPLAY format into the specified buffer, not exceeding the maximum number of bytes.

See Also

WM_PAINTCLIPBOARD

WM_CANCELMODE (2.x)

```
WM_CANCELMODE
```

The WM_CANCELMODE message is sent to inform a window to cancel any internal mode. This message is sent to the focus window when a dialog box or message box is displayed, giving the focus window the opportunity to cancel modes such as mouse capture.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

The **DefWindowProc** function processes this message by calling the **ReleaseCapture** function. **DefWindowProc** does not cancel any other modes.

See Also

DefWindowProc, **ReleaseCapture**

WM_CHANGECBCHAIN (2.x)

```
WM_CHANGECBCHAIN
hwndRemoved = (HWND) wParam;        /* handle of removed window */
hwndNext = (HWND) LOWORD(lParam);   /* handle of next window    */
```

The WM_CHANGECBCHAIN message notifies the first window in the clipboard-viewer chain that a window is being removed from the chain.

Parameter	Description
hwndRemoved	Value of *wParam.* Identifies the window that is being removed from the clipboard-viewer chain.
hwndNext	Value of the low-order word of *lParam.* Identifies the window that follows the window being removed from the clipboard-viewer chain.

Returns

An application should return zero if it processes this message.

Comments

Each window that receives the WM_CHANGECBCHAIN message should call the **SendMessage** function to pass the message on to the next window in the clipboard-viewer chain. If the window being removed is the next window in the chain, the window specified by the *hwndNext* parameter becomes the next window and clipboard messages are passed on to it.

See Also

ChangeClipboardChain, **SendMessage**

WM_CHAR (2.x)

```
WM_CHAR
nVKey = wParam;               /* virtual-key code */
dwKeyData = (DWORD) lParam;   /* key data         */
```

The WM_CHAR message is sent when a **WM_KEYUP** message and a **WM_KEYDOWN** message are translated. The WM_CHAR message contains the value of the key being pressed or released.

Parameter	Description
nVKey	Value of *wParam.* Specifies the virtual-key code value of the key.
dwKeyData	Value of *lParam.* Specifies the repeat count, scan code, extended key, context code, previous key state, and key-transition state, as shown in the following table:

Bit	Description
0-15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16-23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).
24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.
25-26	Not used.
27-28	Used internally by Windows.
29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.
30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.
31	Specifies the key-transition state. The value is 1 if the key is being released, or it is 0 if the key is being pressed.

Returns

An application should return zero if it processes this message.

Comments

Because there is not necessarily a one-to-one correspondence between keys pressed and character messages generated, the information in the high-order word of the *dwKeyData* parameter is usually not useful to applications. The information in the high-order word applies only to the most recent **WM_KEYUP** or **WM_KEYDOWN** message that precedes the posting of the character message.

For IBM Enhanced 101- and 102-key keyboards, enhanced keys are the right ALT key and the right CTRL key on the main section of the keyboard; the INS, DEL, HOME, END, PAGE UP, PAGE DOWN, and arrow keys in the clusters to the left of the numeric keypad; and the division (*/*) and ENTER keys on the numeric keypad. Some other keyboards may support the extended-key bit in the *dwKeyData* parameter.

See Also

WM_KEYDOWN, **WM_KEYUP**

WM_CHARTOITEM (3.0)

```
WM_CHARTOITEM
nKey = wParam;                          /* key value       */
hwndListBox = (HWND) LOWORD(lParam);    /* list box handle */
iCaretPos = HIWORD(lParam);             /* caret position  */
```

The WM_CHARTOITEM message is sent by a list box with the **LBS_WANTKEYBOARDINPUT** style to its owner in response to a **WM_CHAR** message.

Parameter	Description
nKey	Value of *wParam.* Specifies the value of the key the user pressed.
hwndListBox	Value of the low-order word of *lParam.* Identifies the list box.
iCaretPos	Value of the high-order word of *lParam.* Specifies the current caret position.

Returns

The return value specifies the action that the application performed in response to the message. A return value of -2 indicates that the application handled all aspects of selecting the item and requires no further action by the list box. A return value of -1 indicates that the list box should perform the default action in response to the keystroke. A return value of 0 or greater specifies the zero-based index of an item in the list box and indicates that the list box should perform the default action for the keystroke on the given item.

Comments

Only owner-drawn list boxes that do not have the **LBS_HASSTRINGS** style can receive this message.

See Also

WM_CHAR, **WM_VKEYTOITEM**

WM_CHILDACTIVATE (2.x)

`WM_CHILDACTIVATE`

The WM_CHILDACTIVATE message is sent to a multiple document interface (MDI) child window when the user clicks the window's title bar or when the window is activated, moved, or sized.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

See Also

MoveWindow, **SetWindowPos**

WM_CHOOSEFONT_GETLOGFONT (3.1)

```
WM_CHOOSEFONT_GETLOGFONT
wParam = 0;                    /* not used, must be zero         */
lplf = (LPLOGFONT) lParam;     /* address of a LOGFONT structure */
```

An application sends a WM_CHOOSEFONT_GETLOGFONT message to the Font dialog box created by the **ChooseFont** function to retrieve the current **LOGFONT** structure.

Parameter	Description
lplf	Points to a **LOGFONT** structure that receives information about the current logical font.

Returns

This message does not return a value.

Comments

An application uses this message to retrieve the **LOGFONT** structure while the Font dialog box is open. When the user closes the dialog box, the **ChooseFont** function receives information about the **LOGFONT** structure.

See Also

WM_GETFONT, **ChooseFont**, **LOGFONT**

WM_CLEAR (2.x)

```
WM_CLEAR
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a WM_CLEAR message to an edit control or combo box to delete (clear) the current selection, if any, in the edit control.

Parameters

This message has no parameters.

Returns

The return value is nonzero if this message is sent to an edit control or a combo box.

Comments

The deletion performed by the WM_CLEAR message can be undone by sending the edit control an **EM_UNDO** message.

To delete the current selection and place the deleted contents into the clipboard, use the **WM_CUT** message.

Example

This example sends an **EM_SETSEL** message to select the entire contents of an edit control. It then sends a WM_CLEAR message to delete the contents of the edit control.

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETSEL, 0, MAKELONG(0, -1));
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    WM_CLEAR, 0, 0);
```

See Also

EM_UNDO, **WM_COPY**, **WM_CUT**, **WM_PASTE**

WM_CLOSE (2.x)

```
WM_CLOSE
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

The WM_CLOSE message is sent as a signal that a window or an application should terminate. An application can prompt the user for confirmation prior to destroying the window by processing the WM_CLOSE message and calling the **DestroyWindow** function only if the user confirms the choice.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Example

This example processes a WM_CLOSE message and requests confirmation from the user before terminating the application:

```
case WM_CLOSE:
    if (MessageBox(hwnd, "Are you sure you want to exit?", "MyApp",
          MB_ICONQUESTION | MB_OKCANCEL) == IDOK)
        DestroyWindow(hwnd);
    return 0L;
```

See Also

DestroyWindow, **PostQuitMessage**, **WM_DESTROY**, **WM_QUERYENDSESSION**, **WM_QUIT**

WM_COMMAND (2.x)

```
WM_COMMAND
idItem = wParam;        /* control or menu item identifier      */
hwndCtl = (HWND) LOWORD(lParam); /* handle of control           */
wNotifyCode = HIWORD(lParam);    /* notification message        */
```

The WM_COMMAND message is sent to a window when the user selects an item from a menu, when a control sends a notification message to its parent window, or when an accelerator keystroke is translated.

Parameter	Description
idItem	Value of *wParam.* Specifies the identifier of the menu item or control.
hwndCtl	Value of the low-order word of *lParam.* Identifies the control sending the message if the message is from a control. Otherwise, this parameter is zero.
wNotifyCode	Value of the high-order word of *lParam.* Specifies the notification message if the message is from a control. If the message is from an accelerator, this parameter is 1. If the message is from a menu, this parameter is 0.

Returns
An application should return zero if it processes this message.

Comments
Accelerator keystrokes that are defined to select items from the System menu (sometimes referred to as the Control menu) are translated into **WM_SYSCOMMAND** messages.

If an accelerator keystroke that corresponds to a menu item occurs when the window that owns the menu is minimized, no WM_COMMAND message is sent. However, if an accelerator keystroke occurs that does not match any of the items on the window's menu or on the System menu, a WM_COMMAND message is sent even if the window is minimized.

Example
This example creates an Options dialog box in response to a WM_COMMAND message sent as a result of a menu selection:

```
FARPROC lpProc;

case WM_COMMAND:
    switch (wParam) {
        case IDM_OPTIONS:
            lpProc = MakeProcInstance(OptionsProc, hInstance);
            DialogBox(hInstance, "OptionsBox", hwnd, (DLGPROC) lpProc);
            FreeProcInstance(lpProc);
            break;
        .
        . /* Process other menu commands. */
        .
    }
    break;
```

See Also
WM_SYSCOMMAND

WM_COMMNOTIFY (3.1)

```
WM_COMMNOTIFY
idDevice = wParam;              /* communication-device ID  */
nNotifyStatus = LOWORD(lParam); /* notification-status flag */
```

The WM_COMMNOTIFY message is posted by a communication device driver whenever a COM port event occurs. The message indicates the status of a window's input or output queue.

Parameter	Description
idDevice	Value of *wParam.* Specifies the identifier of the communication device that is posting the notification message.
nNotifyStatus	Value of the low-order word of *lParam.* Specifies the notification status in the low-order word. The notification status may be one or more of the following flags:

Value	Meaning
CN_EVENT	Indicates that an event has occurred that was enabled in the event word of the communication device. This event was enabled by a call to the **SetCommEventMask** function. The application should call the **GetCommEventMask** function to determine which event occurred and to clear the event.
CN_RECEIVE	Indicates that at least *cbWriteNotify* bytes are in the input queue. The *cbWriteNotify* parameter is a parameter of the **EnableCommNotification** function.
CN_TRANSMIT	Indicates that fewer than *cbOutQueue* bytes are in the output queue waiting to be transmitted. The *cbOutQueue* parameter is a parameter of the **EnableCommNotification** function.

Returns

An application should return zero if it processes this message.

Comments

This message is sent only when the event word changes for the communication device. The application that sends WM_COMMNOTIFY must clear each event to be sure of receiving future notifications.

See Also

EnableCommNotification

WM_COMPACTING (3.0)

```
WM_COMPACTING
wCompactRatio = wParam;  /* compacting ratio */
```

The WM_COMPACTING message is sent to all top-level windows when Windows detects that more than 12.5 percent of system time over a 30- to 60-second interval is being spent compacting memory. This indicates that system memory is low.

Parameter	Description
wCompactRatio	Value of *wParam.* Specifies the ratio of central processing unit (CPU) time currently spent by Windows compacting memory to CPU time currently spent by Windows performing other operations. For example, 0x8000 represents 50 percent of CPU time spent compacting memory.

Returns

An application should return zero if it processes this message.

Comments

When an application receives this message, it should free as much memory as possible, taking into account the current level of activity of the application and the total number of applications running with Windows. The application can call the **GetNumTasks** function to determine how many applications are running.

See Also

GetNumTasks

WM_COMPAREITEM (3.0)

```
WM_COMPAREITEM
idCtl = wParam;                              /* control identifier */
lpcis = (const COMPAREITEMSTRUCT FAR*) lParam; /* structure     */
```

The WM_COMPAREITEM message determines the relative position of a new item in the sorted list of an owner-drawn combo box or list box. Whenever the application adds a new item, Windows sends this message to the owner of a combo box or list box created with the **CBS_SORT** or **LBS_SORT** style.

Parameter	Description
idCtl	Value of *wParam.* Specifies the identifier of the control that sent the WM_COMPAREITEM message.
lpcis	Value of *lParam.* Points to a **COMPAREITEMSTRUCT** data structure that contains the identifiers and application-supplied data for two items in the combo box or list box.

Returns

The return value indicates the relative position of the two items. It may be any of the following values:

Value	Meaning
-1	Item 1 precedes item 2 in the sorted order.
0	Item 1 and item 2 are equivalent in the sorted order.
1	Item 1 follows item 2 in the sorted order.

Comments

When the owner of an owner-drawn combo box or list box receives this message, the owner returns a value indicating which of the items specified in the **COMPAREITEMSTRUCT** structure should appear before the other. Typically, Windows sends this message several times until it determines the exact position for the new item.

See Also

COMPAREITEMSTRUCT

Windows 3.1 changes

The meaning of the *wParam* parameter has changed. The *wParam* parameter specifies the identifier of the control.

WM_COPY (2.x)

```
WM_COPY
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a WM_COPY message to an edit control or combo box to copy the current selection to the clipboard in CF_TEXT format.

Parameters

This message has no parameters.

Returns

The return value is nonzero if this message is sent to an edit control or a combo box.

Example

This example sends an **EM_SETSEL** message to select the entire contents of an edit control. It then sends a WM_COPY message to copy the contents of the edit control to the clipboard.

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETSEL, 0, MAKELONG(0, -1));
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    WM_COPY, 0, 0);
```

See Also

WM_CLEAR, **WM_CUT**, **WM_PASTE**

WM_CREATE (2.x)

```
WM_CREATE
lpcs = (CREATESTRUCT FAR*) lParam;      /* structure address          */
```

The WM_CREATE message is sent when an application requests that a window be created by calling the **CreateWindowEx** or **CreateWindow** function. The window procedure for the new window receives this message after the window is created but before the window becomes visible. The message is sent to the window before the **CreateWindowEx** or **CreateWindow** function returns.

Parameter	Description
lpcs	Value of *lParam.* Points to a **CREATESTRUCT** data structure containing information about the window being created. The members of the **CREATESTRUCT** structure are identical to the parameters of the **CreateWindowEx** function.

Returns

If an application processes this message, it should return 0 to continue creation of the window. If the application returns -1, the window will be destroyed and the **CreateWindowEx** or **CreateWindow** function will return a NULL handle.

See Also

CreateWindow, **CreateWindowEx**, **WM_NCCREATE**, **CREATESTRUCT**

WM_CTLCOLOR (2.x)

```
WM_CTLCOLOR
hdcChild = (HDC) wParam;            /* child-window display context */
hwndChild = (HWND) LOWORD(lParam);  /* handle of child window       */
nCtlType = (int) HIWORD(lParam);    /* type of control              */
```

The WM_CTLCOLOR message is sent to the parent of a system-defined control class or a message box when the control or message box is about to be drawn. The following controls send this message:

Combo boxes
Edit controls
List boxes
Buttons
Static controls
Scroll bars

Parameter	Description
hdcChild	Value of *wParam.* Identifies the display context for the child window.
hwndChild	Value of the low-order word of *lParam.* Identifies the child window.
nCtlType	Value of the high-order word of *lParam.* Specifies the type of the control. This parameter can be one of the following values:

Value	Meaning
CTLCOLOR_BTN	Button
CTLCOLOR_DLG	Dialog box
CTLCOLOR_EDIT	Edit control
CTLCOLOR_LISTBOX	List box
CTLCOLOR_MSGBOX	Message box
CTLCOLOR_SCROLLBAR	Scroll bar
CTLCOLOR_STATIC	Static control

Returns

If an application processes the WM_CTLCOLOR message, it must return a handle to the brush that is to be used for painting the control background or it must return NULL.

Comments

The WM_CTLCOLOR message is sent to the parent window for all control types except dialog boxes. When the *nCtlType* parameter specifies CTLCOLOR_DLG, the message is sent to the dialog box procedure.

To change the text color, the application should call the **SetTextColor** function with the desired red, green, and blue (**RGB**) values.

To change the background color of a single-line edit control, the application must set the brush handle in both the CTLCOLOR_EDIT and CTLCOLOR_MSGBOX message codes, and the application must call the **SetBkColor** function in response to the CTLCOLOR_EDIT code.

The return value from this message has no effect on a button with the **BS_PUSHBUTTON** or **BS_DEFPUSHBUTTON** style.

To change the color of the list box for a drop-down combo box, applications should subclass the combo box and check for the WM_CTLCOLOR message with CTLCOLOR_LISTBOX in the *nCtlType* parameter. This procedure can return a handle to the brush that will be used to paint the background. In this case, the **SetBkColor** function must be used to set the background color for the text.

Example

This example creates a green brush and passes the handle of the brush to a single-line edit control in

response to a WM_CTLCOLOR message:

```
static HBRUSH hbrGreen;

switch(msg) {
    case WM_INITDIALOG:

        /* Create a green brush */

        hbrGreen = CreateSolidBrush(RGB(0, 255, 0));
        return TRUE;

    case WM_CTLCOLOR:
        switch(HIWORD(lParam)) {
            case CTLCOLOR_EDIT:

                /* Set text to white and background to green */

                SetTextColor((HDC) wParam, RGB(255, 255, 255));
                SetBkColor((HDC) wParam, RGB(0, 255, 0));
                return (LRESULT) hbrGreen;

            case CTLCOLOR_MSGBOX:

                /*
                 * For single-line edit controls, this code must be
                 * processed so that the background color of the format
                 * rectangle will also be painted with the new color.
                 */

                return (LRESULT) hbrGreen;
        }
        return (LRESULT) NULL;
}
```

See Also
SetBkColor

WM_CUT (2.x)

```
WM_CUT
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a WM_CUT message to an edit control or combo box to delete (cut) the current selection, if any, in the edit control and copy the deleted text to the clipboard in CF_TEXT format.

Parameters

This message has no parameters.

Returns

The return value is nonzero if this message is sent to an edit control or a combo box.

Comments

An **EM_UNDO** message can be sent to the edit control to undo the deletion performed by the WM_CUT message.

To delete the current selection without placing the deleted text onto the clipboard, use the **WM_CLEAR** message.

Example

This example sends an **EM_SETSEL** message to select the entire contents of an edit control. It then sends a WM_CUT message to delete the contents of the edit control and to copy the deleted text to the clipboard.

```
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    EM_SETSEL, 0, MAKELONG(0, -1));
SendDlgItemMessage(hdlg, ID_MYEDITCONTROL,
    WM_CUT, 0, 0);
```

See Also

WM_CLEAR, **WM_COPY**, **WM_PASTE**

WM_DDE_ACK (2.x)

```
#include <dde.h>

WM_DDE_ACK
wParam = (WPARAM) hwnd;             /* handle of posting window      */
lParam = MAKELPARAM(wLow, wHigh);  /* depending on received message */
```

The WM_DDE_ACK message notifies an application of the receipt and processing of a **WM_DDE_INITIATE**, **WM_DDE_EXECUTE**, **WM_DDE_DATA**, **WM_DDE_ADVISE**, **WM_DDE_UNADVISE**, or **WM_DDE_POKE** message, and in some cases, of a **WM_DDE_REQUEST** message.

Parameter	Description
hwnd	Value of *wParam.* Specifies the handle of the window posting the message.
wLow	Value of the low-order word of *lParam.* Specifies data as follows, depending on the message to which the WM_DDE_ACK message is responding:

Message	Parameter	Description
WM_DDE_INITIATE	*aApplication*	An atom that contains the name of the replying application.
WM_DDE_EXECUTE and all other messages	*wStatus*	A series of flags that indicate the status of the response.

wHigh	Value of high-order word of *lParam.* Specifies data as follows, depending on the message to which the WM_DDE_ACK message is responding:

Message	Parameter	Description
WM_DDE_INITIATE	*aTopic*	An atom that contains the topic with which the replying server window is associated.
WM_DDE_EXECUTE	*hCommands*	A handle that identifies the data item containing the command string.
All other messages	*aItem*	An atom that specifies the data item for which the response is sent.

Returns

This message does not return a value.

Comments

The *wStatus* word consists of a **DDEACK** data structure.

Posting

Except in response to the **WM_DDE_INITIATE** message, the application posts the WM_DDE_ACK message by calling the **PostMessage** function, not the **SendMessage** function. When responding to WM_DDE_INITIATE, the application sends the WM_DDE_ACK message by calling **SendMessage**.

When acknowledging any message with an accompanying *aItem* atom, the application posting WM_DDE_ACK can either reuse the *aItem* atom that accompanied the original message or delete it and create a new one.

When acknowledging **WM_DDE_EXECUTE**, the application that posts WM_DDE_ACK should reuse the *hCommands* object that accompanied the original WM_DDE_EXECUTE message.

If an application has initiated the termination of a conversation by posting **WM_DDE_TERMINATE** and

is awaiting confirmation, the waiting application should not acknowledge (positively or negatively) any subsequent messages sent by the other application. The waiting application should delete any atoms or shared memory objects received in these intervening messages (but should not delete the atoms in response to the WM_DDE_ACK message).

Receiving

The application that receives WM_DDE_ACK should delete all atoms accompanying the message.

If the application receives WM_DDE_ACK in response to a message with an accompanying *hData* object, the application should delete the *hData* object.

If the application receives a negative WM_DDE_ACK message posted in reply to a **WM_DDE_ADVISE** message, the application should delete the *hOptions* object posted with the original WM_DDE_ADVISE message.

If the application receives a negative WM_DDE_ACK message posted in reply to a **WM_DDE_EXECUTE** message, the application should delete the *hCommands* object posted with the original WM_DDE_EXECUTE message.

See Also

DDEACK, **PostMessage**, **WM_DDE_ADVISE**, **WM_DDE_DATA**, **WM_DDE_EXECUTE**, **WM_DDE_INITIATE**, **WM_DDE_POKE**, **WM_DDE_REQUEST**, **WM_DDE_TERMINATE**, **WM_DDE_UNADVISE**, **DDEACK**

WM_DDE_ADVISE (2.x)

```
#include <dde.h>

WM_DDE_ADVISE
wParam = (WPARAM) hwnd;                /* handle of posting window   */
lParam = MAKELPARAM(hOptions, aItem); /* send options and data item */
```

A dynamic data exchange (DDE) client application posts the WM_DDE_ADVISE message to a DDE server application to request the server to supply an update for a data item whenever it changes.

Parameter	Description
hwnd	Value of *wParam.* Identifies the sending window.
hOptions	Value of the low-order word of *lParam.* Specifies a handle of a global memory object that specifies how the data is to be sent.
aItem	Value of the high-order word of *lParam.* Specifies the data item being requested.

Returns

This message does not return a value.

Comments

The global memory object identified by the *hOptions* parameter consists of a **DDEADVISE** data structure.

If an application supports more than one clipboard format for a single topic and item, it can post multiple WM_DDE_ADVISE messages for the topic and item, specifying a different clipboard format with each message.

Posting

The application posts the WM_DDE_ADVISE message by calling the **PostMessage** function, not the **SendMessage** function.

The application allocates *hOptions* by calling the **GlobalAlloc** function with the **GMEM_DDESHARE** option.

The application allocates *aItem* by calling the **GlobalAddAtom** function.

If the receiving (server) application responds with a negative **WM_DDE_ACK** message, the posting (client) application must delete the *hOptions* object.

Receiving

The application posts the **WM_DDE_ACK** message to respond positively or negatively. When posting WM_DDE_ACK, the application can reuse the *aItem* atom or delete it and create a new one. If the WM_DDE_ACK message is positive, the application should delete the *hOptions* object; otherwise, the application should not delete the object.

See Also

DDEADVISE, **GlobalAddAtom**, **GlobalAlloc**, **PostMessage**, **WM_DDE_DATA**, **WM_DDE_REQUEST**, **DDEADVISE**

WM_DDE_DATA (2.x)

```
#include <dde.h>

WM_DDE_DATA
wParam = (WPARAM) hwnd;              /* handle of posting window    */
lParam = MAKELPARAM(hData, aItem);  /* memory object and data item */
```

A dynamic data exchange (DDE) server application posts a WM_DDE_DATA message to a DDE client application to pass a data item to the client or to notify the client of the availability of a data item.

Parameter	Description
hwnd	Value of *wParam.* Specifies the handle of the window posting the message.
hData	Value of the low-order word of *lParam.* Identifies the global memory object containing the data and additional information. The handle should be set to NULL if the server is notifying the client that the data item value has changed during a warm link. A warm link is established when the client sends a **WM_DDE_ADVISE** message with the *fDeferUpd* bit set.
aItem	Value of the high-order word of *lParam.* Specifies the data item for which data or notification is sent.

Returns

This message does not return a value.

Comments

The global memory object identified by the *hData* parameter consists of a **DDEDATA** structure.

Posting

The application posts the WM_DDE_DATA message by calling the **PostMessage** function, not the **SendMessage** function.

The application allocates *hData* by calling the **GlobalAlloc** function with the **GMEM_DDESHARE** option.

The application allocates *aItem* by calling the **GlobalAddAtom** function.

If the receiving (client) application responds with a negative **WM_DDE_ACK** message, the posting (server) application must delete the *hData* object.

If the posting (server) application sets the **fRelease** member of the **DDEDATA** structure to FALSE, the posting application is responsible for deleting *hData* upon receipt of either a positive or negative acknowledgment.

The application should not set both the **fAckReq** and **fRelease** members of the **DDEDATA** structure to FALSE. If both members are set to FALSE, it is difficult for the posting (server) application to determine when to delete *hData.*

Receiving

If **fAckReq** is TRUE, the application posts the **WM_DDE_ACK** message to respond positively or negatively. When posting WM_DDE_ACK, the application can reuse the *aItem* atom or delete it and create a new one.

If **fAckReq** is FALSE, the application deletes the *aItem* atom.

If the posting (server) application specified *hData* as NULL, the receiving (client) application can request the server to send the actual data by posting a **WM_DDE_REQUEST** message.

After processing a WM_DDE_DATA message in which *hData* is not NULL, the application should delete *hData* unless either of the following conditions is true:

- The **fRelease** member is FALSE.
- The **fRelease** member is TRUE, but the receiving (client) application responds with a negative

WM_DDE_ACK message.

See Also
DDEDATA, **GlobalAddAtom**, **GlobalAlloc**, **PostMessage**, **WM_DDE_ACK**, **WM_DDE_ADVISE**, **WM_DDE_POKE**, **WM_DDE_REQUEST**

WM_DDE_EXECUTE (2.x)

```
#include <dde.h>

WM_DDE_EXECUTE
wParam = (WPARAM) hwnd;                    /* handle of posting window */
lParam = MAKELPARAM(reserved, hCommands); /* commands to execute      */
```

A dynamic data exchange (DDE) client application posts a WM_DDE_EXECUTE message to a DDE server application to send a string to the server to be processed as a series of commands. The server application is expected to post a **WM_DDE_ACK** message in response.

Parameter	Description
hwnd	Value of *wParam.* Identifies the sending window.
reserved	Value of the low-order word of *lParam.* Reserved; must be zero.
hCommands	Value of the high-order word of *lParam.* Identifies a global memory object containing the command(s) to be executed.

Returns
This message does not return a value.

Comments
The command string is a null-terminated string, consisting of one or more *opcode* strings enclosed in single brackets ([ ]) and separated by spaces.

Each *opcode* string has the following syntax. The *parameters* list is optional.

opcode parameters

The *opcode* is any application-defined single token. It cannot include spaces, commas, parentheses, or quotation marks.

The *parameters* list can contain any application-defined value or values. Multiple parameters are separated by commas, and the entire parameter list is enclosed in parentheses. Parameters cannot include commas or parentheses except inside a quoted string. If a bracket or parenthesis character is to appear in a quoted string, it must be doubled--for example, "((".

The following are valid command strings:

```
[connect][download(query1,results.txt)][disconnect]
[query("sales per employee for each district")]
[open("sample.xlm")][run("r1c1")]
```

Posting

The application posts the WM_DDE_EXECUTE message by calling the **PostMessage** function, not the **SendMessage** function.

The application allocates *hCommands* by calling the **GlobalAlloc** function with the **GMEM_DDESHARE** option.

When processing a **WM_DDE_ACK** message posted in reply to a WM_DDE_EXECUTE message, the application that posted the original WM_DDE_EXECUTE message must delete the *hCommands* object sent back in the WM_DDE_ACK message.

Receiving

The application posts the **WM_DDE_ACK** message to respond positively or negatively, reusing the *hCommands* object.

See Also
PostMessage, **WM_DDE_ACK**

WM_DDE_INITIATE (2.x)

```
#include <dde.h>

WM_DDE_INITIATE
wParam = (WPARAM) hwnd;                      /* sending window's handle */
lParam = MAKELPARAM(aApplication, aTopic); /* app. and topic atoms    */
```

A dynamic data exchange (DDE) client application sends a WM_DDE_INITIATE message to initiate a conversation with server applications responding to the specified application and topic names.

Upon receiving this message, all server applications with names that match the *aApplication* application and that support the *aTopic* topic are expected to acknowledge it (see the **WM_DDE_ACK** message).

Parameter	Description
hwnd	Value of *wParam.* Identifies the sending window.
aApplication	Value of the low-order word of *lParam.* Specifies the atom identifying the name of the application with which a conversation is requested. The application name cannot contain slash marks (/) or backslashes (\). These characters are reserved for future use in network implementations. If *aApplication* is NULL, a conversation with all applications is requested.
aTopic	Value of the high-order word of *lParam.* Specifies the atom identifying the the topic for which a conversation is requested. If the topic is NULL, a conversation for all available topics is requested.

Returns
This message does not return a value.

Comments
If *aApplication* is NULL, any application can respond. If *aTopic* is NULL, any topic is valid. Upon receiving a WM_DDE_INITIATE request with the *aTopic* parameter set to NULL, an application is expected to send a **WM_DDE_ACK** message for each of the topics it supports.

Sending

The application sends the WM_DDE_INITIATE message by calling the **SendMessage** function, not the **PostMessage** function. The application broadcasts the message to all windows by setting the first parameter of **SendMessage** to -1, as shown:

```
SendMessage(-1, WM_DDE_INITIATE, hwndClient, MAKELONG(aApp, aTopic));
```

If the application has already obtained the window handle of the desired server, it can send WM_DDE_INITIATE directly to the server window by passing the server's window handle as the first parameter of **SendMessage**.

The application allocates *aApplication* and *aTopic* by calling **GlobalAddAtom**.

When **SendMessage** returns, the application deletes the *aApplication* and *aTopic* atoms.

Receiving

To complete the initiation of a conversation, the application responds with one or more **WM_DDE_ACK** messages, where each message is for a separate topic. When sending a WM_DDE_ACK message, the application creates new *aApplication* and *aTopic* atoms; it should not reuse the atoms sent with the WM_DDE_INITIATE message.

See Also
GlobalAddAtom, **SendMessage**, **WM_DDE_ACK**

WM_DDE_POKE (2.x)

```
#include <dde.h>

WM_DDE_POKE
wParam = (WPARAM) hwnd;              /* handle of posting window */
lParam = MAKELPARAM(hData, aItem);  /* data handle and item     */
```

A dynamic data exchange (DDE) client application posts a WM_DDE_POKE message to a server application. A client uses this message to request the server to accept an unsolicited data item. The server is expected to reply with a **WM_DDE_ACK** message indicating whether it accepted the data item.

Parameter	Description
hwnd	Value of *wParam.* Specifies the handle of the window posting the message.
hData	Value of the low-order word of *lParam.* Identifies the data being posted. The handle identifies a global memory object that contains a **DDEPOKE** data structure.
aItem	Value of the high-order word of *lParam.* Specifies a global atom that identifies the data item being offered to the server.

Returns

This message does not return a value.

Comments

Posting

The posting (client) application should do the following:

- Use the **PostMessage** function to post the WM_DDE_POKE message.
- Use the **GlobalAlloc** function with the **GMEM_DDESHARE** option to allocate memory for the data.
- Use the **GlobalAddAtom** function to create the atom for the data item.
- Delete the global memory object if the server application responds with a negative **WM_DDE_ACK** message.
- Delete the global memory object if the client has set the **fRelease** member of the **DDEPOKE** structure to FALSE and the server responds with either a positive or negative WM_DDE_ACK.

Receiving

The receiving (server) application should do the following:

- Post the **WM_DDE_ACK** message to respond positively or negatively. When posting WM_DDE_ACK, reuse the data-item atom or delete it and create a new one.
- Delete the global memory object after processing WM_DDE_POKE unless either the **fRelease** flag was set to FALSE or the **fRelease** flag was set to TRUE but the server has responded with a negative **WM_DDE_ACK** message.

See Also

DDEPOKE, **GlobalAlloc**, **PostMessage**, **WM_DDE_ACK**, **WM_DDE_DATA**, **DDEPOKE**

WM_DDE_REQUEST (2.x)

```
#include <dde.h>

WM_DDE_REQUEST
wParam = (WPARAM) hwnd;                /* handle of posting window  */
lParam = MAKELPARAM(cfFormat, aItem); /* clipboard format and item */
```

A dynamic data exchange (DDE) client application posts a WM_DDE_REQUEST message to a DDE server application to request the value of a data item.

Parameter	Description
hwnd	Value of *wParam.* Identifies the sending window.
cfFormat	Value of the low-order word of *lParam.* Specifies a standard or registered clipboard format number.
aItem	Value of the high-order word of *lParam.* Specifies which data item is being requested from the server.

Returns
This message does not return a value.

Comments
Posting

The application posts the WM_DDE_REQUEST message by calling the **PostMessage** function, not the **SendMessage** function.

The application allocates *aItem* by calling the **GlobalAddAtom** function.

Receiving

If the receiving (server) application can satisfy the request, it responds with a **WM_DDE_DATA** message containing the requested data. Otherwise, it responds with a negative **WM_DDE_ACK** message.

When responding with either a **WM_DDE_DATA** or **WM_DDE_ACK** message, the application can reuse the *aItem* atom or delete it and create a new one.

See Also
GlobalAddAtom, **PostMessage**, **WM_DDE_ACK**

WM_DDE_TERMINATE (2.x)

```
#include <dde.h>

WM_DDE_TERMINATE
wParam = (WPARAM) hwnd; /* handle of posting window */
lParam = 0L;            /* not used, must be zero   */
```

A dynamic data exchange (DDE) application (client or server) posts a WM_DDE_TERMINATE message to terminate a conversation.

Parameter	Description
hwnd	Value of *wParam.* Identifies the sending window.

Returns

This message does not return a value.

Comments

Posting

The application posts the WM_DDE_TERMINATE message by calling the **PostMessage** function, not the **SendMessage** function.

While waiting for confirmation of the termination, the posting application should not acknowledge any other messages sent by the receiving application. If the posting application receives messages (other than WM_DDE_TERMINATE) from the receiving application, it should delete any atoms or shared memory objects accompanying the messages.

Receiving

The application responds by posting a WM_DDE_TERMINATE message.

See Also

PostMessage

WM_DDE_UNADVISE (2.x)

```
#include <dde.h>

WM_DDE_UNADVISE
wParam = (WPARAM) hwnd;                  /* handle of posting window   */
lParam = MAKELPARAM(cfFormat, aItem);    /* clipboard format and item  */
```

A dynamic data exchange (DDE) client application posts a WM_DDE_UNADVISE message to inform a server application that the specified item or a particular clipboard format for the item should no longer be updated. This terminates the warm or hot link for the specified item.

Parameter	Description
hwnd	Value of *wParam.* Identifies the sending window.
cfFormat	Value of the low-order word of *lParam.* Specifies the clipboard format of the item for which the update request is being retracted. When the *cfFormat* parameter is NULL, all active **WM_DDE_ADVISE** conversations for the item are to be terminated.
aItem	Value of the high-order word of *lParam.* Specifies the item for which the update request is being retracted. When *aItem* is NULL, all active **WM_DDE_ADVISE** conversations associated with the client are to be terminated.

Returns

This message does not return a value.

Comments

Posting

The application posts the WM_DDE_UNADVISE message by calling the **PostMessage** function, not the **SendMessage** function.

The application allocates *aItem* by calling the **GlobalAddAtom** function.

Receiving

The application posts the **WM_DDE_ACK** message to respond positively or negatively. When posting WM_DDE_ACK, the application can reuse the *aItem* atom or delete it and create a new one.

See Also

GlobalAddAtom, **PostMessage**, **WM_DDE_ACK**

WM_DEADCHAR (2.x)

```
WM_DEADCHAR
chDeadKey = wParam;          /* dead-key character */
dwKeyData = (DWORD) lParam;  /* key data           */
```

The WM_DEADCHAR message is sent when a **WM_KEYUP** message and a **WM_KEYDOWN** message are translated. It specifies the character value of a dead key. A dead key is a key, such as the umlaut (double-dot) character, that is combined with other characters to form a composite character. For example, the umlaut-O character consists of the dead key, umlaut, and the O key.

Parameter	Description
chDeadKey	Value of *wParam.* Specifies the dead-key character value.
dwKeyData	Value of *lParam.* Specifies the repeat count, scan code, extended key, context code, previous key state, and key-transition state, as shown in the following table:

Bit	Description
0-15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16-23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).
24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.
25-26	Not used.
27-28	Used internally by Windows.
29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.
30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.
31	Specifies the key-transition state. The value is 1 if the key is being released, or it is 0 if the key is being pressed.

Returns

An application should return zero if it processes this message.

Comments

An application typically uses the WM_DEADCHAR message to give the user feedback about each key pressed. For example, an application can display the accent in the current character position without moving the caret.

Because there is not necessarily a one-to-one correspondence between keys pressed and character messages generated, the information in the high-order word of the *dwKeyData* parameter is usually not useful to applications. The information in the high-order word applies only to the most recent **WM_KEYUP** or **WM_KEYDOWN** message that precedes the posting of the character message.

For IBM Enhanced 101- and 102-key keyboards, enhanced keys are the right ALT key and the right CTRL key on the main section of the keyboard; the INS, DEL, HOME, END, PAGE UP, PAGE DOWN, and arrow keys in the clusters to the left of the numeric keypad; and the division (*/*) and ENTER keys on the numeric keypad. Some other keyboards may support the extended-key bit in the *dwKeyData* parameter.

See Also

WM_KEYDOWN

WM_DELETEITEM (3.0)

```
WM_DELETEITEM
idCtl = wParam;                              /* control identifier */
lpdis = (const DELETEITEMSTRUCT FAR*) lParam; /* structure      */
```

The WM_DELETEITEM message is sent to the owner of an owner-drawn list box or combo box when the list box or combo box is destroyed or when items are removed by the **LB_DELETESTRING**, **LB_RESETCONTENT**, **CB_DELETESTRING**, or **CB_RESETCONTENT** message.

Parameter	Description
idCtl	Value of *wParam.* Specifies the identifier of the control that sent the WM_DELETEITEM message.
lpdis	Value of *lParam.* Points to a **DELETEITEMSTRUCT** structure that contains information about the item deleted from the list box.

Returns

An application should return TRUE if it processes this message.

See Also

CB_DELETESTRING, **CB_RESETCONTENT**, **LB_DELETESTRING**, **LB_RESETCONTENT**, **DELETEITEMSTRUCT**

Windows 3.1 changes

The meaning of the *wParam* parameter has changed. The *wParam* parameter specifies the identifier of the control.

WM_DESTROY (2.x)

```
WM_DESTROY
```

The WM_DESTROY message is sent when a window is being destroyed. It is sent to the window procedure of the window being destroyed after the window is removed from the screen.

This message is sent first to the window being destroyed and then to the child windows as they are destroyed. During the processing of the WM_DESTROY message, it can be assumed that all child windows still exist.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

If the window being destroyed is part of the clipboard-viewer chain (set by calling the **SetClipboardViewer** function), the window must remove itself from the clipboard-viewer chain by calling the **ChangeClipboardChain** function before returning from the WM_DESTROY message.

Example

This example processes the WM_DESTROY message by calling the **PostQuitMessage** function:

```
case WM_DESTROY:
    PostQuitMessage(0);
    return 0L;
```

See Also

ChangeClipboardChain, **DestroyWindow**, **PostQuitMessage**, **SetClipboardViewer**, **WM_CLOSE**

WM_DESTROYCLIPBOARD (2.x)

```
WM_DESTROYCLIPBOARD
```

The WM_DESTROYCLIPBOARD message is sent to the clipboard owner when the clipboard is emptied by a call to the **EmptyClipboard** function.

Parameters

This message has no parameters.

Returns
An application should return zero if it processes this message.

See Also
EmptyClipboard

WM_DEVMODECHANGE (2.x)

```
WM_DEVMODECHANGE
lpszDev = (LPCSTR) lParam;  /* address of device name */
```

The WM_DEVMODECHANGE message is sent to all top-level windows when the default device-mode settings have changed.

Parameter	Description
lpszDev	Value of *lParam.* Points to the device name specified in the Windows initialization file, WIN.INI.

Returns

An application should return zero if it processes this message.

Comments

Applications that receive this message may reinitialize their device-mode settings. Applications that use the **ExtDeviceMode** function to save and restore device settings typically do not process this message.

This message is not sent when the user changes the default printer from Control Panel. In this case, a **WM_WININICHANGE** message is generated.

See Also

ExtDeviceMode, **WM_WININICHANGE**

WM_DRAWCLIPBOARD (2.x)

```
WM_DRAWCLIPBOARD
```

The WM_DRAWCLIPBOARD message is sent to the first window in the clipboard-viewer chain when the contents of the clipboard change. Only applications that have joined the clipboard-viewer chain by calling the **SetClipboardViewer** function need to process this message.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

Each window that receives the WM_DRAWCLIPBOARD message should call the **SendMessage** function to pass the message on to the next window in the clipboard-viewer chain. The handle of the next window is returned by the **SetClipboardViewer** function; the handle may be modified in response to a **WM_CHANGECBCHAIN** message.

See Also

SendMessage, **SetClipboardViewer**, **WM_CHANGECBCHAIN**

WM_DRAWITEM (3.0)

```
WM_DRAWITEM
idCtl = (int) wParam;                       /* control identifier */
lpdis = (const DRAWITEMSTRUCT FAR*) lParam;    /* structure     */
```

The WM_DRAWITEM message is sent to the owner of an owner-drawn button, combo box, list box, or menu when a visual aspect of the button, combo box, list box, or menu has changed.

Parameter	Description
idCtl	Value of *wParam.* Specifies the identifier of the control that sent the WM_DRAWITEM message. This parameter is zero if the message was sent by a menu.
lpdis	Value of *lParam.* Points to a **DRAWITEMSTRUCT** structure that contains information about the item to be drawn and the type of drawing required.

Returns

An application should return TRUE if it processes this message.

Comments

The **itemAction** member of the **DRAWITEMSTRUCT** structure defines the drawing operation that is to be performed. The data in this member allows the owner of the control to determine what drawing action is required.

Before returning from processing this message, an application should ensure that the device context identified by the *hDC* member of the **DRAWITEMSTRUCT** structure is in the default state.

Example

This example shows how to process the WM_DRAWITEM message:

```
LPDRAWITEMSTRUCT lpdis;

case WM_DRAWITEM:
    lpdis = (DRAWITEMSTRUCT FAR*) lParam;

    switch (lpdis->itemAction) {

        case ODA_DRAWENTIRE:
            .
            . /* Redraw the entire control or menu. */
            .
            return TRUE;

        case ODA_SELECT:
            .
            . /* Redraw to reflect current selection state. */
            .
            return TRUE;

        case ODA_FOCUS:
            .
            . /* Redraw to reflect current focus state. */
            .
            return TRUE;
    }
    break;
```

See Also

WM_COMPAREITEM, **WM_DELETEITEM**, **WM_INITDIALOG**, **WM_MEASUREITEM**,

DRAWITEMSTRUCT

Windows 3.1 changes

The meaning of the *wParam* parameter has changed. If a control sends the WM_DRAWITEM message, the *wParam* parameter specifies the identifier of the control. If a menu sends the message, *wParam* is zero.

WM_DROPFILES (3.1)

```
WM_DROPFILES
hDrop = (HANDLE) wParam;    /* handle of internal drop structure */
```

The WM_DROPFILES message is sent when the user releases the left mouse button over the window of an application that has registered itself as a recipient of dropped files.

Parameter	Description
hDrop	Value of *wParam.* Identifies an internal data structure describing the dropped files. This handle is valid only during the processing of the WM_DROPFILES message; if an application needs to use the data later, it must allocate memory and save the data. This handle is used by the **DragFinish**, **DragQueryFile**, and **DragQueryPoint** functions to retrieve information about the dropped files.

Returns

An application should return zero if it processes this message.

Comments

This message is posted, not sent.

See Also

DragAcceptFiles, **DragFinish**, **DragQueryFile**, **DragQueryPoint**

WM_ENABLE (2.x)

```
WM_ENABLE
fEnabled = (BOOL) wParam;     /* the enabled/disabled flag */
```

The WM_ENABLE message is sent when an application changes the enabled state of a window. It is sent to the window whose enabled state is changing. This message is sent before the **EnableWindow** function returns but after the enabled state (WS_DISABLE style bit) of the window has changed.

Parameter	Description
fEnabled	Value of *wParam.* Specifies whether the window has been enabled or disabled. This parameter is TRUE if the window has been enabled; it is FALSE if the window has been disabled.

Returns

An application should return zero if it processes this message.

See Also

EnableWindow

WM_ENDSESSION (2.x)

```
WM_ENDSESSION
fEndSession = (BOOL) wParam;     /* end-session flag */
```

The WM_ENDSESSION message is sent to an application that has returned a nonzero value in response to a **WM_QUERYENDSESSION** message. The WM_ENDSESSION message informs the application whether the session is actually ending.

Parameter	Description
fEndSession	Value of *wParam.* Specifies whether the session is being ended. It is TRUE if the session is being ended; otherwise, it is FALSE.

Returns

An application should return zero if it processes this message.

Comments

If the *fEndSession* parameter is TRUE, Windows can terminate any time after all applications have returned from processing this message. Therefore, an application should perform all tasks required for termination before returning from this message.

The application does not need to call the **DestroyWindow** or **PostQuitMessage** function when the session is ending.

See Also

DestroyWindow, **ExitWindows**, **PostQuitMessage**, **WM_QUERYENDSESSION**

WM_ENTERIDLE (2.x)

```
WM_ENTERIDLE
fwSource = wParam;                  /* idle-source flag               */
hwndDlg = (HWND) LOWORD(lParam);    /* handle of dialog box or window */
```

The WM_ENTERIDLE message informs an application's main window procedure that a modal dialog box or a menu is entering an idle state. A modal dialog box or menu enters an idle state when no messages are waiting in its queue after it has processed one or more previous messages.

Parameter	Description
fwSource	Value of *wParam.* Specifies whether the message is the result of a dialog box or a menu being displayed. This parameter can be one of the following values:
hwndDlg	Value of the low-order word of *lParam.* Identifies the dialog box (if *fwSource* is MSGF_DIALOGBOX) or the handle of the window containing the displayed menu (if *fwSource* is MSGF_MENU).

Value	Description
MSGF_DIALOGBOX	The system is idle because a dialog box is being displayed.
MSGF_MENU	The system is idle because a menu is being displayed.

Returns

An application should return zero if it processes this message.

Comments

The **DefWindowProc** function returns zero when it processes this message.

See Also

DefWindowProc

WM_ERASEBKGND (2.x)

```
WM_ERASEBKGND
hdc = (HDC) wParam; /* device-context handle */
```

The WM_ERASEBKGND message is sent when the window background needs to be erased (for example, when a window is resized). It is sent to prepare an invalidated region for painting.

Parameter	Description
hdc	Value of *wParam.* Identifies the device context.

Returns
An application should return nonzero if it erases the background; otherwise, it should return zero.

Comments
The **DefWindowProc** function erases the background by using the class background brush specified by the **hbrbackground** member of the **WNDCLASS** structure.

If the **hbrbackground** member is NULL, the application should process the WM_ERASEBKGND message and erase the background color. When processing the WM_ERASEBKGND message, the application must align the origin of the intended brush with the window coordinates by first calling the **UnrealizeObject** function for the brush and then selecting the brush.

An application should return nonzero in response to WM_ERASEBKGND if it processes the message and erases the background; this indicates that no futher erasing is required. If the app returns zero the window will remain marked as needing to be erased. (Typically, this means that the **fErase** member of the **PAINTSTRUCT** structure will be TRUE.)

Windows computes the background by using the MM_TEXT mapping mode. If the device context is using any other mapping mode, the area erased may not be within the visible part of the client area.

See Also
UnrealizeObject, **WM_ICONERASEBKGND**

WM_FONTCHANGE (2.x)

```
WM_FONTCHANGE
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends the WM_FONTCHANGE message to all top-level windows in the system after changing the pool of font resources.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

An application that adds or removes fonts from the system (for example, by using the **AddFontResource** or **RemoveFontResource** function) should send this message to all top-level windows.

To send the WM_FONTCHANGE message to all top-level windows, an application can call the **SendMessage** function with the *hwnd* parameter set to HWND_BROADCAST.

See Also

AddFontResource, **RemoveFontResource**, **SendMessage**

WM_GETDLGCODE (2.x)

`WM_GETDLGCODE`

The WM_GETDLGCODE message is sent to the dialog box procedure associated with a control. Normally, Windows handles all arrow-key and TAB-key input to the control. By responding to the WM_GETDLGCODE message, an application can take control of a particular type of input and process the input itself.

Parameters

This message has no parameters.

Returns

The return value is any combination of the following values, indicating which type of input the application processes:

Value	Meaning
DLGC_BUTTON	Button (generic)
DLGC_DEFPUSHBUTTON	Default push button
DLGC_HASSETSEL	**EM_SETSEL** messages
DLGC_UNDEFPUSHBUTTON	No default push button processing. (An application can use this flag with DLGC_BUTTON to indicate that it processes button input but relies on the system for default push-button processing.)
DLGC_RADIOBUTTON	Radio button
DLGC_STATIC	Static control
DLGC_WANTALLKEYS	All keyboard input
DLGC_WANTARROWS	Arrow keys
DLGC_WANTCHARS	**WM_CHAR** messages
DLGC_WANTMESSAGE	All keyboard input (the application passes this message on to the control)
DLGC_WANTTAB	TAB key

Comments

Although the **DefWindowProc** function always returns zero in response to the WM_GETDLGCODE message, the window procedures for the predefined control classes return a code appropriate for each class.

The WM_GETDLGCODE message and the returned values are useful only with user-defined dialog box controls or standard controls modified by subclassing.

See Also

DefWindowProc

WM_GETFONT (3.0)

```
WM_GETFONT
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a WM_GETFONT message to a control to retrieve the font with which the control is currently drawing its text.

Parameters

This message has no parameters.

Returns

The return value is the handle of the font used by the control, or it is NULL if the control is using the system font.

See Also

WM_SETFONT

WM_GETMINMAXINFO (2.x)

```
WM_GETMINMAXINFO
lpmmi = (MINMAXINFO FAR*) lParam; /* address of structure */
```

The WM_GETMINMAXINFO message is sent to a window whenever Windows needs the maximized position or dimensions of the window or needs the maximum or minimum tracking size of the window. The maximized size of a window is the size of the window when its borders are fully extended. The maximum tracking size of a window is the largest window size that can be achieved by using the borders to size the window. The minimum tracking size of a window is the smallest window size that can be achieved by using the borders to size the window.

Windows fills in a **MINMAXINFO** data structure, specifying default values for the various positions and dimensions. The application may change these values if it processes this message.

Parameter	Description
lpmmi	Value of *lParam.* Points to a **MINMAXINFO** data structure.

Returns

An application should return zero if it processes this message.

Example

This example processes a WM_GETMINMAXINFO message and sets the minimum tracking width of the window to 200 and the minimum tracking height of the window to 500:

```
MINMAXINFO FAR* lpmmi;

case WM_GETMINMAXINFO:
    lpmmi = (MINMAXINFO FAR*) lParam;
    lpmmi->ptMinTrackSize.x = 200;
    lpmmi->ptMinTrackSize.y = 500;

    break;
```

See Also

MINMAXINFO

WM_GETTEXT (2.x)

```
WM_GETTEXT
wParam = (WPARAM) cchTextMax;   /* number of bytes to copy    */
lParam = (LPARAM) lpszText;     /* address of buffer for text */
```

An application sends a WM_GETTEXT message to copy the text that corresponds to a window into a buffer provided by the caller.

Parameter	Description
cchTextMax	Value of *wParam.* Specifies the maximum number of bytes to be copied, including the terminating null character.
lpszText	Value of *lParam.* Points to the buffer that is to receive the text.

Returns

The return value is the number of bytes copied. It is CB_ERR if the message is sent to a combo box that has no edit control.

Comments

For an edit control, the text to be copied is the contents of the edit control. For a combo box, the text is the contents of the edit-control (or static-text) portion of the combo box. For a button, the text is the button name. For other windows, the text is the window title. To copy the text of an item in a list box, an application can use the **LB_GETTEXT** message.

When the WM_GETTEXT message is sent to a static control with the **SS_ICON** style, the handle of the icon will be returned in the first two bytes of the buffer pointed to by *lpszText.* This is true only if the **WM_SETTEXT** message has been used to set the icon.

Example

This example copies text from an edit control to a buffer:

```
HWND hwndMyEdit;
char szBuffer[32];

hwndMyEdit = GetDlgItem(hdlg, ID_MYEDITCONTROL);
SendMessage(hwndMyEdit, WM_GETTEXT, sizeof(szBuffer),
    (LPARAM) ((LPSTR) szBuffer));
```

See Also

LB_GETTEXT, **WM_GETTEXTLENGTH**, **WM_SETTEXT**

WM_GETTEXTLENGTH (2.x)

```
WM_GETTEXTLENGTH
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends a WM_GETTEXTLENGTH message to determine the length, in bytes, of the text associated with a window. The length does not include the terminating null character.

Parameters

This message has no parameters.

Returns

The return value is a word specifying the length, in bytes, of the text.

Comments

For an edit control, the text to be copied is the contents of the edit control. For a combo box, the text is the contents of the edit-control (or static-text) portion of the combo box. For a button, the text is the button name. For other windows, the text is the window title. To determine the length of an item in a list box, an application can use the **LB_GETTEXTLEN** message.

Example

This example enables the push button in a dialog box if the user has entered text in an edit control in the dialog box:

```
case ID_MYEDITCONTROL:
    if (HIWORD(lParam) == EN_CHANGE)
        EnableWindow(GetDlgItem(hdlg, IDOK),
            (BOOL) SendMessage((HWND) LOWORD(lParam),
            WM_GETTEXTLENGTH, 0, 0L));
    return TRUE;
```

See Also

LB_GETTEXTLEN, **WM_GETTEXT**

WM_HSCROLL (2.x)

```
WM_HSCROLL
wScrollCode = wParam;      /* scroll bar code                */
nPos = LOWORD(lParam);     /* current position of scroll box */
hwndCtl = (HWND) HIWORD(lParam); /* handle of the control    */
```

The WM_HSCROLL message is sent to a window when the user clicks the window's horizontal scroll bar.

Parameter	Description
wScrollCode	Value of *wParam.* Specifies a scroll bar code that indicates the user's scrolling request. This parameter can be one of the following values:

Value	Description
SB_BOTTOM	Scroll to bottom.
SB_ENDSCROLL	End scroll.
SB_LINEDOWN	Scroll one line down.
SB_LINEUP	Scroll one line up.
SB_PAGEDOWN	Scroll one page down.
SB_PAGEUP	Scroll one page up.
SB_THUMBPOSITION	Scroll to absolute position. The current position is specified by the *nPos* parameter.
SB_THUMBTRACK	Drag scroll box (thumb) to specified position. The current position is specified by the *nPos* parameter.
SB_TOP	Scroll to top.

nPos	Value of the low-order word of *lParam.* Specifies the current position of the scroll box if the *wScrollCode* parameter is SB_THUMBPOSITION or SB_THUMBTRACK; otherwise, the *nPos* parameter is not used.
hwndCtl	Value of the high-order word of *lParam.* Identifies the control if WM_HSCROLL is sent by a scroll bar. If WM_HSCROLL is sent as a result of the user clicking a pop-up window's scroll bar, the high-order word is not used.

Returns

An application should return zero if it processes this message.

Comments

The SB_THUMBTRACK scroll bar code typically is used by applications that give some feedback while the scroll box is being dragged.

If an application scrolls the contents of the window, it must also reset the position of the scroll box by using the **SetScrollPos** function.

See Also

SetScrollPos, **WM_VSCROLL**

WM_HSCROLLCLIPBOARD (2.x)

```
WM_HSCROLLCLIPBOARD
hwndCBViewer = (HWND) wParam;   /* handle of clipboard viewer */
wScrollCode = LOWORD(lParam);   /* scroll bar code            */
nPos = (int) HIWORD(lParam);    /* scroll box position        */
```

The WM_HSCROLLCLIPBOARD message is sent by the clipboard viewer to the clipboard owner when the clipboard data has the CF_OWNERDISPLAY format and an event occurs in the clipboard viewer's horizontal scroll bar. The owner should scroll the clipboard image, invalidate the appropriate section, and update the scroll bar values.

Parameter	Description
hwndCBViewer	Value of *wParam.* Identifies a clipboard-viewer window.
wScrollCode	Value of the low-order word of *lParam.* Specifies a scroll bar code. This parameter can be one of the following values:

Value	Description
SB_BOTTOM	Scroll to lower right.
SB_ENDSCROLL	End scroll.
SB_LINEDOWN	Scroll one line down.
SB_LINEUP	Scroll one line up.
SB_PAGEDOWN	Scroll one page down.
SB_PAGEUP	Scroll one page up.
SB_THUMBPOSITION	Scroll to absolute position.
SB_TOP	Scroll to upper left.

nPos	Value of the high-order word of *lParam.* Specifies the scroll box position if the scroll bar code is SB_THUMBPOSITION; otherwise, the high-order word of *lParam* is not used.

Returns
An application should return zero if it processes this message.

Comments
The clipboard owner should use the **InvalidateRect** function or repaint as needed. The scroll bar position should also be reset.

See Also
InvalidateRect, **WM_VSCROLLCLIPBOARD**

WM_ICONERASEBKGND (3.0)

```
WM_ICONERASEBKGND
hdc = (HDC) wParam;      /* device-context handle */
```

The WM_ICONERASEBKGND message is sent to a minimized (iconic) window when the background of the icon must be filled before painting the icon. A window receives this message only if a class icon is defined for the window; otherwise, **WM_ERASEBKGND** is sent.

Parameter	Description
hdc	Value of *wParam.* Identifies the device context of the icon.

Returns
An application should return zero if it processes this message.

Comments
The **DefWindowProc** function fills the icon background with the background brush of the parent window.

See Also
DefWindowProc, **WM_ERASEBKGND**

WM_INITDIALOG (2.x)

```
WM_INITDIALOG
hwndFocus = (HWND) wParam;  /* handle of control for focus */
dwData = lParam;            /* application-specific data   */
```

The WM_INITDIALOG message is sent to a dialog box procedure immediately before the dialog box is displayed.

Parameter	Description
hwndFocus	Value of *wParam.* Identifies the first control in the dialog box that can be given the input focus. Usually, this is the first control in the dialog box with the **WS_TABSTOP** style.
dwData	Value of *lParam.* Specifies application-specific data that was passed by the function used to create the dialog box if the dialog box was created by one of the following functions: **CreateDialogParam** **DialogBoxIndirectParam** **DialogBoxParam**

Returns

An application should return nonzero to set the input focus to the control identified by the *hwndFocus* parameter. An application should return zero if the dialog box procedure uses the **SetFocus** function to set the input focus to a different control in the dialog box.

Example

This example changes the font used by controls in a dialog box to a font that is not bold.

```
HFONT hfontDlg;
LOGFONT lFont;

case WM_INITDIALOG:

    /* Get dialog box font and create version that is not bold. */

    hfontDlg = (HFONT) NULL;
    if ((hfontDlg = (HFONT) SendMessage(hdlg, WM_GETFONT, 0, 0L))) {
        if (GetObject(hfontDlg, sizeof(LOGFONT), (LPSTR) &lFont)) {
            lFont.lfWeight = FW_NORMAL;
            if (hfontDlg = CreateFontIndirect((LPLOGFONT) &lFont)) {
                SendDlgItemMessage(hdlg, ID_CTRL1, WM_SETFONT,
                    (WPARAM) hfontDlg, 0);
                SendDlgItemMessage(hdlg, ID_CTRL2, WM_SETFONT,
                    (WPARAM) hfontDlg, 0);
                .
                . /* Set font for remaining controls. */
                .
            }
        }
    }
    return TRUE;
```

CreateDialogParam, **DialogBoxIndirectParam**, **DialogBoxParam**, **SetFocus**

WM_INITMENU (2.x)

```
WM_INITMENU
hmenuInit = (HMENU) wParam; /* handle of menu to initialize */
```

The WM_INITMENU message is sent when a menu is about to become active. It occurs when the user clicks an item on the menu bar or presses a menu key. This allows an application to modify the menu before it is displayed.

Parameter	Description
hmenuInit	Value of *wParam.* Identifies the menu to be initialized.

Returns

An application should return zero if it processes this message.

Comments

This message is sent only when a menu is first accessed; only one WM_INITMENU message is generated for each access. This means, for example, that moving the mouse across several menu items while holding down the button does not generate new messages. WM_INITMENU does not provide information about menu items.

See Also

WM_INITMENUPOPUP

WM_INITMENUPOPUP (2.x)

```
WM_INITMENUPOPUP
hmenuPopup = (HMENU) wParam;          /* handle of pop-up menu */
nIndex = (int) LOWORD(lParam);        /* index of pop-up menu  */
fSystemMenu = (BOOL) HIWORD(lParam); /* System-menu flag      */
```

The WM_INITMENUPOPUP message is sent when a pop-up menu is about to become active. This allows an application to modify the pop-up menu before it is displayed, without changing the entire menu.

Parameter	Description
hmenuPopup	Value of *wParam.* Identifies the pop-up menu.
nIndex	Value of the low-order word of *lParam.* Specifies the index of the pop-up menu in the main menu.
fSystemMenu	Value of the high-order word of *lParam.* Specifies a nonzero value if the pop-up menu is the System menu (sometimes referred to as the Control menu); otherwise, this parameter is zero.

Returns

An application should return zero if it processes this message.

Example

This example initializes the items in a pop-up menu:

```
int  cItems;
int  pos;
UINT id;

case WM_INITMENUPOPUP:
    cItems = GetMenuItemCount((HMENU) wParam);
    for (pos = 0; pos < cItems; pos++) {
        id = GetMenuItemID((HMENU) wParam, pos);
        .
        . /* Initialize menu items. */
        .
    }
    break;
```

WM_INITMENU

WM_KEYDOWN (2.x)

```
WM_KEYDOWN
wVkey = wParam;          /* virtual-key code */
dwKeyData = lParam;      /* key data         */
```

The WM_KEYDOWN message is sent when a nonsystem key is pressed. A nonsystem key is a key that is pressed when the ALT key is *not* pressed, or it is a key that is pressed when a window has the input focus.

Parameter	Description
wVkey	Value of *wParam.* Specifies the virtual-key code of the given key.
dwKeydata	Value of *lParam.* Specifies the repeat count, scan code, extended key, context code, previous key state, and key-transition state, as shown in the following table:

Bit	Description
0-15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16-23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).
24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.
25-26	Not used.
27-28	Used internally by Windows.
29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.
30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.
31	Specifies the key-transition state. The value is 1 if the key is being released, or it is 0 if the key is being pressed.

For a WM_KEYDOWN message, the value of bit 29 (context code) is 0 and the value of bit 31 (key-transition state) is 0.

Returns

An application should return zero if it processes this message.

Comments

Because of the autorepeat feature, more than one WM_KEYDOWN message may occur before a **WM_KEYUP** message is sent. The previous key state (bit 30) can be used to determine whether the WM_KEYDOWN message indicates the first down transition or a repeated down transition.

For IBM Enhanced 101- and 102-key keyboards, enhanced keys are the right ALT key and the right CTRL key on the main section of the keyboard; the INS, DEL, HOME, END, PAGE UP, PAGE DOWN, and arrow keys in the clusters to the left of the numeric keypad; and the division (*/*) and ENTER key on the numeric keypad. Some other keyboards may support the extended-key bit in the *dwKeyData* parameter.

WM_CHAR, **WM_KEYUP**

WM_KEYUP (2.x)

```
WM_KEYUP
wVkey = wParam;          /* virtual-key code */
dwKeyData = lParam;      /* key data         */
```

The WM_KEYUP message is sent when a nonsystem key is released. A nonsystem key is a key that is pressed when the ALT key is *not* pressed, or it is a key that is pressed when a window has the input focus.

Parameter	Description
wVkey	Value of *wParam.* Specifies the virtual-key code of the given key.
dwKeyData	Value of *lParam.* Specifies the repeat count, scan code, extended key, context code, previous key state, and key-transition state, as shown in the following table:

Bit	Description
0-15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16-23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).
24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.
25-26	Not used.
27-28	Used internally by Windows.
29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.
30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.
31	Specifies the key-transition state. The value is 1 if the key is being released, or it is 0 if the key is being pressed.

For a WM_KEYUP message, the value of bit 29 (context code) is 0 and the value of bit 31 (key-transition state) is 1.

Returns

An application should return zero if it processes this message.

Comments

For IBM Enhanced 101- and 102-key keyboards, enhanced keys are the right ALT key and the right CTRL key on the main section of the keyboard; the INS, DEL, HOME, END, PAGE UP, PAGE DOWN, and arrow keys in the clusters to the left of the numeric keypad; and the division (*/*) and ENTER keys on the numeric keypad. Some other keyboards may support the extended-key bit in the *dwKeyData* parameter.

WM_CHAR, **WM_KEYDOWN**

WM_KILLFOCUS (2.x)

```
WM_KILLFOCUS
hwndGetFocus = (HWND) lParam;   /* handle of window receiving focus */
```

The WM_KILLFOCUS message is sent immediately before a window loses the input focus.

Parameter	Description
hwndGetFocus	Value of *wParam.* Identifies the window that receives the input focus. (This parameter may be NULL.)

Returns
An application should return zero if it processes this message.

Comments
If an application is displaying a caret, the caret should be destroyed at this point.

See Also
SetFocus, **WM_SETFOCUS**

WM_LBUTTONDBLCLK (2.x)

```
WM_LBUTTONDBLCLK
fwKeys = wParam;          /* key flags                        */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_LBUTTONDBLCLK message is sent when the user double-clicks the left mouse button.

Parameter	Description
fwKeys	Value of *wParam.* Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_LBUTTON	Set if left button is down.
MK_MBUTTON	Set if middle button is down.
MK_RBUTTON	Set if right button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns

An application should return zero if it processes this message.

Comments

Only windows that have the **CS_DBLCLKS** class style can receive WM_LBUTTONDBLCLK messages. Windows generates a WM_LBUTTONDBLCLK message when the user presses, releases, and again presses the left mouse button within the system's double-click time limit. Double-clicking the left mouse button actually generates four messages: a **WM_LBUTTONDOWN** message, a **WM_LBUTTONUP** message, the WM_LBUTTONDBLCLK message, and another WM_LBUTTONUP message.

WM_LBUTTONDOWN, **WM_LBUTTONUP**

WM_LBUTTONDOWN (2.x)

```
WM_LBUTTONDOWN
fwKeys = wParam;          /* key flags                       */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_LBUTTONDOWN message is sent when the user presses the left mouse button.

Parameter	Description
fwKeys	Value of *wParam.* Specifies whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_MBUTTON	Set if middle button is down.
MK_RBUTTON	Set if right button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns
An application should return zero if it processes this message.

See Also
WM_LBUTTONDBLCLK, **WM_LBUTTONUP**

WM_LBUTTONUP (2.x)

```
WM_LBUTTONUP
fwKeys = wParam;          /* key flags                      */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_LBUTTONUP message is sent when the user releases the left mouse button.

Parameter	Description
fwKeys	Value of *wParam.* Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_MBUTTON	Set if middle button is down.
MK_RBUTTON	Set if right button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns
An application should return zero if it processes this message.

See Also
WM_LBUTTONDBLCLK, **WM_LBUTTONDOWN**

WM_MBUTTONDBLCLK (2.x)

```
WM_MBUTTONDBLCLK
fwKeys = wParam;          /* key flags                       */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_MBUTTONDBLCLK message is sent when the user double-clicks the middle mouse button.

Parameter	Description
fwKeys	Value of *wParam.* Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_LBUTTON	Set if left button is down.
MK_MBUTTON	Set if middle button is down.
MK_RBUTTON	Set if right button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns

An application should return zero if it processes this message.

Comments

Only windows that have the **CS_DBLCLKS** class style can receive WM_MBUTTONDBLCLK messages. Windows generates a WM_MBUTTONDBLCLK message when the user presses, releases, and again presses the middle mouse button within the system's double-click time limit. Double-clicking the middle mouse button actually generates four messages: a **WM_MBUTTONDOWN** message, a **WM_MBUTTONUP** message, the WM_MBUTTONDBLCLK message, and another WM_MBUTTONUP message.

```
WM_MBUTTONDOWN
fwKeys = wParam;          /* key flags                      */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_MBUTTONDOWN message is sent when the user presses the middle mouse button.

Parameter	Description
fwKeys	Value of *wParam.* Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_LBUTTON	Set if left button is down.
MK_RBUTTON	Set if right button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns
An application should return zero if it processes this message.

WM_MBUTTONDBLCLK, **WM_MBUTTONUP**

WM_MBUTTONUP (2.x)

```
WM_MBUTTONUP
fwKeys = wParam;          /* key flags                       */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_MBUTTONUP message is sent when the user releases the middle mouse button.

Parameter	Description
fwKeys	Value of *wParam.* Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_LBUTTON	Set if left button is down.
MK_RBUTTON	Set if right button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns
An application should return zero if it processes this message.

WM_MBUTTONDBLCLK, **WM_MBUTTONDOWN**

WM_MDIACTIVATE (3.0)

```
WM_MDIACTIVATE
/* Message sent to MDI client */
wParam =  (WPARAM) (HWND) hwndChildAct; /* child to activate       */
lParam = 0L;                            /* not used, must be zero  */

/* Message received by MDI child */
wParam = (WPARAM) fActivate;            /* activation flag         */
hwndAct = (HWND) LOWORD(lParam);        /* child being activated   */
hwndDeact = (HWND) HIWORD(lParam);      /* child being deactivated */
```

An application sends the WM_MDIACTIVATE message to a multiple document interface (MDI) client window to instruct the client window to activate a different MDI child window. As the client window processes this message, it sends WM_MDIACTIVATE to the child window being deactivated and to the child window being activated.

Parameter	Description
In message sent to MDI client window:	
hwndChildAct	Value of *wParam.* Identifies the MDI child window to be activated.
In message received by MDI child window:	
fActivate	Value of *wParam.* Specifies whether to activate or deactivate the child window. If this parameter is TRUE, the child window is activated. If this parameter is FALSE, the child window is deactivated.
hwndAct	Value of the low-order word of *lParam.* Identifies the child window being activated.
hwndDeact	Value of the high-order word of *lParam.* Identifies the child window being deactivated.

Returns
An application should return zero if it processes this message.

Comments
An MDI child window is activated independently of the MDI frame window. When the frame window becomes active, the child window that was last activated with the WM_MDIACTIVATE message receives the **WM_NCACTIVATE** message to draw an active window frame and title bar; it does not receive another WM_MDIACTIVATE message.

See Also
WM_MDIGETACTIVE, **WM_NCACTIVATE**, **WM_MDINEXT**

WM_MDICASCADE (3.0)

```
WM_MDICASCADE
fnCascade = wParam;      /* cascade flag */
```

The WM_MDICASCADE message is sent to a multiple document interface (MDI) client window to arrange all its child windows in a cascade format.

Parameter	Description
fnCascade	Value of *wParam.* Specifies a cascade flag. Currently, only the following flag may be specified:

Value	Meaning
MDITILE_SKIPDISABLED	Prevents disabled MDI child windows from being cascaded.

Returns

An application should return zero if it processes this message.

See Also

WM_MDIICONARRANGE, **WM_MDITILE**

Windows 3.1 changes

The following cascade flag has been added:

Value	Meaning
MDITILE_SKIPDISABLED	Prevents disabled MDI child windows from being cascaded.

WM_MDICREATE (3.0)

```
WM_MDICREATE
wParam = 0;                                  /* not used, must be zero */
lParam = (LPARAM) (MDICREATESTRUCT FAR*) lpmcs; /* structure address  */
```

An application sends the WM_MDICREATE message to a multiple document interface (MDI) client window to create a child window.

Parameter	Description
lpmcs	Value of *lParam.* Points to an **MDICREATESTRUCT** structure.

Returns

The return value is the handle of the new window in the low-order word and zero in the high-order word.

Comments

The window is created with the style bits **WS_CHILD**, **WS_CLIPSIBLINGS**, **WS_CLIPCHILDREN**, **WS_SYSMENU**, **WS_CAPTION**, **WS_THICKFRAME**, **WS_MINIMIZEBOX**, and **WS_MAXIMIZEBOX**, plus additional style bits specified in the **MDICREATESTRUCT** structure to which *lpmcs* points. Windows adds the title of the new child window to the window menu of the frame window. An application should create all child windows of the client window with this message.

CreateWindow will override the default style bits if the MDIS_ALLCHILDSTYLES style is set when creating the MDI client window.

If a client window receives any message that changes the activation of child windows while the currently active MDI child window is maximized, Windows restores the currently active child window and maximizes the newly activated child window.

When the MDI child window is created, Windows sends the **WM_CREATE** message to the window. The *lpmcs* parameter of the WM_CREATE message contains a pointer to a **CREATESTRUCT** structure. The **lpCreateParams** member of the **CREATESTRUCT** structure contains a pointer to the **MDICREATESTRUCT** structure passed with the WM_MDICREATE message that created the MDI child window.

An application should not send a second WM_MDICREATE message while a WM_MDICREATE message is still being processed. For example, it should not send a WM_MDICREATE message while an MDI child window is processing its **WM_CREATE** message.

See Also

WM_MDIDESTROY, **CREATESTRUCT**, **MDICREATESTRUCT**

WM_MDIDESTROY (3.0)

```
WM_MDIDESTROY
hwndChild = (HWND) wParam;  /* handle of child to destroy */
```

An application sends the WM_MDIDESTROY message to a multiple document interface (MDI) client window to close an MDI child window.

Parameter	Description
hwndChild	Value of *wParam.* Identifies the child window to destroy.

Returns

An application should return zero if it processes this message.

Comments

This message removes the title of the child window from the frame window and deactivates the child window. An application should close all MDI child windows with this message.

If a client window receives any message that changes the activation of child windows while the currently active MDI child window is maximized, Windows restores the currently active child window and maximizes the newly activated child window.

See Also

WM_MDICREATE

WM_MDIGETACTIVE (3.0)

```
WM_MDIGETACTIVE
```

The WM_MDIGETACTIVE message retrieves the multiple document interface (MDI) child window that is active, along with a flag indicating whether the child window is maximized.

Parameters

This message has no parameters.

Returns

The return value is the handle of the active MDI child window in its low-order word. If the window is maximized, the high-order word is 1; otherwise, the high-order word is 0.

See Also

WM_MDIACTIVATE

WM_MDIICONARRANGE (3.0)

```
WM_MDIICONARRANGE
```

The WM_MDIICONARRANGE message is sent to a multiple document interface (MDI) client window to arrange all minimized document child windows. It does not affect child windows that are not minimized.

Parameters

This message has no parameters.

Returns
An application should return zero if it processes this message.

See Also
WM_MDICASCADE, **WM_MDITILE**

WM_MDIMAXIMIZE (3.0)

```
WM_MDIMAXIMIZE
hwndMaximize = (HWND) wParam;   /* handle of child to maximize */
```

The WM_MDIMAXIMIZE message causes a multiple document interface (MDI) client window to maximize an MDI child window. When a child window is maximized, Windows resizes it to make its client area fill the client window. Windows places the child window's System menu (sometimes referred to as the Control menu) in the frame's menu bar so that the user can restore or minimize the child window; Windows adds the title of the child window to the frame window's menu of child windows.

Parameter	Description
hwndMaximize	Value of *wParam.* Identifies the child window to maximize.

Returns

An application should return zero if it processes this message.

Comments

If an MDI client window receives any message that changes the activation of its child windows while the currently active MDI child window is maximized, Windows restores the currently active child window and maximizes the newly activated child window.

WM_MDINEXT (3.0)

```
WM_MDINEXT
wParam = (WPARAM) hwndChild; /* handle of child window        */
lParam = (LPARAM) fNext;     /* next or previous child window */
```

An application sends the WM_MDINEXT message to a multiple document interface (MDI) client window to activate the child window immediately behind the currently active child window and place the currently active child window behind all other child windows.

Parameter	Description
hwndChild	Value of *wParam.* Specifies the handle of the child window.
fNext	Value of *lParam.* If this parameter is zero, the message specifies that the next MDI child window should be activated. If this parameter is nonzero, the message specifies that the previous MDI child window should be activated.

Returns

An application should return zero if it processes this message.

Comments

If an MDI client window receives any message that changes the activation of its child windows while the currently active MDI child window is maximized, Windows restores the currently active child window and maximizes the newly activated child window.

See Also

WM_MDIACTIVATE, **WM_MDIGETACTIVE**

WM_MDIRESTORE (3.0)

```
WM_MDIRESTORE
wParam = (WPARAM) wIDChild;  /* handle of child window */
```

An application sends the WM_MDIRESTORE message to a multiple document interface (MDI) client window to restore an MDI child window from maximized or minimized size.

Parameter	Description
wIDChild	Value of *wParam.* Specifies the handle of the child window.

Returns

An application should return zero if it processes this message.

See Also

WM_MDIMAXIMIZE

WM_MDISETMENU (3.0)

```
WM_MDISETMENU
wParam = (WPARAM) (BOOL) fRefresh;              /* refresh flag */
lParam = MAKELPARAM(hmenuFrame, hmenuWindow);  /* new menus    */
```

An application sends a WM_MDISETMENU message to replace the menu of a multiple document interface (MDI) frame window, the Window pop-up menu, or both.

Parameter	Description
fRefresh	Value of *wParam.* Specifies whether to refresh the current menus or specify new menus. It is TRUE if the menus should just be refreshed. It is FALSE if, instead, the *hmenuFrame* and *hmenuWindow* parameters should be used to specify new menus for the window.
hmenuFrame	Value of the low-order word of *lParam.* Identifies the new frame-window menu. If this parameter is zero, the frame-window menu is not changed.
hmenuWindow	Value of the high-order word of *lParam.* Identifies the new Window pop-up menu. If this parameter is zero, the Window pop-up menu is not changed.

Returns

The return value is the handle of the frame-window menu replaced by this message.

Comments

After sending this message, an application must call the **DrawMenuBar** function to update the menu bar.

If this message replaces the Window pop-up menu, MDI child-window menu items are removed from the previous Window menu and added to the new Window pop-up menu.

If an MDI child window is maximized and this message replaces the MDI frame-window menu, the System menu (sometimes referred to as the Control menu) and restore controls are removed from the previous frame-window menu and added to the new menu.

See Also

DrawMenuBar

Windows 3.1 changes

The *wParam* parameter specifies whether or not to refresh the same menus. It is nonzero if the menus should just be refreshed. It is zero if, instead, the *lParam* parameter should be used to specify new menus for the window.

The previous release of the documentation stated that *wParam* was not used.

WM_MDITILE (3.0)

```
WM_MDITILE
fTile = wParam;      /* tiling flag */
```

The WM_MDITILE message is sent to a multiple document interface (MDI) client window to arrange all its child windows in a tiled format.

Parameter	Description
fTile	Value of *wParam.* Specifies a tiling flag. This parameter can be one of the following flags:

Value	Meaning
MDITILE_HORIZONTAL	Tiles MDI child windows so that they are wide rather than tall.
MDITILE_SKIPDISABLED	Prevents disabled MDI child windows from being tiled.
MDITILE_VERTICAL	Tiles MDI child windows so that they are tall rather than wide.

Returns
An application should return zero if it processes this message.

See Also
WM_MDICASCADE, **WM_MDIICONARRANGE**

Windows 3.1 changes

The following tiling flags have been added:

Value	Meaning
MDITILE_HORIZONTAL	Tiles MDI child windows horizontally (one window appears beside another).
MDITILE_SKIPDISABLED	Prevents disabled MDI child windows from being tiled.
MDITILE_VERTICAL	Tiles MDI child windows vertically (one window appears above another).

WM_MEASUREITEM (3.0)

```
WM_MEASUREITEM
nIDCtl = (int) wParam;                        /* control identifier   */
lpmisCtl = (MEASUREITEMSTRUCT FAR*) lParam; /* address of structure */
```

The WM_MEASUREITEM message is sent to the owner of an owner-drawn button, combo box, list box, or menu item when the control is created. When the owner receives the message, the owner fills in the **MEASUREITEMSTRUCT** structure pointed to by the *lpmisCtl* message parameter and returns; this informs Windows of the dimensions of the control. If a list box or combo box is created with the **LBS_OWNERDRAWVARIABLE** or **CBS_OWNERDRAWVARIABLE** style, this message is sent to the owner for each item in the control; otherwise, this message is sent once.

Parameter	Description
nIDCtl	Value of *wParam.* Specifies the identifier of the control that sent the WM_MEASUREITEM message. This parameter is 0 if the message was sent by a menu. This parameter is -1 when the system is requesting the dimensions of an edit control in an owner-drawn combo box.
lpmisCtl	Value of *lParam.* Points to a **MEASUREITEMSTRUCT** structure that contains the dimensions of the owner-drawn control.

Returns

An application should return TRUE if it processes this message.

Comments

Windows sends the WM_MEASUREITEM message to the owner of a combo box or list box created with the OWNERDRAWFIXED style before sending WM_INITDIALOG. As a result, when the owner receives this message, Windows has not yet determined the height and width of the font used in the control; function calls and calculations requiring these values should occur in the main function of the application or library.

See Also

WM_COMPAREITEM, **WM_DELETEITEM**, **WM_DRAWITEM**, **WM_INITDIALOG**, **MEASUREITEMSTRUCT**

Windows 3.1 changes

The meaning of the *wParam* parameter has changed. If a control sends the WM_MEASUREITEM message, the *wParam* parameter specifies the identifier of the control. If a menu sends the message, *wParam* is zero.

WM_MENUCHAR (2.x)

```
WM_MENUCHAR
chUser = wParam;                    /* ASCII character    */
fMenu = LOWORD(lParam);             /* menu flag          */
hmenu = (HMENU) HIWORD(lParam);     /* handle of the menu */
```

The WM_MENUCHAR message is sent when the user presses the key corresponding to a menu mnemonic character that doesn't match any of the predefined mnemonics in the current menu. It is sent to the window that owns the menu.

Parameter	Description
chUser	Value of *wParam.* Specifies the ASCII character that corresponds to the key the user pressed.
fMenu	Value of the low-order word of *lParam.* Specifies the type of the selected menu. This parameter can be one of the following values:
hmenu	Value of the high-order word of *lParam.* Identifies the selected menu.

Value	Meaning
MF_POPUP	The menu is a pop-up menu.
MF_SYSMENU	The menu is a System menu (sometimes referred to as a Control menu).

Returns

The return value is one of the following command code values in the high-order word:

Value	Description
0	Informs Windows that it should discard the character corresponding to the key the user pressed, and creates a short beep on the system speaker.
1	Informs Windows that it should close the current menu.
2	Informs Windows that the low-order word of the return value contains the item number for a specific item. This item is selected by Windows.

The low-order word is ignored if the high-order word contains 0 or 1. An application should process this message when an accelerator key has been used to select a bitmap placed in a menu.

Comments

The WM_MENUCHAR message is generated when the user presses ALT and any key, even if the key does not correspond to a mnemonic character. In this case, the *hmenu* parameter contains the window handle of the menu.

WM_MENUSELECT (2.x)

```
WM_MENUSELECT
wIDItem = wParam;               /* item identifier or menu handle */
fwMenu = LOWORD(lParam);        /* menu flags                     */
hmenu = (HMENU) HIWORD(lParam); /* handle of the menu             */
```

The WM_MENUSELECT message is sent to the window associated with a menu when the user selects a menu item.

Parameter	Description
wIDItem	Value of *wParam.* Specifies the menu-item identifier if the selected item is a menu item. If the selected item contains a pop-up menu, *wIDItem* contains the handle of the pop-up menu.
fwMenu	Low word of *lParam.* Specifies one or more menu flags. This parameter can be a combination of the following values:

Flag	Description
MF_BITMAP	Item is a bitmap.
MF_CHECKED	Item is checked.
MF_DISABLED	Item is disabled.
MF_GRAYED	Item is grayed.
MF_MOUSESELECT	Item was selected with a mouse.
MF_OWNERDRAW	Item is an owner-drawn item.
MF_POPUP	Item contains a pop-up menu.
MF_SEPARATOR	Item is a menu-item separator.
MF_SYSMENU	Item is contained in the System menu (sometimes referred to as the Control menu). The *hmenu* parameter identifies the System menu associated with the message.

hmenu	High word of *lParam.* If the *fwMenu* parameter contains the MF_SYSMENU flag, this parameter specifies the menu handle of the System menu.

Returns

An application should return zero if it processes this message.

Comments

If the *fwMenu* parameter contains -1 and the *hmenu* parameter contains 0, Windows has closed the menu. This occurs both when the menu is closed because the user pressed ESC or clicked outside the menu and when the user has selected a menu item.

WM_MOUSEACTIVATE (2.x)

```
WM_MOUSEACTIVATE
hwndTopLevel = (HWND) wParam;    /* handle of top-level parent */
wHitTestCode = LOWORD(lParam);   /* hit-test code              */
wMsg = HIWORD(lParam);           /* mouse-message identifier   */
```

The WM_MOUSEACTIVATE message is sent when the cursor is in an inactive window and the user presses a mouse button. The parent window receives this message only if the child window passes it to the **DefWindowProc** function.

Parameter	Description
hwndTopLevel	Value of *wParam.* Identifies the top-level parent window of the window being activated.
wHitTestCode	Value of the low-order word of *lParam.* Specifies the hit-test area code. A hit test is a test that determines the location of the cursor.
wMsg	Value of the high-order word of *lParam.* Specifies the identifier of the mouse message.

Returns

The return value specifies whether the window should be activated and whether the mouse event should be discarded. It must be one of the following values:

Value	Meaning
MA_ACTIVATE	Activate the window.
MA_NOACTIVATE	Do not activate the window.
MA_ACTIVATEANDEAT	Activate the window and discard the mouse event.
MA_NOACTIVATEANDEAT	Do not activate the window; discard the mouse event.

Comments

If the child window passes the message to the **DefWindowProc** function, **DefWindowProc** passes this message to a window's parent window before any processing occurs. If the parent window returns a nonzero value, processing is halted.

See Also

DefWindowProc

Windows 3.1 changes

The following returns were added:

Value	Meaning
MA_ACTIVATE	Activate the window.
MA_NOACTIVATE	Do not activate the window.
MA_ACTIVATEANDEAT	Activate the window and discard the mouse event.
MA_NOACTIVATEANDEAT	Do not activate the window and discard the mouse event.

WM_MOUSEMOVE (2.x)

```
WM_MOUSEMOVE
fwKeys = wParam;          /* key flags                       */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_MOUSEMOVE message is sent to a window when the mouse cursor moves. If the mouse is not captured, the message goes to the window beneath the cursor. Otherwise, the message goes to the window that has captured the mouse.

Parameter	Description
fwKeys	Value of *wParam.* Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_LBUTTON	Set if left button is down.
MK_MBUTTON	Set if middle button is down.
MK_RBUTTON	Set if right button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, as a screen coordinate.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, as a screen coordinate.

Returns

An application should return zero if it processes this message.

Comments

The **MAKEPOINT** macro can be used to convert the *lParam* parameter to a **POINT** structure.

See Also

SetCapture, **WM_NCHITTEST**, **MAKEPOINT**, **POINT**

WM_MOVE (2.x)

```
WM_MOVE
xPos = (int) LOWORD(lParam);    /* horizontal position */
yPos = (int) HIWORD(lParam);    /* vertical position   */
```

The WM_MOVE message is sent after a window has been moved.

Parameter	Description
xPos	Value of the low-order word of *lParam.* Specifies the new x-coordinate of the upper-left corner of the client area of the window.
yPos	Value of the high-order word of *lParam.* Specifies the new y-coordinate of the upper-left corner of the client area of the window.

Returns

An application should return zero if it processes this message.

Comments

The *xPos* and *yPos* parameters are given in screen coordinates for overlapped and pop-up windows and in parent-client coordinates for child windows.

An application can use the **MAKEPOINT** macro to convert the *lParam* parameter to a **POINT** data structure.

See Also

MAKEPOINT, **POINT**

WM_NCACTIVATE (2.x)

```
WM_NCACTIVATE
fActive = (BOOL) wParam;    /* the active/inactive flag */
```

The WM_NCACTIVATE message is sent to a window when its nonclient area needs to be changed to indicate an active or inactive state.

Parameter	Description
fActive	Value of *wParam.* Specifies when a title bar or icon needs to be changed to indicate an active or inactive state. The *fActive* parameter is TRUE if an active title bar or icon is to be drawn. It is FALSE for an inactive title bar or icon.

Returns

When the *fActive* parameter is FALSE, an application should return TRUE to indicate that Windows should proceed with the default processing or FALSE to prevent the caption bar or icon from being deactivated. When *fActive* is TRUE, the return value is ignored.

Comments

The **DefWindowProc** function draws the title bar and title bar text in their active colors when the *fActive* parameter is TRUE and in their inactive colors when *fActive* is FALSE.

See Also

DefWindowProc

WM_NCCALCSIZE (2.x)

```
WM_NCCALCSIZE
fCalcValidRects = (BOOL) wParam;            /* valid-area flag  */
lpncsp = (NCCALCSIZE_PARAMS FAR*) lParam;   /* address of data  */
```

The WM_NCCALCSIZE message is sent when the size and position of a window's client area needs to be calculated. By processing this message, an application can control the contents of the window's client area when the size or position of the window changes.

Parameter	Description
fCalcValidRects	Value of *wParam.* Specifies whether the application should specify which part of the client area contains valid information. Windows will copy the valid information to the specified area within the new client area. If this parameter is TRUE, the application should specify which part of the client area is valid.
lpncsp	Value of *lParam.* Points to an **NCCALCSIZE_PARAMS** data structure that contains information an application can use to calculate the new size and position of the client rectangle. Regardless of the value of *fCalcValidRects,* the first rectangle in the array specified by the **rgrc** member contains the coordinates of the window. For a child window, the coordinates are relative to the parent window's client area. For top-level windows, the coordinates are screen coordinates. An application should process WM_NCCALCSIZE by modifying the **rgrc[0]** rectangle to reflect the size and position of the client area. The **rgrc[1]** and **rgrc[2]** rectangles are valid only if *fCalcValidRects* is TRUE. In this case, the **rgrc[1]** rectangle contains the coordinates of the window before it was moved or resized. The **rgrc[2]** rectangle contains the coordinates of the window's client area before the window was moved. All coordinates are relative to the parent window or screen.

Returns

An application should return zero if *fCalcValidRects* is FALSE.

An application can return zero or a valid combination of the following values if *fCalcValidRects* is TRUE:

Value Meaning

WVR_ALIGNTOP, WVR_ALIGNLEFT, WVR_ALIGNBOTTOM, WVR_ALIGNRIGHT
: These values, used in combination, specify that the client area of the window is to be preserved and aligned appropriately relative to the new location of the client window. For example, to align the client area to the lower-left, return WVR_ALIGNLEFT | WVR_ALIGNTOP.

WVR_HREDRAW, WVR_VREDRAW
: These values, used in combination with any other values, cause the window to be completely redrawn if the client rectangle changed size horizontally or vertically. These values are similar to the **CS_HREDRAW** and **CS_VREDRAW** class styles.

WVR_REDRAW
: This value causes the entire window to be redrawn. It is a combination of WVR_HREDRAW and WVR_VREDRAW.

WVR_VALIDRECTS
: This value indicates that, upon return from WM_NCCALCSIZE, the **rgrc[1]** and **rgrc[2]** rectangles contain valid source and destination area rectangles, respectively. Windows combines these rectangles to calculate the area of the window that can be preserved. Windows copies any part of the window image that is within the source rectangle and clips the image to the destination rectangle. Both rectangles are in parent-relative or screen-relative coordinates.

  This return value allows an application to implement more elaborate client-area preservation strategies, such as centering or preserving a subset of the client area.

If *fCalcValidRects* is TRUE and an application returns zero, the old client area is preserved and is aligned with the upper-left corner of the new client area.

Comments

Redrawing of the window may occur, depending on whether **CS_HREDRAW** or **CS_VREDRAW** was specified. This is the default, backward-compatible **DefWindowProc** processing of this message (in addition to the usual client rectangle calculation described in the preceding table).

See Also

DefWindowProc, **MoveWindow**, **SetWindowPos**, **NCCALCSIZE_PARAMS**, **RECT**

WM_NCCREATE (2.x)

```
WM_NCCREATE
lpcs = (CREATESTRUCT FAR*) lParam;  /* address of initialization data */
```

The WM_NCCREATE message is sent prior to the **WM_CREATE** message when a window is first created.

Parameter	Description
lpcs	Value of *lParam.* Points to the **CREATESTRUCT** data structure for the window.

Returns

The return value is nonzero if the nonclient area is created. It is zero if an error occurs; in this case, the **CreateWindow** or **CreateWindowEx** function will return NULL.

Comments

Scroll bars are initialized (the scroll bar position and range are set), and the window text is set. Memory used internally to create and maintain the window is allocated.

See Also

CreateWindow, **WM_CREATE**, **CREATESTRUCT**

WM_NCDESTROY (2.x)

```
WM_NCDESTROY
```

The WM_NCDESTROY message informs a window that its nonclient area is being destroyed. The **DestroyWindow** function sends the WM_NCDESTROY message to the window following the **WM_DESTROY** message. WM_NCDESTROY is used to free the allocated memory object associated with the window.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

This message frees any memory internally allocated for the window.

See Also

DestroyWindow, **WM_NCCREATE**

WM_NCHITTEST (2.x)

```
WM_NCHITTEST
xPos = (int) LOWORD(lParam);    /* horizontal position of cursor */
yPos = (int) HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_NCHITTEST message is sent to the window that contains the cursor or to the window that used the **SetCapture** function to capture the mouse input. It is sent every time the mouse is moved.

Parameter	Description
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, in screen coordinates.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, in screen coordinates.

Returns

The return value of the **DefWindowProc** function is one of the following values indicating the position of the cursor:

Value	Meaning
HTBORDER	In the border of a window that does not have a sizing border
HTBOTTOM	In the lower horizontal border of a window
HTBOTTOMLEFT	In the lower-left corner of a window border
HTBOTTOMRIGHT	In the lower-right corner of a window border
HTCAPTION	In a title bar area
HTCLIENT	In a client area
HTERROR	On the screen background or on a dividing line between windows (same as HTNOWHERE except that the **DefWindowProc** function produces a system beep to indicate an error)
HTGROWBOX	In a size box (same as HTSIZE)
HTHSCROLL	In the horizontal scroll bar
HTLEFT	In the left border of a window
HTMAXBUTTON	In a Maximize button
HTMENU	In a menu area
HTMINBUTTON	In a Minimize button
HTNOWHERE	On the screen background or on a dividing line between windows
HTREDUCE	In a Minimize button
HTRIGHT	In the right border of a window
HTSIZE	In a size box (same as HTGROWBOX)
HTSYSMENU	In a System menu (sometimes referred to as a Control menu) or in a close button in a child window
HTTOP	In the upper horizontal border of a window
HTTOPLEFT	In the upper-left corner of a window border
HTTOPRIGHT	In the upper-right corner of a window border
HTTRANSPARENT	In a window currently covered by another window
HTVSCROLL	In the vertical scroll bar
HTZOOM	In a Maximize button

Comments

The **MAKEPOINT** macro can be used to convert the *lParam* parameter to a **POINT** structure.

Example

This example shows a portion of a subclass procedure that detects mouse messages in a static window:

```
LONG lRetVal;

case WM_NCHITTEST:
    lRetVal = DefWindowProc(hwnd, msg, wParam, lParam);
    if (lRetVal == HTTRANSPARENT) {
        .
        . /* Process mouse events in static window. */
        .
    }
    break;

default:
    CallWindowProc(lpStaticProc, hwnd, msg, wParam, lParam);
```

Windows 3.1 changes

The following hit-test code was previously undocumented:

Value	Meaning
HTBORDER	In the border of a window that does not have a sizing border.

WM_NCLBUTTONDBLCLK (2.x)

```
WM_NCLBUTTONDBLCLK
nHittest = wParam;        /* hit-test code              */
xCursor = LOWORD(lParam); /* cursor horizontal position */
yCursor = HIWORD(lParam); /* cursor vertical position   */
```

The WM_NCLBUTTONDBLCLK message is sent when the user double-clicks the left mouse button while the cursor is within a nonclient area of the window.

Parameter	Description
nHittest	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xCursor	Value of the low-order word of *lParam.* Specifies the horizontal position of the cursor, in screen coordinates.
yCursor	Value of the high-order word of *lParam.* Specifies the vertical position of the cursor, in screen coordinates.

Returns

An application should return zero if it processes this message.

Comments

If appropriate, **WM_SYSCOMMAND** messages are sent.

See Also

WM_NCHITTEST, **WM_SYSCOMMAND**, **POINT**

WM_NCLBUTTONDOWN (2.x)

```
WM_NCLBUTTONDOWN
wHitTestCode = wParam;    /* hit-test code              */
xPos = LOWORD(lParam);    /* horizontal cursor position */
yPos = HIWORD(lParam);    /* vertical cursor position   */
```

The WM_NCLBUTTONDOWN message is sent to a window when the user presses the left mouse button while the cursor is within a nonclient area of the window.

Parameter	Description
wHitTestCode	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, in screen coordinates.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, in screen coordinates.

Returns

An application should return zero if it processes this message.

Comments

If appropriate, **WM_SYSCOMMAND** messages are sent.

See Also

WM_NCHITTEST, **WM_NCLBUTTONDBLCLK**, **WM_NCLBUTTONUP**, **WM_SYSCOMMAND**, **POINT**

WM_NCLBUTTONUP (2.x)

```
WM_NCLBUTTONUP
wHitTestCode = wParam;    /* hit-test code              */
xPos = LOWORD(lParam);    /* horizontal cursor position */
yPos = HIWORD(lParam);    /* vertical cursor position   */
```

The WM_NCLBUTTONUP message is sent to a window when the user releases the left mouse button while the cursor is within a nonclient area of the window.

Parameter	Description
wHitTestCode	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, in screen coordinates.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, in screen coordinates.

Returns

An application should return zero if it processes this message.

Comments

If appropriate, **WM_SYSCOMMAND** messages are sent.

xPos = LOWORD(lParam);    /* horizontal cursor position */
yPos = HIWORD(lParam);    /* vertical cursor position   */
```

The **WM_NCRBUTTONDOWN** message is sent to a window when the user double-clicks the middle mouse button while the cursor is within a nonclient area of the window.

Parameter	Description
wHitTestCode	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, as a screen coordinate.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, as a screen coordinate.

Returns

An application should return zero if it processes this message.

xPos = LOWORD(lParam);    /* horizontal cursor position */
yPos = HIWORD(lParam);    /* vertical cursor position   */
```

The WM_NCMBUTTONUP message is sent to a window when the user releases the left mouse button while the cursor is within a nonclient area of the window.

Parameter	Description
wHitTestCode	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, as a screen coordinate.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, as a screen coordinate.

Returns

An application should return zero if it processes this message.

WM_NCMOUSEMOVE (2.x)

```
WM_NCMOUSEMOVE
wHitTestCode = wParam;    /* hit-test code              */
xPos = LOWORD(lParam);    /* horizontal cursor position */
yPos = HIWORD(lParam);    /* vertical cursor position   */
```

The WM_NCMOUSEMOVE message is sent to a window when the cursor is moved within a nonclient area of the window.

Parameter	Description
wHitTestCode	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, as a screen coordinate.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, as a screen coordinate.

Returns
An application should return zero if it processes this message.

Comments
If appropriate, **WM_SYSCOMMAND** messages are sent.

See Also
WM_NCHITTEST, **WM_SYSCOMMAND**, **POINT**

WM_NCPAINT (2.x)

`WM_NCPAINT`

The WM_NCPAINT message is sent to a window when its frame needs painting.

Parameters

This message has no parameters.

Returns
An application should return zero if it processes this message.

Comments
The **DefWindowProc** function paints the window frame.

An application can intercept this message and paint its own custom window frame. The clipping region for a window is always rectangular, even if the shape of the frame is altered.

See Also
DefWindowProc

WM_NCRBUTTONDBLCLK (2.x)

```
WM_NCRBUTTONDBLCLK
wHitTestCode = wParam;    /* hit-test code              */
xPos = LOWORD(lParam);    /* horizontal cursor position */
yPos = HIWORD(lParam);    /* vertical cursor position   */
```

The WM_NCRBUTTONDBLCLK message is sent to a window when the user double-clicks the right mouse button while the cursor is within a nonclient area of the window.

Parameter	Description
wHitTestCode	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, as a screen coordinate.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, as a screen coordinate.

Returns

An application should return zero if it processes this message.

See Also

WM_NCHITTEST, **WM_NCRBUTTONDOWN**, **WM_NCRBUTTONUP**, **POINT**

WM_NCRBUTTONDOWN (2.x)

```
WM_NCRBUTTONDOWN
wHitTestCode = wParam;    /* hit-test code              */
xPos = LOWORD(lParam);    /* horizontal cursor position */
yPos = HIWORD(lParam);    /* vertical cursor position   */
```

The WM_NCRBUTTONDOWN message is sent to a window when the user presses the right mouse button while the cursor is within a nonclient area of the window.

Parameter	Description
wHitTestCode	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, as a screen coordinate.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, as a screen coordinate.

Returns

An application should return zero if it processes this message.

See Also

WM_NCHITTEST, **WM_NCRBUTTONDBLCLK**, **WM_NCRBUTTONUP**, **POINT**

WM_NCRBUTTONUP (2.x)

```
WM_NCRBUTTONUP
wHitTestCode = wParam;    /* hit-test code              */
xPos = LOWORD(lParam);    /* horizontal cursor position */
yPos = HIWORD(lParam);    /* vertical cursor position   */
```

The WM_NCRBUTTONUP message is sent to a window when the user releases the right mouse button while the cursor is within a nonclient area of the window.

Parameter	Description
wHitTestCode	Value of *wParam.* Specifies the code returned by WM_NCHITTEST. For more information, see the description of the **WM_NCHITTEST** message.
xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, as a screen coordinate.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, as a screen coordinate.

Returns

An application should return zero if it processes this message.

See Also

WM_NCHITTEST, **WM_NCRBUTTONDBLCLK**, **WM_NCRBUTTONDOWN**, **POINT**

WM_NEXTDLGCTL (2.x)

```
WM_NEXTDLGCTL
wCtlFocus = wParam;               /* identifies control for focus */
fHandle = (BOOL) LOWORD(lParam);  /* wParam handle flag           */
```

An application sends the WM_NEXTDLGCTL message to a dialog box procedure to set the focus to a different control in a dialog box.

Parameter	Description
wCtlFocus	Value of *wParam.* If the *fHandle* parameter is nonzero, the *wCtlFocus* parameter is the handle of the control that receives the focus. If *fHandle* is zero, *wCtlFocus* is a flag that indicates whether the next or previous control with the **WS_TABSTOP** style receives the focus. If *wCtlFocus* is zero, the next control receives the focus; otherwise, the previous control with the WS_TABSTOP style receives the focus.
fHandle	Low-order word of *lParam.* Indicates how Windows uses the *wParam* parameter. If *fHandle* is nonzero, *wParam* is a handle associated with the control that receives the focus; otherwise, *wParam* is a flag that indicates whether the next or previous control with the **WS_TABSTOP** style receives the focus.

Returns

An application should return zero if it processes this message.

Comments

The effect of this message differs from that of the **SetFocus** function because WM_NEXTDLGCTL modifies the border around the default button.

Do not use the **SendMessage** function to send a WM_NEXTDLGCTL message if your application will concurrently process other messages that set the control focus. In this case, use the **PostMessage** function instead.

See Also

PostMessage, **SendMessage**, **SetFocus**

WM_PAINT (2.x)

```
WM_PAINT
```

The WM_PAINT message is sent when Windows or an application makes a request to repaint a portion of an application's window. The message is sent when the **UpdateWindow** or **RedrawWindow** function is called or by the **DispatchMessage** function when the application obtains a WM_PAINT message by using the **GetMessage** or **PeekMessage** function.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

The **DispatchMessage** function sends this message when there are no other messages in the application's message queue.

A window may receive internal paint messages as a result of calling the **RedrawWindow** function with the **RDW_INTERNALPAINT** flag set. In this case, the window may not have an update region. An application should call the **GetUpdateRect** function to determine whether the window has an update region. If **GetUpdateRect** returns zero, the application should not call the **BeginPaint** and **EndPaint** functions.

It is an application's responsibility to check for any necessary internal repainting or updating by looking at its internal data structures for each WM_PAINT message, because a WM_PAINT message may have been caused by both an invalid area and a call to the **RedrawWindow** function with the **RDW_INTERNALPAINT** flag set.

An internal WM_PAINT message is sent only once by Windows. After an internal WM_PAINT message is returned from the **GetMessage** or **PeekMessage** function or is sent to a window by the **UpdateWindow** function, no further WM_PAINT messages will be sent or posted until the window is invalidated or until the **RedrawWindow** function is called again with the **RDW_INTERNALPAINT** flag set.

See Also

BeginPaint, **DispatchMessage**, **EndPaint**, **GetMessage**, **PeekMessage**, **RedrawWindow**, **UpdateWindow**

Windows 3.1 changes

A window that may receive internal paint messages as a result of calling the **RedrawWindow** function with the **RDW_INTERNALPAINT** flag set. In this case, the window may not have an update region. An application should call the **GetUpdateRect** function to determine whether the window has an update region. If **GetUpdateRect** returns zero, the application should not call the **BeginPaint** and **EndPaint** functions.

It is an application's responsibility to check for any necessary internal repainting or updating by looking at its internal data structures for each WM_PAINT message, since a WM_PAINT message may have been caused by both an invalid area and a call to the **RedrawWindow** function with the **RDW_INTERNALPAINT** flag set.

Internal WM_PAINT messages are only sent once by Windows. After an internal WM_PAINT message is returned from the **GetMessage** or **PeekMessage** function, or sent to a window by the **UpdateWindow** function, no further WM_PAINT messages will be sent or posted until the window is invalidated or until the **RedrawWindow** function is called again with the **RDW_INTERNALPAINT** flag set.

WM_PAINTCLIPBOARD (2.x)

```
WM_PAINTCLIPBOARD
hwndViewer = (HWND) wParam;              /* handle of viewer     */
pps = (PAINTSTRUCT FAR*) LOWORD(lParam); /* points to paint data */
```

The WM_PAINTCLIPBOARD message is sent by a clipboard viewer to the clipboard owner when the owner has placed data on the clipboard in the CF_OWNERDISPLAY format and the clipboard viewer's client area needs repainting.

Parameter	Description
hwndViewer	Value of *wParam.* Specifies a handle to the clipboard viewer window.
pps	Value of the low-order word of *lParam.* Points to a **PAINTSTRUCT** data structure that defines which part of the client area to paint.

Returns

An application should return zero if it processes this message.

Comments

To determine whether the entire client area or just a portion of it needs repainting, the clipboard owner must compare the dimensions of the drawing area given in the **rcPaint** member of the **PAINTSTRUCT** structure to the dimensions given in the most recent **WM_SIZECLIPBOARD** message.

An application must use the **GlobalLock** function to lock the memory that contains the **PAINTSTRUCT** data structure. The application should unlock that memory by using the **GlobalUnlock** function before it yields or returns control.

See Also

GlobalLock, **GlobalUnlock**, **WM_SIZECLIPBOARD**, **PAINTSTRUCT**

WM_PALETTECHANGED (3.0)

```
WM_PALETTECHANGED
hwndPalChg = (HWND) wParam; /* handle of window that changed palette */
```

The WM_PALETTECHANGED message is sent to all top-level and overlapped windows after the window with the input focus has realized its logical palette, thereby changing the system palette. This message allows a window without the input focus that uses a color palette to realize its logical palette and update its client area.

Parameter	Description
hwndPalChg	Value of *wParam.* Specifies the handle of the window that caused the system palette to change.

Returns

An application should return zero if it processes this message.

Comments

This message is sent to all top-level and overlapped windows, including the one that changed the system palette and caused this message to be sent. If any child windows use a color palette, this message must be passed on to them.

To avoid an infinite loop, a window that receives this message should not realize its palette unless it determines that *wParam* does not contain its own window handle.

Example

This example shows how an application selects and realizes its logical palette:

```
HDC hdc;
HPALETTE hpalApp, hpalT;
UINT i;

/*
 * If this application changed the palette, ignore the message.
 */

case WM_PALETTECHANGED:
    if ((HWND) wParam == hwnd)
        return 0;

/* Otherwise, fall through to WM_QUERYNEWPALETTE. */

case WM_QUERYNEWPALETTE:

    /*
     * If realizing the palette causes the palette to change,
     * redraw completely.
     */

    hdc = GetDC(hwnd);
    hpalT = SelectPalette (hdc, hpalApp, FALSE);

    i = RealizePalette(hdc); /* i == entries that changed  */

    SelectPalette (hdc, hpalT, FALSE);
    ReleaseDC(hwnd, hdc);
```

```
    /* If any palette entries changed, repaint the window. */

    if (i > 0)
        InvalidateRect(hwnd, NULL, TRUE);

    return i;
```

See Also

WM_PALETTEISCHANGING, **WM_QUERYNEWPALETTE**, **RealizePalette**

WM_PALETTEISCHANGING (3.1)

```
WM_PALETTEISCHANGING
hwndRealize = (HWND) wParam; /* handle of window to realize palette */
```

The WM_PALETTEISCHANGING message informs applications that an application is going to realize its logical palette.

Parameter	Description
hwndRealize	Value of *wParam.* Specifies the handle of the window that is going to realize its logical palette.

Returns

An application should return zero if it processes this message.

See Also

WM_PALETTECHANGED, **WM_QUERYNEWPALETTE**

WM_PARENTNOTIFY (3.0)

```
WM_PARENTNOTIFY
fwEvent = wParam;          /* event flags                        */
wValue1 = LOWORD(lParam); /* child handle/cursor x-coordinate */
wValue2 = HIWORD(lParam); /* child ID/cursor y-coordinate     */
```

The WM_PARENTNOTIFY message is sent to the parent of a child window when the child window is created or destroyed or when the user clicks a mouse button while the cursor is over the child window. When the child window is being created, the system sends WM_PARENTNOTIFY just before the **CreateWindow** or **CreateWindowEx** function that creates the window returns. When the child window is being destroyed, the system sends the message before any processing to destroy the window takes place.

Parameter	Description
fwEvent	Value of *wParam.* Specifies the event for which the parent is being notified. It can be any of the following values:

Value	Description
WM_CREATE	The child window is being created.
WM_DESTROY	The child window is being destroyed.
WM_LBUTTONDOWN	The user has placed the mouse cursor over the child window and clicked the left mouse button.
WM_MBUTTONDOWN	The user has placed the mouse cursor over the child window and clicked the middle mouse button.
WM_RBUTTONDOWN	The user has placed the mouse cursor over the child window and clicked the right mouse button.

wValue1	Value of the low-order word of *lParam.* If the *fwEvent* parameter is **WM_CREATE** or **WM_DESTROY**, the *wValue1* parameter specifies the handle of the child window. Otherwise, *wValue1* specifies the x-coordinate of the cursor.
wValue2	Value of the high-order word of *lParam.* If *fwEvent* is **WM_CREATE** or **WM_DESTROY**, the *wValue2* parameter specifies the identifier of the child window. Otherwise, *wValue2* specifies the y-coordinate of the cursor.

Returns

An application should return zero if it processes this message.

Comments

This message is also sent to all ancestor windows of the child window, including the top-level window.

All child windows except those that have the **WS_EX_NOPARENTNOTIFY** send this message to their parent windows. By default, child windows in a dialog box have the WS_EX_NOPARENTNOTIFY style unless the **CreateWindowEx** function was called to create the child window without this style.

See Also

CreateWindow, **CreateWindowEx**, **WM_CREATE**, **WM_DESTROY**, **WM_LBUTTONDOWN**, **WM_MBUTTONDOWN**, **WM_RBUTTONDOWN**

WM_PASTE (2.x)

```
WM_PASTE
wParam = 0;      /* not used, must be zero */
lParam = 0L;     /* not used, must be zero */
```

An application sends the WM_PASTE message to an edit control or combo box to insert the data from the clipboard into the edit control at the current cursor position. Data is inserted only if the clipboard contains data in CF_TEXT format.

Parameters

This message has no parameters.

Returns

The return value is nonzero if this message is sent to an edit control or a combo box.

Example

This example pastes data from the clipboard to an edit control:

```
SendDlgItemMessage(hdlg, IDD_MYEDITCONTROL, WM_PASTE, 0, 0L);
```

See Also

WM_CLEAR, **WM_COPY**, **WM_CUT**

WM_POWER (3.1)

```
WM_POWER
fwPowerEvt = wParam;     /* power-event notification message */
```

The WM_POWER message is sent when the system, typically a battery-powered personal computer, is about to enter the suspended mode.

Parameter	Description
fwPowerEvt	Value of *wParam.* Specifies a power-event notification message. This parameter may be one of the following values:

Value	Meaning
PWR_SUSPENDREQUEST	Indicates that the system is about to enter the suspended mode.
PWR_SUSPENDRESUME	Indicates that the system is resuming operation after entering the suspended mode normally--that is, the system sent a PWR_SUSPENDREQUEST notification message to the application before the system was suspended. An application should perform any necessary recovery actions.
PWR_CRITICALRESUME	Indicates that the system is resuming operation after entering the suspended mode without first sending a PWR_SUSPENDREQUEST notification message to the application. An application should perform any necessary recovery actions.

Returns

The value an application should return depends on the value of the *wParam* parameter, as follows:

Value of *wParam*	Return Value
PWR_SUSPENDREQUEST	PWR_FAIL to prevent the system from entering the suspended state; otherwise PWR_OK
PWR_SUSPENDRESUME	0
PWR_CRITICALRESUME	0

Comments

This message is sent only to an application that is running on a system that conforms to the advanced power management (APM) basic input-and-output system (BIOS) specification. The message is sent by the power-management driver to each window returned by the **EnumWindows** function.

The suspended mode is the state in which the greatest amount of power savings occurs, but all operational data and parameters are preserved. Random-access memory (RAM) contents are preserved, but many devices are likely to be turned off.

See Also

EnumWindows

WM_QUERYDRAGICON (3.0)

```
WM_QUERYDRAGICON
```

The WM_QUERYDRAGICON message is sent to a minimized (iconic) window that does not have an icon defined for its class. The system sends this message whenever it needs to display an icon for the window.

Parameters

This message has no parameters.

Returns

An application should return a doubleword value that contains a cursor or icon handle in the low-order word. The cursor or icon must be compatible with the display driver's resolution. If the application returns NULL, the system displays the default cursor. The default return value is NULL.

Comments

If an application returns the handle of an icon or cursor, the system converts it to black-and-white.

The application can call the **LoadCursor** or **LoadIcon** function to load a cursor or icon from the resources in its executable file and to obtain this handle.

Example

This example returns an icon handle in response to the WM_QUERYDRAGICON message. The icon is loaded from the resources in the application's executable file.

```
static HICON hIcon;

switch(msg) {
    case WM_CREATE:

        /* Load icon resource. */

        hIcon = LoadIcon(hInstance, (LPCSTR) "MyIcon");
        .
        . /* Initialize other variables. */
        .

        return 0L;

    case WM_QUERYDRAGICON:

        /* Icon is about to be dragged. Return handle to custom icon. */

        return (hIcon);

    .
    . /* Process other messages. */
    .

}
```

See Also

LoadCursor, **LoadIcon**

WM_QUERYENDSESSION (2.x)

```
WM_QUERYENDSESSION
```

The WM_QUERYENDSESSION message is sent when the user chooses to end the Windows session, or when an application calls the **ExitWindows** function. If any application returns zero, the Windows session is not ended. Windows stops sending WM_QUERYENDSESSION messages as soon as one application returns zero and sends **WM_ENDSESSION** messages, with the *wParam* parameter set to FALSE, to any applications that have already returned nonzero.

Parameters

This message has no parameters.

Returns

An application should return nonzero if it can conveniently terminate; otherwise, it should return zero.

Comments

The **DefWindowProc** function returns nonzero when it processes this message.

See Also

DefWindowProc, **ExitWindows**, **WM_ENDSESSION**

WM_QUERYNEWPALETTE (3.0)

WM_QUERYNEWPALETTE

The WM_QUERYNEWPALETTE message informs an application that it is about to receive the input focus, giving the application an opportunity to realize its logical palette when it receives the focus.

Parameters

This message has no parameters.

Returns

An application should return nonzero if it realizes its logical palette; otherwise, it should return zero.

Example

This example shows how an application selects and realizes its logical palette:

```
HDC hdc;
HPALETTE hpalApp, hpalT;
UINT i;

/*
 * If this application changed the palette, ignore the message.
 */

case WM_PALETTECHANGED:
    if ((HWND) wParam == hwnd)
        return 0;

/* Otherwise, fall through to WM_QUERYNEWPALETTE. */

case WM_QUERYNEWPALETTE:

    /*
     * If realizing the palette causes the palette to change,
     * redraw completely.
     */

    hdc = GetDC(hwnd);
    hpalT = SelectPalette (hdc, hpalApp, FALSE);

    i = RealizePalette(hdc); /* i == entries that changed  */

    SelectPalette (hdc, hpalT, FALSE);
    ReleaseDC(hwnd, hdc);

    /* If any palette entries changed, repaint the window. */

    if (i > 0)
        InvalidateRect(hwnd, NULL, TRUE);

    return i;
```

See Also

WM_PALETTECHANGED, **WM_PALETTEISCHANGING**

WM_QUERYOPEN (2.x)

```
WM_QUERYOPEN
```

The WM_QUERYOPEN message is sent to a minimized window when the user requests that the window be restored to its preminimized size and position.

Parameters

This message has no parameters.

Returns

An application that processes this message should return a nonzero value if the icon can be opened or zero to prevent the icon from opened.

Comments

While processing this message, the application should not perform any action that would cause an activation or focus change (for example, creating a dialog box).

The **DefWindowProc** function returns nonzero when it processes this message.

See Also

DefWindowProc

WM_QUEUESYNC (3.1)

```
WM_QUEUESYNC
```

The WM_QUEUESYNC message is sent by a computer-based training (CBT) application to separate user-input messages from other messages sent through the journal playback hook (**WH_JOURNALPLAYBACK**).

Parameters

This message has no parameters.

Returns

A CBT application should return zero if it processes this message.

Comments

Whenever a CBT application uses the journal playback hook, the first and last messages rendered are WM_QUEUESYNC. This allows the CBT application to intercept and examine user-initiated messages without doing so for events that it sends.

WM_QUIT (2.x)

```
WM_QUIT
wExit = wParam; /* exit code */
```

The WM_QUIT message indicates a request to terminate an application and is generated when the application calls the **PostQuitMessage** function. It causes the **GetMessage** function to return zero.

Parameter	Description
wExit	Value of *wParam.* Specifies the exit code given in the **PostQuitMessage** function.

Returns

This message does not have a return value, because it causes the message loop to terminate before the message is sent to the application's window procedure.

See Also

GetMessage, **PostQuitMessage**

WM_RBUTTONDBLCLK (2.x)

```
WM_RBUTTONDBLCLK
fwKeys = wParam;          /* key flags                       */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_RBUTTONDBLCLK message is sent when the user double-clicks the right mouse button.

Parameter	Description
fwKeys	Value of *wParam.* Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_LBUTTON	Set if left button is down.
MK_MBUTTON	Set if middle button is down.
MK_RBUTTON	Set if right button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns

An application should return zero if it processes this message.

Comments

Only windows that have the **CS_DBLCLKS** class style can receive WM_RBUTTONDBLCLK messages. Windows generates a WM_RBUTTONDBLCLK message when the user presses, releases, and again presses the right mouse button within the system's double-click time limit. Double-clicking the right mouse button actually generates four messages: a **WM_RBUTTONDOWN** message, a **WM_RBUTTONUP** message, the WM_RBUTTONDBLCLK message, and another WM_RBUTTONUP message.

See Also

WM_RBUTTONDOWN, **WM_RBUTTONUP**

WM_RBUTTONDOWN (2.x)

```
WM_RBUTTONDOWN
fwKeys = wParam;          /* key flags                      */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_RBUTTONDOWN message is sent when the user presses the right mouse button.

Parameter	Description
fwKeys	Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_LBUTTON	Set if left mouse button is down.
MK_MBUTTON	Set if middle mouse button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns
An application should return zero if it processes this message.

See Also
WM_RBUTTONDBLCLK, **WM_RBUTTONUP**

WM_RBUTTONUP (2.x)

```
WM_RBUTTONUP
fwKeys = wParam;          /* key flags                      */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_RBUTTONUP message is sent when the user releases the right mouse button.

Parameter	Description
fwKeys	Value of *wParam.* Indicates whether various virtual keys are down. This parameter can be any combination of the following values:

Value	Description
MK_CONTROL	Set if CTRL key is down.
MK_LBUTTON	Set if left mouse button is down.
MK_MBUTTON	Set if middle mouse button is down.
MK_SHIFT	Set if SHIFT key is down.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor. The coordinate is relative to the upper-left corner of the window.

Returns
An application should return zero if it processes this message.

See Also
WM_RBUTTONDBLCLK, **WM_RBUTTONDOWN**

WM_RENDERALLFORMATS (2.x)

WM_RENDERALLFORMATS

The WM_RENDERALLFORMATS message is sent to the clipboard owner when the owner application is being destroyed.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

The clipboard owner should render the data in all the formats it is capable of generating and pass a data handle for each format to the clipboard by calling the **SetClipboardData** function. This ensures that the clipboard contains valid data even though the application that rendered the data is destroyed. The application should call the **OpenClipboard** function before calling **SetClipboardData** and should call the **CloseClipboard** function afterward.

Example

In this example, the application sends a **WM_RENDERFORMAT** message to itself for each clipboard format that the application supports:

```
case WM_RENDERALLFORMATS:
    OpenClipboard(hwnd);
    SendMessage(hwnd, WM_RENDERFORMAT, CF_DIB, 0L);
    SendMessage(hwnd, WM_RENDERFORMAT, CF_BITMAP, 0L);
    CloseClipboard();
    break;
```

See Also

CloseClipboard, **OpenClipboard**, **SetClipboardData**, **WM_RENDERFORMAT**

WM_RENDERFORMAT (2.x)

```
WM_RENDERFORMAT
uFmt = (UINT) wParam;    /* clipboard data format */
```

The WM_RENDERFORMAT message is sent to the clipboard owner when a particular format with delayed rendering needs to be rendered. The receiver should render the data in that format and pass it to the clipboard by calling the **SetClipboardData** function.

Parameter	Description
uFmt	Specifies the data format. It can be any one of the formats described with the **SetClipboardData** function.

Returns

An application should return zero if it processes this message.

Comments

The application should not call the **OpenClipboard** and **CloseClipboard** functions while processing this message.

Example

This example uses an application-defined function to render clipboard data. The function returns a data handle that is passed to the clipboard by the **SetClipboardData** function.

```
HANDLE hData;

case WM_RENDERFORMAT:
    if (hData = RenderFormat(wParam))
        SetClipboardData(wParam, hData);
    break;
```

See Also

CloseClipboard, **OpenClipboard**, **SetClipboardData**, **WM_RENDERALLFORMATS**

WM_SETCURSOR (2.x)

```
WM_SETCURSOR
hwndCursor = (HWND) wParam;    /* handle of window with cursor */
nHittest = LOWORD(lParam);     /* hit-test code                */
wMouseMsg = HIWORD(lParam);    /* mouse-message number         */
```

The WM_SETCURSOR message is sent to a window if mouse input is not captured and the mouse causes cursor movement within the window.

Parameter	Description
hwndCursor	Value of *wParam.* Specifies a handle to the window that contains the cursor.
nHittest	Value of the low-order word of *lParam.* Specifies the hit-test area code.
wMouseMsg	Value of the high-order word of *lParam.* Specifies the number of the mouse message.

Returns

An application should return TRUE to halt further processing or zero to continue.

Comments

If the *nHittest* parameter is HTERROR and the *wMouseMsg* parameter is a mouse button–down message, the **MessageBeep** function is called.

The **DefWindowProc** function passes the WM_SETCURSOR message to a parent window before processing. If the parent window returns TRUE, further processing is halted. Passing the message to a window's parent window gives the parent window control over the cursor's setting in a child window. The **DefWindowProc** function also uses this message to set the cursor to a pointer if it is not in the client area or to the registered-class cursor if it is in the client area.

For a standard dialog box to set the cursor for one of its child window controls, it must force the **DefDlgProc** function to return TRUE in response to the WM_SETCURSOR message. (**DefDlgProc** provides default processing for the standard dialog box class.) When **DefDlgProc** returns TRUE, the dialog procedure retains control over the cursor. When the dialog procedure processes the WM_SETCURSOR message, it can return TRUE by using the **SetWindowLong** function and the **DWL_MSGRESULT** offset, as shown in the following example:

```
SetWindowLong(hwndDlg, DWL_MSGRESULT, MAKELONG(TRUE, 0));
```

See Also

DefWindowProc, **MessageBeep**, **SetWindowLong**

WM_SETFOCUS (2.x)

```
WM_SETFOCUS
hwnd = (HWND) wParam;    /* handle of window losing focus */
```

The WM_SETFOCUS message is sent after a window gains the input focus.

Parameter	Description
hwnd	Value of *wParam.* Contains the handle of the window that loses the input focus. (This parameter may be NULL.)

Returns

An application should return zero if it processes this message.

Comments

To display a caret, an application should call the appropriate caret functions at this point.

WM_SETFONT (3.0)

```
WM_SETFONT
wParam = (WPARAM) hfont;                        /* handle of the font */
lParam = (LPARAM) MAKELONG((WORD) fRedraw, 0); /* redraw flag        */
```

An application sends the WM_SETFONT message to specify the font that a control is to use when drawing text.

Parameter	Description
hfont	Value of *wParam.* Specifies the handle of the font. If this parameter is NULL, the control will use the default system font to draw text.
fRedraw	Value of the low-order word of *lParam.* Specifies whether the control should be redrawn immediately upon setting the font. Setting the *fRedraw* parameter to TRUE causes the control to redraw itself.

Returns

An application should return zero if it processes this message.

Comments

The WM_SETFONT message applies to all controls, not just those in dialog boxes.

The best time for the owner of a dialog box to set the font of the control is when it receives the **WM_INITDIALOG** message. The application should call the **DeleteObject** function to delete the font when it is no longer needed--for example, after the control is destroyed.

The size of the control is not changed as a result of receiving this message. To prevent Windows from clipping text that does not fit within the boundaries of the control, the application should correct the size of the control window before changing the font.

Before Windows creates a dialog box with the DS_SETFONT style, Windows sends the WM_SETFONT message to the dialog box window before creating the controls. An application creates a dialog box with the DS_SETFONT style by calling any of the following functions:

- **CreateDialogIndirect**
- **CreateDialogIndirectParam**
- **DialogBoxIndirect**
- **DialogBoxIndirectParam**

The **DialogBoxHeader** structure that the application passes to these functions must have the DS_SETFONT style set and must contain the **wPointSize** and **szFaceName** members that define the font the dialog box will use to draw text.

For more information about the **DialogBoxHeader** structure, see the **Resource Format Overview**.

Example

This example changes the font used by controls in a dialog box to a font that is not bold.

```
HFONT hfontDlg;
LOGFONT lFont;

case WM_INITDIALOG:

    /* Get dialog box font and create version that is not bold. */

    hfontDlg = (HFONT) NULL;
    if ((hfontDlg = (HFONT) SendMessage(hdlg, WM_GETFONT, 0, 0L))) {
        if (GetObject(hfontDlg, sizeof(LOGFONT), (LPSTR) &lFont)) {
            lFont.lfWeight = FW_NORMAL;
```

```
            if (hfontDlg = CreateFontIndirect((LPLOGFONT) &lFont)) {
                SendDlgItemMessage(hdlg, ID_CTRL1, WM_SETFONT,
                    (WPARAM) hfontDlg, 0);
                SendDlgItemMessage(hdlg, ID_CTRL2, WM_SETFONT,
                    (WPARAM) hfontDlg, 0);
                .
                . /* Set font for remaining controls. */
                .
            }
        }
    }
    return TRUE;
```

See Also

CreateDialogIndirect, **CreateDialogIndirectParam**, **DeleteObject**, **DialogBoxIndirect**, **DialogBoxIndirectParam**, **WM_INITDIALOG**, **WM_SETFONT**

WM_SETREDRAW (2.x)

```
WM_SETREDRAW
wParam = (WPARAM) fRedraw;    /* state of redraw flag   */
lParam = 0L;                  /* not used, must be zero */
```

An application sends a WM_SETREDRAW message to a window to allow changes in that window to be redrawn or to prevent changes in that window from being redrawn.

Parameter	Description
fRedraw	Value of *wParam.* Specifies the state of the redraw flag. If this parameter is nonzero, the redraw flag is set. If this parameter is zero, the flag is cleared.

Returns

An application should return zero if it processes this message.

Comments

This message sets or clears the redraw flag. If the redraw flag is cleared, the contents of the specified window will not be updated after each change, and the window will not be repainted until the redraw flag is set. For example, an application that needs to add several items to a list box can clear the redraw flag, add the items, and then set the redraw flag. Finally, the application can call the **InvalidateRect** function to cause the list box to be repainted.

WM_SETTEXT (2.x)

```
WM_SETTEXT
wParam = 0;                          /* not used, must be zero        */
lParam = (LPARAM) (LPCSTR) pszText; /* address of window-text string */
```

An application sends a WM_SETTEXT message to set the text of a window.

Parameter	Description
pszText	Value of *lParam.* Points to a null-terminated string that is the window text.

Returns

The return value is LB_ERRSPACE (for a list box) or CB_ERRSPACE (for a combo box) if insufficient space is available to set the text in the edit control. It is CB_ERR if this message is sent to a combo box without an edit control.

Comments

For an edit control, the text to be set is the contents of the edit control. For a combo box, the text is the contents of the edit-control (or static-text) portion of the combo box. For a button, the text is the button name. For other windows, the text is the window title.

This message does not change the current selection in the list box of a combo box. An application should use the **CB_SELECTSTRING** message to select the item in the list box that matches the text in the edit control.

See Also

WM_GETTEXT

WM_SHOWWINDOW (2.x)

```
WM_SHOWWINDOW
fShow = (BOOL) wParam;              /* show/hide flag */
fnStatus = LOWORD(lParam);     /* status flag    */
```

The WM_SHOWWINDOW message is sent to a window when it is about to be hidden or shown. A window is hidden or shown when the **ShowWindow** function is called; when an overlapped window is maximized or restored; or when an overlapped or pop-up window is minimized or displayed on the screen. When an overlapped window is minimized, all pop-up windows associated with that window are hidden.

Parameter	Description
fShow	Value of *wParam.* Specifies whether a window is being shown. It is TRUE if the window is being shown; it is FALSE if the window is being hidden.
fnStatus	Value of the low-order word of *lParam.* Specifies the status of the window being shown. The *fnStatus* parameter is zero if the message is sent because of a **ShowWindow** function call; otherwise, *fnStatus* is one of the following values:

Value	Description
SW_PARENTCLOSING	Parent window is being minimized, or a pop-up window is being hidden.
SW_PARENTOPENING	Parent window is opening (being displayed) or a pop-up window is being shown.

Returns

An application should return zero if it processes this message.

Comments

The **DefWindowProc** function hides or shows the window as specified by the message.

The WM_SHOWWINDOW message is not sent under the following circumstances:

- When a main window is created with the **WS_MAXIMIZE** or **WS_MINIMIZE** style
- When the SW_SHOWNORMAL flag is specified in the call to the **ShowWindow** function

See Also

DefWindowProc, **ShowWindow**

WM_SIZE (2.x)

```
WM_SIZE
fwSizeType = wParam;      /* sizing-type flag      */
nWidth = LOWORD(lParam);  /* width of client area  */
nHeight = HIWORD(lParam); /* height of client area */
```

The WM_SIZE message is sent to a window after its size has changed.

Parameter	Description
fwSizeType	Value of *wParam.* Specifies the type of resizing requested. This parameter can be one of the following values:

Value	Description
SIZE_MAXIMIZED	Window has been maximized.
SIZE_MINIMIZED	Window has been minimized.
SIZE_RESTORED	Window has been resized, but neither SIZE_MINIMIZED nor SIZE_MAXIMIZED applies.
SIZE_MAXHIDE	Message is sent to all pop-up windows when some other window is maximized.
SIZE_MAXSHOW	Message is sent to all pop-up windows when some other window has been restored to its former size.

nWidth	Value of the low-order word of *lParam.* Specifies the new width of the client area.
nHeight	Value of the high-order word of *lParam.* Specifies the new height of the client area.

Returns

An application should return zero if it processes this message.

Comments

If the **SetScrollPos** or **MoveWindow** function is called for a child window as a result of the WM_SIZE message, the *fRepaint* parameter should be nonzero to cause the window to be repainted.

See Also

MoveWindow, **SetScrollPos**

WM_SIZECLIPBOARD (2.x)

```
WM_SIZECLIPBOARD
hwndViewer = (HWND) wParam;      /* handle of clipboard viewer */
hglb = (HGLOBAL) LOWORD(lParam); /* handle of global object    */
```

The WM_SIZECLIPBOARD message is sent by the clipboard viewer to the clipboard owner when the clipboard contains data with the CF_OWNERDISPLAY attribute and the size of the client area of the clipboard-viewer window has changed.

Parameter	Description
hwndViewer	Value of *wParam.* Identifies the clipboard-application window.
hglb	Value of the low-order word of *lParam.* Identifies a global memory object that contains a **RECT** data structure. The structure specifies the area that the clipboard owner should paint.

Returns

An application should return zero if it processes this message.

Comments

A WM_SIZECLIPBOARD message is sent with a null rectangle (0,0,0,0) as the new size when the clipboard application is about to be destroyed or minimized. This permits the clipboard owner to free its display resources.

An application must use the **GlobalLock** function to lock the memory that contains the **RECT** data structure. The application should unlock that memory by using the **GlobalUnlock** function before it yields or returns control.

See Also

GlobalLock, **GlobalUnlock**, **SetClipboardData**, **SetClipboardViewer**, **RECT**

WM_SPOOLERSTATUS (3.0)

```
WM_SPOOLERSTATUS
fwJobStatus = wParam;       /* job-status flag          */
cJobsLeft = LOWORD(lParam); /* number of jobs remaining */
```

The WM_SPOOLERSTATUS message is sent from Print Manager whenever a job is added to or removed from the Print Manager queue.

Parameter	Description
fwJobStatus	Value of *wParam.* Specifies the SP_JOBSTATUS flag.
cJobsLeft	Value of the low-order word of *lParam.* Specifies the number of jobs remaining in the Print Manager queue.

Returns

An application should return zero if it processes this message.

Comments

This message is for informational purposes only.

WM_SYSCHAR (2.x)

```
WM_SYSCHAR
wKeyCode = wParam;       /* ASCII key code */
dwKeyData = lParam;      /* key data       */
```

The WM_SYSCHAR message is sent to the window with the input focus when a **WM_SYSKEYUP** and a **WM_SYSKEYDOWN** message are translated. It specifies the virtual-key code of the System-menu key. (The System menu is sometimes referred to as the Control menu.)

Parameter	Description
wKeyCode	Value of *wParam.* Specifies the ASCII-character key code of a System-menu key.
dwKeyData	Value of *lParam.* Specifies the repeat count, scan code, extended key, context code, previous key state, and key-transition state, as shown in the following table:

Bit	Description
0-15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16-23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).
24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.
25-26	Not used.
27-28	Used internally by Windows.
29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.
30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.
31	Specifies the key-transition state. The value is 1 if the key is being released, or it is 0 if the key is being pressed.

Returns

An application should return zero if it processes this message.

Comments

When the context code is zero, the message can be passed to the **TranslateAccelerator** function, which will handle it as though it were a normal key message instead of a System-menu key message. This allows accelerator keys to be used with the active window even if the active window does not have the input focus.

For IBM Enhanced 101- and 102-key keyboards, enhanced keys are the right ALT key and the right CTRL key on the main section of the keyboard; the INS, DEL, HOME, END, PAGE UP, PAGE DOWN, and arrow keys in the clusters to the left of the numeric keypad; and the division (*/*) and ENTER keys on the numeric keypad. Some other keyboards may support the extended-key bit in the *lParam* parameter.

See Also

TranslateAccelerator, **WM_SYSKEYDOWN**, **WM_SYSKEYUP**

WM_SYSCOLORCHANGE (2.x)

`WM_SYSCOLORCHANGE`

The WM_SYSCOLORCHANGE message is sent to all top-level windows when a change is made in the system color setting.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

Windows sends a **WM_PAINT** message to any window that is affected by a system color change.

Applications that have brushes that use the existing system colors should delete those brushes and re-create them by using the new system colors.

See Also

SetSysColors, **WM_PAINT**

WM_SYSCOMMAND (2.x)

```
WM_SYSCOMMAND
wCmdType = wParam;        /* command value                 */
xPos = LOWORD(lParam);    /* horizontal position of cursor */
yPos = HIWORD(lParam);    /* vertical position of cursor   */
```

The WM_SYSCOMMAND message is sent when the user selects a command from the System menu (sometimes referred to as the Control menu) or when the user selects the Maximize button or the Minimize button.

Parameter	Description
wCmdType	Value of *wParam.* Specifies the type of system command requested. This parameter can be one of the following values:

Value	Meaning
SC_CLOSE	Close the window.
SC_HOTKEY	Activate the window associated with the application-specified hot key. The low-order word of *lParam* identifies the window to activate.
SC_HSCROLL	Scroll horizontally.
SC_KEYMENU	Retrieve a menu through a keystroke.
SC_MAXIMIZE (or SC_ZOOM)	Maximize the window.
SC_MINIMIZE (or SC_ICON)	Minimize the window.
SC_MOUSEMENU	Retrieve a menu through a mouse click.
SC_MOVE	Move the window.
SC_NEXTWINDOW	Move to the next window.
SC_PREVWINDOW	Move to the previous window.
SC_RESTORE	Restore window to normal position and size.
SC_SCREENSAVE	Execute the screen-saver application specified in the [boot] section of the SYSTEM.INI file.
SC_SIZE	Size the window.
SC_TASKLIST	Execute or activate the Windows Task Manager application.
SC_VSCROLL	Scroll vertically.

xPos	Value of the low-order word of *lParam.* Specifies the x-coordinate of the cursor, if a System-menu command is chosen with the mouse. Otherwise, this parameter is not used.
yPos	Value of the high-order word of *lParam.* Specifies the y-coordinate of the cursor, if a System-menu command is chosen with the mouse. Otherwise, this parameter is not used.

Returns

An application should return zero if it processes this message.

Comments

The **DefWindowProc** function carries out the System-menu request for the predefined actions specified in the preceding table.

In WM_SYSCOMMAND messages, the four low-order bits of the *wCmdType* parameter are used internally by Windows. When an application tests the value of *wCmdType,* it must combine the value 0xFFF0 with the *wCmdType* value by using the bitwise AND operator to obtain the correct result.

The menu items in a System menu can be modified by using the **GetSystemMenu**, **AppendMenu**,

InsertMenu, and **ModifyMenu** functions. Applications that modify the System menu must process WM_SYSCOMMAND messages. Any WM_SYSCOMMAND messages not handled by the application must be passed to the **DefWindowProc** function. Any command values added by an application must be processed by the application and cannot be passed to **DefWindowProc**.

An application can carry out any system command at any time by passing a WM_SYSCOMMAND message to the **DefWindowProc** function.

Accelerator keystrokes that are defined to select items from the System menu are translated into WM_SYSCOMMAND messages; all other accelerator key strokes are translated into **WM_COMMAND** messages.

See Also

AppendMenu, **DefWindowProc**, **GetSystemMenu**, **InsertMenu**, **ModifyMenu**, **WM_COMMAND**

Windows 3.1 changes

The following system-commmand values have been added:

Value	Meaning
SC_HOTKEY	Activate the window associated with the application-specified hot key. The low-order word of *lParam* identifies the window to activate.
SC_SCREENSAVE	Executes the screen-save application specified in the Desktop section of Control Panel.

WM_SYSDEADCHAR (2.x)

```
WM_SYSDEADCHAR
wDeadKey = wParam;              /* dead-key character */
cRepeat = (int) LOWORD(lParam); /* repeat count       */
cAutoRepeat = HIWORD(lParam);   /* auto-repeat count  */
```

The WM_SYSDEADCHAR message is sent to the window with the input focus when **WM_SYSKEYUP** and **WM_SYSKEYDOWN** messages are translated. It specifies the character value of a dead key.

Parameter	Description
wDeadKey	Value of *wParam.* Specifies the dead-key character value.
cRepeat	Value of the low-order word of *lParam.* Specifies the repeat count.
cAutoRepeat	Value of the high-order word of *lParam.* Specifies the auto-repeat count.

Returns
An application should return zero if it processes this message.

See Also
WM_SYSKEYDOWN, **WM_SYSKEYUP**

WM_SYSKEYDOWN (2.x)

```
WM_SYSKEYDOWN
wVkey = wParam;          /* virtual-key code */
dwKeyData = lParam;      /* key data         */
```

The WM_SYSKEYDOWN message is sent to the window with the input focus when the user holds down the ALT key and then presses another key. If no window currently has the input focus, the WM_SYSKEYDOWN message is sent to the active window. The window that receives the message can distinguish between these two contexts by checking the context code in the *dwKeyData* parameter.

Parameter	Description
wVkey	Value of *wParam.* Specifies the virtual-key code of the key being pressed.
dwKeyData	Value of *lParam.* Specifies the repeat count, scan code, extended key, context code, previous key state, and key-transition state, as shown in the following table:

Bit	Description
0-15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16-23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).
24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.
25-26	Not used.
27-28	Used internally by Windows.
29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.
30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.
31	Specifies the key-transition state. The value is 1 if the key is being released, or it is 0 if the key is being pressed.

For WM_SYSKEYDOWN messages, the value of bit 29 (context code) is 1 if the ALT key is down while the key is pressed; it is 0 if the message is sent to the active window because no window has the input focus. The value of bit 31 (key-transition state) is 0.

Returns

An application should return zero if it processes this message.

Comments

When the context code is zero, the message can be passed to the **TranslateAccelerator** function, which will handle it as though it were a normal key message instead of a system-key message. This allows accelerator keys to be used with the active window even if the active window does not have the input focus.

Because of the autorepeat feature, more than one WM_SYSKEYDOWN message may occur before a **WM_SYSKEYUP** message is sent. The previous key state (bit 30) can be used to determine whether the WM_SYSKEYDOWN message indicates the first down transition or a repeated down transition.

For IBM Enhanced 101- and 102-key keyboards, enhanced keys are the right ALT key and the right CTRL key on the main section of the keyboard; the INS, DEL, HOME, END, PAGE UP, PAGE DOWN, and arrow keys in the clusters to the left of the numeric keypad; and the division (/) and ENTER keys on the numeric keypad. Some other keyboards may support the extended-key bit in the *lParam* parameter.

WM_SYSKEYUP (2.x)

```
WM_SYSKEYUP
wVkey = wParam;          /* virtual-key code */
dwKeyData = lParam;      /* key data         */
```

The WM_SYSKEYUP message is sent to the window with the input focus when the user releases a key that was pressed while the ALT key was held down. If no window currently has the input focus, the WM_SYSKEYUP message is sent to the active window. The window that receives the message can distinguish between these two contexts by checking the context code in the *lParam* parameter.

Parameter	Description
wVkey	Value of *wParam.* Specifies the virtual-key code of the key being pressed.
dwKeyData	Value of *lParam.* Specifies the repeat count, scan code, extended key, context code, previous key state, and key-transition state, as shown in the following table:

Bit	Description
0-15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16-23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).
24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.
25-26	Not used.
27-28	Used internally by Windows.
29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.
30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.
31	Specifies the key-transition state. The value is 1 if the key is being released, or it is 0 if the key is being pressed.

For WM_SYSKEYUP messages, the value of bit 29 (context code) is 1 if the ALT key is down while the key is pressed; it is 0 if the message is sent to the active window because no window has the input focus. The value of bit 31 (key-transition state) is 1.

Returns

An application should return zero if it processes this message.

Comments

When the context code is zero, the message can be passed to the **TranslateAccelerator** function, which will handle it as though it were a normal key message instead of a system-key message. This allows accelerator keys to be used with the active window even if the active window does not have the input focus.

For IBM Enhanced 101- and 102-key keyboards, enhanced keys are the right ALT key and the right CTRL key on the main section of the keyboard; the INS, DEL, HOME, END, PAGE UP, PAGE DOWN, and arrow keys in the clusters to the left of the numeric keypad; and the division (/) and ENTER keys on the numeric keypad. Some other keyboards may support the extended-key bit in the *lParam* parameter.

For non-U.S. Enhanced 102-key keyboards, the right ALT key is handled as the CTRL+ALT key combination. The following list shows the messages that result when the user presses and releases this key, in the sequence they occur:

1 WM_KEYDOWN VK_CONTROL

2 WM_KEYDOWN VK_MENU
3 WM_KEYUP VK_CONTROL
4 WM_SYSKEYUP VK_MENU

TranslateAccelerator, **WM_SYSKEYDOWN**

WM_SYSTEMERROR (3.1)

```
WM_SYSTEMERROR
wErrSpec = wParam;  /* specifies when error occurred */
```

The WM_SYSTEMERROR message is sent when the Windows kernel encounters an error but cannot display the system-error message box.

Parameter	Description
wErrSpec	Value of *wParam.* Specifies when the error occurred. Currently, the only valid value is 1, indicating that the error occurred when a task or library was terminating.

Returns

An application should return zero if it processes this message.

Comments

A shell application should process this message, displaying a message box that indicates an error has occurred.

WM_TIMECHANGE (2.x)

```
WM_TIMECHANGE
wParam = 0;     /* not use, must be zero */
lParam = 0L;    /* not use, must be zero */
```

An application sends the WM_TIMECHANGE message to all top-level windows after changing the system time.

Parameters

This message has no parameters.

Returns

An application should return zero if it processes this message.

Comments

Any application that changes the system time should send this message to all top-level windows. To send the WM_TIMECHANGE message to all top-level windows, an application can use the **SendMessage** function with the *hwnd* parameter set to HWND_BROADCAST.

See Also

SendMessage

WM_TIMER (2.x)

```
WM_TIMER
wTimerID = wParam;                    /* timer identifier              */
tmprc = (TIMERPROC FAR*) lParam;      /* address of timer callback     */
```

The WM_TIMER message is posted to the installing application's message queue or sent to the appropriate **TimerProc** callback function after each interval specified in the **SetTimer** function used to install a timer.

Parameter	Description
wTimerID	Value of *wParam.* Specifies the identifier of the timer.
tmprc	Value of *lParam.* Points to a callback function that was passed to the **SetTimer** function when the timer was installed. If the *tmprc* parameter is not NULL, the system passes the WM_TIMER message to the specified callback function rather than posting the message to the application's message queue.

Returns

An application should return zero if it processes this message.

Comments

The **DispatchMessage** function sends this message when no other messages are in the application's message queue.

Example

This example uses the WM_TIMER message to create a blinking effect for a line of text:

```
DWORD dwXYVal;
WORD wXVal, wYVal;
char szMessage[16];

case WM_TIMER:
    hdc = GetDC(hwnd);
    dwXYVal = GetTextExtent(hdc, (LPCSTR) szMessage,
        lstrlen(szMessage));
    wXVal = LOWORD(dwXYVal);
    wYVal = HIWORD(dwXYVal);
    PatBlt(hdc, 10, 10, (int) wXVal, (int) wYVal, PATINVERT);
    ReleaseDC(hwnd, hdc);
    ValidateRect(hwnd, NULL);
    break;
```

See Also

SetTimer, **TimerProc**

WM_UNDO (2.x)

```
WM_UNDO
```

An application sends the WM_UNDO message to an edit control to undo the last operation. When this message is sent to an edit control, the previously deleted text is restored or the previously added text is deleted.

Parameters

This message has no parameters.

Returns

The return value is nonzero if the operation is successful, or it is zero if an error occurs.

See Also

WM_CLEAR, **WM_COPY**, **WM_CUT**, **WM_PASTE**

WM_USER (2.x)

```
WM_USER
```

WM_USER is a constant used by applications to help define private messages.

Comments
The WM_USER constant is used to distinguish between message values that are reserved for use by Windows and values that can be used by an application to send messages within a private window class. There are four ranges of message numbers:

Range	Meaning
0 through WM_USER - 1	Messages reserved for use by Windows.
WM_USER through 0x7FFF	Integer messages for use by private window classes.
0x8000 through 0xBFFF	Messages reserved for use by Windows.
0xC000 through 0xFFFF	String messages for use by applications.

Message numbers in the first range (0 through WM_USER - 1) are defined by Windows. Values in this range that are not explicitly defined are reserved for future use by Windows. This topic describes messages in this range.

Message numbers in the second range (WM_USER through 0x7FFF) can be defined and used by an application to send messages within a private window class. These values cannot be used to define messages that are meaningful throughout an application, because some predefined window classes already define values in this range. For example, such predefined control classes as BUTTON, EDIT, **LISTBOX**, and **COMBOBOX** may use these values. Messages in this range should not be sent to other applications unless the applications have been designed to exchange messages and to attach the same meaning to the message numbers.

Message numbers in the third range (0x8000 through 0xBFFF) are reserved for future use by Windows.

Message numbers in the fourth range (0xC000 through 0xFFFF) are defined at run time when an application calls the **RegisterWindowMessage** function to obtain a message number for a string. All applications that register the same string can use the associated message number for exchanging messages. The actual message number, however, is not a constant and cannot be assumed to be the same in different Windows sessions.

RegisterWindowMessage

WM_VKEYTOITEM (3.0)

```
WM_VKEYTOITEM
wVkey = wParam;                     /* virtual-key code       */
hwndLB = (HWND) LOWORD(lParam);     /* handle of the list box */
nCaretPos = HIWORD(lParam);         /* caret position         */
```

The WM_VKEYTOITEM message is sent by a list box with the **LBS_WANTKEYBOARDINPUT** style to its owner in response to a **WM_KEYDOWN** message.

Parameter	Description
wVkey	Value of *wParam.* Specifies the virtual-key code of the key that the user pressed.
hwndLB	Value of the low-order word of *lParam.* Identifies the list box.
nCaretPos	Value of the high-order word of *lParam.* Specifies the current position of the caret.

Returns

The return value specifies the action that the application performed in response to the message. A return value of -2 indicates that the application handled all aspects of selecting the item and requires no further action by the list box. A return value of -1 indicates that the list box should perform the default action in response to the keystroke. A return value of 0 or greater specifies the zero-based index of an item in the list box and indicates that the list box should perform the default action for the keystroke on the given item.

Comments

Only list boxes that have the **LBS_HASSTRINGS** style can receive this message.

WM_CHARTOITEM, **WM_KEYDOWN**

WM_VSCROLL (2.x)

```
WM_VSCROLL
wScrollCode = wParam;      /* scroll bar code             */
nPos = LOWORD(lParam);     /* current scroll box position */
hwndCtl = (HWND) HIWORD(lParam); /* handle of the control */
```

The WM_VSCROLL message is sent to a window when the user clicks the window's vertical scroll bar.

Parameter	Description
wScrollCode	Value of *wParam.* Specifies a scroll bar code that indicates the user's scrolling request. This parameter can be one of the following values:

Value	Description
SB_BOTTOM	Scroll to bottom.
SB_ENDSCROLL	End scroll.
SB_LINEDOWN	Scroll one line down.
SB_LINEUP	Scroll one line up.
SB_PAGEDOWN	Scroll one page down.
SB_PAGEUP	Scroll one page up.
SB_THUMBPOSITION	Scroll to absolute position. The current position is specified by the *nPos* parameter.
SB_THUMBTRACK	Drag scroll box (thumb) to specified position. The current position is specified by the *nPos* parameter.
SB_TOP	Scroll to top.

nPos	Value of the low-order word of *lParam.* Specifies the current position of the scroll box if *wScrollCode* is SB_THUMBPOSITION or SB_THUMBTRACK; otherwise, this parameter is not used.
hwndCtl	Value of the high-order word of *lParam.* Identifies the control if WM_VSCROLL is sent by a scroll bar. If WM_VSCROLL is sent as a result of the user clicking a pop-up window's scroll bar, the high-order word is not used.

Returns

An application should return zero if it processes this message.

Comments

The SB_THUMBTRACK message typically is used by applications that give some feedback while the scroll box is being dragged.

If an application scrolls the contents of the window, it must also reset the position of the scroll box by using the **SetScrollPos** function.

See Also

SetScrollPos, **WM_HSCROLL**

WM_VSCROLLCLIPBOARD (2.x)

```
WM_VSCROLLCLIPBOARD
hwndViewer = (HWND) wParam;      /* handle of clipboard viewer */
wScrollCode = LOWORD(lParam);    /* scroll bar code            */
wThumbPos = HIWORD(lParam);      /* scroll box position        */
```

The **WM_HSCROLLCLIPBOARD** message is sent by the clipboard viewer to the clipboard owner when the clipboard data has the CF_OWNERDISPLAY format and there is an event in the clipboard viewer's vertical scroll bar. The owner should scroll the clipboard image, invalidate the appropriate section, and update the scroll bar values.

Parameter	Description
hwndViewer	Value of *wParam.* Specifies a handle to a clipboard-viewer window.
wScrollCode	Value of the low-order word of *lParam.* Specifies one of the following scroll bar values:

Value	Description
SB_BOTTOM	Scroll to lower right.
SB_ENDSCROLL	End scroll.
SB_LINEDOWN	Scroll one line down.
SB_LINEUP	Scroll one line up.
SB_PAGEDOWN	Scroll one page down.
SB_PAGEUP	Scroll one page up.
SB_THUMBPOSITION	Scroll to absolute position.
SB_TOP	Scroll to upper left.

wThumbPos	Value of the high-order word of *lParam.* Specifies the scroll box position if the scroll bar code is SB_THUMBPOSITION; otherwise, the high-order word is not used.

Returns

An application should return zero if it processes this message.

Comments

The clipboard owner should use the **InvalidateRect** function or repaint the window as needed. The scroll bar position should also be reset.

See Also

InvalidateRect, **WM_HSCROLLCLIPBOARD**

WM_WINDOWPOSCHANGED (3.1)

```
WM_WINDOWPOSCHANGED
pwp = (const WINDOWPOS FAR*) lParam;    /* structure address          */
```

The WM_WINDOWPOSCHANGED message is sent to a window whose size, position, or z-order has changed as a result of a call to **SetWindowPos** or another window-management function.

Parameter	Description
pwp	Value of *lParam.* Points to a **WINDOWPOS** data structure that contains information about the window's new size and position.

Returns

An application should return zero if it processes this message.

Comments

The **DefWindowProc** function, when it processes the WM_WINDOWPOSCHANGED message, sends the **WM_SIZE** and **WM_MOVE** messages to the window. These messages are not sent if an application handles the WM_WINDOWPOSCHANGED message without calling **DefWindowProc**. It is more efficient to perform any move or size change processing during the WM_WINDOWPOSCHANGED message without calling **DefWindowProc**.

See Also

WM_MOVE, **WM_SIZE**, **WM_WINDOWPOSCHANGING**, **EndDeferWindowPos**, **SetWindowPos**

WM_WINDOWPOSCHANGING (3.1)

```
WM_WINDOWPOSCHANGING
pwp = (WINDOWPOS FAR*) lParam;  /* address of WINDOWPOS structure */
```

The WM_WINDOWPOSCHANGING message is sent to a window whose size, position, or z-order is about to change as a result of a call to **SetWindowPos** or another window-management function.

Parameter	Description
pwp	Value of *lParam.* Points to a **WINDOWPOS** data structure that contains information about the window's new size and position.

Returns

An application should return zero if it processes this message.

Comments

During this message, modifying any of the values in the **WINDOWPOS** structure affects the new size, position, or z-order. An application can prevent changes to the window by setting or clearing the appropriate bits in the **flags** member of the **WINDOWPOS** structure.

For a window with the **WS_OVERLAPPED** or **WS_THICKFRAME** style, the **DefWindowProc** function handles a WM_WINDOWPOSCHANGING message by sending a **WM_GETMINMAXINFO** message to the window. This is done to validate the new size and position of the window and to enforce the **CS_BYTEALIGNCLIENT** and CS_BYTEALIGN client styles. An application can override this functionality by not passing the WM_WINDOWPOSCHANGING message to the **DefWindowProc** function.

See Also

WM_WINDOWPOSCHANGED, **EndDeferWindowPos**, **SetWindowPos**

WM_WININICHANGE (2.x)

```
WM_WININICHANGE
wParam = 0;                              /* not used, must be zero */
lParam = (LPARAM) (LPCSTR) pszSection; /* address of string     */
```

An application sends the WM_WININICHANGE message to all top-level windows after making a change to the Windows initialization file, WIN.INI. The **SystemParametersInfo** function sends the WM_WININICHANGE message after an application uses the function to change a setting in the WIN.INI file.

Parameter	Description
pszSection	Value of *lParam.* Points to a string that specifies the name of the section that has changed (the string does not include the square brackets that enclose the section name).

Returns

An application should return zero if it processes this message.

Comments

To send the WM_WININICHANGE message to all top-level windows, an application can use the **SendMessage** function with the *hwnd* parameter set to HWND_BROADCAST.

If an application changes many different sections in WIN.INI at the same time, the application should send the WM_WININICHANGE message once with the *pszSection* parameter set to NULL. Otherwise, an application should send a separate WM_WININICHANGE message for each change it makes to WIN.INI.

If an application receives a WM_WININICHANGE message with the *pszSection* parameter set to NULL, the application should check all sections in WIN.INI that affect the application.

Messages (3.1)

BM_GETCHECK	Retrieves the check state of a button
BM_GETSTATE	Retrieves the state of a button
BM_SETCHECK	Sets the check state of a button
BM_SETSTATE	Sets the highlight state of a button
BM_SETSTYLE	Changes the style of a button
CB_ADDSTRING	Adds a string to the list box of a combo box
CB_DELETESTRING	Deletes a string in the list box of a combo box
CB_DIR	Adds filenames to the list box of a combo box
CB_FINDSTRING	Finds exact string in the list box of a combo box
CB_FINDSTRINGEXACT	Finds prefix string in the list box of a combo box
CB_GETCOUNT	Gets the number of list-box items in a combo box
CB_GETCURSEL	Gets index of selected list-box item in combo box
CB_GETDROPPEDCONTROLRECT	Gets rectangle of drop-down list box in combo box
CB_GETDROPPEDSTATE	Determines if list box of combo box is visible
CB_GETEDITSEL	Gets position of a selection in an edit control
CB_GETEXTENDEDUI	Determines if combo box has extended interface
CB_GETITEMDATA	Retrieves value associated with combo-box item
CB_GETITEMHEIGHT	Retrieves the height of list items in a combo box
CB_GETLBTEXT	Gets string from the list box of a combo box
CB_GETLBTEXTLEN	Gets length of string in list-box of combo box
CB_INSERTSTRING	Inserts a string into the list box of a combo box
CB_LIMITTEXT	Limits amount of edit-control text in a combo box
CB_RESETCONTENT	Removes all items from the list box of a combo box
CB_SELECTSTRING	Selects matching string in list box of combo box
CB_SETCURSEL	Selects indexed string in list box of combo box
CB_SETEDITSEL	Selects characters in edit control of combo box
CB_SETEXTENDEDUI	Sets the default or extended user interface
CB_SETITEMDATA	Associates a value with combo-box item
CB_SETITEMHEIGHT	Sets the height of list items in a combo box
CB_SHOWDROPDOWN	Shows or hides the list box of a combo box
DM_GETDEFID	Gets the identifier of the default push button
DM_SETDEFID	Sets the default push button of a dialog box
EM_CANUNDO	Determines if edit-control operation can be undone
EM_EMPTYUNDOBUFFER	Resets (clears) undo flag of edit control
EM_FMTLINES	Sets soft line break characters on or off
EM_GETFIRSTVISIBLELINE	Determines topmost line in an edit control
EM_GETHANDLE	Gets handle of memory for multiline edit control
EM_GETLINE	Retrieves line from multiline edit control
EM_GETLINECOUNT	Retrieves number of lines in an MLE
EM_GETMODIFY	Checks whether edit-control contents have changed
EM_GETPASSWORDCHAR	Retrieves edit-control password character
EM_GETRECT	Retrieves coordinates of edit-control rectangle
EM_GETSEL	Gets position of current edit-control selection
EM_GETWORDBREAKPROC	Retrieves the edit-control wordwrap function
EM_LIMITTEXT	Limits the amount of text in an edit control
EM_LINEFROMCHAR	Retrieves a line number from a character index
EM_LINEINDEX	Retrieves character index of edit-control line
EM_LINELENGTH	Retrieves length of line in edit control
EM_LINESCROLL	Scrolls text of a multiline edit control
EM_REPLACESEL	Replaces the current selection in an edit control
EM_SETHANDLE	Sets memory handle for multiline edit control
EM_SETMODIFY	Sets or clears edit-control modification flag
EM_SETPASSWORDCHAR	Sets or removes edit-control password character
EM_SETREADONLY	Sets the read-only state of an edit control
EM_SETRECT	Sets the formatting rectangle of an edit control

EM_SETRECTNP	Sets the formatting rectangle of an edit control
EM_SETSEL	Selects text in a multiline edit control
EM_SETTABSTOPS	Sets tab stops in multiline edit control
EM_SETWORDBREAKPROC	Provides custom word breaks in an edit control
EM_UNDO	Undoes the last edit-control operation
LB_ADDSTRING	Adds a string to a list box
LB_DELETESTRING	Deletes a string in a list box
LB_DIR	Adds a list of filenames to a list box
LB_FINDSTRING	Finds a prefix string in a list box
LB_FINDSTRINGEXACT	Finds an exact string in a list box
LB_GETCARETINDEX	Gets index of list-box item with focus rectangle
LB_GETCOUNT	Retrieves the number of items in a list box
LB_GETCURSEL	Retrieves index of selected item in a list box
LB_GETHORIZONTALEXTENT	Retrieves the horizontal extent of a list box
LB_GETITEMDATA	Retrieves the value associated with list-box item
LB_GETITEMHEIGHT	Determines the height of items in a list box
LB_GETITEMRECT	Retrieves the bounding rectangle for an item
LB_GETSEL	Retrieves the selection state of an item
LB_GETSELCOUNT	Retrieves the count of selected list-box items
LB_GETSELITEMS	Lists item numbers of selected list-box items
LB_GETTEXT	Retrieves a string from a list box
LB_GETTEXTLEN	Retrieves the length of a string in a list box
LB_GETTOPINDEX	Retrieves index of first visible list-box item
LB_INSERTSTRING	Inserts a string into a list box
LB_RESETCONTENT	Removes all items from a list box
LB_SELECTSTRING	Selects a matching string in a list box
LB_SELITEMRANGE	Selects consecutive items in a list box
LB_SETCARETINDEX	Sets the focus rectangle in a list box
LB_SETCOLUMNWIDTH	Sets the width of columns in a list box
LB_SETCURSEL	Selects an indexed string in a list box
LB_SETHORIZONTALEXTENT	Sets the horizontal extent of a list box
LB_SETITEMDATA	Associates a value with a list-box item
LB_SETITEMHEIGHT	Sets the height of items in a list box
LB_SETSEL	Selects a string in a multiple-selection list box
LB_SETTABSTOPS	Sets tab stops in a list box
LB_SETTOPINDEX	Ensures that a list-box item is visible
STM_GETICON	Gets icon handle associated with icon resource
STM_SETICON	Associates icon handle with icon resource
WM_ACTIVATE	Indicates a change in the activation state
WM_ACTIVATEAPP	Notifies applications when a new task is activated
WM_ASKCBFORMATNAME	Retrieves the name of the clipboard format
WM_CANCELMODE	Notifies a window to cancel internal modes
WM_CHANGECBCHAIN	Notifies clipboard viewer of removal from chain
WM_CHAR	Passes keyboard events to focus window
WM_CHARTOITEM	Provides list-box keystrokes to owner window
WM_CHILDACTIVATE	Notifies a child window of activation
WM_CHOOSEFONT_GETLOGFONT	Retrieves **LOGFONT** structure for Font dialog box
WM_CLEAR	Clears an edit control or combo box
WM_CLOSE	Signals a window or application to terminate
WM_COMMAND	Specifies a command message
WM_COMMNOTIFY	Notifies a window about the status of its queues
WM_COMPACTING	Indicates a low memory condition
WM_COMPAREITEM	Determines position of combo-box or list-box item
WM_COPY	Copies a selection to the clipboard
WM_CREATE	Indicates that a window is being created
WM_CTLCOLOR	Indicates that a control is about to be drawn

WM_CUT	Deletes a selection and copies it to the clipboard
WM_DDE_ACK	Acknowledges the receipt of a DDE transaction
WM_DDE_ADVISE	Starts an advise loop with a DDE server
WM_DDE_DATA	Passes a data item to a DDE client
WM_DDE_EXECUTE	Passes a command to a DDE server
WM_DDE_INITIATE	Initiates a DDE conversation
WM_DDE_POKE	Sends an unsolicited data item to a server
WM_DDE_REQUEST	Requests value of a data item from a DDE server
WM_DDE_TERMINATE	Terminates a DDE conversation
WM_DDE_UNADVISE	Ends a DDE advise loop
WM_DEADCHAR	Indicates when a dead key is pressed
WM_DELETEITEM	Indicates owner-drawn item or control is altered
WM_DESTROY	Indicates window is about to be destroyed
WM_DESTROYCLIPBOARD	Notifies owner when clipboard is emptied
WM_DEVMODECHANGE	Indicates when device-mode settings are changed
WM_DRAWCLIPBOARD	Indicates when clipboard contents are changed
WM_DRAWITEM	Indicates when owner-drawn control or menu changes
WM_DROPFILES	Indicates when a file is dropped
WM_ENABLE	Indicates when enable state of window is changing
WM_ENDSESSION	Indicates whether the Windows session is ending
WM_ENTERIDLE	Indicates a modal dialog box or menu is idle
WM_ERASEBKGND	Indicates when background of window needs erasing
WM_FONTCHANGE	Indicates a change in the font-resource pool
WM_GETDLGCODE	Allows processing of control input
WM_GETFONT	Retrieves the font that a control is using
WM_GETMINMAXINFO	Retrieves minimum and maximum sizing information
WM_GETTEXT	Copies the text that corresponds to a window
WM_GETTEXTLENGTH	Determines length of text associated with a window
WM_HSCROLL	Indicates a click in a horizontal scroll bar
WM_HSCROLLCLIPBOARD	Prompts owner to scroll clipboard contents
WM_ICONERASEBKGND	Notifies minimized window to fill icon background
WM_INITDIALOG	Initializes a dialog box
WM_INITMENU	Indicates when a menu is about to become active
WM_INITMENUPOPUP	Indicates when a pop-up menu is being created
WM_KEYDOWN	Indicates when a nonsystem key is pressed
WM_KEYUP	Indicates when a nonsystem key is released
WM_KILLFOCUS	Indicates window is about to lose input focus
WM_LBUTTONDBLCLK	Indicates double-click of left mouse button
WM_LBUTTONDOWN	Indicates when left mouse button is pressed
WM_LBUTTONUP	Indicates when left mouse button is released
WM_MBUTTONDBLCLK	Indicates double-click of middle mouse button
WM_MBUTTONDOWN	Indicates when middle mouse button is pressed
WM_MBUTTONUP	Indicates when middle mouse button is released
WM_MDIACTIVATE	Activates a new MDI child window
WM_MDICASCADE	Arranges MDI child windows in a cascade format
WM_MDICREATE	Prompts an MDI client to create a child window
WM_MDIDESTROY	Closes an MDI child window
WM_MDIGETACTIVE	Retrieves data about the active MDI child window
WM_MDIICONARRANGE	Arranges minimized MDI child windows
WM_MDIMAXIMIZE	Maximizes an MDI child window
WM_MDINEXT	Activates the next MDI child window
WM_MDIRESTORE	Prompts an MDI client to restore a child window
WM_MDISETMENU	Replaces the menu of a MDI frame window
WM_MDITILE	Arranges MDI child windows in a tiled format
WM_MEASUREITEM	Requests dimensions of owner-drawn control
WM_MENUCHAR	Indicates when unknown menu mnemonic is pressed

WM_MENUSELECT	Indicates when a menu item is selected
WM_MOUSEACTIVATE	Indicates a mouse click in an inactive window
WM_MOUSEMOVE	Indicates mouse-cursor movement
WM_MOVE	Indicates the position of a window has changed
WM_NCACTIVATE	Changes the active state of a nonclient area
WM_NCCALCSIZE	Calculates the size of a window's client area
WM_NCCREATE	Indicates a nonclient area is being created
WM_NCDESTROY	Indicates when nonclient area is being destroyed
WM_NCHITTEST	Indicates mouse-cursor movement
WM_NCLBUTTONDBLCLK	Indicates non-client left button double-click
WM_NCLBUTTONDOWN	Indicates left button pressed in nonclient area
WM_NCLBUTTONUP	Indicates left button released in nonclient area
WM_NCMBUTTONDBLCLK	Indicates middle button nonclient double-click
WM_NCMBUTTONDOWN	Indicates middle button pressed in nonclient area
WM_NCMBUTTONUP	Indicates middle button released in nonclient area
WM_NCMOUSEMOVE	Indicates mouse-cursor movement in nonclient area
WM_NCPAINT	Indicates a window's frame needs painting
WM_NCRBUTTONDBLCLK	Indicates right button nonclient double-click
WM_NCRBUTTONDOWN	Indicates right button pressed in nonclient area
WM_NCRBUTTONUP	Indicates right button released in nonclient area
WM_NEXTDLGCTL	Sets the focus to a different dialog box control
WM_PAINT	Indicates a window frame needs painting
WM_PAINTCLIPBOARD	Paints the specified portion of the window
WM_PALETTECHANGED	Indicates focus-window has realized its palette
WM_PALETTEISCHANGING	Informs windows about change to palette
WM_PARENTNOTIFY	Notifies parent of child-window activity
WM_PASTE	Inserts clipboard data into an edit control
WM_POWER	Indicates the system is entering suspended mode
WM_QUERYDRAGICON	Requests a cursor handle for a minimized window
WM_QUERYENDSESSION	Requests that the Windows session be ended
WM_QUERYNEWPALETTE	Allows a window to realize its logical palette
WM_QUERYOPEN	Requests that a minimized window be restored
WM_QUEUESYNC	Delimits CBT messages
WM_QUIT	Requests that an application be terminated
WM_RBUTTONDBLCLK	Indicates a double-click of right mouse button
WM_RBUTTONDOWN	Indicates when the right mouse button is pressed
WM_RBUTTONUP	Indicates when the right mouse button is released
WM_RENDERALLFORMATS	Notifies owner to render all clipboard formats
WM_RENDERFORMAT	Notifies owner to render particular clipboard data
WM_SETCURSOR	Displays the appropriate mouse cursor shape
WM_SETFOCUS	Indicates when a window has gained input focus
WM_SETFONT	Sets the font for a control
WM_SETREDRAW	Allows or prevents redrawing in a window
WM_SETTEXT	Sets the text of a window
WM_SHOWWINDOW	Indicates a window is about to be hidden or shown
WM_SIZE	Indicates a change in window size
WM_SIZECLIPBOARD	Indicates a change in clipboard size
WM_SPOOLERSTATUS	Indicates when a print job is added or removed
WM_SYSCHAR	Indicates when a System-menu key is pressed
WM_SYSCOLORCHANGE	Indicates when a system color setting is changed
WM_SYSCOMMAND	Indicates when a System-command is requested
WM_SYSDEADCHAR	Indicates when a system dead key is pressed
WM_SYSKEYDOWN	Indicates that ALT plus another key was pressed
WM_SYSKEYUP	Indicates that ALT plus another key was released
WM_SYSTEMERROR	Indicates that a system error has occurred
WM_TIMECHANGE	Indicates that the system time has been set

WM_TIMER	Indicates timeout interval for a timer has elapsed
WM_UNDO	Undoes the last operation in an edit control
WM_USER	Indicates a range of message values
WM_VKEYTOITEM	Provides list-box keystrokes to owner window
WM_VSCROLL	Indicates a click in a vertical scroll bar
WM_VSCROLLCLIPBOARD	Prompts the owner to scroll clipboard contents
WM_WINDOWPOSCHANGED	Notifies a window of a size or position change
WM_WINDOWPOSCHANGING	Notifies a window of a new size or position
WM_WININICHANGE	Notifies applications of change to WIN.INI

BN_CLICKED (2.x)

BN_CLICKED

The BN_CLICKED notification message is sent to the parent window when the user clicks a button. Unlike the other button-notification messages, this message is intended for applications written for any version of Windows.

Parameter	Description
wParam	Specifies the control identifier.
lParam	Contains a handle that identifies the button control in its low-order word and the BN_CLICKED notification code in its high-order word.

See Also

DRAWITEMSTRUCT, **WM_DRAWITEM**

BN_DISABLE (2.x)

BN_DISABLE

The BN_DISABLE notification message is sent when a button is disabled. This notification is provided for compatibility with applications written prior to Windows version 3.0. New applications should use the **BS_OWNERDRAW** button style and the **DRAWITEMSTRUCT** structure for this task.

See Also
DRAWITEMSTRUCT, **WM_DRAWITEM**

BN_DOUBLECLICKED (2.x)

BN_DOUBLECLICKED

The BN_DOUBLECLICKED notification message is sent when the user double clicks a button. This notification is provided for compatibility with applications written prior to Windows version 3.0. New applications should use the **BS_OWNERDRAW** button style and the **DRAWITEMSTRUCT** structure for this task.

See Also
DRAWITEMSTRUCT, **WM_DRAWITEM**

BN_HILITE (2.x)

BN_HILITE

The BN_HILITE notification message is sent when the user highlights a button. This notification is provided for compatibility with applications written prior to Windows version 3.0. New applications should use the **BS_OWNERDRAW** button style and the **DRAWITEMSTRUCT** structure for this task.

See Also
DRAWITEMSTRUCT, **WM_DRAWITEM**

BN_PAINT (2.x)

BN_PAINT

The BN_PAINT notification message is sent when a button should be painted. This notification is provided for compatibility with applications written prior to Windows version 3.0. New applications should use the **BS_OWNERDRAW** button style and the **DRAWITEMSTRUCT** structure for this task.

See Also
DRAWITEMSTRUCT, **WM_DRAWITEM**

BN_UNHILITE (2.x)

BN_UNHILITE

The BN_UNHILITE notification message is sent when the highlight should be removed from a button. This notification is provided for compatibility with applications written prior to Windows version 3.0. New applications should use the **BS_OWNERDRAW** button style and the **DRAWITEMSTRUCT** structure for this task.

See Also
DRAWITEMSTRUCT, **WM_DRAWITEM**

CBN_CLOSEUP (3.1)

CBN_CLOSEUP

The CBN_CLOSEUP notification message is sent when the list box of a combo box is hidden. The control's parent window receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_CLOSEUP notification message in the high-order word.

Comments

This notification message is not sent to a combo box that has the **CBS_SIMPLE** style.

The order in which notifications will be sent cannot be predicted. In particular, a **CBN_SELCHANGE** notification may occur either before or after a CBN_CLOSEUP notification.

See Also

CBN_DROPDOWN, **CBN_SELCHANGE**, **WM_COMMAND**

CBN_DBLCLK (3.0)

CBN_DBLCLK

The CBN_DBLCLK notification message is sent when the user double-clicks a string in the list box of a combo box. The control's parent window receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word and the CBN_DBLCLK notification message in the high-order word.

Comments

This notification message can occur only for a combo box with the **CBS_SIMPLE** style. For a combo box with the **CBS_DROPDOWN** or **CBS_DROPDOWNLIST** style, a double-click cannot occur because a single click hides the list box.

See Also

CBN_SELCHANGE, **WM_COMMAND**

CBN_DROPDOWN (3.0)

CBN_DROPDOWN

The CBN_DROPDOWN notification message is sent when the list box of a combo box is about to be dropped down (made visible). The parent window of the combo box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_DROPDOWN notification message in the high-order word.

Comments

This notification message can occur only for a combo box with the **CBS_DROPDOWN** or **CBS_DROPDOWNLIST** style.

See Also

CBN_CLOSEUP, **WM_COMMAND**

CBN_EDITCHANGE (3.0)

CBN_EDITCHANGE

The CBN_EDITCHANGE notification message is sent after the user has taken an action that may have altered the text in the edit-control portion of a combo box. Unlike the **CBN_EDITUPDATE** notification message, this notification message is sent after Windows updates the screen. The parent window of the combo box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_EDITCHANGE notification message in the high-order word.

Comments

This message does not occur if the combo box has the **CBS_DROPDOWNLIST** style.

See Also

CBN_EDITUPDATE, **WM_COMMAND**

CBN_EDITUPDATE (3.0)

CBN_EDITUPDATE

The CBN_EDITUPDATE notification message is sent when the edit-control portion of a combo box is about to display altered text. This notification is sent after the control has formatted the text, but before it displays the text. The parent window of the combo box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_EDITUPDATE notification message in the high-order word.

Comments

This message does not occur if the combo box has the **CBS_DROPDOWNLIST** style.

See Also

CBN_EDITCHANGE, **WM_COMMAND**

CBN_ERRSPACE (3.0)

CBN_ERRSPACE

The CBN_ERRSPACE notification message is sent when a combo box cannot allocate enough memory to meet a specific request. The parent window of the combo box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_ERRSPACE notification message in the high-order word.

See Also
WM_COMMAND

CBN_KILLFOCUS (3.0)

CBN_KILLFOCUS

The CBN_KILLFOCUS notification message is sent when a combo box loses the input focus. The parent window of the combo box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_KILLFOCUS notification message in the high-order word.

See Also

CBN_SETFOCUS, **WM_COMMAND**

CBN_SELCHANGE (3.0)

CBN_SELCHANGE

The CBN_SELCHANGE notification message is sent when the selection in the list box of a combo box is about to be changed as a result of the user either clicking in the list box or changing the selection by using the arrow keys. The parent window of the combo box receives this code through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_SELCHANGE notification message in the high-order word.

See Also

CBN_DBLCLK, **CB_SETCURSEL**, **WM_COMMAND**

CBN_SELENDCANCEL (3.1)

CBN_SELENDCANCEL

The CBN_SELENDCANCEL notification message is sent when the user clicks an item and then clicks another window or control to hide the list box of a combo box. This notification message is sent before the **CBN_CLOSEUP** notification message to indicate that the user's selection should be ignored.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_SELENDCANCEL notification message in the high-order word.

Comments

The CBN_SELENDCANCEL or **CBN_SELENDOK** notification message is sent even if the **CBN_CLOSEUP** notification message is not sent (as in the case of a combo box with the **CBS_SIMPLE** style).

See Also

CBN_SELENDOK, **WM_COMMAND**

CBN_SELENDOK (3.1)

CBN_SELENDOK

The CBN_SELENDOK notification message is sent when the user selects an item and then either presses the ENTER key or clicks the DOWN ARROW key to hide the list box of a combo box. This notification message is sent before the **CBN_CLOSEUP** notification message to indicate that the user's selection should be considered valid.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_SELENDOK notification message in the high-order word.

Comments

The CBN_SELENDOK or **CBN_SELENDCANCEL** notification message is sent even if the **CBN_CLOSEUP** notification message is not sent (as in the case of a combo box with the **CBS_SIMPLE** style).

See Also

CBN_SELENDCANCEL, **WM_COMMAND**

CBN_SETFOCUS (3.0)

CBN_SETFOCUS

The CBN_SETFOCUS notification message is sent when a combo box receives the input focus. The parent window of the combo box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the combo box.
lParam	Specifies the handle of the combo box in the low-order word, and specifies the CBN_SETFOCUS notification message in the high-order word.

See Also

CBN_KILLFOCUS, **WM_COMMAND**

EN_CHANGE (2.x)

EN_CHANGE

The EN_CHANGE notification message is sent when the user has taken an action that may have altered text in an edit control. Unlike the **EN_UPDATE** notification message, this notification message is sent after Windows updates the display. The control's parent window receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the edit control.
lParam	Specifies the handle of the edit control in the low-order word, and specifies the EN_CHANGE notification message in the high-order word.

See Also

EN_UPDATE, **WM_COMMAND**

EN_ERRSPACE (2.x)

EN_ERRSPACE

The EN_ERRSPACE notification message is sent when an edit control cannot allocate enough memory to meet a specific request. The control's parent window receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the edit control.
lParam	Specifies the handle of the edit control in the low-order word, and specifies the EN_ERRSPACE notification message in the high-order word.

See Also
WM_COMMAND

EN_HSCROLL (2.x)

EN_HSCROLL

The EN_HSCROLL notification message is sent when the user clicks an edit control's horizontal scroll bar. The control's parent window receives this notification message through a **WM_COMMAND** message. The parent window is notified before the screen is updated.

Parameter	Description
wParam	Specifies the identifier of the edit control.
lParam	Specifies the handle of the edit control in the low-order word, and specifies the EN_HSCROLL notification message in the high-order word.

See Also

EN_VSCROLL, **WM_COMMAND**

EN_KILLFOCUS (2.x)

EN_KILLFOCUS

The EN_KILLFOCUS notification message is sent when an edit control loses the input focus. The control's parent window receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the edit control.
lParam	Specifies the handle of the edit control in the low-order word, and specifies the EN_KILLFOCUS notification message in the high-order word.

See Also
EN_SETFOCUS, **WM_COMMAND**

EN_MAXTEXT (3.0)

EN_MAXTEXT

The EN_MAXTEXT notification message is sent when the current insertion has exceeded the specified number of characters for the edit control. The insertion has been truncated.

This message is also sent when an edit control does not have the **ES_AUTOHSCROLL** style and the number of characters to be inserted would exceed the width of the edit control.

This message is also sent when an edit control does not have the **ES_AUTOVSCROLL** style and the total number of lines resulting from a text insertion would exceed the height of the edit control.

The control's parent window receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the edit control.
lParam	Specifies the handle of the edit control in the low-order word, and specifies the EN_MAXTEXT notification message in the high-order word.

See Also
EM_LIMITTEXT, **WM_COMMAND**

EN_SETFOCUS (2.x)

EN_SETFOCUS

The EN_SETFOCUS notification message is sent when an edit control receives the input focus. The control's parent window receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the edit control.
lParam	Specifies the handle of the edit control in the low-order word, and specifies the EN_SETFOCUS notification message in the high-order word.

See Also
EN_KILLFOCUS, **WM_COMMAND**

EN_UPDATE (2.x)

EN_UPDATE

The EN_UPDATE notification message is sent when an edit control is about to display altered text. This notification is sent after the control has formatted the text but before it screens the text. This makes it possible to alter the window size, if necessary. The control's parent window receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the edit control.
lParam	Specifies the handle of the edit control in the low-order word, and specifies the EN_UPDATE notification message in the high-order word.

See Also

EN_CHANGE, **WM_COMMAND**

EN_VSCROLL (2.x)

EN_VSCROLL

The EN_VSCROLL notification message is sent when the user clicks an edit control's vertical scroll bar. The control's parent window receives this notification message through a **WM_COMMAND** message. The parent window is notified before the screen is updated.

Parameter	Description
wParam	Specifies the identifier of the edit control.
lParam	Specifies the handle of the edit control in the low-order word, and specifies the EN_VSCROLL notification message in the high-order word.

See Also

EN_HSCROLL, **WM_COMMAND**

LBN_DBLCLK (2.x)

LBN_DBLCLK

The LBN_DBLCLK notification message is sent when the user double-clicks a string in a list box. The parent window of the list box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the list box.
lParam	Specifies the handle of the list box in the low-order word, and specifies the LBN_DBLCLK notification message in the high-order word.

Comments

Only a list box that has **LBS_NOTIFY** style will send this notification message.

See Also

LBN_SELCHANGE, **WM_COMMAND**

LBN_ERRSPACE (2.x)

LBN_ERRSPACE

The LBN_ERRSPACE notification message is sent when a list box cannot allocate enough memory to meet a specific request. The parent window of the list box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the list box.
lParam	Specifies the handle of the list box in the low-order word, and specifies the LBN_ERRSPACE notification message in the high-order word.

See Also
WM_COMMAND

LBN_KILLFOCUS (3.0)

LBN_KILLFOCUS

The LBN_KILLFOCUS notification message is sent when a list box loses the input focus. The parent window of the list box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the list box.
lParam	Specifies the handle of the list box in the low-order word, and specifies the LBN_KILLFOCUS notification message in the high-order word.

See Also

LBN_SETFOCUS, **WM_COMMAND**

LBN_SELCANCEL (3.1)

LBN_SELCANCEL

The LBN_SELCANCEL notification message is sent when the user cancels the selection in a list box. The parent window of the list box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the list box.
lParam	Specifies the handle of the list box in the low-order word, and specifies the LBN_SELCANCEL notification message in the high-order word.

Comments

This notification applies only to a list box that has the **LBS_NOTIFY** style.

See Also

LBN_DBLCLK, **LBN_SELCHANGE**, **LB_SETCURSEL**, **WM_COMMAND**

LBN_SELCHANGE (2.x)

LBN_SELCHANGE

The LBN_SELCHANGE notification message is sent when the selection in a list box is about to change. The parent window of the list box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the list box.
lParam	Specifies the handle of the list box in the low-order word, and specifies the LBN_SELCHANGE notification message in the high-order word.

Comments

This notification is not sent if the selection is changed by the **LB_SETCURSEL** message.

This notification applies only to a list box that has the **LBS_NOTIFY** style.

The LBN_SELCHANGE notification is sent for a multiple-selection list box whenever the user presses an arrow key, even if the selection does not change.

See Also

LBN_DBLCLK, **LBN_SELCANCEL**, **LB_SETCURSEL**, **WM_COMMAND**

LBN_SETFOCUS (3.0)

LBN_SETFOCUS

The LBN_SETFOCUS notification message is sent when a list box receives the input focus. The parent window of the list box receives this notification message through a **WM_COMMAND** message.

Parameter	Description
wParam	Specifies the identifier of the list box.
lParam	Specifies the handle of the list box in the low-order word, and specifies the LBN_SETFOCUS notification message in the high-order word.

See Also

LBN_KILLFOCUS, **WM_COMMAND**

Notification messages (3.1)

BN_CLICKED	Indicates the user clicked a button
BN_DISABLE	Indicates a button is disabled
BN_DOUBLECLICKED	Indicates the user double-clicked a button
BN_HILITE	Indicates the user highlighted a button
BN_PAINT	Indicates the button should be painted
BN_UNHILITE	Indicates the highlight should be removed
CBN_CLOSEUP	Indicates the list box of a combo box has closed
CBN_DBLCLK	Indicates the user double-clicked a string
CBN_DROPDOWN	Indicates the list box of a combo box is dropping down
CBN_EDITCHANGE	Indicates the user has changed text in the edit control
CBN_EDITUPDATE	Indicates altered text is about to be displayed
CBN_ERRSPACE	Indicates the combo box is out of memory
CBN_KILLFOCUS	Indicates the combo box is losing the input focus
CBN_SELCHANGE	Indicates a new combo box list item is selected
CBN_SELENDCANCEL	Indicates the user's selection should be cancelled
CBN_SELENDOK	Indicates the user's selection is valid
CBN_SETFOCUS	Indicates the combo box is receiving the input focus
EN_CHANGE	Indicates the display is updated after text changes
EN_ERRSPACE	Indicates the edit control is out of memory
EN_HSCROLL	Indicates the user clicked the scroll bar
EN_KILLFOCUS	Indicates the edit control is losing the input focus
EN_MAXTEXT	Indicates the insertion is truncated
EN_SETFOCUS	Indicates the edit-control is receiving the input focus
EN_UPDATE	Indicates edit-control is about to display altered text
EN_VSCROLL	Indicates the user clicked the vertical scroll bar
LBN_DBLCLK	Indicates that the user double-clicked a string
LBN_ERRSPACE	Indicates the list box is out of memory
LBN_KILLFOCUS	Indicates the list box is losing the input focus
LBN_SELCANCEL	Indicates the selection is cancelled
LBN_SELCHANGE	Indicates the selection is about to change
LBN_SETFOCUS	Indicates the list box is receiving the input focus

OleActivate (3.1)

#include ole.h

OLESTATUS OleActivate(*lpObject, verb, fShow, fTakeFocus, hwnd, lprcBound***)**

```
LPOLEOBJECT lpObject;          /* address of object to activate          */
UINT verb;                     /* operation to perform                   */
BOOL fShow;                    /* whether to show window                 */
BOOL fTakeFocus;               /* whether server gets focus              */
HWND hwnd;                     /* window handle of destination document */
const RECT FAR* lprcBound;     /* bounding rectangle for object display  */
```

The **OleActivate** function opens an object for an operation. Typically, the object is edited or played.

Parameter	Description
lpObject	Points to the object to activate.
verb	Specifies which operation to perform (0 = the primary verb, 1 = the secondary verb, and so on).
fShow	Specifies whether the window is to be shown. If the window is to be shown, this value is TRUE; otherwise, it is FALSE.
fTakeFocus	Specifies whether the server should get the focus. If the server should get the focus, this value is TRUE; otherwise, it is FALSE. This parameter is relevant only if the *fShow* parameter is TRUE.
hwnd	Identifies the window of the document containing the object.
lprcBound	Points to a **RECT** structure containing the coordinates of the bounding rectangle in which the destination document displays the object. The mapping mode of the device context determines the units for these coordinates.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_OBJECT
OLE_WAIT_FOR_RELEASE

Comments

Typically, a server is launched in a separate window; editing then occurs asynchronously. The client is notified of changes to the object through the callback function.

A client application might set the *fShow* parameter to FALSE if a server needed to remain active without being visible on the display. (In this case, the application would also use the **OleSetData** function.)

Client applications typically specify the primary verb when the user double-clicks an object. The server can take any action in response to the specified verb. If the server supports only one action, it takes that action no matter which value is passed in the *verb* parameter.

In future releases of the object linking and embedding (**OLE**) protocol, the *hwnd* and *lprcBound* parameters will be used to help determine the placement of the server's editing window.

See Also

OleQueryOpen, **OleSetData**, **RECT**

OleBlockServer (3.1)

#include ole.h

OLESTATUS OleBlockServer(*lhSrvr***)**

LHSERVER *lhSrvr;* /* handle of server */

The **OleBlockServer** function causes requests to the server to be queued until the server calls the **OleUnblockServer** function.

Parameter	Description
lhSrvr	Identifies the server for which requests are to be queued.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.

Comments

The server must call the **OleUnblockServer** function after calling the **OleBlockServer** function.

A server application can use the **OleBlockServer** and **OleUnblockServer** functions to control when the server library processes requests from client applications. Because only messages from the client to the server are blocked, a blocked server can continue to send messages to client applications.

A server application receives a handle when it calls the **OleRegisterServer** function.

See Also

OleRegisterServer, **OleUnblockServer**

OleClone (3.1)

#include ole.h

OLESTATUS OleClone(*lpObject, lpClient, lhClientDoc, lpszObjname, lplpObject***)**

```
LPOLEOBJECT lpObject;          /* address of object to copy          */
LPOLECLIENT lpClient;          /* address of OLECLIENT for new object */
LHCLIENTDOC lhClientDoc;       /* long handle of client document     */
LPCSTR lpszObjname;            /* address of string for object name  */
LPOLEOBJECT FAR* lplpObject;   /* address of pointer to new object   */
```

The **OleClone** function makes a copy of an object. The copy is identical to the source object, but it is not connected to the server.

Parameter	Description
lpObject	Points to the object to copy.
lpClient	Points to an **OLECLIENT** structure for the new object.
lhClientDoc	Identifies the client document in which the object is to be created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).
lplpObject	Points to a variable where the library will store the long pointer to the new object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_HANDLE
OLE_ERROR_OBJECT
OLE_WAIT_FOR_RELEASE

Comments

Client applications often use the **OleClone** function to support the Undo command.

A client application can supply a new **OLECLIENT** structure for the cloned object, if required.

See Also

OleEqual, **OLECLIENT**

OleClose (3.1)

#include ole.h

OLESTATUS OleClose(*lpObject***)**

LPOLEOBJECT *lpObject;* /* address of object to close */

The **OleClose** function closes the specified open object. Closing an object terminates the connection with the server application.

Parameter	**Description**
lpObject	Points to the object to close.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_OBJECT
OLE_WAIT_FOR_RELEASE

See Also

OleActivate, **OleDelete**, **OleReconnect**

OleCopyFromLink (3.1)

#include ole.h

OLESTATUS OleCopyFromLink(*lpObject, lpszProtocol, lpClient, lhClientDoc, lpszObjname, lplpObject***)**

```
LPOLEOBJECT lpObject;          /* address of object to embed        */
LPCSTR lpszProtocol;           /* address of protocol name          */
LPOLECLIENT lpClient;          /* address of client structure       */
LHCLIENTDOC lhClientDoc;       /* long handle of client document    */
LPCSTR lpszObjname;            /* address of string for object name */
LPOLEOBJECT FAR* lplpObject;   /* address of pointer to new object  */
```

The **OleCopyFromLink** function makes an embedded copy of a linked object.

Parameter	Description
lpObject	Points to the linked object that is to be embedded.
lpszProtocol	Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).
lpClient	Points to an **OLECLIENT** structure for the new object.
lhClientDoc	Identifies the client document in which the object is to be created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object.
lplpObject	Points to a variable where the library will store the long pointer to the new object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_HANDLE
OLE_ERROR_NAME
OLE_ERROR_OBJECT
OLE_ERROR_PROTOCOL
OLE_WAIT_FOR_RELEASE

Comments

Making an embedded copy of a linked object may involve starting the server application.

See Also

OleObjectConvert

OleCopyToClipboard (3.1)

#include ole.h

OLESTATUS OleCopyToClipboard(*lpObject***)**

LPOLEOBJECT *lpObject;* /* address of object */

The **OleCopyToClipboard** function puts the specified object on the clipboard.

Parameter	Description
lpObject	Points to the object to copy to the clipboard.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_OBJECT.

Comments

A client application typically calls the **OleCopyToClipboard** function when a user chooses the Copy or Cut command from the Edit menu.

The client application should open and empty the clipboard, call the **OleCopyToClipboard** function, and close the clipboard.

OleCreate (3.1)

#include ole.h

OLESTATUS OleCreate(*lpszProtocol, lpClient, lpszClass, lhClientDoc, lpszObjname, lplpObject, renderopt, cfFormat***)**

```
LPCSTR lpszProtocol;              /* address of string for protocol name */
LPOLECLIENT lpClient;             /* address of client structure         */
LPCSTR lpszClass;                 /* address of string for classname     */
LHCLIENTDOC lhClientDoc;          /* long handle of client document      */
LPCSTR lpszObjname;               /* address of string for object name   */
LPOLEOBJECT FAR* lplpObject;      /* address of pointer to object        */
OLEOPT_RENDER renderopt;          /* rendering options                   */
OLECLIPFORMAT cfFormat;           /* clipboard format                    */
```

The **OleCreate** function creates an embedded object of a specified class. The server is opened to perform the initial editing.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).
lpClient	Points to an **OLECLIENT** structure for the new object.
lpszClass	Points to a null-terminated string specifying the registered name of the class of the object to be created.
lhClientDoc	Identifies the client document in which the object is to be created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (*/*).
lplpObject	Points to a variable where the library will store the long pointer to the new object.
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The client calls the **OleGetData** function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

Returns

cfFormat Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats. The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_ERROR_NAME
OLE_ERROR_PROTOCOL
OLE_WAIT_FOR_RELEASE

Comments

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (**OLE**) may also exploit the flexibility that is inherent in this option.

OleCreateFromClip (3.1)

#include ole.h

OLESTATUS OleCreateFromClip(*lpszProtocol, lpClient, lhClientDoc, lpszObjname, lplpObject, renderopt, cfFormat***)**

```
LPCSTR lpszProtocol;              /* address of string for protocol name */
LPOLECLIENT lpClient;             /* address of client structure         */
LHCLIENTDOC lhClientDoc;          /* long handle of client document      */
LPCSTR lpszObjname;               /* address of string for object name   */
LPOLEOBJECT FAR* lplpObject;      /* address of pointer to object        */
OLEOPT_RENDER renderopt;          /* rendering options                   */
OLECLIPFORMAT cfFormat;           /* clipboard format                    */
```

The **OleCreateFromClip** function creates an object from the clipboard.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol) or Static (for uneditable pictures only).
lpClient	Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.
lhClientDoc	Identifies the client document in which the object is being created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (*/*).
lplpObject	Points to a variable where the library will store the long pointer to the new object.
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The client calls the **OleGetData** function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat	Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLIP
OLE_ERROR_FORMAT
OLE_ERROR_HANDLE
OLE_ERROR_NAME
OLE_ERROR_OPTION
OLE_ERROR_PROTOCOL
OLE_WAIT_FOR_RELEASE

Comments

The client application should open and empty the clipboard, call the **OleCreateFromClip** function, and close the clipboard.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (**OLE**) may also exploit the flexibility that is inherent in this option.

OleCreateFromFile (3.1)

#include ole.h

OLESTATUS OleCreateFromFile(*lpszProtocol, lpClient, lpszClass, lpszFile, lhClientDoc, lpszObjname, lplpObject, renderopt, cfFormat***)**

```
LPCSTR lpszProtocol;          /* address of string for protocol name */
LPOLECLIENT lpClient;         /* address of client structure         */
LPCSTR lpszClass;             /* address of string for class name    */
LPCSTR lpszFile;              /* address of string for filename      */
LHCLIENTDOC lhClientDoc;      /* long handle of client document      */
LPCSTR lpszObjname;           /* address of string for object name   */
LPOLEOBJECT FAR* lplpObject;  /* address of pointer to object        */
OLEOPT_RENDER renderopt;      /* rendering options                   */
OLECLIPFORMAT cfFormat;       /* clipboard format                    */
```

The **OleCreateFromFile** function creates an embedded object from the contents of a named file.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).
lpClient	Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.
lpszClass	Points to a null-terminated string specifying the name of the class for the new object. If this value is NULL, the library uses the extension of the filename pointed to by the *lpszFile* parameter to find the class name for the object.
lpszFile	Points to a null-terminated string specifying the name of the file containing the object.
lhClientDoc	Identifies the client document in which the object is being created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).
lplpObject	Points to a variable where the library will store the long pointer to the new object.
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The client calls the **OleGetData** function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat	Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLASS
OLE_ERROR_HANDLE
OLE_ERROR_MEMORY
OLE_ERROR_NAME
OLE_ERROR_PROTOCOL
OLE_WAIT_FOR_RELEASE

Comments

When a client application calls the **OleCreateFromFile** function, the server is started to render the Native and presentation data and then is closed. (If the server and document are already open, this function simply retrieves the information, without closing the server.) The server does not show the object to the user for editing.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (**OLE**) may also exploit the flexibility that is inherent in this option.

If a client application accepts files dropped from File Manager, it should respond to the **WM_DROPFILES** message by calling **OleCreateFromFile** and specifying Packager for the *lpszClass* parameter to indicate Microsoft Windows Object Packager.

See Also

OleCreate, **OleCreateFromTemplate**, **OleDraw**, **OleGetData**

OleCreateFromTemplate (3.1)

#include ole.h

OLESTATUS OleCreateFromTemplate(*lpszProtocol, lpClient, lpszTemplate, lhClientDoc, lpszObjname, lplpObject, renderopt, cfFormat***)**

```
LPCSTR lpszProtocol;          /* address of string for protocol name */
LPOLECLIENT lpClient;         /* address of client structure         */
LPCSTR lpszTemplate;          /* address of string for path of file  */
LHCLIENTDOC lhClientDoc;      /* long handle of client document      */
LPCSTR lpszObjname;           /* address of string for object name   */
LPOLEOBJECT FAR* lplpObject;  /* address of pointer to object        */
OLEOPT_RENDER renderopt;      /* rendering options                   */
OLECLIPFORMAT cfFormat;       /* clipboard format                    */
```

The **OleCreateFromTemplate** function creates an object by using another object as a template. The server is opened to perform the initial editing.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).
lpClient	Points to an **OLECLIENT** structure for the new object.
lpszTemplate	Points to a null-terminated string specifying the path of the file to be used as a template for the new object. The server is opened for editing and loads the initial state of the new object from the named template file.
lhClientDoc	Identifies the client document in which the object is being created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).
lplpObject	Points to a variable where the library will store the long pointer to the new object.
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The client calls the **OleGetData** function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat	Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to the **OleGetData** function. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLASS
OLE_ERROR_HANDLE
OLE_ERROR_MEMORY

OLE_ERROR_NAME
OLE_ERROR_PROTOCOL
OLE_WAIT_FOR_RELEASE

Comments

The client library uses the filename extension of the file specified in the *lpszTemplate* parameter to identify the server for the object. The association between the extension and the server is stored in the registration database.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (**OLE**) may also exploit the flexibility that is inherent in this option.

OleCreateInvisible (3.1)

#include ole.h

OLESTATUS OleCreateInvisible(*lpszProtocol, lpClient, lpszClass, lhClientDoc, lpszObjname, lplpObject, renderopt, cfFormat, fActivate***)**

```
LPCSTR lpszProtocol;          /* address of string for protocol name */
LPOLECLIENT lpClient;         /* address of client structure         */
LPCSTR lpszClass;             /* address of string for classname     */
LHCLIENTDOC lhClientDoc;      /* long handle of client document      */
LPCSTR lpszObjname;           /* address of string for object name   */
LPOLEOBJECT FAR* lplpObject;  /* address of pointer to object        */
OLEOPT_RENDER renderopt;      /* rendering options                   */
OLECLIPFORMAT cfFormat;       /* clipboard format                    */
BOOL fActivate;               /* server activation flag              */
```

The **OleCreateInvisible** function creates an object without displaying the server application to the user. The function either starts the server to create the object or creates a blank object of the specified class and format without starting the server.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol) or Static (for uneditable pictures only).
lpClient	Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.
lpszClass	Points to a null-terminated string specifying the registered name of the class of the object to be created.
lhClientDoc	Identifies the client document in which the object is being created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).
lplpObject	Points to a variable where the library will store the long pointer to the new object.
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The client calls the **OleGetData** function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat	Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.
fActivate	Specifies whether to start the server for the object. If this parameter is TRUE the server is started (but not shown). If this parameter is FALSE, the server is not started and the function creates a blank object of the specified class and format.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_ERROR_NAME
OLE_ERROR_PROTOCOL

Comments

An application can avoid redrawing an object repeatedly by calling the **OleCreateInvisible** function before using such functions as **OleSetBounds**, **OleSetColorScheme**, and **OleSetTargetDevice** to set up the object. After setting up the object, the application can either call the **OleActivate** function to display the object or call the **OleUpdate** and **OleClose** functions to update the object without displaying it.

See Also

OleActivate, **OleClose**, **OleSetBounds**, **OleSetColorScheme**, **OleSetTargetDevice**, **OleUpdate**

OleCreateLinkFromClip (3.1)

#include ole.h

OLESTATUS OleCreateLinkFromClip(*lpszProtocol, lpClient, lhClientDoc, lpszObjname, lplpObject, renderopt, cfFormat***)**

```
LPCSTR lpszProtocol;              /* address of string for protocol name */
LPOLECLIENT lpClient;             /* address of client structure         */
LHCLIENTDOC lhClientDoc;          /* long handle of client document      */
LPCSTR lpszObjname;               /* address of string for object name   */
LPOLEOBJECT FAR* lplpObject;      /* address of pointer to object        */
OLEOPT_RENDER renderopt;          /* rendering options                   */
OLECLIPFORMAT cfFormat;           /* clipboard format                    */
```

The **OleCreateLinkFromClip** function typically creates a link to an object from the clipboard.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the required protocol. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).
lpClient	Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.
lhClientDoc	Identifies the client document in which the object is being created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (*/*).
lplpObject	Points to a variable where the library will store the long pointer to the new object.
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The client calls the **OleGetData** function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat	Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLIP
OLE_ERROR_FORMAT
OLE_ERROR_HANDLE
OLE_ERROR_NAME
OLE_ERROR_PROTOCOL
OLE_WAIT_FOR_RELEASE

Comments

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call the **OleDraw** function and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (**OLE**) may also exploit the flexibility that is inherent in this option.

OleCreateLinkFromFile (3.1)

#include ole.h

OLESTATUS OleCreateLinkFromFile(*lpszProtocol, lpClient, lpszClass, lpszFile, lpszItem, lhClientDoc, lpszObjname, lplpObject, renderopt, cfFormat***)**

```
LPCSTR lpszProtocol;              /* address of string for protocol name  */
LPOLECLIENT lpClient;             /* address of client structure          */
LPCSTR lpszClass;                 /* string for class name                */
LPCSTR lpszFile;                  /* address of string for filename       */
LPCSTR lpszItem;                  /* address of string for doc. part to link */
LHCLIENTDOC lhClientDoc;          /* long handle of client document       */
LPCSTR lpszObjname;               /* address of string for object name    */
LPOLEOBJECT FAR* lplpObject;      /* address of pointer to new object     */
OLEOPT_RENDER renderopt;          /* rendering options                    */
OLECLIPFORMAT cfFormat;           /* clipboard format                     */
```

The **OleCreateLinkFromFile** function creates a linked object from a file that contains an object. If necessary, the library starts the server to render the presentation data, but the object is not shown in the server for editing.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the required protocol. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).
lpClient	Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.
lpszClass	Points to a null-terminated string specifying the name of the class for the new object. If this value is NULL, the library uses the extension of the filename pointed to by the *lpszFile* parameter to find the class name for the object.
lpszFile	Points to a null-terminated string specifying the name of the file containing the object.
lpszItem	Points to a null-terminated string identifying the part of the document to link to. If this value is NULL, the link is to the entire document.
lhClientDoc	Identifies the client document in which the object is being created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).
lplpObject	Points to a variable where the library will store the long pointer to the new object.
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The client calls the **OleGetData** function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat	Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data

and draws the object. The library does not support drawing for any other formats.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLASS
OLE_ERROR_HANDLE
OLE_ERROR_MEMORY
OLE_ERROR_NAME
OLE_ERROR_PROTOCOL
OLE_WAIT_FOR_RELEASE

Comments

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (**OLE**) may also exploit the flexibility that is inherent in this option.

OleDelete (3.1)

#include ole.h

OLESTATUS OleDelete(*lpObject***)**

LPOLEOBJECT *lpObject;* /* address of object to delete */

The **OleDelete** function deletes an object and frees memory that was associated with that object. If the object was open, it is closed.

Parameter	**Description**
lpObject	Points to the object to delete.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_OBJECT
OLE_WAIT_FOR_RELEASE

Comments

An application uses the **OleDelete** function when the object is no longer part of the client document.

The **OleDelete** function, unlike **OleRelease**, indicates that the object has been permanently removed.

#include ole.h

OLESTATUS OleDraw(*lpObject, hdc, lprcBounds, lprcWBounds, hdcFormat***)**

```
LPOLEOBJECT lpObject;                 /* address of object to draw              */
HDC hdc;                              /* handle of DC for drawing object        */
const RECT FAR* lprcBounds;           /* bounding rectangle for drawing object  */
const RECT FAR* lprcWBounds;          /* bounding rectangle for metafile DC     */
HDC hdcFormat;                        /* handle of DC for formatting object     */
```

The **OleDraw** function draws a specified object into a bounding rectangle in a device context.

Parameter	Description
lpObject	Points to the object to draw.
hdc	Identifies the device context in which to draw the object.
lprcBounds	Points to a **RECT** structure defining the bounding rectangle, in logical units for the device context specified by the *hdc* parameter, in which to draw the object.
lprcWBounds	Points to a **RECT** structure defining the bounding rectangle if the *hdc* parameter specifies a metafile. The **left** and **top** members of the **RECT** structure should specify the window origin, and the **right** and **bottom** members should specify the window extents.
hdcFormat	Identifies a device context describing the target device for which to format the object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_ABORT
OLE_ERROR_BLANK
OLE_ERROR_DRAW
OLE_ERROR_MEMORY
OLE_ERROR_OBJECT

Comments

This function returns OLE_ERROR_ABORT if the callback function returns FALSE during drawing.

When the *hdc* parameter specifies a metafile device context, the rectangle specified by the *lprcWBounds* parameter contains the rectangle specified by the *lprcBounds* parameter. If *hdc* does not specify a metafile device context, the *lprcWBounds* parameter is ignored.

The library may use an object handler to render the object, and this object handler may need information about the target device. Therefore, the device-context handle specified by the *hdcFormat* parameter is required. The *lprcBounds* parameter identifies the rectangle on the device context (relative to its current mapping mode) that the object should be mapped onto. This may involve scaling the picture and can be used by client applications to impose a view scaling between the displayed view and the final printed image.

An object handler should format an object as if it were to be drawn at the size specified by a call to the **OleSetBounds** function for the device context specified by the *hdcFormat* parameter. Often this formatting will already have been done by the server application; in this case, the library simply renders the presentation data with suitable scaling for the required bounding rectangle. If cropping or banding is required, the device context in which the object is drawn may include a clipping region smaller than the specified bounding rectangle.

OleSetBounds

OleEnumFormats (3.1)

#include ole.h

OLECLIPFORMAT OleEnumFormats(*lpObject, cfFormat***)**

LPOLEOBJECT *lpObject;* /* address of object to query */
OLECLIPFORMAT *cfFormat;* /* format from previous function call */

The **OleEnumFormats** function enumerates the data formats that describe a specified object.

Parameter	Description
lpObject	Points to the object to be queried.
cfFormat	Specifies the format returned by the last call to the **OleEnumFormats** function. For the first call to this function, this parameter is zero.

Returns

The return value is the next available format if any further formats are available. Otherwise, the return value is NULL.

Comments

When an application specifies NULL for the *cfFormat* parameter, the **OleEnumFormats** function returns the first available format. Whenever an application specifies a format that was returned by a previous call to **OleEnumFormats**, the function returns the next available format, in sequence. When no more formats are available, the function returns NULL.

See Also

OleGetData

OleEnumObjects (3.1)

#include ole.h

OLESTATUS OleEnumObjects(*lhDoc, lplpObject***)**

LHCLIENTDOC *lhDoc;* /* document handle */
LPOLEOBJECT FAR* *lplpObject;* /* address of pointer to object */

The **OleEnumObjects** function enumerates the objects in a specified document.

Parameter	Description
lhDoc	Identifies the document for which the objects are enumerated.
lplpObject	Points to an object in the document when the function returns. For the first call to this function, this parameter should point to a NULL object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_ERROR_OBJECT

Comments

When an application specifies a NULL object for the *lplpObject* parameter, the **OleEnumObjects** function returns the first object in the document. Whenever an application specifies an object that was returned by a previous call to **OleEnumObjects**, the function returns the next object, in sequence. When there are no more objects in the document, the *lplpObject* parameter points to a NULL object.

Only objects that have been loaded and not released are enumerated by this function.

See Also

OleDelete, **OleRelease**

OleEqual (3.1)

#include ole.h

OLESTATUS OleEqual(*lpObject1, lpObject2***)**

LPOLEOBJECT *lpObject1;* /* address of first object to compare */
LPOLEOBJECT *lpObject2;* /* address of second object to compare */

The **OleEqual** function compares two objects for equality.

Parameter	Description
lpObject1	Points to the first object to test for equality.
lpObject2	Points to the second object to test for equality.

Returns

The return value is OLE_OK if the specified objects are equal. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_OBJECT
OLE_ERROR_NOT_EQUAL

Comments

Embedded objects are equal if their class, item, and native data are identical. Linked objects are equal if their class, document, and item are identical.

See Also

OleClone, **OleQueryOutOfDate**

OleExecute (3.1)

#include ole.h

OLESTATUS OleExecute(*lpObject, hglbCmds, reserved***)**

```
LPOLEOBJECT lpObject;     /* address of object receiving DDE commands */
HGLOBAL hglbCmds;         /* handle of memory with commands           */
UINT reserved;            /* reserved                                 */
```

The **OleExecute** function sends dynamic data exchange (DDE) execute commands to the server for the specified object.

Parameter	Description
lpObject	Points to an object identifying the server to which DDE execute commands are sent.
hglbCmds	Identifies the memory containing one or more DDE execute commands.
reserved	Reserved; must be zero.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_COMMAND
OLE_ERROR_MEMORY
OLE_ERROR_NOT_OPEN
OLE_ERROR_OBJECT
OLE_ERROR_PROTOCOL
OLE_ERROR_STATIC
OLE_WAIT_FOR_RELEASE

Comments

The client application should call the **OleQueryProtocol** function, specifying StdExecute, before calling the **OleExecute** function. The **OleQueryProtocol** function succeeds if the server for an object supports the **OleExecute** function.

See Also

OleQueryProtocol

OleGetData (3.1)

#include ole.h

OLESTATUS OleGetData(*lpObject, cfFormat, lphData***)**

```
LPOLEOBJECT lpObject;          /* address of object to query          */
OLECLIPFORMAT cfFormat;        /* format for retrieved data           */
HANDLE FAR* lphData;           /* address of memory to contain data   */
```

The **OleGetData** function retrieves data in the requested format from the specified object and supplies the handle of a memory or graphics device interface (GDI) object containing the data.

Parameter	Description
lpObject	Points to the object from which data is retrieved.
cfFormat	Specifies the format in which data is returned. This parameter can be one of the predefined clipboard formats or the value returned by the **RegisterClipboardFormat** function.
lphData	Points to the handle of a memory object that contains the data when the function returns.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_BLANK
OLE_ERROR_FORMAT
OLE_ERROR_OBJECT
OLE_WARN_DELETE_DATA

Comments

If the **OleGetData** function returns OLE_WARN_DELETE_DATA, the client application owns the data and should free the memory associated with the data when the client has finished using it. For other return values, the client should not free the memory or modify the data, because the data is controlled by the client library. If the application needs the data for long-term use, it should copy the data.

The **OleGetData** function typically returns OLE_WARN_DELETE_DATA if an object handler generates data for an object that the client library cannot interpret. In this case, the client application is responsible for controlling that data.

When the **OleGetData** function specifies CF_METAFILE or CF_BITMAP, the *lphData* parameter points to a GDI object, not a memory object, when the function returns. **OleGetData** supplies the handle of a memory object for all other formats.

See Also

OleEnumFormats, **OleSetData**, **RegisterClipboardFormat**

OleGetLinkUpdateOptions (3.1)

#include ole.h

OLESTATUS OleGetLinkUpdateOptions(*lpObject, lpUpdateOpt***)**

LPOLEOBJECT *lpObject;* /* address of object to query */
OLEOPT_UPDATE FAR* *lpUpdateOpt;* /* address of update options */

The **OleGetLinkUpdateOptions** function retrieves the link-update options for the presentation of a specified object.

Parameter	Description
lpObject	Points to the object to query.
lpUpdateOpt	Points to a variable in which the function stores the current value of the link-update option for the specified object. The link-update option setting may be one of the following values:

Value	Meaning
oleupdate_always	Update the linked object whenever possible. This option supports the Automatic link-update radio button in the Links dialog box.
oleupdate_oncall	Update the linked object only on request from the client application. This option supports the Manual link-update radio button in the Links dialog box.
oleupdate_onsave	Update the linked object when the source document is saved by the server.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_OBJECT
OLE_ERROR_STATIC

See Also

OleSetLinkUpdateOptions

OleIsDcMeta (3.1)

#include ole.h

BOOL OleIsDcMeta(*hdc***)**

HDC *hdc;* /* device-context handle */

The **OleIsDcMeta** function determines whether the specified device context is a metafile device context.

Parameter	Description
hdc	Identifies the device context to query.

Returns

The return value is a positive value if the device context is a metafile device context. Otherwise, it is NULL.

OleLoadFromStream (3.1)

#include ole.h

OLESTATUS OleLoadFromStream(*lpStream, lpszProtocol, lpClient, lhClientDoc, lpszObjname, lplpObject***)**

```
LPOLESTREAM lpStream;          /* address of stream for object        */
LPCSTR lpszProtocol;           /* address of string for protocol name */
LPOLECLIENT lpClient;          /* address of client structure         */
LHCLIENTDOC lhClientDoc;       /* long handle of client document      */
LPCSTR lpszObjname;            /* address of string for object name   */
LPOLEOBJECT FAR* lplpObject;   /* address of pointer to object        */
```

The **OleLoadFromStream** function loads an object from the containing document.

Parameter	Description
lpStream	Points to an **OLESTREAM** structure that was allocated and initialized by the client application. The library calls the **Get** function in the **OLESTREAMVTBL** structure to obtain the data for the object.
lpszProtocol	Points to a null-terminated string specifying the name of the required protocol. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol) or Static (for uneditable pictures only).
lpClient	Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.
lhClientDoc	Identifies the client document in which the object is being created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object.
lplpObject	Points to a variable in which the library stores a pointer to the loaded object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_ERROR_NAME
OLE_ERROR_PROTOCOL
OLE_ERROR_STREAM
OLE_WAIT_FOR_RELEASE

Comments

To load an object, the client application needs only the location of that object in a file. A client typically loads an object only when the object is needed (for example, when it must be displayed).

If an object cannot be loaded when the *lpszProtocol* parameter specifies StdFileEditing, the application can call the **OleLoadFromStream** function again, specifying Static.

If the object is linked and the server and document are open, the library automatically makes the link between the client and server applications when an application calls **OleLoadFromStream**.

See Also

OleQuerySize, **OleSaveToStream**

OleLockServer (3.1)

#include ole.h

OLESTATUS OleLockServer(*lpObject, lphServer***)**

LPOLEOBJECT *lpObject;* /* address of object */
LHSERVER FAR* *lphServer;* /* address of handle of server */

The **OleLockServer** function is called by a client application to keep an open server application in memory. Keeping the server application in memory allows the client library to use the server application to open objects quickly.

Parameter	Description
lpObject	Points to an object the client library uses to identify the open server application to keep in memory. When the server has been locked, this object can be deleted.
lphServer	Points to the handle of the server application when the function returns.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_COMM
OLE_ERROR_LAUNCH
OLE_ERROR_OBJECT

Comments

A client calls **OleLockServer** to speed the opening of objects when the same server is used for a number of different objects. Before the client terminates, it must call the **OleUnlockServer** function to release the server from memory.

When **OleLockServer** is called more than once for a given server, even by different client applications, the server's lock count is increased. Each call to **OleUnlockServer** decrements the lock count. The server remains locked until the lock count is zero. If the object identified by the *lpObject* parameter is deleted before calling the **OleUnlockServer** function, **OleUnlockServer** must still be called to decrement the lock count.

If necessary, a server can terminate even though a client has called the **OleLockServer** function.

See Also

OleUnlockServer

OleObjectConvert (3.1)

#include ole.h

OLESTATUS OleObjectConvert(*lpObject, lpszProtocol, lpClient, lhClientDoc, lpszObjname, lplpObject***)**

```
LPOLEOBJECT lpObject;          /* address of object to convert          */
LPCSTR lpszProtocol;           /* address of string for protocol name */
LPOLECLIENT lpClient;          /* address of client for new object      */
LHCLIENTDOC lhClientDoc;       /* long handle of client document        */
LPCSTR lpszObjname;            /* address of string for object name     */
LPOLEOBJECT FAR* lplpObject;   /* address of pointer to new object      */
```

The **OleObjectConvert** function creates a new object that supports a specified protocol by converting an existing object. This function neither deletes nor replaces the original object.

Parameter	Description
lpObject	Points to the object to convert.
lpszProtocol	Points to a null-terminated string specifying the name of the required protocol. Currently this value can be Static (for uneditable pictures only).
lpClient	Points to an **OLECLIENT** structure for the new object.
lhClientDoc	Identifies the client document in which the object is being created.
lpszObjname	Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).
lplpObject	Points to a variable in which the library stores a pointer to the new object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_HANDLE
OLE_ERROR_NAME
OLE_ERROR_OBJECT
OLE_ERROR_STATIC

Comments

The only conversion currently supported is that of changing a linked or embedded object to a static object.

See Also

OleClone

OleQueryBounds (3.1)

#include ole.h

OLESTATUS OleQueryBounds(*lpObject, lpBounds***)**

LPOLEOBJECT *lpObject;* /* address of object to query */
RECT FAR* *lpBounds;* /* address of structure for bounding rectangle */

The **OleQueryBounds** function retrieves the extents of the bounding rectangle on the target device for the specified object. The coordinates are in MM_HIMETRIC units.

Parameter	Description
lpObject	Points to the object to query.
lpBounds	Points to a **RECT** structure for the extents of the bounding rectangle. The members of the **RECT** structure have the following meanings:

Member	Meaning
rect.left	0
rect.top	0
rect.right	x-extent
rect.bottom	y-extent

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_BLANK
OLE_ERROR_MEMORY
OLE_ERROR_OBJECT

See Also

OleSetBounds, **SetMapMode**, **RECT**

OleQueryClientVersion (3.1)

#include ole.h

DWORD OleQueryClientVersion(void)

The **OleQueryClientVersion** function retrieves the version number of the client library.

Returns
The return value is a doubleword value. The major version number is in the low-order byte of the low-order word, and the minor version number is in the high-order byte of the low-order word. The high-order word is reserved.

See Also
OleQueryServerVersion

OleQueryCreateFromClip (3.1)

#include ole.h

OLESTATUS OleQueryCreateFromClip(*lpszProtocol, renderopt, cfFormat***)**

```
LPCSTR lpszProtocol;        /* address of string for protocol name */
OLEOPT_RENDER renderopt;    /* rendering options                   */
OLECLIPFORMAT cfFormat;     /* format for clipboard data           */
```

The **OleQueryCreateFromClip** function checks whether the object on the clipboard supports the specified protocol and rendering options.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the protocol needed by the client. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol) or Static (for uneditable pictures only).
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat	Specifies the clipboard format. This parameter is used only when the *renderopt* parameter is **olerender_format**. If the clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_FORMAT
OLE_ERROR_PROTOCOL

Comments

The **OleQueryCreateFromClip** function is typically used to check whether to enable a Paste command.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls the **OleGetData** function only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (**OLE**) may also exploit the flexibility that is inherent in this option.

See Also

OleCreateFromClip, **OleDraw**, **OleGetData**

OleQueryLinkFromClip (3.1)

#include ole.h

OLESTATUS OleQueryLinkFromClip(*lpszProtocol, renderopt, cfFormat***)**

```
LPCSTR lpszProtocol;        /* address of string for protocol name */
OLEOPT_RENDER renderopt;    /* rendering options                   */
OLECLIPFORMAT cfFormat;     /* format for clipboard data           */
```

The **OleQueryLinkFromClip** function checks whether a client application can use the data on the clipboard to produce a linked object that supports the specified protocol and rendering options.

Parameter	Description
lpszProtocol	Points to a null-terminated string specifying the name of the protocol needed by the client. Currently this value can be StdFileEditing (the name of the object linking and embedding protocol).
renderopt	Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the **OleDraw** function, and the library obtains and manages presentation data.
olerender_format	The library obtains and manages the data in the requested format, as specified by the *cfFormat* parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat	Specifies the clipboard format. This parameter is used only when the *renderopt* parameter is **olerender_format**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_FORMAT
OLE_ERROR_PROTOCOL

Comments

The **OleQueryLinkFromClip** function is typically used to check whether to enable a Paste Link command.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls the **OleGetData** function only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (**OLE**) may also exploit the flexibility that is inherent in this option.

OleCreateLinkFromClip, **OleDraw**, **OleGetData**

OleQueryName (3.1)

#include ole.h

OLESTATUS OleQueryName(*lpObject, lpszObject, lpwBuffSize***)**

```
LPOLEOBJECT lpObject;       /* address of object                  */
LPSTR lpszObject;           /* address of string for object name  */
UINT FAR* lpwBuffSize;      /* address of word for size of buffer */
```

The **OleQueryName** function retrieves the name of a specified object.

Parameter	Description
lpObject	Points to the object whose name is being queried.
lpszObject	Points to a character array that contains a null-terminated string. When the function returns, this string specifies the name of the object.
lpwBuffSize	Points to a variable containing the size, in bytes, of the buffer pointed to by the *lpszObject* parameter. When the function returns, this value is the number of bytes copied to the buffer.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_OBJECT.

See Also

OleRename

OleQueryOpen (3.1)

#include ole.h

OLESTATUS OleQueryOpen(*lpObject***)**

LPOLEOBJECT *lpObject;* /* address of object to query */

The **OleQueryOpen** function checks whether the specified object is open.

Parameter	Description
lpObject	Points to the object to query.

Returns

The return value is OLE_OK if the object is open. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_COMM
OLE_ERROR_OBJECT
OLE_ERROR_STATIC

See Also

OleActivate

OleQueryOutOfDate (3.1)

#include ole.h

OLESTATUS OleQueryOutOfDate(*lpObject***)**

LPOLEOBJECT *lpObject;* /* address of object to query */

The **OleQueryOutOfDate** function checks whether an object is out-of-date.

Parameter	Description
lpObject	Points to the object to query.

Returns

The return value is OLE_OK if the object is up-to-date. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_OBJECT
OLE_ERROR_OUTOFDATE

Comments

The **OleQueryOutOfDate** function has not been implemented for the current version of object linking and embedding (**OLE**). For linked objects, **OleQueryOutOfDate** always returns OLE_OK.

A linked object might be out-of-date if the document that is the source for the link has been updated. An embedded object that contains links to other objects might also be out-of-date.

See Also

OleEqual, **OleUpdate**

OleQueryProtocol (3.1)

#include ole.h

void FAR* OleQueryProtocol(*lpobj, lpszProtocol***)**

LPOLEOBJECT *lpobj;* /* address of object to query */
LPCSTR *lpszProtocol;* /* address of string for protocol to query */

The **OleQueryProtocol** function checks whether an object supports a specified protocol.

Parameter	Description
lpobj	Points to the object to query.
lpszProtocol	Points to a null-terminated string specifying the name of the requested protocol. This value can be StdFileEditing or StdExecute.

Returns

The return value is a void pointer to an **OLEOBJECT** structure if the function is successful, or it is NULL if the object does not support the requested protocol. The library can return OLE_WAIT_FOR_RELEASE when an application calls this function.

Comments

The **OleQueryProtocol** function queries whether the specified protocol is supported and returns a modified object pointer that allows access to the function table for the protocol. This modified object pointer points to a structure that has the same form as the **OLEOBJECT** structure; the new structure also points to a table of functions and may contain additional state information. The new pointer does not point to a different object--if the object is deleted, secondary pointers become invalid. If a protocol includes delete functions, calling a delete function invalidates all pointers to that object.

A client application typically calls **OleQueryProtocol**, specifying StdExecute for the *lpszProtocol* parameter, before calling the **OleExecute** function. This allows the client application to check whether the server for an object supports dynamic data exchange (DDE) execute commands.

See Also

OleExecute

OleQueryReleaseError (3.1)

#include ole.h

OLESTATUS OleQueryReleaseError(*lpobj***)**

LPOLEOBJECT *lpobj;* /* address of object to query */

The **OleQueryReleaseError** function checks the error value for an asynchronous operation on an object.

Parameter	Description
lpobj	Points to an object for which the error value is to be queried.

Returns

The return value, if the function is successful, is either OLE_OK if the asynchronous operation completed successfully or the error value for that operation. If the pointer passed in the *lpobj* parameter is invalid, the function returns OLE_ERROR_OBJECT.

Comments

A client application receives the OLE_RELEASE notification when an asynchronous operation has terminated. The client should then call **OleQueryReleaseError** to check whether the operation has terminated successfully or with an error value.

See Also

OleQueryReleaseMethod, **OleQueryReleaseStatus**

OleQueryReleaseMethod (3.1)

#include ole.h

OLE_RELEASE_METHOD OleQueryReleaseMethod(*lpobj***)**

LPOLEOBJECT *lpobj;* /* address of object to query */

The **OleQueryReleaseMethod** function finds out the operation that finished for the specified object.

Parameter	Description
lpobj	Points to an object for which the operation is to be queried.

Returns

The return value indicates the server operation (method) that finished. It can be one of the following values:

Value	Server operation
OLE_ACTIVATE	Activate
OLE_CLOSE	Close
OLE_COPYFROMLNK	CopyFromLink (autoreconnect)
OLE_CREATE	Create
OLE_CREATEFROMFILE	CreateFromFile
OLE_CREATEFROMTEMPLATE	CreateFromTemplate
OLE_CREATEINVISIBLE	CreateInvisible
OLE_CREATELINKFROMFILE	CreateLinkFromFile
OLE_DELETE	Object Delete
OLE_EMBPASTE	Paste and Update
OLE_LNKPASTE	PasteLink (autoreconnect)
OLE_LOADFROMSTREAM	LoadFromStream (autoreconnect)
OLE_NONE	No operation active
OLE_OTHER	Other miscellaneous asynchronous operations
OLE_RECONNECT	Reconnect
OLE_REQUESTDATA	OleRequestData
OLE_RUN	Run
OLE_SERVERUNLAUNCH	Server is stopping
OLE_SETDATA	OleSetData
OLE_SETUPDATEOPTIONS	Setting update options
OLE_SHOW	Show
OLE_UPDATE	Update

If the pointer passed in the *lpobj* parameter is invalid, the function returns OLE_ERROR_OBJECT.

Comments

A client application receives the OLE_RELEASE notification when an asynchronous operation has ended. The client can then call **OleQueryReleaseMethod** to check which operation caused the library to send the OLE_RELEASE notification. The client calls **OleQueryReleaseError** to determine whether the operation terminated successfully or with an error value.

See Also

OleQueryReleaseError, **OleQueryReleaseStatus**

OleQueryReleaseStatus (3.1)

#include ole.h

OLESTATUS OleQueryReleaseStatus(*lpobj***)**

LPOLEOBJECT *lpobj;* /* address of object to query */

The **OleQueryReleaseStatus** function determines whether an operation has finished for the specified object.

Parameter	Description
lpobj	Points to an object for which the operation is queried.

Returns

The return value, if the function is successful, is either OLE_BUSY if an operation is in progress or OLE_OK. If the pointer passed in the *lpobj* parameter is invalid, the function returns OLE_ERROR_OBJECT.

See Also

OleQueryReleaseError, **OleQueryReleaseMethod**

OleQueryServerVersion (3.1)

#include ole.h

DWORD OleQueryServerVersion(void)

The **OleQueryServerVersion** function retrieves the version number of the server library.

Returns
The return value is a doubleword value. The major version number is in the low-order byte of the low-order word, and the minor version number is in the high-order byte of the low-order word. The high-order word is reserved.

See Also
OleQueryClientVersion, **HIBYTE**, **LOBYTE**

OleQuerySize (3.1)

#include ole.h

OLESTATUS OleQuerySize(*lpObject, pdwSize***)**

LPOLEOBJECT *lpObject;* /* address of object to query */
DWORD FAR* *pdwSize;* /* address of size of object */

The **OleQuerySize** function retrieves the size of the specified object.

Parameter	Description
lpObject	Points to the object to query.
pdwSize	Points to a variable for the size of the object. This variable contains the size of the object when the function returns.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_BLANK
OLE_ERROR_MEMORY
OLE_ERROR_OBJECT

See Also

OleLoadFromStream

OleQueryType (3.1)

#include ole.h

OLESTATUS OleQueryType(*lpObject, lpType***)**

LPOLEOBJECT *lpObject;* /* address of object to query */
LONG FAR* *lpType;* /* address of type of object */

The **OleQueryType** function checks whether a specified object is embedded, linked, or static.

Parameter	Description
lpObject	Points to the object for which the type is to be queried.
lpType	Points to a long variable that contains the type of the object when the function returns. This parameter can be one of the following values:

Value	Meaning
OT_EMBEDDED	Object is embedded.
OT_LINK	Object is a link.
OT_STATIC	Object is a static picture.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_GENERIC
OLE_ERROR_OBJECT

See Also

OleEnumFormats

OleReconnect (3.1)

#include ole.h

OLESTATUS OleReconnect(*lpObject***)**

LPOLEOBJECT *lpObject;* /* address of object to reconnect to */

The **OleReconnect** function reestablishes a link to an open linked object. If the specified object is not open, this function does not open it.

Parameter	Description
lpObject	Points to the object to reconnect to.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_NOT_LINK
OLE_ERROR_OBJECT
OLE_ERROR_STATIC
OLE_WAIT_FOR_RELEASE

Comments

A client application can use **OleReconnect** to keep the presentation for a linked object up-to-date.

See Also

OleActivate, **OleClose**, **OleUpdate**

OleRegisterClientDoc (3.1)

#include ole.h

OLESTATUS OleRegisterClientDoc(*lpszClass, lpszDoc, reserved, lplhDoc***)**

```
LPCSTR lpszClass;                /* address of string for class name      */
LPCSTR lpszDoc;                  /* address of string for document name   */
LONG reserved;                   /* reserved                              */
LHCLIENTDOC FAR* lplhDoc;        /* address of handle of document         */
```

The **OleRegisterClientDoc** function registers an open client document with the library and returns the handle of that document.

Parameter	Description
lpszClass	Points to a null-terminated string specifying the class of the client document.
lpszDoc	Points to a null-terminated string specifying the location of the client document. (This value should be a fully qualified path.)
reserved	Reserved. Must be zero.
lplhDoc	Points to the handle of the client document when the function returns. This handle is used to identify the document in other document-management functions.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_ALREADY_REGISTERED
OLE_ERROR_MEMORY
OLE_ERROR_NAME

Comments

When a document being copied onto the clipboard exists only because the client application is copying Native data that contains objects, the name specified in the *lpszDoc* parameter must be Clipboard.

Client applications should register open documents with the library and notify the library when a document is renamed, closed, saved, or restored to a changed state.

See Also

OleRenameClientDoc, **OleRevertClientDoc**, **OleRevokeClientDoc**, **OleSavedClientDoc**

OleRegisterServerDoc (3.1)

#include ole.h

OLESTATUS OleRegisterServerDoc(*lhsrvr, lpszDocName, lpdoc, lplhdoc***)**

```
LHSERVER lhsrvr;                /* server handle                    */
LPCSTR lpszDocName;             /* address of string for document name */
LPOLESERVERDOC lpdoc;           /* address of OLESERVERDOC structure */
LHSERVERDOC FAR* lplhdoc;       /* handle of registered document    */
```

The **OleRegisterServerDoc** function registers a document with the server library in case other client applications have links to it. A server application uses this function when the server is started with the **/Embedding** *filename* option or when it creates or opens a document that is not requested by the library.

Parameter	Description
lhsrvr	Identifies the server. Server applications obtain this handle by calling the **OleRegisterServer** function.
lpszDocName	Points to a null-terminated string specifying the permanent name for the document. This parameter should be a fully qualified path.
lpdoc	Points to an **OLESERVERDOC** structure allocated and initialized by the server application.
lplhdoc	Points to a handle that will identify the document. This parameter points to the handle when the function returns.

Returns

If the function is successful, the return value is OLE_OK. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_ADDRESS
OLE_ERROR_HANDLE
OLE_ERROR_MEMORY

Comments

If the document was created or opened in response to a request from the server library, the server should not register the document by using **OleRegisterServerDoc**. Instead, the server should return a pointer to the **OLESERVERDOC** structure through the parameter to the relevant function.

See Also

OleRegisterServer, **OleRevokeServerDoc**

OleRegisterServer (3.1)

#include ole.h

OLESTATUS OleRegisterServer(*lpszClass, lpsrvr, lplhserver, hinst, srvruse***)**

```
LPCSTR lpszClass;          /* address of string for class name      */
LPOLESERVER lpsrvr;        /* address of OLESERVER structure        */
LHSERVER FAR* lplhserver;  /* address of server handle              */
HINSTANCE hinst;           /* instance handle                       */
OLE_SERVER_USE srvruse;    /* single or multiple instances          */
```

The **OleRegisterServer** function registers the specified server, class name, and instance with the server library.

Parameter	Description
lpszClass	Points to a null-terminated string specifying the class name being registered.
lpsrvr	Points to an **OLESERVER** structure allocated and initialized by the server application.
lplhserver	Points to a variable of type **LHSERVER** in which the library stores the handle of the server. This handle is used in such functions as **OleRegisterServerDoc** and **OleRevokeServer**.
hinst	Identifies the instance of the server application. This handle is used to ensure that clients connect to the correct instance of a server application.
srvruse	Specifies whether the server uses a single instance or multiple instances to support multiple objects. This value must be either OLE_SERVER_SINGLE or OLE_SERVER_MULTI.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLASS
OLE_ERROR_MEMORY
OLE_ERROR_PROTECT_ONLY

Comments

When the server application starts, it creates an **OLESERVER** structure and calls the **OleRegisterServer** function. Servers that support several class names can allocate a structure for each or reuse the same structure. The class name is passed to server-application functions that are called through the library, so that servers supporting more than one class can check which class is being requested.

The *srvruse* parameter is used when the libraries open an object. When OLE_SERVER_MULTI is specified for this parameter and all current instances are already editing an object, a new instance of the server is started. Servers that support the multiple document interface (MDI) typically specify OLE_SERVER_SINGLE.

See Also

OleRegisterServerDoc, **OleRevokeServer**

OleRelease (3.1)

#include ole.h

OLESTATUS OleRelease(*lpObject***)**

LPOLEOBJECT *lpObject;* /* address of object to release */

The **OleRelease** function releases an object from memory and closes it if it was open. This function does not indicate that the object has been deleted from the client document.

Parameter	**Description**
lpObject	Points to the object to release.

Returns

If the function is successful, the return value is OLE_OK. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_OBJECT
OLE_WAIT_FOR_RELEASE

Comments

The **OleRelease** function should be called for all objects when closing the client document.

See Also

OleDelete

OleRename (3.1)

#include ole.h

OLESTATUS OleRename(*lpObject, lpszNewname***)**

LPOLEOBJECT *lpObject;* /* address of object being renamed */
LPCSTR *lpszNewname;* /* address of string for new object name */

The **OleRename** function renames an object.

Parameter	Description
lpObject	Points to the object that is being renamed.
lpszNewname	Points to a null-terminated string specifying the new name of the object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_OBJECT.

Comments

Object names need not be seen by the user. They must be unique within the containing document and must be preserved when the document is saved.

See Also

OleQueryName

OleRenameClientDoc (3.1)

#include ole.h

OLESTATUS OleRenameClientDoc(*lhClientDoc, lpszNewDocname***)**

LHCLIENTDOC *lhClientDoc;* /* handle of client document */
LPCSTR *lpszNewDocname;* /* address of string for new document name */

The **OleRenameClientDoc** function informs the client library that a document has been renamed. A client application calls this function when a document name has changed--for example, when the user chooses the Save or Save As command from the File menu.

Parameter	Description
lhClientDoc	Identifies the document that has been renamed.
lpszNewDocname	Points to a null-terminated string specifying the new name of the document.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.

Comments

Client applications should register open documents with the library and notify the library when a document is renamed, closed, saved, or restored to a changed state.

See Also

OleRegisterClientDoc, **OleRevertClientDoc**, **OleRevokeClientDoc**, **OleSavedClientDoc**

OleRenameServerDoc (3.1)

#include ole.h

OLESTATUS OleRenameServerDoc(*lhDoc, lpszDocName***)**

LHSERVERDOC *lhDoc;* /* handle of document */
LPCSTR *lpszDocName;* /* address of string for path and filename */

The **OleRenameServerDoc** function informs the server library that a document has been renamed.

Parameter	Description
lhDoc	Identifies the document that has been renamed.
lpszDocName	Points to a null-terminated string specifying the new name of the document. This parameter is typically a fully qualified path.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_ERROR_MEMORY

Comments

The **OleRenameServerDoc** function has the same effect as sending the OLE_RENAMED notification to the client application's callback function. The server application calls this function when it renames a document to which the active links need to be reconnected or when the user chooses the Save As command from the File menu while working with an embedded object.

Server applications should register open documents with the server library and notify the library when a document is renamed, closed, saved, or restored to a changed state.

See Also

OleRegisterServerDoc, **OleRevertServerDoc**, **OleRevokeServerDoc**, **OleSavedServerDoc**

OleRequestData (3.1)

#include ole.h

OLESTATUS OleRequestData(*lpObject, cfFormat***)**

LPOLEOBJECT *lpObject;* /* address of object to query */
OLECLIPFORMAT *cfFormat;* /* format for retrieved data */

The **OleRequestData** function requests the library to retrieve data in a specified format from a server.

Parameter	Description
lpObject	Points to the object that is associated with the server from which data is to be retrieved.
cfFormat	Specifies the format in which data is to be returned. This parameter can be one of the predefined clipboard formats or the value returned by the **RegisterClipboardFormat** function.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_NOT_OPEN
OLE_ERROR_OBJECT
OLE_ERROR_STATIC
OLE_WAIT_FOR_RELEASE

Comments

The client application should be connected to the server application when the client calls the **OleRequestData** function. When the client receives the OLE_RELEASE notification, it can retrieve the data from the object by using the **OleGetData** function or query the data by using such functions as **OleQueryBounds**.

If the requested data format is the same as the presentation data for the object, the library manages the data and updates the presentation.

The **OleRequestData** function returns OLE_WAIT_FOR_RELEASE if the server is busy. In this case, the application should continue to dispatch messages until it receives a callback notification with the OLE_RELEASE argument.

See Also

OleEnumFormats, **OleGetData**, **OleSetData**, **RegisterClipboardFormat**

OleRevertClientDoc (3.1)

#include ole.h

OLESTATUS OleRevertClientDoc(*lhClientDoc***)**

LHCLIENTDOC *lhClientDoc;* /* handle of client document */

The **OleRevertClientDoc** function informs the library that a document has been restored to a previously saved condition.

Parameter	Description
lhClientDoc	Identifies the document that has been restored to its saved state.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.

Comments

A client application should call the **OleRevertClientDoc** function when it reloads a document without saving changes to the document.

Client applications should register open documents with the library and notify the library when a document is renamed, closed, saved, or restored to a saved state.

See Also

OleRegisterClientDoc, **OleRenameClientDoc**, **OleRevokeClientDoc**, **OleSavedClientDoc**

OleRevertServerDoc (3.1)

#include ole.h

OLESTATUS OleRevertServerDoc(*lhDoc***)**

LHSERVERDOC *lhDoc;* /* handle of document */

The **OleRevertServerDoc** function informs the server library that the server has restored a document to its saved state without closing it.

Parameter	Description
lhDoc	Identifies the document that has been restored to its saved state.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.

Comments

Server applications should register open documents with the server library and notify the library when a document is renamed, closed, saved, or restored to a saved state.

See Also

OleRegisterServerDoc, **OleRenameServerDoc**, **OleRevokeServerDoc**, **OleSavedServerDoc**

OleRevokeClientDoc (3.1)

#include ole.h

OLESTATUS OleRevokeClientDoc(*lhClientDoc***)**

LHCLIENTDOC *lhClientDoc;* /* handle of client document */

The **OleRevokeClientDoc** function informs the client library that a document is no longer open.

Parameter	Description
lhClientDoc	Identifies the document that is no longer open. This handle is invalid following the call to **OleRevokeClientDoc**.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_ERROR_NOT_EMPTY

Comments

The client application should delete all the objects in a document before calling **OleRevokeClientDoc**.

Client applications should register open documents with the library and notify the library when a document is renamed, closed, saved, or restored to a changed state.

See Also

OleRegisterClientDoc, **OleRenameClientDoc**, **OleRevertClientDoc**, **OleSavedClientDoc**

OleRevokeServerDoc (3.1)

#include ole.h

OLESTATUS OleRevokeServerDoc(*lhdoc***)**

LHSERVERDOC *lhdoc;* /* document handle */

The **OleRevokeServerDoc** function revokes the specified document. A server application calls this function when a registered document is being closed or otherwise made unavailable to client applications.

Parameter	Description
lhdoc	Identifies the document to revoke. This handle was returned by a call to the **OleRegisterServerDoc** function or was associated with a document by using one of the server-supplied functions that create documents.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_WAIT_FOR_RELEASE

Comments

If this function returns OLE_WAIT_FOR_RELEASE, the server application should not free the **OLESERVERDOC** structure or exit until the library calls the server's **Release** function.

See Also

OleRegisterServerDoc, **OleRevokeObject**, **OleRevokeServer**, **OLESERVERDOC**

OleRevokeObject (3.1)

#include ole.h

OLESTATUS OleRevokeObject(*lpClient***)**

LPOLECLIENT *lpClient;* /* address of OLECLIENT structure */

The **OleRevokeObject** function revokes access to an object. A server application typically calls this function when the user destroys an object.

Parameter	**Description**
lpClient	Points to the **OLECLIENT** structure associated with the object being revoked.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value.

See Also

OleRevokeServer, **OleRevokeServerDoc**

OleRevokeServer (3.1)

#include ole.h

OLESTATUS OleRevokeServer(*lhServer***)**

LHSERVER *lhServer;* /* server handle */

The **OleRevokeServer** function is called by a server application to close any registered documents.

Parameter	Description
lhServer	Identifies the server to revoke. A server application obtains this handle in a call to the **OleRegisterServer** function.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_WAIT_FOR_RELEASE

Comments

The **OleRevokeServer** function returns OLE_WAIT_FOR_RELEASE if communications between clients and the server are in the process of terminating. In this case, the server application should continue to send and dispatch messages until the library calls the server's **Release** function.

See Also

OleRegisterServer, **OleRevokeObject**, **OleRevokeServerDoc**

OleSavedClientDoc (3.1)

#include ole.h

OLESTATUS OleSavedClientDoc(*lhClientDoc***)**

LHCLIENTDOC *lhClientDoc;* /* handle of client document */

The **OleSavedClientDoc** function informs the client library that a document has been saved.

Parameter	Description
lhClientDoc	Identifies the document that has been saved.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.

Comments

Client applications should register open documents with the client library and notify the library when a document is renamed, closed, saved, or restored to a saved state.

See Also

OleRegisterClientDoc, **OleRenameClientDoc**, **OleRevertClientDoc**, **OleRevokeClientDoc**

OleSavedServerDoc (3.1)

#include ole.h

OLESTATUS OleSavedServerDoc(*lhDoc***)**

LHSERVERDOC *lhDoc;* /* handle of document */

The **OleSavedServerDoc** function informs the server library that a document has been saved.

Parameter	Description
lhDoc	Identifies the document that has been saved.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CANT_UPDATE_CLIENT
OLE_ERROR_HANDLE

Comments

The **OleSavedServerDoc** function has the same effect as sending the OLE_SAVED notification to the client application's callback function. The server application calls this function when saving a document or when updating an embedded object without closing the document.

When a server application receives the OLE_ERROR_CANT_UPDATE_CLIENT error value, it should display a message box indicating that the user cannot update the document until the server terminates.

Server applications should register open documents with the server library and notify the library when a document is renamed, closed, saved, or restored to a saved state.

See Also

OleRegisterServerDoc, **OleRenameServerDoc**, **OleRevertServerDoc**, **OleRevokeServerDoc**

OleSaveToStream (3.1)

#include ole.h

OLESTATUS OleSaveToStream(*lpObject, lpStream***)**

LPOLEOBJECT *lpObject;* /* address of object to save */
LPOLESTREAM *lpStream;* /* address of OLESTREAM structure */

The **OleSaveToStream** function saves an object to the stream.

Parameter	Description
lpObject	Points to the object to be saved to the stream.
lpStream	Points to an **OLESTREAM** structure allocated and initialized by the client application. The library calls the **Put** function in the **OLESTREAM** structure to store the data from the object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_BLANK
OLE_ERROR_MEMORY
OLE_ERROR_OBJECT
OLE_ERROR_STREAM

Comments

An application can use the **OleQuerySize** function to find the number of bytes to allocate for the object.

See Also

OleLoadFromStream, **OleQuerySize**

OleSetBounds (3.1)

#include ole.h

OLESTATUS OleSetBounds(*lpObject, lprcBound***)**

LPOLEOBJECT *lpObject;* /* address of object */
RECT FAR* *lprcBound;* /* address of structure for bounding rectangle */

The **OleSetBounds** function sets the coordinates of the bounding rectangle for the specified object on the target device.

Parameter	Description
lpObject	Points to the object for which the bounding rectangle is set.
lprcBound	Points to a **RECT** structure containing the coordinates of the bounding rectangle. The coordinates are specified in MM_HIMETRIC units. Neither the width nor height of an object should exceed 32,767 MM_HIMETRIC units.

Returns
The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_MEMORY
OLE_ERROR_OBJECT
OLE_WAIT_FOR_RELEASE

The **OleSetBounds** function returns OLE_ERROR_OBJECT when it is called for a linked object.

Comments
The **OleSetBounds** function is ignored for linked objects, because the size of a linked object is determined by the source document for the link.

A client application uses **OleSetBounds** to change the bounding rectangle. The client does not need to call **OleSetBounds** every time a server is opened.

The bounding rectangle specified in the **OleSetBounds** function does not necessarily have the same dimensions as the rectangle specified in the call to the **OleDraw** function. These dimensions may be different because of the view scaling used by the container application. An application can use **OleSetBounds** to cause the server to reformat the picture to fit the rectangle more closely.

In the MM_HIMETRIC mapping mode, the positive y-direction is up.

See Also
OleDraw, **OleQueryBounds**, **SetMapMode**, **RECT**

OleSetColorScheme (3.1)

#include ole.h

OLESTATUS OleSetColorScheme(*lpObject, lpPalette***)**

LPOLEOBJECT *lpObject;* /* address of object */
const LOGPALETTE FAR* *lpPalette;* /* address of preferred palette */

The **OleSetColorScheme** function specifies the palette a client application recommends be used when the server application edits the specified object. The server application can ignore the recommended palette.

Parameter	Description
lpObject	Points to an **OLEOBJECT** structure describing the object for which a palette is recommended.
lpPalette	Points to a **LOGPALETTE** structure specifying the recommended palette.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_COMM
OLE_ERROR_MEMORY
OLE_ERROR_OBJECT
OLE_ERROR_PALETTE
OLE_ERROR_STATIC
OLE_WAIT_FOR_RELEASE

The **OleSetColorScheme** function returns OLE_ERROR_OBJECT when it is called for a linked object.

Comments

A client application uses **OleSetColorScheme** to change the color scheme. The client does not need to call **OleSetColorScheme** every time a server is opened.

The first palette entry in the **LOGPALETTE** structure specifies the foreground color recommended by the client application. The second palette entry specifies the background color. The first half of the remaining palette entries are fill colors, and the second half are colors for lines and text.

Client applications should specify an even number of palette entries. When there is an uneven number of entries, the server interprets the odd entry as a fill color; that is, if there are five entries, three are interpreted as fill colors and two as line and text colors.

When server applications render metafiles, they should use the suggested palette.

See Also

LOGPALETTE

OleSetData (3.1)

#include ole.h

OLESTATUS OleSetData(*lpObject, cfFormat, hData***)**

```
LPOLEOBJECT lpObject;          /* address of object          */
OLECLIPFORMAT cfFormat;        /* format of data to send     */
HANDLE hData;                  /* memory containing data     */
```

The **OleSetData** function sends data in the specified format to the server associated with a specified object.

Parameter	Description
lpObject	Points to an object specifying the server to which data is to be sent.
cfFormat	Specifies the format of the data.
hData	Identifies a memory object containing the data in the specified format.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_BLANK
OLE_ERROR_MEMORY
OLE_ERROR_NOT_OPEN
OLE_ERROR_OBJECT
OLE_WAIT_FOR_RELEASE

If the specified object cannot accept the data, the function returns an error value. If the server is not open and the requested data format is different from the format of the presentation data, the return value is OLE_ERROR_NOT_OPEN.

See Also

OleGetData, **OleRequestData**

OleSetHostNames (3.1)

#include ole.h

OLESTATUS OleSetHostNames(*lpObject, lpszClient, lpszClientObj***)**

```
LPOLEOBJECT lpObject;      /* address of object                          */
LPCSTR lpszClient;         /* address of string with name of client app  */
LPCSTR lpszClientObj;      /* address of string with client's name for object */
```

The **OleSetHostNames** function specifies the name of the client application and the client's name for the specified object. This information is used in window titles when the object is being edited in the server application.

Parameter	Description
lpObject	Points to the object for which a name is to be set.
lpszClient	Points to a null-terminated string specifying the name of the client application.
lpszClientObj	Points to a null-terminated string specifying the client's name for the object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_MEMORY
OLE_ERROR_OBJECT
OLE_WAIT_FOR_RELEASE

The **OleSetHostNames** function returns OLE_ERROR_OBJECT when it is called for a linked object.

Comments

When a server application is started for editing of an embedded object, it displays in its title bar the string specified in the *lpszClientObj* parameter. The object name specified in this string should be the name of the client document containing the object.

A client application uses **OleSetHostNames** to set the name of an object the first time that object is activated or to change the name of an object. The client does not need to call **OleSetHostNames** every time a server is opened.

OleSetLinkUpdateOptions (3.1)

#include ole.h

OLESTATUS OleSetLinkUpdateOptions(*lpObject, UpdateOpt***)**

LPOLEOBJECT *lpObject;* /* address of object */
OLEOPT_UPDATE *UpdateOpt;* /* link-update options */

The **OleSetLinkUpdateOptions** function sets the link-update options for the presentation of the specified object.

Parameter	Description
lpObject	Points to the object for which the link-update option is set.
UpdateOpt	Specifies the link-update option for the specified object. This parameter can be one of the following values:

Option	Description
oleupdate_always	Update the linked object whenever possible. This option supports the Automatic link-update radio button in the Links dialog box.
oleupdate_oncall	Update the linked object only on request from the client application. This option supports the Manual link-update radio button in the Links dialog box.
oleupdate_onsave	Update the linked object when the source document is saved by the server.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_OBJECT
OLE_ERROR_OPTION
OLE_ERROR_STATIC
OLE_WAIT_FOR_RELEASE

See Also

OleGetLinkUpdateOptions

OleSetTargetDevice (3.1)

#include ole.h

OLESTATUS OleSetTargetDevice(*lpObject, hotd***)**

```
LPOLEOBJECT lpObject;     /* address of object                        */
HGLOBAL hotd;             /* handle of OLETARGETDEVICE structure      */
```

The **OleSetTargetDevice** function specifies the target output device for an object.

Parameter	Description
lpObject	Points to the object for which a target device is specified.
hotd	Identifies an **OLETARGETDEVICE** structure that describes the target device for the object.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_MEMORY
OLE_ERROR_OBJECT
OLE_ERROR_STATIC
OLE_WAIT_FOR_RELEASE

Comments

The **OleSetTargetDevice** function allows a linked or embedded object to be formatted correctly for a target device, even when the object is rendered on a different device. A client application should call this function whenever the target device changes, so that servers can be notified to change the rendering of the object, if necessary. The client application should call the **OleUpdate** function to ensure that the information is sent to the server, so that the server can make the necessary changes to the object's presentation. The client application should call the library to redraw the object if it receives a notification from the server that the object has changed.

A client application uses the **OleSetTargetDevice** function to change the target device. The client does not need to call **OleSetTargetDevice** every time a server is opened.

OLETARGETDEVICE

OleUnblockServer (3.1)

#include ole.h

OLESTATUS OleUnblockServer(*lhSrvr, lpfRequest***)**

LHSERVER *lhSrvr;* /* handle of server */
BOOL FAR* *lpfRequest;* /* address of flag for more requests */

The **OleUnblockServer** function processes a request from a queue created by calling the **OleBlockServer** function.

Parameter	Description
lhSrvr	Identifies the server for which requests were queued.
lpfRequest	Points to a flag indicating whether there are further requests in the queue. If there are further requests in the queue, this flag is TRUE when the function returns. Otherwise, it is FALSE when the function returns.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_ERROR_MEMORY

Comments

A server application can use the **OleBlockServer** and **OleUnblockServer** functions to control when the server library processes requests from client applications. It is best to use **OleUnblockServer** outside the **GetMessage** function in a message loop, unblocking all blocked messages before getting the next message. Unblocking message loops should not be run inside server-defined functions that are called by the library.

See Also

OleBlockServer

OleUnlockServer (3.1)

#include ole.h

OLESTATUS OleUnlockServer(*hServer***)**

LHSERVER *hServer;* /* handle of server to unlock */

The **OleUnlockServer** function unlocks a server that was locked by the **OleLockServer** function.

Parameter	Description
hServer	Identifies the server to release from memory. This handle was retrieved by a call to the **OleLockServer** function.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE
OLE_WAIT_FOR_RELEASE

Comments

When the **OleLockServer** function is called more than once for a given server, the server's lock count is incremented. Each call to **OleUnlockServer** decrements the lock count. The server remains locked until the lock count is zero.

If the **OleUnlockServer** function returns OLE_WAIT_FOR_RELEASE, the application should call the **OleQueryReleaseStatus** function to determine whether the unlocking process has finished. In the call to **OleQueryReleaseStatus**, the application can cast the server handle to a long pointer to an object linking and embedding (**OLE**) object (**LPOLEOBJECT**):

```
OleQueryReleaseStatus((LPOLEOBJECT) lhserver);
```

When **OleQueryReleaseStatus** no longer returns OLE_BUSY, the server has been unlocked.

See Also

OleLockServer, **OleQueryReleaseStatus**

OleUpdate (3.1)

#include ole.h

OLESTATUS OleUpdate(*lpObject***)**

LPOLEOBJECT *lpObject;* /* address of object */

The **OleUpdate** function updates the specified object. This function updates the presentation of the object and ensures that the object is up-to-date with respect to any linked objects it contains.

Parameter	Description
lpObject	Points to the object to be updated.

Returns

The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY
OLE_ERROR_OBJECT
OLE_ERROR_STATIC
OLE_WAIT_FOR_RELEASE

OleQueryOutOfDate

OLE functions (3.1)

OleActivate	Activates an object
OleBlockServer	Queues incoming requests for the server
OleClone	Makes a copy of an object
OleClose	Closes a specified open object
OleCopyFromLink	Makes an embedded copy of a linked object
OleCopyToClipboard	Puts the specified object on the clipboard
OleCreate	Creates an embedded object of a specified class
OleCreateFromClip	Creates an object from the clipboard
OleCreateFromFile	Creates an embedded object from a file
OleCreateFromTemplate	Creates an object from a template
OleCreateInvisible	Creates an object without displaying it
OleCreateLinkFromClip	Creates link to object from the clipboard
OleCreateLinkFromFile	Creates a link to an object in a file
OleDelete	Deletes an object and frees associated memory
OleDraw	Draws a specified object into a device context
OleEnumFormats	Enumerates data formats for an object
OleEnumObjects	Enumerates objects in a document
OleEqual	Compares two objects for equality
OleExecute	Sends DDE execute commands to a server
OleGetData	Retrieves data from an object in a specified format
OleGetLinkUpdateOptions	Retrieves link-update options for an object
OleIsDcMeta	Identifies a metafile device context
OleLoadFromStream	Loads an object from the containing document
OleLockServer	Keeps an open server application in memory
OleObjectConvert	Creates a new object using a specified protocol
OleQueryBounds	Retrieves a bounding rectangle for the object
OleQueryClientVersion	Retrieves the version number of a client library
OleQueryCreateFromClip	Retrieves presentation data for a clipboard object
OleQueryLinkFromClip	Retrieves link data for a clipboard object
OleQueryName	Retrieves the name of an object
OleQueryOpen	Determines whether an object is open
OleQueryOutOfDate	Determines whether an object is out-of-date
OleQueryProtocol	Determines whether an object supports a protocol
OleQueryReleaseError	Determines the status of a released operation
OleQueryReleaseMethod	Determines which server operation released
OleQueryReleaseStatus	Determines whether an operation released
OleQueryServerVersion	Retrieves the version number of a server library
OleQuerySize	Retrieves the size of an object
OleQueryType	Checks if object is linked, embedded, or static
OleReconnect	Reconnects to an open linked object
OleRegisterClientDoc	Registers an open client document with the library
OleRegisterServerDoc	Registers a document with the server library
OleRegisterServer	Registers the specified server
OleRelease	Releases an object from memory and closes it
OleRename	Informs library that an object is renamed
OleRenameClientDoc	Informs library that a document is renamed
OleRenameServerDoc	Informs library that a document is renamed
OleRequestData	Retrieves data from a server in a specified format
OleRevertClientDoc	Informs library that a doc reverted to saved state
OleRevertServerDoc	Informs library that a doc is reset to saved state
OleRevokeClientDoc	Informs library that a document is not open
OleRevokeServerDoc	Revokes the specified document
OleRevokeObject	Revokes access to an object
OleRevokeServer	Revokes the specified server
OleSavedClientDoc	Informs library that a document has been saved

OleSavedServerDoc	Informs library that a document has been saved
OleSaveToStream	Saves an object to the stream
OleSetBounds	Sets a bounding rectangle for the object
OleSetColorScheme	Specifies a client's recommended object colors
OleSetData	Sends data in specified format to server
OleSetHostNames	Sets the client name and object name for a server
OleSetLinkUpdateOptions	Sets link-update options for an object
OleSetTargetDevice	Sets target output device for an object
OleUnblockServer	Processes requests from a queue
OleUnlockServer	Releases a server locked with OleLockServer
OleUpdate	Updates an object

Windows Overviews (3.1)

File Formats (3.1)

Video Techniques

This topic describes some techniques that can improve the video performance of applications for the Microsoft Windows operating system. These techniques include using an identity palette to speed up image drawing, accommodating differences in video adapters, and modifying device-independent bitmaps (DIBs) by using the DIB driver.

Using an Identity Palette

Windows reserves a group of system palette entries for a fixed number of colors. These colors, which are named system colors, are used for drawing screen elements such as scroll bars. Windows also uses the system colors as replacement color entries when inactive windows request more color entries than are available in the system palette. Windows places the system colors at the top and bottom of the system palette to ensure that logical operations (such as XOR) work correctly.

By arranging logical palettes the same way that Windows arranges the system palette, you can avoid unexpected color changes and improve the speed at which your application draws DIBs. To do this, you must create an identity palette, a logical palette that matches the system palette. To use identity palettes, however, you need to understand how Windows sets up the system palette.

Understanding the System Palette

When an application realizes a palette (that is, requests the palette be given specified colors), Windows adds the logical palette entries to the system palette. Windows always reserves system palette entries for the system colors. For example, a 256-color video graphics adapter (VGA) driver with 20 system colors allows an application to use a maximum of 236 system palette entries. If a logical palette contains more entries than can fit in the system palette (after the system colors are added), Windows truncates the palette, using only as many colors as it can fit without encroaching on the reserved system colors. You can force Windows to relinquish the system color entries (by using the **SetSystemPaletteUse** function), but by doing so you change the coloring of all Windows screen elements to black and white.

The maximum number of colors available to a foreground window equals the number of colors supported by the video driver minus the number of system reserved colors and the number of palette entries reserved by the application.

Windows places the system colors at the top and bottom of the system palette. For example, a 256-color VGA driver uses the top 10 and bottom 10 system palette entries for the system colors. If a logical palette does not contain the system colors or if the system colors appear in locations other than the default positions, Windows changes the ordering of the palette entries when your application realizes its palette. At this point, logical palette entry *n* does not necessarily match system palette entry *n.* When your application draws a bitmap to the device context, Windows must translate the bitmap palette indices to the new locations on the system palette. This translation step takes time.

The goal is to make the logical palette exactly match the system palette. By doing so, your images can be colored exactly as you expect. The video driver can also draw the images faster because the translation step is avoided.

Creating an Identity Palette

An identity palette is a logical palette that exactly matches the system palette and therefore has the same number of entries as the system palette and includes color entries for the system colors. The system colors appear at the top and bottom of the color table.

The Microsoft Windows Paintbrush application always saves bitmaps with an identity palette. To convert a bitmap palette to an identity palette, you can open the bitmap in Paintbrush and then save it.

Accommodating Different Video Adapters and Drivers

This section contains information on adapting your logical palette to a different display type.

Distinguishing Between Standard VGA and Super VGA

Most super VGA adapters are single-plane devices, which makes them well-suited for displaying DIBs. On a super VGA adapter, there is little speed difference between drawing DIBs and drawing device-dependent bitmaps--you can choose whichever format is more convenient for your application.

Standard VGA adapters have multiple planes and are not as well suited for displaying DIBs. It is faster to work with device-dependent bitmaps on standard VGA. To determine whether a standard VGA adapter is present, use the following code:

```
hDC = CreateDC("DISPLAY", NULL, NULL, NULL);

bIsMultiplane = (GetDeviceCaps(hDC, PLANES) > 1);

DeleteDC(hDC);
```

Adapting Identity Palettes to Different Display Adapters

Even if two display devices use the same number of system colors, you cannot assume that the red, green, and blue (**RGB**) values for the low-intensity colors match. One particular problem is the difference between super VGA and 8514 systems. Both provide 256 colors and use 20 system colors, but the low-intensity system color values for the VGA are different from those for the 8514. An identity palette created on a VGA system is not the same as an identity palette on an 8514 system.

If you create an identity palette on a VGA system and then display the DIB on an 8514 system, Windows recognizes the low-intensity colors in the logical palette as custom colors rather than system colors. It puts these colors in the custom-color section of the palette (in entries 10 through 245) and the 8514 system colors in the top and bottom of the system palette.

To avoid misrecognition of colors, an application can do the following:

1 When the application loads, it should use the **GetSystemColors** function to retrieve the system colors from the system palette and compare these colors against the system colors used in the DIB palettes.

2 If the colors do not match, the application should copy the current system colors (retrieved from the system palette) over the DIB system colors.

Using a Device-Independent Bitmap Driver

Many MS-DOS applications manipulate screen memory directly. To maintain the device independence of Windows, it is not possible to allow an application to access screen memory directly. However, an application can use the DIB driver (DIB.DRV) to directly manipulate an image in memory.

Creating a Driver Display Context

An application can load the DIB driver by passing the DIB driver name and a **BITMAPINFO** structure containing the DIB bits to the **CreateDC** function. For example, the following example creates a DIB display context that represents the packed DIB described by the **BITMAPINFO** structure *bi:*

```
hdc = CreateDC("DIB", NULL, NULL, &bi);
```

An application must observe the following rules when working with a device context created in this manner:

- If the last parameter of **CreateDC** is NULL, the display context is associated with a 0-by-0 8-bit DIB. Any attempt to draw with it will fail.
- The **BITMAPINFO** structure must remain locked for the life of the device context.
- The DIB driver supports 1-bit, 4-bit, or 8-bit DIB bitmaps. The run-length encoding (RLE) format is not supported.
- The DIB driver supports only Windows version 3.0 or later DIB headers.
- Multiple DIB-driver display contexts can be active.

- DIBs reside in the memory-based image buffer in the CF_DIB (packed-DIB) format.
- The DIB driver expects the **RGBQUAD** structure for color matching; it does not use palette indices. (If an application uses an **RGB** value for drawing, the DIB driver uses the closest match found in the color table of the DIB.)

The following example uses the DIB driver to draw a circle in a DIB copied from the clipboard:

```
if (IsClipboardFormatAvailable(CF_DIB) && OpenClipboard()) {
    HANDLE hdib;
    HDC     hdc;

    /* Get the DIB from the clipboard.             */

    hdib = GetClipboardData(CF_DIB);

    /* Create a DIB driver hdc on the DIB surface. */

    hdc = CreateDC("DIB", NULL, NULL,
        (LPBITMAPINFO) GlobalLock(hdib));

    /* Draw a circle in the DIB.                   */

    Ellipse(hdc, 0, 0, 100, 100);

    /* Delete the DIB driver HDC now that you are done with it. */

    DeleteDC(hdc);

    /* Unlock the DIB.                             */

    GlobalUnlock(hdib);

    /* Release the clipboard.                      */

    CloseClipboard();
}
```

Moving Bitmaps to and from the Display

The DIB driver is a separate driver and is not associated with the display driver. Because of this, an application cannot use the **BitBlt** function to move bitmaps between a DIB-driver device context and a screen device context. An application can use the **GetDIBits** function to copy from the screen device context to a DIB device context. To copy a DIB device context to the screen device context, an application can use the **StretchDIBits** function.

An application can maximize the speed of **StretchDIBits** by using one of the following methods:

- One-to-one mapping for the palette
- **DIB_PAL_COLORS**, an option that prevents color matching by the graphics device interface (GDI)

Modifying Bitmaps

DIBs offer many advantages over device-dependent bitmaps. Unlike device-dependent bitmaps, however, DIBs cannot be selected into a video device context. Before the DIB driver was available, this meant that applications could not take advantage of the extensive graphics device interface (GDI) functions to modify DIBs directly. To use GDI routines to draw in or otherwise modify a DIB, an application would follow a procedure such as this:

1 Create a memory device context.

2 Use the **CreateDIBitmap** function to convert the DIB to device-dependent format.

3 Select the device-dependent bitmap into the memory device context.

4 Call GDI routines to modify the device-dependent bitmap.

5 Use the **GetDIBits** function to convert the device-dependent bitmap to DIB format.

This method works well if you only use GDI routines to modify the bitmap. If you want to speed up certain operations by writing replacement functions that directly modify the DIB bits, however, the procedure can become complicated. The direct-manipulation routines work on the DIB, but the GDI routines work on the device-dependent bitmap.

Direct manipulation can be considerably faster than using equivalent GDI routines; in one sample application, a direct-manipulation function (drawing a triangle) ran eight times faster than the equivalent GDI operation. Also, direct-manipulation routines for other products may be reusable.

The DIB driver makes it possible for you to mix GDI calls with direct-manipulation routines, so you can combine the advantages of both methods.

Creating a Driver Device Context

The DIB driver makes it possible for you to create a DIB device context. To create the DIB device context, call the **CreateDC** function, supplying a pointer to a **BITMAPINFO** structure:

```
hdc = CreateDC("DIB", NULL, NULL, lpbi);
```

You can use the device-context handle returned by the **CreateDC** function with most GDI functions to modify the bitmap. Concurrently, you can call your own direct-manipulation functions to modify the actual bitmap bits. Any changes made directly to the bitmap bits are reflected in the DIB-driver device context. When you finish modifying the bitmap, you can use the **StretchDIBits** function to transfer the DIB to the video device context.

The DIB driver can handle 1-bit, 4-bit, or 8-bit DIBs. You can create multiple DIB driver contexts. Note the following limitations:

1 The **BITMAPINFO** structure must be locked for the life of the device context.

2 The DIB driver handles only the Windows **BITMAPINFOHEADER** format.

3 The RLE format is not supported.

4 The DIB must use the **DIB_RGB_COLORS** format. The DIB driver does not support the **DIB_PAL_COLORS** (palette indexes) format.

You can distribute the DIB driver with applications that run under Windows.

Fonts Overview

This topic describes the fonts an application can use with the Microsoft Windows 3.1 operating system and discusses how to use Windows font functions in applications. The information includes a description of TrueType font technology, which is new for Windows 3.1.

The following topics discuss the use of fonts in Windows applications:

Font Fundamentals
Fonts in Windows
TrueType Font Technology
Using Fonts in Applications

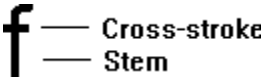
Font Fundamentals

The vocabulary used to describe fonts may be unfamiliar to application developers. This section defines some of the terms and concepts that a developer needs to use when describing a font.

Font Organization

A typeface is a collection of characters that share design characteristics; for example, Courier is a common typeface. A font is a collection of characters that have the same typeface and size.

The Windows graphics device interface (GDI) organizes fonts by family; each family consists of fonts that have a common design. Families are distinguished by stroke width and serif characteristics. A stroke is a horizontal or vertical line. A horizontal stroke is called a cross-stroke. The main vertical line in a character is called a stem.



Serifs are short cross-lines drawn at the ends of the main strokes of a letter. Typefaces without serifs are called sans serif typefaces.

Within a font family, fonts are distinguished by stylistic variations that generally involve their weight and slant. Weights are described by adjectives such as "extra light," "light," "demi," "demi bold," "book," "bold," "heavy bold," "extra bold," and "black." The slant of a font is described by "roman," "italic," and "oblique." A roman font is the upright form of the font; an oblique font is slanted; and an italic font is both slanted and relatively cursive. Font families usually do not include both italic and oblique fonts.

GDI uses five family names to categorize typefaces and fonts. A sixth name (FF_DONTCARE) allows an application to use the default font. Following are the font-family names, each described briefly:

Font-family name	Description
FF_DECORATIVE	Specifies a novelty font. An example is Old English.
FF_DONTCARE	Specifies a generic family name. This name is used when information about a font does not exist or does not matter.
FF_MODERN	Specifies a font that has a constant stroke width, with or without serifs. Fixed-pitch fonts are usually modern; examples include Pica, Elite, and Courier New®.
FF_ROMAN	Specifies a font that has a variable stroke width, with serifs. An example is Times New Roman®.
FF_SCRIPT	Specifies a font that is designed to look like handwriting; examples include Script and Cursive.
FF_SWISS	Specifies a font that has a variable stroke width, without serifs. An example is Arial®.

GDI family names do not always correspond to traditional typographic categories.

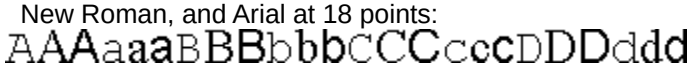
Measuring Characters

Both the visible and invisible parts of a character affect its measurement. The visible part of a character is called a glyph. The invisible part is a rectangular region that contains the character; this region is called a character cell. The origin of a character cell is its upper-left corner. When a text-output function specifies coordinates at which the text should appear, GDI places the origin of the first character cell at those coordinates. (This is the default behavior for GDI. An application can change

this at any time by using the **SetTextAlign** function.)

The most common unit of measurement for measuring characters is the point. In the computer industry, a point is exactly 1/72 of an inch. Font heights in Windows can be specified in "twips," which are 1/20 of a point (that is, 1/1440 of an inch). Point size refers to the size of the character cell, but only loosely to the size of the visible characters; the glyphs from different 12-point fonts can have different heights.

The following example shows the different font heights in alternating glyphs from Courier New, Times New Roman, and Arial at 18 points:



Following are some of the character-cell measurements an application can affect or query when it creates a font:

Measurement	Description
Ascent	Specifies the distance from the base line to the top of a character. The ascender of a character is the part of the character above the base line. In Windows, the value for the ascent is the distance from the base line to the top of the character cell; this can include white space. The typographic ascent, on the other hand, corresponds to the tallest character in a font. For TrueType fonts, this character is often the lowercase "f."
Base line	Specifies the line on which all characters stand. The base line is typically the lowest point of most of the capital letters in a font. (Though the tail of the "Q," for example, can extend below the base line.)
Descent	Specifies the distance from the base line to the bottom of a character. The descender of a character is the part of the character below the base line. For example, the tail of the letter "g" is a descender. In Windows, the value for the descent is the distance from the base line to the bottom of the character cell; this can include white space. The typographic descent, on the other hand, corresponds to the character in a font that extends farthest beneath the base line. For TrueType fonts, this character is often the lowercase "g."
Height	Specifies the vertical space required for a font. The height of a font is the sum of the ascent, descent, and internal leading for that font.
Width	Specifies the horizontal space required for a character cell in a font. GDI returns widths for the average character cell in a font and for the widest character cell. The average width can be simple or weighted, depending on the font. An application can also retrieve the widths for individual characters. These widths include the empty space preceding and following the glyph.

Measuring Line and Intercharacter Spacing

Line spacing, like character size, is typically specified in points. If a 10-point font is displayed with 12-point line spacing, this is abbreviated as "10/12" and is called "ten on twelve" line spacing.

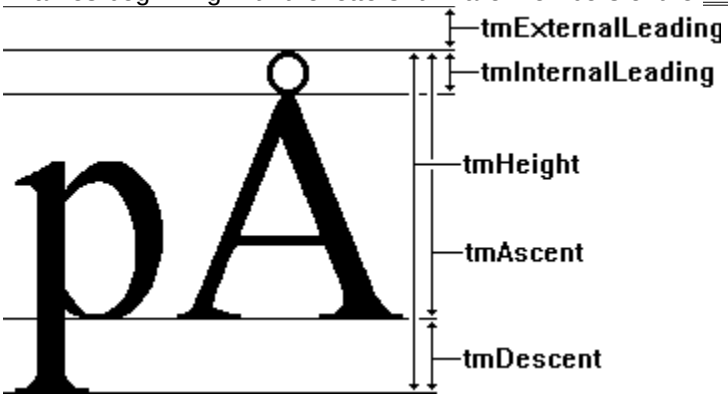
Following are some of the line and intercharacter measurements an application can affect or query when it creates a font:

Measurement	Description
External leading	Specifies the space between rows of text. External leading is not part of the character cell. When the internal leading for a font does not contain parts of characters, the apparent line spacing is the external leading plus the internal leading. Windows does not support negative values for external leading.
Internal leading	Specifies the difference between the height of the character glyphs for a font (the font's em square) and the height of the character cell for a font. Applications use internal leading to determine the point size for a font; the point size is the height of

	the character cell minus its internal leading. Some applications have used internal leading incorrectly; specifically, internal leading is not strictly reserved for diacritical marks, nor should it be used as the space to be removed from the first line on a page.
Overhang	Specifies a characteristic of some glyphs that occupy the same horizontal space as adjacent glyphs. All of the characters in most italic fonts use overhangs to keep the characters relatively close together--for example, in the italic word *Is,* the top part of the letter "I" is directly over the bottom of the letter "s."
Pitch	Specifies the general type of horizontal character spacing. A font can have either fixed or variable pitch. The character cells in a fixed-pitch font are all the same size, but in a variable-pitch font they vary depending on the width of the glyph. Another term for a fixed-pitch font is a monospace font.

The external leading for a font is specified by the designers of the font. The concept of internal leading is specific to Windows.

The following figure shows internal and external leading and their relationship to the height of a font. The names beginning with the letters "tm" are members of the **TEXTMETRIC** structure.



Character Sets

All fonts use a character set. A character set contains punctuation marks, numerals, uppercase and lowercase letters, and all other printable characters. Each element of a character set is identified by a number.

Most character sets used in Windows are supersets of the U.S. ASCII character set, which defines characters for the 96 numeric values from 32 through 127. There are four major groups of character sets:

- Windows
- OEM
- Symbol
- Vendor-specific

Windows Character Set

The Windows character set is the most commonly used character set in Windows programming. It is essentially equivalent to the ANSI character set. The blank character is the first character in the Windows character set. It has a hexadecimal value of 0x20 (decimal 32). The last character in the Windows character set has a hexadecimal value of 0xFF (decimal 255).

Many fonts specify a default character. Whenever a request is made for a character that is not in the font, GDI provides this default character. Many fonts using the Windows character set specify the period (.) as the default character. TrueType fonts typically use an open box as the default character.

Fonts use a break character to separate words and justify text. Most fonts using the Windows

character set specify the blank character, whose hexadecimal value is 0x20 (decimal 32).

For Windows version 3.1, 24 characters have been added to the Windows code page:

Character	Name	Windows character code
‚	base line single quote	130
f	florin	131
„	base line double quote	132
…	ellipsis	133
†	dagger	134
‡	double dagger	135
ˆ	circumflex	136
‰	permille	137
Š	S Hacek	138
‹	left single guillemet	139
Œ	OE ligature	140
‘	left single quote	145
’	right single quote	146
“	left double quote	147
”	right double quote	148
•	bullet	149
–	en dash	150
—	em dash	151
˜	tilde	152
™	trademark ligature	153
š	s Hacek	154
›	right single guillemet	155
œ	oe ligature	156
Ÿ	Y Dieresis	159

The characters for left and right single quote were added to the character set for the release of Windows version 3.0.

OEM Character Set

The OEM character set is typically used in full-screen MS-DOS sessions for screen display. Characters 32 through 127 are usually the same in the OEM, U.S. ASCII, and Windows character sets. The other characters in the OEM character set (0 through 31 and 128 through 255) correspond to the characters that can be displayed in a full-screen MS-DOS session. These characters are generally different from the Windows characters.

Symbol Character Set

The Symbol character set contains special characters typically used to represent mathematical and scientific formulas.

Vendor-Specific Character Sets

Many printers and other output devices provide fonts based on character sets that differ from the Windows and OEM sets--for example, the EBCDIC character set. To use one of these character sets, the printer driver translates from the Windows character set to the vendor-specific character set.

Fonts in Windows

Windows applications can use three different kinds of font technologies to display and print text. This section discusses these font technologies and gives Windows-specific background information about fonts.

Raster, Vector, and TrueType Fonts

Previous versions of Windows had two types of fonts: raster and vector. Windows version 3.1 introduces a third type--TrueType fonts.

Raster fonts are stored as bitmaps. These bitmaps are designed for output devices of a particular resolution. GDI typically synthesizes bold, italic, underline, and strikeout characteristics for raster fonts; however, the results are not always attractive. When GDI must change the size of a raster font, aliasing problems can also reduce the attractiveness of the text. Raster fonts are useful for specialized applications in which TrueType fonts are not available. Another possible advantage to using raster fonts derives from the large number of raster fonts that are often present on a user's system; an application could look for the name of a particular specialized or decorative font and use a TrueType font if the specified font was not present.

When an application requests an italic or bold font that is not available, GDI synthesizes the font by transforming the character bitmaps. When an application using only raster fonts requests a point size that is not available, GDI also transforms the bitmaps to produce the font. Because TrueType font families include bold, italic, and bold italic fonts, and because TrueType fonts are scalable to any requested point size, GDI does not synthesize fonts as frequently as it did for earlier versions of Windows.

Windows version 3.1 contains a new set of raster fonts. This set, called Small Fonts, is for use at resolutions of less than 8 points. Although TrueType fonts can be scaled to less than 8 points, glyphs this small may not be legible enough for regular use. Because glyphs this small contain very little detail, it is more efficient to use the raster small fonts than to scale TrueType fonts to the small size. (GDI synthesizes bold and italic attributes for the raster small fonts, when necessary.)

Vector fonts are stored as collections of GDI calls. They are time-consuming to generate but are useful for such devices as plotters, on which bitmapped characters cannot be used. (By drawing lines, GDI can simulate vector fonts on a device that does not directly support them.) Prior to the introduction of TrueType fonts, vector fonts were also useful for applications that used very large or distorted characters or characters that needed to be perpendicular to a base line that was at an angle across the display surface.

TrueType fonts are stored as collections of points and hints that define character outlines. (Hints are algorithms that distort scaled font outlines to improve the appearance of the bitmaps at specific resolutions.) When an application requests a TrueType font, the TrueType rasterizer uses the outline and the hints to produce a bitmap of the size requested by the application.

The default font for a device context is the System font, a proportionally spaced raster font representing characters in the Windows character set. Its font name is System. Windows uses the System font for menus, window titles, and other text.

It is possible to have multiple fonts in the system that have the same name (for example, a Courier device font and a Courier GDI raster font). However, applications typically do not present a font name to the user more than once--instead, they discard duplicates. Applications can control which font is presented to the user when duplicate font names occur by using the **lfOutPrecision** member of the **LOGFONT** structure.

Font Resource Files

The SYSTEM subdirectory of a user's Windows directory (the directory in which Windows is installed) contains the system's font resource files. A font resource file is an empty Windows library; it contains no code or data but does contain resources.

Raster and vector font resource files are identified by the .FON filename extension. TrueType font resource files have the .FOT filename extension. Each .FOT file is a relatively short header that refers to a file containing TrueType font information. These TrueType font-information files have the same base filename as the .FOT files, but have the .TTF filename extension.

Some of the filenames for raster and vector fonts are followed by a lowercase letter that indicates the resolution for which the font was designed. This letter varies according to the type of display device that was specified when the fonts were installed. Following are the lowercase letters used to identify different resolutions:

Letter	Device
a	CGA
b	EGA
c	Okidata printers
d	IBM and Epson printers
e	VGA
f	IBM 8514/A

For more information about the format of font resource files, see **Resource Formats**.

Basics of TrueType Fonts

The TrueType fonts incorporated into Windows 3.1 are much more versatile than the fonts that were available in previous versions of Windows. TrueType fonts can be scaled and rotated; they allow the same fonts to be used on the screen as are used on printers; and they allow documents to be portable between printers, applications, and systems.

The following table lists the 13 core TrueType fonts distributed with Windows version 3.1. (Windows 3.1 may include additional TrueType fonts that supplement this core set.)

Font family	Font name	Type
Arial	Arial	Sans serif, variable pitch
	Arial Bold	Sans serif, variable pitch
	Arial Italic	Sans serif, variable pitch
	Arial Bold Italic	Sans serif, variable pitch
Courier New	Courier New	Serif, fixed pitch
	Courier New Bold	Serif, fixed pitch
	Courier New Italic	Serif, fixed pitch
	Courier New Bold Italic	Serif, fixed pitch
Symbol®	Symbol	N/A
Times New Roman	Times New Roman	Serif, variable pitch
	Times New Roman Bold	Serif, variable pitch
	Times New Roman Italic	Serif, variable pitch
	Times New Roman Bold Italic	Serif, variable pitch

TrueType font technology offers many benefits to application designers, at little or no cost. It is not necessary to revise an application written for Windows version 3.0 for that application to use TrueType fonts. If you want your application to take full advantage of the greater precision and versatility available with TrueType fonts, however, you can use the following new font functions:

Function	Description
CreateScalableFontResource	Creates a font resource file for a specified TrueType font.
EnumFontFamilies	Retrieves the fonts available on a specified device.
GetCharABCWidths	Retrieves the widths of consecutive TrueType characters.

GetFontData	Retrieves font-metric data (or the entire font) from a TrueType font file.
GetGlyphOutline	Retrieves data describing an individual character in a TrueType font.
GetOutlineTextMetrics	Retrieves font metrics for TrueType fonts.
GetRasterizerCaps	Determines whether TrueType is installed.

Benefits of TrueType

TrueType fonts offer many advantages over previous font technologies for Windows:

- What you see is what you get (WYSIWYG).

  Applications can scale and rotate TrueType fonts. TrueType fonts are attractive at all sizes. An application can use the same fonts on the screen and the printer.
- Printer portability.

  TrueType fonts work on different printers. Because detailed font metrics are available, an application can compose documents in a device-independent fashion.
- Document portability.

  Applications can embed TrueType fonts in documents. TrueType fonts work on different platforms. Applications can use the detailed font metrics to compose documents in a platform-independent fashion.
- Simplicity.

  The versatility of TrueType fonts reduces the number of required choices and compromises.

TrueType solves two important problems: matching fonts to the printer in use, and presenting high-quality fonts at any size on all devices.

The most obvious benefit of TrueType fonts is that they are scalable. Users can use TrueType to get virtually any point size they like. With TrueType, Windows users no longer need to think about the availability of point sizes on their printer or screen, about running a utility to create raster fonts, or about disk storage for these bitmaps.

TrueType fonts are presented to applications through the same enumeration and selection functions as the raster fonts. As a result, TrueType fonts work with every Windows application. Windows printer drivers have also been modified as required to support the use of TrueType.

Compatibility with Earlier Windows Versions

The introduction of TrueType fonts introduces a few issues that are important for applications developed for earlier versions of Windows.

Identifying TrueType Fonts for Users

Before TrueType fonts were introduced, some users had many different fonts to choose between; now, these users have still more choices. (Users can simplify their choices by selecting the "Enable TrueType Fonts" and "Show Only TrueType Fonts in Applications" check boxes in the Fonts dialog box from Control Panel.) Applications can use the standard font dialog box to make it easier for users to manage the fonts on their systems.

Character Widths

TrueType fonts use **ABC** character spacing, a spacing method that does not rely on the width of a character cell and any overhang (the method used for raster fonts). The extra accuracy of ABC spacing can introduce a problem for applications written prior to Windows version 3.1. Older applications that use character widths instead of ABC widths with TrueType fonts incorrectly calculate the end of the last glyph in the line. This calculation could be off by as much as several pixels. It is also possible that a line could start slightly to the left of the starting point specified by the application. These inaccuracies sometimes lead to problems when the screen is redrawn or when a selection of text is highlighted; pieces of glyphs can be handled incorrectly at either end of a line of text.

Many applications written before TrueType became available use the **ExtTextOut** function to clip or redraw lines of text that extend beyond the visible margins of the document.This method prevents any extra pieces of glyphs from being left behind because of incorrect character-width calculations.

MS Serif and MS Sans Serif Fonts

In Windows version 3.1, the raster fonts Tms Rmn and Helv have been replaced by identical fonts named MS Serif and MS Sans Serif, respectively. The Tms Rmn and Helv font names are mapped to their replacements in a new section of WIN.INI called [FontSubstitutes]. Whenever an application requests Helv or Tms Rmn, the font mapper checks this section and makes the appropriate substitution. The [FontSubstitutes] section also maps Helvetica® to Arial and Times® to Times New Roman.

A user could change the [FontSubstitutes] section to map any font name to any other font name. For example, a user could map Tms Rmn and Helv to the Times New Roman and Arial TrueType fonts. Entries in [FontSubstitutes] do not change the names of fonts, however; a user could not force Arial to appear as Helvetica in font menus.

The **EnumFonts** and **EnumFontFamilies** functions use the [FontSubstitutes] section of WIN.INI so that applications written prior to Windows version 3.1 do not fail unexpectedly when enumerating preexisting font names. If an application specifies Helv in a call to **EnumFontFamilies**, GDI enumerates the available MS Sans Serif fonts. When an application calls either of these functions with a NULL family name, GDI enumerates a representative font from each available family, returning the actual names of the fonts, not the remapped names.

Because most Windows applications display font menus that include only the fonts that can be printed on the current printer, this change in font names does not affect most users. Only users of dot-matrix printers see the new names in font menus and dialog boxes.

Font-Height Metrics Can Depend on Attributes

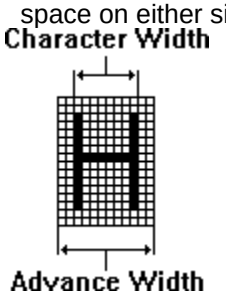
Because the members of a TrueType font family, such as bold and italic, come from different outlines, in some cases the font-height metrics could be different within a TrueType font family. For raster fonts this is not a problem, because when Windows simulates attributes, these metrics are preserved, and because hand-tuned bitmaps were made with matching heights. For the set of fonts shipped with Windows 3.1, most (but not all) of the height metrics match.

Text and Character Attributes

Character attributes are such features as whether a character is bold or italic and whether it has serifs. Text attributes are such features as line and character spacing and text justification. This section introduces some of these attribute categories. For descriptions of individual attributes, see the descriptions of the **LOGFONT**, **NEWTEXTMETRIC**, **TEXTMETRIC**, and **OUTLINETEXTMETRIC** structures in the *Microsoft Windows Programmer's Reference, Volume 3.*

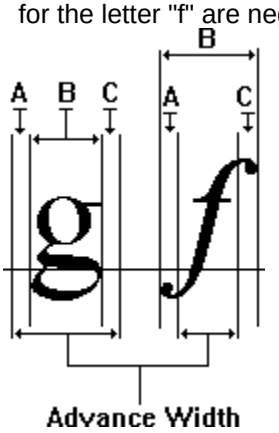
Line and Character Spacing

Before the introduction of TrueType fonts, it was difficult for an application to position characters exactly, especially if the characters were in a string that included bold or italic text. Instead of the width of the character glyph, most Windows functions use the advance width of characters, which includes space on either side of the glyph, as in the following figure:



Applications can control the spacing of TrueType characters accurately by using **ABC** character spacing. GDI constructs ABC spacing from information provided by the TrueType rasterizer. The "A" spacing is the width to add to the current position before placing the glyph. The "B" spacing is the width of the glyph itself. The "C" spacing is the white space to the right of the glyph. The total advance width is given by A+B+C.

Because either or both of the A and C increments can be negative, characters can overhang or underhang the character cell in a way that was not previously possible with GDI. For example, in the following figure the A, B, and C increments for the letter "g" are all positive, but the A and C increments for the letter "f" are negative.



An application can use the **GetCharABCWidths** function to retrieve the **ABC** spacing for characters in a TrueType font.

When an application using TrueType fonts calls a text-output function, GDI uses the font's complete set of **ABC** widths to provide character-placement information to the device driver.

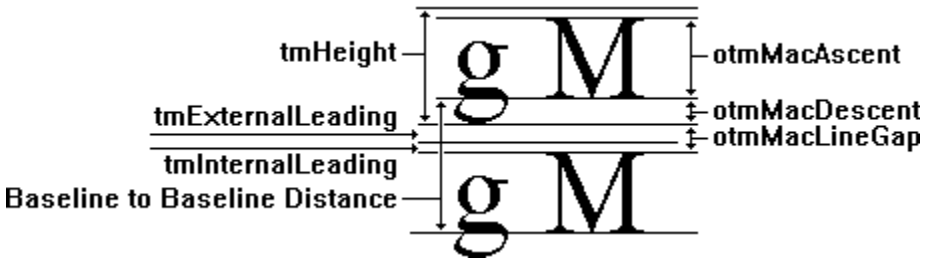
Some applications determine the line spacing between text lines of different sizes by using a font's maximum ascender and descender. An application can retrieve these values by calling the **GetTextMetrics** function and then checking the **tmAscent** and **tmDescent** members of the **NEWTEXTMETRIC** structure.

The maximum ascent and descent are different from the typographic ascent and descent; in TrueType fonts, the typographic ascent and descent are typically the top of the "f" glyph and bottom of the "g" glyph. Rounded characters typically extend slightly beyond the limits of characters with straight edges, to overcome an optical illusion that would make them appear too small otherwise. An application can retrieve the typographic ascender and descender for a TrueType font by calling the **GetOutlineTextMetrics** function and checking the values in the **otmAscent** and **otmDescent** members of the **OUTLINETEXTMETRIC** structure.

Applications that use the HPPCL5A printer driver may experience problems with line spacing for the scalable fonts that are built into the HP LaserJet III printer. These fonts use external leading in the place of internal leading; accent marks for capital letters print outside the character cell reported by the **tmHeight** member of the **NEWTEXTMETRIC** structure.

TrueType font metrics do not correspond exactly to the metrics for Windows raster fonts, because TrueType font metrics have been designed by Apple Computer, Inc. TrueType metrics are required for any application that produces a document that is portable between Windows and an Apple Macintosh computer.

The following figure shows the difference between the vertical text metric values returned in the **NEWTEXTMETRIC** and **OUTLINETEXTMETRIC** structures. (The names beginning with "otm" are members of the **OUTLINETEXTMETRIC** structure.)



The overhang added by GDI when it synthesizes a bold or italic font is not taken into account by the **GetTextExtent** function.

Logical and Physical Inches

A logical inch is a measure Windows uses for presenting legible fonts on the screen; it is generally 30 to 40 percent larger than a physical inch. A 10-point font on a screen is larger than a 10-point font produced by a printer. Fonts on the screen are made larger because most screens do not have high enough resolutions to make a 10-point font legible. Furthermore, users generally read text on screens from a greater distance than they read text on paper.

Although logical inches solve the problem of legible fonts on the screen, they prevent a perfect match between the output of the screen and printer. The text on a screen is not simply a scaled version of the text that will appear on the page, particularly if graphics are incorporated into the text.

An application can retrieve the physical dimensions of a font by calling the **GetOutlineTextMetrics** function. To determine the dimensions of an output device, an application can call the **GetDeviceCaps** function. **GetDeviceCaps** returns both physical and logical dimensions.

Font Sizes

Most Windows applications use the MM_TEXT mapping mode instead of MM_TWIPS, because MM_TEXT makes possible a relatively simple conversion from logical to physical font sizes. With MM_TEXT, each logical unit is mapped to one pixel.

To determine the point size for a font, an application must first convert the information returned in the **NEWTEXTMETRIC** or **OUTLINETEXTMETRIC** structure using the size of the logical inch for the output device. For example, an application using MM_TEXT units might use a font that has a cell height (**tmHeight**) of 12 and an internal leading (**tmInternalLeading**) of 2. The cell height minus the internal leading gives the point size in logical units; in this case, the point size of the font is 10 units (pixels).

To convert this value into a typographic point size (that is, a value in which one point equals 1/72 inch), the application should use the **GetDeviceCaps** function to determine the vertical size and resolution of the screen and the number of pixels per logical inch supported by that device. For example, if an application working in MM_TEXT mapping mode requires a 12-point font, it could use the value produced by the following algorithm in the **lfHeight** member of the **LOGFONT** structure:

-1 * ((LOGPIXELSY * 12) / 72)

Using a negative value in the **lfHeight** member causes GDI to use the value as the height of the character glyphs, not the height of the character cell. The LOGPIXELSY value is returned by a call to the **GetDeviceCaps** function. The point size of the requested font is 12, and the number of points in a physical inch is 72.

Similarly, an application could use the following algorithm to determine the point size of a font from information returned in the **NEWTEXTMETRIC** structure:

((**tmHeight** - **tmInternalLeading**) * 72) / LOGPIXELSY

Font Mapper

When calling a font-creation function, an application describes the font either by using a **LOGFONT** structure in a call to the **CreateFontIndirect** function or by using the parameters of the **CreateFont** function. The font returned by these functions is called a logical font, because a font matching the described characteristics is not necessarily available in the system. GDI uses the logical font to create a physical font, by finding the closest match to the logical font among the available TrueType, raster, vector, and device-dependent fonts.

The Windows font mapper determines which of the available fonts is the closest match to the requested logical font. The font mapper often chooses a TrueType font as the closest match; it will choose a raster or vector font only when the logical font matches the characteristics of the raster or vector font very closely or when the logical font specifies the name of the raster or vector font. Typically, a TrueType font is chosen when it is specifically requested or when GDI would otherwise have to synthesize the font. For example, if a font name is not specified in the logical font or if the specified name does not exist, the font mapper chooses a TrueType font that matches the requested point size, serif characteristics, and pitch.

When the font mapper determines that a TrueType font is the closest match for a requested logical font, the TrueType engine produces enhanced GDI raster characters that are presented to the raster device. (The characters are enhanced by the use of **ABC** character widths.) For devices that do not have raster font capabilities, the driver must request the TrueType engine to provide the glyphs in a form the driver can use.

When the font mapper chooses between raster fonts, it chooses the font that is closest to the requested size without being larger than that size.

When an application requests a very small font, the font mapper may choose one of the small fonts stored in the SMALL*X*.FON font resource file. TrueType fonts specify a suggested minimum size, which can be retrieved by calling the **GetOutlineTextMetrics** function and checking the **otmusMinimumPPEM** member of the **OUTLINETEXTMETRIC** structure. When an application requests a font smaller than this size, the font mapper typically chooses a small font instead of a TrueType font. If the requested size is not available as a small font, however, GDI scales the TrueType font instead. Microsoft's 13 core TrueType fonts are designed to be readable as small as 8 points on a VGA screen, although they can be used at smaller sizes.

Standard Font Dialog Box

Windows applications should take advantage of the standard font dialog box for Windows 3.1. Following are the advantages of this dialog box:

- It shows the user the font family name (for example, Times New Roman) along with the styles (for example, Regular, Bold Italic, and other combinations of italic and weight) for the installed fonts.
- It allows Windows version 3.0 simulations and effects to be applied, if the user wants them. When bold or italic simulations are applied, the user is warned that the font may not print as selected.
- It displays weights or styles outside the four standard styles (regular, bold, italic, bold italic).
- It clearly tells the user which fonts are TrueType and which are not.

The standard font dialog box also introduces a consistent user interface and frees applications from having to implement their own dialog boxes for fonts, while retaining enough flexibility for applications to add custom controls. The dialog box looks like this:

TrueType Font Technology

With TrueType fonts, applications have much greater control over the final appearance of documents than was possible with previous Windows font technologies. Much of this added control is the result of the portability of TrueType fonts: An application can move them from the system to a printer, from a printer to the system, from one system to another system (by "embedding" them in documents), and even port them between incompatible operating systems.

Sophisticated desktop-publishing and word-processing applications go to great lengths to make the screen output mimic the printer output. Some applications even change the way the fonts appear on the screen, in an attempt to show users what the printer output will look like. This kind of application benefits greatly from exploiting the advantages of TrueType.

What You See Is What You Get: WYSIWYG

WYSIWYG means that the screen output matches the printer output. With perfect WYSIWYG, the user would be able to place a page of printed output over the same screen output and see every character and graphic element in exactly the same place. If the screen and printer have different resolutions, however, this degree of matching is impossible. Usually, WYSIWYG simply means that line breaks, paragraph breaks, and page breaks are the same on both devices and that justified paragraphs are presented properly. WYSIWYG does not mean the same document on two different printers will be formatted in exactly the same way. Because most applications make the best use of the available printer, WYSIWYG often applies only to the correspondence between the screen and printer for a given printer.

TrueType offers a higher level of WYSIWYG than was available with earlier versions of Windows, because it works on every device. Most Windows applications lay out the screen based on the target printer. The fonts they enumerate for the user are the fonts that can be printed. Because TrueType fonts work on the target printer, they are enumerated by the printer driver to the application and are typically displayed to the user as printer fonts. When the application and GDI match screen fonts to the printer fonts, the TrueType fonts are used on the screen as well.

If no screen font matches the widths of characters in the chosen printer font, WYSIWYG is difficult to achieve. When this happens, applications sometimes make the average width of the characters match, with as little variation in specific characters as possible. More exact matching is achieved with a technique known as metric coercion. There are two basic methods of coercing character metrics: width coercion and shape coercion. Width coercion simply adjusts the spacing between words and characters, and shape coercion applies a transformation to each character to force it into a bounding box. Because shape coercion can lead to unacceptably deformed characters, width coercion is typographically preferred.

Although Windows does not include a function to deform individual characters, the **lfWidth** member of the **LOGFONT** structure allows an application to scale the width of a TrueType font independently of its height. (Most applications do not scale TrueType fonts in this manner, however, because the results are usually unattractive.)

Embedded Fonts

Embedding a font is the technique of bundling the fonts used by a document into the document itself for transmission to another computer. Embedding a font guarantees that a font specified in a transmitted document will be present on the computer receiving the document. Not all fonts can be moved from computer to computer, however, since most fonts are licensed to only one computer at a time. In Windows, only TrueType fonts can be embedded.

Applications should embed a font in a document only on request from a user. An application cannot be distributed along with documents that contain embedded fonts, nor can an application itself contain an embedded font. Whenever an application distributes a font, in any format, the proprietary rights of the owner of the font must be acknowledged.

A font's license may not allow embedding; it may give read-write permission for a font to be installed

and used on the destination computer; or it may give read-only permission. Read-only permission allows a document to be viewed and printed (but not modified) by the destination computer; documents with read-only embedded fonts are themselves read-only. Read-only embedded fonts may not be unbundled from the document and installed on the destination computer.

Applications that support embedded fonts determine the license status of a font by checking the **otmfsType** member of the **OUTLINETEXTMETRIC** structure. If bit 1 of **otmfsType** is set, embedding is not permitted for the font. If bit 1 is clear, the font can be embedded. If bit 2 is set, the embedding is read-only.

It may be a violation of a font vendor's proprietary rights and/or user license agreement to embed any fonts for which embedding is not permitted or to fail to observe the following guidelines on embedding fonts.

Embedding a Font in a Document

When an application has determined that a font can be embedded, it can use the **GetFontData** function to read the font file. (Setting the *dwTable* and *dwOffset* parameters of **GetFontData** to 0L and the *cbData* parameter to -1L ensures that the application will read the entire font file, starting at the beginning of the font).

After retrieving the font data, the application can store it with the document, using any applicable format. Most applications build a font directory in the document, listing which fonts are embedded and whether the embedding is read-write or read-only. (An application can use the **otmpStyleName** and **otmFamilyName** members of the **OUTLINETEXTMETRIC** structure to identify the font.)

If the read-only bit is set for the embedded font, applications must encrypt the font data before storing it with the document. The encryption method need not be complicated; for example, using the XOR operator to combine the font data with an application-specified constant is adequate and fast.

Installing and Using an Embedded Font

An embedded font must be separated from the containing document and installed in the user's system before Windows can use it. Although the exact procedure for separating the font from the document depends on the method the application uses to embed it, the following three steps are always taken:

1 Resolve name conflicts before installing the font.

2 Write the font data to a file, decoding read-only fonts as necessary.

3 Use the **CreateScalableFontResource** function to create a font resource file for the unembedded font.

An application should avoid installing a font with the same name as a preexisting font. To determine whether there is duplication in style names, an application could compare the information returned by **EnumFontFamilies** against the family name and style name stored with the embedded font.

Embedded fonts that have read-write permission (that is, that can be permanently installed on the user's system) should be written to a file that has the .TTF filename extension. Embedded fonts with read-only permission should not use the .TTF extension and should avoid the .FOT and .FON extensions. (A typical filename extension for read-only embedded fonts is .TTR.) Because files for read-only embedded fonts must be removed from the system and from storage as soon as the containing document is closed, their names do not need to be meaningful except to the application.

Most applications put the files for embedded fonts that have read-write permission into either the SYSTEM subdirectory of the user's Windows directory or into the application's working directory. Files for read-only embedded fonts are typically put into a temporary directory.

Before installing an embedded font, an application must use the **CreateScalableFontResource** function to create a font resource file. Font resource files for fonts with read-write permission should use the .FOT filename extension. Font resource files for read-only fonts should use a different extension (for example, .FOR) and should be hidden from other applications in the system by specifying 1 for the first parameter of **CreateScalableFontResource**. The font resource files can be installed by using the

AddFontResource function.

Applications should offer users the option of permanently installing embedded fonts that have read-write permission. To permanently install a font, applications should concatenate the family and style names and then use the **WriteProfileString** function to insert this string along with the .FOT file name in the [Fonts] section of the WIN.INI file. A typical font entry in the [Fonts] section looks like this example:

```
Times New Roman Bold (TrueType)=TIMESBD.FOT
```

If a document contains one or more read-only embedded fonts, the user must not be permitted to edit the document. If the user is allowed to edit the document in any way, the application must first strip away and delete the read-only embedded fonts. As mentioned earlier, read-only embedded fonts must be removed from the system and storage immediately when the document in which they were bundled is closed.

To delete read-only embedded fonts, an application should follow these steps:

1 Call the **RemoveFontResource** function for each font to be deleted.

2 Delete the font resource file for each font.

3 Delete each TrueType font file for each font.

When an application creating a file for a read-only embedded font specifies 1 for the first parameter of the **CreateScalableFontResource** function, the **EnumFonts** and **EnumFontFamilies** functions will not enumerate this font. Hiding read-only embedded fonts in this manner makes it unlikely that another application could use them, even though Windows resources are theoretically available to all processes in Windows. If an application does use a read-only embedded font installed by another application, it could be difficult for the installing application to delete the font. The **RemoveFontResource** function will not delete a font that is currently in use. In this case, an application should delete the resource file and the TrueType font file when the user closes the document that contained the read-only fonts.

It is very important that applications delete the TrueType font file for read-only embedded fonts. If the delete operation fails when the user closes the document, the application should periodically attempt to delete the file as the application runs, when it closes, and the next time it starts.

In some cases, an application could be unable to delete a TrueType font file for a read-only embedded font because of external events (such as a system failure). There is no legal liability for events that are out of the control of the application.

Printer Portability

A document with printer portability is formatted identically on all output devices under Windows--all monitors and all printers. Although TrueType allows the same font to be used on all output devices, this does not guarantee that line breaks will be the same on all devices. For line breaks to match, applications must take advantage of TrueType design metrics. These design metrics allow an application to compute the fractional portion of the spacing at the ends of lines and make up the difference in the interword spacing. This computation reduces the round-off error from a half-pixel per character to a half-pixel per line, preserving line breaks in all cases.

Line Breaks and Justification

Applications must cooperate in order to guarantee the printer portability enabled by TrueType technology, because different devices may have different resolutions. Even when fonts are portable across printers, glyphs designed or rasterized for different resolutions must have different pixel widths. For applications that use the **TextOut** function, for example, different character widths can lead to accumulated round-off errors that change line breaks and paragraph placement.

Applications that lay out a document at the highest printer resolution attempt to distribute any difference in character resolutions in white spaces. This method is not always successful; for example, it fails when all glyphs are one pixel larger at 600 dots per inch (DPI) than at 300 DPI. In this case, fonts with a width of 45 at 600 DPI would have a width of 23 at 300 DPI, a width of 11 at 150 DPI, and

so on. There could easily be insufficient white space to absorb the glyphs at the lower resolutions if line breaks were being preserved, because the glyphs become larger in relation to the resolution of the device. In this case, the characters would have to overlap to preserve the line breaks. Even if all the character widths exactly doubled when changing from a resolution of 300 DPI to 600 DPI, the line breaks might not be the same if an application justified text--that is, aligned it on both the left and right. It is possible that another half-pixel of white space at the lower resolution would allow one more word on the line. At the higher resolution, the half-pixel would become a full pixel and the line breaks would change. (Similar device-resolution problems occur in the vertical direction.) TrueType exposes the design width of characters to help applications maintain line breaks.

Different printers, or even different production runs of the same printer, can have different limits for their printable areas. If a document has been laid out up to the margins of one printer, it may not format identically on a different printer. If glyphs are in contact with the margins on the first printer, parts of the glyph may be beyond the printable area on the second printer. Depending on the printer, the glyph will either be clipped or dropped completely.

Prior to the introduction of TrueType, sophisticated desktop-publishing and word-processing applications were forced to "reflow" the entire document whenever a user selected a different printer. Applications can now use TrueType font metrics to solve this problem.

Performance and Printer Portability

Printer portability can potentially downgrade font performance, quality, or both, depending on such factors as the type of connection between the computer and printer, the speed of the computer, the memory in the printer and the computer, the number of fonts being used, differing resolutions between the screen and printer, and the number of characters used in each font. Documents that are fully portable between printers necessarily cannot take advantage of the specialized features of a particular printer.

GDI cannot perform text operations to printer-compatible memory device contexts. This means that it is not possible to build a bitmap describing a page to be printed and then send the completed bitmap to the printer.

Document Portability

A portable document appears the same on different operating systems. In the case of TrueType, documents can be portable between Windows and the Apple Macintosh computer; this could also be called platform portability. If a document appears the same on the Macintosh and with Windows, it can also look the same imported into different applications on either platform.

Since the same TrueType fonts work on the Macintosh, in Windows, and on all devices supported by both systems, the same characters and metrics could be exposed for all applications. Currently, however, fully portable documents are not possible. Windows and the Macintosh computer have slightly different character sets. Even though TrueType fonts contain the default Macintosh and PostScript character sets, Windows does not give applications access to the Macintosh characters. Likewise, a Macintosh application cannot gain access to the Windows characters present in TrueType fonts. Document portability is also a problem with international document exchange. Localized versions of TrueType fonts will still be in use for both the Apple System 7 and Windows version 3.1, leading to further character-set incompatibilities when documents that use these fonts are transmitted to a system that does not have them.

Disk Space, Memory Usage, and Speed

An application's overall font performance could decrease if a large font cache forced the paging of more segments to the disk. With previous font technologies, this could occur even in situations that were not "low memory." Because fonts are cached glyph by glyph as they are used, however, less memory is used for the cache than would be required to keep the corresponding raster fonts in memory; this leads to a net performance gain. The only time the font cache uses more memory than fonts required in earlier versions of Windows is when multiple logical fonts would have been mapped to the same raster font. Typically, however, any additional swapping to disk caused by these larger

caches is still faster overall than discarding and subsequently re-rendering bitmaps.

Hard-disk space is not a large problem for TrueType fonts, although more disk space is required for fonts with the introduction of TrueType. The two reasons for this increased space requirement are that raster fonts are shipped with TrueType fonts, for backward-compatibility reasons, and that users may have preexisting soft fonts on their hard disks.

Hard-disk space is not the only limitation imposed on TrueType fonts. GDI imposes an internal limit to the number of TrueType fonts that can exist simultaneously on a system. The maximum number of physical fonts is 1170. (The maximum number of logical fonts that can exist simultaneously on a system is 253.)

Font Design and Scaling

Raster fonts are designed to be attractive and readable at a particular aspect ratio. (The aspect ratio is the ratio of the width and height of a pixel.) The digitized aspect of a font is the ideal x-aspect and y-aspect of that font. Windows provides an aspect-ratio filter to select fonts designed for a particular aspect ratio from all of the available fonts. The **GetAspectRatioFilter** function retrieves the setting for the current aspect-ratio filter. An application can use the **SetMapperFlags** function to change the algorithm the font mapper uses when it maps physical fonts to logical fonts.

The aspect ratio of the screen is not as critical for scalable fonts as it is for raster fonts. The dimensions of the em square for a TrueType font are used when scaling the font to a specified point size. (An em square is a square whose width is approximately equal to the width of the uppercase M.) Because the height of the em square is given in pixels, it can be thought of as the point size in device units. For example, a font could be referred to as a 50-ppem (pixels per em square) font. The pixel size determines the physical point size. For example, a 75-ppem font on a 300-DPI device is an 18-point font, while on a 150-DPI device it would be a 36-point font. The number of pixels required for the desired point size is computed by using the resolution of the output device and the em square size, according to the following formula:

ppem = (*PointSize*/72) * *DeviceResolution*

According to this formula, a 12-point font on a 72-DPI screen is at 12 ppem, while on a 300-DPI device it is at 50 ppem.

TrueType fonts can be scaled linearly, nonlinearly, or optically, depending on their design. Linear scaling means that the character width is scaled and rounded to the appropriate ppem. Nonlinear scaling means that hinted character widths can be larger or smaller than the scaled widths. Optical scaling is a superset of nonlinear scaling; it includes the preservation of the color and contrast of a font across point sizes. Optical scaling can involve changing the proportions of the stroke widths to preserve their perceived width and color.

The TrueType fonts shipped with Windows 3.1 scale nonlinearly. Windows applications can also support linearly and optically scaled TrueType fonts.

Designing Portable Fonts

Most application developers need not be concerned with font-portability issues. This discussion is included here with other portability issues for those developers who need to create fonts that are portable between systems. Microsoft currently publishes a TrueType Font Files Specification, which teaches font vendors how to create a single TrueType font that will work in Windows, on the Macintosh computer, and in TrueImage.

Microsoft uses the same byte ordering in TrueType font files as Apple uses in its font files, to help make the fonts portable between the systems. As a result, Windows fonts can be moved directly to the Macintosh computer, where they can quickly be converted into font suitcases for installation. (The format of TrueType font files precisely follows the format of the Apple "sfnt" resource. To convert an MS-DOS binary TrueType font into an sfnt resource requires editing the file information, setting Type to sfnt and Creator to bass. The sfnt resource can then be integrated into a standard Macintosh font suitcase. To move a font suitcase to Windows, an application need only extract the sfnt portion from

the data fork and move the suitcase, unaltered, to Windows. After the suitcase has been moved to Windows, it can be installed by using Control Panel or the **CreateScalableFontResource** and **AddFontResource** functions.

If a Macintosh font is installed that does not contain the Windows "cmap" mapping table, the system maps text fonts (for example, Times or ITC Zapf Chancery®) from the Macintosh character set onto the Windows character set. Novelty fonts (like ITC Zapf Dingbats®), which have no formal character set, are not mapped; these fonts are taken along with the Macintosh character encodings. The decision whether to remap is based on a test that looks at the "post" table (which contains PostScript names). Whenever necessary, Windows compensates for missing metric tables based on other metric data in the font; anything that cannot be computed in a reasonable manner is given a default value.

The creation of portable fonts requires more than just the right characters and the right character-mapping tables. All the metrics needed by all systems must be included and must yield the same results. Matching metrics for the individual characters is not a problem; since the characters and their hints and metrics appear only once in the TrueType font, the same metrics are available across platforms. The more difficult problems in the creation of portable fonts have to do with line-spacing metrics, the determination of font styles, and making these factors match across systems.

The Apple System 7 core TrueType fonts ship with metrics designed to be compatible with the raster fonts in System 6. The "hdmx" table will be used to force widths onto TrueType fonts that match those for the bitmaps at bitmap sizes. The "name" table (and its ability to group fonts by separating the family and subfamily names) is not used. (The name used comes from the FOND Macintosh font resource.) Only the macStyle bits (from the "head" table) denoting regular, bold, italic, or bold italic are used.

Apple's line spacing recommendations are less robust than the line-spacing used by Microsoft. The following formula defines the default recommended line spacing for a Macintosh font:

line spacing = ascent - descent + leading

The values for ascent, descent and leading come directly from TrueType values:

Macintosh	TrueType
ascent	**otmMacAscent**
descent	**otmMacDescent**
leading	**otmMacLineGap**

For its TrueType fonts, Apple recommends that Ascender - Descender = unitsPerEm, and LineGap = 0. This recommendation is based on the definition of point size for Macintosh raster fonts. Macintosh documentation defines the point size of a font as being equal to the line spacing (ascent - descent + leading). Although this definition is compatible with previous Apple font metrics, it ties line spacing to the size of the em square. Because some fonts (for example, Palatino) have ascenders and descenders that extend beyond the em square, the line-spacing definition is inconsistent for these fonts.

Windows and the Macintosh have the same default line spacing for a font only if the following formula is true:

otmMacLineGap >= (**tmAscent** + **tmDescent**) -
(**otmMacAscent** - **otmMacDescent**)

Microsoft TrueType fonts follow this formula to ensure that default line spacing is preserved between the Macintosh and Windows. The core fonts and all fonts from vendors that follow the Microsoft specification will have the same character widths, the same default line spacing, and the same character forms.

Unless the Windows and Macintosh font heights are equal, a font with a line gap of zero will yield different default line spacings in Windows and on the Macintosh.

Despite some incompatibilities, TrueType and GDI accept Macintosh-only fonts. Metrics that are not present in Macintosh-only fonts are set to default values. Although these default values are imperfect, using them allows Macintosh-only fonts to work in Windows.

Using Fonts in Applications

The remainder of this topic discusses the implementation of font functions in Windows applications.

Using Stock Fonts

GDI offers a variety of stock fonts that an application can retrieve and use. For many applications, the stock fonts provide all the functionality required for basic text output. To use stock fonts, an application specifies the type of font in the **GetStockObject** function. **GetStockObject** creates a handle to a logical font. When the application selects that handle into a device context, the font mapper uses the logical font to create a physical font. The application can select and use this physical font for text output.

GDI offers the following stock fonts:

Font	Description
ANSI_FIXED_FONT	Specifies a fixed-pitch font based on the Windows character set. A Courier font is typically used.
ANSI_VAR_FONT	Specifies a variable-pitch font based on the Windows character set. MS Sans Serif is typically used.
DEVICE_DEFAULT_FONT	Specifies a font preferred by the given device. Because this font depends on how the GDI font mapper interprets font requests, the font may vary widely from device to device.
OEM_FIXED_FONT	Specifies a fixed-pitch font based on an OEM character set. OEM character sets vary from system to system. For IBM computers and compatibles, the OEM font is based on the IBM PC character set.
SYSTEM_FONT	Specifies the System font. This is a variable-pitch font based on the Windows character set, and is used by the system to display window titles, menu names, and text in dialog boxes. The System font is always available. Other fonts are available only if they have been installed.

The following example retrieves a handle of the Windows variable stock font, selects it into a device context, and then writes a string using that font:

```
HFONT hfnt, hOldFont;

    hfnt = GetStockObject(ANSI_VAR_FONT);
    if (hOldFont = SelectObject(hdc, hfnt)) {
        TextOut(hdc, 10, 50, "Sample ANSI_VAR_FONT text.", 26);
        SelectObject(hdc, hOldFont);
    }
```

If no other stock fonts are available, **GetStockObject** returns a handle to the System font (**SYSTEM_FONT**).

Applications that use the **GetStockObject** function to retrieve the handle of a logical font should work in MM_TEXT units. The logical font identified by the handle returned by **GetStockObject** may specify a height that does not match the height of the requested logical font when the application works in mapping modes other than MM_TEXT.

Enumerating Fonts

An application can discover which fonts are available for a given device by using the **EnumFonts** or **EnumFontFamilies** function. These functions send information about the available fonts to a callback function that the application supplies. The callback function receives information in **LOGFONT** and **NEWTEXTMETRIC** structures. (The **NEWTEXTMETRIC** structure contains information about a TrueType font. When the callback function receives information about a non-TrueType font, the

information is contained in a **TEXTMETRIC** structure.) By using this information, an application can allow the user to choose among only those fonts that are available.

The **EnumFontFamilies** function is similar to the **EnumFonts** function but includes some extra functionality. New and upgrading applications should use **EnumFontFamilies** instead of **EnumFonts**. **EnumFontFamilies** allows an application to take advantage of the style name that is available with TrueType fonts.

In previous versions of Windows, the only style attributes were weight and italic; any other styles were specified in the family name for the font. If an application used the **EnumFonts** function to query the available Courier fonts, for example, **EnumFonts** might return information for Courier, Courier Bold, Courier Bold Italic, and Courier Italic, but it would not return information about any other Courier fonts that might be installed, because any other Courier fonts would typically have a different family name.

TrueType fonts are organized around a family name (for example, Courier New) and style names (for example, italic, bold, and extra-bold). The **EnumFontFamilies** function enumerates all the styles associated with a given family name, not simply the bold and italic attributes; if the system included a TrueType font called Courier New Extra-Bold, **EnumFontFamilies** would list it with the other Courier New fonts. The capabilities of **EnumFontFamilies** are helpful for fonts with many or unusual styles and for fonts that cross international borders. (Because a style name often changes with the language spoken in a country, an application that depends on the **EnumFonts** function could enumerate fonts whose names would change from country to country, while **EnumFontFamilies** would continue to enumerate the font families correctly.)

If an application does not supply a typeface name, the **EnumFonts** and **EnumFontFamilies** functions supply information about one font in each available family. To enumerate all the fonts in a device context, an application can specify NULL for the typeface name, compile a list of the available typefaces, and then enumerate each font in each typeface.

The following example uses the **EnumFontFamilies** function to retrieve the number of available raster, vector, and TrueType fonts:

```
FONTENUMPROC lpEnumFamCallBack;
UINT uAlignPrev;
int aFontCount[] = { 0, 0, 0 };
char szCount[8];

lpEnumFamCallBack = (FONTENUMPROC) MakeProcInstance(
    (FARPROC) EnumFamCallBack, hinstApp);
EnumFontFamilies(hdc, NULL, lpEnumFamCallBack,
    (LPARAM) aFontCount);
FreeProcInstance((FARPROC) lpEnumFamCallBack);

uAlignPrev = SetTextAlign(hdc, TA_UPDATECP);

MoveTo(hdc, 10, 50);
TextOut(hdc, 0, 0, "Number of raster fonts: ", 24);
itoa(aFontCount[0], szCount, 10);
TextOut(hdc, 0, 0, szCount, strlen(szCount));

MoveTo(hdc, 10, 75);
TextOut(hdc, 0, 0, "Number of vector fonts: ", 24);
itoa(aFontCount[1], szCount, 10);
TextOut(hdc, 0, 0, szCount, strlen(szCount));

MoveTo(hdc, 10, 100);
TextOut(hdc, 0, 0, "Number of TrueType fonts: ", 26);
itoa(aFontCount[2], szCount, 10);
TextOut(hdc, 0, 0, szCount, strlen(szCount));
```

```
    SetTextAlign(hdc, uAlignPrev);
        .
        .
        .

BOOL FAR PASCAL EnumFamCallBack(lplf, lpntm, FontType, aFontCount)
LPLOGFONT lplf;
LPNEWTEXTMETRIC lpntm;
short FontType;
LPSTR aFontCount;
{
    int far * aiFontCount = (int far *) aFontCount;

    if (FontType & RASTER_FONTTYPE)
        aiFontCount[0]++;
    else if (FontType & TRUETYPE_FONTTYPE)
        aiFontCount[2]++;
    else
        aiFontCount[1]++;

    if (aiFontCount[0] || aiFontCount[1] || aiFontCount[2])
        return TRUE;
    else
        return FALSE;
}
```

This example uses two masks, RASTER_FONTTYPE and TRUETYPE_FONTTYPE, to determine the type of font being enumerated. If the RASTER_FONTTYPE bit is set, the font is a raster font. If the TRUETYPE_FONTTYPE bit is set, the font is a TrueType font. If neither bit is set, the font is a vector font. A third mask, DEVICE_FONTTYPE, is set when a device (for example, a laser printer) supports downloading TrueType fonts; it is zero if the device is a display adapter, dot-matrix printer, or other raster device. An application can also use the DEVICE_FONTTYPE mask to distinguish GDI-supplied raster fonts from device-supplied fonts. GDI can simulate bold, italic, underline, and strikeout attributes for GDI-supplied raster fonts, but not for device-supplied fonts.

An application can also check bit 1 and 2 in the **tmPitchandFamily** member of the **NEWTEXTMETRIC** structure to identify a TrueType font. If bit 1 is zero and bit 2 is 1, the font is a TrueType font.

Vector fonts are categorized as OEM_CHARSET instead of ANSI_CHARSET. Some applications identify vector fonts by using this information, checking the **tmCharSet** member of the **NEWTEXTMETRIC** structure. This categorization usually prevents the font mapper from choosing vector fonts unless they are specifically requested. (Most applications do not use vector fonts, because they are slow and generally unattractive, and because TrueType fonts offer many of the same scaling and rotation features that required the use of vector fonts in earlier versions of Windows.)

Checking a Device's Text Capabilities

Applications can use the **EnumFonts** and **EnumFontFamilies** functions to enumerate the fonts in a printer-compatible memory device context. An application can also use the **GetDeviceCaps** function to retrieve information about the text capabilities of a device. By calling the **GetDeviceCaps** function with the NUMFONTS index, an application can determine the minimum number of fonts supported by a printer. (An individual printer may support more fonts than specified in the return value from **GetDeviceCaps** with the NUMFONTS index.) By using the TEXTCAPS index, an application can identify many of the text capabilities of the specified device.

The following example uses the **GetDeviceCaps** function to determine whether a device supports text rotation:

```
int result;

result = GetDeviceCaps(hdc, TEXTCAPS);
if (result & TC_CR_90)
    TextOut(hdc, 10, 100, "Device can rotate text 90 degrees",
        33);
if (result & TC_CR_ANY)
    TextOut(hdc, 10, 120, "Device can rotate text at any angle",
        35);
else if ((result & TC_CR_90) == 0 && (result & TC_CR_ANY) == 0)
    TextOut(hdc, 10, 100, "Device cannot rotate text", 25);
```

Creating a Logical Font

A logical font is a list of font attributes, such as height, width, character set, and typeface. An application creates a logical font to describe the font that is best suited for a given task; the font mapper uses this logical font to choose the available physical font that best matches the specified characteristics.

An application can use either the **CreateFont** or the **CreateFontIndirect** function to create a logical font. Most applications use **CreateFontIndirect**, assigning values to a **LOGFONT** structure. These functions return a handle of a logical font, which can then be selected into a device context and used.

The following example is a function that takes a handle of a device context, the name of a font, and a nominal point size as input. It creates a logical font of the requested size and face name and selects that font into the specified device context.

```
BOOL FAR PASCAL CreateLogFont(hdc, pszFace, PointSize)
HDC hdc;
PSTR pszFace;
int PointSize;
{
    HFONT hfnt, hfntOld;
    PLOGFONT plf = (PLOGFONT) LocalAlloc(GPTR, sizeof(LOGFONT));

    if (GetMapMode(hdc) != MM_TEXT) {
        TextOut(hdc, 100, -200, "Mapping mode must be MM_TEXT",
            28);
        return FALSE;
    }

    plf->lfHeight = -MulDiv(PointSize,
        GetDeviceCaps(hdc, LOGPIXELSY), 72);
    lstrcpy(plf->lfFaceName, pszFace);

    hfnt = CreateFontIndirect(plf);

    hfntOld = SelectObject(hdc, hfnt);

        .
        . /* Use font for text output. */
        .
    LocalFree((LOCALHANDLE) plf);
    SelectObject(hdc, hfntOld);
    if (DeleteObject(hfnt))
        return TRUE;
    else
        return FALSE;
```

}

Memory for the logical font in this example is allocated and initialized to zero (by using the **LocalAlloc** function with the **GPTR** constant); this means the logical font created by the **CreateFontIndirect** function uses default values for all members except **lfHeight** and **lfFaceName**. (Applications should always specify values for at least these two members.) For a description of all of the members of the **LOGFONT** structure, see the *Microsoft Windows Programmer's Reference, Volume 3.*

The function in this example uses the Windows **MulDiv** function to convert the specified point size into a different negative value and then assigns that value to the **lfHeight** member. This conversion is required because logical inches are larger than physical inches. The **MulDiv** function multiplies the requested point size by the result of dividing the number of pixels per logical inch by the number of points in a physical inch (72). A negative value is specified for **lfHeight** to indicate that the system should interpret this value as the height of the character glyphs in the font; when a positive value is specified, GDI interprets it as the height of a font's character cells, including internal leading.

An application would use a positive value for the **lfHeight** member to choose a font that fits within a specific height. For example, to display a page in "print preview" mode, an application would retrieve the height of the printer font from the **tmHeight** member of the **NEWTEXTMETRIC** structure, scale that height to the screen resolution, and use this value for the **lfHeight** member. The formula in this case would look like this:

$$\textbf{lfHeight} = \frac{\textbf{tmHeight} * \text{DPI of screen}}{\text{DPI of printer}}$$

The results of this calculation should always be rounded down to the nearest whole number.

When an application specifies the handle of a logical font in a call to the **SelectObject** function, the font mapper returns a handle of the physical font that is the best match for the requested attributes.

An application that requires a raster font can identify the available raster fonts by calling the **EnumFontFamilies** function and checking the RASTER_FONTTYPE bit. The application can then specify the typeface name in a **LOGFONT** structure. Similarly, vector fonts can be selected by checking the RASTER_FONTTYPE and TRUETYPE_FONTTYPE bits. An application can also specify a vector font by specifying OEM_CHARSET in the **lfCharSet** member of the **LOGFONT** structure, as discussed in Section 18.4.2, "Enumerating Fonts."

An application can use TrueType fonts exclusively by specifying OUT_TT_ONLY_PRECIS in the **lfOutPrecision** member of the **LOGFONT** structure. This is important for applications that use object linking and embedding (OLE), because metafiles can be scaled much better when they use only TrueType fonts.

Retrieving Information About the Selected Font

Applications can retrieve font information from a device context by using the **GetTextMetrics**, **GetTextFace**, and **GetOutlineTextMetrics** functions.

The **GetTextMetrics** function copies a **TEXTMETRIC** structure into a buffer. The **TEXTMETRIC** structure contains a description of the physical font, including the average dimensions of the character cells within the font, the spacing between lines of text, the number of characters in the font, and the character set on which the font is based. An application working with TrueType fonts can call the **GetOutlineTextMetrics** function to retrieve information in an **OUTLINETEXTMETRIC** structure.

Applications often use the **TEXTMETRIC** structure to determine how much space to specify between lines of text. For example, to compute an appropriate value for single-line spacing, an application could add the values of the **tmHeight** and **tmExternalLeading** members. The **tmHeight** member specifies the height of each character cell, and **tmExternalLeading** specifies the font designer's recommended spacing between the bottom of one character cell and the top of the next. (More accurate information can be retrieved for TrueType fonts from the **OUTLINETEXTMETRIC** structure; in this case, applications can add the values of the **otmAscent**, **otmDescent**, and **otmLineGap**

members.) The following example writes several lines of single-spaced text:

```
TEXTMETRIC tm;
int LineSpacing, i, YIncrement;

GetTextMetrics(hdc, &tm);
LineSpacing = tm.tmHeight + tm.tmExternalLeading;

YIncrement = 50;
for (i = 0; i < 4; i++) {
    TextOut(hdc, 10, YIncrement, "Single-line spacing", 19);
    YIncrement += LineSpacing;
}
```

The **GetTextFace** function copies a name identifying the typeface of the selected font into a buffer. An application can use this information in dialog boxes and menus.

Retrieving Information About a Logical Font

An application can retrieve information about a font by specifying the font handle in a call to the **GetObject** function. The **GetObject** function copies logical-font information to a **LOGFONT** structure.

The following example uses the **GetObject** function to retrieve logical-font information for a font and then checks whether the font is italic:

```
LOGFONT lf;

GetObject(hfnt, sizeof(LOGFONT), &lf);
if (lf.lfItalic)
    return TRUE;
else
    return FALSE;
```

Drawing Text

An application can use the following functions to draw text:

Function	Description
DrawText	Draws formatted text in a rectangle. **DrawText** formats text by expanding tabs into appropriate spaces, aligning text to the left, right, or center of the given rectangle, and breaking text into lines that fit within the given rectangle. This is not a GDI function; it is in USER.EXE.
ExtTextOut	Writes a character string within a rectangular region. The rectangular region can be opaque (filled with the current background color), and it can be a clipping region.
GrayString	Draws gray text by writing the text in a memory bitmap, graying the bitmap, and then copying the bitmap to the device. **GrayString** grays the text regardless of the selected brush and background. This is not a GDI function; it is in USER.EXE.
TabbedTextOut	Writes a character string, expanding tabs to the values specified in an array of tab-stop positions.
TextOut	Writes a character string at a specified location.

The **ExtTextOut** function is the fastest Windows text-output function. The **DrawText** function is the slowest (although it offers the richest formatting options).

Instead of using the **GrayString** function, an application could simply set the text color to gray, as follows:

```
dwColorPrevious = SetTextColor(hdc, GetSysColor(COLOR_GRAYTEXT));
```

Setting the Text Alignment

An application can query and set the text alignment for a device context by using the **GetTextAlign** and **SetTextAlign** functions. The text-alignment settings determine how text is positioned relative to a given location. Text can be aligned to the right or left of the position or centered over it; it can also be aligned above or below the point. In addition, an application can use the **SetTextAlign** function to update the current position when a text-output function is called.

For example, the following example uses the **SetTextAlign** function to update the current position when the **TextOut** function is called. In this example, cArial is an integer that specifies the number of Arial fonts:

```
UINT uAlignPrev;
char szCount[8];

uAlignPrev = SetTextAlign(hdc, TA_UPDATECP);
MoveTo(hdc, 10, 50);
TextOut(hdc, 0, 0, "Number of Arial fonts: ", 23);
itoa(cArial, szCount, 10);
TextOut(hdc, 0, 0, (LPSTR) szCount, strlen(szCount));
SetTextAlign(hdc, uAlignPrev);
```

Using Color

When an application first creates a device context, the text color is black and the background color is white. An application can add color to text by setting the text and background colors of the device context. The text color determines the color of the character to be written; the background color determines the color of everything in the character cell except the character.

An application can set the text and background colors by using the **SetTextColor** and **SetBkColor** functions. The following example sets the text color to red and the background color to green:

```
SetTextColor(hdc, RGB(255,0,0));
SetBkColor(hdc, RGB(0,255,0));
```

The background color applies only when the background mode is opaque. The background mode determines whether the background color in the character cell has any effect on what is already on the screen. If the mode is opaque, the background color overwrites anything already on the screen; if the mode is transparent, anything on the screen that would otherwise be overwritten by the background is preserved. The background color for an italic string that GDI has synthesized is sheared along with the characters; this can lead to unexpected results when the text background color is different from the window background color. An application can set and retrieve the background mode by using the **SetBkMode** function and **GetBkMode** functions. Similarly, an application can retrieve the current text and background color by using the **GetTextColor** and **GetBkColor** functions.

Using Multiple Fonts in a Line

Different type styles within a font family can have different widths. For example, bold and italic styles of a family are always wider than the roman style for a given point size. An application that can display or print several type styles on a single line must keep track of the width of the line to avoid having characters print on top of one another.

An application can use the following functions to retrieve the width (or extent) of text in the current font:

Function	Description
GetTabbedTextExtent	Computes the width and height of a character string. If the string contains one or more tab characters, the width of the string is based upon a specified array of tab-stop positions.
GetTextExtent	Computes the width and height of a line of text.

When necessary, GDI synthesizes a font by changing the character bitmaps. To synthesize a character in a bold font, GDI draws the character twice: once at the starting point, and again one pixel to the right of the starting point. To synthesize a character in an italic font, GDI draws the two rows of pixels at the bottom of the character cell, moves the starting point one pixel to the right, draws the next two rows, and continues until the character has been drawn. The base line of a synthesized italic character is shifted to the right by an amount determined by the height of the character cell. To determine the amount a base line is shifted to the right, an application can perform the following calculation, using values retrieved by a call to the **GetTextMetrics** function:

units base line shifted right = (**tmDescent** * **tmOverhang**) / **tmAscent**

One way to write a line of text that contains multiple fonts is to use the **GetTextExtent** function after each call to **TextOut** and add the length to a current position. The following example writes the line "This is a sample string.", using bold characters for the words "This is a", italic characters for the word "sample", and system default characters for "string.":

```
int XIncrement;
TEXTMETRIC tm;
HFONT hfntDefault, hfntItalic, hfntBold;

XIncrement = 10;
hfntDefault = SelectObject(hdc, hfntBold);
TextOut(hdc, XIncrement, 50, "This is a ", 10);

XIncrement += LOWORD(GetTextExtent(hdc, "This is a ", 10));
GetTextMetrics(hdc, &tm);
XIncrement -= tm.tmOverhang;
SelectObject(hdc, hfntItalic);
GetTextMetrics(hdc, &tm);
XIncrement -= tm.tmOverhang;
TextOut(hdc, XIncrement, 50, "sample ", 7);

XIncrement += LOWORD(GetTextExtent(hdc, "sample ", 7));
SelectObject(hdc, hfntDefault);
TextOut(hdc, XIncrement - tm.tmOverhang, 50, "string.", 7);
```

In this example, the **GetTextExtent** function returns a 32-bit value (of type **DWORD**) containing both the length and height of the specified string. The **LOWORD** macro then retrieves the length of the string, which is added to the current position. The **GetTextMetrics** function retrieves the overhang for the current font. Because the overhang is zero if the font is a TrueType font, the overhang value does not change the string placement in that case. For raster fonts, however, it is important to use the overhang value. The overhang is subtracted from the bold string once, to bring subsequent characters closer to the end of the string if the font is a raster font. Because overhang affects both the beginning and end of the italic string in a raster font, the glyphs begin to the right of the specified location and end to the left of the endpoint of the last character cell. (The **GetTextExtent** function retrieves the extent of the character cells, not the extent of the glyphs.) To account for the overhang for the raster italic string, this example subtracts the overhang before placing the string and subtracts it again before placing subsequent characters.

An application that must place characters with greater precision can use the **GetCharWidth** or **GetCharABCWidths** function to retrieve the widths of individual characters in a font. The **GetCharABCWidths** function is more accurate than the **GetCharWidth** function, but only when it is used with TrueType fonts; when **GetCharABCWidths** is used with non-TrueType fonts, it retrieves the same information as **GetCharWidth**.

The **SetTextJustification** function adds extra space to the break characters in a line of text. An application can use the **GetTextExtent** function to determine the extent of a string, subtract the extent from the total amount of space the line should occupy, and use the **SetTextJustification** function to

distribute the extra space among the break characters in the string. The **SetTextCharacterExtra** function adds extra space to every character cell in the selected font, including the break character. (An application can use the **GetTextCharacterExtra** function to determine the current amount of extra space being added to the character cells; the default setting is zero.)

ABC spacing also allows an application to perform very accurate text alignment. For example, when an application right aligns a raster roman font without using ABC spacing, the advance width is calculated as the character width. This means the white space to the right of the glyph in the bitmap is aligned, not the glyph itself. By using ABC widths, applications have more flexibility in the placement and removal of white space when aligning text, because they have information that allows them to finely control intercharacter spacing.

Rotating Text

Applications can rotate TrueType fonts at any angle. This is useful for labeling charts and other illustrations. The following example rotates a string in 10-degree increments around the center of the client area by changing the value of the **lfEscapement** member of the **LOGFONT** structure used to create the font:

```
RECT rc;
int angle;
HFONT hfnt, hfntPrev;
LPSTR lpszRotate = "String to be rotated.";
PLOGFONT plf = (PLOGFONT) LocalAlloc(LPTR, sizeof(LOGFONT));

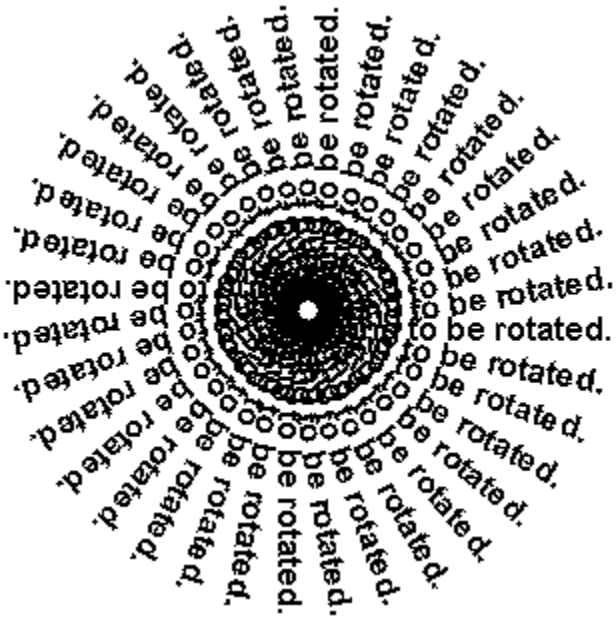
lstrcpy(plf->lfFaceName, "Arial");
plf->lfWeight = 700;

GetClientRect(hwnd, &rc);
SetBkMode(hdc, TRANSPARENT);

for (angle = 0; angle < 3600; angle += 100) {
    plf->lfEscapement = angle;
    hfnt = CreateFontIndirect(plf);
    hfntPrev = SelectObject(hdc, hfnt);
    TextOut(hdc, rc.right / 2, rc.bottom / 2,
        lpszRotate, lstrlen(lpszRotate));
    SelectObject(hdc, hfntPrev);
    DeleteObject(hfnt);
}

SetBkMode(hdc, OPAQUE);
LocalFree((LOCALHANDLE) plf);
```

This example produces the following pattern:



The **lfOrientation** member of the **LOGFONT** structure is ignored by GDI, which currently, assumes that the values for **lfEscapement** and **lfOrientation** are identical.

TrueType Font Functions and Structures

Some of the functions and structures that allow an application to take advantage of the extra functionality of TrueType are discussed elsewhere in this topic. This section describes some of the TrueType functions that are useful for applications that must take full advantage of the new font technology.

Retrieving Character Outlines

Applications can use the **GetGlyphOutline** function to retrieve the outline of a glyph from a TrueType font. **GetGlyphOutline** returns the outline as a bitmap or as a series of polylines and splines.

When an application retrieves a glyph outline as a series of polylines and splines, the information is returned in a **TTPOLYGONHEADER** structure followed by as many **TTPOLYCURVE** structures as are required to describe the glyph. All points are returned as **POINTFX** structures and represent absolute positions, not relative moves. The starting point given by the **pfxStart** member of the **TTPOLYGONHEADER** structure is the point at which the outline for a contour begins. The **TTPOLYCURVE** structures that follow can be either polyline records or spline records. Polyline records are a series of points; lines drawn between the points describe the outline of the character. Spline records represent the quadratic curves used by TrueType (that is, quadratic b-splines).

Each polyline and spline record contains as many sequential points as possible, to minimize the number of records returned.

The starting point given in the **TTPOLYGONHEADER** structure is always on the outline of the glyph. The specified point is both the starting point and the ending point for the contour.

A polyline record begins with the last point in the previous record (or with the starting point, for the first record in the contour). Each point in the record is on the glyph outline and can be connected simply by using straight lines.

A spline record begins with the last point in the previous record (or with the starting point, for the first record in the contour). For the first spline record, the starting point and the last point in the record are on the glyph outline. For all other spline records, only the last point is on the glyph outline. All other points in the spline records are off the glyph outline and must be rendered as the control points of b-

splines.

The last spline or polyline record in a contour always ends with the contour's starting point. This ensures that every contour is closed.

Because b-splines require three points (one point that is off the glyph outline between two that are on the outline), applications must perform some calculations when a spline record contains more than one off-curve point.

For example, if a spline record contains three points (A, B, and C) and it is not the first record, points A and B are off the glyph outline. To interpret point A, an application can use the current position (which is always on the glyph outline) and the point on the glyph outline between points A and B. To find this point between A and B, the application can perform the following calculation:

M = A + (B - A)/2

The midpoint between consecutive off-outline points in a spline record is a point that is on the glyph outline, according to the definition of the spline format used in TrueType fonts. In preceding formula, M is the midpoint on the line between points A and B.

If the current position is designated by P, the two quadratic splines defined by this spline record are (P, A, M) and (M, B, C).

To render a TrueType character outline in GDI, an application must use both the polyline and the spline records. GDI can render polylines easily, but it does not support any spline formats. To use the spline records, an application must convert them into a series of polylines that approximate the spline.

The glyph outline returned by the **GetGlyphOutline** function is for a grid-fitted glyph. (A grid-fitted glyph has been modified so that its bitmap image conforms as closely as possible to the original design of the glyph.) If an application requires an unmodified glyph outline, it should request the glyph outline for a character in a font whose size is equal to the font's em units. (To create a font with this size, an application can set the **lfHeight** member of the **LOGFONT** structure to the negative of the value of the **ntmSizeEM** member of the **NEWTEXTMETRIC** structure.)

Using Portable TrueType Metrics

Applications that use the TrueType font metrics can achieve a high degree of printer and document portability. Applications that must maintain compatibility with earlier versions of Windows can use the TrueType metrics, as can applications that are written specifically for Windows version 3.1.

Design Widths

Design widths overcome most of the problems of device-dependent text introduced by physical devices. Design widths are a kind of logical width. Independent of any rasterization problems or scaling transformations, each glyph has a logical width and height. Composed to a logical page, each character in a string has a place independent of the physical device widths. Although a logical width implies that widths can be scaled linearly at all point sizes, this is not necessarily true for either nonportable or most TrueType fonts. At smaller point sizes, some glyphs are made wider relative to their height for better readability.

The characters in TrueType core fonts are designed against a 2048-by-2048 grid. The design width is the width of a character in these grid units. (TrueType supports any integer grid size up to 16,384 by 16,384; grid sizes that are integer powers of 2 scale faster than other grid sizes.)

The outline of a font is designed in notional units. The em square is the notional grid against which the font outline is fitted. (The **otmEMSquare** member of **OUTLINETEXTMETRIC** and the **ntmSizeEM** member of **NEWTEXTMETRIC** give the size of the em square in notional units.) When a font is created that has a point size (in device units) equal to the size of its em square, the **ABC** widths for this font are the desired design widths. For example, if the size of an em square is 1000 and the ABC widths of a character in the font are 150, 400, and 150, a character in this font that has a height of 10 in device units would have ABC widths of 1.5, 4, and 1.5, respectively. Since the MM_TEXT mapping mode is most commonly used with fonts (and MM_TEXT is equivalent to device units), this is a simple

calculation.

Because of the high resolution of TrueType design widths, applications that use them must take into account the large numeric values that can be created.

Device vs. Design Units

Portable metrics in fonts are known as design units. To apply to a given device, design units must be converted to device units. An application can use the following formula to convert design units to device units:

DeviceUnits = (*DesignUnits*/*unitsPerEm*) * (*PointSize*/72) * *DeviceResolution*

The variables in this formula have the following meanings:

Variable	Description
DeviceUnits	Specifies the *DesignUnits* font metric converted to device units. This value is in the same units as the value given for *DeviceResolution.*
DesignUnits	Specifies the font metric to be converted to device units. This value could be any font metric, including the width of a character or the ascender value for an entire font.
unitsPerEm	Specifies the em square size for the font.
PointSize	Specifies size of the font in points. (One point equals 1/72 of an inch.)
DeviceResolution	Specifies number of device units (pixels) per inch. Typical values might be 300 for a laser printer or 96 for a VGA screen.

Note: This formula should not be used to convert device units back to design units. Device units are always rounded to the nearest pixel. The propagated round-off error can become very large, especially when an application is working with screen sizes.

Requesting Design-Unit Metrics

Font metrics for a physical font can be retrieved only after a font has been selected into a device context. When a font is selected into a device context, it is scaled for the device, which makes the font metrics specific to the device. To request design units, an application should create a logical font whose height is specified as *-unitsPerEm.* Applications can retrieve the value for *unitsPerEm* by calling the **EnumFontFamilies** function and checking the **ntmSizeEM** member of the **NEWTEXTMETRIC** structure.

Metrics for Portable Documents

The following table specifies the most important font metrics for applications that require portable documents and the functions that allow an application to retrieve them:

Function	Metric	Use
EnumFontFamilies	**ntmSizeEM**	Retrieving design metrics; conversion to device metrics
GetCharABCWidths	**ABCWidths**	Accurate placement of characters at the start and end of margins, picture boundaries, and other text breaks
GetCharWidth	**AdvanceWidths**	Placement of characters on a line. (This function is not new for Windows 3.1.)
GetOutlineTextMetrics	**otmfsType**	Font-embedding bits
	otmsCharSlopeRise	Y-component for slope of cursor for italic fonts
	otmsCharSlopeRun	X-component for slope of cursor for italic fonts
	otmAscent	Line spacing
	otmDescent	Line spacing

otmLineGap	Line spacing
otmpFamilyName	Font identification
otmpStyleName	Font identification
otmpFullName	Font identification (typically, family and style name)

The **otmsCharSlopeRise**, **otmsCharSlopeRun**, **otmAscent**, **otmDescent**, and **otmLineGap** members of the **OUTLINETEXTMETRIC** structure are scaled or transformed to correspond to the current device mode and physical height (as given in the **tmHeight** member of the **NEWTEXTMETRIC** structure).

Font identification is important if the same font must be selected when a document is reopened or moved to a different system. The font mapper always selects the correct font when it is asked for by full name. The family and style names are needed in order to provide input to the standard font dialog box for proper placement of the selection bars.

The **otmsCharSlopeRise** and **otmsCharSlopeRun** values are used to produce a close approximation of the main italic angle of the font. For typical roman fonts, **otmsCharSlopeRise** is 1 and **otmsCharSlopeRun** is 0. For italic fonts, the values attempt to approximate the sine and cosine of the main italic angle of the font (in counterclockwise degrees past vertical); note that the italic angle for upright fonts is 0. Because these values are not expressed in design units, they should not be converted into device units.

The character placement and line spacing metrics allow an application to compute device-independent line breaks that are portable across screens, printers, typesetters, and even platforms. If all applications adopt these techniques, documents moved from one application to another will not reflow.

Device-independent page layout requires seven basic steps:

1 Normalize all design metrics to a common ultra-high resolution (UHR) value (for example, 65,536 DPI); this prevents round-off errors.

2 Compute line breaks based on UHR metrics and physical page width; this yields a starting point and an ending point of a line within the text stream.

3 Compute the device page width in device units (for example, pixels).

4 Fit each line of text into the device page width, using the line breaks computed in step 2.

5 Compute page breaks by using UHR metrics and the physical page length; this yields the number of lines per page.

6 Compute the line heights in device units.

7 Fit the lines of text onto the page, using the lines per page from step 5 and the line heights from step 6.

Panose Numbers

TrueType font files include Panose numbers, which applications can use to choose a font that closely matches their specifications. The Panose system classifies faces by 10 different attributes. These attributes are each rated on a scale. The resulting values are concatenated to produce a number. Given this number for a font and a mathematical metric to measure distances in the Panose space, an application can determine nearest neighbors. A **PANOSE** structure is part of the **OUTLINETEXTMETRIC** structure (whose values are filled in by calling the **GetOutlineTextMetrics** function).

Creating Customized Fonts

GDI keeps a system font table containing all the fonts that applications can use. GDI chooses a font from this table when an application calls the **CreateFont** or **CreateFontIndirect** function. There can be up to 253 entries in the system font table.

A font resource is a group of individual fonts representing characters in a given character set that have various combinations of heights, widths, and pitches. Applications can load font resources and add the fonts in the resource to the system font table by using the **AddFontResource** function. After a font resource has been added, the application can use the individual fonts in the resource. In other words, the **CreateFont** function takes the fonts into account when it tries to match a physical font with the specified logical font. (Fonts in the system font table are never directly accessible to an application. They are available only through the **CreateFontIndirect** and **CreateFont** functions, which return handles of the fonts, not memory addresses.)

An application can add a font resource to the system font table by using the **AddFontResource** function. To remove a font resource, an application can use the **RemoveFontResource** function.

Whenever an application adds or removes a font resource, it should inform all other applications of the change by sending a **WM_FONTCHANGE** message to them. An application can use the following call to the **SendMessage** function to send the message to all windows:

```
SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0);
```

An application can use the **GetProfileString** function to retrieve a list of any fonts the user has used Control Panel to install. The application would use **GetProfileString** to search the [Fonts] section of the WIN.INI file.

An application can create font resources by creating font files and adding them as resources to a font resource file. To create a font resource file, an application should follow these steps:

1 Create the font files.

2 Create a resource-definition file for the font.

3 Create a dummy code module.

4 Create a module-definition file that describes the fonts and the devices that use the fonts.

5 Compile and link the sources.

A font resource file is an empty Windows dynamic-link library; it contains no code or data, but does contain resources. An application can add a font file to an empty library, along with such resources as icons, cursors, and menus, by using Microsoft Windows Resource Compiler (RC).

Creating Font Files

An application can create raster font files by using Microsoft Windows Font Editor (FONTEDIT.EXE), as described in *Microsoft Windows Programming Tools.* (Font Editor cannot be used to generate vector or TrueType fonts.) The application can use any number, size, and type of font files in a font resource. In most cases, enough fonts should be included to reasonably satisfy most logical-font requests for the target device.

GDI can scale device-independent raster fonts by 1 to 8 times vertically and 1 to 5 times horizontally. GDI can also simulate bold, underlined, strikeout, and italic fonts. Font designers may choose to allow GDI to synthesize some sizes and properties of a font, rather than providing separate font files.

Font Editor modifies existing .FNT files; it cannot create font files from scratch. The Microsoft Windows 3.1 Software Development Kit (SDK) includes two .FNT files that font designers can load into Font Editor, modify, and save as customized fonts. The file named ATRM1111.FNT is a fixed-width font. The file named VGASYS.FNT is a variable-width font.

The Save As dialog box in Font Editor includes two File Format radio buttons. Font files saved in Font Editor 3.0 format can be used only in 386 enhanced mode. Font files saved in Font Editor 2.0 format can be used in all modes.

Creating the Resource-Definition File for a Font

An application can add resources to a font file by adding one or more **FONT** statements to the

resource-definition file. The resource-definition file can add .FNT files to a Windows library, a device driver, or a resource-only file that contains only icons, cursor, fonts, and other resources. Because font resources are available to all applications, they should not be added to application modules.

The **FONT** statement has the following form:

number **FONT** *filename*

One statement is required for each font file to be placed in the resource. The *number* must be unique, because it is used to identify the font later. The following is a typical resource-definition file for a font resource:

```
1  FONT FNTFIL01.FNT
2  FONT FNTFIL02.FNT
3  FONT FNTFIL03.FNT
4  FONT FNTFIL04.FNT
5  FONT FNTFIL05.FNT
6  FONT FNTFIL06.FNT
```

You can add fonts to modules that contain other resources by adding them to the existing resource-definition file. An application can have icon, menu, cursor, and dialog box definitions in the resource-definition file, as well as **FONT** statements.

Creating a Dummy Code Module

A dummy code module provides the object file from which the font resource file is made. A developer can create the dummy code module by using the assembler and the Cmacros. The module's source file could look like this:

```
 TITLE   FONTRES - Stub file to build a .FON resource file

 .xlist
 include cmacros.inc
 .list

 sBegin CODE
 db 0
 sEnd   CODE
 end
```

Microsoft Segmented Executable Linker LINK version 4 allows empty code segments, but LINK versions 5.12 and later does not. The inclusion of "db 0" between sBegin and sEnd in the preceding example prevents an empty code segment.

The developer can assemble this source file by using the **masm** command. The object file that will be created will contain no code and no data, but it can be linked to an empty Windows library to which the font resources can be added.

Developers who build font files using version 6.0 of Microsoft Macro Assembler (ML) should use version 5.3 of the CMACROS.INC file (included with ML) instead of version 5.2 of the file, which is included with the SDK.

Creating a Module-Definition File

The module-definition file for the font resource must contain a **LIBRARY** statement that defines the resource name, a **DESCRIPTION** statement that describes the font resource characteristics, and a **DATA** statement. The module-definition file for a font resource should look like this:

```
LIBRARY FONTRES

DESCRIPTION 'FONTRES 133,96,72 : System, Terminal (Set #3)'
```

```
EXETYPE WINDOWS

STUB 'WINSTUB.EXE'
DATA NONE
```

The **DESCRIPTION** statement provides device-specific information about the font that is used to match a font with a given screen or printer. The following are the three possible formats for the **DESCRIPTION** statement in a font resource. In each case, the first characters in the description must be a single quote and the name of the library module (FONTRES):

DESCRIPTION 'FONTRES *Aspect*, *LogPixelsX*, *LogPixelsY*: *Cmt*' **DESCRIPTION 'FONTRES CONTINUOUSSCALING:** *Cmt*' **DESCRIPTION 'FONTRES DEVICESPECIFIC** *DeviceTypeGroup*: *Cmt*'

The first format specifies a font that was designed for a specific aspect ratio and logical pixel width and height, and can be used with any device having the same aspect and logical pixel dimensions. *Aspect* is the value (100**AspectY*)/*AspectX* rounded to an integer. The *AspectX, AspectY, LogPixelsX,* and *LogPixelsY* values are the same as the values given in the corresponding device's **GDIINFO** structure (values that are accessible by using the **GetDeviceCaps** function). You can specify more than one set of *Aspect, LogPixelsX,* and *LogPixelsY* values. The *Cmt* value is a comment. The following statements are examples:

```
DESCRIPTION 'FONTRES 133,96,72: System, Terminal (Set #3)'
DESCRIPTION 'FONTRES 200,96,48; 133,96,72; 83,60,72; 167,120,72: \
    MS Sans Serif'
```

The second format specifies a continuous scaling font. This typically corresponds to vector fonts that can be drawn to any size and that do not depend on the aspect or logical pixel width of the output device. The following statement is an example:

```
DESCRIPTION 'FONTRES CONTINUOUSSCALING : Modern, Roman, Script'
```

The third format specifies a font that is specific to a particular device or group of devices. The *DeviceTypeGroup* can be **DISPLAY** or a list of device-type names--the same names an application might specify as the second parameter in a call to the **CreateDC** function. Following is an example of the third format:

```
DESCRIPTION 'FONTRES DISPLAY: HP 7470 plotters'
DESCRIPTION 'FONTRES DEVICESPECIFIC HP 7470A, HP 7475A: \
    HP 7470 plotters'
```

Note: The maximum length of a **DESCRIPTION** line is 127 characters. Because GDI is capable of synthesizing attributes, such as bold, italic, and underline, the font designer need not create separate .FNT files for fonts with these attributes. Windows may use other fonts that do not correspond to the user's screen aspect ratio. These are generic raster fonts that are intended for output devices such as bitmap printers, which rely on the display driver to draw text.

Compiling and Linking a Font Resource File

The following makefile lists the commands required to compile and link a font resource file:

```
fontres.obj: fontres.asm
    masm fontres;

fontres.exe: fontres.def fontres.obj fontres.rc fontres.exe \
                fntfil01.fnt fntfil02.fnt fntfil03.fnt \
                fntfil04.fnt fntfil05.fnt fntfil06.fnt
    link fontres.obj, fontres.exe, NUL, /nod, fontres.def
    rc fontres.rc
    rename fontres.exe custom.fon
```

By convention, all raster font resource files have the .FON filename extension. The last line in the makefile renames the executable file to CUSTOM.FON.

Adding TrueType Fonts

Because Windows cannot directly interpret the native TrueType font file format, a file that mimics the standard .FON file (called a .FOT file) is required to make internal bookkeeping and enumeration easier. The **CreateScalableFontResource** function produces a .FOT file that points to the TrueType font file. Once this .FOT file is produced, Windows applications can use TrueType fonts transparently by using the **AddFontResource** and **RemoveFontResource** functions. Applications could also use the **CreateScalableFontResource** function to install special fonts for logos, icons, and other graphics.

Messages

Messages are the input to an application. They represent events that the application may need to respond to. A message is a structure that contains a message identifier and message parameters. The content of the parameters varies with the message type.

Generating and Processing Messages

Windows generates an input message for each input event, such as when the user moves the mouse or presses a key. Windows collects input messages in a systemwide message queue and then places the messages, as well as timer and paint messages, in an application message queue. An application message queue is a first in, first out queue. Timer and paint messages are exceptions to the first in, first out rule; these messages are held in an application's message queue until the application has processed all other messages. Windows places messages that belong to a specific application in that application's message queue. The application then reads the messages by using the **GetMessage** function and dispatches them to the appropriate window procedure by using the **DispatchMessage** function.

Windows sends some messages directly to the window procedure in the appropriate application instead of placing the messages in the application's message queue. Such messages are called unqueued messages. Typically, an unqueued message is any message that affects the window only. The **SendMessage** function sends messages directly to a window procedure. For more information about window procedures, see Window Procedures.

For example, the **CreateWindow** function directs Windows to send a **WM_CREATE** message to a window procedure of an application and to wait until the window procedure has processed the message. Windows sends this message directly to the window procedure and does not place it in the application's message queue.

Although Windows generates most messages, an application can create its own messages and place them in its own message queue or that of another application.

An application typically uses the **GetMessage** function in a loop within its **WinMain** function to remove messages from the application's message queue. This loop is called the main message loop. The **GetMessage** function searches an application's message queue and, if any messages exist, returns the top message in the queue. If the message queue is empty, **GetMessage** waits for a message to be placed in the queue. While waiting, **GetMessage** relinquishes control to Windows, allowing other applications to take control and process their own messages.

Once an application's **WinMain** function has retrieved a message from the application's message queue, it can dispatch the message to a window procedure by using the **DispatchMessage** function. This function directs Windows to call the window procedure of the window associated with the message, and then passes the content of the message as function arguments. The window procedure can then process the message and carry out any requested changes to the window. When the window procedure returns, Windows returns control to the main message loop in the **WinMain** function. The main message loop can then retrieve the next message from the queue.

Note: Unless noted otherwise, Windows can send messages in any sequence. An application should not rely on receiving messages in a particular order.

Windows generates a message each time the user presses a key. The message contains a virtual-key code that defines which key was pressed, but does not define the character value of that key. To retrieve the character value, the main message loop in the **WinMain** function must translate the virtual-key message by using the **TranslateMessage** function. This function puts another message with an appropriate character value in the application's message queue. The message can then be dispatched to a window procedure.

Translating Messages

In general, a **WinMain** function should use the **TranslateMessage** function to translate every message, not just virtual-key messages. Although **TranslateMessage** has no effect on other types of

messages, it guarantees that keyboard input is translated correctly.

The following example illustrates the typical main message loop that a **WinMain** function uses to retrieve messages from the application's message queue and dispatch them to the application's window procedures:

```
int PASCAL WinMain(HINSTANCE hinstCurrent, HINSTANCE hinstPrevious,
    LPSTR lpszCmdLine, int nCmdShow)
{
    MSG msg;

        .
        .
        .

    while (GetMessage(&msg, NULL, 0, 0)) {
        TranslateMessage(&msg); /* translates virtual key codes    */
        DispatchMessage(&msg);  /* dispatches message to window    */
    }
    return (int) msg.wParam;    /* return value of PostQuitMessage */
}
```

An application that uses accelerator keys must load an accelerator table from the resource-definition file by using the **LoadAccelerators** function and then translate keyboard messages into accelerator-key messages by using the **TranslateAccelerator** function.

The main message loop for an application that uses accelerator keys should have the following form:

```
while (GetMessage(&msg, NULL, 0, 0)) {
    if (TranslateAccelerator(hwnd, haccel, &msg) == 0) {
        TranslateMessage(&msg);
        DispatchMessage(&msg);
     }
}
return (int) msg.wParam;
```

The **TranslateAccelerator** function must appear before the standard **TranslateMessage** and **DispatchMessage** functions. Furthermore, because **TranslateAccelerator** automatically dispatches the accelerator-key message to the appropriate window procedure, the **TranslateMessage** and **DispatchMessage** functions should not be called if **TranslateAccelerator** returns a nonzero value.

Examining Messages

An application can use the **PeekMessage** function to examine its message queue for specific messages without removing them from the queue. The function returns a nonzero value if a message exists in the queue and lets the application retrieve the message and process it without going through the application's main message loop.

Typically, an application uses **PeekMessage** to check periodically for messages when the application is carrying out a lengthy operation, such as processing input and output. For example, this function can be used to check for messages that end the operation. **PeekMessage** also gives the application a chance to yield control if no messages are present, because **PeekMessage** can yield if no messages are in the message queue.

Sending Messages

The **SendMessage** and **PostMessage** functions let applications pass messages to their windows or to the windows of other applications. The **PostAppMessage** function is a variation on **PostMessage** that posts a message using the application's module handle rather than a window handle.

The **PostMessage** function directs Windows to post a message--that is, place the message in an

application's message queue. The **PostMessage** function immediately returns control to the calling application, and any action to be carried out as a result of the message does not occur until the message is read from the queue.

The **SendMessage** function directs Windows to send a message directly to the given window procedure, bypassing the application's message queue. Windows does not return control to the calling application until the window procedure that receives the message processes the message or returns control as a result of a call to the **ReplyMessage** function.

When an application transmits a message, it must do so by calling **SendMessage** if the application relies on the return value of a message. The return value of **SendMessage** is the same as the value returned by the window procedure that processed the message. **PostMessage** returns immediately after sending the message, so its return value is only a Boolean value indicating whether the message was successfully placed in the queue and does not indicate how the message was processed.

Avoiding Message Deadlocks

An application can create a deadlock condition in Windows if it yields control while processing a message sent from another application (or by Windows on behalf of another application) by using the **SendMessage** function.

Typically, a task that calls **SendMessage** to send a message to another task does not continue running until the window procedure that receives the message returns. When the task that receives the message yields control, the sending task cannot continue to run and to process messages because it is waiting for **SendMessage** to return, resulting in a message deadlock.

The application processing the message does not have to yield explicitly to cause the problem. Calling any one of the following functions can result in the application yielding control:

- **DialogBox**
- **DialogBoxIndirect**
- **DialogBoxIndirectParam**
- **DialogBoxParam**
- **GetMessage**
- **MessageBox**
- **PeekMessage**
- **Yield**

Before calling any of these functions while processing a message, a window procedure should first call the **InSendMessage** function to find out whether the message was sent by the **SendMessage** function from another application. If **InSendMessage** returns a nonzero value, the window procedure must call the **ReplyMessage** function before calling any function that yields control.

Creating and Managing Windows

This section describes how to create, destroy, modify, and obtain information about windows.

Window Classes

A window class is a set of attributes that defines how a window looks and behaves. Before an application can create and use a window, a window class must have been created and registered for that window. An application registers a class by filling a **WNDCLASS** structure and passing a pointer to the structure to the **RegisterClass** function. Any number of window classes can be registered. Once a class has been registered, Windows lets the application create any number of windows belonging to that class. The registered class remains available until it is deleted or the application closes.

Although the complete window class consists of many elements, Windows requires only that an application supply a class name, the address of the window procedure that will process all messages sent to windows belonging to this class, and an instance handle identifying the application that registered the class. The other elements of the window class define default attributes for windows of the class, such as the shape of the cursor and the content of the menu for the window.

There are three types of window classes: system global classes, application global classes, and application local classes. These types differ in scope and in when and how they are created and destroyed.

System Global Classes

Windows creates system global classes when it starts. These classes are available for use by all applications at all times. Because Windows creates system global classes on behalf of all applications, an application cannot create or destroy any of these classes. System global classes include edit-control and list-box control classes.

Application Global Classes

An application or (more likely) a dynamic-link library (DLL) creates an application global class by specifying the **CS_GLOBALCLASS** style for the class. Once created, it is globally available to all applications within the system. Typically, a DLL creates an application global class so that applications that call the DLL can use the class. Windows destroys an application global class when the application that created it closes or the DLL that created it is unloaded. For this reason, it is essential that all applications destroy all windows using that class before the application that created the class closes or the DLL that created the class is unloaded. Use the **UnregisterClass** function to remove an application global class and free the storage associated with it.

Application Local Classes

An application local class is any window class created by an application for its exclusive use. This is the more common type of class created by an application. Use the **UnregisterClass** function to remove an application local class and free the storage associated with it.

How Windows Locates a Class

When an application creates a window with a specified class, Windows uses the following procedure to find the class:

1. Windows searches for a local class of the specified name.
2. If Windows does not find a local class with the name, it searches the application global class list.
3. If Windows does not find the name in the application global class list, it searches the system global class list.

This procedure is used for all windows created by the application, including windows created by Windows on the application's behalf, such as dialog boxes. It is possible, then, to override system global

classes without affecting other applications.

Class Ownership

Windows determines class ownership from the **hInstance** member of the **WNDCLASS** structure passed to the **RegisterClass** function when the application or DLL registers the class. For Windows DLLs, the **hInstance** member *must* be the instance handle of the DLL. When the application that registered the class closes or the DLL that registered the class is unloaded, the class is destroyed. For this reason, all windows using the class must be destroyed before the application closes or the DLL is unloaded.

Registering a Window Class

When Windows registers a window class, it copies the attributes into its own memory area. Windows uses these internally stored attributes when an application refers to the window class by name; it is not necessary for the application that originally registers the class to keep the structure available.

Shared Window Classes

An application must not share its registered classes with other applications. Some information in a window class, such as the address of the window procedure, is specific to a given application and cannot be used by other applications. However, applications can share an application global class. For more information, see Application Global Classes.

Although an application must not share one of its registered classes with other applications, different instances of the same application can share a registered class. Once a window class has been registered by an application, it is available to all subsequent instances of that application. This means that new instances of an application do not need to, and should not, register window classes that have been registered by previous instances.

Predefined Window Classes

Windows provides several predefined system-global window classes. These classes define special control windows that carry out common input tasks, such as letting the user direct scrolling, type text, and select from a list of names. The predefined window classes are available to all applications and can be used any number of times to create any number of control windows.

Elements of a Window Class

The elements of a window class define the default behavior of windows created from that class. The application that registers a window class assigns elements to the class by setting appropriate members in a **WNDCLASS** structure and passing the structure to the **RegisterClass** function. An application can retrieve information about a given window class with the **GetClassInfo** function. The window class elements are as follows:

Element	Purpose
Class name	Distinguishes the class from other registered classes.
Window-procedure address	Points to the function that processes all messages that are sent to windows in the class, and defines the behavior of the window.
Instance handle	Identifies the application or DLL that registered the class.
Class cursor	Defines the shape of the cursor when the cursor is in a window of the class.
Class icon	Defines the shape of the icon Windows displays when a window belonging to the class is minimized.
Class background brush	Defines the color and pattern Windows uses to fill the client area when the window is opened or painted. If this parameter is set to NULL, the window must paint its own background whenever it receives the **WM_ERASEBKGND** message.
Class menu	Specifies the default menu used for any window belonging to the class

	that does not explicitly define a menu.
Class styles	Defines how to update the window after moving or resizing, how to process double-clicks of the mouse, how to allocate space for the display context, and other aspects of the window.
Class extra	Specifies the amount of extra memory, in bytes, that Windows should reserve at the end of the **WNDCLASS** structure. Windows initializes this memory to zero.
Window extra	Specifies the amount of extra memory, in bytes, that Windows should reserve at the end of any window structure an application creates that has this class. Windows initializes this memory to zero.

The following sections describe the elements of a window class and explain the default values for these elements if no explicit value is given when the class is registered.

Class Name

Every window class needs a class name. The class name distinguishes one class from another. An application assigns a class name to the class by setting the **lpszClassName** member of the **WNDCLASS** structure to the address of a null-terminated string that specifies the name.

In the case of an application global class, the class name must be unique to distinguish it from other application global classes. If an application registers another application global class with the name of an existing application global class, the **RegisterClass** function returns zero, indicating failure. The conventional method for ensuring this uniqueness is to include the application name in the name of the application global class.

The class name must be unique among all the classes registered by an application. An application cannot register an application local class and an application global class with the same class name.

Window-Procedure Address

Every class needs a window-procedure address. The address defines the entry point of the window procedure that is used to process all messages for windows in the class. Windows passes messages to the procedure when it requires the window to carry out tasks, such as painting its client area or responding to input from the user. An application assigns a window-procedure to a class by copying its address to the **lpfnWndProc** member of the **WNDCLASS** structure. The window procedure must be exported in the module-definition (.DEF) file. For more information about exporting functions, see the EXPORTS topic.

Instance Handle

Every window class needs an instance handle to identify the application or DLL that registered the class. As a multitasking system, Windows lets several applications or DLLs run at the same time, so it needs instance handles to keep track of all applications and DLLs. Windows assigns a unique handle to each copy of a running application or DLL.

Multiple instances of the same application or DLL all use the same code segment, but each has its own data segment. Windows uses an instance handle to identify the data segment that corresponds to a particular instance of an application or DLL.

Windows passes an instance handle to an application or DLL when the application first begins operation. The application or DLL assigns this instance handle to the class by copying it to the **hInstance** member of the **WNDCLASS** structure.

Class Cursor

The class cursor defines the shape of the cursor when the cursor is in the client area of a window in the class. Windows automatically sets the cursor to the given shape as soon as the cursor enters the window's client area, and ensures that the cursor keeps that shape while it remains in the client area. To assign a cursor shape to a window class, an application typically loads a predefined cursor shape by using the **LoadCursor** function, and then assigns the returned cursor handle to the **hCursor**

member of the **WNDCLASS** structure. Alternatively, you can use Microsoft Image Editor (IMAGEDIT.EXE) to create your own custom cursor, and use Microsoft Windows Resource Compiler (RC) to add the cursor as a resource to your application's executable file. The application can then use the **LoadCursor** function to load the custom cursor from the application's resources.

Windows does not require a class cursor. If an application sets the **hCursor** member of the **WNDCLASS** structure to NULL, a class cursor is not defined. Windows assumes that the window will set the cursor shape each time the cursor moves into the window. A window can set the cursor shape by calling the **SetCursor** function whenever the window receives the **WM_MOUSEMOVE** message.

Class Icon

The class icon defines the shape of the icon used when the window of the given class is minimized. To assign an icon to a window class, an application typically loads the icon from the application's resources by using the **LoadIcon** function, and then assigns the returned icon handle to the **hIcon** member of the **WNDCLASS** structure.

Windows does not require that a window class have a class icon. If an application sets the **hIcon** member of the **WNDCLASS** structure to NULL, a class icon is not defined. In this case, Windows sends the **WM_ICONERASEBKGND** message to a window of the class whenever the window must paint the background of the icon. If the window does not process the WM_ICONERASEBKGND message, Windows draws an image of the contents of the window's client area onto the icon when it is minimized.

Class Background Brush

A class background brush is the brush used to prepare the client area of a window for subsequent drawing by the application. Windows uses the brush to fill the client area with a solid color or pattern, thereby removing all previous images from that location whether they belonged to the window or not. Windows notifies a window that its background needs to be painted by sending the **WM_ERASEBKGND** message to the window.

To assign a background brush to a class, an application can create a brush by using the appropriate functions from the graphics device interface (GDI) and then assign the returned brush handle to the **hbrBackground** member of the **WNDCLASS** structure.

Instead of creating a brush, an application can use a standard system color by setting the **hbrBackground** member to one of the standard system color values.

To use a standard system color, the application must increase the background-color value by one. For example, **COLOR_BACKGROUND** + 1 is the system background color.

Class Menu

A class menu defines the default menu to be used by the windows in the class if no explicit menu is given when the windows are created. A menu is a list of commands from which a user can select actions for the application to carry out. To assign a menu to a class, an application sets the **lpszMenuName** member of the **WNDCLASS** structure to the address of a null-terminated string that specifies the resource name of the menu. The menu is assumed to be a resource in the given application. Windows automatically loads the menu when it is needed. Note that if the menu resource is identified by an integer and not by a name, the application can set the **lpszMenuName** member to that integer value by applying the **MAKEINTRESOURCE** macro before assigning the value.

Windows does not require a class menu. If an application sets the **lpszMenuName** member of the **WNDCLASS** structure to NULL, Windows assumes that the windows in the class have no menu bars. Even if no class menu is given, an application can still define a menu bar for a window when it creates the window.

Windows does not allow menu bars with child windows. If a menu is given for a class and a child window of that class is created, the menu is ignored. For more information about menus, see Menus.

Class Styles

The class styles define additional elements of the window class. Two or more styles can be combined by using the bitwise OR (|) operator. The class styles are as follows:

Style	Description
CS_BYTEALIGNCLIENT	Aligns the window's client area on a byte boundary (in the x direction).
CS_BYTEALIGNWINDOW	Aligns the window on a byte boundary (in the x direction).
CS_CLASSDC	Allocates one display context to be shared by all windows in the class. For more information about device contexts, see Class and Private Display Contexts, and Display Context Types.
CS_DBLCLKS	Sends double-click messages to the window procedure.
CS_GLOBALCLASS	Specifies that the window class is an application global class. An application global class is created by an application or DLL and is available to all applications. The class is destroyed when the application or DLL that created the class closes; it is essential, therefore, that all windows created with the application global class be closed before the application or DLL closes.
CS_HREDRAW	Requests that the entire client area be redrawn if a movement or size adjustment changes the width of the client area.
CS_NOCLOSE	Inhibits the Close command on the System menu (sometimes referred to as the Control menu).
CS_OWNDC	Allocates a unique display context for each window in the class. For more information about device contexts, see Class and Private Display Contexts, and Display Context Types.
CS_PARENTDC	Gives the parent window's display context to the child windows. For more information about device contexts, see Class and Private Display Contexts, and Display Context Types.
CS_SAVEBITS	Saves, as a bitmap, the portion of the screen image that is obscured by a window; Windows uses the saved bitmap to re-create the screen image when the window is removed. Windows displays the bitmap at its original location and does not send **WM_PAINT** messages to windows that had been obscured by the window if the memory used by the bitmap has not been discarded and if other screen actions have not invalidated the stored image.
CS_VREDRAW	Requests that the entire client area be redrawn if a movement or size adjustment changes the height of the client area.

To assign a style to a window class, an application assigns the style value to the **style** member of the **WNDCLASS** structure.

Internal Data Structures

Windows maintains internal data structures for each window class and window. These structures are not directly accessible to applications but can be examined and modified by using the following functions:

- **GetClassInfo**
- **GetClassLong**
- **GetClassName**
- **GetClassWord**
- **GetWindowLong**
- **GetWindowWord**
- **SetClassLong**
- **SetClassWord**
- **SetWindowLong**
- **SetWindowWord**

Window Subclassing

A subclass is a window or set of windows that belong to the same window class, and whose messages are intercepted and processed by another window procedure (or procedures) before being passed to the class window procedure.

To create the subclass, the **SetWindowLong** function is used to change which window procedure is associated with a particular window, causing Windows to call the new window procedure instead of the previous one. An application must call the **CallWindowProc** function to pass to the previous window procedure any messages not processed by the new window procedure. This allows Windows to create a chain of window procedures. The application can retrieve the address of the previous window procedure by using the **GetWindowLong** function before using the **SetWindowLong** function.

Similarly, the **SetClassLong** function changes which window procedure is associated with a window class. Any window that is subsequently created with that class will be associated with the replacement window procedure for that class, as will the window whose handle is passed to **SetClassLong**. Other existing windows that were previously created with the class are not affected, however.

When an application subclasses a window or class of windows, it must export the replacement window procedure in its module-definition file, call the **MakeProcInstance** function to create the address of the procedure, and pass the address to the **SetWindowLong** or **SetClassLong** function.

Redrawing the Client Area

When a window is moved, Windows automatically copies the contents of the client area to the new location. This saves time because a window does not have to recalculate and redraw the contents of the client area as part of the move. If the window moves and changes size, Windows copies only as much of the previous client area as is needed to fill the new location. If the window increases in size, Windows copies the entire client area and sends a **WM_PAINT** message to the window to fill in the newly exposed areas.

When a window is moved, Windows assumes the contents of the client area remain valid and can be copied without modification to the new location. For some windows, however, the contents of the client area are not valid after a move, especially if the move includes a change in size. For example, a clock application whose window must always contain the complete image of the clock has to redraw the window anytime the window changes size, *and* has to update the time after the move. To redraw the entire client area instead of copying the previous contents each time a window changes size, a window should specify the **CS_VREDRAW** and **CS_HREDRAW** styles in the window class.

Class and Private Display Contexts

A display context is a special set of values that applications use for drawing in the client area of their windows. Windows requires a display context for each window on the system display but allows some flexibility in how that display context is stored and treated by the system.

If no display-context style is explicitly given, Windows assumes that each window will use a display context retrieved from a pool of contexts maintained by Windows. In such cases, each window must retrieve and initialize the display context before painting, and then free it after painting.

To avoid retrieving a display context each time it needs to paint inside a window, an application can specify the **CS_OWNDC** style for the window class. This class style directs Windows to create a private display context--that is, to allocate a unique display context for each window in the class. The application need only retrieve the context once, and then use it for all subsequent painting. Although the CS_OWNDC style is convenient, it must be used carefully because each display context uses a significant amount of system resources.

By specifying the **CS_CLASSDC** style, an application can have some of the convenience of a private display context without allocating a separate display context for each window. The CS_CLASSDC style directs Windows to create a single class display context--that is, one display context to be shared by all windows in the class. An application need only retrieve the display context for a window; as long as no other window in the class retrieves that display context, the window can continue to use the

context.

Similarly, by specifying the **CS_PARENTDC** style, an application can create child windows that inherit the device context of their parent.

Window Procedures

A window procedure processes all messages sent to all windows in a given class. Windows sends messages to a window procedure when it receives input from the user that is intended for the given window, or when it needs the procedure to carry out some action on its window, such as painting inside the client area.

A window procedure receives the following types of messages:

- Input messages from the keyboard, mouse or other pointing device, and timer
- Requests for information, such as a request for the window title
- Reports of changes made to the system by other windows, such as a change to the WIN.INI file
- Messages that give the window procedure an opportunity to modify the standard system response to certain actions, such as an opportunity to adjust a menu before it is displayed
- Requests to carry out some action on its window or client area, such as a request to update the client area
- Information about its status in relation to other windows, such as its losing access to the keyboard or becoming the active window

Most of the messages a window procedure receives are from Windows, but it can also receive messages from other windows, including windows it owns. These messages can be requests for information or notification that a given event has occurred within another window.

A window procedure continues to receive messages from the system and possibly other windows in the system until the window procedure, the window procedure of a parent window, or the system destroys the window. Even while the window is in the process of being destroyed, the window procedure receives additional messages that give it the opportunity to carry out any cleanup tasks before terminating. These messages include **WM_CLOSE**, **WM_DESTROY**, **WM_QUERYENDSESSION**, and WM_ENDSESSION. But once the window is destroyed, no more messages are passed to the procedure for that particular window. If there is more than one window of the class, however, the window procedure continues to receive messages for the other windows until they, too, are destroyed.

A window procedure defines how all windows of a given window actually behave; that is, it defines what response the windows make to commands from the user or system. The window procedure must examine messages it receives from the system and determine what action, if any, to take. For example, if the user clicks the scroll bar, the window procedure may scroll the contents of the client area. Windows passes information that affects a window and provides some tools to carry out tasks, such as drawing and scrolling, but the window procedure must carry out each actual task.

A window procedure can also choose not to respond to a given message. If it does not respond, the procedure must pass the message to the **DefWindowProc** function to give the system the opportunity to respond. This function carries out default actions based on the given message and its parameters. Many messages, especially nonclient-area messages, must be processed, so the **DefWindowProc** function is required in all window procedures.

A window procedure also receives messages that are really intended to be processed by the system. These messages, called nonclient-area messages, inform the procedure either that the user has carried out some action in a nonclient area of the window, such as clicking the title bar, or that some information about the window is required by the system to carry out an action, such as to move or adjust the size of the window. Although Windows passes these messages to the window procedure, the procedure should pass them to the **DefWindowProc** function and not attempt to process them. In any case, the window procedure must not ignore the message or return without passing it to **DefWindowProc**.

Window Messages

A window message is a set of values that Windows sends to a window procedure to provide input to the window or request the window to carry out some action. Windows includes a wide variety of

messages that it or applications can send to a window procedure. Most messages are sent to a window as a result of a given function being executed or as a result of input from the user.

Every message consists of four values: a handle that identifies the window, a message identifier, a 16-bit message-specific value, and a 32-bit message-specific value. These values are passed as individual parameters to the window procedure. The window procedure then examines the message identifier to determine what response to make and how to interpret the 16- and 32-bit values.

A window procedure must use the Pascal calling convention. The following illustrates the window procedure syntax:

LONG FAR PASCAL *WndProc***(***hwnd***,** *wMsg***,** *wParam***,** *lParam***)**
HWND *hwnd***;**
WORD *wMsg***;**
WORD *wParam***;**
DWORD *lParam***;**

The *hwnd* parameter identifies the window receiving the message; the *wMsg* parameter is the message identifier; the *wParam* parameter is 16 bits of additional message-specific information; and *lParam* is 32 bits of additional message-specific information. The window procedure must return a 32-bit value that indicates the result of message processing. The possible return values depend on the actual message sent.

Windows expects to make an intersegment call to the window procedure, so the procedure must be declared with the **FAR** attribute. The window-procedure name must be exported by including it in an **EXPORTS** statement in the application's module-definition file.

Default Window Procedure

The **DefWindowProc** function is the default message processor for window procedures that do not or cannot process some of the messages sent to them. For most window procedures, the **DefWindowProc** function carries out most, if not all, processing of nonclient-area messages. These are the messages that signify actions to be carried out on parts of the window other than the client area. The messages that **DefWindowProc** processes and the default actions for each are as follows:

Message	Default action
WM_ACTIVATE	Activates or deactivates a window.
WM_CANCELMODE	Cancels internal processing of standard scroll bar input, cancels internal menu processing, and releases mouse capture.
WM_CHARTOITEM	Returns -1.
WM_CLOSE	Calls the **DestroyWindow** function.
WM_CTLCOLOR	Sets the background and text color and returns a handle of the brush used to fill the control background.
WM_DRAWITEM	Draws the focus rectangle for an owner-drawn list box item.
WM_ERASEBKGND	Fills the client area with the color and pattern specified by the class brush, if any.
WM_GETTEXT	Copies the window title into a specified buffer.
WM_GETTEXTLENGTH	Returns the length, in bytes, of the window title.
WM_ICONERASEBKGND	Fills the icon's client area with the window's background brush.
WM_KEYUP	Sends a **WM_SYSCOMMAND** message to the top-level window if the F10 key or the ALT key was released. The *wParam* parameter of the message is set to SC_KEYMENU.
WM_MOUSEACTIVATE	Sends the **WM_MOUSEACTIVATE** response to the parent window. The parent determines whether to activate the child window.
WM_NCACTIVATE	Activates or deactivates the window and draws the icon or title bar to show the new state.

WM_NCCALCSIZE	Computes the size of the client area.
WM_NCCREATE	Initializes standard scroll bars, if any, and sets the default title for the window.
WM_NCDESTROY	Frees any space internally allocated for the window title.
WM_NCHITTEST	Finds out what part of the window the mouse is in.
WM_NCLBUTTONDBLCLK	Tests the given point to find out the location of the mouse and, if necessary, generates additional messages.
WM_NCLBUTTONDOWN	Finds out whether the left mouse button was pressed while the mouse was in the nonclient area of a window.
WM_NCLBUTTONUP	Tests the given point to find out the location of the mouse and, if necessary, generates additional messages.
WM_NCMOUSEMOVE	Tests the given point to find out the location of the mouse and, if necessary, generates additional messages.
WM_NCPAINT	Paints the nonclient areas of the window.
WM_PAINT	Validates the current update region, but does not paint the region.
WM_QUERYENDSESSION	Returns TRUE.
WM_QUERYOPEN	Returns TRUE.
WM_SETCURSOR	Displays the appropriate mouse cursor, based on the position of the cursor.
WM_SETREDRAW	Forces an immediate update of information about the clipping region of the complete window.
WM_SETTEXT	Sets and displays the window title.
WM_SHOWWINDOW	Opens or closes a window.
WM_SYSCHAR	Generates a **WM_SYSCOMMAND** message for menu input.
WM_SYSCOMMAND	Carries out the requested system command.
WM_SYSKEYDOWN	Examines the given key and generates a **WM_SYSCOMMAND** message if the key is either TAB or ENTER.
WM_SYSKEYUP	Sends a **WM_SYSCOMMAND** message to the top-level window if the F10 key or the ALT key was released. The *wParam* parameter of the message is set to SC_KEYMENU.
WM_VKEYTOITEM	Returns -1.
WM_WINDOWPOSCHANGED	Sends the **WM_SIZE** and **WM_MOVE** messages to the window.
WM_WINDOWPOSCHANGING	Sends the **WM_GETMINMAXINFO** message to the window if the window has the **WS_OVERLAPPED** or **WS_THICKFRAME** style.

Window Styles

Windows provides several different window styles that can be combined to form different kinds of windows. The styles are used in the **CreateWindow** function when the window is created.

Overlapped Windows

An overlapped window is always a top-level window. In other words, an overlapped window never has a parent window. It has a client area, a border, and a title bar. It can also have a System menu, Minimize and Maximize buttons, scroll bars, and a menu, if these items are specified when the window is created. For a window used as a main interface, the System menu and Minimize and Maximize buttons are strongly recommended.

Every overlapped window can have a corresponding icon that Windows displays when the window is minimized. A minimized window is not destroyed. It can be restored to its previous size and position. An application minimizes a window to save screen space when several windows are open at the same time.

An application creates an overlapped window by using the **WS_OVERLAPPED** or **WS_OVERLAPPEDWINDOW** style with the **CreateWindow** function. An overlapped window created with the WS_OVERLAPPED style always has a title bar and a border. The WS_OVERLAPPEDWINDOW style creates an overlapped window with a title bar, a thick-frame border, a System menu, and Minimize and Maximize buttons.

Owned Windows

An owned window is a special type of overlapped window. Every owned window must be owned by an overlapped window. Being owned forces several constraints on a window:

- An owned window is always in front of its owner when the windows are in z-order. Attempting to move the owner--that is, on an imaginary z-axis extending in front of the owned window from the screen toward the user--causes the owned window also to change position to ensure that it will always be in front of its owner.
- Windows automatically destroys an owned window when it destroys the window's owner.
- An owned window is hidden when its owner is minimized.

An application creates an owned window by specifying the owner's window handle as the *hWndParent* parameter of the **CreateWindow** function when creating a window that has the **WS_OVERLAPPED** style.

Dialog boxes are owned windows by default. The function that creates the dialog box receives the handle of the owner window as its *hWndParent* parameter.

Pop-up Windows

Pop-up windows are another special type of overlapped window. The main difference between a pop-up window and other overlapped windows is that an overlapped window always has a title bar, whereas the title bar is optional for a pop-up window. Like other overlapped windows, pop-up windows can be owned.

You create a pop-up window by using the **WS_POPUP** window style with the **CreateWindow** function. An application can use the **ShowWindow** function to open or close a pop-up window.

Child Windows

A child window is a window that is confined to the client area of a parent window. Child windows are typically used to divide the client area of a parent window into different functional areas.

You create a child window by using the **WS_CHILD** window style with the **CreateWindow** function. An application can use the **ShowWindow** function to show or hide a child window.

Every child window must have a parent window. The parent window can be an overlapped window, a pop-up window, or even another child window. The parent window relinquishes a portion of its client area to the child window, and the child window receives all input from this area. The window class does not have to be the same for each of the child windows of the parent window. This means an application can fill a parent window with child windows that look different and carry out different tasks.

A child window has a client area, but it does not have any other features unless these are explicitly requested. An application can request a border, title bar, Minimize and Maximize buttons, and scroll bars for a child window. In most cases, the application designs its own features for the child window.

Although it is not required, every child window should have a unique integer identifier. The identifier, given in the *hmenu* parameter of the **CreateWindow** function in place of a menu, helps identify the child window when its parent window has other child windows. The child window should use this identifier in any messages it sends to the parent window. This is the way a parent window with multiple child windows can identify which child window is sending the message. Child windows that share the same parent window are sibling windows.

Windows always positions the child window relative to the upper-left corner of the parent window's client area. The coordinates are always client coordinates. (For information about mapping, see Graphics Device Interface Overview.) If all or part of a child window is moved outside the visible

portion of the parent window's client area, the child window is clipped; that is, the portion outside the parent window's client area is not displayed.

A child window is an independent window that receives its own input and other messages. Input intended for a child window goes directly to the child window and is not passed through the parent window. The only exception is if input to the child window has been disabled by the **EnableWindow** function. In this case, Windows passes any input that would have gone to the child window to the parent window instead. This gives the parent window an opportunity to examine the input and enable the child window, if necessary.

Actions that affect the parent window can also affect the child window, as follows:

Parent window	Child window
Shown	Shown after the parent window is shown.
Hidden	Hidden before the parent window is hidden. A child window can be visible only when the parent window is visible.
Destroyed	Destroyed before the parent window is destroyed.
Moved	Moved with the parent window's client area. The child window is responsible for painting after the move.
Increased in size or maximized	Paints any portions of the parent window that have been exposed as a result of the increased size of the client area.

Windows does not automatically clip a child window from the parent window's client area. This means the parent window draws over the child window if it carries out any drawing in the same location as the child window. Windows does clip the child window from the parent window's client area if the parent window has a **WS_CLIPCHILDREN** style. If the child window is clipped, the parent window cannot draw over it.

A child window can overlap other child windows in the same client area. Sibling windows can draw in each other's client area unless one child window has a **WS_CLIPSIBLINGS** style. If the application specifies this style for a child window, any portion of that child's sibling window that lies within this window is clipped.

If a window has either the **WS_CLIPCHILDREN** or **WS_CLIPSIBLINGS** style, a slight loss in performance occurs.

Each window takes up system resources, so an application should not use child windows indiscriminately. For optimum performance, an application that needs to logically divide its main window should do so in the window procedure of the main window rather than by using child windows.

Multiple Document Interface Windows

Windows MDI provides applications with a standard interface for displaying multiple documents within the same instance of an application. An MDI application creates a frame window that contains a client window in place of its client area. An application creates an MDI client window by calling **CreateWindow** with the class MDICLIENT and passing a **CLIENTCREATESTRUCT** structure as the function's *lpParam* parameter. This client window in turn can own multiple child windows, each of which displays a separate document. An MDI application controls these child windows by sending messages to its client window.

Title Bar

The title bar, a rectangle at the top of the window, provides space for the window title or name. An application defines the window title when it creates the window. It can also change this name anytime by using the **SetWindowText** function. A title bar makes it possible for the user to move the window by using a mouse or other pointing device.

System Menu

The System menu, identified by a box at the left end of the title bar, is a pop-up menu that contains the

system commands. (The System menu is sometimes referred to as the Control menu.) The system commands are commands that can be selected by the user to direct Windows to carry out actions that affect the window, such as moving and closing it.

To create a window with a System menu or Close box, the application must specify both the **WS_SYSMENU** and **WS_CAPTION** window styles when the window is created.

Scroll Bars

The horizontal and vertical scroll bars are bars on the lower and right sides of a window, respectively, making it possible for a user to scroll the contents of the client area. Windows sends scroll requests to a window as **WM_HSCROLL** and **WM_VSCROLL** messages. If the window permits scrolling, the window procedure must process these messages.

A window can have one or both scroll bars. To create a window with a scroll bar, the application must specify the **WS_HSCROLL** or **WS_VSCROLL** window style when the window is created. An application can use the **ShowScrollBar** function to show or hide a scroll bar of a window with the WS_HSCROLL or WS_VSCROLL style.

Menus

A menu is a list of commands from which the user can select using the mouse or other pointing device or the keyboard. When the user selects an item, Windows sends a corresponding message to the window procedure to indicate which command was selected. Windows provides two types of menus: menu bars (sometimes called static menus) and pop-up menus.

A menu bar is a horizontal menu that appears at the top of a window and below the title bar, if one exists. Any window except a child window can have a menu bar. If an application does not specify a menu when it creates a window, the window receives the default menu bar (if any) defined by the window class.

A pop-up menu contains a vertical list of items and is often displayed when a user selects a menu-bar item. In turn, a pop-up menu item can display another pop-up menu. A pop-up menu can float--that is, it can appear anywhere on the screen designated by the application. An application creates an empty pop-up menu by calling the **CreatePopupMenu** function, and then fills in the menu using the **AppendMenu** and **InsertMenu** functions. It displays the pop-up menu by calling **TrackPopupMenu**.

An application can create or modify an individual menu item with the **MF_OWNERDRAW** style, indicating that the item is an owner-drawn item. In this case, the owner of the menu is responsible for drawing all visual aspects of the menu item, including checked, grayed, and highlighted states. When the menu is displayed for the first time, the window that owns the menu receives a **WM_MEASUREITEM** message. The *lParam* parameter of this message points to a **MEASUREITEMSTRUCT** structure. The owner then fills in this structure with the dimensions of the item and returns. Windows uses the information in the structure to determine the size of the item so that Windows can appropriately detect the user's interaction with the item. Windows sends the **WM_DRAWITEM** message whenever the owner of the menu must update the visual appearance of an owner-drawn menu item. A top-level menu item cannot be an owner-drawn item.

An application can call the **AppendMenu**, **InsertMenu**, or **ModifyMenu** function to add an owner-drawn menu item to a menu or to change an existing menu item to be an owner-drawn menu item. To maintain additional data associated with the item, the application can supply a 32-bit value for the *lpNewItem* parameter of the function. This value is available to the application as the **itemData** member of the structures pointed to by the *lParam* parameter of the **WM_MEASUREITEM** and **WM_DRAWITEM** messages. For example, if an application were to draw the text in a menu item by using a specific color, the 32-bit value could contain a pointer to a string. The application could then set the text color before drawing the item when it received the WM_DRAWITEM message.

Window State

The window state can be open (minimized, maximized, or restored), hidden or visible, and enabled or disabled. The initial state of a window depends on whether the following window styles are used:

- **WS_DISABLED**
- **WS_MINIMIZE**
- **WS_MAXIMIZE**
- **WS_VISIBLE**

By default, Windows creates windows that are initially enabled--that is, windows that can start receiving input messages immediately. An application can disable input to a new window by specifying the **WS_DISABLED** window style.

A new window is not displayed until an application opens it by using the **ShowWindow** function or specifies the **WS_VISIBLE** window style when it creates the window. For overlapped windows, the **WS_ICONIC** window style creates a window that is minimized initially.

Life Cycle of a Window

Because the purpose of any window is to make it possible for the user to specify data or for the application to display information, a window starts its life cycle when the application has a need for input or output. A window continues its life cycle until there is no longer a need for it or the application is closed. Some windows, such as the window used for the application's main user interface, last the life of the application. Other windows, such as a window used as a dialog box, may last only a few seconds.

The first step in a window's life cycle is creation. Given a registered window class with a corresponding window procedure, the application uses the **CreateWindow** function to create the window. This function directs Windows to prepare internal structures for the window and to return a unique integer value, called a window handle, that the application can use to identify the window in subsequent function calls.

The first message most windows process is **WM_CREATE**, the window-creation message. The **CreateWindow** function sends this message to inform the window procedure that it can now perform any initialization, such as allocating memory and preparing data files. The *wParam* parameter is not used, but the *lParam* parameter contains a long pointer to a **CREATESTRUCT** structure, whose members correspond to the parameters passed to **CreateWindow**.

The **WM_CREATE** message is sent directly to the window procedure, bypassing the application's message queue. This means an application creates a window and processes the WM_CREATE message before it enters the main message loop.

After a window has been created, it must be opened (displayed) before it can be used. An application can open the window in one of two ways: It can specify the **WS_VISIBLE** window style in the **CreateWindow** function to open the window immediately after creation, or it can wait until later and call the **ShowWindow** function to open the window. When creating a main window, an application should not specify WS_VISIBLE, but should call **ShowWindow** from the **WinMain** function with the *nCmdShow* parameter set to specify the window state.

When the window is no longer needed or the application is terminated, the window must be destroyed. This is done by using the **DestroyWindow** function. **DestroyWindow** removes the window from the system display and invalidates the window handle. It also sends **WM_DESTROY** and **WM_NCDESTROY** messages to the window procedure. The **DestroyWindow** function also destroys all of the window's child and owned windows.

The window procedure also receives a **WM_DESTROY** message when the **WM_CLOSE** message is processed by the **DefWindowProc** function. When a window procedure receives a WM_DESTROY message, it should free any allocated memory and close any open data files.

The window used as the application's main user interface should always be the last window destroyed and should always cause the application to terminate. When this window receives a **WM_DESTROY** message, it should call the **PostQuitMessage** function. This function copies a **WM_QUIT** message to the application's message queue as a signal for the application to close when the message is read from the queue.

Painting

This section describes the system display and the preparation of windows for painting and other general-purpose graphics operations.

How Windows Manages the Display

The system display is the principal display device for all applications running with Windows. All applications are free to display some form of output on the system display; but because many applications can run at one time, the complete system display must be shared. Windows shares the system display by carefully managing the access that applications have to it. Windows ensures that each application has space to display output but does not draw in the space reserved for other applications.

Windows manages the system display by using display contexts. The display context is a special device context that treats each window as a separate display surface. An application that retrieves a display context for a specific window has complete control of the system display within that window, but cannot access or paint over any part of the display outside the window.

Display Context Types

There are four types of display contexts: common, class, private, and window. The common, class, and private display contexts permit drawing in the client area of a given window. The window display context permits drawing anywhere in the window. When a window is created, Windows assigns a common, class, or private display context to it, based on the type of display context specified in that window's class style. A window display context can be used for painting within a window's nonclient area.

Common Display Context

A common display context is the default context for all windows. Windows assigns a common display context to the window if a display-context type is not explicitly specified in the window's class style.

A common display context permits drawing in a window's client area, but it is not immediately available for use by a window. A common display context must be retrieved from a cache of display contexts before a window can carry out any drawing in its client area. The **GetDC** or **BeginPaint** function retrieves the display context and returns a handle of the context. The handle can be used with GDI functions to draw in the client area of the given window. After drawing is complete, an application must use the **ReleaseDC** or **EndPaint** function to return the context to the cache. After the context is released, drawing cannot occur until another display context is retrieved.

When a common display context is retrieved, Windows gives it default selections for the tools currently available to carry out the actual drawing. The default selections for a common display context are as follows:

Attribute	Default
Background color	Background color setting from Windows Control Panel (typically, white).
Background mode	OPAQUE.
Bitmap	No default.
Brush	WHITE_BRUSH.
Brush origin	(0,0).
Clipping region	Entire client area with the update region clipped as appropriate. Child and pop-up windows in the client area may also be clipped.
Color palette	DEFAULT_PALETTE.
Current pen position	(0,0).
Device origin	Upper-left corner of client area.
Drawing mode	R2_COPYPEN.

Font	**SYSTEM_FONT** (**SYSTEM_FIXED_FONT** for applications written to run with Windows versions 3.0 or earlier).
Intercharacter spacing	0.
Mapping mode	MM_TEXT.
Pen	BLACK_PEN.
Polygon-filling mode	ALTERNATE.
Relative-absolute flag	ABSOLUTE.
Stretching mode	BLACKONWHITE.
Text color	Text color setting from Control Panel (typically, black).
Viewport extent	(1,1).
Viewport origin	(0,0).
Window extent	(1,1).
Window origin	(0,0).

An application can modify the attributes of the display context by using the selection functions and display-context attribute functions. For example, applications typically change the selected pen, brush, and font.

When a common display context is released, the current selections, such as mapping mode and clipping region, are lost. Windows does not preserve the previous selections of a common display context. Applications that modify the attributes of a common display context must do so each time another context is retrieved.

Class Display Context

A window has a class display context if the window class specifies the **CS_CLASSDC** style. A class display context is shared by all windows in a given class. A class display context is not part of the display context cache. Instead, Windows specifically allocates a class context for exclusive use by the window class.

A class display context must be retrieved before it can be used, but it does not have to be released after use. As long as only one window from the class uses the context, the class display context can be kept and reused. If another window in the class needs to use the context, that window must retrieve it before any drawing occurs. Retrieving the context sets the correct device origin and clipping region for the new window and ensures that the context is applied to the correct window. An application can use the **GetDC** or **BeginPaint** function to retrieve a handle of the class display context. The **ReleaseDC** and **EndPaint** functions have no effect on a class display context.

A class display context is given the same default selections as a common display context when the first window of the class is created. These selections can be modified at any time. Windows preserves all new selections made for the class display context, except for the clipping region and device origin, which are adjusted for the current window when the context is retrieved. This means a change made by one window applies to all windows that subsequently use the context.

Note: Changing the mapping mode of a class display context may have an undesirable effect on how a window's background is erased. For more information, see Window Background, and Graphics Device Interface Overview.

Private Display Context

A window has a private display context if the window class specifies the **CS_OWNDC** style. A private display context is used exclusively by a given window. A private display context is not part of the display context cache. Instead, Windows specifically allocates the context for exclusive use by the window. Although using private display contexts is convenient, they are expensive in terms of system resources, so an application should use them sparingly.

A private display context needs to be retrieved only once. Thereafter, it can be kept and used any number of times by the window. Windows automatically updates the context to reflect changes to the

window, such as moving or sizing. An application can use the **GetDC** or **BeginPaint** function to retrieve a handle of a private display context. The **ReleaseDC** and **EndPaint** functions have no effect on a private display context.

A private display context is given the same default selections as a common display context when the window is created. These selections can be modified at any time. Windows preserves any new selections made for the context. New selections, such as of a clipping region or brush, remain selected until the window specifically makes a change.

Note: Changing the mapping mode of a private display context may have an undesirable effect on how the window's background is erased. For more information, see Window Background, and Graphics Device Interface Overview.

Window Display Context

A window display context permits painting anywhere in a window, including the title bar, menus, and scroll bars. Its origin is the upper-left corner of the window instead of the upper-left corner of the client area.

The **GetWindowDC** function retrieves a window display context from the same cache as it does common display contexts. Therefore, a window that uses a window display context must release it with the **ReleaseDC** function immediately after drawing.

Windows always sets the current selections of a window display context to the same default selections as a common display context and does not preserve any change the window may have made to these selections. The **CS_OWNDC** and **CS_CLASSDC** class styles have no effect on the window display context.

A window display context is intended to be used for special painting within a window's nonclient area. Because painting in nonclient areas of overlapped windows is not recommended, most applications reserve a display context for designing custom child windows. For example, an application can use the display context to draw a custom border around the window. In such cases, the window usually processes the **WM_NCPAINT** message instead of passing it to the **DefWindowProc** function. For applications that do not process WM_NCPAINT messages but still need to paint within the nonclient area, the **GetSystemMetrics** function can be used to retrieve the dimensions of various parts of the nonclient area, such as the title bar, menu bar, and scroll bars.

Display-Context Cache

Windows maintains a cache of display contexts that it uses for common display contexts and window display contexts. This cache contains five display contexts, which means only five common display contexts can be active at any one time. To prevent more than five from being retrieved, a window that uses a common or window display context must release that context immediately after drawing.

If a window fails to release a common display context, all five display contexts may eventually be active and unavailable for any other window. In such a case, Windows ignores all subsequent requests for a common display context. In the retail version of Windows, the system appears to be deadlocked, while the debugging version of Windows undergoes a fatal exit, alerting you of a problem.

The **ReleaseDC** function releases a display context and returns it to the cache. Class and private display contexts are individually allocated for each class or window; they do not belong to the cache, so they do not need to be released after use.

Painting Sequence

To manage the system display, Windows carries out many operations that affect the contents of the client area. If Windows moves, sizes, or alters the appearance of the screen, the change may affect a given window. If so, Windows marks the area changed by the operation as ready for updating and, at the next opportunity, sends a **WM_PAINT** message to the window so that it can update the window in the update region. If a window paints in its client area, it must call the **BeginPaint** function to retrieve a handle of a display context, must update the changed area as defined by the update region, and finally, must call the **EndPaint** function to complete the operation.

A window can paint within its client area at any time--that is, at times other than in response to a **WM_PAINT** message. The only requirement is that it retrieve a display context for the client area before carrying out any operations.

WM_PAINT Message

The **WM_PAINT** message is a request from Windows to a given window to update its display. Windows sends a WM_PAINT message to a window whenever it is necessary to repaint a portion of the window. When a window receives a WM_PAINT message, it should retrieve the update region by using the **BeginPaint** function, and it should carry out whatever operations are necessary to update that part of the client area.

The **InvalidateRect** and **InvalidateRgn** functions do not actually generate **WM_PAINT** messages. Instead, Windows accumulates the changes made by these functions and its own changes while a window processes other messages in its message queue. Postponing the WM_PAINT message lets a window process all changes at once instead of updating bits and pieces in time-consuming individual steps.

To direct Windows to send a **WM_PAINT** message, an application can use the **UpdateWindow** function. The **UpdateWindow** function sends the message directly to the window, regardless of the number of other messages in the application's message queue. **UpdateWindow** is typically used when a window needs to update its client area immediately, such as just after the window is created.

Once a window receives a **WM_PAINT** message, it must call the **BeginPaint** function to retrieve the display context for the client area and to retrieve other information such as the update region and whether the background has been erased.

Windows automatically selects the update region as the clipping region of the display context. Since GDI discards (clips) drawing that extends outside the clipping region, only drawing that is in the update region is actually visible. For more information about the clipping region, see Graphics Device Interface Overview.

The **BeginPaint** function clears the update region to prevent the same region from generating subsequent **WM_PAINT** messages.

After completing the painting operation, the window must call the **EndPaint** function to release the display context.

Update Region

An update region defines the part of the client area that is marked for painting on the next **WM_PAINT** message. The purpose of the update region is to save applications the time it takes to paint the entire contents of the client area. If only the part that needs painting is added to the update region, only that part is painted. For example, if a word changes in the client area of a word-processing application, only the word needs to be painted, not the entire line of text. This saves the time it takes the application to draw the text, especially if there are many different sizes and fonts.

The **InvalidateRect** and **InvalidateRgn** functions add a given rectangle or region to the update region. The rectangle or region must be given in client coordinates. The update region itself is defined in client coordinates. Windows adds its own rectangles and regions to a window's update region after operations such as moving, sizing, and scrolling the window.

The **ValidateRect** and **ValidateRgn** functions remove a given rectangle or region from the update region. These functions are typically used when the window has updated a specific part of the display in the update region before receiving the **WM_PAINT** message.

The **GetUpdateRect** function retrieves the smallest rectangle that encloses the entire update region. The **GetUpdateRgn** function retrieves the update region itself. These functions can be used to compute the current size of the update region to determine if painting is required.

Window Background

The window background is the color or pattern the client area is filled with before a window begins

painting in the client area. Windows paints the background for a window or gives the window the opportunity to do so by sending a **WM_ERASEBKGND** message to the window when the application calls the **BeginPaint** function.

The background is important because if it is not erased, the client area will contain whatever was originally on the screen before the window was moved there. Windows erases the background by filling it with the background brush specified by the window's class.

Windows applications that use class or private display contexts should be careful about erasing the background. Windows assumes the background is to be computed by using the MM_TEXT mapping mode. If the display context has any other mapping mode, the area erased may not be within the visible part of the client area.

Brush Alignment

Brush alignment is particularly important on the system display where scrolling and moving are commonplace. A brush is a pattern of bits with a minimum size of 8-by-8 bits. GDI paints with a brush by repeating the pattern again and again within a given rectangle or region. If the region is moved by an arbitrary amount--for example, if the window is scrolled--and the brush is used again to fill empty areas around the original area, there is no guarantee that the original pattern and the new pattern will be aligned. For example, if the scroll moves the original filled area up one pixel, the intersection of the original area and any new painting will be out of alignment by one pixel, or bit. Depending on the pattern, this may have an undesirable visual effect. For more information about brushes, see Graphics Device Interface Overview.

To ensure that a brush is aligned after a window is moved, an application must take the following steps:

1. Call the **SelectObject** function to select a different brush to be the current brush.
2. Call the **SetBrushOrg** function to realign the current brush.
3. Call the **UnrealizeObject** function to realign the origin of the original brush when it is selected next. (**UnrealizeObject** should not be used on stock objects, only on brushes created by the application.)
4. Call the **SelectObject** function to select the original brush.

Painting Rectangular Areas

The **FillRect**, **FrameRect**, and **InvertRect** functions provide an easy way to carry out painting operations on rectangles in the client area.

The **FillRect** function fills a rectangle with the color and pattern of a given brush. This function fills all parts of the rectangle, including the edges or borders.

The **FrameRect** function uses a brush to draw a border around a rectangle. The border width and height is one unit.

The **InvertRect** function inverts the contents of the given rectangle. On monochrome displays, white pixels become black, and vice versa. On color displays, the results depend on the method used by the display to generate color. In either case, calling **InvertRect** twice with the same rectangle restores the screen to its original colors.

Drawing Icons

The **DrawIcon** function draws an icon at a given location in the client area. An icon is a bitmap that a window uses as a symbol to represent an item, such as an application or a warning.

You can use the Image Editor to create an icon and then use Microsoft Windows Resource Compiler (RC) to add the icon to your application's resources. Your application can then call the **LoadIcon** function to load the icon into memory.

Applications can also call the **CreateIcon** function to create an icon and can modify a previously

loaded or created icon at any time. An icon resource is in global memory, and the icon's handle is the handle of that memory. An application can free memory used to store an icon created by **CreateIcon** by calling the **DeleteIcon** function.

Drawing Formatted Text

The **DrawText** function formats and draws text within a given rectangle in the client area. This function provides simple text processing that most applications can use to display text. **DrawText** output is similar to the output generated by a terminal, except it uses the selected font and can clip the text if it extends outside a given rectangle. **DrawText** provides many different formatting styles.

The **DrawText** function uses the currently selected font, so applications can draw formatted text in a font other than the system font.

DrawText does not hyphenate, and although it can left align, right align, or center text, it cannot combine alignment styles. In other words, it cannot align to both the left and right.

DrawText recognizes a number of control characters and carries out special actions when it encounters them. The control characters and their respective actions are as follows:

Windows character	Action
Carriage return (13)	Interpreted as a line-break character. The text is immediately broken and continued on the next line down in the rectangle.
Linefeed (10)	Interpreted as a line-break character. The text is immediately broken and continued on the next line down in the rectangle. A carriage return–linefeed character combination is interpreted as a single line-break character.
Space (32)	Interpreted as a wordwrap character if the **DT_WORDBREAK** style is given. If the text is too long to fit on the current line in the formatting rectangle, the line is broken at the wordwrap character that is closest to the end of the line.
Tab (9)	Expanded into a given number of spaces if the **DT_EXPANDTABS** style is given. The number of spaces depends on which tab-stop value is given with the **DT_TABSTOP** style. The default value is eight.

Drawing Gray Text

An application can draw gray text by calling the **SetTextColor** function to set the current text color to **COLOR_GRAYTEXT**, the solid gray system color used to draw disabled text. However, if the current display driver does not support a solid gray color, this value is set to zero.

The **GrayString** function is a multiple-purpose function that gives applications another way to gray text or carry out other customized operations on text or bitmaps before drawing the result in a client area. To gray text, the function creates a memory bitmap, draws the string in the bitmap, and then grays the string by combining it with a gray brush. The **GrayString** function finally copies the gray text to the display. However, an application can intercept or modify each step of this process to carry out custom effects, such as changing the gray brush to a patterned brush or drawing an icon instead of a string.

If **GrayString** is used to draw gray text only, **GrayString** uses the selected font of the given display context. First, **GrayString** sets text color to black. It then creates a bitmap and uses the **TextOut** function to write a given string to the bitmap. It then uses the **PatBlt** function and a gray brush to gray the text, and uses the **BitBlt** function to copy the bitmap to the client area.

GrayString assumes that the display context for the client area has MM_TEXT mapping mode. Other mapping modes cause undesirable results.

GrayString lets an application modify this graying procedure in three ways: by defining an additional brush to be combined with the text before the text is displayed, by replacing the call to the **TextOut** function with a call to an application-supplied function, and by disabling the call to the **PatBlt** function.

If an additional brush is combined with text, it is defined for the *hbr* parameter of **GrayString**. The brush is combined with the text as the text is copied to the client area by the **BitBlt** function. The

additional brush is intended to be used to give the text a desired color, because the bitmap used to draw the text is a monochrome bitmap.

If an application-supplied function replaces **TextOut**, it is defined for the *gsprc* parameter of **GrayString**. When *gsprc* is not NULL, **GrayString** automatically calls the application-supplied function instead of the **TextOut** function and passes it a handle of the display context for the memory bitmap and the long pointer and count passed to **GrayString**. The function can carry out any operation and interpret the long pointer and count in any way. For example, a negative count could be used to indicate that the long pointer points to an icon handle that signals the application-supplied function to draw the icon and let **GrayString** gray and display it. No matter what type of drawing the function carries out, **GrayString** assumes it is successful if the application-supplied function returns a nonzero value.

GrayString suppresses graying if it receives a *cch* parameter equal to -1 and the application-supplied function returns zero. This provides a way to combine custom patterns with the text without interference from the gray brush.

Nonclient-Area Painting

Windows sends a **WM_NCPAINT** message to the window whenever a part of the nonclient area of the window, such as the title bar, menu bar, or window frame, needs painting. Processing this message is not recommended because a window that does so must be able to paint all the required parts of the nonclient area for the window. Unless the Windows application is creating a custom nonclient area for a child window, a window should pass this message to the **DefWindowProc** function for default processing.

Dialog Boxes

A dialog box is a temporary window that Windows creates for special-purpose input and then destroys immediately after use. An application typically uses a dialog box to prompt the user for additional information about a current command selection.

Uses for Dialog Boxes

For convenience and to keep from introducing device-dependent values into the application code, applications use dialog boxes instead of creating their own windows. This device independence is maintained by using logical coordinates in the dialog box template. A dialog box is convenient to use because all aspects of the dialog box, except how to carry out its tasks, are predefined. A dialog box supplies a window class and procedure; the window for the dialog box is created automatically. The application supplies a dialog box procedure to carry out tasks and a dialog box template that describes the dialog box style and content.

Modeless Dialog Box

A modeless dialog box allows the user to supply information to the dialog box and return to the previous task without canceling or removing the dialog box. A modeless dialog box makes it possible for a user to supply more than one piece of information about the current task without having to select a command from a menu each time. For example, a modeless dialog box is often used with a text-search command in word-processing applications. The dialog box remains displayed while the search is carried out. The user can then return to the dialog box and search for the same word again, or change the entry in the dialog box and search for a new word.

An application with a modeless dialog box processes messages for that box by using the **IsDialogMessage** function inside the main message loop. The dialog box procedure of a modeless dialog box must send a message to the parent window when it has input for the parent window. The dialog box procedure must also destroy the dialog box when it is no longer needed. An application can call the **DestroyWindow** function to destroy a modeless dialog box. The application must not call the **EndDialog** function to destroy a modeless dialog box.

Modal Dialog Box

A modal dialog box requires the user to respond to a request before the application continues. Typically, a modal dialog box is used when a chosen command needs additional information before it can proceed.

A modal dialog box disables its parent window, and it creates its own message loop, temporarily taking control of the application's message queue from the application's main message loop.

By default, a modal dialog box cannot be moved by the user. An application can create a movable modal dialog box by specifying the **WS_CAPTION** window style.

The dialog box is displayed until the dialog box procedure calls the **EndDialog** function, or until Windows is closed. The parent window remains disabled unless the dialog box enables it. Note that enabling the parent window is not recommended because it defeats the purpose of the modal dialog box.

System-Modal Dialog Box

A system-modal dialog box is identical to a modal dialog box except that all windows, not just the parent window, are disabled. System-modal dialog boxes must be used with care because they effectively shut down the system until the user supplies the required information.

Creating a Dialog Box

A dialog box is typically created by using either the **CreateDialog** or **DialogBox** function. These functions load a dialog box template from the application's executable file and then create a pop-up window that matches the template's specifications. The dialog box belongs to the predefined dialog

box class unless another class is explicitly defined. The **DialogBox** function creates a modal dialog box; the **CreateDialog** function creates a modeless dialog box.

Use the **WS_VISIBLE** style for the dialog box template if you want the dialog box to appear upon creation.

Dialog Box Template

The dialog box template is a description of the dialog box: its height and width, the controls it contains, its style, the type of border it uses, and so on. A template is an application's resource. You use the Resource Compiler to convert the text description of the template to the required binary form and to add that binary form to the application's executable file.

Because a dialog box is system-independent, you can easily modify the template without changing the source code.

The **CreateDialog** or **DialogBox** function loads the resource into memory when it creates the dialog box and then uses the information in the dialog box template to create the dialog box, position it, and create and position the controls for the dialog box.

Dialog Box Measurements

Dialog box and control dimensions and coordinates are device-independent. Because a dialog box may be displayed on system displays that have widely varying pixel resolutions, dialog box dimensions are specified in system-character widths and heights instead of pixels. This ensures the best possible appearance of characters. One unit in the x-direction is equal to one-fourth of the dialog box base width unit. One unit in the y-direction is equal to one-eighth of the dialog box base height unit. The dialog box base units are computed from the height and width of the system font; the **GetDialogBaseUnits** function returns the dialog box base units for the current display. Applications can convert these measurements to pixels by using the **MapDialogRect** function.

Windows does not allow the height of a dialog box to exceed the height of a full-screen window, and it does not allow the width of a dialog box to be greater than the width of the screen.

Return Values from a Dialog Box

The **DialogBox** function that creates a modal dialog box does not return until the dialog box procedure has called the **EndDialog** function to signal the destruction of the dialog box. When control finally returns from the **DialogBox** function, the return value is equal to the value specified in the **EndDialog** function. This means a modal dialog box can return a value through the **EndDialog** function.

Modeless dialog boxes cannot return values in this way because they do not use the **EndDialog** function to close and do not return control in the same way a modal dialog box does. Instead, a modeless dialog box returns values to its parent window by using the **SendMessage** function to send a notification message to the parent window. Although Windows does not explicitly define the content of a notification message, most applications use a **WM_COMMAND** message with an integer value that identifies the dialog box in the *wParam* parameter and the return value in the *lParam* parameter. A modal dialog box can also use this technique to return values to its parent window before closing.

Controls in a Dialog Box

A control is a child window that belongs to a predefined or application-defined window class and that gives the user a method of supplying input to the application. A dialog box can contain any number and any types of controls. Examples of controls are push buttons and edit controls. Most dialog boxes contain one or more controls of the predefined class. The number of controls, the order in which they should be created, and the location of each in the dialog box are defined by the control statements given in the dialog box template.

Control Identifiers

Every control in a dialog box needs a unique control identifier, or ID, to distinguish it from other controls. Because all controls send information to the dialog box procedure through **WM_COMMAND**

messages, the control identifiers are essential for the dialog box to determine which control sent a given message.

Each control in the dialog box must have a unique identifier. If a dialog box has a menu bar, there must be no conflict between menu-item identifiers and control identifiers. Because Windows sends menu input to a dialog box procedure as **WM_COMMAND** messages, conflicts with menu and control identifiers can cause errors. Menus in dialog boxes are not recommended.

The dialog box procedure usually identifies each dialog box control by using its control identifier. Occasionally the dialog box procedure requires the window handle that was given to the control when it was created. The dialog box procedure can retrieve this window handle by using the **GetDlgItem** function.

The WS_TABSTOP and WS_GROUP Control Styles

The **WS_TABSTOP** style specifies that the user can move the input focus to the given control by pressing the TAB key or SHIFT+TAB keys. Typically, every control in the dialog box has this style, so the user can move the input focus from one control to the other. If two or more controls are in the dialog box, the TAB key moves the input focus to the controls in the order in which they have been created. The SHIFT+TAB keys move the input focus in reverse order. For modal dialog boxes, the TAB and SHIFT+TAB keys are automatically enabled for moving the input focus. For modeless dialog boxes, the **IsDialogMessage** function must be used to filter messages for the dialog box and to process these keystrokes. Otherwise, the keys have no special meaning and the WS_TABSTOP style is ignored.

The **WS_GROUP** style specifies that the user can move the input focus within a group of controls by using the arrow keys. The first control in a group of controls must have the WS_GROUP style. The next control that has the WS_GROUP style marks the bottom boundary of the group; the input focus cannot be moved to this control by using the arrow keys. The DOWN ARROW and RIGHT ARROW keys move the input focus to controls in the order in which they have been created. The UP ARROW and LEFT ARROW keys move the input focus in reverse order. For modal dialog boxes, the arrow keys are automatically enabled for moving the input focus. For modeless dialog boxes, the **IsDialogMessage** function must be used to filter messages for the dialog box and to process these keystrokes. Otherwise, the keys have no special meaning and the WS_GROUP style is ignored.

Buttons

Buttons are the principal interface of a dialog box. Almost all dialog boxes have at least one push button, and most have one default push button (a push button having the **BS_DEFPUSHBUTTON** style) and one or more other push buttons. Many dialog boxes have collections of radio buttons enclosed in group boxes or have lists of check boxes.

Most modal or modeless dialog boxes that use the special keyboard interface have a default push button whose control identifier is set to **IDOK** so that the action the dialog box procedure takes when the button is chosen is identical to the action taken when the ENTER key is pressed. There can be only one button with the default style; however, an application can assign the default style to any button at any time. Most dialog boxes that use the special keyboard interface can also set the control identifier of another push button to **IDCANCEL** so that the action of the ESC key is duplicated by choosing that button.

When a dialog box first starts, the dialog box procedure can set the initial state of each button by using the **CheckDlgButton** function, which sets or clears the button state. This function is most useful when used to set the state of radio buttons or check boxes. If the dialog box contains a group of radio buttons in which only one button should be set at any given time, the dialog box procedure can use the **CheckRadioButton** function to set the appropriate radio button and automatically clear any other radio button.

Before a dialog box terminates, the dialog box procedure can check the state of each button control by using the **IsDlgButtonChecked** function, which returns the current state of the button. A dialog box typically saves this information to initialize the buttons the next time the dialog box is created.

Edit Controls

Many dialog boxes have edit controls that let the user supply text as input. Most dialog box procedures initialize an edit control when the dialog box first starts. For example, the dialog box procedure may place a proposed filename in the control that the user can select, modify, or replace. The dialog box procedure can set the text in an edit control by using the **SetDlgItemText** function, which copies text from a given buffer to the edit control. When the edit control receives the input focus, the complete text is automatically selected for editing.

Because edit controls do not automatically return their text to the dialog box, the dialog box procedure must retrieve the text before terminating. It can retrieve the text by using the **GetDlgItemText** function, which copies the edit-control text to a buffer. The dialog box procedure typically saves this text to initialize the edit control later or passes it on to the parent window for processing.

Some dialog boxes use edit controls that let the user enter numbers. The dialog box procedure can retrieve a number from an edit control by using the **GetDlgItemInt** function, which retrieves the text from the edit control and converts the text to a decimal value. The user enters the number in decimal digits. It can be either signed or unsigned. The dialog box procedure can display an integer by using the **SetDlgItemInt** function. **SetDlgItemInt** converts a signed or unsigned integer to a string of decimal digits.

List Boxes and Directory Listings

Some dialog boxes display lists, such as a list of filenames, from which the user can select one or more items. To display a list of filenames, a dialog box typically uses a list box and the **DlgDirList** and **DlgDirSelect** functions. The **DlgDirList** function automatically fills a list box with the filenames in the current directory. The **DlgDirSelect** function retrieves the selected filename from the list box. Together, these two functions provide a convenient way for a dialog box to display a directory listing that makes it possible for the user to select a file without having to type the location and name of the file.

Combo Boxes

Another method for providing a list of items to a user is by using a combo box. A combo box consists of either a static control or edit control combined with a list box. The list box can be displayed at all times or pulled down by the user. If the combo box contains a static control, that control always displays the current selection (if any) from the list box portion of the combo box. If the combo box uses an edit control, the user can type a selection; the list box highlights the first item (if any) that matches what the user has entered in the edit control. The user can choose the OK button or press ENTER to complete the choice.

Owner-Drawn Dialog Box Controls

List boxes, combo boxes, and buttons can be designated as owner-drawn controls by creating them with the appropriate style. Following are available styles:

Style	Meaning
LBS_OWNERDRAWFIXED	Creates an owner-drawn list box with items that have the same, fixed height.
LBS_OWNERDRAWVARIABLE	Creates an owner-drawn list box with items that have different heights.
CBS_OWNERDRAWFIXED	Creates an owner-drawn combo box with items that have the same, fixed height.
CBS_OWNERDRAWVARIABLE	Creates an owner-drawn combo box with items that have different heights.
BS_OWNERDRAW	Creates an owner-drawn button.

When a control has the owner-drawn style, Windows handles the user's interaction with the control as usual, performing such tasks as detecting when a user has chosen a button and notifying the button's owner of the event. However, because the control is owner-drawn, the owner of the control is completely responsible for the visual appearance of the control. Owner-drawn list boxes and combo boxes can control the display of only the individual elements within a list box or combo box, not the entire list box or

combo box.

When Windows first creates a dialog box containing owner-drawn controls, it sends the owner a **WM_MEASUREITEM** message for each owner-drawn control. The *lParam* parameter of this message contains a pointer to a **MEASUREITEMSTRUCT** structure. When the owner receives the message for a control, the owner fills in the appropriate members of the structure and returns. This informs Windows of the dimensions of the control or of its items so that Windows can appropriately detect the user's interaction with the control. If a list box or combo box is created with the **LBS_OWNERDRAWVARIABLE** or **CBS_OWNERDRAWVARIABLE** style, the WM_MEASUREITEM message is sent to the owner for each item in the control, because each item can differ in height. Otherwise, this message is sent once for the entire owner-drawn control.

Whenever an owner-drawn control needs to be redrawn, Windows sends the **WM_DRAWITEM** message to the owner of the control. The *lParam* parameter of this message contains a pointer to a **DRAWITEMSTRUCT** structure that contains information about the drawing required for the control. Similarly, if an item is deleted from a list box or combo box, Windows sends the **WM_DELETEITEM** message containing a pointer to a **DELETEITEMSTRUCT** structure that describes the deleted item.

Messages for Dialog Box Controls

Many controls recognize predefined messages that, when sent to the control, cause it to carry out some action. A dialog box procedure can send a message to a control by supplying the control identifier and using the **SendDlgItemMessage** function, which is identical to the **SendMessage** function except that it uses a control identifier instead of a window handle to identify the control that is to receive the message.

Keyboard Interface for Dialog Boxes

Windows provides a special keyboard interface for modal dialog boxes and modeless dialog boxes that use the **IsDialogMessage** function to filter messages. This keyboard interface carries out special processing for several keys and generates messages that correspond to certain buttons in the dialog box or change the input focus from one control to another. The keys used in this interface and the respective actions are as follows:

Key	Action
DOWN ARROW	Moves the input focus to the next control in the group.
ENTER	Sends a **WM_COMMAND** message to the dialog box procedure. The *wParam* parameter is set to 1 or the default button.
ESC	Sends a **WM_COMMAND** message to the dialog box procedure. The *wParam* parameter is set to 2.
LEFT ARROW	Moves the input focus to the previous control in the group.
RIGHT ARROW	Moves the input focus to the next control in the group.
SHIFT+TAB	Moves the input focus to the previous control that has the **WS_TABSTOP** style.
TAB	Moves the input focus to the next control that has the **WS_TABSTOP** style.
UP ARROW	Moves the input focus to the previous control in the group.

The TAB key and the arrow keys have no effect if the controls in the dialog box do not have the **WS_TABSTOP** or **WS_GROUP** style. The keys have no effect in a modeless dialog box if the **IsDialogMessage** function is not used to filter messages for the dialog box.

Note: For applications that use accelerator keys and have modeless dialog boxes, the **IsDialogMessage** function must be called before the **TranslateAccelerator** function. Otherwise, the keyboard interface for the dialog box may not be processed correctly.

Applications that have modeless dialog boxes and need those boxes to have the special keyboard interface must filter all messages retrieved from the application's message queue through the **IsDialogMessage** function before carrying out any other processing. This means that the application must pass the message to **IsDialogMessage** immediately after retrieving the message by using the

GetMessage or **PeekMessage** function. Most applications that have modeless dialog boxes incorporate the **IsDialogMessage** function as part of the main message loop in the **WinMain** function. The **IsDialogMessage** function automatically processes any messages for the dialog box. This means that if the function returns a nonzero value, the message does not require additional processing and must not be passed to the **TranslateMessage** or **DispatchMessage** function.

The **IsDialogMessage** function also processes ALT+application-defined mnemonic key sequences.

In modal dialog boxes, the arrow keys have specific functions that depend on the controls in the box. For example, the keys move the input focus from control to control in group boxes, move the cursor in edit controls, and scroll the contents of list boxes. The arrow keys cannot be used to scroll the contents of any dialog box that has its own scroll bars. If a dialog box has scroll bars, the application must provide an appropriate keyboard interface for the scroll bars. Note that the mouse interface for scrolling is available if the system has a mouse.

Scrolling

Scrolling is the movement of data in and out of the client area at the request of the user. It is a way for the user to see a document or graphic in parts if Windows cannot fit the entire document or graphic inside the client area. A scroll bar allows the user to control scrolling.

Standard Scroll Bars and Scroll-Bar Controls

A standard scroll bar is a part of the nonclient area of a window. It is created with the window and displayed when the window is displayed. The sole purpose of a standard scroll bar is to let users generate scrolling requests for the window's client area. A window has standard scroll bars if it is created with the **WS_VSCROLL** or **WS_HSCROLL** style. A standard scroll bar is either vertical or horizontal. A vertical scroll bar, if used, always appears at the right of the client area; a horizontal scroll bar, if used, always appears at the bottom. A standard scroll bar always has the standard scroll-bar height and width as defined by the **SM_CXVSCROLL** and **SM_CYHSCROLL** system metric values.

A scroll-bar control is a control window that looks and acts like a standard scroll bar. But unlike a standard scroll bar, a scroll-bar control is not part of any window. As a separate window, a scroll-bar control can receive the input focus and indicates that it has the focus by displaying a flashing caret in the scroll box (also called the thumb). When a scroll-bar control has the input focus, the user can use the keyboard to direct the scrolling. Unlike standard scroll bars, a scroll-bar control provides a built-in keyboard interface. Scroll-bar controls also can be used for other purposes. For example, a scroll-bar control can be used to select values from a range of values, such as a color from a spectrum of colors.

Scroll Box

The scroll box is the small rectangle in a scroll bar. It shows the approximate location within the current document or file of the data currently displayed in the client area. For example, the scroll box is in the middle of the scroll bar when page three of a five-page document is in the client area.

The **SetScrollPos** function sets the scroll box position in a scroll bar. Because Windows does not automatically update the scroll box position when an application scrolls, **SetScrollPos** must be used to update the position. The **GetScrollPos** function retrieves the current position.

A scroll box position is represented as an integer. The position is relative to the left or upper end of the scroll bar, depending on whether the scroll bar is horizontal or vertical. The position must be within the scroll-bar range, which is defined by minimum and maximum values. The positions are distributed equally along the scroll bar. For example, if the range is 0 through 100, there are 101 positions along the scroll bar, each equally spaced so that position 50 is in the middle of the scroll bar. The initial range depends on the scroll bar. Standard scroll bars have an initial range of 0 through 100; scroll-bar controls have an empty range (both minimum and maximum values are 0) if no explicit range is given when the control is created. An application can change the range by using the **SetScrollRange** function to set new minimum and maximum values so that applications can change the range at any time. The **GetScrollRange** function retrieves the current minimum and maximum values. The minimum and maximum values can be any integers. For example, a spreadsheet program with 255 rows can set the vertical scroll range to 1 through 255.

If **SetScrollPos** specifies a position value that is less than the minimum or more than the maximum, the minimum or maximum value is used instead. **SetScrollPos** moves the scroll box along the scroll bar.

Scrolling Requests

A user makes a scrolling request by clicking in a scroll bar. Windows sends the request to the given window in the form of **WM_HSCROLL** and **WM_VSCROLL** messages. The messages' *lParam* parameter contains a position value and the handle of the scroll-bar control that generated the message (*lParam* is zero if a standard scroll bar generated the message). The *wParam* parameter specifies the type of scrolling; for example, the user may scroll up one line, scroll down a page, or scroll to the bottom. The type of scrolling is determined by which area of the scroll bar the user clicks.

The user can also make a scrolling request by using the scroll box, the small rectangle inside the scroll bar. The user moves the scroll box by moving the mouse while holding the left mouse button down when the cursor is positioned on the scroll box. The scroll bar sends SB_THUMBTRACK and SB_THUMBPOSITION flags with a **WM_HSCROLL** or **WM_VSCROLL** message to an application as the user moves the scroll box. Each message specifies the current position of the scroll box.

Processing Scroll Messages

A window that permits scrolling needs a standard scroll bar or a scroll-bar control to let the user generate scrolling requests, and it needs a window procedure to process the **WM_HSCROLL** and **WM_VSCROLL** messages that represent the scrolling requests. Although the result of a scrolling request depends entirely on how the window processes it, a window typically carries out a scroll operation by moving through the application's displayed information in some direction from the current location or to a known beginning or end and by displaying the data at the new location. For example, a word-processing application can scroll to the next line, the next page, or to the end of the document.

Scrolling the Client Area

The simplest way to scroll is to erase the current contents of the client area, and then paint the new information. This is the method an application is likely to use with SB_PAGEUP, SB_PAGEDOWN, SB_TOP, and SB_END requests, which require completely new contents.

For some requests, such as SB_LINEUP and SB_LINEDOWN, not all the contents need to be erased, since some are still visible after the scroll. The **ScrollWindow** function preserves a portion of the client area's contents, moves the preserved portion the specified amount, and prepares the rest of the client area for painting new information. **ScrollWindow** uses the **BitBlt** function to move a specific part of the client area to a new location within the client area. Any part of the client area that is uncovered (not in the part to be preserved) is invalidated and is erased and painted over at the next **WM_PAINT** message.

ScrollWindow also lets an application clip a part of the client area from the scroll. This keeps items that have fixed positions in the client area, such as child windows, from moving. This action automatically invalidates the part of the client area that is to receive the new information so that the application does not have to compute its own clipping regions.

Hiding a Standard Scroll Bar

For standard scroll bars, if the minimum and maximum values are equal, the scroll bar is hidden and, in effect, disabled. Using this technique, you can temporarily hide a scroll bar when it is not needed for the current contents of the client area.

The **SetScrollRange** function hides and disables a standard scroll bar when equal minimum and maximum values are specified. No scrolling requests can be made through the scroll bar when it is hidden. **SetScrollRange** enables the scroll bar and shows it again when it sets the minimum and maximum values to unequal values. The **ShowScrollBar** function can also be used to hide or show a scroll bar. It does not affect the scroll bar's range or scroll box's position.

The Caret

The Windows caret is a flashing line, block, or bitmap that marks a location in a window's client area. The caret is especially useful in word-processing applications to mark a location in text for keyboard editing.

Creating and Displaying a Caret

Windows forms a caret by inverting the pixel color within the rectangle given by the caret's position, width, and height. Windows flashes the caret by alternately inverting the display and restoring it to its previous appearance. The caret's flash rate, in milliseconds, defines the elapsed time between inverting and restoring the display. A complete flash (on-off-on) takes twice the blink time.

The **CreateCaret** function creates the caret shape and assigns ownership of the caret to the given window. The caret can vary in color and shape; a bitmap caret can be given any pattern.

Windows displays a solid caret by inverting everything in the rectangle defined by the caret's width and height. For a gray caret, Windows inverts every other pixel. For a pattern, Windows inverts only the white bits of the bitmap that defines the pattern. The width and height of a caret are given in logical units, which means they are subject to the window's mapping mode.

Sharing the Caret

There is only one caret, so only one caret shape can be active at a time. All applications must cooperatively share the caret. Because Windows does not inform an application when a caret is created or destroyed, each window should create, move, show, or hide a caret only when it has the input focus or is active. A window should destroy the caret before losing the input focus or becoming inactive.

Your application can use the **CreateBitmap** function to create a bitmap for the caret; or, after you have used the Image Editor to create a bitmap and have used the Resource Compiler to add it to your application's resources, your application can use the **LoadBitmap** function to load the bitmap from the application's resources.

The Cursor

The cursor is a bitmap, displayed on the screen. The user can use a mouse or other pointing device to move this bitmap to an item on the screen, such as a window or an icon. (In the remainder of section, the term mouse is used for any pointing device.)

The Mouse and the Cursor

When a system has a mouse, the cursor shows the current location of the mouse. Windows automatically displays and moves the cursor when the mouse is moved. If a system does not have a mouse, Windows does not automatically display or move the cursor. Applications can use the cursor functions to display or move the cursor when a system does not have a mouse.

Displaying and Hiding the Cursor

In a system without a mouse, Windows does not display or move the cursor unless the user chooses certain system commands, such as commands for sizing and moving. This means that after a call to the **SetCursor** function, the cursor remains on the screen until a subsequent call to **SetCursor** with the parameter set to NULL removes the cursor, or until a system command is carried out. Applications that need to use the cursor without a mouse usually simulate mouse input by using keys, such as the arrow keys, and display and move the cursor by using the cursor functions.

The **ShowCursor** function shows or hides the cursor. It is used to temporarily hide the cursor, and then restore it without changing the current cursor shape. This function actually sets an internal counter that determines whether the cursor should be drawn. Showing the cursor increments the counter; hiding the cursor decrements the counter. The cursor is only visible when the count is not a negative value.

Positioning the Cursor

The **SetCursorPos** and **GetCursorPos** functions set and retrieve the current screen coordinates of the cursor. Although the cursor can be set at a location other than the current mouse location, if the system has a mouse any mouse movement causes the cursor to be redrawn at the mouse location. The **SetCursorPos** and **GetCursorPos** functions are most often used in applications that use the keyboard and specified keystrokes to move the cursor. Note that screen coordinates are not affected by the mapping mode in a window's client area.

The Cursor Hot Spot and Confining the Cursor

The hot spot of the cursor is the location in the cursor bitmap that is tracked and recognized as the position of the mouse or keyboard arrow key. For example, the hot spot on the pointer is the point at the tip of the arrow.

The **ClipCursor** function confines the cursor to a given rectangle on the screen. The cursor can move to the edge of the rectangle but cannot move out of it. **ClipCursor** is typically used to restrict the cursor to a given window, such as a dialog box that contains a warning about a serious error. The rectangle is always given in screen coordinates and does not have to be within the window of the active application.

Creating a Custom Cursor

The **SetCursor** function sets the cursor shape and draws the cursor. When a system has a mouse, Windows automatically changes the shape of the cursor when it crosses a window border or enters a different part of a window, such as a title or menu bar. Windows uses standard cursor shapes for the different parts of the screen, such as a pointer in a title bar. The **SetCursor** function lets an application delete the standard cursor and draw its own custom cursor. The cursor keeps its new shape until the mouse moves or a system command is carried out.

Cursor Functions

Cursor functions set, move, show, hide, and confine the cursor. Following are the cursor functions:

Function	Description
ClipCursor	Restricts the cursor to a given rectangle.
CopyCursor	Copies a cursor.
CreateCursor	Creates a cursor from two bit masks.
DestroyCursor	Destroys a cursor created by the **CreateCursor** function.
GetClipCursor	Retrieves the screen coordinates of the rectangle to which the cursor has been restricted.
GetCursor	Retrieves the handle of the current cursor.
GetCursorPos	Stores the cursor position (in screen coordinates).
LoadCursor	Loads a cursor from the resource file.
SetCursor	Sets the cursor shape.
SetCursorPos	Sets the position of the cursor.
ShowCursor	Increases or decreases the cursor display count.

Hooks

A hook is a point in the Windows message-handling mechanism that an application can use to gain access to the message stream. Windows provides many types of hooks; each type provides access to a particular type or range of messages. To take advantage of a particular hook, an application can install a filter function that processes the messages associated with the hook. A filter function processes the messages before they reach the destination window procedure.

Filter-Function Chain

A filter-function chain is a series of connected filter functions for a particular system hook. For example, all keyboard filter functions are installed by **WH_KEYBOARD** and all journaling-record filter functions are installed by WH_JOURNALRECORD. An application passes a filter function to a system hook with a call to the **SetWindowsHook** function. Each call adds a new filter function to the beginning of the chain. Whenever an application passes the address of a filter function to a system hook, it must reserve space for the address of the next filter function in the chain. **SetWindowsHook** installs a hook function into a hook chain and returns a handle of the hook.

Once each filter function completes its task, it must call the **DefHookProc** function. **DefHookProc** uses the address stored in the location reserved by the application to access the next filter function in the chain.

To remove a filter function from a filter chain, an application must call the **UnhookWindowsHook** function with the type of hook and a pointer to the function.

The standard window hooks and debugging hooks are as follows:

Type	Purpose
WH_CALLWNDPROC	Installs a window filter.
WH_CBT	Installs a computer-based training (CBT) filter.
WH_DEBUG	Installs a debugging filter.
WH_GETMESSAGE	Installs a message filter (on debugging versions only).
WH_HARDWARE	Installs a nonstandard hardware-message filter.
WH_JOURNALPLAYBACK	Installs a journaling playback filter.
WH_JOURNALRECORD	Installs a journaling record filter.
WH_KEYBOARD	Installs a keyboard filter.
WH_MOUSE	Installs a mouse-message filter.
WH_MSGFILTER	Installs a message filter.
WH_SYSMSGFILTER	Installs a systemwide message filter.

Note: The **WH_CALLWNDPROC** and **WH_GETMESSAGE** hooks will affect system performance. They are supplied for debugging purposes only.

Installing a Filter Function

To install a filter function, an application must do the following:

1 Export the function in its module-definition (.DEF) file.

2 Obtain the function's address by using the **GetProcAddress** function. (The **MakeProcInstance** function is used only when the filter function is not in a DLL.)

3 Call the **SetWindowsHook** function, specifying the type of hook function and the address of the function (returned by **GetProcAddress**).

4 Store the return value from **SetWindowsHook** in a reserved location. This value is the handle of the previous filter function.

Note: Filter functions for system-wide hooks must reside in a dynamic-link library (DLL). Application-

specific filter functions can reside in a DLL or the application.

Property Lists

A property list is a storage area that contains handles for data that the application needs to associate with a window.

Using Property Lists

Once a data handle is in a window's property list, any application that can access the window can also access the handle. Using the property list is a convenient way to make data (for example, an alternate title or menu for a window) available when the application needs to modify a window.

Every window has its own property list. When a window is created, the list is empty. The **SetProp** function adds entries to the list. Each entry contains a unique Windows character string and a data handle.

The data handle can identify any object that the application needs to associate with the window. The **GetProp** function retrieves the data handle of an entry from the list without removing the entry. The handle can then be used to retrieve or use the data. The **RemoveProp** function removes an entry from the list when it is no longer needed.

Although the purpose of the property list is to associate data with a window for use by the application that owns the window, the handles in a property list are accessible to any application that has access to the window. This means an application can retrieve and use a data handle from the property list of a window created by another application. But using another application's data handles must be done with care. Only shared, global memory objects, such as GDI drawing objects, can be used by other applications. If a property list contains local or global memory handles or resource handles, only the application that has created the window can use them. An application can use the Windows clipboard to share global memory handles with other applications. Local memory handles cannot be shared.

The contents of a property list can be enumerated by using the **EnumProps** function. The function passes the string and data handle of each entry in the list to an application-supplied function. The application-supplied function can then carry out the necessary task.

The data handles in a property list always belong to the application that created them. The property list itself, like other window-related data, belongs to Windows. A window's property list is allocated in the USER heap, the local heap of the USER library. Although there is no defined limit to the number of entries in a property list, the number of entries depends on how much space is available in the USER heap. The available space depends on how many windows, window classes, and other window-related objects have been created.

The application creates the entries in a property list. Before a window is destroyed or the application that owns the window closes, all entries in the property list must be removed by using the **RemoveProp** function. Failure to remove the entries leaves the property list in the USER heap and makes the space it occupies unusable for subsequent applications. This can ultimately cause an overflow of the USER heap.

An application can use the **RemoveProp** function at any time to remove entries from the property list. If there are entries in the property list when the **WM_DESTROY** message is received for the window, the entries must be removed at that time. To ensure that all entries are removed, use the **EnumProps** function to enumerate all entries in the property list. An application should remove only those properties that it added to the property list. Windows adds properties for its own use and disposes of them automatically. An application must not remove properties that Windows has added to the list.

Rectangles

In Windows, a rectangle is defined by a **RECT** structure. The structure specifies two points: the upper-left and lower-right corners of the rectangle. The sides of a rectangle extend from these two points and are parallel to the x- and y-axes.

Using Rectangles in a Windows Application

Rectangles are used to specify rectangular areas on the screen or in a window, such as the cursor clipping region, the client repaint area, a formatting area for formatted text, and the scroll area. Rectangles are also used to fill, frame, or invert an area in the client area with a given brush, and to retrieve the coordinates of a window or a window's client area.

Because rectangles are used for many different purposes, the rectangle functions do not use an explicit unit of measure. Instead, all rectangle coordinates and dimensions are given in signed, logical values. The units of measure are determined by the function in which the rectangle is used.

Rectangle Coordinates

Valid coordinate values for a rectangle are in the range -32,768 through 32,767. Valid widths and heights, which must be positive, are in the range 0 through 32,767. This means that a rectangle whose left and right sides or whose top and bottom are further apart than 32,768 units is not valid.

Creating and Manipulating Rectangles

The **SetRect** function creates a rectangle, the **CopyRect** function makes a copy of a given rectangle, and the **SetRectEmpty** function creates an empty rectangle. An empty rectangle is any rectangle that has zero width, zero height, or both.

The **InflateRect** function increases or decreases the width or height of a rectangle, or both. It can add or remove width from both ends of the rectangle; it can add or remove height from both the top and bottom of the rectangle.

The **OffsetRect** function moves the rectangle by a given amount. It moves the rectangle by adding the given x-amount, y-amount, or x- and y-amounts to the corner coordinates.

The **PtInRect** function finds out whether a given point lies within a given rectangle. The point is in the rectangle if it lies on the left or top side or is completely within the rectangle.

The **IsRectEmpty** function finds out whether the given rectangle is empty.

The **IntersectRect** function creates a new rectangle that is the intersection of two existing rectangles. The intersection is the largest rectangle contained in both existing rectangles.

The **UnionRect** function creates a new rectangle that is the union of two existing rectangles. The union is the smallest rectangle that contains both existing rectangles.

For information about functions that draw ellipses and polygons, see Graphics Device Interface Overview.

Graphics Device Interface Overview

The following topics describe the functions that perform device-independent graphics operations in an application for the Microsoft Windows operating system. These operations include the creation of line, text, and bitmap output on different output devices. The functions performing those operations constitute the Windows graphics device interface (GDI).

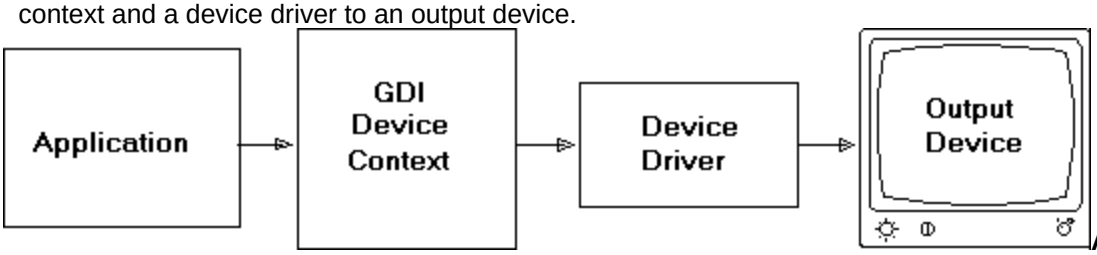
Device Contexts
Specifying Colors
Color-palette functions
Drawing-attribute functions
Mapping functions
Coordinate functions
Line-output functions
Ellipse and polygon functions
Metafile functions

Some Windows functions in the USER application programming interface (API) are closely related to these GDI function groups.

Device Contexts

A device context (DC) is a link between a Windows application, a device driver, and an output device, such as a printer or plotter. Windows maintains a cache of five special device contexts for the system display. Applications must release these device contexts after using them.

The following illustration shows the flow of information from a Windows application through a device context and a device driver to an output device.



Accessing Output Devices

Any Windows application can use GDI functions to access an output device. GDI passes calls, which are device independent, from the application to the device driver. The device driver then translates the calls into device-dependent operations.

Saving and Restoring a Device Context

The **SaveDC** and **RestoreDC** functions save and restore device contexts. The former saves the original attributes, and the latter makes them available at a later time. For example, a Windows application may need to save its original clipping region so that it can restore the original state of the client area after a series of alterations occur.

Deleting a Device Context

The **DeleteDC** function deletes a device context and ensures that shared resources are not removed until the last context is deleted. The device driver is a shared resource. **DeleteDC** should be used to delete device contexts created by the application. If the application uses the **GetDC** function to retrieve a device context, it should use the **ReleaseDC** function, not **DeleteDC**.

Creating a Compatible Device Context

The **CreateCompatibleDC** function causes Windows to treat a portion of memory as a virtual device. Then Windows prepares a device context that has the same attributes as the device for which the virtual device was created, but the device context has no connected output device.

To use the compatible device context, the application creates a compatible bitmap and selects it into the device context. Any output the application sends to the device is drawn in the selected bitmap. Because the device context is compatible with an actual device, the context of the bitmap can be copied directly to the actual device, or vice versa. This also means that the application can send output to memory (prior to sending it to the device).

Note: The **CreateCompatibleDC** function works only for devices that support raster operations. To discover whether a device supports raster operations, an application can call the **GetDeviceCaps** function with the RC_BITBLT index.

Creating an Information Context

The **CreateIC** function creates an information context for a device. An information context is a device context with limited capabilities; it cannot be used to write to the device. An application uses an information context to gather information about the selected device. Information contexts are useful in large applications that require memory conservation.

By using an information context and the **GetDeviceCaps** function, you can obtain the following device information:

- Device technology

- Physical display size
- Color capabilities of the device
- Color-palette capabilities of the device
- Drawing objects available on the device
- Clipping capabilities of the device
- Raster capabilities of the device
- Curve-drawing capabilities of the device
- Line-drawing capabilities of the device
- Polygon-drawing capabilities of the device
- Text capabilities of the device

Device-Context Attributes

Device-context attributes describe selected drawing objects (pens and brushes), the selected font and its color, the way in which objects are drawn (or mapped) to the device, the area on the device available for output (clipping region), and other important information. The structure that contains the device-context attributes is called the device-context data block. The default attributes and the GDI functions that affect or use them are as follows.

Attribute	Default	GDI functions
Background color	White	**SetBkColor**
Background mode	OPAQUE	**SetBkMode**
Bitmap	No default	**CreateBitmap** **CreateBitmapIndirect** **CreateCompatibleBitmap** **SelectObject**
Brush	WHITE_BRUSH	**CreateBrushIndirect** **CreateDIBPatternBrush** **CreateHatchBrush** **CreatePatternBrush** **CreateSolidBrush** **SelectObject**
Brush origin	(0,0)	**SetBrushOrg** **UnrealizeObject**
Clipping region	Display surface	**CreateEllipticRgn** **CreateEllipticRgnIndirect** **CreatePolygonRgn** **CreatePolyPolygonRgn** **CreateRectRgn** **CreateRoundRectRgn** **ExcludeClipRect** **IntersectClipRect** **OffsetClipRgn** **SelectClipRgn**
Color palette	DEFAULT_PALETTE	**CreatePalette** **RealizePalette** **SelectPalette** **UnrealizeObject**
Current pen position	(0,0)	**LineTo** **MoveTo**
Drawing mode	R2_COPYPEN	**SetROP2**
Font	SYSTEM_FONT	**CreateFont** **CreateFontIndirect** **SelectObject**
Intercharacter spacing	0	**SetTextCharacterExtra**
Mapping mode	MM_TEXT	**SetMapMode**
Pen	BLACK_PEN	**CreatePen** **CreatePenIndirect** **SelectObject**
Polygon-filling mode	ALTERNATE	**SetPolyFillMode**
Stretching mode	BLACKONWHITE	**SetStretchBltMode**
Text color	Black	**SetTextColor**
Viewport extent	(1,1)	**SetViewportExt**
Viewport origin	(0,0)	**SetViewportOrg**
Window extent	(1,1)	**SetWindowExt**
Window origin	(0,0)	**SetWindowOrg**

Specifying Colors

Many of the GDI functions that create pens and brushes require that the calling application specify a color in the form of a doubleword. The color can be specified as:

- An explicit **RGB** value
- An index to a logical-palette entry
- A palette-relative **RGB** value

The second and third methods of specifying color require the application to create a logical palette.

An explicit **RGB** doubleword value is a long integer that contains a red, a green, and a blue color field. The first (low-order) byte contains the red field, the second byte contains the green field, the third byte contains the blue field, and the fourth (high-order) byte must be zero. Each field specifies the intensity of the color; zero indicates the lowest intensity, and 255 indicates the highest. For example, 0x00FF0000 specifies pure blue, and 0x0000FF00 specifies pure green. The RGB macro accepts values for the relative intensities of the three colors and returns an explicit RGB doubleword value.

When GDI receives the **RGB** value as a function parameter, it passes the RGB color value directly to the output device driver, which selects the closest available color on the device. The **GetNearestColor** function returns the logical color closest to a specified logical color that a given device can represent.

If the device is a plotter, the driver converts the **RGB** value to a single color that matches one of the pens on the device.

If the device uses color raster technology and the **RGB** value specifies a color for a pen, the driver selects a solid color. If the device uses color raster technology and the RGB value specifies a color for a brush, the driver selects from a variety of available color combinations. Because many color devices can display only a few colors, the actual color is simulated by dithering (that is, mixing pixels of colors that the device can actually render).

If the device is monochrome (black-and-white), the driver selects black, white, or a shade of gray, depending on the **RGB** value. If the sum of the RGB values is zero, the driver selects a black brush. If the sum of the RGB values is 765, the driver selects a white brush. If the sum of the RGB values is between zero and 765, the driver selects one of the gray patterns available.

The **GetRValue**, **GetGValue**, and **GetBValue** macros extract the values for red, green, and blue from an explicit **RGB** doubleword value.

Color Palettes

Many color graphics displays are capable of displaying a wide range of colors. In most cases, however, the actual number of colors that the display can render at any given time is more limited. For example, a display that is potentially able to produce over 262,000 different colors may be able to show only 256 of those colors at a time because of hardware limitations.

To render colors, a display device often maintains a palette of colors. When an application requests a color that is not currently displayed, the display device adds the requested color to the palette. However, when the number of requested colors exceeds the maximum number for the device, it must replace an existing color with the requested color. As a result, if the total number of colors requested by one or more windows exceeds the number available on the display, many of the actual colors displayed will be incorrect.

Windows color palettes act as a buffer between color-intensive applications and the system. When a window has the input focus, Windows ensures that the window displays all the colors it requests, up to the maximum number simultaneously available on the display, and displays additional colors by matching them to available colors. In addition, Windows matches the colors requested by inactive windows as closely as possible to the available colors. This process significantly reduces undesirable changes in the colors displayed in inactive windows.

Understanding Color Palettes

Color palettes provide a device-independent method for accessing the color capabilities of a display device by managing the physical, or system, palette of the device, if one is available. Typically, devices that can display at least 256 colors use a system palette.

An application employs the system palette by creating and using one or more logical palettes. Each entry in the system palette contains a specific color. Then, instead of specifying an explicit value for a color when performing graphics operations, the application indicates which color is to be displayed by supplying an index into the logical palette.

Because more than one application can use logical palettes, it is possible that the total number of colors requested for display can exceed the capacity of the display device. Windows acts as a mediator among the applications.

When a window requests that its logical palette be given its requested colors (a process known as realizing its palette), Windows first matches entries in the logical palette to current entries in the system palette. If an exact match for a given logical palette entry is not possible, Windows sets the entry in the logical palette into an unused entry in the system palette.

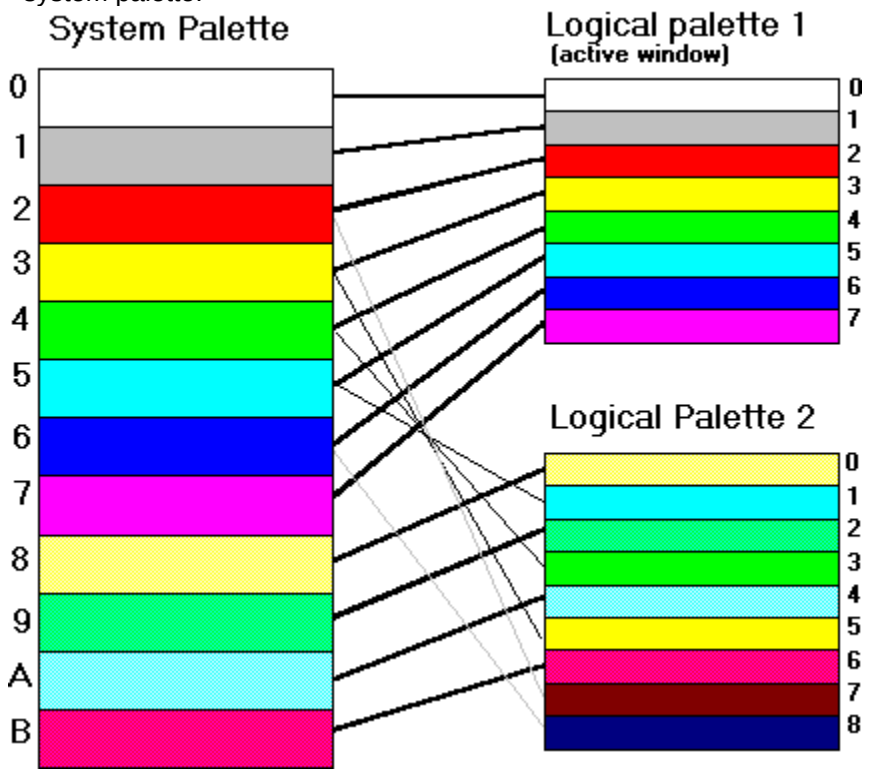
When all entries in the system palette have been used, Windows takes the logical palette entries that do not exactly match and matches them as closely as possible to entries already in the system palette. To further aid color matching, Windows sets aside 20 static colors in the system palette (the default palette) to which it can match entries in a background palette.

Windows always satisfies the color requests of the foreground window first; this procedure ensures that the active window has the best color display possible. For the remaining windows, Windows satisfies the color requests of the window that most recently received the input focus, the window that was active before that one, and so on.

The following illustration shows this process. In this illustration, a hypothetical display has a system palette capable of containing 12 colors. The application that created Logical Palette 1 owns the active window and was the first to realize its logical palette, which consists of 8 colors. Because the active window was active when it realized its palette, Windows mapped all of the colors in Logical Palette 1 directly to the system palette.

Logical Palette 2 is owned by a window that realized its logical palette while it was inactive. Three of the colors (1, 3, and 5) in Logical Palette 2 were identical to colors in the system palette. To save space in the palette, Windows simply matched those colors to existing system colors when the second application realized its palette. Colors 0, 2, 4, and 6 were not already in the system palette, however,

so Windows mapped those colors into the system palette. Because the system palette became full, Windows was not able to map the remaining two colors (which did not exactly match existing colors in the system palette) into the system palette. Instead, it matched them to the closest colors in the system palette.



Using a Color Palette

Before drawing to the display device with a color palette, an application must first create a logical palette by calling the **CreatePalette** function and then use the **SelectPalette** function to select the palette for the device context of the output device for which it will be used. An application cannot select a palette into a device context by using the **SelectObject** function.

All functions with a color parameter accept an index to an entry in the logical palette. The palette index specifier is a long integer value with the first bit in its high-order byte set to 1 and the palette index in the two low-order bytes. For example, 0x01000005 specifies the palette entry with an index of 5. The **PALETTEINDEX** macro accepts an integer value representing the index of a logical palette entry and returns a palette index value, which an application can use as a parameter for GDI functions that require a color.

An application can also specify a palette index indirectly by using a palette-relative **RGB** value. If the target display device supports logical palettes, Windows matches the palette-relative RGB value to the closest palette entry. If the target device does not support palettes, the RGB value is used as though it were an explicit RGB value. The palette-relative RGB value is identical to an explicit RGB value except that the second bit of the high-order byte is set to 1. For example, 0x02FF0000 specifies a palette-relative RGB value for pure blue. The **PALETTERGB** macro accepts values for red, green, and blue and returns a palette-relative RGB value, which an application can use as a parameter for GDI functions that require a color.

If an application specifies an **RGB** value instead of a palette entry, Windows uses the closest matching color in the default palette of 20 static colors.

If the source and destination device contexts have selected and realized different palettes, the **BitBlt**

function does not properly move bitmap bits to or from a memory device context. In this case, you must call the **GetDIBits** function with the **DIB_RGB_COLORS** flag to retrieve the bitmap bits from the source bitmap in a device-independent format. Then you use the **SetDIBits** function to set the retrieved bits in the destination bitmap. This ensures that Windows properly matches colors between the two device contexts.

Note: The **BitBlt** function successfully moves bitmap bits between two screen display contexts, even if they have selected and realized different palettes. The **StretchBlt** function properly moves bitmap bits between device contexts whether or not they use different palettes.

Color-Palette Functions

Windows color palettes allow an application to use as many colors as needed without interfering with its own color display or colors displayed by other windows. Following are the functions an application calls to use color palettes:

Function	Description
AnimatePalette	Replaces entries in a logical palette; Windows maps the new entries into the system palette immediately.
CreatePalette	Creates a logical palette.
GetNearestColor	Retrieves the solid color closest to a specified logical color that a given device can represent.
GetNearestPaletteIndex	Retrieves the index of a logical palette entry most nearly matching a specified **RGB** value.
GetPaletteEntries	Retrieves entries from a logical palette.
GetSystemPaletteEntries	Retrieves a range of palette entries from the system palette.
GetSystemPaletteUse	Determines whether an application has access to the full system palette.
ResizePalette	Changes the size of the specified logical palette.
SetPaletteEntries	Sets new palette entries in a logical palette; Windows does not map the new entries to the system palette until the application realizes the logical palette.
SetSystemPaletteUse	Allows an application to use the full system palette.
UpdateColors	Performs a pixel-by-pixel translation of each pixel's current color to the system palette. This process allows an inactive window to correct its colors without redrawing its client area.

The USER API also provides two palette-management functions:

Function	Description
RealizePalette	Maps entries in a logical palette to the system palette.
SelectPalette	Selects a logical palette into a device context.

For more information about these USER functions, Window Management.

Drawing Attributes

A drawing attribute can take one of the following forms: line, brush, text, or bitmap output.

Setting Colors

Line output can be solid or broken (dashed, dotted, or a combination of the two). If it is broken, the space between the breaks can be filled by setting the background mode to **OPAQUE** and selecting a color. By setting the background mode to **TRANSPARENT**, the space between breaks is left in its original state. The **SetBkMode** and **SetBkColor** functions set the background mode and color.

Brush output is solid, patterned, or hatched. The space between hatch marks can be filled by setting the background mode to **OPAQUE** and selecting a color. When Windows creates brush output on a display, it combines the existing color on the display surface with the brush color to yield a new and final color; this is a binary raster operation. If the default raster operation is not appropriate, a new one is chosen by using the **SetROP2** function.

The appearance of text output is limited only by the number of available fonts and the color capabilities of the output device. The **SetBkColor** function sets the color of the text background (the unused portion of each character cell), and the **SetTextColor** function sets the color of the character itself.

Controlling Stretch

The appearance of bitmap output can be affected by the stretch mode, which determines how lines eliminated from the bitmap are combined. If an application copies a bitmap to a device and it is necessary to shrink or expand the bitmap before drawing, the effects of the **StretchBlt** and **StretchDIBits** functions can be controlled by calling the **SetStretchBltMode** function to set the current stretch mode for a device context.

Mapping Modes

To maintain device independence, GDI creates output in a logical space and maps it to the display. The mapping mode defines the relationship between units in the logical space and pixels on a device.

There are eight different GDI mapping modes, each of which has a specific use in a Windows application. Following are these mapping modes:

Mapping mode	Description
MM_ANISOTROPIC	Maps one logical unit to an arbitrary physical unit. The x-axis and y-axis are arbitrarily scaled.
MM_HIENGLISH	Maps one logical unit to 0.001 inch. The positive y-axis extends upward.
MM_HIMETRIC	Maps one logical unit to 0.01 millimeter. The positive y-axis extends upward.
MM_ISOTROPIC	Maps one logical unit to an arbitrary physical unit. One unit along the x-axis is always equal to one unit along the y-axis.
MM_LOENGLISH	Maps one logical unit to 0.01 inch. The positive y-axis extends upward.
MM_LOMETRIC	Maps one logical unit to 0.1 millimeter. The positive y-axis extends upward.
MM_TEXT	Maps one logical unit to one pixel. The positive y-axis extends downward.
MM_TWIPS	Maps one logical unit to 1/1440 inch (1/20 of a point; a point is 1/72 inch). The positive y-axis extends upward.

Constrained Mapping Modes

GDI classifies six of the mapping modes as constrained mapping modes. These mapping modes are constrained because the scaling factor is fixed, so an application cannot change the number of logical units that Windows maps to a physical unit. The relationship of logical units to physical units for each constrained mapping mode follows:

Mapping mode	Logical units	Physical unit
MM_HIENGLISH	1000	1 inch
MM_HIMETRIC	100	1 millimeter
MM_LOENGLISH	100	1 inch
MM_LOMETRIC	10	1 millimeter
MM_TEXT	1	Device pixel
MM_TWIPS	1440	1 inch

> Note: The MM_HIENGLISH, MM_HIMETRIC, MM_LOENGLISH, MM_LOMETRIC, and MM_TWIPS mapping modes sometimes map logical units to device units in ways that do not correspond exactly to the preceding table. This typically occurs on displays; for example, on an VGA display there is a 33 percent increase in the dimensions of the device units. The increase in the dimensions of device units occurs so that the same output looks equally crisp and readable whatever the device resolution and the display technology for the device. An application can use the **GetDeviceCaps** function with the LOGPIXELSX and LOGPIXELSY indices to discover the scaling factor.

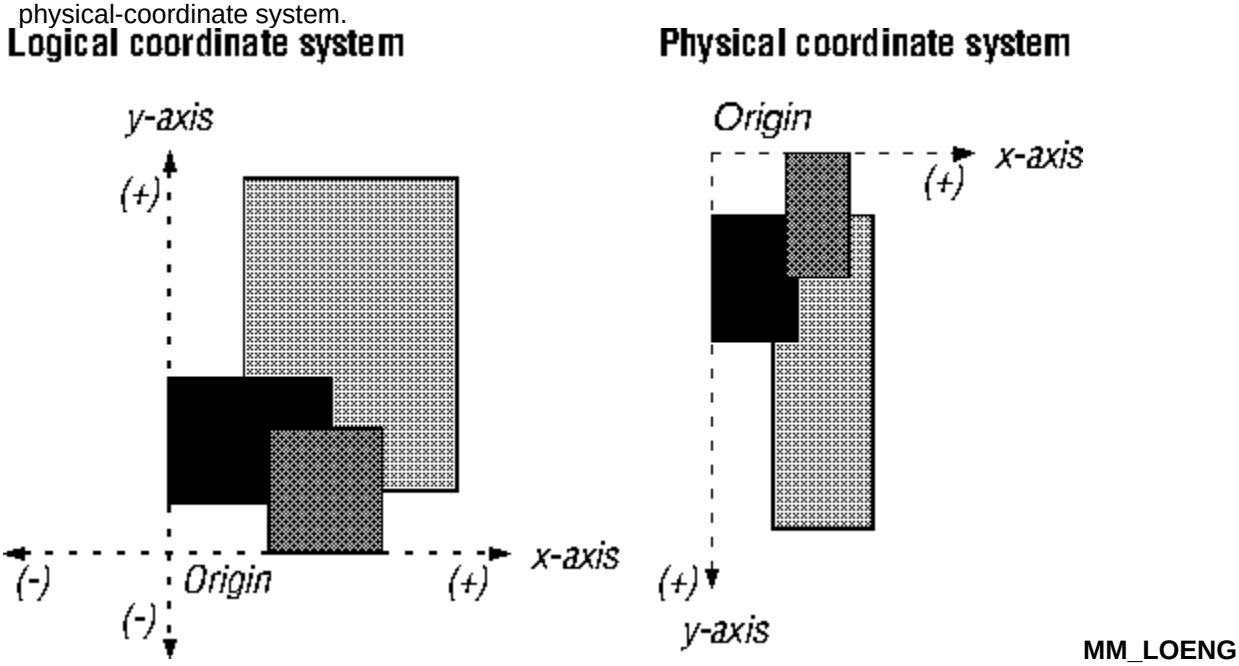
In each of the six constrained modes, one logical unit is mapped to a predefined physical unit. For instance, the MM_TEXT mapping mode maps one logical unit to one device pixel, and the MM_LOENGLISH mapping mode maps one logical unit to 0.01 inch on the device. Examples for these two modes follow.

MM_TEXT Mapping Mode

The default mapping mode is MM_TEXT. In this mapping mode, one logical unit is mapped to one pixel on the device or display.

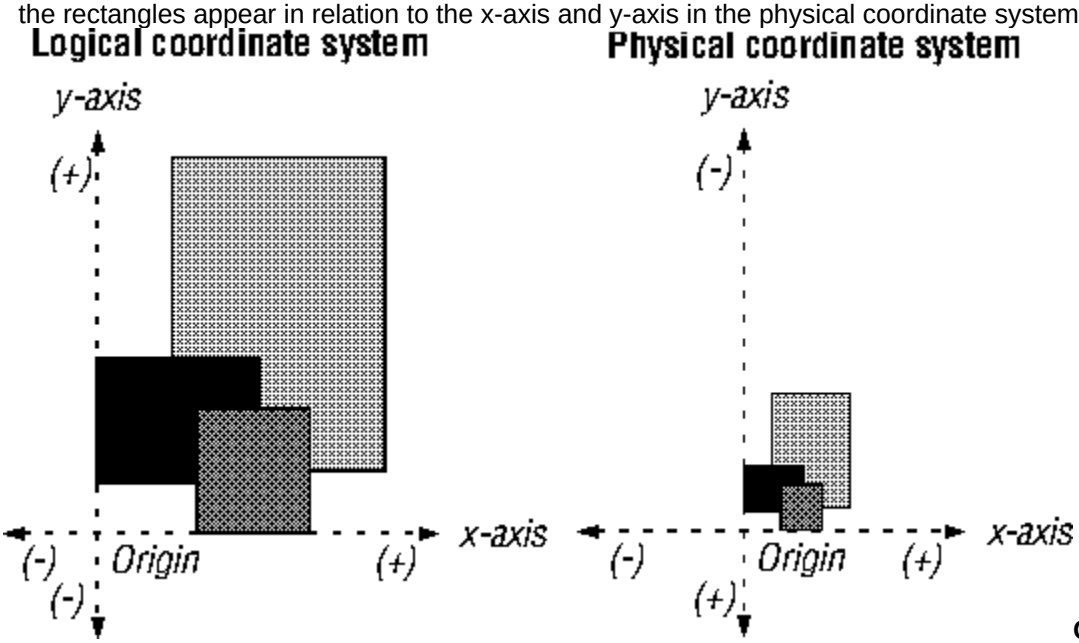
The following illustration shows three rectangles created by a Windows application by using the MM_TEXT mapping mode. The drawing on the left illustrates the logical coordinate space, and the

one on the right illustrates the device, or physical, coordinate space. The rectangles appear vertically elongated in the physical space because pixels on the chosen display are longer than they are wide. The rectangles appear to be upside-down because the positive y-axis extends downward in the physical-coordinate system.



MM_LOENGLISH Mapping Mode

The following illustration shows three rectangles created by a Windows application by using the MM_LOENGLISH mapping mode. The drawing on the left illustrates how the rectangles appear in relation to the x-axis and y-axis in the logical coordinate system. The one on the right illustrates how the rectangles appear in relation to the x-axis and y-axis in the physical coordinate system.



Other Mapping Modes

The MM_ISOTROPIC and MM_ANISOTROPIC mapping modes, which are not constrained, use two rectangular regions to derive a scaling factor and an orientation: the window and the viewport. The window lies within the logical-coordinate space, and the viewport lies within the physical-coordinate space. Both possess an origin, an x-extent, and a y-extent. The origin may be any one of the four

corners. The x-extent is the horizontal distance from the origin to its opposing corner. The y-extent is the vertical distance from the origin to its opposing corner.

Windows creates a horizontal scaling factor by dividing the viewport's x-extent by the window's x-extent and creates a vertical scaling factor by dividing the viewport's y-extent by the window's y-extent. These scaling factors determine the number of logical units that Windows maps to a number of pixels. In addition to determining scaling factors, the window and viewport determine the orientation of an object. Windows always maps the window origin to the viewport origin, the window x-extent to the viewport x-extent, and the window y-extent to the viewport y-extent.

Partially Constrained Mapping Mode

An application creates output with equally scaled axes by using the MM_ISOTROPIC mapping mode. As the term isotropic implies, Windows maps a symmetrical object (for example, a square or a circle) in the logical space as a symmetrical object in the physical space. In order to maintain this symmetry, GDI shrinks one of the viewport extents. The amount of shrinkage depends on the requested extents and the aspect ratio of the device. This mapping mode is called partially constrained because the application does not have complete control in altering the scaling factor.

Unconstrained Mapping Mode

An application can completely alter the horizontal and vertical scaling factors by using the MM_ANISOTROPIC mapping mode and setting the window and viewport extents to any value after selecting this mapping mode. Windows does not alter either scaling factor in this mode.

Coordinate Functions

Coordinate functions convert client coordinates to screen coordinates (or vice versa). These functions are useful in graphics-intensive applications. Following are the coordinate functions:

Function	Description
DPtoLP	Converts device points (that is, points relative to the window origin) into logical points.
GetCurrentPosition	Retrieves the current position, in logical coordinates.
GetCurrentPositionEx	Retrieves position in logical units.
LPtoDP	Converts logical points into device points.

GDI uses the following equations to transform logical points to device points and device points to logical points:

- Transforming logical points to device points:

  D*x* = (L*x* - *x*WO) * *x*VE/*x*WE + *x*VO
  D*y* = (L*y* - *y*WO) * *y*VE/*y*WE + *y*VO

- Transforming device points to logical points:

  L*x* = (D*x* - *x*VO) * *x*WE/*x*VE + *x*WO
  L*y* = (D*y* - *y*VO) * *y*WE/*y*VE + *y*WO

Following are descriptions of the variables used in these transformation equations:

Variable	Description
*x*WO	Window origin x-coordinate
*y*WO	Window origin y-coordinate
*x*WE	Window extent x-coordinate
*y*WE	Window extent y-coordinate
*x*VO	Viewport origin x-coordinate
*y*VO	Viewport origin y-coordinate
*x*VE	Viewport extent x-coordinate
*y*VE	Viewport extent y-coordinate
L*x*	Logical-coordinate system x-coordinate
L*y*	Logical-coordinate system y-coordinate
D*x*	Device x-coordinate
D*y*	Device y-coordinate

The following four ratios are scaling factors used to determine the necessary stretching or compressing of logical units: *x*VE/*x*WE, *y*VE/*y*WE, *x*WE/*x*VE, and *y*WE/*y*VE.

The subtraction and addition of viewport and window origins is referred to as the translational component of the equation.

In addition, applications can use the following functions from the USER API to convert coordinates from one system to another:

Function	Description
ChildWindowFromPoint	Determines which, if any, of the child windows belonging to a given parent window contains a specified point.
ClientToScreen	Converts the client coordinates of a given point on the display to screen coordinates.
ScreenToClient	Converts the screen coordinates of a given point on the display to client coordinates.

WindowFromPoint	Retrieves the handle of the window that contains a given point.

Line Output

Line output functions require coordinates in logical units, which GDI uses to draw a line in logical space. (The use of logical units ensures device independence in Windows.) GDI maps this line from the logical space to pixels on the device. The number of logical units that GDI maps to a pixel depends on the current mapping mode. When GDI draws a line, it excludes the last specified point.

If an application draws lines and does not create a new pen, GDI uses the default pen. This pen is black and is one pixel wide when the mapping mode is MM_TEXT. An application can create a new pen of a different width, style, and color by using the **CreatePen** function. The new color is dependent on the color capabilities of the output device. The new style can be solid, dotted, dashed, or combined (dotted and dashed). Once an application creates a new pen, it can select the pen into a display context by using the **SelectObject** function.

Ellipses and Polygons

Ellipse and polygon functions require coordinates in logical units, which GDI uses to determine the location and size of an object in logical space. (The use of logical units ensures device independence in Windows.) GDI maps the object from logical space to pixels on the device. The number of logical units that Windows maps to a pixel depends on the current mapping mode. The default mapping mode, MM_TEXT, maps one logical unit to one pixel.

Rectangles

The **Rectangle** function draws a rectangle, using the current pen. The **RoundRect** function also draws a rectangle, but with rounded rather than square corners.

When GDI draws a rectangle, it uses four arguments. The first two arguments specify the upper-left corner of the rectangle. The last two arguments do not actually specify part of the rectangle; they specify the point adjacent to the lower-right corner. For example, if the first point is specified by (*x1, y1*) and the second point is specified by (*x2, y2*), the rectangle's upper-left corner will be (*x1, y1*) and the lower-right corner will be (*x2* - 1, *y2* - 1).

Bounding Rectangles

The **Chord**, **Ellipse**, and **Pie** functions use a bounding rectangle, instead of a radius or circumference measurement, to define the size of the object they create. The bounding rectangle is hidden; GDI uses it only to describe the location and size of the object.

Ellipse and Polygon Functions

Ellipse and polygon functions, which draw ellipses and polygons, are particularly useful in drawing and charting applications. GDI draws the perimeter of each object with the selected pen and fills the interior by using the selected brush. Following are the ellipse and polygon functions:

Function	Description
Chord	Draws a chord.
Ellipse	Draws an ellipse.
Pie	Draws a pie.
Polygon	Draws a polygon.
PolyPolygon	Draws a series of closed polygons that are filled as though they were a single polygon.
Rectangle	Draws a rectangle.
RoundRect	Draws a rounded rectangle.

Metafiles

A metafile is a collection of GDI commands that creates desired text or images. Metafiles provide a convenient method of storing graphics commands that create text or images. Metafiles are especially useful in applications that use specific text or a particular image repeatedly. They are also device-independent; by creating text or images with GDI commands and then placing the commands in a metafile, an application can re-create the text or images repeatedly on a variety of devices. Metafiles are also useful in applications that need to pass graphics information to other applications.

Creating a Metafile

A Windows application must create a metafile in a special device context. It cannot use the device contexts that the **CreateDC** or **GetDC** function returns; instead, it must use the device context that the **CreateMetaFile** function returns.

Windows allows an application to use a subset of the GDI functions to create a metafile. This subset consists of all GDI functions that create output (rather than functions that provide state information, such as the **GetDeviceCaps** function). The following list shows GDI functions that an application can use in a metafile:

AnimatePalette	**OffsetViewportOrg**	**SetBkMode**
Arc	**OffsetWindowOrg**	**SetDIBitsToDevice**
BitBlt	**PatBlt**	**SetMapMode**
Chord	**Pie**	**SetMapperFlags**
CreateBrushIndirect	**Polygon**	**SetPixel**
CreateDIBPatternBrush	**Polyline**	**SetPolyFillMode**
CreateFontIndirect	**PolyPolygon**	**SetROP2**
CreatePatternBrush	**RealizePalette**	**SetStretchBltMode**
Ellipse	**RestoreDC**	**SetTextColor**
Escape	**RoundRect**	**SetTextJustification**
ExcludeClipRect	**SaveDC**	**SetViewportExt**
ExtTextOut	**ScaleViewportExt**	**SetViewportOrg**
FloodFill	**ScaleWindowExt**	**SetWindowExt**
IntersectClipRect	**SelectClipRgn**	**SetWindowOrg**
LineTo	**SelectObject**	**StretchBlt**
MoveTo	**SelectPalette**	**StretchDIBits**
OffsetClipRgn	**SetBkColor**	**TextOut**

To create output in a metafile, an application must follow four steps:

1 Create a special device context by using the **CreateMetaFile** function.

2 Send GDI commands to the metafile by using the special device context.

3 Close the metafile by calling the **CloseMetaFile** function. This function returns a metafile handle.

4 Display the image or text on a device by using the **PlayMetaFile** function and passing to the function the metafile handle obtained from **CloseMetaFile** and a device-context handle for the device on which the metafile is to be played.

The device context that the **CreateMetaFile** function creates does not have default attributes of its own. Whatever device-context attributes are in effect for the output device when an application plays a metafile will be the defaults for the metafile. The metafile can change these attributes while it is playing. If the application needs to retain the same device-context attributes after the metafile has finished playing, it should save the output device context by calling the **SaveDC** function before calling the

PlayMetaFile function. Then, when **PlayMetaFile** returns, the application can call the **RestoreDC** function to restore the original device-context attributes.

Although the maximum size of a metafile is 2^32 bytes or records, the actual size of a metafile is limited by the amount of memory or disk space available.

Storing a Metafile

An application can store a metafile in system memory or in a disk file.

To store the metafile in memory, an application calls the **CreateMetaFile** function and passes NULL as the function parameter. The application can free the memory that Windows uses to store the metafile by calling the **DeleteMetaFile** function. This function removes a metafile from memory and invalidates its handle. **DeleteMetaFile** has no effect on disk files.

There are two ways of storing a metafile in a disk file:

- When the application calls the **CreateMetaFile** function to open a metafile, it passes a filename as the function parameter; the metafile is then recorded in a disk file.
- After the application has created a metafile in memory, it calls the **CopyMetaFile** function. This function accepts the handle of a memory metafile and the name of the disk file to which the metafile will be saved.

The **GetMetaFile** function opens a metafile stored in a disk file and makes it available for replay or modification. This function accepts the filename of a metafile stored on disk and returns a metafile handle.

Changing How Windows Plays a Metafile

A metafile does not have to be played back in its entirety or exactly in the form in which it was recorded. An application can use the **EnumMetaFile** function to locate a specific metafile record. **EnumMetaFile** calls a callback function supplied by the application and passes it the following information:

- The metafile device context
- A pointer to the metafile handle table
- A pointer to a metafile record
- The number of associated objects with handles in the handle table
- A pointer to application-supplied data

The callback function can then use this information to play a single record, to query the record, to copy it, or to modify it.

The **PlayMetaFileRecord** function plays a metafile record by executing the GDI function contained in the record.

When Windows plays or enumerates the records in a metafile, it identifies each object with an index into a handle table. Functions that select objects (such as **SelectObject** and **SelectPalette**) identify the object by means of the object handle that the application passes to the function.

Objects are added to the table in the order in which they are created. For example, if a brush is the first object created in a metafile, the brush is given index 0. If the second object is a pen, it is given index 1, and so on. For information about the format of the handle table, see the description of the **HANDLETABLE** structure in the *Microsoft Windows Programmer's Reference, Volume 3.*

Common Dialog Box Overview (3.1)

Common dialog boxes make it easier for you to develop applications for the Microsoft Windows operating system. A common dialog box is a dialog box that an application displays by calling a single function rather than by creating a dialog box procedure and a resource file containing a dialog box template. The dynamic-link library COMMDLG.DLL provides a default procedure and template for each type of common dialog box. Each default dialog box procedure processes messages and notifications for a common dialog box and its controls. A default dialog box template defines the appearance of a common dialog box and its controls.

In addition to simplifying the development of Windows applications, a common dialog box assists users by providing a standard set of controls for performing certain operations. As Windows developers begin using the common dialog boxes in their applications, users will find that after they master using a common dialog box in one application, they can easily perform the same operations in other applications.

This topic describes the various common dialog boxes and includes sample code to help you use common dialog boxes in your Windows applications.

Following are the types of common dialog boxes in the order in which they are presented in this topic:

Name	Description
Color	Displays available colors, from which the user can select one; displays controls that let the user define a custom color.
Font	Displays lists of fonts, point sizes, and colors that correspond to available fonts; after the user selects a font, the dialog box displays sample text rendered with that font.
Open	Displays a list of filenames matching any specified extensions, directories, and drives. By selecting one of the listed filenames, the user indicates which file an application should open.
Save As	Displays a list of filenames matching any specified extensions, directories, and drives. By selecting one of the listed filenames, the user indicates which file an application should save.
Print	Displays information about the installed printer and its configuration. By altering and selecting controls in this dialog box, the user specifies how output should be printed and starts the printing process.
Print Setup	Displays the current list of available printers. The user can select a printer from this list. This common dialog box also provides options for setting the paper orientation, size, and source (when the printer driver supports these options). In addition to being called directly, the Print Setup dialog can be opened from within the Print dialog.
Find	Displays an edit control in which the user can type a string for which the application should search. The user can specify the direction of the search, whether the application should match the case of the specified string, and whether the string to match is an entire word.
Replace	Displays two edit controls in which the user can type strings: the first string identifies a word or value that the application should replace, and the second string identifies the replacement word or value.

Applications that use the common dialog boxes should specify at least 8K for the stack size, as shown in the following example:

```
NAME cd

EXETYPE WINDOWS

STUB    'WINSTUB.EXE'
```

```
CODE    PRELOAD MOVEABLE DISCARDABLE

DATA    PRELOAD MOVEABLE MULTIPLE

HEAPSIZE  1024

STACKSIZE 8192

EXPORTS
  FILEOPENHOOKPROC  @1
```

Customizing Common Dialog Boxes

Color Dialog Box (3.1)

Using Color Dialog Boxes

The Color dialog box contains controls that make it possible for a user to select and create colors.

Following is a Color dialog box.

The Basic Colors control displays up to 48 colors. The actual number of colors displayed is determined by the display driver. For example, a VGA driver displays 48 colors, and a monochrome display driver displays only 16. With the Basic Colors control, the user can select a displayed color.

To display the Custom Colors control, the user clicks the Define Custom Colors button. The Custom Colors control displays custom colors. The user can select one of the 16 rectangles in this control and then create a new color by using one of the following methods:

- Specifying red, green, and blue (**RGB**) values by using the Red, Green, and Blue edit controls, and then choosing the Add to Custom Colors button to display the new color in the selected rectangle.
- Moving the cursor in the color spectrum control (at the upper-right of the dialog box) to select hue and saturation values; moving the cursor in the luminosity control (the rectangle to the right of the spectrum control); and then choosing the Add to Custom Colors button to display the new color in the selected rectangle.
- Specifying hue, saturation, and luminosity (HSL) values by using the Hue, Sat, and Lum edit controls and then choosing the Add to Custom Colors button to display the new color in the selected rectangle.

The Color|Solid control displays the dithered and solid colors that correspond to the user's selection. (A dithered color is a color created by combining one or more pure or solid colors.) The **Flags** member of the **CHOOSECOLOR** structure contains a flag bit that, when set, displays a Help button.

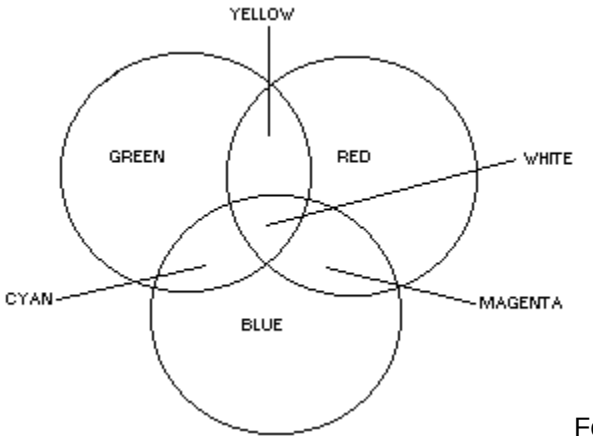
An application can display the Color dialog box in one of two ways: fully open or partially open. When the Color dialog box is displayed partially open, the user cannot change the custom colors.

Color Models Used by the Color Dialog Box

The Color dialog box uses two models for specifying colors: the **RGB** model and the HSL model. Regardless of the model used, internal storage is accomplished by use of the RGB model.

RGB Color Model

The **RGB** model is used to designate colors for displays and other devices that emit light. Valid red, green, and blue values are in the range 0 through 255, with 0 indicating the minimum intensity and 255 indicating the maximum intensity. The following illustration shows how the primary colors red, green, and blue can be combined to produce four additional colors. (With display devices, the color black results when the red, green, and blue values are set to 0--that is, with display technology, black is the absence of all colors.)



Following are eight colors and their associated **RGB**

values:

Color	RGB values
Red	255, 0, 0
Green	0, 255, 0
Blue	0, 0, 255
Cyan	0, 255, 255
Magenta	255, 0, 255
Yellow	255, 255, 0
White	255, 255, 255
Black	0, 0, 0

Windows stores internal colors as 32-bit **RGB** values. The high-order byte of the high-order word is reserved; the low-order byte of the high-order word specifies the intensity of the blue component; the high-order byte of the low-order word specifies the intensity of the green component; and the low-order byte of the low-order word specifies the intensity of the red component.

HSL Color Model

The Color dialog box provides controls for specifying HSL values. The following illustration shows the color spectrum control and the vertical luminosity control that appear in the Color dialog box and shows the ranges of values the user can specify with these controls.

In the Color dialog box, the saturation and luminosity values must be in the range 0 through 240 and the hue value must be in the range 0 through 239.

Converting HSL Values to RGB Values

The dialog box procedure provided in COMMDLG.DLL for the Color dialog box contains code that converts HSL values to the corresponding **RGB** values. Following are several colors with their associated HSL and RGB values:

Color	HSL values	RGB values
Red	(0, 240, 120)	(255, 0, 0)
Yellow	(40, 240, 120)	(255, 255, 0)
Green	(80, 240, 120)	(0, 255, 0)
Cyan	(120, 240, 120)	(0, 255, 255)
Blue	(160, 240, 120)	(0, 0, 255)
Magenta	(200, 240, 120)	(255, 0, 255)
White	(0, 0, 240)	(255, 255, 255)
Black	(0, 0, 0)	(0, 0, 0)

Using the Color Dialog Box to Display Basic Colors

An application can display the Color dialog box so that a user can select one color from a list of basic screen colors. This section describes how you can provide code and structures in your application that make this possible.

Initializing the CHOOSECOLOR Structure

Before you display the Color dialog box you need to initialize a **CHOOSECOLOR** structure. This structure should be global or declared as a **static** variable. The members of this structure contain information about such items as the following:

- Structure size
- Which window owns the dialog box
- Whether the application is customizing the common dialog box
- The hook function and custom dialog box template to use for a customized version of the Color dialog box
- **RGB** values for the selected basic color

If your application does not customize the dialog box and you want the user to be able to select a single color from the basic colors, you should initialize the **CHOOSECOLOR** structure in the following manner:

```
/* Color variables */

CHOOSECOLOR cc;
COLORREF clr;
COLORREF aclrCust[16];
int i;

/* Set the custom color controls to white. */

for (i = 0; i < 16; i++)
    aclrCust[i] = RGB(255, 255, 255);

/* Initialize clr to black. */

clr = RGB(0, 0, 0);

/* Set all structure fields to zero. */

memset(&cc, 0, sizeof(CHOOSECOLOR));

/* Initialize the necessary CHOOSECOLOR members. */

cc.lStructSize = sizeof(CHOOSECOLOR);
cc.hwndOwner = hwnd;
cc.rgbResult = clr;
cc.lpCustColors = aclrCust;
cc.Flags = CC_PREVENTFULLOPEN;

if (ChooseColor(&cc))
    .
    . /* Use cc.rgbResult to select the user-requested color. */
    .
```

In the previous example, the array to which the **lpCustColors** member points contains 16 doubleword **RGB** values that specify the color white, and the CC_PREVENTFULLOPEN flag is set in the **Flags** member to disable the Define Custom Colors button and prevent the user from selecting a custom color.

Calling the ChooseColor Function

After you initialize the structure, you should call the **ChooseColor** function. If the function is successful and the user chooses the OK button to close the dialog box, the **rgbResult** member contains the **RGB** values for the basic color that the user selected.

Using the Color Dialog Box to Display Custom Colors

An application can display the Color dialog box so that the user can create and select a custom color. This section describes how you can provide code and structures in your application that make this possible.

Initializing the CHOOSECOLOR Structure

Before you display the Color dialog box, you need to initialize a **CHOOSECOLOR** structure. This structure should be global or declared as a **static** variable. The members of this structure contain information about such items as the following:

- Structure size
- Which window owns the dialog box
- Whether the application is customizing the common dialog box
- The hook function and custom dialog box template to use for a customized version of the Color dialog box
- **RGB** values for the custom color control

If your application does not customize the dialog box and you want the user to be able to create and select custom colors, you should initialize the **CHOOSECOLOR** structure in the following manner:

```
/* Color Variables */

CHOOSECOLOR chsclr;
DWORD dwCustClrs[16] = { RGB(255, 255, 255), RGB(239, 239, 239),
                         RGB(223, 223, 223), RGB(207, 207, 207),
                         RGB(191, 191, 191), RGB(175, 175, 175),
                         RGB(159, 159, 159), RGB(143, 143, 143),
                         RGB(127, 127, 127), RGB(111, 111, 111),
                         RGB(95, 95, 95),    RGB(79, 79, 79),
                         RGB(63, 63, 63),    RGB(47, 47, 47),
                         RGB(31, 31, 31),    RGB(15, 15, 15)
                       };
BOOL fSetColor = FALSE;
int i;

chsclr.lStructSize = sizeof (CHOOSECOLOR);
chsclr.hwndOwner = hwnd;
chsclr.hInstance = NULL;
chsclr.rgbResult = 0L;
chsclr.lpCustColors = (LPDWORD) dwCustClrs;
chsclr.Flags = CC_FULLOPEN;
chsclr.lCustData = 0L;
chsclr.lpfnHook = (FARPROC) NULL;
chsclr.lpTemplateName = (LPSTR)NULL;
```

In the previous example, the array to which **lpCustColors** points contains sixteen 32-bit **RGB** values that specify 16 scales of gray, and the CC_FULLOPEN flag is set in the **Flags** member to display the complete Color dialog box.

Calling the ChooseColor Function

After you initialize the structure, you should call the **ChooseColor** function as shown in the following code fragment:

```
if (fSetColor = ChooseColor(&chsclr))
.
. /* Use chsclr.lpCustColors to select user specified colors*/
.
```

If the function is successful and the user chooses the OK button to close the dialog box, the **lpCustColors** member points to an array that contains the **RGB** values for the custom colors requested by the application's user.

Applications can exercise more control over custom colors by creating a new message identifier for the string defined by the COLOROKSTRING constant. The application creates the new message identifier by calling the **RegisterWindowMessage** function and passing this constant as the single parameter. After calling **RegisterWindowMessage**, the application receives a message immediately prior to the dismissal of the dialog box. The *lParam* parameter of this message contains a pointer to the **CHOOSECOLOR** structure. The application can use the **lpCustColors** member of this structure to check the current color. If the application returns a nonzero value when it processes this message, the dialog box is not dismissed.

Similarly, applications can create a new message identifier for the string defined by the SETRGBSTRING constant. The application's hook function can use the message identifier returned by calling **RegisterWindowMessage** with the SETRGBSTRING constant to set a color in the dialog box. For example, the following line of code sets the color selection to blue:

```
SendMessage(hwhndDlg, wSetRGBMsg, 0, (LPARAM) RGB(0, 0, 255));
```

In this example, wSetRGBMsg is the message identifier returned by the **RegisterWindowMessage** function. The *lParam* parameter of the **SendMessage** function is set to the **RGB** values of the desired color. The *wParam* parameter is not used.

The application can specify any valid **RGB** values in this call to **SendMessage**. If the RGB values match one of the basic colors, the system selects the basic color and updates the spectrum and luminosity controls. If the RGB values do not match one of the basic colors, the system updates the spectrum and luminosity controls, but the basic color selection remains unchanged.

Note that if the Color dialog box is not fully open and the application sends **RGB** values that do not match one of the basic colors, the system does not update the dialog box. Updates are unnecessary because the spectrum and luminosity controls are not visible when the dialog box is only partially open.

For more information about processing registered window messages, see Using Find and Replace Dialog Boxes.

Font Dialog Box (3.1)

Using Font Dialog Boxes

The Font dialog box contains controls that make it possible for a user to select a font, a font style (such as bold, italic, or regular), a point size, and an effect (such as underline, strikeout, or a text color).

Following is a Font dialog box.

Displaying the Font Dialog Box in Your Application

The Font dialog box appears after you initialize the members in a **CHOOSEFONT** structure and call the **ChooseFont** function. This structure should be global or declared as a **static** variable. The members of the **CHOOSEFONT** structure contain information about such items as the following:

- The attributes of the font that initially is to appear in the dialog box.
- The attributes of the font that the user selected.
- The point size of the font that the user selected.
- Whether the list of fonts corresponds to a printer, a screen, or both.
- Whether the available fonts listed are TrueType only.
- Whether the Effects box should appear in the dialog box.
- Whether dialog box messages should be processed by an application-supplied hook function.
- Whether the point sizes of the selectable fonts should be limited to a specified range.
- Whether the dialog box should display only what-you-see-is-what-you-get (WYSIWIG) fonts. (These fonts are resident on both the screen and the printer.)
- The color that the **ChooseFont** function should use to render text in the Sample box the first time the application displays the dialog box.
- The color that the user selected for text output.

To display the Font dialog box, an application should perform the following steps:

1. If the application requires printer fonts, retrieve a device-context handle for the printer and use this handle to set the **hDC** member of the **CHOOSEFONT** structure. (If the Font dialog box displays only screen fonts, this member should be set to NULL.)
2. Set the appropriate flags in the **Flags** member of the **CHOOSEFONT** structure. This setting must include CF_SCREENFONTS, CF_PRINTERFONTS, or CF_BOTH.
3. Set the **rgbColors** member of the **CHOOSEFONT** structure if the default color (black) is not appropriate.
4. Set the **nFontType** member of the **CHOOSEFONT** structure using the appropriate constant.
5. Set the **nSizeMin** and **nSizeMax** members of the **CHOOSEFONT** structure if the CF_LIMITSIZE value is specified in the **Flags** member.
6. Call the **ChooseFont** function.

The following example initializes the **CHOOSEFONT** structure and calls the **ChooseFont** function:

```
LOGFONT lf;
CHOOSEFONT cf;

/* Set all structure fields to zero. */

memset(&cf, 0, sizeof(CHOOSEFONT));

cf.lStructSize = sizeof(CHOOSEFONT);
cf.hwndOwner = hwnd;
cf.lpLogFont = &lf;
```

```
cf.Flags = CF_SCREENFONTS | CF_EFFECTS;
cf.rgbColors = RGB(0, 255, 255); /* light blue */
cf.nFontType = SCREEN_FONTTYPE;

ChooseFont(&cf);
```

When the user closes the Font dialog box by choosing the OK button, the **ChooseFont** function returns information about the selected font in the **LOGFONT** structure to which the **lpLogFont** member points. An application can use this **LOGFONT** structure to select the font that will be used to render text. The following example selects a font by using the **LOGFONT** structure and renders a string of text:

```
hdc = GetDC(hwnd);
hFont = CreateFontIndirect(cf.lpLogFont);
hFontOld = SelectObject(hdc, hFont);
TextOut(hdc, 50, 150,
     "AaBbCcDdEeFfGgHhIiJjKkLlMmNnOoPpQqRrSsTtUuVvWwXxYyZz", 52);
SelectObject(hdc, hFontOld);
DeleteObject(hFont);
ReleaseDC(hwnd, hdc);
```

An application can also use the **WM_CHOOSEFONT_GETLOGFONT** message to retrieve the current **LOGFONT** structure for the Font dialog box before the user closes the dialog box.

Filename Dialog Boxes (3.1)

Using Open and Save As Dialog Boxes

The Open dialog box and the Save As dialog box are similar in appearance. Each contains controls that make it possible for the user to specify the location and name of a file or set of files. In the case of the Open dialog box, the user selects the file or files to be opened; in the case of the Save As dialog box, the user selects the file or files to be saved.

Displaying the Open Dialog Box in Your Application

The Open dialog box appears after you initialize the members of an **OPENFILENAME** structure and call the **GetOpenFileName** function.

Following is an Open dialog box.

Before the call to **GetOpenFileName**, structure members contain such data as the name of the directory and the filter that are to appear in the dialog box. (A filter is a filename extension. The common dialog box code uses the extension to filter appropriate filenames from a directory.) After the call, structure members contain such data as the name of the selected file and the number of characters in that filename.

To display an Open dialog box, an application should perform the following steps:

1 Store the valid filters in a character array.

2 Set the **lpstrFilter** member to point to this array.

3 Set the **nFilterIndex** member to the value of the index that identifies the default filter.

4 Set the **lpstrFile** member to point to an array that contains the initial filename and receives the selected filename.

5 Set the **nMaxFile** member to the value that specifies the length of the filename array.

6 Set the **lpstrFileTitle** member to point to a buffer that receives the title of the selected file.

7 Set the **nMaxFileTitle** member to specify the length of the buffer.

8 Set the **lpstrInitialDir** member to point to a string that specifies the initial directory. (If this member does not point to a valid string, it must be set to 0 or point to a string that is set to NULL.)

9 Set the **lpstrTitle** member to point to a string specifying the name that should appear in the title bar of the dialog box. (If this pointer is NULL, the title will be Open.)

10 Initialize the **lpstrDefExt** member to point to the default extension. (This extension can be 0, 1, 2, or 3 characters long.)

11 Call the **GetOpenFileName** function.

The following example initializes an **OPENFILENAME** structure, calls the **GetOpenFileName** function, and opens the file by using the **lpstrFile** member of the structure. The **OPENFILENAME** structure should be global or declared as a **static** variable.

```
OPENFILENAME ofn;
char szDirName[256];
char szFile[256], szFileTitle[256];
UINT  i, cbString;
char  chReplace;    /* string separator for szFilter */
char  szFilter[256];
HFILE hf;

/* Get the system directory name, and store in szDirName */
```

```
GetSystemDirectory(szDirName, sizeof(szDirName));
szFile[0] = '\0';

if ((cbString = LoadString(hinst, IDS_FILTERSTRING,
        szFilter, sizeof(szFilter))) == 0) {
    ErrorHandler();
    return 0L;
}
chReplace = szFilter[cbString - 1]; /* retrieve wildcard */

for (i = 0; szFilter[i] != '\0'; i++) {
    if (szFilter[i] == chReplace)
       szFilter[i] = '\0';
}

/* Set all structure members to zero. */

memset(&ofn, 0, sizeof(OPENFILENAME));

ofn.lStructSize = sizeof(OPENFILENAME);
ofn.hwndOwner = hwnd;
ofn.lpstrFilter = szFilter;
ofn.nFilterIndex = 1;
ofn.lpstrFile= szFile;
ofn.nMaxFile = sizeof(szFile);
ofn.lpstrFileTitle = szFileTitle;
ofn.nMaxFileTitle = sizeof(szFileTitle);
ofn.lpstrInitialDir = szDirName;
ofn.Flags = OFN_SHOWHELP | OFN_PATHMUSTEXIST | OFN_FILEMUSTEXIST;

if (GetOpenFileName(&ofn)) {
    hf = _lopen(ofn.lpstrFile, OF_READ);
        .
        . /* Perform file operations. */
        .
}
else
    ErrorHandler();
```

The string referred to by the IDS_FILTERSTRING constant in the preceding example is defined as follows in the resource-definition file:

```
STRINGTABLE
BEGIN
 IDS_FILTERSTRING  "Write Files(*.WRI)|*.wri|Word Files(*.DOC)|*.doc|"
END
```

The vertical bars in this string are used as wildcards. After using the **LoadString** function to retrieve the string, the wildcards are replaced with NULL. The wildcard can be any unique character and must be included as the last character in the string. Initializing strings in this manner guarantees that the parts of the string are contiguous in memory and that the string is terminated with two null characters.

Applications that can open files over a network can create a new message identifier for the string defined by the SHAREVISTRING constant. The application creates the new message identifier by calling the **RegisterWindowMessage** function and passing this constant as the single parameter. After calling **RegisterWindowMessage**, the application is notified whenever a sharing violation occurs during a call to the **OpenFile** function. For more information about processing registered window messages,

see Using Find and Replace Dialog Boxes.

Displaying the Save As Dialog Box in Your Application

The Save As dialog box appears after you initialize the members of an **OPENFILENAME** structure and call the **GetSaveFileName** function.

Following is a Save As dialog box.

Before the call to **GetSaveFileName**, structure members contain such data as the name of the initial directory and a filter string. After the call, structure members contain such data as the name of the file to be saved and the number of characters in that filename.

The following example initializes an **OPENFILENAME** structure, calls **GetSaveFileName** function, and saves the file. The **OPENFILENAME** structure should be global or declared as a **static** variable.

```
OPENFILENAME ofn;
char szDirName[256];
char szFile[256], szFileTitle[256];
UINT  i, cbString;
char  chReplace;    /* string separator for szFilter */
char  szFilter[256];
HFILE hf;

/*
 * Retrieve the system directory name, and store it in
 * szDirName.
 */

GetSystemDirectory(szDirName, sizeof(szDirName));

if ((cbString = LoadString(hinst, IDS_FILTERSTRING,
        szFilter, sizeof(szFilter))) == 0) {
    ErrorHandler();
    return 0;
}

chReplace = szFilter[cbString - 1]; /* retrieve wildcard */

for (i = 0; szFilter[i] != '\0'; i++) {
    if (szFilter[i] == chReplace)
       szFilter[i] = '\0';
}

/* Set all structure members to zero. */

memset(&ofn, 0, sizeof(OPENFILENAME));

/* Initialize the OPENFILENAME members. */

szFile[0] = '\0';

ofn.lStructSize = sizeof(OPENFILENAME);
ofn.hwndOwner = hwnd;
ofn.lpstrFilter = szFilter;
ofn.lpstrFile= szFile;
ofn.nMaxFile = sizeof(szFile);
```

```
ofn.lpstrFileTitle = szFileTitle;
ofn.nMaxFileTitle = sizeof(szFileTitle);
ofn.lpstrInitialDir = szDirName;
ofn.Flags = OFN_SHOWHELP | OFN_OVERWRITEPROMPT;

if (GetSaveFileName(&ofn)) {
    .
    . /* Perform file operations. */
    .
}
else
    ErrorHandler();
```

The string referred to by the IDS_FILTERSTRING constant in the preceding example is defined in the resource-definition file. It is used in exactly the same way as the IDS_FILTERSTRING constant discussed in Displaying the Open Dialog Box in Your Application.

Monitoring List Box Controls in an Open or Save As Dialog Box

An application can monitor list box selections in order to process and display data in custom controls. For example, an application can use a custom control to display the total length, in bytes, of all of the files selected in the File Name box. One method the application can use to obtain this value is to recompute the total count of bytes each time the user selects a file or cancels the selection of a file. A faster method is for the application to use the LBSELCHSTRING message to identify a new selection and add the corresponding file length to the value that appears in the custom control. (Note that in this example, the custom control is a standard Windows control that you identify in a resource file template for one of the common dialog boxes.)

An application registers the selection-change message with the **RegisterWindowMessage** function. Once the application registers the message, it uses this function's return value to identify messages from the dialog box. The message is processed in the application-supplied hook function for the common dialog box. The *wParam* parameter of each message identifies the list box in which the selection occurred. The low-order word of the *lParam* parameter identifies the list box item. The high-order word of the *lParam* parameter is one of the following values:

Value	Meaning
CD_LBSELCHANGE	Specifies that the item identified by the low-order word of *lParam* was the item in a single-selection list box.
CD_LBSELSUB	Specifies that the item identified by the low-order word of *lParam* is no longer selected in a multiple-selection list box.
CD_LBSELADD	Specifies that the item identified by the low-order word of *lParam* was selected from a multiple-selection list box.
CD_LBSELNOITEMS	Specifies that no items exist in a multiple-selection list box.

For an example that registers a common dialog box message, see **Find and Replace Dialogs**.

Monitoring Filenames in an Open or Save As Dialog Box

Applications can alter the normal processing of an Open or Save As dialog box by monitoring which filename the user types and by performing other, unique operations. For example, one application could prevent the user from closing the dialog box if the selected filename is prohibited; another application could make it possible for the user to select multiple filenames.

To monitor filenames, an application should register the **FILEOKSTRING** message. An application registers this message by calling the **RegisterWindowMessage** function and passing the message name as its single parameter. After the message is registered, the dialog box procedure in COMMDLG.DLL uses it to signal that the user has selected a filename and chosen the OK button and that the dialog box has checked the filename and is ready to return. The dialog box procedure signals these actions by sending the message to the application's hook function. After receiving the message,

the hook function should return a value to the dialog box procedure that called it. If the hook function did not process the message, it should return 0; if the hook function did process the message and the dialog box should close, the hook function should return 0; if the hook function did process the message but the dialog box should not close, the hook function should return 1. (All other return values are reserved.)

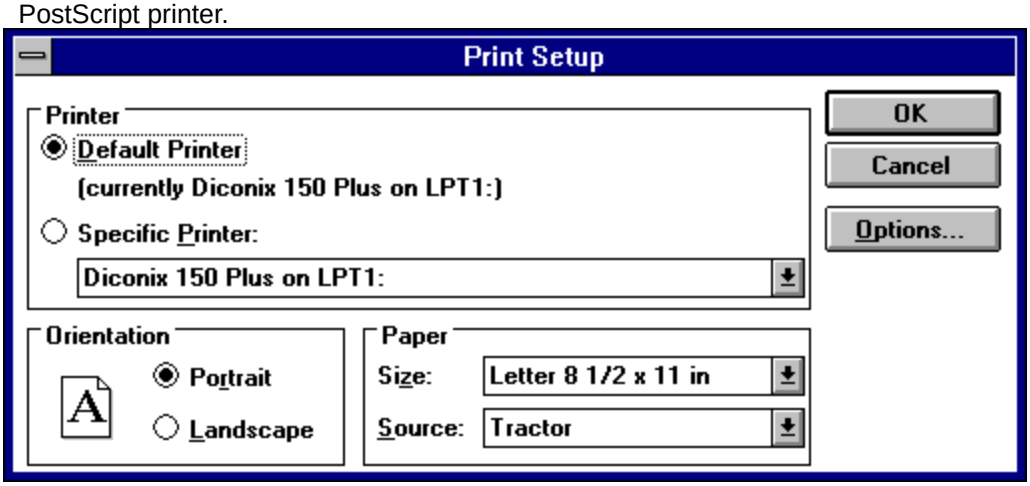
Print Dialog Box (3.1)

Using Print and Print Setup Dialog Boxes

A Print dialog box contains controls that let a user configure a printer for a particular print job. The user can make such selections as print quality, page range, and number of copies (if the printer supports multiple copies).

Following is a Print dialog box.

Choosing the Setup button in the Print dialog box displays the following Print Setup dialog box for a PostScript printer.



The Print Setup dialog box provides controls that make it possible for the user to reconfigure the selected printer.

Device Drivers and the Print Dialog Box

The Print dialog box differs from other common dialog boxes in that part of its dialog box procedure resides in COMMDLG.DLL and part in a printer driver. A printer driver is a program that configures a printer, converts graphics device interface (GDI) commands to low-level printer commands, and stores commands for a particular print job in a printer's queue.

A printer driver exports a function called **ExtDeviceMode**, which displays a dialog box and its controls. In previous versions of Windows, an application called the **LoadLibrary** function to load a device driver and the **GetProcAddress** function to obtain the address of the **ExtDeviceMode** function. This is no longer necessary with the Windows common dialog box interface. Instead of calling **LoadLibrary** and **GetProcAddress**, a Windows application can call a single function, **PrintDlg**, to display the Print dialog box and begin a print job. The code for **PrintDlg** resides in COMMDLG.DLL. The dialog box that appears when an application calls **PrintDlg** differs slightly from the dialog box that appears when the application calls directly into the device driver. The functionality is very similar in spite of the different appearance.

Displaying a Print Dialog Box for the Default Printer

To display a Print dialog box for the default printer, an application must initialize a **PRINTDLG** structure and then call the **PrintDlg** function.

The members of the **PRINTDLG** structure can contain information about such items as the following:

- The printer device context
- Values that should appear in the dialog box controls
- The hook function and custom dialog box template to use for a customized version of the Print dialog box or Print Setup dialog box

An application can display a Print dialog box for the currently installed printer by performing the following

steps:

1 Setting the PD_RETURNDC flag in the **Flags** member of the **PRINTDLG** structure. (This flag should only be set if the application requires a device-context handle.)

2 Initializing the **lStructSize**, **hDevMode**, and **hDevNames** members.

3 Calling the **PrintDlg** function and passing a pointer to the **PRINTDLG** structure just initialized.

Setting the PD_RETURNDC flag causes **PrintDlg** to display the Print dialog box and return a handle identifying a printer device context in the **hDC** member of the **PRINTDLG** structure. (The application passes the device-context handle as the first parameter to the GDI functions that render output on the printer.)

The following example initializes the members of the **PRINTDLG** structure and calls the **PrintDlg** function prior to printing output. This structure should be global or declared as a **static** variable.

```
PRINTDLG pd;

/* Set all structure members to zero. */

memset(&pd, 0, sizeof(PRINTDLG));

/* Initialize the necessary PRINTDLG structure members. */

pd.lStructSize = sizeof(PRINTDLG);
pd.hwndOwner = hwnd;
pd.Flags = PD_RETURNDC;

/* Print a test page if successful */

if (PrintDlg(&pd) != 0) {
    Escape(pd.hDC, STARTDOC, 8, "Test-Doc", NULL);

    /* Print text and rectangle */

    TextOut(pd.hDC, 50, 50, "Common Dialog Test Page", 23);
    Rectangle(pd.hDC, 50, 90, 625, 105);
    Escape(pd.hDC, NEWFRAME, 0, NULL, NULL);
    Escape(pd.hDC, ENDDOC, 0, NULL, NULL);
    DeleteDC(pd.hDC);
    if (pd.hDevMode != NULL)
       GlobalFree(pd.hDevMode);
    if (pd.hDevNames != NULL)
       GlobalFree(pd.hDevNames);
}
else {
    if (pd.hDevMode != NULL)
       GlobalFree(pd.hDevMode);
    if (pd.hDevNames != NULL)
       GlobalFree(pd.hDevNames);
    ErrorHandler();
}
```

Find and Replace Dialog Boxes (3.1)

Using Find and Replace Dialog Boxes

The Find dialog box and the Replace dialog box are similar in appearance. You can use the Find dialog box to add string-search capabilities to your application and use the Replace dialog box to add both string-search and string-substitution capabilities.

Displaying the Find Dialog Box

The Find dialog box contains controls that make it possible for a user to specify the following:

- The string that the application should find
- Whether the string specifies a complete word or part of a word
- Whether the application should match the case of the specified string
- The direction in which the application should search (preceding or following the current cursor location)
- Whether the application should resume the search, searching for the next occurrence of the string

Following is a Find dialog box.

To display the Find dialog box, you need to initialize a **FINDREPLACE** structure and call the **FindText** function. Members of the **FINDREPLACE** structure contain information about such items as the following:

- Which window owns the dialog box
- How the application should perform the search
- A character buffer that is to receive the string

To initialize the **FINDREPLACE** structure, you need to perform the following tasks:

1. Set the **lStructSize** member by using the **sizeof** operator.
2. Set the **hwndOwner** member by using the handle that identifies the owner window of the dialog box.
3. If you are customizing the Find dialog box, set the **hInstance** member to identify the instance of the module that contains your custom dialog box template.
4. Set the **Flags** member to indicate the selection state of the dialog box options. (For example, setting the FR_NOUPDOWN flag disables the Up and Down buttons, setting the FR_NOWHOLEWORD flag disables the Match Whole Word Only check box, and setting the FR_NOMATCHCASE flag disables the Match Case check box).
5. If you are supplying a custom dialog box template or hook function, set additional flags in the **Flags** member.
6. Set the **lpstrFindWhat** member to point to the buffer that will receive the string to be found.
7. Set the **wFindWhatLen** member to specify the size, in bytes, of the buffer to which **lpstrFindWhat** points.
8. Set the **lCustData** member with any custom data your application may need to access.
9. If your application customizes the Find dialog box, set the **lpfnHook** member to point to your hook function.
10. If your application uses a custom dialog box template, set the **lpTemplateName** member to point to the string that identifies the template.

The following example initializes the **FINDREPLACE** structure and then calls the **FindText** function. This structure should be global or declared as a **static** variable.

```
static FINDREPLACE fr;
```

```
/* Set all structure fields to zero. */

memset(&fr, 0, sizeof(FINDREPLACE));

fr.lStructSize = sizeof(FINDREPLACE);
fr.hwndOwner = hwnd;
fr.lpstrFindWhat = szFindWhat;
fr.wFindWhatLen = sizeof(szFindWhat);

hDlg = FindText(&fr);

break;
```

Displaying the Replace Dialog Box

The Replace dialog box is similar to the Find dialog box. However, the Replace dialog box has no Direction box and has three additional controls that make it possible for the user to specify the following:

- The replacement string
- Whether the application should replace the occurrence of the string that is currently highlighted
- Whether the application should replace all occurrences of the string

Following is a Replace dialog box.

To display the Replace dialog box, you need to initialize a **FINDREPLACE** structure and call the **ReplaceText** function.

Processing Dialog Box Messages for a Find or Replace Dialog Box

The Find and Replace dialog boxes differ from the other common dialogs in two respects: First, they are modeless; and second, their respective dialog box procedures send messages to the application that calls the **FindText** or **ReplaceText** function. These messages contain data specified by the user in the dialog box controls, such as the direction in which the application should search for a string, whether the application should match the case of the specified string, and whether the application should match the entire string.

To process messages from a Find or Replace dialog box, an application must register the dialog box's unique message, **FINDMSGSTRING**.

The application registers this message with the **RegisterWindowMessage** function. Once the application registers the message, it uses the function's return value to identify messages from the Find or Replace dialog box. The following example registers the message with the **RegisterWindowMessage** function:

```
UINT uFindReplaceMsg;

/* Register the FindReplace message. */

uFindReplaceMsg = RegisterWindowMessage(FINDMSGSTRING);
```

After the application registers this message, it can process messages for the Find or Replace dialog box by using the **RegisterWindowMessage** return value. The following example processes messages for the Find dialog box and then calls its own **SearchFile** function to locate the string of text. If the user is closing the dialog box (that is, if the **Flags** member of the **FINDREPLACE** structure is FR_DIALOGTERM), the handle is invalidated and the procedure returns zero.

```
LRESULT CALLBACK MainWndProc(HWND hwnd, UINT msg, WPARAM wParam,
    LPARAM lParam)
{
```

```
static FINDREPLACE FAR* lpfr;

if (msg == uFindReplaceMsg) {
    lpfr = (FINDREPLACE FAR*) lParam;
    if (lpfr->Flags & FR_DIALOGTERM) {
        hDlg = NULL;
        return 0;
    }
    SearchFile((BOOL) (lpfr->Flags & FR_DOWN),
        (BOOL) (lpfr->Flags & FR_MATCHCASE));
    return 0;
}
```

Customizing Common Dialog Boxes (3.1)

A custom common dialog box is a common dialog box that has been altered to suit a particular Windows application. The customization may be complex and include the hiding of original controls, the addition of new controls, or a change in the size of the original dialog box; or it may be simple, such as the alteration of a single existing control.

Developers who need to customize a common dialog box must provide a special hook function and, in most cases, a custom dialog box template. Customizations of this kind require a significant amount of additional code--displaying a customized common dialog box is not as simple as initializing the members of a structure and calling a single function.

Applications that subclass controls in any of the common dialog boxes must do so while processing the **WM_INITDIALOG** message in the application's hook function. This allows the application to receive the control-specific messages first, because it will have subclassed the control after the common dialog box has installed its subclassing procedures. (The previous hook function should be called for all messages that are not handled by the application's subclass function, as is standard for subclassing.)

An application cannot subclass a control by defining a local class to override a specific control type. The reason is that the data segment would not be correctly initialized when the class was called--the data segment would be the common dialog box's data segment, not the application's data segment.

Appropriate and Inappropriate Customizations

From the user's perspective, the chief benefit of the common dialog box is its consistent appearance and functionality from application to application. Therefore, it becomes important that a developer only customize a common dialog box when it is absolutely necessary for an application. Otherwise, the consistent appearance and simple coding interface are lost. Appropriate customizations leave intact as many of the original controls as possible. Increasing the size of the dialog box or adding new controls in available space that already appears in the dialog box would be an appropriate customization. Hiding original controls or otherwise changing the intended functionality of the original controls would be an inappropriate customization.

Hook Functions and Custom Dialog Box Templates

Each common dialog box uses the dialog box procedure and dialog box template provided for it in COMMDLG.DLL. The dialog box procedure processes messages and notifications for the common dialog box and its controls. The dialog box template defines the appearance of the dialog box--its dimensions, its location, and the dimensions and locations of controls that appear within it.

In addition to the provided dialog box procedure and dialog box template, a custom dialog box requires a hook function that you provide and, usually, a custom version of the dialog box template.

The Hook Function

The dialog box procedure provided in COMMDLG.DLL for a common dialog box calls the application's hook function if the application sets the appropriate flag and pointer in the structure for that common dialog box. The structure for each common dialog box contains a **Flags** member that specifies whether the application supplies a hook function and contains an **lpfnHook** member that points to the hook function if one exists. If the application sets the **Flags** member to indicate that a hook function exists, it must also set the **lpfnHook** member. The following example sets the **Flags** and **lpfnHook** members of an **OPENFILENAME** structure to support an application's hook function:

```
#define STRICT

#include <windows.h>    /* required for all Windows applications */
#include <commdlg.h>
#include <string.h>
#include "header.h"     /* specific to this program              */
```

```
OPENFILENAME ofn;

    /* Get the system directory name, and store in szDirName. */

    GetSystemDirectory((LPSTR)szDirName, 255);

    /* Initialize the OPENFILENAME members. */

    szFile[0] = '\0';
    ofn.lStructSize = sizeof(OPENFILENAME);
    ofn.hwndOwner = hwnd;
    ofn.hInstance = hInst;
    ofn.lpstrFilter = szFilter[0];
    ofn.lpstrCustomFilter = NULL;
    ofn.nMaxCustFilter = 0L;
    ofn.nFilterIndex = 1L;
    ofn.lpstrFile= szFile;
    ofn.nMaxFile = sizeof(szFile);
    ofn.lpstrFileTitle = szFileTitle;
    ofn.nMaxFileTitle = sizeof(szFileTitle);
    ofn.lpstrInitialDir = szDirName;
    ofn.lpstrTitle = NULL;
    ofn.Flags = OFN_ENABLEHOOK | OFN_ENABLETEMPLATE;
    ofn.nFileOffset = 0;
    ofn.nFileExtension = 0;
    ofn.lpstrDefExt = NULL;
    ofn.lpfnHook = MakeProcInstance((FARPROC) FileOpenHookProc, hInst);
    ofn.lpTemplateName = "FileOpen";
```

In the previous example, the **MakeProcInstance** function is called to create a procedure-instance address for the hook function. This address is assigned to the **lpfnHook** member of the **OPENFILENAME** structure. If the hook function is part of a dynamic-link library (rather than an application), the procedure address is obtained by calling the **GetProcAddress** function (instead of **MakeProcInstance**).

The hook function processes any messages or notifications that the custom dialog box requires. With the exception of one message (**WM_INITDIALOG**), the hook function receives messages and notifications before the dialog box procedure provided in COMMDLG.DLL receives them. In the case of WM_INITDIALOG, the hook function receives the message after the dialog box procedure. When the hook function finishes processing a message, it returns a value that indicates whether the dialog box procedure provided in COMMDLG.DLL should also process the message. If the dialog box procedure should process the message, the return value is FALSE; if the dialog box procedure should ignore the message, the return value is TRUE.

To process the message from the OK button after the dialog box procedure processes it, an application must post a message to itself when the OK message is received. When the application receives the message it has posted, the common dialog box procedure will have finished processing messages for the dialog box. This technique is particularly useful when working with the Find and Replace dialog boxes, because the **Flags** member of the **FINDREPLACE** structure does not reflect changes to the dialog box until after the messages have been processed by COMMDLG.DLL.

The following example shows a hook function for a custom Open dialog box:

```
UINT CALLBACK FileOpenHookProc(HWND hdlg, UINT msg, WPARAM wParam,
    LPARAM lParam)
{
    switch(msg) {
        case WM_INITDIALOG:
```

```
            return TRUE;

        case WM_COMMAND:

            /* Use IsDlgButtonChecked to set lCustData. */

            if (wParam == IDOK) {

                /* Set backup flag. */

                ofn.lCustData =
                    (DWORD) IsDlgButtonChecked(hdlg, ID_CUSTCHX);
            }

            return FALSE; /* Allow standard processing. */
    }

    /* Allow standard processing. */

    return FALSE;
}
```

This hook function tests a custom check box when the user chooses the OK button. If the check box was selected, the hook function sets the **lCustData** member of the **OPENFILENAME** structure to 1; otherwise, it sets the **lCustData** member to 0.

A hook function should never call the **EndDialog** function. Instead, if a hook function contains code that abnormally terminates a common dialog box, this code should pass the **IDABORT** value to the dialog box procedure by using the **PostMessage** function as shown in the following example:

```
PostMessage(hDlg, WM_COMMAND, IDABORT, (LONG) FALSE);
```

When a hook function posts the **IDABORT** value, the common dialog box function returns the value contained in the low word of the *lParam* parameter. For example, if the hook function for **GetOpenFileName** called the **PostMessage** function with (**LONG**) 100 as the last parameter, **GetOpenFileName** would return 100.

A hook function must be exported in an application's module-definition (.DEF) file as shown in the following example:

```
NAME cd

EXETYPE WINDOWS

STUB    'WINSTUB.EXE'

CODE    PRELOAD MOVEABLE DISCARDABLE

DATA    PRELOAD MOVEABLE MULTIPLE

HEAPSIZE  1024

STACKSIZE 8192

EXPORTS
  FILEOPENHOOKPROC  @1
```

Customizing a Dialog Box Template

The dialog box template provided in COMMDLG.DLL for each common dialog box contains the data that the dialog box procedure uses to display that common dialog box. Most applications that customize a common dialog box also need to create a custom dialog box template to use instead of the dialog box template in COMMDLG.DLL. (A custom dialog box template is not required for all custom dialog boxes. For instance, a template would not be necessary if an application changed a dialog box in a relatively minor way and only in an unusual situation.)

A developer should create a custom dialog box template by modifying the appropriate dialog box template in COMMDLG.DLL. Following are the template filenames and the names of their corresponding common dialog boxes:

Template filename	Corresponding dialog box
COLOR.DLG	Color
FILEOPEN.DLG	Open (single selection)
FILEOPEN.DLG	Open (multiple selection)
FINDTEXT.DLG	Find
FINDTEXT.DLG	Replace
FONT.DLG	Font
PRNSETUP.DLG	Print
PRNSETUP.DLG	Print Setup

The following excerpt is from a custom dialog box template created for an Open dialog box:

```
    CONTROL "&Backup File", ID_CUSTCHX, "button",
            BS_AUTOCHECKBOX | WS_CHILD | WS_TABSTOP | WS_GROUP,
            208,  86,  50,  12

END
```

This entry supports the addition of a new Backup File check box immediately below the existing Read Only check box.

The custom template should be added to the application's resource file. You must use all of the unique control identifiers (that is, all identifiers whose values are other than -1) in the template, even if the dialog box does not use those controls. If you do not want to display all of the controls, you can specify coordinates for them that are outside the dialog box. You should also disable the unwanted buttons and remove unnecessary tab stops.

Displaying the Custom Dialog Box

After your application creates the hook function and the dialog box template, it should set the members of the structure for the common dialog box being customized and call the appropriate function to display the custom dialog box.

The following example calls the **GetOpenFileName** function and creates a backup file if the user selected the custom Backup File check box in the custom Open dialog box:

```
/* Open the file and create a backup. */

if (GetOpenFileName(&ofn)) {

    hf = _lopen(ofn.lpstrFile, OF_READWRITE);

    /* Create the backup file. */

    if (ofn.lCustData) {

        /* Process files with extension. */
```

```
        if (ofn.nFileExtension){

           for (i=0; i<(int)ofn.nFileExtension; i++)
                szChar[i] = *ofn.lpstrFile++;

        }/*endif */

        /* Process files without extension. */

        else {

           i=0;

           while (*ofn.lpstrFile!='\0')
               szChar[i++] = *ofn.lpstrFile++;

           szChar[i]='.';
        }/*end else*/

        pszNewPAFN = lstrcat(szChar, "BAK");

        /* Create the backup file. */

        hfBackup = _lcreat(pszNewPAFN, 0);

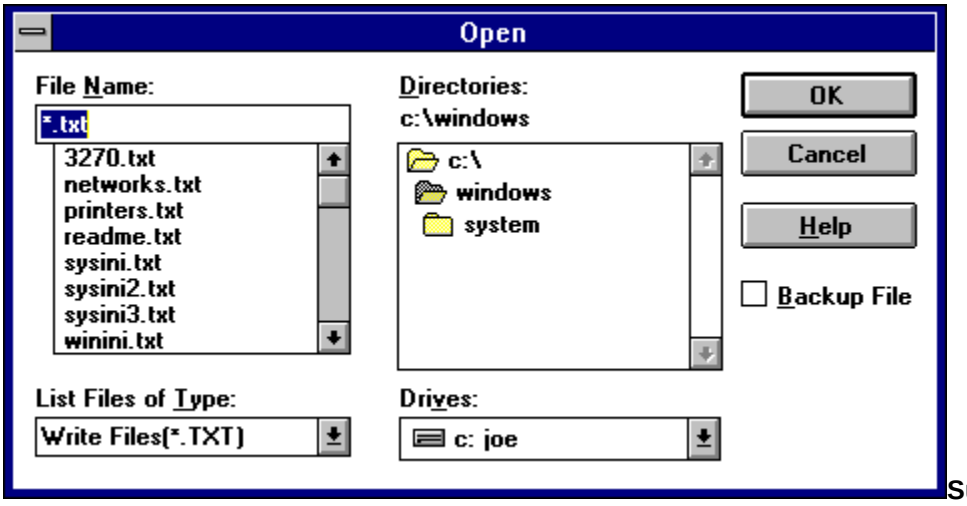
        /* Copy contents of original file to the backup file. */

        while ((cBufLngth=_lread(hf, cBuf1, 256)) == 256)
             _lwrite(hfBackup, cBuf1, cBufLngth);
        _lwrite(hfBackup, cBuf1, cBufLngth);
        _lclose(hfBackup);
    } /*endif GetOpenFileName*/

    /* File operations begin here. */

}   /* endif (GetOpenFileName)     */
```

The following is the custom Open dialog box. The new Backup File check box appears in the lower-right corner.



Supporting and Processing Help for the Common Dialog Boxes

An application can display a Help button in any of the common dialog boxes by setting the appropriate flag in the **Flags** member of the structure for that common dialog box. Following are the structures for the common dialog boxes and the Help flag that corresponds to each structure:

Structure	Flag value
OPENFILENAME	OFN_SHOWHELP
CHOOSECOLOR	CC_SHOWHELP
FINDREPLACE	FR_SHOWHELP
CHOOSEFONT	CF_SHOWHELP
PRINTDLG	PD_SHOWHELP

If an application displays the Help button, it must process the user's request for Help. This can be done either in one of the application's window procedures or in a hook function.

If the application processes the request for Help in one of the application's window procedures, it must first create a new message identifier for the string defined by the HELPMSGSTRING constant. The application creates the new message identifier by calling the **RegisterWindowMessage** function and passing this constant as the single parameter. (For more information about processing registered window messages, see Using Find and Replace Dialog Boxes.) In addition to creating a new message identifier, the application must set the **hwndOwner** member of the appropriate structure for the common dialog box so that this member contains the handle of the dialog box's owner window. After the message identifier is created and the **hwndOwner** member is set, the dialog box procedure notifies the window procedure of the owner window whenever the user chooses the Help button.

The following example processes a user's request for Help in the window procedure of its owner window. The **if** statement should be in the **default:** section of the switch statement that processes messages.

```
MyHelpMsg = RegisterWindowMessage(HELPMSGSTRING);
          .
          .
          .
if (message == MyHelpMsg)
   WinHelp(hWnd, "appfile.hlp", HELP_CONTEXT, ID_MY_CONTEXT);
```

If the application processes the request for Help in a hook function, it should test for the following condition in the **WM_COMMAND** message:

```
wParam == pshHelp
```

When this condition is true, the hook function should call the **WinHelp** function as shown in the preceding example. (To process Help in a hook function, you must include the header file DLGS.H in the source file that contains the hook-function code.)

Error Detection

Whenever a common dialog box function fails, an application can call the **CommDlgExtendedError** function to find out the cause of the failure. The **CommDlgExtendedError** function returns an error value that identifies the cause of the most recent error.

Six constants are defined in the CDERR.H header file that identify the ranges of error values for categories of errors returned by **CommDlgExtendedError**. Following are these constants in ascending order by value range:

Constant	Meaning
CDERR_GENERALCODES	General error codes for common dialog boxes. These errors are in the range 0x0000 through 0x0FFF.
PDERR_PRINTERCODES	Error codes for the Print common dialog box. These errors are in the range 0x1000 through 0x1FFF.

CFERR_CHOOSEFONTCODES	Error codes for the Font common dialog box. These errors are in the range 0x2000 through 0x2FFF.
FNERR_FILENAMECODES	Error codes for the Open and Save As common dialog boxes. These errors are in the range 0x3000 through 0x3FFF.
FRERR_FINDREPLACECODES	Error codes for the Find and Replace common dialog boxes. These errors are in the range 0x4000 through 0x4FFF.
CCERR_CHOOSECOLORCODES	Error codes for the Color common dialog box. These errors are in the range 0x5000 through 0x5FFF.

Dynamic Data Exchange Management Library (3.1)

This topic describes how to use the Dynamic Data Exchange Management Library (**DDEML**). The DDEML is a dynamic-link library (DLL) that applications running with the Microsoft Windows operating system can use to share data.

The following topics discuss the concepts of DDE and describe how to use the DDE Management Library to add DDE functionality to an application:

DDEML Concepts
DDEML Initialization
Callback Function
String Management
Conversation Management
Data Management
Transaction Management
Server-Name Service

DDEML Monitor Applications

Dynamic data exchange (DDE) is a form of interprocess communication that uses shared memory to exchange data between applications. Applications can use DDE for one-time data transfers and for ongoing exchanges in which the applications send updates to one another as new data becomes available.

Dynamic data exchange differs from the clipboard data-transfer mechanism that is also part of the Windows operating system. One difference is that the clipboard is almost always used as a one-time response to a specific action by the user--such as choosing the Paste command from a menu. Although DDE may also be initiated by a user, it typically continues without the user's further involvement.

The **DDEML** provides an application programming interface (API) that simplifies the task of adding DDE capability to a Windows application. Instead of sending, posting, and processing DDE messages directly, an application uses the functions provided by the DDEML to manage DDE conversations. (A DDE conversation is the interaction between client and server applications.) The DDEML also provides a facility for managing the strings and data that are shared among DDE applications. Instead of using atoms and pointers to shared memory objects, DDE applications create and exchange string handles, which identify strings, and data handles, which identify global memory objects. DDEML provides a service that makes it possible for a server application to register the service names that it supports. The names are broadcast to other applications in the system, which can then use the names to connect to the server. The DDEML also ensures compatibility among DDE applications by forcing them to implement the DDE protocol in a consistent manner.

Existing applications that use the message-based DDE protocol are fully compatible with those that use the DDEML. That is, an application that uses message-based DDE can establish conversations and perform transactions with applications that use the DDEML. Because of the many advantages of the **DDEML**, new applications should use it rather than the DDE messages.

The **DDEML** can run on systems that have Microsoft Windows version 3.0 or later installed. The DDEML does not support real mode. To use the API elements of the DDE management library, you must include the DDEML.H header file in your source files, link with DDEML.LIB, and ensure that DDEML.DLL resides in the system's path.

DDEML Concepts

Basic Concepts

The concepts in this section are key to understanding DDE and the DDEML.

Client and Server Interaction

Dynamic data exchange always takes place between a client application and a server application. The client initiates the exchange by establishing a conversation with the server so that it can send transactions to the server. (A transaction is a request for data or services.) The server responds to these transactions by providing data or services to the client. A server can have many clients at the same time, and a client can request data from multiple servers. Also, an application can be both a client and a server. A client terminates a conversation when it no longer needs a server's data or services.

For example, a graphics application might contain a bar graph that represents a corporation's quarterly profits, and the data for the bar graph might be contained in a spreadsheet application. To obtain the latest profit figures, the graphics application (the client) establishes a conversation with the spreadsheet application (the server). The graphics application then sends a transaction to the spreadsheet application, requesting the latest profit figures.

Transactions and the DDE Callback Function

The **DDEML** notifies an application of DDE activity that affects the application by sending transactions to the application's DDE callback function. A transaction is similar to a message--it is a named constant accompanied by other parameters that contain additional information about the transaction.

The **DDEML** passes a transaction to an application-defined DDE callback function, which carries out the appropriate action depending on the type of the transaction. For example, when a client application attempts to establish a conversation with a server application, the client calls the **DdeConnect** function. This causes the DDEML to send an **XTYP_CONNECT** transaction to the server's DDE callback function. The callback function can allow the conversation by returning TRUE to the DDEML, or it can deny the conversation by returning FALSE.

For a detailed discussion of transactions, see Transaction Management.

Service Names, Topic Names, and Item Names

A DDE server uses a three-level hierarchy--service name (called "application name" in previous DDE documentation), topic name, and item name--to uniquely identify a unit of data that the server can exchange during a conversation. A service name is a string that a server application responds to when a client attempts to establish a conversation with the server. A client must specify this service name to be able to establish a conversation with the server. Although a server can respond to many service names, most servers respond to only one name.

A topic name is a string that identifies a logical data context. For servers that operate on file-based documents, topic names are typically filenames; for other servers, they are other application-specific strings. A client must specify a topic name along with a server's service name when it attempts to establish a conversation with a server.

An item name is a string that identifies a unit of data that a server can pass to a client during a transaction. For example, an item name might identify an integer, a string, several paragraphs of text, or a bitmap.

To a client, these names are the keys that make it possible for the client to establish a conversation with a server and to receive data from the server.

System Topic

The System topic provides a context for information that may be of general interest to any DDE client. Server applications are encouraged to support the System topic at all times. (The System topic is

defined in the **DDEML** header file as SZDDESYS_TOPIC.)

To find out which servers are present and the kinds of information they can provide, a client can request a conversation on the System topic with the service name set to NULL when the client application starts. Such wildcard conversations should be kept to a minimum, because they are costly in terms of system performance.

For more information about initiating DDE conversations, see Conversation Management.

A server should support the following item names within the System topic and any other item names that may be useful to a client:

Item	Description
SZDDE_ITEM_ITEMLIST	A list of the items that are supported under a non-System topic. (This list may vary from moment to moment and from topic to topic.)
SZDDESYS_ITEM_FORMATS	A list of clipboard format numbers that the server can render. This list should be ordered with the most descriptive formats first. A server may not be able to render all items in all formats within this list. At a minimum, a server should support the CF_TEXT clipboard format for item names associated with the System topic.
SZDDESYS_ITEM_HELP	General help information.
SZDDESYS_ITEM_RTNMSG	Supporting detail for the most recently used **WM_DDE_ACK** message. This is useful when more than 8 bits of application-specific return data are required.
SZDDESYS_ITEM_STATUS	An indication of the current status of the server. Typically, this item supports only the CF_TEXT format and contains the Ready or Busy string.
SZDDESYS_ITEM_SYSITEMS	A list of the items supported under the System topic by this server.
SZDDESYS_ITEM_TOPICS	A list of the topics supported by the server at the current time. (This list may vary from moment to moment.)

These item names are string constants defined in the **DDEML** header files. To obtain string handles for these strings, an application must use the DDEML string-management functions, just as it would for any other string in a DDEML application. For more information about managing strings, see String Management.

DDEML Initialization

The **DDEML** requires that Windows be running; otherwise, the system cannot load the DDEML dynamic-link library. Before calling any DDEML function, an application should call the **GetWinFlags** function, checking the return value for the **WF_PMODE** flag. If this flag is returned, the application can call DDEML functions.

Before calling any other **DDEML** function, an application must call the **DdeInitialize** function. The **DdeInitialize** function obtains an instance identifier for the application, registers the application's DDE callback function with the DDEML, and specifies the transaction filter flags for the callback function.

The **DDEML** uses instance identifiers so that it can support applications that allow multiple DDEML instances. Each instance of an application must pass its instance identifier as the *idInst* parameter to any other DDEML function that requires it. An application that uses multiple DDEML instances should assign a different DDE callback function to each instance. This makes it possible for the application to identify each instance within its callback function.

The purpose for multiple **DDEML** instances is to support DLLs using the DDEML. It is not recommended that an application have multiple DDE instances.

Transaction filters optimize system performance by preventing the **DDEML** from passing unwanted transactions to the application's DDE callback function. An application sets the transaction filters when it calls the **DdeInitialize** function. An application should specify a transaction filter flag for each type of transaction that it does not process in its callback function. An application can change its transaction filters with a subsequent call to the **DdeInitialize** function. For a complete list of transaction filter flags, see the description of the **DdeInitialize** function in the *Microsoft Windows Programmer's Reference, Volume 2.*

For more information about transactions, see Transaction Management.

The following example shows how to initialize an application to use the **DDEML**:

```
DWORD idInst = 0L;  /* instance identifier        */
HANDLE hInst;       /* instance handle            */
FARPROC lpDdeProc;  /* procedure instance address */

lpDdeProc = MakeProcInstance((FARPROC) DdeCallback, hInst);
if (DdeInitialize(&idInst,       /* receives instance identifier     */
        (PFNCALLBACK) lpDdeProc, /* address of callback function     */
        CBF_FAIL_EXECUTES |      /* filter XTYP_EXECUTE transactions */
        CBF_FAIL_POKES, 0L);     /* filter XTYP_POKE transactions    */
    return FALSE;
```

This example obtains a procedure-instance address for the callback function named **DdeCallback** and then passes the address to the DDEML. The CBF_FAIL_EXECUTES and CBF_FAIL_POKES filters prevent the **DDEML** from passing **XTYP_EXECUTE** or **XTYP_POKE** transactions to the callback function.

An application should call the **DdeUninitialize** function when it no longer needs to use the DDEML. This function terminates any conversations currently open for the application and frees the **DDEML** resources that the system allocated for the application.

The **DDEML** may have difficulty terminating a conversation. This occurs when the other partner in a conversation fails to terminate its end of the conversation. In this case, the system enters a modal loop while it waits for any conversations to be terminated. A system-defined timeout period is associated with this loop. If the timeout period expires before the conversations have been terminated, a message box appears that gives the user the choice of waiting for another timeout period (Retry), waiting indefinitely (Ignore), or exiting the modal loop (Abort). An application should call **DdeUninitialize** after it has become invisible to the user and after its message loop has terminated.

DDEML Callback Function

An application that uses the **DDEML** must provide a callback function that processes the DDE events that affect the application. The DDEML notifies an application of such events by sending transactions to the application's DDE callback function. The transactions that a callback function receives depend on the callback-filter flags that the application specified in the **DdeInitialize** function and on whether the application is a client, a server, or both. The following example shows the general structure of a callback function for a typical client application:

```
HDDEDATA CALLBACK DdeCallback(<type>, <fmt>, <hconv>, <hsz1>,
    <hsz2>, <hData>, <dwData1>, <dwData2>)
UINT <type>,        /* transaction type                */
UINT <fmt>,         /* clipboard data format           */
HCONV <hconv>,      /* handle of conversation          */
HSZ <hsz1>,         /* handle of string                */
HSZ <hsz2>,         /* handle of string                */
HDDEDATA <hData>,   /* handle of global memory object  */
DWORD <dwData1>,    /* transaction-specific data       */
DWORD <dwData2>,    /* transaction-specific data       */
{
    switch (type) {
        case XTYP_REGISTER:
        case XTYP_UNREGISTER:
            .
            .
            .
            return (HDDEDATA) NULL;

        case XTYP_ADVDATA:
            .
            .
            .
            return (HDDEDATA) DDE_FACK;

        case XTYP_XACT_COMPLETE:
            .
            .
            .
            return (HDDEDATA) NULL;

        case XTYP_DISCONNECT:
            .
            .
            .
            return (HDDEDATA) NULL;

        default:
            return (HDDEDATA) NULL;
    }
}
```

The *type* parameter specifies the transaction type sent to the callback function by the DDEML. The values of the remaining parameters depend on the transaction type. The transaction types and the events that generate them are described in the following sections of this topic. For detailed information about each transaction type, see Transaction Management.

DDEML String Management

Many **DDEML** functions require access to strings in order to carry out a DDE task. For example, a client must specify a service name and a topic name when it calls the **DdeConnect** function to request a conversation with a server. An application specifies a string by passing a string handle rather than a pointer in a DDEML function. A string handle is a doubleword value, assigned by the system, that identifies a string.

An application can obtain a string handle for a particular string by calling the **DdeCreateStringHandle** function. This function registers the string with the system and returns a string handle to the application. The application can pass the handle to **DDEML** functions that need to access the string. The following example obtains string handles for the System topic string and the service-name string:

```
HSZ hszServName;
HSZ hszSysTopic;

hszServName = DdeCreateStringHandle(
    idInst,         /* instance identifier */
    "MyServer",     /* string to register  */
    CP_WINANSI);    /* code page           */

hszSysTopic = DdeCreateStringHandle(
    idInst,         /* instance identifier */
    SZDDESYS_TOPIC, /* System topic        */
    CP_WINANSI);    /* code page           */
```

The *idInst* parameter in the preceding example specifies the instance identifier obtained by the **DdeInitialize** function.

An application's DDE callback function receives one or more string handles during most DDE transactions. For example, a server receives two string handles during the **XTYP_REQUEST** transaction: One identifies a string specifying a topic name; the other identifies a string specifying an item name. An application can obtain the length of the string that corresponds to a string handle and copy the string to an application-defined buffer by calling the **DdeQueryString** function, as the following example demonstrates:

```
DWORD idInst;
DWORD cb;
HSZ hszServ;
PSTR pszServName;

cb = DdeQueryString(idInst, hszServ, (LPSTR) NULL, 0L, CP_WINANSI) + 1;
pszServName = (PSTR) LocalAlloc(LPTR, (WORD) cb);
DdeQueryString(idInst, hszServ, pszServName, cb, CP_WINANSI);
```

An instance-specific string handle is not mappable from string handle to string to string handle again. For instance, in the following example, the **DdeQueryString** function creates a string from a string handle and then **DdeCreateStringHandle** creates a string handle from that string, but the two handles are not the same:

```
DWORD cb;
HSZ hszInst, hszNew;
PSZ pszInst;

DdeQueryString(idInst, hszInst, pszInst, cb, CP_WINANSI);
hszNew = DdeCreateStringHandle(idInst, pszInst, CP_WINANSI);
/* hszNew != hszInst ! */
```

A string handle that is passed to an application's DDE callback function becomes invalid when the

callback function returns. An application can save a string handle for use after the callback function returns by using the **DdeKeepStringHandle** function.

When an application calls **DdeCreateStringHandle**, the system enters the specified string into a systemwide string table and generates a handle that it uses to access the string. The system also maintains a usage count for each string in the string table.

When an application calls the **DdeCreateStringHandle** function and specifies a string that already exists in the table, the system increments the usage count rather than adding another occurrence of the string. (An application can also increment the usage count by using the **DdeKeepStringHandle** function.) When an application calls the **DdeFreeStringHandle** function, the system decrements the usage count.

A string is removed from the table when its usage count equals zero. Because more than one application can obtain the handle of a particular string, an application should not free a string handle more times than it has created or kept the handle. Otherwise, the application could cause the string to be removed from the table, denying other applications access to the string.

The **DDEML** string-management functions are based on the Windows atom manager and are subject to the same size restrictions as atoms.

DDEML Server Name Service

The **DDEML** makes it possible for a server application to register the service names that it supports and to prevent the DDEML from sending **XTYP_CONNECT** transactions for unsupported service names to the server's DDE callback function. The remaining topics in this section describe this service.

Service-Name Registration

By registering its service names with the **DDEML**, a server informs other DDE applications in the system that a new server is available. A server registers a service name by calling the **DdeNameService** function, specifying a string handle that identifies the name. As a result, the DDEML sends an **XTYP_REGISTER** transaction to the callback function of each DDEML application in the system (except those that specified the CBF_SKIP_REGISTRATIONS filter flag in the **DdeInitialize** function). The XTYP_REGISTER transaction passes two string handles to a callback function: The first identifies the string specifying the base service name; the second identifies the string specifying the instance-specific service. A client typically uses the base service name in a list of available servers, so that the user can select a server from the list. The client uses the instance-specific service name to establish a conversation with a specific instance of a server application if more than one instance is running.

A server can use the **DdeNameService** function to unregister a service name. This causes the **DDEML** to send **XTYP_UNREGISTER** transactions to the other DDE applications in the system, informing them that they can no longer use the name to establish conversations.

A server should call the **DdeNameService** function to register its service names soon after calling the **DdeInitialize** function. A server should unregister its service names just before calling the **DdeUninitialize** function.

Service-Name Filter

Besides registering service names, the **DdeNameService** function makes it possible for a server to turn its service-name filter on or off. When a server turns off its service-name filter, the **DDEML** sends the **XTYP_CONNECT** transaction to the server's DDE callback function whenever any client calls the **DdeConnect** function, regardless of the service name specified in the function. When a server turns on its service-name filter, the DDEML sends the XTYP_CONNECT transaction to the server only when the **DdeConnect** function specifies a service name that the server has specified in a call to the **DdeNameService** function.

By default, the service-name filter is on when an application calls the **DdeInitialize** function. This prevents the **DDEML** from sending the **XTYP_CONNECT** transaction to a server before the server has created the string handles that it needs. A server can turn off its service-name filter by specifying the DNS_FILTEROFF flag in a call to the **DdeNameService** function. The DNS_FILTERON flag turns on the filter.

DDEML Conversation Management

A conversation between a client and a server is always established at the request of the client. When a conversation is established, each partner receives a handle that identifies the conversation. The partners use this handle in other **DDEML** functions to send transactions and manage the conversation.

A client can request a conversation with a single server, or it can request multiple conversations with one or more servers. The remaining topics in this section describe how an application establishes conversations and explain how an application can obtain information about conversations that are already established.

Single Conversations

A client application requests a single conversation with a server by calling the **DdeConnect** function, specifying string handles that identify the strings specifying the service name of the server and the topic name of interest. The **DDEML** responds by sending the **XTYP_CONNECT** transaction to the DDE callback function of each server application that either has registered a service name that matches the one specified in the **DdeConnect** function or has turned service-name filtering off by calling the **DdeNameService** function. A server can also filter the XTYP_CONNECT transactions by specifying the CBF_FAIL_CONNECTIONS filter flag in the **DdeInitialize** function. During the XTYP_CONNECT transaction, the DDEML passes the service name and the topic name to the server. The server should examine the names and return TRUE if it supports the service/topic name pair or FALSE if it does not.

If no server returns TRUE from the **XTYP_CONNECT** transaction, the client receives NULL from the **DdeConnect** function and no conversation is established. If a server does return TRUE, a conversation is established and the client receives a conversation handle--a doubleword value that identifies the conversation. The client uses the handle in subsequent **DDEML** calls to obtain data from the server. The server receives the **XTYP_CONNECT_CONFIRM** transaction (unless the server specified the CBF_FAIL_CONFIRMS filter flag). This transaction passes the conversation handle to the server.

The following example requests a conversation on the System topic with a server that recognizes the service name MyServer. The *hszServName* and *hszSysTopic* parameters are previously created string handles.

```
HCONV hConv;
HWND hwndParent;
HSZ hszServName;
HSZ hszSysTopic;

hConv = DdeConnect(
    idInst,         /* instance identifier              */
    hszServName,    /* service-name string handle       */
    hszSysTopic,    /* System-topic string handle       */
    (PCONVCONTEXT) NULL); /* reserved--must be NULL     */

if (hConv == NULL) {
    MessageBox(hwndParent, "MyServer is unavailable.",
        (LPSTR) NULL, MB_OK);
    return FALSE;
}
```

The **DdeConnect** function in the preceding example causes the DDE callback function of the MyServer application to receive an **XTYP_CONNECT** transaction.

In the following example, the server responds to the **XTYP_CONNECT** transaction by comparing the topic-name string handle that the **DDEML** passed to the server with each element in the array of topic-name string handles that the server supports. If the server finds a match, it establishes the conversation.

```
#define CTOPICS 5

HSZ hsz1;                   /* string handle passed by DDEML  */
HSZ ahszTopics[CTOPICS];    /* array of supported topics      */
int i;                      /* loop counter                   */

.
. /* Use switch statement to examine transaction types. */
.

case XTYP_CONNECT:
    for (i = 0; i < CTOPICS; i++) {
        if (hsz1 == ahszTopics[i])
            return TRUE;    /* establish a conversation       */
    }

    return FALSE; /* topic not supported; deny conversation  */

.
. /* Process other transaction types. */
.
```

If the server returns TRUE in response to the **XTYP_CONNECT** transaction, the **DDEML** sends an **XTYP_CONNECT_CONFIRM** transaction to the server's DDE callback function. The server can obtain the handle for the conversation by processing this transaction.

A client can establish a wildcard conversation by specifying NULL for the service-name string handle, the topic-name string handle, or both in a call to the **DdeConnect** function. When at least one of the string handles is NULL, the **DDEML** sends the **XTYP_WILDCONNECT** transaction to the callback functions of all DDE applications (except those that filter the XTYP_WILDCONNECT transaction). Each server application should respond by returning a data handle that identifies a null-terminated array of **HSZPAIR** structures. If the server application has not called the **DdeNameService** function to register its service names and filtering is on, the server does not receive XTYP_WILDCONNECT transactions. For more information about data handles, see Data Management.

The array should contain one structure for each service/topic name pair that matches the pair specified by the client. The **DDEML** selects one of the pairs to establish a conversation and returns to the client a handle that identifies the conversation. The DDEML sends the **XTYP_CONNECT_CONFIRM** transaction to the server (unless the server filters this transaction). The following example shows a typical server response to the **XTYP_WILDCONNECT** transaction:

```
#define CTOPICS 2

UINT type;
UINT fmt;
HSZPAIR ahp[(CTOPICS + 1)];
HSZ ahszTopicList[CTOPICS];
HSZ hszServ, hszTopic;
WORD i, j;

if (type == XTYP_WILDCONNECT) {

     /*
      * Scan the topic list, and create array of HSZPAIR
      * structures.
      */
```

```
    j = 0;
    for (i = 0; i < CTOPICS; i++) {
        if (hszTopic == (HSZ) NULL ||
                hszTopic == ahszTopicList[i]) {
            ahp[j].hszSvc = hszServ;
            ahp[j++].hszTopic = ahszTopicList[i];
        }
    }

    /*
     * End the list with an HSZPAIR structure that contains NULL
     * string handles as its members.
     */

    ahp[j].hszSvc = NULL;
    ahp[j++].hszTopic = NULL;

    /*
     * Return a handle to a global memory object containing the
     * HSZPAIR structures.
     */

    return DdeCreateDataHandle(
        idInst,           /* instance identifier     */
        &ahp,             /* points to HSZPAIR array */
        sizeof(HSZ) * j,  /* length of the array     */
        0,                /* start at the beginning  */
        NULL,             /* no item-name string     */
        fmt,              /* return the same format  */
        0);               /* let the system own it   */
}
```

Either the client or the server can terminate a conversation at any time by calling the **DdeDisconnect** function. This causes the callback function of the partner in the conversation to receive the **XTYP_DISCONNECT** transaction (unless the partner specified the CBF_SKIP_DISCONNECTS filter flag). Typically, an application responds to the XTYP_DISCONNECT transaction by using the **DdeQueryConvInfo** function to obtain information about the conversation that terminated. After the callback function returns from processing the XTYP_DISCONNECT transaction, the conversation handle is no longer valid.

A client application that receives an **XTYP_DISCONNECT** transaction in its DDE callback function can attempt to reestablish the conversation by calling the **DdeReconnect** function. The client must call **DdeReconnect** from within its DDE callback function.

Multiple Conversations

A client application can use the **DdeConnectList** function to determine whether any servers of interest are available in the system. A client specifies a service name and topic name when it calls the **DdeConnectList** function, causing the **DDEML** to broadcast the **XTYP_WILDCONNECT** transaction to the DDE callback functions of all servers that match the service name (except those that filter the transaction). A server's callback function should return a data handle that identifies a null-terminated array of **HSZPAIR** structures. The array should contain one structure for each service/topic name pair that matches the pair specified by the client. The DDEML establishes a conversation for each **HSZPAIR** structure filled by the server and returns a conversation-list handle to the client. The server receives the conversation handle by way of the **XTYP_CONNECT_CONFIRM** transaction (unless the server filters this transaction).

A client can specify NULL for the service name, topic name, or both when it calls the **DdeConnectList**

function. If the service name is NULL, all servers in the system that support the specified topic name respond. A conversation is established with each responding server, including multiple instances of the same server. If the topic name is NULL, a conversation is established on each topic recognized by each server that matches the service name.

A client can use the **DdeQueryNextServer** and **DdeQueryConvInfo** functions to identify the servers that respond to the **DdeConnectList** function. The **DdeQueryNextServer** function returns the next conversation handle in a conversation list; the **DdeQueryConvInfo** function fills a **CONVINFO** structure with information about the conversation. The client can keep the conversation handles that it needs and discard the rest from the conversation list.

The following example uses the **DdeConnectList** function to establish conversations with all servers that support the System topic and then uses the **DdeQueryNextServer** and **DdeQueryConvInfo** functions to obtain the servers' service-name string handles and store them in a buffer:

```
HCONVLIST hconvList; /* conversation list       */
DWORD idInst;        /* instance identifier     */
HSZ hszSystem;       /* System topic            */
HCONV hconv = NULL;  /* conversation handle     */
CONVINFO ci;         /* holds conversation data */
UINT cConv = 0;      /* count of conv. handles  */
HSZ *pHsz, *aHsz;    /* point to string handles */

/* Connect to all servers that support the System topic. */

hconvList = DdeConnectList(idInst, NULL, hszSystem, NULL, NULL);

/* Count the number of handles in the conversation list. */

while ((hconv = DdeQueryNextServer(hconvList, hconv)) != NULL) cConv++;

/* Allocate a buffer for the string handles. */

hconv = NULL;
aHsz = (HSZ *) LocalAlloc(LMEM_FIXED, cConv * sizeof(HSZ));

/* Copy the string handles to the buffer. */

pHsz = aHsz;
while ((hconv = DdeQueryNextServer(hconvList, hconv)) != NULL) {
    DdeQueryConvInfo(hconv, QID_SYNC, (PCONVINFO) &ci);
    DdeKeepStringHandle(idInst, ci.hszSvcPartner);
    *pHsz++ = ci.hszSvcPartner;
}

.
. /* Use the handles; converse with servers. */
.

/* Free the memory, and terminate conversations. */

LocalFree((HANDLE) aHsz);
DdeDisconnectList(hconvList);
```

An application can terminate an individual conversation in a conversation list by calling the **DdeDisconnect** function. An application can terminate all conversations in a conversation list by calling the **DdeDisconnectList** function. Both functions cause the **DDEML** to send **XTYP_DISCONNECT** transactions to each partner's DDE callback function. The **DdeDisconnectList** function sends a

XTYP_DISCONNECT transaction for each conversation handle in the list.

A client can use the **DdeConnectList** function to enumerate the conversation handles in a conversation list by passing an existing conversation-list handle to the **DdeConnectList** function. The enumeration process removes the handles of terminated conversations from the list.

If the **DdeConnectList** function specifies an existing conversation-list handle and a service name or topic name that is different from those used to create the existing conversation list, the function creates a new conversation list that contains the handles of any new conversations and the handles from the existing list.

The **DdeConnectList** function attempts to prevent duplicate conversations in a conversation list. A duplicate conversation is a second conversation with the same server on the same service name and topic name. Two such conversations would have different handles, yet they would be duplicate conversations.

DDEML Data Management

Because DDE uses global memory to pass data from one application to another, the **DDEML** provides a set of functions that DDE applications can use to create and manage global memory objects.

All transactions that involve the exchange of data require the application supplying the data to create a local buffer containing the data and then to call the **DdeCreateDataHandle** function. This function allocates a global memory object, copies the data from the buffer to the memory object, and returns a data handle of the application. A data handle is a doubleword value that the **DDEML** uses to provide access to data in the global memory object. To share the data in a global memory object, an application passes the data handle to the DDEML, and the DDEML passes the handle to the DDE callback function of the application that is receiving the data transaction.

The following example shows how to create a global memory object and obtain a handle of the object. During the **XTYP_ADVREQ** transaction, the callback function converts the current time to an ASCII string, copies the string to a local buffer, then creates a global memory object that contains the string. The callback function returns the handle of the global memory object to the **DDEML**, which passes the handle to the client application.

```
typedef struct { /* tm */
    int hour;
    int minute;
    int second;
} TIME;

TIME tmTime;
HSZ hszTime;
HSZ hszNow;
HDDEDATA EXPENTRY DdeProc(wType, wFmt, hConv, hsz1, hsz2,
    hData, dwData1, dwData2)
WORD wType;
WORD wFmt;
HCONV hConv;
HSZ hsz1;
HSZ hsz2;
HDDEDATA hData;
DWORD dwData1;
DWORD dwData2;
{
    char szBuf[32];

    switch (wType) {

        case XTYP_ADVREQ:
            if ((hsz1 == hszTime && hsz2 == hszNow)
                    && (wFmt == CF_TEXT)) {

                /* Copy formatted time string to buffer. */

                itoa(tmTime.hour, szBuf, 10);
                strcat(szBuf, ":");
                if (tmTime.minute < 10)
                    strcat(szBuf, "0");
                itoa(tmTime.minute, &szBuf[strlen(szBuf)], 10);
                strcat(szBuf, ":");
                if (tmTime.second < 10)
                    strcat(szBuf, "0");
```

```
                itoa(tmTime.second, &szBuf[strlen(szBuf)], 10);
                szBuf[strlen(szBuf)] = '\0';

                /* Create global object, and return data handle. */

                return (DdeCreateDataHandle(
                    idInst,             /* instance identifier   */
                    (LPBYTE) szBuf,     /* source buffer         */
                    strlen(szBuf) + 1, /* size of global object */
                    0L,                 /* offset from beginning */
                    hszNow,             /* item-name string      */
                    CF_TEXT,            /* clipboard format      */
                    0));                /* no creation flags     */
            } else
                return (HDDEDATA) NULL;

        .
        . /* Process other transaction types. */
        .
    }
}
```

The receiving application obtains a pointer to the global memory object by passing the data handle to the **DdeAccessData** function. The pointer returned by **DdeAccessData** provides read-only access. The application should use the pointer to review the data and then call the **DdeUnaccessData** function to invalidate the pointer. The application can copy the data to a local buffer by using the **DdeGetData** function.

The following example obtains a pointer to the global memory object identified by the *hData* parameter, copies the contents to a local buffer, and then invalidates the pointer:

```
HDDEDATA hData;
LPBYTE lpszAdviseData;
DWORD cbDataLen;
DWORD i;
char szData[32];

case XTYP_ADVDATA:

    lpszAdviseData = DdeAccessData(hData, &cbDataLen);
    for (i = 0; i < cbDataLen; i++)
        szData[i] = *lpszAdviseData++;
    DdeUnaccessData(hData);
    return (HDDEDATA) TRUE;
```

Usually, when an application that created a data handle passes that handle to the **DDEML**, the handle becomes invalid in the creating application. This is fine if the application needs to share data with just a single application. If an application needs to share the same data with multiple applications, however, the creating application should specify the HDATA_APPOWNED flag in **DdeCreateDataHandle**. Doing so gives ownership of the memory object to the creating application and prevents the DDEML from invalidating the data handle. When the creating application finishes using a memory object it owns, it should free the object by calling the **DdeFreeDataHandle** function.

If an application has not yet passed the handle of a global memory object to the **DDEML**, the application can add data to the object or overwrite data in the object by using the **DdeAddData** function. Typically, an application uses **DdeAddData** to fill an uninitialized global memory object. After an application passes a data handle to the DDEML, the global memory object identified by the handle cannot be changed; it can only be freed.

The **DDEML** data-management functions can handle huge memory objects. A DDEML application should check the size of a global memory object and allocate a huge buffer of the appropriate size before copying the object.

DDEML Transaction Management

After a client has established a conversation with a server, the client can send transactions to obtain data and services from the server. The remaining topics in this section describe the types of transactions that clients can use to interact with a server.

Request Transaction

A client application can use the **XTYP_REQUEST** transaction to request a data item from a server application. The client calls the **DdeClientTransaction** function, specifying XTYP_REQUEST as the transaction type and specifying the data item the application needs.

The **DDEML** passes the **XTYP_REQUEST** transaction to the server, specifying the topic name, item name, and data format requested by the client. If the server supports the requested topic, item, and data format, the server should return a data handle that identifies the current value of the item. The DDEML passes this handle to the client as the return value from the **DdeClientTransaction** function. The server should return NULL if it does not support the topic, item, or format requested.

The **DdeClientTransaction** function uses the *lpdwResult* parameter to return a transaction status flag to the client. If the server does not process the **XTYP_REQUEST** transaction, **DdeClientTransaction** returns NULL, and *lpdwResult* points to the DDE_FNOTPROCESSED or DDE_FBUSY flag. If the DDE_FNOTPROCESSED flag is returned, the client has no way to determine why the server did not process the transaction.

If a server does not support the **XTYP_REQUEST** transaction, it should specify the CBF_FAIL_REQUESTS filter flag in the **DdeInitialize** function. This prevents the **DDEML** from sending this transaction to the server.

Poke Transaction

A client can send unsolicited data to a server by using the **DdeClientTransaction** function to send an **XTYP_POKE** transaction to a server's callback function.

The client application first creates a buffer that contains the data to send to the server and then passes a pointer to the buffer as a parameter to the **DdeClientTransaction** function. Alternatively, the client can use the **DdeCreateDataHandle** function to obtain a data handle that identifies the data and then pass the handle to **DdeClientTransaction**. In either case, the client also specifies the topic name, item name, and data format when it calls **DdeClientTransaction**.

The **DDEML** passes the **XTYP_POKE** transaction to the server, specifying the topic name, item name, and data format that the client requested. To accept the data item and format, the server should return DDE_FACK. To reject the data, the server should return DDE_FNOTPROCESSED. If the server is too busy to accept the data, the server should return DDE_FBUSY.

When the **DdeClientTransaction** function returns, the client can use the *lpdwResult* parameter to access the transaction status flag. If the flag is DDE_FBUSY, the client should send the transaction again later.

If a server does not support the **XTYP_POKE** transaction, it should specify the CBF_FAIL_POKES filter flag in the **DdeInitialize** function. This prevents the **DDEML** from sending this transaction to the server.

Advise Transaction

A client application can use the **DDEML** to establish one or more links to items in a server application. When such a link is established, the server sends periodic updates about the linked item to the client (typically, whenever the value of the item associated with the server application changes). This establishes an advise loop between the two applications that remains in place until the client ends it.

There are two kinds of advise loops: "hot" and "warm." In a hot advise loop, the server immediately sends a data handle that identifies the changed value. In a warm advise loop, the server notifies the client that the value of the item has changed but does not send the data handle until the client

requests it.

A client can request a hot advise loop with a server by specifying the **XTYP_ADVSTART** transaction type in a call to the **DdeClientTransaction** function. To request a warm advise loop, the client must combine the XTYPF_NODATA flag with the XTYP_ADVSTART transaction type. In either event, the **DDEML** passes the XTYP_ADVSTART transaction to the server's DDE callback function. The server's DDE callback function should examine the parameters that accompany the XTYP_ADVSTART transaction (including the requested format, topic name, and item name) and then return TRUE to allow the advise loop or FALSE to deny it.

After an advise loop is established, the server application should call the **DdePostAdvise** function whenever the value of the item associated with the requested item name changes. This results in an **XTYP_ADVREQ** transaction being sent to the server's own DDE callback function. The server's DDE callback function should return a data handle that identifies the new value of the data item. The **DDEML** then notifies the client that the specified item has changed by sending the **XTYP_ADVDATA** transaction to the client's DDE callback function.

If the client requested a hot advise loop, the **DDEML** passes the data handle for the changed item to the client during the **XTYP_ADVDATA** transaction. Otherwise, the client can send an **XTYP_REQUEST** transaction to obtain the data handle.

It is possible for a server to send updates faster than a client can process the new data. This can be a problem for a client that must perform long processing operations on the data. In this case, the client should specify the XTYPF_ACKREQ flag when it requests an advise loop. This causes the server to wait for the client to acknowledge that it has received and processed a data item before the server sends the next data item. Advise loops that are established with the XTYPF_ACKREQ flag are more robust with fast servers but may occasionally miss updates. Advise loops established without the XTYPF_ACKREQ flag are guaranteed not to miss updates as long as the client keeps up with the server.

A client can end an advise loop by specifying the **XTYP_ADVSTOP** transaction type in a call to the **DdeClientTransaction** function.

If a server does not support advise loops, it should specify the CBF_FAIL_ADVISES filter flag in the **DdeInitialize** function. This prevents the **DDEML** from sending the **XTYP_ADVSTART** and **XTYP_ADVSTOP** transactions to the server.

Execute Transaction

A client can use the **XTYP_EXECUTE** transaction to cause a server to execute a command or series of commands.

To execute a server command, the client first creates a buffer that contains a command string for the server to execute and then passes either a pointer to the buffer or a data handle identifying the buffer when it calls the **DdeClientTransaction** function. Other required parameters include the conversation handle, the item-name string handle, the format specification, and the **XTYP_EXECUTE** transaction type. When an application creates a data handle for passing execute data, the application must specify NULL for the *hszItem* parameter of the **DdeCreateDataHandle** function.

The **DDEML** passes the **XTYP_EXECUTE** transaction to the server's DDE callback function specifying the format name, conversation handle, topic name, and data handle identifying the command string. If the server supports the command, it should use the **DdeAccessData** function to obtain a pointer to the command string, execute the command, and then return DDE_FACK. If the server does not support the command or cannot complete the transaction, it should return DDE_FNOTPROCESSED. The server should return DDE_FBUSY if it is too busy to complete the transaction.

When the **DdeClientTransaction** function returns, the client can use the *lpdwResult* parameter to access the transaction status flag. If the flag is DDE_FBUSY, the client should send the transaction again later.

If a server does not support the **XTYP_EXECUTE** transaction, it should specify the CBF_FAIL_EXECUTES filter flag in the **DdeInitialize** function. Doing so prevents the **DDEML** from

sending this transaction to the server.

Synchronous and Asynchronous Transactions

A client can send either synchronous or asynchronous transactions. In a synchronous transaction, the client specifies a timeout value that indicates the maximum amount of time to wait for the server to process the transaction. The **DdeClientTransaction** function does not return until the server processes the transaction, the transaction fails, or the timeout value expires. The client specifies the timeout value when it calls **DdeClientTransaction**.

During a synchronous transaction, the client enters a modal loop while waiting for the transaction to be processed. The client can still process user input but cannot send another synchronous transaction until the **DdeClientTransaction** function returns.

A client sends an asynchronous transaction by specifying the TIMEOUT_ASYNC flag in the **DdeClientTransaction** function. The function returns after the transaction is begun, passing a transaction identifier to the client. When the server finishes processing the asynchronous transaction, the **DDEML** sends an **XTYP_XACT_COMPLETE** transaction to the client. One of the parameters that the DDEML passes to the client during the XTYP_XACT_COMPLETE transaction is the transaction identifier. By comparing this transaction identifier with the identifier returned by the **DdeClientTransaction** function, the client identifies which asynchronous transaction the server has finished processing.

A client can use the **DdeSetUserHandle** function as an aid to processing an asynchronous transaction. This function makes it possible for a client to associate an application-defined doubleword value with a conversation handle and transaction identifier. The client can use the **DdeQueryConvInfo** function during the **XTYP_XACT_COMPLETE** transaction to obtain the application-defined doubleword value. This saves an application from having to maintain a list of active transaction identifiers.

If a server does not process an asynchronous transaction in a timely manner, the client can abandon the transaction by calling the **DdeAbandonTransaction** function. The **DDEML** releases all resources associated with the transaction and discards the results of the transaction when the server finishes processing it.

The asynchronous transaction method is provided for applications that must send a high volume of DDE transactions while simultaneously performing a substantial amount of processing, such as calculations. The asynchronous method is also useful in applications that need to stop processing DDE transactions temporarily so they can complete other tasks without interruption. In most other situations, an application should use the synchronous method.

Synchronous transactions are simpler to maintain and faster than asynchronous transactions. However, only one synchronous transaction can be performed at a time, whereas many asynchronous transactions can be performed simultaneously. With synchronous transactions, a slow server can cause a client to remain idle while waiting for a response. Also, synchronous transactions cause the client to enter a modal loop that could bypass message filtering in the application's own message loop.

Transaction Control

An application can suspend transactions to its DDE callback function--either those transactions associated with a specific conversation handle or all transactions regardless of the conversation handle. This is useful when an application receives a transaction that requires lengthy processing. In this case, an application can return CBR_BLOCK to suspend future transactions associated with that transaction's conversation handle, leaving the application free to process other conversations.

When processing is complete, the application calls the **DdeEnableCallback** function to resume transactions associated with the suspended conversation. Calling **DdeEnableCallback** causes the **DDEML** to resend the transaction that resulted in the application suspending the conversation. Therefore, the application should store the result of the transaction in such a way that it can obtain and return the result without reprocessing the transaction.

An application can suspend all transactions associated with a specific conversation handle by specifying the handle and the EC_DISABLE flag in a call to the **DdeEnableCallback** function. By specifying a NULL handle, an application can suspend all transactions for all conversations.

When a conversation is suspended, the **DDEML** saves transactions for the conversation in a transaction queue. When the application reenables the conversation, the DDEML removes the saved transactions from the queue, passing each transaction to the appropriate callback function. Even though the capacity of the transaction queue is large, an application should reenable a suspended conversation as soon as possible to avoid losing transactions.

An application can resume usual transaction processing by specifying the EC_ENABLEALL flag in the **DdeEnableCallback** function. For a more controlled resumption of transaction processing, the application can specify the EC_ENABLEONE flag. This removes one transaction from the transaction queue and passes it to the appropriate callback function; after the single transaction is processed, any conversations are again disabled.

Transaction Classes

The **DDEML** has four classes of transactions. Each class is identified by a constant that begins with the XCLASS_ prefix. The classes are defined in the DDEML header file. The class constant is combined with the transaction-type constant and is passed to the DDE callback function of the receiving application.

A transaction's class determines the return value that a callback function is expected to return if it processes the transaction. The following table shows the return values and transaction types associated with each of the four transaction classes:

Class	Return value	Transaction
XCLASS_BOOL	TRUE or FALSE	XTYP_ADVSTART XTYP_CONNECT
XCLASS_DATA	A data handle, CBR_BLOCK, or NULL	XTYP_ADVREQ XTYP_REQUEST XTYP_WILDCONNECT
XCLASS_FLAGS	A transaction flag: DDE_FACK, DDE_FBUSY, or DDE_FNOTPROCESSED	XTYP_ADVDATA XTYP_EXECUTE XTYP_POKE
XCLASS_NOTIFICATION	None	XTYP_ADVSTOP XTYP_CONNECT_CONFIRM XTYP_DISCONNECT XTYP_ERROR XTYP_REGISTER XTYP_UNREGISTER XTYP_XACT_COMPLETE

Transaction Summary

The following list shows each DDE transaction type, the receiver of each type, and a description of the activity that causes the **DDEML** to generate each type:

Transaction type	Receiver	Cause
XTYP_ADVDATA	Client	A server responded to an XTYP_ADVREQ transaction by returning a data handle.
XTYP_ADVREQ	Server	A server called the **DdePostAdvise** function, indicating that the value of a data item in an advise loop had changed.

XTYP_ADVSTART	Server	A client specified the XTYP_ADVSTART transaction type in a call to the **DdeClientTransaction** function.
XTYP_ADVSTOP	Server	A client specified the XTYP_ADVSTOP transaction type in a call to the **DdeClientTransaction** function.
XTYP_CONNECT	Server	A client called the **DdeConnect** function, specifying a service name and topic name supported by the server.
XTYP_CONNECT_CONFIRM	Server	The server returned TRUE in response to an XTYP_CONNECT or XTYP_WILDCONNECT transaction.
XTYP_DISCONNECT	Client/Server	A partner in a conversation called the **DdeDisconnect** function, causing both partners to receive this transaction.
XTYP_ERROR	Client/Server	A critical error has occurred. The DDEML may not have sufficient resources to continue.
XTYP_EXECUTE	Server	A client specified the XTYP_EXECUTE transaction type in a call to the **DdeClientTransaction** function.
XTYP_MONITOR	DDE monitoring application	A DDE event occurred in the system.
XTYP_POKE	Server	A client specified the XTYP_POKE transaction type in a call to the **DdeClientTransaction** function.
XTYP_REGISTER	Client/Server	A server application used the **DdeNameService** function to register a service name.
XTYP_REQUEST	Server	A client specified the XTYP_REQUEST transaction type in a call to the **DdeClientTransaction** function.
XTYP_UNREGISTER	Client/Server	A server application used the **DdeNameService** function to unregister a service name.
XTYP_WILDCONNECT	Server	A client called the **DdeConnect** or **DdeConnectList** function, specifying NULL for the service name, the topic name, or both.
XTYP_XACT_COMPLETE	Client	An asynchronous transaction, sent when the client specified the TIMEOUT_ASYNC flag in a call to the **DdeClientTransaction** function, has concluded.

DDEML Error Detection

Whenever a **DDEML** function fails, an application can call the **DdeGetLastError** function to determine the cause of the failure. The **DdeGetLastError** function returns an error value that specifies the cause of the most recent error.

Monitoring Applications

Microsoft Windows **DDESpy** (DDESPY.EXE) monitors DDE activity in the system. You can use DDESpy as a tool for debugging your DDE applications.

You can use the API elements of the **DDEML** to create your own DDE monitoring applications. Like any DDEML application, a DDE monitoring application contains a DDE callback function. The DDEML notifies a monitoring application's DDE callback function whenever a DDE event occurs, passing information about the event to the callback function. The application typically displays the information in a window or writes it to a file.

To receive notifications from the **DDEML**, an application must have registered itself as a DDE monitor by specifying the APPCLASS_MONITOR flag in a call to the **DdeInitialize** function. In this same call, the application can specify one or more monitor flags to indicate the types of events of which the DDEML is to notify the application's callback function. The following table describes each of the monitor flags an application can specify:

Flag	Meaning
MF_CALLBACKS	Notifies the callback function whenever a transaction is sent to any DDE callback function in the system.
MF_CONV	Notifies the callback function whenever a conversation is established or terminated.
MF_ERRORS	Notifies the callback function whenever a **DDEML** error occurs.
MF_HSZ_INFO	Notifies the callback function whenever a **DDEML** application creates, frees, or increments the use count of a string handle or whenever a string handle is freed as a result of a call to the **DdeUninitialize** function.
MF_LINKS	Notifies the callback function whenever an advise loop is started or ended.
MF_POSTMSGS	Notifies the callback function whenever the system or an application posts a DDE message.
MF_SENDMSGS	Notifies the callback function whenever the system or an application sends a DDE message.

The following example shows how to register a DDE monitoring application so that its DDE callback function receives notifications of all DDE events:

```
DWORD idInst;
PFNCALLBACK lpDdeProc;
hInst = hInstance;

lpDdeProc = (PFNCALLBACK) MakeProcInstance(
    (FARPROC) DDECallback,   /* points to callback function      */
    hInstance);              /* instance handle                  */

if (DdeInitialize(
        (LPDWORD) &idInst,  /* instance identifier              */
        lpDdeProc,          /* points to callback function      */
        APPCLASS_MONITOR |  /* this is a monitoring application */
        MF_CALLBACKS     |  /* monitor callback functions       */
        MF_CONV          |  /* monitor conversation data        */
        MF_ERRORS        |  /* monitor DDEML errors             */
        MF_HSZ_INFO      |  /* monitor data-handle activity     */
        MF_LINKS         |  /* monitor advise loops             */
        MF_POSTMSGS      |  /* monitor posted DDE messages      */
        MF_SENDMSGS,        /* monitor sent DDE messages        */
        0L))                /* reserved                         */
    return FALSE;
```

The **DDEML** informs a monitoring application of a DDE event by sending an **XTYP_MONITOR** transaction to the application's DDE callback function. During this transaction, the DDEML passes a monitor flag that specifies the type of DDE event that has occurred and a handle of a global memory object that contains detailed information about the event. The DDEML provides a set of structures that the application can use to extract the information from the memory object. There is a corresponding structure for each type of DDE event. The following table describes each of these structures:

Structure	Description
MONCBSTRUCT	Contains information about a transaction.
MONCONVSTRUCT	Contains information about a conversation.
MONERRSTRUCT	Contains information about the latest DDE error.
MONLINKSTRUCT	Contains information about an advise loop.
MONHSZSTRUCT	Contains information about a string handle.
MONMSGSTRUCT	Contains information about a DDE message that was sent or posted.

The following example shows the DDE callback function of a DDE monitoring application that formats information about each string handle event and then displays the information in a window. The function uses the **MONHSZSTRUCT** structure to extract the information from the global memory object.

```
HDDEDATA CALLBACK DDECallback(wType, wFmt, hConv, hsz1, hsz2,
    hData, dwData1, dwData2)
WORD wType;
WORD wFmt;
HCONV hConv;
HSZ hsz1;
HSZ hsz2;
HDDEDATA hData;
DWORD dwData1;
DWORD dwData2;
{
    LPVOID lpData;
    char *szAction;
    char buf[256];
    DWORD cb;

    switch (wType) {
        case XTYP_MONITOR:

            /* Obtain a pointer of the global memory object. */

            if (lpData = DdeAccessData(hData, &cb)) {

                /* Examine the monitor flag. */

                switch (dwData2) {
                    case MF_HSZ_INFO:

#define PHSZS ((MONHSZSTRUCT FAR *)lpData)

                        /*
                         * The global memory object contains
                         * string-handle data. Use the MONHSZSTRUCT
                         * structure to access the data.
                         */
```

```
                        switch (PHSZS->fsAction) {

                            /*
                             * Examine the action flags to determine
                             * the action performed on the handle.
                             */

                            case MH_CREATE:
                                szAction = "Created";
                                break;

                            case MH_KEEP:
                                szAction = "Incremented";
                                break;

                            case MH_DELETE:
                                szAction = "Deleted";
                                break;

                            case MH_CLEANUP:
                                szAction = "Cleaned up";
                                break;

                            default:
                                DdeUnaccessData(hData);
                                return ((HDDEDATA) 0);
                        }

                        /* Write formatted output to a buffer. */

                        wsprintf(buf,
                            "Handle %s, Task: %x, Hsz: %lx(%s)",
                            (LPSTR) szAction, PHSZS->hTask, PHSZS->hsz,
                            (LPSTR) PHSZS->str);
                        .
                        . /* Display text in window or write to file. */
                        .

                        break;

#undef PHSZS

                    .
                    . /* Process other MF_* flags. */
                    .

                    default:
                        break;
                }
            }

            /* Free the global memory object. */

            DdeUnaccessData(hData);
            break;

        default:
```

```
            break;
        }
        return ((HDDEDATA) 0);
    }
```

Object Linking and Embedding Overview (3.1)

This topic describes the implementation of object linking and embedding (OLE) for applications that run with the Microsoft Windows operating system. The topic also describes how an application can use linked and embedded objects to create compound documents. The following topics discuss the behavior and implementation of object linking and embedding:

Compound Documents
Data Transfer in OLE
Client Applications
Server Applications
Object Handlers
Direct Use of Dynamic Data Exchange

This topic does not go into detail about the recommended user interface for applications that use linked and embedded objects.

Compound Documents

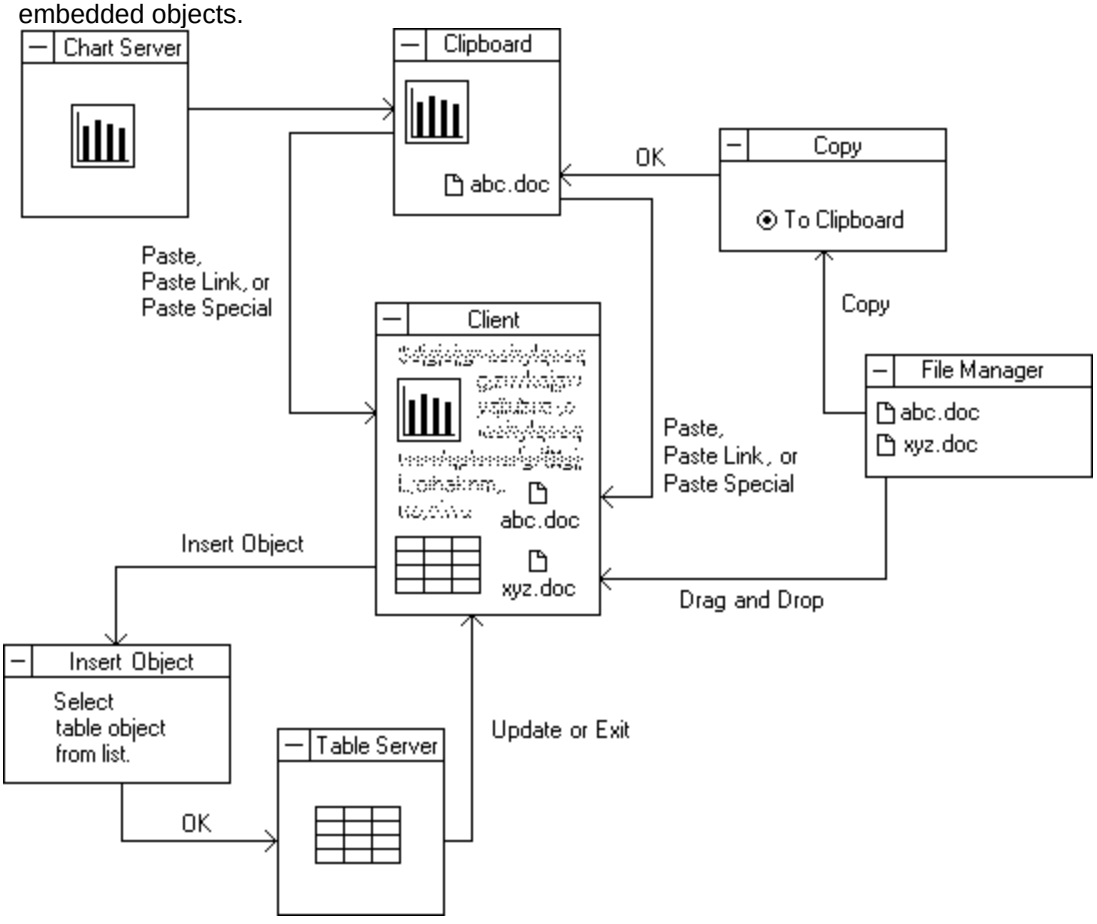
Compound Documents

An application that uses OLE can cooperate with other OLE applications to produce a document containing different kinds of data, all of which can be easily manipulated by the user. The user editing such a document is able to improve the document by using the best features of many different applications. An application that implements OLE gives its users the ability to move away from an application-centered view of computing and toward a document-centered view. In application-centered computing, the tool used to complete a task is often a single application; whereas, in document-centered computing, a user can combine the advantages of many tools to complete a job.

A document that uses linked and embedded objects can contain many kinds of data in many different formats; such a document is called a compound document. A compound document uses the facilities of different OLE applications to manipulate the different kinds of data it displays. Any kind of data format can be incorporated into a compound document; with little or no extra code, OLE applications can even support data formats that have not yet been invented. The user working with a compound document does not need to know which data formats are compatible with one another or how to find and start any applications that created the data. Whenever a user chooses to work with part of a compound document, the application responsible for that part of the document starts automatically.

For example, a compound document could be a brochure that included text, charts, ranges of cells in a spreadsheet, and illustrations. The information could be embedded in the document, or the document could contain links to certain information instead of containing the information itself. The user working with the brochure could automatically switch between the applications that produced its components.

The following illustration shows the relationships between a compound document and its linked and embedded objects.



Linked and Embedded Objects

An object is any data that can be presented in a compound document and manipulated by a user. Anything from a single cell in a spreadsheet to an entire document can be an object. When an object is incorporated into a document, it maintains an association with the application that produced it. That association can be a link, or the object can be embedded in the file.

If the object is linked, the document provides only minimal storage for the data to which the object is linked, and the object can be updated automatically whenever the data in the original application changes. For example, if a range of spreadsheet cells were linked to information in a text file, the data would be stored in some other file and only a link to the data would be saved with the text file.

If an object is embedded, all the data associated with it is saved as part of the file in which it is embedded. If a range of spreadsheet cells were embedded in a text file, the data in the cells would be saved with the text file, including any necessary formulas; the name of the server for the spreadsheet cells would be saved along with this data. The user could select this embedded object while working with the text file, and the spreadsheet application would be started automatically for editing those cells. The presentation and the behavior of the data is the same for a linked and an embedded object.

Packages

A package is a type of OLE object that encapsulates another object, a file, or a command line inside a graphic representation (such as an icon or bitmap). When the user double-clicks the graphic object, the OLE libraries activate the object inside the package. The package itself is always an embedded object, not a link. The contents of a package can be an embedded object, a link, or even a file dropped from Windows File Manager.

Packages are useful for presenting compact token views of large files or OLE objects. An application could also use a package as it would use a hyperlink--that is, to connect information in different documents.

Windows version 3.1 includes the application Microsoft Windows Object Packager (PACKAGER.EXE). With Packager, a user can associate a file or data selection with an icon or graphic.

Verbs

The types of actions a user can perform on an object are called verbs. Two typical verbs for an object are Play and Edit.

The nature of an object determines its behavior when a user works with it. The most typical use for some objects, such as voice annotations and animated scripts, is to play them. For example, a user could play an animated script by double-clicking it. In this case, Play is the primary verb for the object.

For other objects, the most typical use is to edit them. In the case of text produced by a word processor, for example, the primary verb could be Edit.

The client application typically specifies the primary verb when the user double-clicks an object. However, the server application determines the meaning of that verb. A user can invoke an object's subsidiary verbs by using the *Class Name* Object command or the Links dialog box. For more information about these topics, see Client User Interface.

The action taken when a user double-clicks a package is that of the primary verb of the object inside the package. The secondary verb for a packaged object is Edit Package; when the user chooses this verb, Packager starts. The user can use Packager to gain access to the secondary verb for the object inside the package.

Many objects support only one verb--for example, an object created by a text editor might support only Edit. If an object supports only one verb, that verb is used no matter what the client application specifies.

For more information about verbs, see Registration.

Benefits of Object Linking and Embedding

OLE offers the following benefits:

- An application can specialize in performing one job very well. For example, a drawing application that implements OLE does not need any text-editing tools; a user could put text into the drawing and edit that text by using any text editor that supports OLE.
- An application is automatically extensible for future data formats, because the content of an object does not matter to the containing document.
- A user can concentrate on the task instead of on any software required to complete the task.
- A file can be more compact, because linking to objects allows a file to use an object without having to store that object's data.
- A document can be printed or transmitted without using the application that originally produced the document.
- Linked objects in a file can be updated dynamically.

Future implementations of this protocol could take advantage of a wide variety of object types. For example, the user of a voice-recorder application could dictate a comment, package the comment as an object with a visual representation, and embed the graphic as an object in a text file. When a user double-clicked the graphic for this object (a pair of lips, perhaps), the voice-recorder application would play the recorded comment. Linked and embedded objects also lend themselves to implementations such as animated drawings, executable macro scripts, hypertext, and annotations.

Choosing Between OLE and the DDEML

Applications can exchange data by using either OLE or the DDEML. Unless an application has a strong requirement for managing multiple items in a single conversation with another application, the application should use OLE instead of the DDEML.

Both OLE and the **DDEML** are message-based systems supported by dynamic-link libraries. Developers are encouraged to use these libraries rather than using the underlying message-based protocols. For more information about the message-based OLE protocol, see Direct Use of Dynamic Data Exchange.

Unlike OLE, the **DDEML** supports multiple items per conversation. With OLE, a client needing links to several objects in a document must establish a separate conversation for each object.

OLE offers the following advantages that the **DDEML** does not:

Advantage	Description
Extensibility to future enhancements	The OLE libraries may be updated in future releases to support new data formats, link tracking, editing without exiting the client application, and other enhancements that will not be immediately available to applications that use the DDEML.
Persistent embedding and linking of objects	The OLE libraries do most of the work of activating objects when an embedded document is reopened, by reestablishing the conversation between a client and server. In contrast, establishing a DDE link (DDE advise loop) is the responsibility of either the user (if the link is not persistent) or of the application (if the link is persistent).
Rendering of common data formats	The OLE libraries assume the burden of rendering common data formats on a display context. DDE applications, however, must do this work themselves.
Server rendering of specialized data formats	The OLE libraries facilitate the rendering of specialized data formats in the client's display context. (The server application or object handler actually performs the rendering.) The client application has to do very little work to render the embedded or linked data in its

	display context. Such rendering of embedded or linked data is beyond the scope of the **DDEML** alone.
Activating embedded and linked objects	The OLE libraries support activating a server to edit a linked or embedded object or to render data. Activating servers for data rendering and editing is beyond the scope of the DDEML.
Creating objects and links from the clipboard	The OLE libraries do most of the work when an application is using the clipboard to copy and paste links or exchange objects. In contrast, DDE applications must call the Windows clipboard functions directly to perform such operations.
Creating objects and links from files	The OLE libraries provide direct support for using files to exchange data. No DDE protocol is defined for this purpose.

The OLE libraries use DDE messages instead of the **DDEML**, because the libraries were written before the DDEML was available.

Using OLE for Standard DDE Operations

Although most of the OLE application programming interface (API) was designed for linked and embedded objects, it can also be applied to standard DDE items. In particular, an application can use the OLE API to perform the following DDE tasks:

- Initializing conversations based on application and topic names or wildcards.
- Requesting data for named items in negotiated formats from a server.
- Establishing an advise loop--that is, requesting that a DDE server notify the client of changes to the values of specified items and, optionally, that the server send the data when the change occurs.
- Sending data from a server to a client.
- Poking data from a client to a server.
- Sending a DDE command. (This is supported by the **OleExecute** function.)

An OLE client application receives a pointer to an **OLEOBJECT** structure; this structure includes class name, document name, and item name information. These names correspond exactly to DDE counterparts, as follows:

OLE name	DDE name
Class name	Service name (formerly called "application name")
Document name	Topic name
Item name	Item name

The client can use the **OleCreateFromFile** function to make an object and specify all three names. If the client application needs multiple items from the same topic, it must have an **OLEOBJECT** structure for each item, which causes a DDE conversation to be created for each item.

The client library maps OLE functions that work on the **OLEOBJECT** structure to DDE messages as follows:

OLE function	DDE message
OleExecute	**WM_DDE_EXECUTE**
OleRequestData	**WM_DDE_REQUEST**
OleSetData	**WM_DDE_POKE**

Some functions (such as **OleActivate**) are too complicated for this one-to-one mapping of function to DDE message. For these functions, the DDE message depends on the circumstance.

If a client application needs to duplicate the functionality of **WM_DDE_ADVISE** with OLE, the client must create the link with **olerender_format** for the *renderopt* parameter, specify the required format, and use the **OleGetData** function to retrieve the value when the callback function receives the OLE_CHANGED

notification. If more than one item or format is required, the client must create an **OLEOBJECT** structure for each item/format pair. Although this method creates a conversation for each advise transaction, it may be inefficient if the client needs to create many such conversations.

A server application can make itself accessible to DDE by calling the **OleRegisterServer** function to make the System topic available and the **OleRegisterServerDoc** function to make other topics available. When a client connects and asks for an item, the server library calls the **GetObject** function in the server's **OLESERVERDOCVTBL** structure, followed by other server-implemented functions that are appropriate to the client's request. (Usually, the library calls the **GetData** function in the server's **OLEOBJECTVTBL** structure.) As long as the object allocated by the call to **GetObject** has not been released, the server should send a notification when the item has changed, so that the OLE libraries can send data to clients that have sent WM_DDE_ADVISE.

Using Both OLE and the DDEML

Some applications may need features supported only by OLE and may also need to use the **DDEML** to support simultaneous links for many items that are updated frequently. Client applications of this kind can use the OLE libraries to initiate conversations with OLE servers and the DDEML to initiate conversations with DDE servers.

Server applications that need to support both OLE and the **DDEML** must use different service names (DDE application names) for OLE and DDE conversations; otherwise, the OLE and DDEML libraries cannot determine which library should respond when an initiation request is received. Typically, the application changes the service name for the OLE conversation in this case, because other applications and the user must use the service name for the DDE conversation, but the OLE service name is hidden.

Data Transfer

Data Transfer in OLE

This section gives a brief overview of how applications share information under OLE. Details of the implementation are given in later sections of this topic.

Applications use three dynamic-link libraries (DLLs), OLECLI.DLL, OLESVR.DLL, and SHELL.DLL, to implement object linking and embedding. Object linking and embedding is supported by OLECLI.DLL and OLESVR.DLL. The registration database is supported by SHELL.DLL.

Client Applications

An OLE client application can accept, display, and store OLE objects. The objects themselves can contain any kind of data. A client application typically identifies an object by using a distinctive border or other visual cue, as described in *Microsoft Windows User Interface Guidelines.*

Server Applications

An OLE server is any application that can edit an object when the OLE libraries inform it that the user of a client application has selected the object. (Some servers can perform operations on an object other than editing.) When the user double-clicks an object in a client application, the server associated with that object starts and the user works with the object inside the server application. When the server starts, its window is typically sized so that only the object is visible. If the user double-clicks a linked object, the entire linked file is loaded and the linked portion of the file is selected. For embedded objects, the user chooses the Update command from the File menu to save changes to the object and chooses Exit when finished.

Many applications are capable of acting as both clients and servers for linked and embedded objects.

Object Handlers

Some OLE server applications implement an additional kind of OLE library called an object handler. Object handlers are dynamic-link libraries that act as intermediaries between client and server applications. Typically, an object handler is supplied by the developers of a server application as a way of improving performance. For example, an object handler could be used to redraw a changed object if the presentation data for that object could not be rendered by the client library.

Communication Between OLE Libraries

Client applications use functions from the OLE API to inform the client library, OLECLI.DLL, that a user wants to perform an operation on an object. The client library uses DDE messages to communicate with the server library, OLESVR.DLL. The server library is responsible for starting and stopping the server application, directing the interaction with the server's callback functions, and maintaining communication with the client library.

When a server application modifies an embedded object, the server notifies the server library of changes. The server library then notifies the client library, and the client library calls back to the client application, informing it that the changes have occurred. Typically, the client application then forces a repaint of the embedded object in the document file. If the server changes a linked object, the server library notifies the client library that the object has changed and should be redrawn.

Clipboard Conventions

When first embedding or linking an object, OLE client and server applications typically exchange data by using the clipboard. When a server application puts an object on the clipboard, it represents the object with data formats, such as Native data, OwnerLink data, ObjectLink data, and a presentation format. The order in which these formats are put on the clipboard is very important, because the order determines the type of object. For example, if the first format is Native and the second is OwnerLink, client applications can use the data to create an embedded object. If the first format is OwnerLink,

however, the data describes a linked object.

Native data completely defines an object for a particular server. The data can be meaningful only to the server application. The client application provides storage for Native data, in the case of embedded objects.

OwnerLink data identifies the owner of a linked or embedded object.

Presentation formats allow the client library to display the object in a document. CF_METAFILEPICT, CF_DIB, and CF_BITMAP are typical presentation formats. Native data can be used as a presentation format, typically when an object handler has been defined for that class of data. Native data cannot be used twice in the definition of an object, however; if the server puts Native and OwnerLink data on the clipboard to describe an embedded object, it cannot use Native data as a presentation format for that object. The ability of object handlers to use Native data as the presentation data accounts for the significance of the order of the formats: the order is the only way to distinguish between an embedded object and a link that uses Native data for its presentation.

ObjectLink data identifies a linked object's class and document and the item that is the source for the linked object. (If the item name specified in the ObjectLink format is NULL, the link refers to the entire server document.)

The following table describes the contents of the ObjectLink, OwnerLink, and Native clipboard formats:

Format name	Contents
ObjectLink	Null-terminated string for class name, null-terminated string for document name, string for item name with two terminating null characters.
OwnerLink	Null-terminated string for class name, null-terminated string for document name, string for item name with two terminating null characters.
Native	Stream of bytes interpreted only by the server application or object-handler library. This format can be unique to the server application and must allow the server to load and work with the object.

Although the ObjectLink and OwnerLink formats contain the same information, the OLE libraries use them differently. The libraries use OwnerLink format to identify the owner of an object (which can be different from the source of the object) and ObjectLink format to identify the source of the data for an object.

The class name in the ObjectLink or OwnerLink format is a unique name for a class of objects that a server supports. Server applications register the class name or names they support in the registration database. (For example, the class name used by Windows Paintbrush™ is PBrush.) An application can use the class name to look up information about a server in the registration database. (For more information about registration, see Registration.) The document name is typically a fully qualified path that identifies the file containing a document. The item name uniquely identifies the part of a document that is defined as an object. Item names are assigned by server applications; an item name can be any string that the server uses to identify part of a document. Items names cannot contain the forward-slash (/) character.

Data in OwnerLink or ObjectLink format could look like the following example:

```
Microsoft Excel Worksheet\0c:\directry\docname.xls\0R1C1:R5C3\0\0
```

The order in which various data formats are put on the clipboard depends on the type of data being copied to the clipboard and the capabilities of the server application. The following table shows the order of clipboard data formats for four different types of data selections. An object does not necessarily use all of the formats listed for it.

Source selection	Clipboard contents, in order
Embedded object	Native& OwnerLink& Picture or other presentation format (optional)& ObjectLink (included only if the server also supports links)
Linked object	OwnerLink& Picture or other presentation format (optional; for linked objects,

	this can be Native data)& ObjectLink
Pictorial data	Application-specific formats& Native& OwnerLink& Picture& ObjectLink
Structured data	Structured data formats (if selection is structured data only)& Native& OwnerLink& Picture, text, and so on& ObjectLink

Before copying data for an embedded or linked object to the clipboard, a server puts descriptions of the data formats on the clipboard. These data formats are listed in order of their level of description, from most descriptive to least. (For example, Microsoft Word would put rich-text format (RTF) onto the clipboard first, then the CF_TEXT clipboard format.)

When a user chooses the Paste command, the client application queries the formats on the clipboard and uses the first format that is compatible with the destination for the object. Because server applications put data onto the clipboard in order of their fidelity of description, the first acceptable format found by a client application is the best format for it to use. If the client application finds an acceptable format prior to the Native format, it incorporates the data into the target document without making it an embedded object. (For example, a Microsoft Word document would not make an embedded object from clipboard data that was in RTF format. Similarly, structured data or a structured document would be embedded into a drawing application but would be converted into the destination document's native data type if the destination were a worksheet or structured document.) If the client application cannot accept any of the data formats prior to Native and OwnerLink, it uses the Native and OwnerLink formats to make an embedded object and then finds an appropriate presentation format. The destination application may require different formats depending on where the selection is to be placed in the destination document; for example, pasting into a picture frame and pasting into a stream of text could require different formats.

When a user chooses the Paste Link command from the Edit menu, the client application looks for the ObjectLink format on the clipboard and ignores the Native and OwnerLink formats. The ObjectLink format identifies the source class, document, and object. If the application finds the ObjectLink format and a useful presentation format, it uses them to make an OLE link to the source document for the object. If the ObjectLink format is not available, the client application may look for the Link format and create a DDE link. This type of link does not support the OLE protocol.

When an application that does not support OLE copies from an OLE item on the clipboard, it ignores the Native, OwnerLink and ObjectLink formats; the behavior of the copying application does not change.

Registration

The registration database supports linked and embedded objects by providing a systemwide source of information about whether server applications support the OLE protocol, the names of the executable files for these applications, the verbs for classes of objects, and whether an object-handler library exists for a given class of object. For more information about this database, see The Windows Shell Overview.

When a server application is installed, it registers itself as an OLE server with the registration database. (This database is supported by the dynamic-link library SHELL.DLL.) To register itself as an OLE server, a server application records in the database that it supports one or more OLE protocols. The only protocols supported by version 1.*x* of the Microsoft OLE libraries are StdFileEditing and StdExecute. StdFileEditing is the current protocol for linked and embedded objects. StdExecute is used only by applications that support the **OleExecute** function. (A third name, Static, describes a picture than cannot be edited by using standard OLE techniques.)

When a client activates a linked or embedded object, the client library finds the command line for the server in the database, appends the **/Embedding** or **/Embedding** *filename* command-line option, and uses the new command line to start the server. Starting the server with either of these options differs from the user starting it directly. Either a slash (/) or a hyphen (-) can precede the word Embedding. For details about how a server reacts when it is started with these options, see Opening and Closing Objects.

The entries in the registration database are used whenever an application or library needs information about an OLE server. For example, client applications that support the Insert Object command refer to

the database in order to list the OLE server applications that could provide a new object. The client application also uses the registration database to retrieve the name of the server application for the Paste Special dialog box.

Registration Database

Applications typically add key and value pairs to the registration database by using Microsoft Windows Registration Editor (REGEDIT.EXE). Applications could also use the registration functions to add this information to the database.

The registration database stores keys and values as null-terminated strings. Keys are hierarchically structured, with the names of the components of the keys separated by backslash characters (\) . The class name and server path should be registered for every class the server supports. (This class name must be the same string as the server uses when it calls the **OleRegisterServer** function.) If a class has an object-handler library, it should be registered using the **handler** keyword. An application should also register all the verbs its class or classes support. (An application's verbs must be sequential; for example, if an object supports three verbs, the primary verb is 0 and the other verbs must be 1 and 2.)

To be available for OLE transactions, a server should register the key and value pairs shown in the following example when it is installed. This example shows the form of key and value pairs as they would be added to a database with Registration Editor. Although the text string sometimes wraps to the next line in this example, the lines should not include newline characters when they are added to the database.

HKEY_CLASSES_ROOT*class name* = *readable version of class name*
HKEY_CLASSES_ROOT\.*ext* = *class name*
HKEY_CLASSES_ROOT*class name*\protocol\StdFileEditing\server =
    executable file name
HKEY_CLASSES_ROOT*class name*\protocol\StdFileEditing\handler =
    dll name
HKEY_CLASSES_ROOT*class name*\protocol\StdFileEditing\verb\0 =
    primary verb
HKEY_CLASSES_ROOT*class name*\protocol\StdFileEditing\verb\1 =
    secondary verb

Servers that support the **OleExecute** function also add the following line to the database:

HKEY_CLASSES_ROOT*class name*\protocol\StdExecute\server =
    executable file name

An ampersand (&) can be used in the verb specification to indicate that the following character is an accelerator key. For example, if a verb is specified as &Edit, the E key is an accelerator key.

A server can register the entire path for its executable file, rather than registering only the filename and arguments. Registering only the filename fails if the application is installed in a directory that is not mentioned in the PATH environment variable. Usually, registering the path and filename is less ambiguous than registering only the filename.

Servers can register data formats that they accept on calls to the **OleSetData** function or that they can return when a client calls the **OleRequestData** function. Clients can use this information to initialize newly created objects (for example, from data selected in the client) or when using the server as an engine (for example, when sending data to a chart and getting a new picture back). Client applications should not depend on the requested data format, because the calls can be rejected by the server.

In the following example, *format* is the string name of the format as passed to the **RegisterClipboardFormat** function or is one of the system-defined clipboard formats (for example, CF_METAFILEPICT):

HKEY_CLASSES_ROOT*class name*\protocol\StdFileEditing
    \SetDataFormats = *format*[,*format*]

HKEY_CLASSES_ROOT*class name*\protocol\StdFileEditing
\RequestDataFormats = *format*[,*format*]

For compatibility with earlier applications, the system registration service also reads and writes registration information in the [embedding] section of the WIN.INI initialization file.

In the following example, the keyword **picture** indicates that the server can produce metafiles for use when rendering objects:

[embedding]
*classname=comment,textual class name,path/arguments,*picture

Version Control for Servers

Server applications should store version numbers in their Native data formats. New versions of servers that are intended to replace old versions should be capable of dealing with data in Native format that was created by older versions. It is sometimes important to give the user the option of saving the data in the old format, to support an environment with a mixture of new and old versions, or to permit data to be read by other applications that can interpret only the old format.

There can be only one application at a time (on one workstation) registered as a server for a given class name. The class name (which is stored with the Native data for objects) and the server application are associated in the registration database when the server application registers during installation.

If a new version of a server application allows the user to keep the old version available, a new class name should be allocated for the new server. A good way to do this is to append a version number to the class name. This allows the user to easily differentiate between the two versions when necessary. (The OLE libraries do not check these numbers.)

When the new version of the server is installed, the user should be given the option of either mapping the old objects to the new server (registering the new server as the server for both class names) or keeping them separate. When the user keeps them separate, the user will be aware of two kinds of object (for example, Graph1 and Graph2).

The user should be able to discard the old server version at a later time by remapping the registration database, typically with the help of the server setup program. To remap the database, the old and new objects are given the same value for *readable version of class name* (although their class names remain distinct). The OLE client library removes duplicate names when it produces the list in the Insert Object dialog box. When a client application produces a list by enumerating the registration database, the application must do this filtering itself.

Client User Interface

When a user opens a document that contains a linked or embedded object, the client application uses the OLE functions to communicate with OLECLI.DLL. This library assists the client application with such tasks as loading and drawing objects, updating objects (when necessary), and interacting with server applications.

New and Changed Commands

An OLE client application typically implements the following new or changed commands as part of its Edit menu. (Although this user interface is not mandatory, it is recommended for consistency with existing OLE applications.)

Command	Description
Copy	Copies an object from a document to the clipboard.
Cut	Removes an object from a document and places it on the clipboard.
Paste	Copies an object from the clipboard to a document.
Paste Link	Inserts a link between a document and the file that contains an object.

Class Name Object	Makes it possible for the user to activate the verbs for a linked or embedded object. The actual text used instead of the *Class Name* placeholder depends upon the selected object.
Links	Makes it possible for the user to change link updating options, update linked objects, cancel links, repair broken links, and activate the verbs associated with linked objects.
Insert Object	Starts the server application chosen by the user from a dialog box and embeds in a document the object produced by the server. This command is optional.
Paste Special	Transfers an object from the clipboard to a document or inserts a link to the object, using the data format chosen by the user from a dialog box. This command is optional.

In addition to the listed menu changes, client applications must also implement changes to their Copy and Cut commands. When a linked or embedded object is selected in the client application, the application can use the **OleCopyToClipboard** function to implement the Cut and Copy commands.

When the user chooses the Paste command, a client application should insert the contents of the clipboard at the current position in a document. If the clipboard contains an object, choosing this command typically embeds the object in the document.

When the user chooses the Paste Link command, the client library typically inserts a linked object at the current position in a document. The object is displayed in the document, but the Native data that defines that object is stored elsewhere.

If a user copies a linked object to the clipboard, other documents can use this object to produce a link to the original data.

The *Class Name* Object command allows the user to choose one of an object's verbs. If the selection in the document is an embedded object, the *Class Name* placeholder is typically replaced by the class and name of the object; for example, if a user selects an object that is a range of spreadsheet cells for Microsoft Excel, the text of the command might be "Microsoft Excel Worksheet Object." If an object supports only one verb, the name of the verb should precede the class name in the menu item; for example, if the only verb for a text object is Edit, the text of the command might be "Edit WPDocument Object." When an object supports more than one verb, choosing the *Class Name* Object command brings up a cascading menu listing each of the verbs.

For more information about verbs, see Verbs.

Choosing the Links command brings up a Links dialog box, which lists the selected links and their source documents and gives the user the opportunity to change how the links are updated, cancel the link, change the link, or activate the verbs for the link. A user can use this dialog box to repair links to objects that have been moved or renamed.

When the user chooses the Paste Special command, a client application should bring up a dialog box listing the data formats the client supports that are presently on the clipboard. The Paste Special dialog box makes if possible for the user to override the default behaviors of the Paste and Paste Link commands. For example, if the first format on the clipboard can be edited by the client application, the default behavior is for the client to copy the data into the document without making it into an object. The user could override this default behavior and create an object from such data by using the Paste Special command.

When the user chooses the Insert Object command, a client application should allow the user to insert an object of a specified class at the current position in a document. For example, to insert a range of spreadsheet cells in a text document, a user could choose the Insert Object command and select "Microsoft Excel Worksheet" from the dialog box. Selecting this item would start Microsoft Excel. The user would use Microsoft Excel to create the object to be embedded in the text document. When finished, the user would quit Microsoft Excel; the range of spreadsheet cells would automatically be embedded in the text document.

The Insert Object command is optional because a user could achieve the same results without it,

although the procedure is less convenient. To use the same example as that shown in the preceding paragraph, the user could leave the client application, start Microsoft Excel, and use the Microsoft Excel Cut or Copy command to transfer data to the clipboard. After returning to the client application, the user could choose the Paste command to move the data from the clipboard into the text document.

If the user chooses the Undo command after activating an object, all of the changes made since the object was last updated (or since the object was activated, if it has not been updated) are discarded and the object returns to its state prior to the update. The Undo command closes the connection to the server.

For more information about these commands, including illustrations of the dialog boxes, see *Microsoft Windows User Interface Guidelines.*

Using Packages

A package is an embedded graphical object that contains another object, which can be linked or embedded. For example, a user can package a file in an icon and embed the icon in an OLE document. Most of the packaging capabilities are provided by the dynamic-link library SHELL.DLL.

A user can put a package into an OLE document in a number of different ways:

- Copy a file from File Manager to the clipboard, and then choose the Paste or Paste Link command from the Edit menu in the client application.
- Drag a file from File Manager and drop it in the open window for a document in a client application.
- Select Package from the list of objects in the Insert Object dialog box. This starts Object Packager, with which the user can associate a file or data selection with an icon or graphic. Choosing Update and then Exit from Object Packager's File menu puts the package in the client document.
- Run Packager directly, following the steps outlined in the previous list item.

For information about how a client application should react when a user drops a file from File Manager in the client's window, see the description of the **OleCreateFromFile** function.

A user whose system does not include the Windows version 3.1 File Manager can follow these steps to create a package by using Object Packager:

- Copy to the clipboard the data to be packaged.
- Open Object Packager and paste the data into it. (At this point, the user could modify the default icon, the default label identifying the icon, or both.)
- Choose Copy Package from the Object Packager Edit menu to copy the package to the clipboard.
- Choose the Paste command from the Edit menu in the client application to embed the package.

For more information about Object Packager, see Packages, or *Microsoft Windows User Interface Guidelines.*

Server User Interface

A server for linked and embedded objects is any application that can be used to edit an object when the OLE libraries inform it that the user of a client application has activated the object. (Some servers can use verbs other than Edit to work with an object.) Although client applications implement many changes to the user interface to support OLE, the user interface does not change significantly for server applications.

OLE servers typically implement changes to the following commands in the Edit menu. (Although this user interface is not mandatory, it is recommended for consistency with existing OLE applications.)

Command	Description
Cut	Transfers data from the application to the clipboard, deleting the data from the source document. A client application can use this data to create an embedded object.
Copy	Transfers a copy of the data from the application to the clipboard. A client application can use this data to create an embedded object and may be able to establish a link to the source document.

Some menu items change names or behave differently when a server is started as part of activating an object from within a compound document. The exact behavior of the server depends on whether the server supports the multiple document interface (MDI).

Updating Objects from Multiple-Instance Servers

When an embedded object is edited or played by a multiple-instance server--that is, a server that does not support the multiple document interface (MDI), the Save command on the File menu should change to Update. (This change does not occur when a server starts for a linked object.) When the user chooses the Update command, the object in the client is updated but the focus remains with the server window. To close the server window, the user chooses the Exit command.

When the user chooses the Save As, New, or Open command, the application should display a warning message asking the user whether to update the object in the compound document before performing the action. The New and Open commands break the link between the client and server applications. The Save As command also breaks the link between the client and server if the server was editing an embedded object.

Updating Objects from Single-Instance Servers

The same rules for updating objects from multiple-instance servers apply to single-instance (MDI) servers, with the following differences:

- When the focus in an MDI server changes from a window in which an embedded object was activated to a window in which a document that does not contain an embedded object is being edited, the Update command should change back to Save.
- When the user chooses the New or Open command, the window containing the embedded object remains open. (This eliminates the need to prompt the user to update the object.)

Object Storage Formats

The presentation data in linked or embedded objects can be thought of as a presentation object. A presentation objects can be standard, generic, or NULL. A standard presentation object is used when the format is metafile, bitmap, or device-independent bitmap (DIB). The client library supports the presentation objects, including drawing them. Neither client applications nor object handlers can use the presentation objects; they are solely for the use of the client library.

The following list gives the storage format for strings in OLE. The items appear in the order listed.

Type	Description
LONG	Length of string, including terminating null character.
Variable	Null-terminated stream of bytes.

The following list gives the storage format for the standard presentation object used for linked and embedded objects. The items appear in the order listed.

Type	Description
LONG	OLE version number.
LONG	Format identifier. This value is 5.
Variable	Class string. For standard presentation objects, this string is **METAFILEPICT**, **BITMAP**, or DIB.
LONG	Width of object, in MM_HIMETRIC units.
LONG	Height of object, in MM_HIMETRIC units.
LONG	Size of presentation data, in bytes.
Variable	Presentation data.

The following list gives the storage format for the generic presentation object used for linked and embedded objects. Generic objects are used when the clipboard format is other than metafile, bitmap, or DIB. The items appear in the order listed.

Type	Description
LONG	OLE version number.
LONG	Format identifier. This value is 5.
Variable	Class string.
LONG	Clipboard format value. If this value exists, the next item in storage is the size of the presentation data.
LONG	Clipboard format name. This value exists only if the clipboard format value is NULL.
LONG	Size of presentation data, in bytes.
Variable	Presentation data.

The following list gives the storage format for embedded objects. The items appear in the order listed.

Type	Description
LONG	OLE version number.
LONG	Format identifier. This value is 2.
Variable	Class string.
Variable	Topic string.
Variable	Item string.
LONG	Size of Native data, in bytes.
Variable	Native data.
Variable	Presentation object (standard, generic, or NULL).

The following list gives the storage format for linked objects. The items appear in the order listed.

Type	Description
LONG	OLE version number.
LONG	Format identifier. This value is 1.
Variable	Class string.
Variable	Topic string.
Variable	Item string.
Variable	Network name string.
short	Network type.
short	Network driver version number.
LONG	Link update options.
Variable	Presentation object (standard, generic, or NULL).

The following list gives the storage format for static objects. The only difference between the format for static objects and the format for standard presentation objects is the value of the format identifier. The items appear in the order listed.

Type	Description
LONG	OLE version number.
LONG	Format identifier. This value is 3.
Variable	Class string. For static objects, this string is **METAFILEPICT**, **BITMAP**, or DIB.
LONG	Width of object, in MM_HIMETRIC units.
LONG	Height of object, in MM_HIMETRIC units.
LONG	Size of presentation data, in bytes.
Variable	Presentation data.

Client Applications

Client Applications

A client application uses a server application to activate and render an object contained by a compound document. A client application provides storage for embedded objects, such contextual information as the target printer and page position, and a means for the user to activate the object and the server application associated with that object. Client applications also provide ways of putting embedded and linked objects into a document and taking them out again.

Client applications must provide permanent storage for objects in the compound document's file. When an item being saved is an embedded object, the client library stores the object's Native data, the presentation data for the object (for example, a metafile), and the OwnerLink information. When the item being saved is a link to another document, the client library stores the presentation data and the ObjectLink format.

Client applications accommodate asynchronous operations by defining a callback function to which the library sends notifications about current operations. As long as the client continues to dispatch messages, it can react to the notifications being sent to the callback function and to input from the user. For more information about asynchronous operations, see Asynchronous Operations.

Starting a Client Application

When a client application starts, it should follow these steps:

1 Register the clipboard formats that it requires.

2 Allocate and initialize as many **OLECLIENT** structures as required.

3 Allocate and initialize an **OLESTREAM** structure.

A client application can register the clipboard formats by calling the **RegisterClipboardFormat** function for each format, specifying such formats as Native, OwnerLink, ObjectLink, and any other formats it requires.

A client application uses two structures to receive information from the client library: **OLECLIENT** and **OLESTREAM**.

The **OLECLIENT** structure points to an **OLECLIENTVTBL** structure, which in turn points to a callback function supplied by the client application. The OLE libraries use this callback function to notify the client of any changes to an object. The parameters for the callback function are a pointer to the client structure, a pointer to the relevant object, and a value giving the reason for the notification. Typically, an application creates one **OLECLIENT** structure for each **OLEOBJECT** structure. Having a separate **OLECLIENT** structure for each object allows an application to take object-specific action in response to the OLE_QUERY_PAINT callback notification.

The **OLECLIENT** structure can also point to data that describes the state of an object. This data, when present, is supplied and used only by the client application. The client application allocates a separate **OLECLIENT** structure for each object and stores state information about that object in the structure. Because one argument to the callback function is a pointer to the **OLECLIENT** structure, this is an efficient method of retrieving the object's state information when the callback function is called.

The **OLESTREAM** structure points to an **OLESTREAMVTBL** structure, which is a table of pointers to client-supplied functions for stream input and output. The client libraries use these functions when loading and saving objects. A client can customize functions for particular situations, and a client can make such changes as varying the permanent storage for an object; for example, a client could store an object in a database, instead of in a file with the rest of the document.

The client application should create a pointer to the callback function in the **OLECLIENTVTBL** structure and pointers to the functions in the **OLESTREAMVTBL** structure by using the **MakeProcInstance** function. Callback functions should be exported in the module-definition file.

Opening a Compound Document

To open a compound document, a client application should take the following steps:

1 Register the document with the client library.

2 Load the document data from a file.

3 For each object in the document, call the **OleLoadFromStream** function.

4 List any objects with manual links so that the user can update them. Automatically update any automatic links.

The **OleRegisterClientDoc** function registers a document with the client library and returns a handle that is used in object-creation functions and document-management functions. (This registration does not involve the registration database.)

A client application should call the **OleLoadFromStream** function for each object in the document that will be shown on the screen or otherwise activated. (It is often not necessary to load every object in a document immediately when the document is opened.) Parameters for this function include a pointer to the **OLECLIENT** structure, which is used to locate the client's callback function (and which is sometimes used by the client to store private state information for the object), and a pointer to the **OLESTREAM** structure. The library calls the **Get** function in the **OLESTREAMVTBL** structure to load the object.

Document Management

A client application should notify the library when it opens, closes, saves, or renames a document, or causes a document to revert to a previously saved state. A client application can use the following functions to accomplish these tasks:

Function	Description
OleRegisterClientDoc	Registers an opened document with the library.
OleRenameClientDoc	Informs the library that a document has been renamed.
OleRevertClientDoc	Informs the library that a document has reverted to a previously saved state.
OleRevokeClientDoc	Informs the library that a document should be closed or no longer exists.
OleSavedClientDoc	Informs the library that a document has been saved.

A client application should also maintain a persistent name for each object. This name should be unique within the scope of the client document and should be stored with the document. This name is specified when the object is created and should persist when the document is saved and reopened. When a client uses the **OleRename** function to change the name of an object, the new name must also be unique and must be stored with the document.

Saving a Document

A client application should follow these steps to save a document:

1 Save the data for the document in the document's file.

2 For each object in the document, call the **OleSaveToStream** function.

3 When the library confirms that all objects have been saved, call the **OleSavedClientDoc** function.

A client application can call the **OleQuerySize** function to determine the size of the buffer required to store an object before calling **OleSaveToStream**.

Closing a Document

A client application should follow these steps to close a document:

1 For each object in the document, call the **OleRelease** function.

2 Use either the **OleRevertClientDoc** or the **OleSavedClientDoc** function to register the current

state of the document with the library.

3 When the library confirms that all objects have been closed, call the **OleRevokeClientDoc** function.

Asynchronous Operations

When a client application calls a function that invokes a server application, actions taken by the client and server can be asynchronous. For example, the actions of updating a document and closing a server are asynchronous. Whenever an asynchronous operation begins, the client library returns OLE_WAIT_FOR_RELEASE. When a client application receives this notification, it must wait for the OLE_RELEASE notification before it quits. If the client cannot take further action until the asynchronous operation finishes, it should enter a message-dispatch loop and wait for OLE_RELEASE. Otherwise, it should allow the main message loop to continue dispatching messages so that processing can continue.

An application can run only one asynchronous operation at a time for an object; each asynchronous operation must end with the OLE_RELEASE notification before the next one begins. The client's callback function must receive OLE_RELEASE for all pending asynchronous operations before calling the **OleRevokeClientDoc** function.

Some of the object-creation functions return OLE_WAIT_FOR_RELEASE. The client application can continue to work with the document while waiting for OLE_RELEASE, but some functions (for example, **OleActivate**) cannot be called until the asynchronous operation has been completed.

If an application calls a function for an object before receiving OLE_RELEASE for that object, the function may return OLE_BUSY. The server also returns OLE_BUSY when processing a new request would interfere with the processing of a current request from a client application or user. When a function returns OLE_BUSY, the client application can display a message reporting the busy condition at this point or it can enter a loop to wait for the function to return OLE_OK. (The OLE_QUERY_RETRY notification is also sent to the client's callback function when the server is busy; when the callback function returns FALSE, the transaction with the server is ended.) Note that if the server uses the **OleBlockServer** function to postpone OLE activities, the OLE_QUERY_RETRY notification is not sent to the client.

The following example shows a message-dispatch loop that allows a client application to transact messages while waiting for the OLE_RELEASE notification:

```
while ((olestat = OleQueryReleaseStatus(lpObject)) == OLE_BUSY) {
    if (GetMessage(&msg, NULL, NULL, NULL)) {
        TranslateMessage(&msg);
        DispatchMessage(&msg);
    }
}
if (olestat == OLE_ERROR_OBJECT) {
    .
    .  /* The lpObject parameter is invalid. */
    .
}
else { /* if olestat == OLE_OK */
    .
    . /* The object is released, or the server has terminated. */
    .
}
```

A server application could end unexpectedly while a client is waiting for OLE_RELEASE. In this case, the client library recovers properly only if the client uses the **OleQueryReleaseStatus** function, as shown in the preceding example.

The following table shows which OLE functions can return the OLE_WAIT_FOR_RELEASE or

OLE_BUSY value to a client application:

Function	OLE_BUSY	OLE_WAIT_FOR_RELEASE
OleActivate	Yes	Yes
OleClose	Yes	Yes
OleCopyFromLink	Yes	Yes
OleCreate	No	Yes
OleCreateFromClip	No	Yes
OleCreateFromFile	No	Yes
OleCreateFromTemplate	No	Yes
OleCreateLinkFromClip	No	Yes
OleCreateLinkFromFile	No	Yes
OleDelete	Yes	Yes
OleExecute	Yes	Yes
OleLoadFromStream	No	Yes
OleObjectConvert	Yes	No
OleReconnect	Yes	Yes
OleRelease	Yes	Yes
OleRequestData	Yes	Yes
OleSetBounds	Yes	Yes
OleSetColorScheme	Yes	Yes
OleSetData	Yes	Yes
OleSetHostNames	Yes	Yes
OleSetLinkUpdateOptions	Yes	Yes
OleSetTargetDevice	Yes	Yes
OleUnlockServer	No	Yes
OleUpdate	Yes	Yes

Displaying and Printing Objects

When an object has been loaded and, if necessary, brought up to date, the object can be displayed or printed with the container document. To display an object, the client application should set up the device context and bounding rectangle (ensuring that they use the same mapping mode) and then call the **OleDraw** function. The client application can use the **OleQueryBounds** function to retrieve the size of the bounding rectangle on the target device.

An object handler can be used to draw an object. If an object handler exists for an object, the call to the **OleDraw** function is received and processed by the object handler. If there is no object handler, the client library uses the object's presentation data to display or print the object.

If the presentation data for an object is a metafile, the library periodically sends an OLE_QUERY_PAINT notification to the client's callback function while drawing the object. If the callback function returns FALSE, the **OleDraw** function returns immediately and the drawing is ended. A client could also use the OLE_QUERY_PAINT notification to take some actions within the callback function and then return TRUE to indicate that drawing should continue. Any actions the client takes at this time should not interfere with the drawing operation; for example, the client should not scroll the window.

If the target device for an object changes (for example, when the user changes printers), the client application should call the **OleSetTargetDevice** function. The client should also call **OleSetTargetDevice** whenever an object is created or loaded.

If the size of the presentation rectangle for the object changes (for example, through action by the

user) the client application should call the **OleSetBounds** function. After calling **OleSetBounds**, the client should call the **OleUpdate** function to update the object and then **OleDraw** to redisplay it.

Opening and Closing Objects

When the user requests the client application to activate an object, the client should check whether the object is busy by calling the **OleQueryReleaseStatus** function. If the object is busy, the client should either refuse the request to open the object or enter a message-dispatch loop, waiting for the OLE_RELEASE notification.

If the object to be activated is not busy, the client should call the **OleActivate** function. The library notifies the client when the server is open or when an error occurs.

The **OleActivate** function allows the client application to specify whether to display the activated object in a window of the server application. A client might hide the server window if an object is updated automatically.

A client application can use the **OleQueryOpen** function to determine whether a specified object is open. The **OleClose** function allows the client to close an open object. Closing an object terminates the connection with the server. To reestablish a terminated connection between a linked object and an open server, the client can use the **OleReconnect** function. To close an open object and release it from memory, a client application can call the **OleRelease** function.

The first time a client application activates a particular embedded object, the client should call the **OleSetHostNames** function, specifying the string the server window should display in its title bar. This string should be the name of the client document containing the object. The client does not need to call **OleSetHostNames** every time an embedded object is activated, because the library maintains a record of the specified names.

Deleting Objects

To permanently delete an object from a document, the client should call the **OleDelete** function. **OleDelete** closes the specified object, if necessary, before deleting it.

Client Cut and Copy Commands

A client application can copy an object to the clipboard by simply opening the clipboard, calling the **OleCopyToClipboard** function, and closing the clipboard again. If the client supports delayed rendering, however, it should follow these steps to cut or copy an object to the clipboard:

1 Open and empty the clipboard.

2 Put the preferred data formats on the clipboard.

3 Call the **OleEnumFormats** function to retrieve the formats for the object.

4 Call the **SetClipboardData** function to put the formats on the clipboard, specifying NULL for the handle of the data.

   If the call to the **OleEnumFormats** function retrieves the ObjectLink format, the client should call **SetClipboardData** with OwnerLink instead of ObjectLink format. (For more information, see the following description of the **OleCopyToClipboard** function.)

5 Put any additional presentation data formats on the clipboard.

6 Close the clipboard.

To support the Cut command on the Edit menu, an application can call **OleCopyToClipboard** and then delete the object by using the **OleDelete** function. (The client can put only one of the selected objects on the clipboard, even when the user has selected and cut or copied multiple objects. In this case, the client typically puts the first object in the selection onto the clipboard.)

The **OleCopyToClipboard** function always copies OwnerLink format, not ObjectLink format, to the clipboard. For embedded objects, Native data always precedes the OwnerLink format. If a linked object

uses Native data, OwnerLink format always precedes the Native data. If an application uses the **OleGetData** function to retrieve data from a linked object that has been copied by using **OleCopyToClipboard**, it should specify ObjectLink format, not OwnerLink format, even if OwnerLink format was put on the clipboard.

When an application that can act as both a client and server copies a selection to the clipboard that contains one or more objects, it should first allocate enough memory for the selection. To discover how much memory is required for each object, the application can call the **OleQuerySize** function. When memory has been allocated, the application should call the **OleRegisterClientDoc** function, specifying Clipboard for the document name. (In this case, the handle returned by the call to **OleRegisterClientDoc** identifies a document that is used only during the copy operation.) To save each object to memory, the application calls the **OleClone** function, calls the **OleSaveToStream** function for the cloned object, and then calls the **OleRelease** function to free the memory for the cloned object. When the selection has been saved to the stream, the application can call the **SetClipboardData** function. If **SetClipboardData** is successful, the application should call the **OleSavedClientDoc** function. The application then calls the **OleRevokeClientDoc** function, specifying the handle retrieved by the call to **OleRegisterClientDoc**.

For more information about the Cut and Copy commands, see Server Cut and Copy Commands.

Creating Objects

A client application can put linked and embedded objects in a document by pasting them from the clipboard, creating them from a file, copying them from other objects, or by starting a server application to create them directly.

Object-Creation Functions

Each of the following functions creates an embedded or linked object in a specified document:

Function	Description
OleClone	Creates an exact copy of an object.
OleCopyFromLink	Creates an embedded object that is a copy of a linked object.
OleCreate	Creates an embedded object of a specified class.
OleCreateFromClip	Creates an object from the clipboard. This function typically creates an embedded object.
OleCreateFromFile	Creates an object by using the contents of a file. This function typically creates an embedded object.
OleCreateFromTemplate	Creates an embedded object by using another object as a template.
OleCreateInvisible	Creates an object without displaying the server application to the user.
OleCreateLinkFromClip	Creates an object by using information on the clipboard. This function typically creates a linked object.
OleCreateLinkFromFile	Creates an object by using the contents of a file. This function typically creates a linked object.
OleObjectConvert	Creates an object that supports a specified protocol by converting an existing object.

Each of these functions requires a parameter that points to an **OLEOBJECT** structure when the function returns. Server applications often create an **OLEOBJECT** structure whenever an object is created; **OLEOBJECT** points to functions that describe how the server interacts with the object. Before the client library gives the client application a pointer to this structure, the library includes with the structure some internal information corresponding to the OwnerLink or ObjectLink data. This internal information allows the client library to identify the correct server when an OLE function such as **OleActivate** passes it a pointer to an **OLEOBJECT** structure. For more information about the **OLEOBJECT** structure, see Starting a Server Application.

Each new object must have a name that is unique to the client document. Although meaningful object

names can be helpful, some applications assign unique object names simply by incrementing a counter for each new object. For more information about object names, see Document Management.

If a client application implements the Insert Object command, it should use the registration database to find out what OLE servers are available and then list those servers for the user. When the user selects one of the servers and chooses the OK button, the client can use the **OleCreate** function to create an object at the current position.

The **OleCopyFromLink**, **OleCreate**, and **OleCreateFromTemplate** functions always create an embedded object. The other object-creation functions can create either an embedded object or a linked object, depending on the order and type of available data.

If a client application's callback function receives the OLE_RELEASE notification after the client calls the **OleCreate** or **OleCreateFromFile** function, the client should respond by calling the **OleQueryReleaseError** function. If **OleQueryReleaseError** shows that there was an error when the object was created, the client application should delete the object.

Whenever an object-creation function returns OLE_WAIT_FOR_RELEASE, the calling application should either wait for the OLE_RELEASE notification or notify the user that the object cannot be created. For more information, see Asynchronous Operations.

If a client application accepts files dropped from File Manager, it should respond to the **WM_DROPFILES** message by calling the **OleCreateFromFile** function and specifying Packager for the lpszClass parameter.

Paste and Paste Link Commands

A client application should follow these steps to create an embedded or linked object by pasting from the clipboard:

1. Call the **OleQueryCreateFromClip** function to determine whether to enable the Paste command. If this function fails when StdFileEditing is specified for the *lpszProtocol* parameter, call it again, specifying Static.
2. Call the **OleQueryLinkFromClip** function to determine whether to enable the Paste Link command.

- If the user chooses the Paste command, open the clipboard and call the **OleCreateFromClip** function.
- If the user chooses Paste Link, open the clipboard and call the **OleCreateLinkFromClip** function.

3. Close the clipboard.
4. Call the **OleQueryType** function to determine the kind of object created by the creation function. (Depending on the order of clipboard data, **OleCreateFromClip** can sometimes create a linked object and **OleCreateLinkFromClip** can sometimes create an embedded object.)

The client application should put the pasted data or object into the document at the current position. The client should select the object so that the user can work with it immediately. If both the **OleQueryCreateFromClip** and **OleQueryLinkFromClip** functions fail but there is data on the clipboard that the client can interpret, the client should enable the Paste command.

If the information on the clipboard is incomplete--for example, if Native data is not accompanied by the OwnerLink format--the Paste command should insert a static object into the document. (A static object consists of the presentation data for an object; it cannot be edited by using standard OLE techniques. Attempts to open static objects fail and generate no notifications.)

If the client application implements the Paste Special command, it should use the **EnumClipboardFormats** function to produce a list of data formats on the clipboard. The client should also check the registration database to find the full name of the server application. The Paste Link button in the Paste Special dialog box works in exactly the same way as the Paste Link command on the Edit menu.

If the DDE Link format is available on the clipboard instead of ObjectLink format, the client application

should perform the same link operation that it supported prior to the implementation of OLE.

Undo Command

A client application can use the **OleClone** function to support the Undo command. A cloned object is identical to the original except for connections to the server application; the cloned object is not automatically connected to the server. When the server is closed and the object is updated, the saved copy of the object gives the user the opportunity to undo all of the changes made in the server. Support for the Undo command is provided by the client application, because the server cannot maintain a record of the prior states of objects.

The Undo command restores an object to its condition prior to the last update from the server. To support this behavior, the client application must clone the object when it is first activated and then clone the updated object when an update occurs; the client must maintain two clones of the object. The clone of the original object must be maintained so that an updated object can be restored if the user chooses the Undo command. The clone of the updated object must be maintained to support the Undo command if the updated object is updated again. Because the data changes when the update occurs, the clone for supporting the Undo command must be made before any updates occur.

Because the client application cannot distinguish between different types of object activation, the client must clone an object for verbs that do not edit the object, even though no updates can occur in those cases.

Class Name Object Command

A client application can implement the *Class Name* Object command by using the **OleActivate** function. **OleActivate** includes a parameter that allows the client to specify the verb chosen by the user.

Links Command

When a user chooses the Links command, a dialog box appears listing every linked object in the document. The selected links are highlighted in the dialog box. The dialog box makes it possible for the user to invoke the verbs for an object, select whether link updating should be automatic or manual, update a link immediately, cancel a link, and repair broken links. For more information about this dialog box, see *Microsoft Windows User Interface Guidelines.*

The Links dialog box includes buttons that allow the user to activate the primary and secondary verbs for an object. A client application can implement these buttons by using the **OleActivate** function.

A client application can use the **OleGetLinkUpdateOptions** and **OleSetLinkUpdateOptions** functions to support the link-update radio buttons in the Links dialog box. The following are the three possible update options:

Option	Description
oleupdate_always	Update the linked object whenever possible. This option supports the Automatic link-update radio button in the Links dialog box.
oleupdate_onsave	Update the linked object when the source document is saved by the server.
oleupdate_oncall	Update the linked object only on request from the client application. This option supports the Manual link-update radio button in the Links dialog box.

These update options control when updates to the presentation of an object occur. The contents of the source document are used to update the presentation whenever the link is activated.

To support the Update Now button in the Links dialog box, an application can call the **OleUpdate** function. When a user chooses Update Now, the client application should update the links the user selected.

A user's choosing the Cancel Link button in the Links dialog box changes an object into a picture that an application cannot edit by using standard OLE techniques. An application can implement the Cancel Link button by using the **OleObjectConvert** function.

A client application should activate the Change Link button in the Links dialog box only if all the selected links are to the same source document. When the client has the correct information, it can repair the link by using the **OleGetData** and **OleSetData** functions. To retrieve the link information for an object, a client can call the **OleGetData** function, specifying the ObjectLink format. (The call to **OleGetData** fails if ObjectLink is specified and the object is not a link.) A client can retrieve class information by using **OleGetData** and specifying either the OwnerLink format (for embedded objects) or the ObjectLink format (for linked objects). The client can make it possible for the user to edit the link information and store it in the object by using the **OleSetData** function, specifying the ObjectLink format.

Closing a Client Application

A client application should use the **OleRelease** function to remove all objects from memory when it shuts down. If the library returns the OLE_WAIT_FOR_RELEASE value instead of OLE_OK, the client should not quit. The client can perform many cleanup tasks while waiting for the OLE_RELEASE notification--for example, it can close files, free memory, and hide windows.

The OLE_RELEASE notification to the client's callback function indicates that an operation has finished in a server application, but it does not identify the operation or indicate whether the operation was successful. A client application can call the **OleQueryReleaseStatus** function to determine whether an operation has been completed for a specified object. The **OleQueryReleaseMethod** function indicates the nature of the operation that has finished for a specified object. To discover the error value for the operation, the client can call the **OleQueryReleaseError** function.

If a client owns the clipboard when it quits, it should make sure that the data on the clipboard is complete and in the correct order.

Server Applications

Server Applications

An OLE server supplies functions that the server library calls when a user works with an object. The server library, OLESVR.DLL, uses DDE commands to communicate with the client library. When the client application calls one of the functions in the OLE API, the client library informs the server library and the server library routes the request to the appropriate function in the server-supplied list of function pointers.

In addition to the specialized functions that the server creates and which are called by the server library, there are ten OLE functions that allow a server to control the library's ability to gain access to the server and the documents and objects it controls:

Function	Description
OleBlockServer	Queues requests to the server until the server calls the **OleUnblockServer** function.
OleRegisterServer	Registers the specified server with the library. Information registered includes the class name and instance and whether the server supports single or multiple instances.
OleRegisterServerDoc	Registers a document with the server library.
OleRenameServerDoc	Renames the specified document.
OleRevertServerDoc	Restores a document to a previously saved state, without closing the document.
OleRevokeObject	Revokes access to the specified object.
OleRevokeServer	Revokes access to the specified server, closing any documents and ending communication with client applications.
OleRevokeServerDoc	Revokes access to the specified document.
OleSavedServerDoc	Informs the library that a document has been saved. Calling this function is equivalent to sending the OLE_SAVED notification.
OleUnblockServer	Processes a request from a queue created when the server application called the **OleBlockServer** function.

The **OleRevokeServer** and **OleRevokeServerDoc** functions can return OLE_WAIT_FOR_RELEASE. When a server application receives this error value, it should take the same action as a client application, dispatching messages until the server library calls the corresponding **Release** function.

Starting a Server Application

When a server application starts, it should follow these steps:

1. Register window classes and window procedures for the main window, documents, and objects.
2. Initialize the function tables for the **OLESERVERVTBL**, **OLESERVERDOCVTBL**, and **OLEOBJECTVTBL** structures.
3. Register the clipboard formats.
4. Allocate memory for the **OLESERVER** structure.
5. Register the server with the library by calling the **OleRegisterServer** function.
6. Check for the **/Embedding** and **/Embedding** *filename* options on the command line and act according to the following guidelines. (Applications should also check for **-Embedding** whenever they check for these options.)

- If neither **/Embedding** nor **/Embedding** *filename* is present, call the **OleRegisterServerDoc** function, specifying an untitled document.

- If the **/Embedding** option is present, do not register a document or display a window. (In this case, the server takes actions only in response to calls from the server library.)
- If the **/Embedding** *filename* option is present, do not display a window. Process the filename string and call the **OleRegisterServerDoc** function.

The **OLESERVERVTBL**, **OLESERVERDOCVTBL**, and **OLEOBJECTVTBL** structures are tables of function pointers. The server library uses these structures to route requests from the client application to the server. The server application should create the function pointers in these structures by using the **MakeProcInstance** function. The functions should also be exported in the application's module-definition file.

The **OLESERVER** structure contains a pointer to an **OLESERVERVTBL** structure. The **OLESERVERVTBL** structure contains pointers to functions that control such fundamental server tasks as opening files, creating objects, and terminating after an editing session. Several of the functions pointed to by the **OLESERVERVTBL** structure cause the server to allocate and initialize an **OLESERVERDOC** structure.

The **OLESERVERDOC** structure contains a pointer to an **OLESERVERDOCVTBL** structure. The **OLESERVERDOCVTBL** structure contains pointers to functions that control such tasks as saving or closing documents or setting document dimensions. The **OLESERVERDOCVTBL** structure also contains a function that causes the server to allocate and initialize an **OLEOBJECT** structure.

The **OLEOBJECT** structure contains a pointer to an **OLEOBJECTVTBL** structure. The **OLEOBJECTVTBL** structure contains pointers to functions that operate on objects. After the server application creates an **OLEOBJECT** structure, the server library gives information about the structure to the client library. The client library then creates a parallel **OLEOBJECT** structure (including internal information identifying the server application, the document, and the item for the object) and passes a pointer to that structure to the client application.

This hierarchy of structures--**OLESERVER**, **OLESERVERDOC**, and **OLEOBJECT**--makes it possible for a server to open as many documents as the library requests and for each document to contain as many objects as necessary.

A server application can register the clipboard formats by calling the **RegisterClipboardFormat** function for each format, specifying Native, OwnerLink, ObjectLink, and any other formats it requires.

When the server application starts, it creates an **OLESERVER** structure and then registers it with the library by calling the **OleRegisterServer** function. When this function returns, one of its parameters points to a server handle. The library uses this handle of refer to the server, and the server uses it in calls to the server-specific OLE functions.

If an OLE server application is also a DDE server, the class name specified in the call to the **OleRegisterServer** function cannot be the same as the name of the executable file for the application.

When a client working with a compound document opens a linked or embedded object for editing, the client library starts the server using the **/Embedding** command-line option. The server uses this option to determine whether the object has been opened directly by a user or as part of an editing session for linked and embedded objects. (If the object is a linked object, the **/Embedding** option is followed by a filename.) When a server is started for an embedded object with the **/Embedding** option, the server should not create a document or show a window. Instead, it should call the **OleRegisterServer** function and then enter a message-dispatch loop. (If the server is started with the **/Embedding** *filename* option, it should also call the **OleRegisterServerDoc** function.) The server then takes actions in response to calls from the library. The server should not make itself visible until the library calls the **Show** or **DoVerb** function in the **OLEOBJECTVTBL** structure. (Server applications should check for both -Embedding and /Embedding.)

By calling the **OleBlockServer** function, a server application can cause requests from the client library to be saved in a queue. When the server is ready for the server library to process the requests, it can call the **OleUnblockServer** function. It is best to use the **OleUnblockServer** function prior to the **GetMessage** function in a message loop, so that all blocked requests are unblocked before getting the next message. (Often a server returns OLE_BUSY instead of calling **OleBlockServer**. Returning

OLE_BUSY has two advantages: It allows the client to decide whether to retry the message or discontinue the operation, and it allows the server to choose which requests to process.)

When an error occurs in a server-supplied function, the server should return the **OLESTATUS** error value that best describes the error. The OLE libraries use these error values to help determine the appropriate behavior in error situations. However, the client application does not necessarily receive the error values the server returns; the OLE libraries may change error values before passing them to the client application.

Opening a Document or Object

Whenever the server library calls the **Open**, **Create**, **CreateFromTemplate**, or **Edit** function in the **OLESERVERVTBL** structure, the server creates an **OLESERVERDOC** structure. If the document is opened by a call from the server library, the server application returns the **OLESERVERDOC** structure to the library. If the document is opened directly by a user, however, the server should call the **OleRegisterServerDoc** function to register the document with the library. The library then uses the **GetObject** function in the **OLESERVERDOCVTBL** structure to request the server to create an **OLEOBJECT** structure for each object requested by the client application.

A new instance of the server application is typically started when the client activates a linked or embedded object. This new instance is unnecessary if the object is already open in an instance of the server or if the server is a single-instance (MDI) server that is already open. For more information about the rules for starting new instances of server applications, see *Microsoft Windows User Interface Guidelines.*

Whether the server library starts a new instance of a server to edit an embedded or linked object depends upon the value specified when the server calls the **OleRegisterServer** function.

Server Cut and Copy Commands

A server application should follow these steps to cut or copy onto the clipboard data that a client can then use to create an embedded or linked object:

1 Open and empty the clipboard.

2 Put the data formats that describe the selection on the clipboard, using the **SetClipboardData** function.

3 Close the clipboard.

If the server cuts data onto the clipboard, rather than copying it, the server typically does not offer ObjectLink or Link formats, because the source for the data has been removed from the document.

The server should put data on the clipboard in the order given in Clipboard Conventions.

Typically, the server puts server-specific formats, Native format, OwnerLink format, and presentation formats on the clipboard. If it can support links, the server also puts ObjectLink format and, when appropriate, Link format on the clipboard. The server must provide a presentation format (CF_METAFILE, CF_BITMAP, or CF_DIB) if the server does not have an object handler. Native data can be used as a presentation format only if the server has an object handler that can use the Native data.

If a user copies onto the clipboard a selection that includes an embedded object or a link, the data formats the server should copy depend upon whether the container document modifies the object or link. If the document does not modify the object or link, the best formats are the Native and OwnerLink formats from the original source of the object. If the document modifies the object or link--for example, by recoloring it--the best formats are the Native and OwnerLink formats from the container document.

If a server uses a metafile as the presentation format for an object, the mapping mode for that metafile must be MM_ANISOTROPIC. When a server application uses fonts in these metafiles, it can improve performance by using TrueType fonts. (Metafiles scale better when they use TrueType fonts.) To use TrueType fonts exclusively, the server should set bit 2 (04h) of the **lpPitchandFamily** member of the **LOGFONT** structure.

The OLE libraries express the size of every object in MM_HIMETRIC units. Neither the width nor height of an object should exceed 32,767 in MM_HIMETRIC units.

Update, Save As, and New Commands

When a server is started as part of editing an object from within a compound document, the server application should change the Save command on the File menu to Update. When the user chooses the Update command, the server should call the **OleSavedServerDoc** function.

When the user chooses the Save As, New, or Open command in a single-document server, the application should display a message asking the user whether to update the object in the compound document before performing the action. When the user chooses the Save As command, the server should call the **OleRenameServerDoc** function. If the user responds to the message by choosing to save changes in the object before renaming the document, the server should call the **OleSavedServerDoc** function before calling **OleRenameServerDoc**. For embedded objects, choosing the Save As command causes the connection with the client to be broken, because this command reassociates a document in memory with the specified new file. For linked objects, calling **OleRenameServerDoc** when the user chooses Save As makes it possible for the client to associate the link with the new file.

Most server applications maintain a "dirty" flag that records whether changes have been made to each open document in an instance. The following table shows the rules that apply to this flag when the server edits an embedded object. By following these rules, a server can ensure that this flag is TRUE when the document being edited in the server matches the embedded object in the client and that, otherwise, this flag is FALSE.

Flag	Condition
TRUE	Library calls the **Create** function in the **OLESERVERVTBL** structure.
TRUE	Library calls the **CreateFromTemplate** function in **OLESERVERVTBL**.
TRUE	Document is changed in server.
FALSE	Library calls the **Edit** function in **OLESERVERVTBL**.
FALSE	Library calls the **GetData** function in **OLEOBJECTVTBL** with the Native data format. (The flag should not change for any other formats.)

A server following these rules displays the message asking whether to update the object whenever it destroys a document that was editing an embedded object and the "dirty" flag is TRUE.

In an MDI server application, the New and Open commands on the File menu simply open a new window, and the connection with the client application remains unchanged. The user can continue to work with the server application after choosing one of these commands, but when the user exits the server application, the focus does not necessarily return to the client application.

Typically, a server can call the **OleSavedServerDoc** function whenever an object needs to be updated in the client document, including when the server closes the document. When the server closes the document and the object should be updated, the server sends the OLE_CLOSED notification. Client applications receive the OLE_CLOSED notification for embedded objects but not for linked objects, because the server library intercepts the notification for linked objects.

Closing a Server Application

The server library calls the **Exit** function in the **OLESERVERVTBL** structure when the server must quit. The server library calls the **Release** function to inform the server that it is safe to quit; the server does not necessarily stop when the library calls **Release**.

The server must exit when it is invisible and the library calls **Release**. (The only exception is when an application supports multiple servers; in this case, an invisible server is sometimes not revocable when the library calls **Release**.) If the server has no open documents and it was started with the **/Embedding** option (indicating that it was started by a client application), the server should exit when the library calls the **Release** function. If the user explicitly loads a document into a single-instance (MDI) server, however, the server should not exit when the library calls **Release**.

When the user closes a server that has edited an embedded object without updating changes to the client application, the server should display a message asking whether to save the changes. If the user chooses to save the changes, the server should send the OLE_CLOSED notification and call the **OleRevokeServerDoc** function. (Because sending OLE_CLOSED prompts the server library to send data to the client library, it is not necessary to send OLE_CHANGED or OLE_SAVED. If the user chooses not to save the changes, the server should simply call the **OleRevokeServerDoc** function (without sending OLE_CLOSED).

A server can use the **OleRevokeObject** function to revoke a client's access to an object--for example, if the user destroys the object. Similarly, the **OleRevokeServerDoc** function revokes a client's access to a document. (Because **OleRevokeServerDoc** revokes a client's access to all objects in a document, an application that uses **OleRevokeServerDoc** does not need to call the **OleRevokeObject** function for objects in that document.) To terminate all conversations with client applications, the server can call the **OleRevokeServer** function. These functions inform the server library that the specified items are no longer available.

A server application can receive OLE_WAIT_FOR_RELEASE--for example, the **OleRevokeServerDoc** function can return this value. Although a server can enter a message-dispatch loop and wait for the library to call the server's **Release** function, servers should never enter message-dispatch loops inside any of the server-supplied functions that are called by the server library.

The client application should not instruct the server to close the document or exit when the server is editing a linked object, unless the server is updating the link without displaying the object to the user. Because a linked object exists independently of the client, the user controls saving and closing the document by using the server application.

If a server application owns the clipboard when it closes, it should make sure that the data on the clipboard is complete and in the correct order. For example, any Native data should be accompanied by the OwnerLink format.

Object Handlers

Object Handlers

An application developer can use object handlers to introduce customized features into implementations of linked and embedded objects. When an object handler exists for a class of object, the object handler supplants some or all of the functionality that is usually provided by the client library and the server application. The object handler can take specialized action for any of the functions it intercepts. The object handler passes functions that it does not take action on to the client library, which then implements the default processing for that class.

An application might use an object handler to render Native data as the presentation data for an object, instead of using metafiles or bitmaps. Object handlers could also be used to implement special behavior when an object is opened.

Implementing Object Handlers

A server installing an object handler registers the handler with the registration database, using the keyword **handler**. Whenever a client application calls one of the object-creation functions, the client library uses the class name specified for the object and the **handler** keyword to search the registration database. If the library finds an object handler, the client library loads the handler and calls it to create the object. The handler can create an object for which all of the creation functions and methods are defined by the handler, or it can call default object-creation functions in the client library.

The client library exports the object-creation OLE functions with new names; in each case, the prefix "Ole" is changed to "Def" (for "default"). Object handlers can import any of these functions and use them when creating objects.

Object handlers must import the following functions:

OLE function	Name exported by client library
OleCreate	DefCreate
OleCreateFromClip	DefCreateFromClip
OleCreateFromFile	DefCreateFromFile
OleCreateFromTemplate	DefCreateFromTemplate
OleCreateLinkFromClip	DefCreateLinkFromClip
OleCreateLinkFromFile	DefCreateLinkFromFile
OleLoadFromStream	DefLoadFromStream

When an object handler defines a function that is to be called by the client application, it should use the same name as the corresponding OLE function the client calls, with the prefix "Ole" replaced by "Dll". For example, when an object handler uses the **DefCreate** function exported by the client library, the handler should use it inside a function named **DllCreate**. When the client library finds an object handler for a class of object, it calls handler-specific object-creation functions by specifying this "Dll" prefix.

When the handler calls one of the default object-creation functions, it receives a handle of an **OLEOBJECT** structure, which in turn points to the **OLEOBJECTVTBL** structure containing the current object-management functions. The object handler should copy this **OLEOBJECTVTBL** structure and customize the structure by replacing any function pointers in the structure with pointers to functions of its own. (If the object handler saves the pointers to the default functions, any of the replacement functions can also call the default functions in the table of function pointers.) When the object handler has finished customizing the structure, it should replace the pointer to the old **OLEOBJECTVTBL** structure with a pointer to the modified **OLEOBJECTVTBL** structure.

When the client makes a call to a function in the client library, the call is dispatched through the object handler's **OLEOBJECTVTBL** structure. If the object handler has replaced the function pointer, the call is routed to the function supplied by the handler. Otherwise, the call is routed to the client library.

Each **OLECLIENT**, **OLEOBJECT**, **OLESERVER**, **OLESERVERDOC**, or **OLESTREAM** structure contains a pointer to a structure that contains a table of function pointers. (Structures containing tables of function pointers are identified with the "VTBL" suffix.) Each of the structures containing a pointer to a "VTBL" structure can also contain extra instance-specific information. This information is meaningful only to the application that supplies it and should not be used by other applications; for example, an object handler should not attempt to use any instance-specific information in an **OLECLIENT** structure.

The object handler should use the "Def" and "Dll" renaming conventions when it defines specialized functions. For example, if an object handler modifies the **Draw** function from an object's **OLEOBJECTVTBL** structure, it should copy that **Draw** function to a function named **DefDraw** and replace the **Draw** function with a specialized function named **DllDraw**. Inside the **DllDraw** function, the object handler can call **DefDraw** if the default drawing operation is appropriate in a particular case.

The following example demonstrates this process of copying and replacing pointers to functions. Functions with the "Dll" prefix should be exported in the module-definition file.

```
/* Declare the DllDraw and DefDraw functions.            */

OLESTATUS FAR PASCAL DllDraw(LPOLEOBJECT, HDC, LPRECT, LPRECT, HDC);
OLESTATUS (FAR PASCAL *DefDraw)(LPOLEOBJECT, HDC, LPRECT, LPRECT, HDC);

/* Copy the Draw function from OLEOBJECTVTBL to DefDraw. */

    DefDraw             = lpobj->lpvtbl->Draw;

/* Copy DllDraw to OLEOBJECTVTBL.                        */

    *lpobj->lpvtbl->Draw = DllDraw;

OLESTATUS FAR PASCAL DllDraw(lpObject, hdc, lpBounds, lpWBounds,
        hdcFormat)
LPOLEOBJECT     lpObject;
HDC             hdc;
LPRECT          lpBounds;
LPRECT          lpWBounds;
HDC             hdcFormat;
{
    /* Return DefDraw if Native data is not available.   */

    if ((*lpobj->lpvtbl->GetData) (lpobj, cfNative, &hData) != OLE_OK)
        return (*DefDraw) (lpobj, hdc, lpBounds, lpWBounds, hdcFormat);
    .
    .
    .
}
```

Creating Objects in an Object Handler

Most of the object-creation functions in the OLE API work in exactly the same way when they are renamed and used by object-handler DLLs. Two functions are somewhat different, however: **OleCreateFromClip** and **OleLoadFromStream**.

DefCreateFromClip and DllCreateFromClip

When the client library calls the **DllCreateFromClip** function, the library includes a parameter that is not specified in the original call to the **OleCreateFromClip** function. This parameter, *objtype,* specifies whether the object being created is an embedded object or a link; its value can be either OT_LINK or OT_EMBEDDED.

The following syntax block shows the *objtype* parameter when an object handler uses the **DefCreateFromClip** function. The **DllCreateFromClip** function has exactly the same syntax as **DefCreateFromClip**. For a full description of all the parameters, see the description of the **OleCreateFromClip** function.

OLESTATUS DefCreateFromClip(lpszProtocol, lpclient, lhclientdoc, lpszObjname, lplpobject, renderopt, cfFormat, objtype);

```
LPSTR lpszProtocol;              /* address of string for protocol name */
LPOLECLIENT lpclient;            /* address of client structure         */
LHCLIENTDOC lhclientdoc;         /* long handle of client document      */
LPSTR lpszObjname;               /* string for object name              */
LPOLEOBJECT FAR * lplpobject;    /* address of pointer to object        */
OLEOPT_RENDER renderopt;         /* rendering options                   */
OLECLIPFORMAT cfFormat;          /* clipboard format                    */
LONG objtype;                    /* OT_LINKED or OT_EMBEDDED            */
```

If **DllCreateFromClip** calls **DefCreateFromClip**, **DllCreateFromClip** should pass it the *objtype* parameter along with the other parameters from the version of **DefCreateFromClip** that was exported by the client library. **DllCreateFromClip** can modify some of these parameters before passing them back to **DefCreateFromClip**. For example, the object handler could specify a different value for the *renderopt* parameter when it calls **DefCreateFromClip**. If the client calls this function with **olerender_draw** for *renderopt* and the handler performs the drawing with Native data, the handler could change **olerender_draw** to **olerender_none**. If the client calls this function with **olerender_draw** for *renderopt* and the handler calls the **GetData** function and performs the drawing based on a class-specific format, the handler could change **olerender_draw** to **olerender_format**. If the handler needed a different rendering format than the format specified by the client application, the object handler could also change the value of the *cfFormat* parameter in the call to **DefCreateFromClip**.

If an object handler uses Native data to render an embedded object, the handler can call the library and specify **olerender_none**. If a handler uses Native data to render a linked object, it can use **olerender_format** and specify Native data. When the handler's **Draw** function is called, the handler calls the **GetData** function, specifying Native data, to do the rendering. If a handler uses a private data format, the procedure is the same--except that the private format is specified with the **olerender_format** option and with the **GetData** function.

DefLoadFromStream and DllLoadFromStream

When the client library calls the **DllLoadFromStream** function, the library includes three parameters that are not specified in the original call to the **OleLoadFromStream** function. One of the additional parameters is *objtype,* as described for **DefCreateFromClip** and **DllCreateFromClip**. The other two parameters are *aClass,* which is an atom containing the class name for the object, and *cfFormat,* which specifies a private clipboard format that the object handler can use for rendering the object.

The following syntax block shows the *objtype, aClass,* and *cfFormat* parameters when an object handler uses the **DefLoadFromStream** function. The **DllLoadFromStream** function has exactly the same syntax as **DefLoadFromStream**. For a full description of all the parameters, see the description of the **OleLoadFromStream** function in the *Microsoft Windows Programmer's Reference, Volume 2.*

```
OLESTATUS DefLoadFromStream(lpstream, lpszProtocol, lpclient,
    lhclientdoc, lpszObjname, lplpobject, objtype, aClass, cfFormat);
LPOLESTREAM lpstream;          /* address of stream for object        */
LPSTR lpszProtocol;            /* address of string for protocol name */
LPOLECLIENT lpclient;          /* address of client structure         */
LHCLIENTDOC lhclientdoc;       /* long handle of client document      */
LPSTR lpszObjname;             /* string for object name              */
LPOLEOBJECT FAR * lplpobject; /* address of pointer to object        */
LONG objtype;                  /* OT_LINKED or OT_EMBEDDED            */
```

```
ATOM aClass;                    /* atom containing object's class name */
OLECLIPFORMAT cfFormat;         /* private data format for rendering   */
```

If **DllLoadFromStream** calls **DefLoadFromStream**, **DllLoadFromStream** should pass it the three additional parameters along with the other parameters from the version of **DefLoadFromStream** that was exported by the client library. **DllLoadFromStream** can modify some of these parameters before passing them back to **DefLoadFromStream**. For example, the object handler could modify the value of the *cfFormat* parameter to specify a private data format it would use to render the object.

When the client calls the object handler with **DefLoadFromStream**, the handler uses the **Get** function from the **OLESTREAMVTBL** structure to obtain the data for the object.

Direct Use of Dynamic Data Exchange

The OLE libraries, OLECLI.DLL and OLESVR.DLL, use DDE messages to communicate with each other. Although client and server applications can use DDE directly, without employing OLECLI.DLL or OLESVR.DLL, this method of implementing OLE is not recommended. Future enhancements to the OLE libraries will benefit applications that use the libraries but will not benefit applications that use DDE directly.

The following information about the DDE-based OLE protocol is provided for applications that must implement DDE directly, despite losing the ability to take advantage of future enhancements to the system.

Implementation of the OLE protocol requires implementation of the underlying DDE protocol. All the standard DDE rules and facilities apply. Applications that conform to this protocol must also conform to the DDE specification. Conforming to this specification implies supporting the System topic and the standard items in that topic.

Client Applications and Direct Use of Dynamic Data Exchange

When opening a link or an embedded document, the client application should look up the class name in the registration database, as described in Registration.

The following pseudocode illustrates the chain of events for a client implementing OLE through DDE. Whenever a client that attempts to establish a conversation with a server receives responses from more than one server, the client should accept the first server and reject the others.

Linked object:

```
WM_DDE_INITIATE class name, document name
if not found {
        WM_DDE_INITIATE class name, OLESystem
        if not found {
                WM_DDE_INITIATE class name, System
                if not found {
                        launch application name, /Embedding
                        fLaunched = true
                        WM_DDE_INITIATE class name, OLESystem
                        if not found {
                                WM_DDE_INITIATE class name, System
                                if not found
                                        return error
                        }
                }
        }

        /*
         * Now there is a conversation with the server on the System or
         * OLESystem topic.
         */

        WM_DDE_EXECUTE StdOpenDocument(DocumentName)
        WM_DDE_INITIATE class name, document name
        if not found {
                if(fLaunched) WM_DDE_EXECUTE StdExit /* clean up */
                        return error
        }
}
```

```
/*
 * Now there is a conversation with the correct document.
 */
```

Embedded object:

```
WM_DDE_INITIATE class name, OLESystem
if not found {
        WM_DDE_INITIATE class name, System
        if not found {
                launch application name, /Embedding
                fLaunched = true
                WM_DDE_INITIATE class name, OLESystem
                if not found {
                        WM_DDE_INITIATE class name, System
                        if not found
                                return error
                }
        }
}

/*
 * Now there is a conversation with the server on the system or
 * OLESystem topic.
 */

DDE_EXECUTE StdEditDocument(DocumentName)

/*
 * Or StdCreateDoc if this is an Insert Object command
 */

WM_DDE_INITIATE class name, document name
if not found {
        if(fLaunched) DDE_EXECUTE StdExit          /* clean up */
                return error
}

/* Now there is a conversation with the correct document. */
```

Server Applications and Direct Use of Dynamic Data Exchange

When a server receives the **/Embedding** command-line argument, it should not create a new default document. Instead, it should wait until the client sends either the **StdOpenDocument** command or the **StdEditDocument** command followed by the Native data and then instructs the server to show the window. The server can use the **StdHostNames** item to display the client's name in the window title.

The following pseudocode illustrates the chain of events for a server implementing OLE through DDE. The example shows two cases: one in which the server reuses a single instance for editing all objects (in MDI child windows), and another in which a new instance is used for each object. Applications that use a new instance for each object should reject requests to open or create a new document when they already have a document open.

MDI application:

```
case WM_DDE_INITIATE:
     if class name == this class {
```

```
        if (DocumentName == OLESystem || DocumentName == System)
            WM_DDE_ACK
        else if DocumentName == name of some open document
            WM_DDE_ACK
    }
```

Multiple-instance application:

```
case WM_DDE_INITIATE:
    if class name == this class {
        if (DocumentName == OLESystem || DocumentName == System) {
            if no documents are open
                WM_DDE_ACK
        }
        else if DocumentName == name of some open document
            WM_DDE_ACK
    }
```

Conversations

Document operations are performed during conversations with an application's OLESystem or System topic. The document's class name is used to establish the conversation.

Data transfer and negotiation operations are performed during conversations with the document (that is, the topic). The document name is used to establish the conversation.

Note that the topic name is used only in initiating conversations and is not fixed throughout the conversation; permitting the document to be renamed does not mean that there will be two names. Therefore, it is reasonable to tie the topic name to the document name.

Items for the System Topic

An application using DDE-based OLE can use three new items for the System topic: the Topics item, the Protocols item, and the Status item.

The Topics item returns a list of DDE topic names that the server application has open. Where topics correspond to documents, the topic name is the document name.

The Protocols item returns a list of protocol names supported by the application. The list is returned in tab-separated text format. A protocol is a defined set of DDE execute strings and item and format conventions that the application understands. The protocol currently defined for linked and embedded objects is the following:

Protocol: StdFileEditing *commands*/*items*/*formats*

For compatibility with client applications that were written before the implementation of the OLE protocol, server applications that use the DDE protocol directly should also include the string Embedding in the list of protocols.

The Status item is a text item that returns Ready if the server is prepared to respond to DDE requests; otherwise, it returns Busy. This item can be queried to determine if the client should offer such functions as one that gives the user an opportunity to update the object. Because it is possible that a server could reject or defer a request even if Status returns Ready, client applications should not depend solely on the Ready item.

Standard Item Names and Notification Control

Applications supporting OLE with direct DDE use four clipboard formats in addition to the regular data and picture formats. These are ObjectLink, OwnerLink, Native, and Binary. Binary format is a stream of bytes whose interpretation is implicit in the item; for example, the **EditEnvItems**, **StdTargetDevice**, and **StdHostNames** items are in Binary format. The ObjectLink, OwnerLink, and Native formats are

described in Clipboard Conventions.

New items available on each topic other than the System topic are defined for this protocol. These items are the following:

Item	Description
StdDocumentName	Contains the permanent document name associated with the topic. If no permanent storage is associated with the topic, this item is empty. This item supports both request and advise transactions and can be used to detect the renaming of open documents.
EditEnvItems	Returns a list in tab-separated text format of the items that contain environmental information supported by the server for its documents. Currently defined items are **StdHostNames**, **StdDocDimensions**, and **StdTargetDevice**. Applications can declare other items (and define their interpretations if Binary format is used) to permit clients that are informed of these items to provide more detailed information. Servers that cannot use particular items should omit their names from the EditEnvItems item. Clients should use the **WM_DDE_REQUEST** message with this item to find out which items the server can use and should supply the data through a **WM_DDE_POKE** message.

StdHostNames	Accepts information about the client application, in Binary format interpreted as the following structure:
	
	`struct {`
	`  WORD clientNameOffset;`
	`  WORD documentNameOffset;`
	`  BYTE data[];`
	`} StdHostNames;`
	
	The offsets are relative to the start of the data array. They indicate the starting point for the appropriate information in the array.

StdTargetDevice	Accepts information about the target device that the client is using. This information is in Binary format, interpreted as the following structure. Offsets are relative to the start of the data array.
	
	`typedef struct _OLETARGETDEVICE {`
	`  WORD otdDeviceNameOffset;`
	`  WORD otdDriverNameOffset;`
	`  WORD otdPortNameOffset;`
	`  WORD otdExtDevmodeOffset;`
	`  WORD otdExtDevmodeSize;`
	`  WORD otdEnvironmentOffset;`
	`  WORD otdEnvironmentSize;`
	`  BYTE otdData[];`
	`} OLETARGETDEVICE;`
