    print "had two kittens: ", join(' and ', @{$cat->kittens}), "\n";

```

Author and Modification History

Modified by Damian Conway, 2001-09-10, v0.62.

Modified implicit construction of nested objects.
 Now will also take an object ref instead of requiring a hash ref.
 Also default initializes nested object attributes to undef, rather than calling object constructor without args

Original over-helpfulness was fraught with problems:

- * the class's constructor might not be called 'new'
- * the class might not have a hash-like-arguments constructor
- * the class might not have a no-argument constructor
- * "recursive" data structures didn't work well:

```

package Person;
struct { mother => 'Person', father => 'Person' };

```

Modified by Casey West, 2000-11-08, v0.59.

Added the ability for compile time class creation.

Modified by Damian Conway, 1999-03-05, v0.58.

Added handling of hash-like arg list to class ctor.

Changed to two-argument blessing in ctor to support derivation from created classes.

Added classname prefixes to keys in hash-based classes (refer to "Perl Cookbook", Recipe 13.12 for rationale).

Corrected behaviour of accessors for '*@' and '*%' struct elements. Package now implements documented behaviour when returning a reference to an entire hash or array element. Previously these were returned as a reference to a reference to the element.

Renamed to `Class::Struct` and modified by Jim Miner, 1997-04-02.

```

members() function removed.
Documentation corrected and extended.
Use of struct() in a subclass prohibited.
User definition of accessor allowed.
Treatment of '*' in element types corrected.
Treatment of classes as element types corrected.
Class name to struct() made optional.
Diagnostic checks added.

```

Originally `Class::Template` by Dean Roehrich.

```

# Template.pm --- struct/member template builder
# 12mar95
# Dean Roehrich
#

```

```
# changes/bugs fixed since 28nov94 version:
#   - podified
# changes/bugs fixed since 21nov94 version:
#   - Fixed examples.
# changes/bugs fixed since 02sep94 version:
#   - Moved to Class::Template.
# changes/bugs fixed since 20feb94 version:
#   - Updated to be a more proper module.
#   - Added "use strict".
#   - Bug in build_methods, was using @var when @$var needed.
#   - Now using my() rather than local().
#
# Uses perl5 classes to create nested data types.
# This is offered as one implementation of Tom Christiansen's "structs.pl"
# idea.
```

NAME

constant – Perl pragma to declare constants

SYNOPSIS

```
use constant PI      => 4 * atan2(1, 1);
use constant DEBUG => 0;

print "Pi equals ", PI, "...\\n" if DEBUG;

use constant {
    SEC  => 0,
    MIN  => 1,
    HOUR => 2,
    MDAY => 3,
    MON  => 4,
    YEAR => 5,
    WDAY => 6,
    YDAY => 7,
    ISDST => 8,
};

use constant WEEKDAYS => qw(
    Sunday Monday Tuesday Wednesday Thursday Friday Saturday
);

print "Today is ", (WEEKDAYS)[ (localtime)[WDAY] ], "...\\n";
```

DESCRIPTION

This will declare a symbol to be a constant with the given value.

When you declare a constant such as PI using the method shown above, each machine your script runs upon can have as many digits of accuracy as it can use. Also, your program will be easier to read, more likely to be maintained (and maintained correctly), and far less likely to send a space probe to the wrong planet because nobody noticed the one equation in which you wrote 3.14195.

When a constant is used in an expression, perl replaces it with its value at compile time, and may then optimize the expression further. In particular, any code in an if (CONSTANT) block will be optimized away if the constant is false.

NOTES

As with all use directives, defining a constant happens at compile time. Thus, it's probably not correct to put a constant declaration inside of a conditional statement (like if (\$foo) { use constant ... }).

Constants defined using this module cannot be interpolated into strings like variables. However, concatenation works just fine:

```
print "Pi equals PI...\\n";      # WRONG: does not expand "PI"
print "Pi equals ".PI."...\\n";  # right
```

Even though a reference may be declared as a constant, the reference may point to data which may be changed, as this code shows.

```
use constant ARRAY => [ 1,2,3,4 ];
print ARRAY->[1];
ARRAY->[1] = " be changed";
print ARRAY->[1];
```

Dereferencing constant references incorrectly (such as using an array subscript on a constant hash reference, or vice versa) will be trapped at compile time.

Constants belong to the package they are defined in. To refer to a constant defined in another package, specify the full package name, as in `Some::Package::CONSTANT`. Constants may be exported by modules, and may also be called as either class or instance methods, that is, as `<Some::Package-CONSTANT` or as `< $obj-CONSTANT` where `$obj` is an instance of `Some::Package`. Subclasses may define their own constants to override those in their base class.

The use of all caps for constant names is merely a convention, although it is recommended in order to make constants stand out and to help avoid collisions with other barewords, keywords, and subroutine names. Constant names must begin with a letter or underscore. Names beginning with a double underscore are reserved. Some poor choices for names will generate warnings, if warnings are enabled at compile time.

List constants

Constants may be lists of more (or less) than one value. A constant with no values evaluates to `undef` in scalar context. Note that constants with more than one value do *not* return their last value in scalar context as one might expect. They currently return the number of values, but **this may change in the future**. Do not use constants with multiple values in scalar context.

NOTE: This implies that the expression defining the value of a constant is evaluated in list context. This may produce surprises:

```
use constant TIMESTAMP => localtime;           # WRONG!
use constant TIMESTAMP => scalar localtime;     # right
```

The first line above defines `TIMESTAMP` as a 9-element list, as returned by `localtime()` in list context. To set it to the string returned by `localtime()` in scalar context, an explicit `scalar` keyword is required.

List constants are lists, not arrays. To index or slice them, they must be placed in parentheses.

```
my @workdays = WEEKDAYS[1 .. 5];               # WRONG!
my @workdays = (WEEKDAYS)[1 .. 5];             # right
```

Defining multiple constants at once

Instead of writing multiple `use constant` statements, you may define multiple constants in a single statement by giving, instead of the constant name, a reference to a hash where the keys are the names of the constants to be defined. Obviously, all constants defined using this method must have a single value.

```
use constant {
    FOO => "A single value",
    BAR => "This", "won't", "work!",           # Error!
};
```

This is a fundamental limitation of the way hashes are constructed in Perl. The error messages produced when this happens will often be quite cryptic — in the worst case there may be none at all, and you'll only later find that something is broken.

When defining multiple constants, you cannot use the values of other constants defined in the same declaration. This is because the calling package doesn't know about any constant within that group until *after* the `use` statement is finished.

```
use constant {
    BITMASK => 0xAFBAEBA8,
    NEGMASK => ~BITMASK,                       # Error!
};
```

Magic constants

Magical values and references can be made into constants at compile time, allowing for way cool stuff like this. (These error numbers aren't totally portable, alas.)

```
use constant E2BIG => ($! = 7);
print E2BIG, "\n";           # something like "Arg list too long"
```

```
print 0+E2BIG, "\n";           # "7"
```

You can't produce a tied constant by giving a tied scalar as the value. References to tied variables, however, can be used as constants without any problems.

TECHNICAL NOTES

In the current implementation, scalar constants are actually inlinable subroutines. As of version 5.004 of Perl, the appropriate scalar constant is inserted directly in place of some subroutine calls, thereby saving the overhead of a subroutine call. See *Constant Functions in perlsyn* for details about how and when this happens.

In the rare case in which you need to discover at run time whether a particular constant has been declared via this module, you may use this function to examine the hash `%constant::declared`. If the given constant name does not include a package name, the current package is used.

```
sub declared ($) {
    use constant 1.01;           # don't omit this!
    my $name = shift;
    $name =~ s/^\s*/main::/;
    my $pkg = caller;
    my $full_name = $name =~ /\s*? $name : "${pkg}::$name";
    $constant::declared{$full_name};
}
```

BUGS

In the current version of Perl, list constants are not inlined and some symbols may be redefined without generating a warning.

It is not possible to have a subroutine or a keyword with the same name as a constant in the same package. This is probably a Good Thing.

A constant with a name in the list `STDIN STDOUT STDERR ARGV ARGVOUT ENV INC SIG` is not allowed anywhere but in package `main::`, for technical reasons.

Unlike constants in some languages, these cannot be overridden on the command line or via environment variables.

You can get into trouble if you use constants in a context which automatically quotes barewords (as is true for any subroutine call). For example, you can't say `$hash{CONSTANT}` because `CONSTANT` will be interpreted as a string. Use `$hash{CONSTANT() }` or `$hash{+CONSTANT}` to prevent the bareword quoting mechanism from kicking in. Similarly, since the `< =` operator quotes a bareword immediately to its left, you have to say `< CONSTANT() = 'value'` (or simply use a comma in place of the big arrow) instead of `< CONSTANT = 'value'`.

AUTHOR

Tom Phoenix, <rootbeer@redcat.com>, with help from many other folks.

Multiple constant declarations at once added by Casey West, <casey@geeknest.com>.

Documentation mostly rewritten by Ilmari Karonen, <perl@itz.pp.sci.fi>.

NAME

CPAN – query, download and build perl modules from CPAN sites

SYNOPSIS

Interactive mode:

```
perl -MCPAN -e shell;
```

Batch mode:

```
use CPAN;

autobundle, clean, install, make, recompile, test
```

DESCRIPTION

The CPAN module is designed to automate the make and install of perl modules and extensions. It includes some searching capabilities and knows how to use Net::FTP or LWP (or lynx or an external ftp client) to fetch the raw data from the net.

Modules are fetched from one or more of the mirrored CPAN (Comprehensive Perl Archive Network) sites and unpacked in a dedicated directory.

The CPAN module also supports the concept of named and versioned *bundles* of modules. Bundles simplify the handling of sets of related modules. See Bundles below.

The package contains a session manager and a cache manager. There is no status retained between sessions. The session manager keeps track of what has been fetched, built and installed in the current session. The cache manager keeps track of the disk space occupied by the make processes and deletes excess space according to a simple FIFO mechanism.

For extended searching capabilities there's a plugin for CPAN available, [CPAN:::WAIT/CPAN:::WAIT](#). CPAN:::WAIT is a full-text search engine that indexes all documents available in CPAN authors directories. If CPAN:::WAIT is installed on your system, the interactive shell of CPAN.pm will enable the `wq`, `wr`, `wd`, `wl`, and `wh` commands which send queries to the WAIT server that has been configured for your installation.

All other methods provided are accessible in a programmer style and in an interactive shell style.

Interactive Mode

The interactive mode is entered by running

```
perl -MCPAN -e shell
```

which puts you into a readline interface. You will have the most fun if you install Term::ReadKey and Term::ReadLine to enjoy both history and command completion.

Once you are on the command line, type 'h' and the rest should be self-explanatory.

The function call `shell` takes two optional arguments, one is the prompt, the second is the default initial command line (the latter only works if a real ReadLine interface module is installed).

The most common uses of the interactive modes are

Searching for authors, bundles, distribution files and modules

There are corresponding one-letter commands `a`, `b`, `d`, and `m` for each of the four categories and another, `i` for any of the mentioned four. Each of the four entities is implemented as a class with slightly differing methods for displaying an object.

Arguments you pass to these commands are either strings exactly matching the identification string of an object or regular expressions that are then matched case-insensitively against various attributes of the objects. The parser recognizes a regular expression only if you enclose it between two slashes.

The principle is that the number of found objects influences how an item is displayed. If the search finds

one item, the result is displayed with the rather verbose method `as_string`, but if we find more than one, we display each object with the terse method `<as_glimpse>`.

make, test, install, clean modules or distributions

These commands take any number of arguments and investigate what is necessary to perform the action. If the argument is a distribution file name (recognized by embedded slashes), it is processed. If it is a module, CPAN determines the distribution file in which this module is included and processes that, following any dependencies named in the module's `Makefile.PL` (this behavior is controlled by *prerequisites_policy*.)

Any `make` or `test` are run unconditionally. An

```
install <distribution_file>
```

also is run unconditionally. But for

```
install <module>
```

CPAN checks if an install is actually needed for it and prints *module up to date* in the case that the distribution file containing the module doesn't need to be updated.

CPAN also keeps track of what it has done within the current session and doesn't try to build a package a second time regardless if it succeeded or not. The `force` command takes as a first argument the method to invoke (currently: `make`, `test`, or `install`) and executes the command from scratch.

Example:

```
cpan> install OpenGL
OpenGL is up to date.
cpan> force install OpenGL
Running make
OpenGL-0.4/
OpenGL-0.4/COPYRIGHT
[...]
```

A `clean` command results in a

```
make clean
```

being executed within the distribution file's working directory.

get, readme, look module or distribution

`get` downloads a distribution file without further action. `readme` displays the `README` file of the associated distribution. `look` gets and untars (if not yet done) the distribution file, changes to the appropriate directory and opens a subshell process in that directory.

ls author

`ls` lists all distribution files in and below an author's CPAN directory. Only those files that contain modules are listed and if there is more than one for any given module, only the most recent one is listed.

Signals

`CPAN.pm` installs signal handlers for `SIGINT` and `SIGTERM`. While you are in the `cpan-shell` it is intended that you can press `^C` anytime and return to the `cpan-shell` prompt. A `SIGTERM` will cause the `cpan-shell` to clean up and leave the shell loop. You can emulate the effect of a `SIGTERM` by sending two consecutive `SIGINT`s, which usually means by pressing `^C` twice.

`CPAN.pm` ignores a `SIGPIPE`. If the user sets `inactivity_timeout`, a `SIGALRM` is used during the run of the `perl Makefile.PL` subprocess.

CPAN::Shell

The commands that are available in the shell interface are methods in the package `CPAN::Shell`. If you enter the shell command, all your input is split by the `Text::ParseWords::shellwords()` routine which

acts like most shells do. The first word is being interpreted as the method to be called and the rest of the words are treated as arguments to this method. Continuation lines are supported if a line ends with a literal backslash.

autobundle

`autobundle` writes a bundle file into the `$CPAN::Config->{cpan_home}/Bundle` directory. The file contains a list of all modules that are both available from CPAN and currently installed within `@INC`. The name of the bundle file is based on the current date and a counter.

recompile

`recompile()` is a very special command in that it takes no argument and runs the `make/test/install` cycle with brute force over all installed dynamically loadable extensions (aka XS modules) with `'force'` in effect. The primary purpose of this command is to finish a network installation. Imagine, you have a common source tree for two different architectures. You decide to do a completely independent fresh installation. You start on one architecture with the help of a Bundle file produced earlier. CPAN installs the whole Bundle for you, but when you try to repeat the job on the second architecture, CPAN responds with a "Foo up to date" message for all modules. So you invoke CPAN's `recompile` on the second architecture and you're done.

Another popular use for `recompile` is to act as a rescue in case your perl breaks binary compatibility. If one of the modules that CPAN uses is in turn depending on binary compatibility (so you cannot run CPAN commands), then you should try the `CPAN::Nox` module for recovery.

The four CPAN::* Classes: Author, Bundle, Module, Distribution

Although it may be considered internal, the class hierarchy does matter for both users and programmer. CPAN.pm deals with above mentioned four classes, and all those classes share a set of methods. A classical single polymorphism is in effect. A metaclass object registers all objects of all kinds and indexes them with a string. The strings referencing objects have a separated namespace (well, not completely separated):

Namespace	Class
words containing a "/" (slash)	Distribution
words starting with <code>Bundle::</code>	Bundle
everything else	Module or Author

Modules know their associated Distribution objects. They always refer to the most recent official release. Developers may mark their releases as unstable development versions (by inserting an underbar into the module version number which will also be reflected in the distribution name when you run `'make dist'`), so the really hottest and newest distribution is not always the default. If a module `Foo` circulates on CPAN in both version 1.23 and 1.23_90, CPAN.pm offers a convenient way to install version 1.23 by saying

```
install Foo
```

This would install the complete distribution file (say `BAR/Foo-1.23.tar.gz`) with all accompanying material. But if you would like to install version 1.23_90, you need to know where the distribution file resides on CPAN relative to the `authors/id/` directory. If the author is `BAR`, this might be `BAR/Foo-1.23_90.tar.gz`; so you would have to say

```
install BAR/Foo-1.23_90.tar.gz
```

The first example will be driven by an object of the class `CPAN::Module`, the second by an object of class `CPAN::Distribution`.

Programmer's interface

If you do not enter the shell, the available shell commands are both available as methods (`CPAN::Shell->install(...)`) and as functions in the calling package (`install(...)`).

There's currently only one class that has a stable interface – `CPAN::Shell`. All commands that are available in the CPAN shell are methods of the class `CPAN::Shell`. Each of the commands that produce listings of modules (`r`, `autobundle`, `u`) also return a list of the IDs of all modules within the list.

expand(\$type,@things)

The IDs of all objects available within a program are strings that can be expanded to the corresponding real objects with the `CPAN::Shell->expand("Module",@things)` method. Expand returns a list of `CPAN::Module` objects according to the `@things` arguments given. In scalar context it only returns the first element of the list.

expandany(@things)

Like `expand`, but returns objects of the appropriate type, i.e. `CPAN::Bundle` objects for bundles, `CPAN::Module` objects for modules and `CPAN::Distribution` objects for distributions.

Programming Examples

This enables the programmer to do operations that combine functionalities that are available in the shell.

```
# install everything that is outdated on my disk:
perl -MCPAN -e 'CPAN::Shell->install(CPAN::Shell->r)'

# install my favorite programs if necessary:
for $mod (qw(Net::FTP Digest::MD5 Data::Dumper)) {
    my $obj = CPAN::Shell->expand('Module', $mod);
    $obj->install;
}

# list all modules on my disk that have no VERSION number
for $mod (CPAN::Shell->expand("Module", "/./")) {
    next unless $mod->inst_file;
    # MakeMaker convention for undefined $VERSION:
    next unless $mod->inst_version eq "undef";
    print "No VERSION in ", $mod->id, "\n";
}

# find out which distribution on CPAN contains a module:
print CPAN::Shell->expand("Module", "Apache::Constants")->cpan_file
```

Or if you want to write a cronjob to watch The CPAN, you could list all modules that need updating. First a quick and dirty way:

```
perl -e 'use CPAN; CPAN::Shell->r;'
```

If you don't want to get any output in the case that all modules are up to date, you can parse the output of above command for the regular expression `//modules are up to date//` and decide to mail the output only if it doesn't match. Ick?

If you prefer to do it more in a programmer style in one single process, maybe something like this suits you better:

```
# list all modules on my disk that have newer versions on CPAN
for $mod (CPAN::Shell->expand("Module", "/./")) {
    next unless $mod->inst_file;
    next if $mod->uptodate;
    printf "Module %s is installed as %s, could be updated to %s from CPAN\n",
        $mod->id, $mod->inst_version, $mod->cpan_version;
}
```

If that gives you too much output every day, you maybe only want to watch for three modules. You can write

```
for $mod (CPAN::Shell->expand("Module", "/Apache|LWP|CGI/")) {
```

as the first line instead. Or you can combine some of the above tricks:

```
# watch only for a new mod_perl module
$mod = CPAN::Shell->expand("Module","mod_perl");
exit if $mod->uptodate;
# new mod_perl arrived, let me know all update recommendations
CPAN::Shell->r;
```

Methods in the other Classes

The programming interface for the classes `CPAN::Module`, `CPAN::Distribution`, `CPAN::Bundle`, and `CPAN::Author` is still considered beta and partially even alpha. In the following paragraphs only those methods are documented that have proven useful over a longer time and thus are unlikely to change.

`CPAN::Author::as_glimpse()`

Returns a one-line description of the author

`CPAN::Author::as_string()`

Returns a multi-line description of the author

`CPAN::Author::email()`

Returns the author's email address

`CPAN::Author::fullname()`

Returns the author's name

`CPAN::Author::name()`

An alias for `fullname`

`CPAN::Bundle::as_glimpse()`

Returns a one-line description of the bundle

`CPAN::Bundle::as_string()`

Returns a multi-line description of the bundle

`CPAN::Bundle::clean()`

Recursively runs the `clean` method on all items contained in the bundle.

`CPAN::Bundle::contains()`

Returns a list of objects' IDs contained in a bundle. The associated objects may be bundles, modules or distributions.

`CPAN::Bundle::force($method,@args)`

Forces CPAN to perform a task that normally would have failed. Force takes as arguments a method name to be called and any number of additional arguments that should be passed to the called method. The internals of the object get the needed changes so that `CPAN.pm` does not refuse to take the action. The force is passed recursively to all contained objects.

`CPAN::Bundle::get()`

Recursively runs the `get` method on all items contained in the bundle

`CPAN::Bundle::inst_file()`

Returns the highest installed version of the bundle in either `@INC` or `$CPAN::Config->{cpan_home}`. Note that this is different from `CPAN::Module::inst_file`.

`CPAN::Bundle::inst_version()`

Like `CPAN::Bundle::inst_file`, but returns the `$VERSION`

`CPAN::Bundle::uptodate()`

Returns 1 if the bundle itself and all its members are uptodate.

CPAN::Bundle::install()

Recursively runs the `install` method on all items contained in the bundle

CPAN::Bundle::make()

Recursively runs the `make` method on all items contained in the bundle

CPAN::Bundle::readme()

Recursively runs the `readme` method on all items contained in the bundle

CPAN::Bundle::test()

Recursively runs the `test` method on all items contained in the bundle

CPAN::Distribution::as_glimpse()

Returns a one-line description of the distribution

CPAN::Distribution::as_string()

Returns a multi-line description of the distribution

CPAN::Distribution::clean()

Changes to the directory where the distribution has been unpacked and runs `make clean` there.

CPAN::Distribution::containsmods()

Returns a list of IDs of modules contained in a distribution file. Only works for distributions listed in the `02packages.details.txt.gz` file. This typically means that only the most recent version of a distribution is covered.

CPAN::Distribution::cvs_import()

Changes to the directory where the distribution has been unpacked and runs something like

```
cvs -d $cvs_root import -m $cvs_log $cvs_dir $userid v$version
there.
```

CPAN::Distribution::dir()

Returns the directory into which this distribution has been unpacked.

CPAN::Distribution::force(\$method,@args)

Forces CPAN to perform a task that normally would have failed. Force takes as arguments a method name to be called and any number of additional arguments that should be passed to the called method. The internals of the object get the needed changes so that CPAN.pm does not refuse to take the action.

CPAN::Distribution::get()

Downloads the distribution from CPAN and unpacks it. Does nothing if the distribution has already been downloaded and unpacked within the current session.

CPAN::Distribution::install()

Changes to the directory where the distribution has been unpacked and runs the external command `make install` there. If `make` has not yet been run, it will be run first. A `make test` will be issued in any case and if this fails, the install will be canceled. The cancellation can be avoided by letting `force` run the `install` for you.

CPAN::Distribution::isa_perl()

Returns 1 if this distribution file seems to be a perl distribution. Normally this is derived from the file name only, but the index from CPAN can contain a hint to achieve a return value of true for other filenames too.

CPAN::Distribution::look()

Changes to the directory where the distribution has been unpacked and opens a subshell there. Exiting the subshell returns.

CPAN::Distribution::make()

First runs the `get` method to make sure the distribution is downloaded and unpacked. Changes to the directory where the distribution has been unpacked and runs the external commands `perl Makefile.PL` and `make` there.

CPAN::Distribution::prereq_pm()

Returns the hash reference that has been announced by a distribution as the `PREREQ_PM` hash in the `Makefile.PL`. Note: works only after an attempt has been made to make the distribution. Returns `undef` otherwise.

CPAN::Distribution::readme()

Downloads the `README` file associated with a distribution and runs it through the pager specified in `$CPAN::Config->{pager}`.

CPAN::Distribution::test()

Changes to the directory where the distribution has been unpacked and runs `make test` there.

CPAN::Distribution::uptodate()

Returns 1 if all the modules contained in the distribution are uptodate. Relies on `containsmods`.

CPAN::Index::force_reload()

Forces a reload of all indices.

CPAN::Index::reload()

Reloads all indices if they have been read more than `$CPAN::Config->{index_expire}` days.

CPAN::InfoObj::dump()

`CPAN::Author`, `CPAN::Bundle`, `CPAN::Module`, and `CPAN::Distribution` inherit this method. It prints the data structure associated with an object. Useful for debugging. Note: the data structure is considered internal and thus subject to change without notice.

CPAN::Module::as_glimpse()

Returns a one-line description of the module

CPAN::Module::as_string()

Returns a multi-line description of the module

CPAN::Module::clean()

Runs a clean on the distribution associated with this module.

CPAN::Module::cpan_file()

Returns the filename on CPAN that is associated with the module.

CPAN::Module::cpan_version()

Returns the latest version of this module available on CPAN.

CPAN::Module::cvs_import()

Runs a `cvs_import` on the distribution associated with this module.

CPAN::Module::description()

Returns a 44 character description of this module. Only available for modules listed in The Module List (`CPAN/modules/00modlist.long.html` or `00modlist.long.txt.gz`)

CPAN::Module::force(\$method,@args)

Forces CPAN to perform a task that normally would have failed. `Force` takes as arguments a method name to be called and any number of additional arguments that should be passed to the called method. The internals of the object get the needed changes so that `CPAN.pm` does not refuse to take the action.

CPAN::Module::get()

Runs a `get` on the distribution associated with this module.

CPAN::Module::inst_file()

Returns the filename of the module found in `@INC`. The first file found is reported just like `perl` itself stops searching `@INC` when it finds a module.

CPAN::Module::inst_version()

Returns the version number of the module in readable format.

CPAN::Module::install()

Runs an `install` on the distribution associated with this module.

CPAN::Module::look()

Changes to the directory where the distribution associated with this module has been unpacked and opens a subshell there. Exiting the subshell returns.

CPAN::Module::make()

Runs a `make` on the distribution associated with this module.

CPAN::Module::manpage_headline()

If module is installed, peeks into the module's manpage, reads the headline and returns it. Moreover, if the module has been downloaded within this session, does the equivalent on the downloaded module even if it is not installed.

CPAN::Module::readme()

Runs a `readme` on the distribution associated with this module.

CPAN::Module::test()

Runs a `test` on the distribution associated with this module.

CPAN::Module::uptodate()

Returns 1 if the module is installed and up-to-date.

CPAN::Module::userid()

Returns the author's ID of the module.

Cache Manager

Currently the cache manager only keeps track of the build directory (`$CPAN::Config->{build_dir}`). It is a simple FIFO mechanism that deletes complete directories below `build_dir` as soon as the size of all directories there gets bigger than `$CPAN::Config->{build_cache}` (in MB). The contents of this cache may be used for later re-installations that you intend to do manually, but will never be trusted by CPAN itself. This is due to the fact that the user might use these directories for building modules on different architectures.

There is another directory (`$CPAN::Config->{keep_source_where}`) where the original distribution files are kept. This directory is not covered by the cache manager and must be controlled by the user. If you choose to have the same directory as `build_dir` and as `keep_source_where` directory, then your sources will be deleted with the same fifo mechanism.

Bundles

A bundle is just a perl module in the namespace `Bundle::` that does not define any functions or methods. It usually only contains documentation.

It starts like a perl module with a package declaration and a `$VERSION` variable. After that the pod section looks like any other pod with the only difference being that *one special pod section* exists starting with (verbatim):

```
=head1 CONTENTS
```

In this pod section each line obeys the format

```
Module_Name [Version_String] [- optional text]
```

The only required part is the first field, the name of a module (e.g. `Foo::Bar`, ie. *not* the name of the distribution file). The rest of the line is optional. The comment part is delimited by a dash just as in the man page header.

The distribution of a bundle should follow the same convention as other distributions.

Bundles are treated specially in the CPAN package. If you say 'install Bundle::Tkkit' (assuming such a bundle exists), CPAN will install all the modules in the CONTENTS section of the pod. You can install your own Bundles locally by placing a conformant Bundle file somewhere into your @INC path. The `autobundle()` command which is available in the shell interface does that for you by including all currently installed modules in a snapshot bundle file.

Prerequisites

If you have a local mirror of CPAN and can access all files with "file:" URLs, then you only need a perl better than perl5.003 to run this module. Otherwise Net::FTP is strongly recommended. LWP may be required for non-UNIX systems or if your nearest CPAN site is associated with a URL that is not `ftp:`.

If you have neither Net::FTP nor LWP, there is a fallback mechanism implemented for an external `ftp` command or for an external `lynx` command.

Finding packages and VERSION

This module presumes that all packages on CPAN

- declare their \$VERSION variable in an easy to parse manner. This prerequisite can hardly be relaxed because it consumes far too much memory to load all packages into the running program just to determine the \$VERSION variable. Currently all programs that are dealing with version use something like this

```
perl -MExtUtils::MakeMaker -le \
    'print MM->parse_version(shift)' filename
```

If you are author of a package and wonder if your \$VERSION can be parsed, please try the above method.

- come as compressed or gzipped tarfiles or as zip files and contain a Makefile.PL (well, we try to handle a bit more, but without much enthusiasm).

Debugging

The debugging of this module is a bit complex, because we have interferences of the software producing the indices on CPAN, of the mirroring process on CPAN, of packaging, of configuration, of synchronicity, and of bugs within CPAN.pm.

For code debugging in interactive mode you can try "o debug" which will list options for debugging the various parts of the code. You should know that "o debug" has built-in completion support.

For data debugging there is the `dump` command which takes the same arguments as `make/test/install` and outputs the object's `Data::Dumper dump`.

Floppy, Zip, Offline Mode

CPAN.pm works nicely without network too. If you maintain machines that are not networked at all, you should consider working with file: URLs. Of course, you have to collect your modules somewhere first. So you might use CPAN.pm to put together all you need on a networked machine. Then copy the `$CPAN::Config-{keep_source_where}` (but not `$CPAN::Config-{build_dir}`) directory on a floppy. This floppy is kind of a personal CPAN. CPAN.pm on the non-networked machines works nicely with this floppy. See also below the paragraph about CD-ROM support.

CONFIGURATION

When the CPAN module is installed, a site wide configuration file is created as CPAN/Config.pm. The default values defined there can be overridden in another configuration file: CPAN/MyConfig.pm. You can store this file in \$HOME/.cpan/CPAN/MyConfig.pm if you want, because \$HOME/.cpan is added to the search path of the CPAN module before the use() or require() statements.

Currently the following keys in the hash reference \$CPAN::Config are defined:

build_cache	size of cache for directories to build modules
build_dir	locally accessible directory to build modules
index_expire	after this many days refetch index files
cache_metadata	use serializer to cache metadata
cpan_home	local directory reserved for this package
dontload_hash	anonymous hash: modules in the keys will not be loaded by the CPAN::has_inst() routine
gzip	location of external program gzip
inactivity_timeout	breaks interactive Makefile.PLs after this many seconds inactivity. Set to 0 to never break.
inhibit_startup_message	if true, does not print the startup message
keep_source_where	directory in which to keep the source (if we do)
make	location of external make program
make_arg	arguments that should always be passed to 'make'
make_install_arg	same as make_arg for 'make install'
makepl_arg	arguments passed to 'perl Makefile.PL'
pager	location of external program more (or any pager)
prerequisites_policy	what to do if you are missing module prerequisites ('follow' automatically, 'ask' me, or 'ignore')
proxy_user	username for accessing an authenticating proxy
proxy_pass	password for accessing an authenticating proxy
scan_cache	controls scanning of cache ('atstart' or 'never')
tar	location of external program tar
term_is_latin	if true internal UTF-8 is translated to ISO-8859-1 (and nonsense for characters outside latin range)
unzip	location of external program unzip
urllist	arrayref to nearby CPAN sites (or equivalent locations)
wait_list	arrayref to a wait server to try (See CPAN::WAIT)
ftp_proxy,	} the three usual variables for configuring
http_proxy,	} proxy requests. Both as CPAN::Config variables
no_proxy	} and as environment variables configurable.

You can set and query each of these options interactively in the cpan shell with the command set defined within the o conf command:

- o conf <scalar option>
prints the current value of the *scalar option*
- o conf <scalar option> <value>
Sets the value of the *scalar option* to *value*
- o conf <list option>
prints the current value of the *list option* in MakeMaker's neatvalue format.
- o conf <list option> [shift|pop]
shifts or pops the array in the *list option* variable

- o `conf <list option> [unshift|push|splice] <list>`

works like the corresponding perl commands.

Note on urllist parameter's format

urllist parameters are URLs according to RFC 1738. We do a little guessing if your URL is not compliant, but if you have problems with file URLs, please try the correct format. Either:

```
file://localhost/whatever/ftp/pub/CPAN/
```

or

```
file:///home/ftp/pub/CPAN/
```

urllist parameter has CD-ROM support

The urllist parameter of the configuration table contains a list of URLs that are to be used for downloading. If the list contains any file URLs, CPAN always tries to get files from there first. This feature is disabled for index files. So the recommendation for the owner of a CD-ROM with CPAN contents is: include your local, possibly outdated CD-ROM as a file URL at the end of urllist, e.g.

- o `conf urllist push file://localhost/CDROM/CPAN`

CPAN.pm will then fetch the index files from one of the CPAN sites that come at the beginning of urllist. It will later check for each module if there is a local copy of the most recent version.

Another peculiarity of urllist is that the site that we could successfully fetch the last file from automatically gets a preference token and is tried as the first site for the next request. So if you add a new site at runtime it may happen that the previously preferred site will be tried another time. This means that if you want to disallow a site for the next transfer, it must be explicitly removed from urllist.

SECURITY

There's no strong security layer in CPAN.pm. CPAN.pm helps you to install foreign, unmasked, unsigned code on your machine. We compare to a checksum that comes from the net just as the distribution file itself. If somebody has managed to tamper with the distribution file, they may have as well tampered with the CHECKSUMS file. Future development will go towards strong authentication.

EXPORT

Most functions in package CPAN are exported per default. The reason for this is that the primary use is intended for the cpan shell or for one-liners.

POPULATE AN INSTALLATION WITH LOTS OF MODULES

Populating a freshly installed perl with my favorite modules is pretty easy if you maintain a private bundle definition file. To get a useful blueprint of a bundle definition file, the command autobundle can be used on the CPAN shell command line. This command writes a bundle definition file for all modules that are installed for the currently running perl interpreter. It's recommended to run this command only once and from then on maintain the file manually under a private name, say Bundle/my_bundle.pm. With a clever bundle file you can then simply say

```
cpan> install Bundle::my_bundle
```

then answer a few questions and then go out for a coffee.

Maintaining a bundle definition file means keeping track of two things: dependencies and interactivity. CPAN.pm sometimes fails on calculating dependencies because not all modules define all MakeMaker attributes correctly, so a bundle definition file should specify prerequisites as early as possible. On the other hand, it's a bit annoying that many distributions need some interactive configuring. So what I try to accomplish in my private bundle file is to have the packages that need to be configured early in the file and the gentle ones later, so I can go out after a few minutes and leave CPAN.pm untended.

WORKING WITH CPAN.pm BEHIND FIREWALLS

Thanks to Graham Barr for contributing the following paragraphs about the interaction between perl, and various firewall configurations. For further informations on firewalls, it is recommended to consult the documentation that comes with the ncftp program. If you are unable to go through the firewall with a simple Perl setup, it is very likely that you can configure ncftp so that it works for your firewall.

Three basic types of firewalls

Firewalls can be categorized into three basic types.

http firewall

This is where the firewall machine runs a web server and to access the outside world you must do it via the web server. If you set environment variables like `http_proxy` or `ftp_proxy` to a values beginning with `http://` or in your web browser you have to set proxy information then you know you are running an http firewall.

To access servers outside these types of firewalls with perl (even for ftp) you will need to use LWP.

ftp firewall

This where the firewall machine runs an ftp server. This kind of firewall will only let you access ftp servers outside the firewall. This is usually done by connecting to the firewall with ftp, then entering a username like "user@outside.host.com"

To access servers outside these type of firewalls with perl you will need to use Net::FTP.

One way visibility

I say one way visibility as these firewalls try to make themselves look invisible to the users inside the firewall. An FTP data connection is normally created by sending the remote server your IP address and then listening for the connection. But the remote server will not be able to connect to you because of the firewall. So for these types of firewall FTP connections need to be done in a passive mode.

There are two that I can think off.

SOCKS

If you are using a SOCKS firewall you will need to compile perl and link it with the SOCKS library, this is what is normally called a 'socksified' perl. With this executable you will be able to connect to servers outside the firewall as if it is not there.

IP Masquerade

This is the firewall implemented in the Linux kernel, it allows you to hide a complete network behind one IP address. With this firewall no special compiling is needed as you can access hosts directly.

Configuring lynx or ncftp for going through a firewall

If you can go through your firewall with e.g. lynx, presumably with a command such as

```
/usr/local/bin/lynx -pscott:tiger
```

then you would configure CPAN.pm with the command

```
o conf lynx "/usr/local/bin/lynx -pscott:tiger"
```

That's all. Similarly for ncftp or ftp, you would configure something like

```
o conf ncftp "/usr/bin/ncftp -f /home/scott/ncftplogin.cfg"
```

Your mileage may vary...

FAQ

- 1) I installed a new version of module X but CPAN keeps saying, I have the old version installed

Most probably you **do** have the old version installed. This can happen if a module installs itself into a different directory in the @INC path than it was previously installed. This is not really a CPAN.pm problem, you would have the same problem when installing the module manually. The easiest way to prevent this behaviour is to add the argument UNINST=1 to the make install call, and that is why many people add this argument permanently by configuring

```
o conf make_install_arg UNINST=1
```

- 2) So why is UNINST=1 not the default?

Because there are people who have their precise expectations about who may install where in the @INC path and who uses which @INC array. In fine tuned environments UNINST=1 can cause damage.

- 3) I want to clean up my mess, and install a new perl along with all modules I have. How do I go about it?

Run the autobundle command for your old perl and optionally rename the resulting bundle file (e.g. Bundle/mybundle.pm), install the new perl with the Configure option prefix, e.g.

```
./Configure -Dprefix=/usr/local/perl-5.6.78.9
```

Install the bundle file you produced in the first step with something like

```
cpan> install Bundle::mybundle
```

and you're done.

- 4) When I install bundles or multiple modules with one command there is too much output to keep track of.

You may want to configure something like

```
o conf make_arg "| tee -ai /root/.cpan/logs/make.out"
o conf make_install_arg "| tee -ai /root/.cpan/logs/make_install.out"
```

so that STDOUT is captured in a file for later inspection.

- 5) I am not root, how can I install a module in a personal directory?

You will most probably like something like this:

```
o conf makepl_arg "LIB=~/.myperl/lib \
                  INSTALLMAN1DIR=~/.myperl/man/man1 \
                  INSTALLMAN3DIR=~/.myperl/man/man3"
install Sybase::Sybperl
```

You can make this setting permanent like all o conf settings with o conf commit.

You will have to add ~/.myperl/man to the MANPATH environment variable and also tell your perl programs to look into ~/.myperl/lib, e.g. by including

```
use lib "$ENV{HOME}/myperl/lib";
```

or setting the PERL5LIB environment variable.

Another thing you should bear in mind is that the UNINST parameter should never be set if you are not root.

- 6) How to get a package, unwrap it, and make a change before building it?

```
look Sybase::Sybperl
```

- 7) I installed a Bundle and had a couple of fails. When I retried, everything resolved nicely. Can this be fixed to work on first try?

The reason for this is that CPAN does not know the dependencies of all modules when it starts out. To decide about the additional items to install, it just uses data found in the generated Makefile. An undetected missing piece breaks the process. But it may well be that your Bundle installs some prerequisite later than some depending item and thus your second try is able to resolve everything. Please note, CPAN.pm does not know the dependency tree in advance and cannot sort the queue of things to install in a topologically correct order. It resolves perfectly well IFF all modules declare the prerequisites correctly with the PREREQ_PM attribute to MakeMaker. For bundles which fail and you need to install often, it is recommended sort the Bundle definition file manually. It is planned to improve the metadata situation for dependencies on CPAN in general, but this will still take some time.

- 8) In our intranet we have many modules for internal use. How can I integrate these modules with CPAN.pm but without uploading the modules to CPAN?

Have a look at the CPAN::Site module.

- 9) When I run CPAN's shell, I get error msg about line 1 to 4, setting meta input/output via the /etc/inputrc file.

Some versions of readline are picky about capitalization in the /etc/inputrc file and specifically RedHat 6.2 comes with a /etc/inputrc that contains the word `on` in lowercase. Change the occurrences of `on` to `On` and the bug should disappear.

- 10) Some authors have strange characters in their names.

Internally CPAN.pm uses the UTF-8 charset. If your terminal is expecting ISO-8859-1 charset, a converter can be activated by setting `term_is_latin` to a true value in your config file. One way of doing so would be

```
cpan> ! $CPAN::Config->{term_is_latin}=1
```

Extended support for converters will be made available as soon as perl becomes stable with regard to charset issues.

BUGS

We should give coverage for **all** of the CPAN and not just the PAUSE part, right? In this discussion CPAN and PAUSE have become equal — but they are not. PAUSE is `authors/`, `modules/` and `scripts/`. CPAN is PAUSE plus the `clpa/`, `doc/`, `misc/`, `ports/`, and `src/`.

Future development should be directed towards a better integration of the other parts.

If a Makefile.PL requires special customization of libraries, prompts the user for special input, etc. then you may find CPAN is not able to build the distribution. In that case, you should attempt the traditional method of building a Perl module package from a shell.

NAME

CPAN::FirstTime – Utility for CPAN::Config file Initialization

SYNOPSIS

```
CPAN::FirstTime::init()
```

DESCRIPTION

The init routine asks a few questions and writes a CPAN::Config file. Nothing special.

NAME

CPAN::Nox – Wrapper around CPAN.pm without using any XS module

SYNOPSIS

Interactive mode:

```
perl -MCPAN::Nox -e shell;
```

DESCRIPTION

This package has the same functionality as CPAN.pm, but tries to prevent the usage of compiled extensions during its own execution. Its primary purpose is a rescue in case you upgraded perl and broke binary compatibility somehow.

CPAN(3)

NAME

Cwd – get pathname of current working directory

SYNOPSIS

```
use Cwd;
my $dir = getcwd;

use Cwd 'abs_path';
my $abs_path = abs_path($file);
```

DESCRIPTION

This module provides functions for determining the pathname of the current working directory. It is recommended that `getcwd` (or another `*cwd()` function) be used in *all* code to ensure portability.

By default, it exports the functions `cwd()`, `getcwd()`, `fastcwd()`, and `fastgetcwd()` into the caller's namespace.

getcwd and friends

Each of these functions are called without arguments and return the absolute path of the current working directory.

getcwd

```
my $cwd = getcwd();
```

Returns the current working directory.

Re-implements the `getcwd(3)` (or `getwd(3)`) functions in Perl.

Taint-safe.

cwd

```
my $cwd = cwd();
```

The `cwd()` is the most natural form for the current architecture. For most systems it is identical to `'pwd'` (but without the trailing line terminator).

Taint-safe.

fastcwd

```
my $cwd = fastcwd();
```

A more dangerous version of `getcwd()`, but potentially faster.

It might conceivably `chdir()` you out of a directory that it can't `chdir()` you back into. If `fastcwd` encounters a problem it will return `undef` but will probably leave you in a different directory. For a measure of extra security, if everything appears to have worked, the `fastcwd()` function will check that it leaves you in the same directory that it started in. If it has changed it will `die` with the message "Unstable directory path, current directory changed unexpectedly". That should never happen.

fastgetcwd

```
my $cwd = fastgetcwd();
```

The `fastgetcwd()` function is provided as a synonym for `cwd()`.

abs_path and friends

These functions are exported only on request. They each take a single argument and return the absolute pathname for it.

abs_path

```
my $abs_path = abs_path($file);
```

Uses the same algorithm as `getcwd()`. Symbolic links and relative-path components (`."` and `".."`)

are resolved to return the canonical pathname, just like `realpath(3)`.

Taint-safe.

`realpath`

```
my $abs_path = realpath($file);
```

A synonym for `abs_path()`.

Taint-safe.

`fast_abs_path`

```
my $abs_path = fast_abs_path($file);
```

A more dangerous, but potentially faster version of `abs_path`.

This function is **Not** taint-safe : you can't use it in programs that work under taint mode.

`$ENV{PWD}`

If you ask to override your `chdir()` built-in function,

```
use Cwd qw(chdir);
```

then your `PWD` environment variable will be kept up to date. Note that it will only be kept up to date if all packages which use `chdir` import it from `Cwd`.

NOTES

- Since the path separators are different on some operating systems ('/' on Unix, ':' on MacPerl, etc...) we recommend you use the `File::Spec` modules wherever portability is a concern.
- Actually, on Mac OS, the `getcwd()`, `fastgetcwd()` and `fastcwd()` functions are all aliases for the `cwd()` function, which, on Mac OS, calls 'pwd'. Likewise, the `abs_path()` function is an alias for `fast_abs_path()`.

NAME

Data::Dumper – stringified perl data structures, suitable for both printing and eval

SYNOPSIS

```
use Data::Dumper;

# simple procedural interface
print Dumper($foo, $bar);

# extended usage with names
print Data::Dumper->Dump([$foo, $bar], [qw(foo *ary)]);

# configuration variables
{
    local $Data::Dump::Purity = 1;
    eval Data::Dumper->Dump([$foo, $bar], [qw(foo *ary)]);
}

# OO usage
$d = Data::Dumper->new([$foo, $bar], [qw(foo *ary)]);
...
print $d->Dump;
...
$d->Purity(1)->Terse(1)->Deepcopy(1);
eval $d->Dump;
```

DESCRIPTION

Given a list of scalars or reference variables, writes out their contents in perl syntax. The references can also be objects. The contents of each variable is output in a single Perl statement. Handles self-referential structures correctly.

The return value can be `eval`d to get back an identical copy of the original reference structure.

Any references that are the same as one of those passed in will be named `$VARn` (where *n* is a numeric suffix), and other duplicate references to substructures within `$VARn` will be appropriately labeled using arrow notation. You can specify names for individual values to be dumped if you use the `Dump()` method, or you can change the default `$VAR` prefix to something else. See `$Data::Dumper::Varname` and `$Data::Dumper::Terse` below.

The default output of self-referential structures can be `eval`d, but the nested references to `$VARn` will be undefined, since a recursive structure cannot be constructed using one Perl statement. You should set the `Purity` flag to 1 to get additional statements that will correctly fill in these references.

In the extended usage form, the references to be dumped can be given user-specified names. If a name begins with a `*`, the output will describe the dereferenced type of the supplied reference for hashes and arrays, and coderefs. Output of names will be avoided where possible if the `Terse` flag is set.

In many cases, methods that are used to set the internal state of the object will return the object itself, so method calls can be conveniently chained together.

Several styles of output are possible, all controlled by setting the `Indent` flag. See [Configuration Variables or Methods](#) below for details.

Methods

PACKAGE-new(*ARRAYREF* [, *ARRAYREF*])

Returns a newly created `Data::Dumper` object. The first argument is an anonymous array of values to be dumped. The optional second argument is an anonymous array of names for the values. The names need not have a leading `$` sign, and must be comprised of alphanumeric characters. You can begin a name with a `*` to specify that the dereferenced type must be dumped instead of the reference

itself, for ARRAY and HASH references.

The prefix specified by `$Data::Dumper::Varname` will be used with a numeric suffix if the name for a value is undefined.

`Data::Dumper` will catalog all references encountered while dumping the values. Cross-references (in the form of names of substructures in perl syntax) will be inserted at all possible points, preserving any structural interdependencies in the original set of values. Structure traversal is depth-first, and proceeds in order from the first supplied value to the last.

`$OBJ-Dump` or `PACKAGE-Dump(ARRAYREF [, ARRAYREF])`

Returns the stringified form of the values stored in the object (preserving the order in which they were supplied to `new`), subject to the configuration options below. In a list context, it returns a list of strings corresponding to the supplied values.

The second form, for convenience, simply calls the `new` method on its arguments before dumping the object immediately.

`$OBJ-Seen([HASHREF])`

Queries or adds to the internal table of already encountered references. You must use `Reset` to explicitly clear the table if needed. Such references are not dumped; instead, their names are inserted wherever they are encountered subsequently. This is useful especially for properly dumping subroutine references.

Expects an anonymous hash of name = value pairs. Same rules apply for names as in `new`. If no argument is supplied, will return the "seen" list of name = value pairs, in a list context. Otherwise, returns the object itself.

`$OBJ-Values([ARRAYREF])`

Queries or replaces the internal array of values that will be dumped. When called without arguments, returns the values. Otherwise, returns the object itself.

`$OBJ-Names([ARRAYREF])`

Queries or replaces the internal array of user supplied names for the values that will be dumped. When called without arguments, returns the names. Otherwise, returns the object itself.

`$OBJ-Reset`

Clears the internal table of "seen" references and returns the object itself.

Functions

`Dumper(LIST)`

Returns the stringified form of the values in the list, subject to the configuration options below. The values will be named `$VARn` in the output, where *n* is a numeric suffix. Will return a list of strings in a list context.

Configuration Variables or Methods

Several configuration variables can be used to control the kind of output generated when using the procedural interface. These variables are usually `localized` in a block so that other parts of the code are not affected by the change.

These variables determine the default state of the object created by calling the `new` method, but cannot be used to alter the state of the object thereafter. The equivalent method names should be used instead to query or set the internal state of the object.

The method forms return the object itself when called with arguments, so that they can be chained together nicely.

`$Data::Dumper::Indent` or `$OBJ-Indent([NEWVAL])`

Controls the style of indentation. It can be set to 0, 1, 2 or 3. Style 0 spews output without any newlines, indentation, or spaces between list items. It is the most compact format possible that can still be called valid perl. Style 1 outputs a readable form with newlines but no fancy indentation (each level in the structure is simply indented by a fixed amount of whitespace). Style 2 (the default) outputs a very readable form which takes into account the length of hash keys (so the hash value lines up). Style 3 is like style 2, but also annotates the elements of arrays with their index (but the comment is on its own line, so array output consumes twice the number of lines). Style 2 is the default.

`$Data::Dumper::Purity` or `$OBJ-Purity([NEWVAL])`

Controls the degree to which the output can be eval'd to recreate the supplied reference structures. Setting it to 1 will output additional perl statements that will correctly recreate nested references. The default is 0.

`$Data::Dumper::Pad` or `$OBJ-Pad([NEWVAL])`

Specifies the string that will be prefixed to every line of the output. Empty string by default.

`$Data::Dumper::Varname` or `$OBJ-Varname([NEWVAL])`

Contains the prefix to use for tagging variable names in the output. The default is "VAR".

`$Data::Dumper::Useqq` or `$OBJ-Useqq([NEWVAL])`

When set, enables the use of double quotes for representing string values. Whitespace other than space will be represented as `[\n\t\r]`, "unsafe" characters will be backslashed, and unprintable characters will be output as quoted octal integers. Since setting this variable imposes a performance penalty, the default is 0. `Dump()` will run slower if this flag is set, since the fast XSUB implementation doesn't support it yet.

`$Data::Dumper::Terse` or `$OBJ-Terse([NEWVAL])`

When set, `Data::Dumper` will emit single, non-self-referential values as atoms/terms rather than statements. This means that the `$VARn` names will be avoided where possible, but be advised that such output may not always be parseable by `eval`.

`$Data::Dumper::Freezer` or `$OBJ-Freezer([NEWVAL])`

Can be set to a method name, or to an empty string to disable the feature. `Data::Dumper` will invoke that method via the object before attempting to stringify it. This method can alter the contents of the object (if, for instance, it contains data allocated from C), and even rebless it in a different package. The client is responsible for making sure the specified method can be called via the object, and that the object ends up containing only perl data types after the method has been called. Defaults to an empty string.

`$Data::Dumper::Toaster` or `$OBJ-Toaster([NEWVAL])`

Can be set to a method name, or to an empty string to disable the feature. `Data::Dumper` will emit a method call for any objects that are to be dumped using the syntax `bless(DATA, CLASS)->METHOD()`. Note that this means that the method specified will have to perform any modifications required on the object (like creating new state within it, and/or reblessing it in a different package) and then return it. The client is responsible for making sure the method can be called via the object, and that it returns a valid object. Defaults to an empty string.

`$Data::Dumper::Deepcopy` or `$OBJ-Deepcopy([NEWVAL])`

Can be set to a boolean value to enable deep copies of structures. Cross-referencing will then only be done when absolutely essential (i.e., to break reference cycles). Default is 0.

`$Data::Dumper::Quotekeys` or `$OBJ-Quotekeys([NEWVAL])`

Can be set to a boolean value to control whether hash keys are quoted. A false value will avoid quoting hash keys when it looks like a simple string. Default is 1, which will always enclose hash keys in quotes.

`$Data::Dumper::Bless` or `$OBJ-Bless([NEWVAL])`

Can be set to a string that specifies an alternative to the `bless` builtin operator used to create objects. A function with the specified name should exist, and should accept the same arguments as the builtin. Default is `bless`.

`$Data::Dumper::Maxdepth` or `$OBJ-Maxdepth([NEWVAL])`

Can be set to a positive integer that specifies the depth beyond which we don't venture into a structure. Has no effect when `Data::Dumper::Purity` is set. (Useful in debugger when we often don't want to see more than enough). Default is 0, which means there is no maximum depth.

`$Data::Dumper::Useperl` or `$OBJ-Useperl([NEWVAL])`

Can be set to a boolean value which controls whether the pure Perl implementation of `Data::Dumper` is used. The `Data::Dumper` module is a dual implementation, with almost all functionality written in both pure Perl and also in XS ('C'). Since the XS version is much faster, it will always be used if possible. This option lets you override the default behavior, usually for testing purposes only. Default is 0, which means the XS implementation will be used if possible.

`$Data::Dumper::Sortkeys` or `$OBJ-Sortkeys([NEWVAL])`

Can be set to a boolean value to control whether hash keys are dumped in sorted order. A true value will cause the keys of all hashes to be dumped in Perl's default sort order. Can also be set to a subroutine reference which will be called for each hash that is dumped. In this case `Data::Dumper` will call the subroutine once for each hash, passing it the reference of the hash. The purpose of the subroutine is to return a reference to an array of the keys that will be dumped, in the order that they should be dumped. Using this feature, you can control both the order of the keys, and which keys are actually used. In other words, this subroutine acts as a filter by which you can exclude certain keys from being dumped. Default is 0, which means that hash keys are not sorted.

`$Data::Dumper::Deparse` or `$OBJ-Deparse([NEWVAL])`

Can be set to a boolean value to control whether code references are turned into perl source code. If set to a true value, `B::Deparse` will be used to get the source of the code reference. Using this option will force using the Perl implementation of the dumper, since the fast XSUB implementation doesn't support it.

Caution : use this option only if you know that your coderefs will be properly reconstructed by `B::Deparse`.

Exports

Dumper

EXAMPLES

Run these code snippets to get a quick feel for the behavior of this module. When you are through with these examples, you may want to add or change the various configuration variables described above, to see their behavior. (See the testsuite in the `Data::Dumper` distribution for more examples.)

```
use Data::Dumper;

package Foo;
sub new {bless {'a' => 1, 'b' => sub { return "foo" }}, $_[0]};

package Fuz;
# a weird REF-REF-SCALAR object
sub new {bless \($_ = \ 'fu\'z'), $_[0]};

package main;
$foo = Foo->new;
$fuz = Fuz->new;
$boo = [ 1, [], "abcd", \*foo,
         {1 => 'a', 023 => 'b', 0x45 => 'c'},
         \\ "p\q\'r", $foo, $fuz];
```

```

#####
# simple usage
#####

$bar = eval(Dumper($boo));
print($@) if $@;
print Dumper($boo), Dumper($bar); # pretty print (no array indices)

$Data::Dumper::Terse = 1;          # don't output names where feasible
$Data::Dumper::Indent = 0;        # turn off all pretty print
print Dumper($boo), "\n";

$Data::Dumper::Indent = 1;        # mild pretty print
print Dumper($boo);

$Data::Dumper::Indent = 3;        # pretty print with array indices
print Dumper($boo);

$Data::Dumper::Useqq = 1;         # print strings in double quotes
print Dumper($boo);

#####
# recursive structures
#####

@c = ('c');
$c = \@c;
$b = {};
$a = [1, $b, $c];
$b->{a} = $a;
$b->{b} = $a->[1];
$b->{c} = $a->[2];
print Data::Dumper->Dump([$a,$b,$c], [qw(a b c)]);

$Data::Dumper::Purity = 1;        # fill in the holes for eval
print Data::Dumper->Dump([$a, $b], [qw(*a b)]); # print as @a
print Data::Dumper->Dump([$b, $a], [qw(*b a)]); # print as %b

$Data::Dumper::Deepcopy = 1;      # avoid cross-refs
print Data::Dumper->Dump([$b, $a], [qw(*b a)]);

$Data::Dumper::Purity = 0;        # avoid cross-refs
print Data::Dumper->Dump([$b, $a], [qw(*b a)]);

#####
# deep structures
#####

$a = "pearl";
$b = [ $a ];
$c = { 'b' => $b };
$d = [ $c ];
$e = { 'd' => $d };
$f = { 'e' => $e };
print Data::Dumper->Dump([$f], [qw(f)]);

$Data::Dumper::Maxdepth = 3;      # no deeper than 3 refs down
print Data::Dumper->Dump([$f], [qw(f)]);

#####
# object-oriented usage

```

```

#####
$d = Data::Dumper->new([$a,$b], [qw(a b)]);
$d->Seen({'*c' => $c});          # stash a ref without printing it
$d->Indent(3);
print $d->Dump;
$d->Reset->Purity(0);           # empty the seen cache
print join "----\n", $d->Dump;

#####
# persistence
#####

package Foo;
sub new { bless { state => 'awake' }, shift }
sub Freeze {
    my $s = shift;
    print STDERR "preparing to sleep\n";
    $s->{state} = 'asleep';
    return bless $s, 'Foo::ZZZ';
}

package Foo::ZZZ;
sub Thaw {
    my $s = shift;
    print STDERR "waking up\n";
    $s->{state} = 'awake';
    return bless $s, 'Foo';
}

package Foo;
use Data::Dumper;
$a = Foo->new;
$b = Data::Dumper->new([$a], ['c']);
$b->Freezer('Freeze');
$b->Toaster('Thaw');
$c = $b->Dump;
print $c;
$d = eval $c;
print Data::Dumper->Dump([$d], ['d']);

#####
# symbol substitution (useful for recreating CODE refs)
#####

sub foo { print "foo speaking\n" }
*other = \&foo;
$bar = [ \&other ];
$d = Data::Dumper->new([\&other,$bar],['*other','bar']);
$d->Seen({'*foo' => \&foo });
print $d->Dump;

#####
# sorting and filtering hash keys
#####

$Data::Dumper::Sortkeys = \&my_filter;
my $foo = { map { (ord, "$_$_$_") } 'I'..'Q' };
my $bar = { %$foo };

```

```

my $baz = { reverse %$foo };
print Dumper [ $foo, $bar, $baz ];

sub my_filter {
    my ($hash) = @_;
    # return an array ref containing the hash keys to dump
    # in the order that you want them to be dumped
    return [
        # Sort the keys of %$foo in reverse numeric order
        $hash eq $foo ? (sort {$b <=> $a} keys %$hash) :
        # Only dump the odd number keys of %$bar
        $hash eq $bar ? (grep {$_ % 2} keys %$hash) :
        # Sort keys in default order for all other hashes
        (sort keys %$hash)
    ];
}

```

BUGS

Due to limitations of Perl subroutine call semantics, you cannot pass an array or hash. Prepend it with a \ to pass its reference instead. This will be remedied in time, now that Perl has subroutine prototypes. For now, you need to use the extended usage form, and prepend the name with a * to output it as a hash or array.

`Data::Dumper` cheats with CODE references. If a code reference is encountered in the structure being processed (and if you haven't set the `Deparse` flag), an anonymous subroutine that contains the string "DUMMY" will be inserted in its place, and a warning will be printed if `Purity` is set. You can `eval` the result, but bear in mind that the anonymous sub that gets created is just a placeholder. Someday, perl will have a switch to cache-on-demand the string representation of a compiled piece of code, I hope. If you have prior knowledge of all the code refs that your data structures are likely to have, you can use the `Seen` method to pre-seed the internal reference table and make the dumped output point to them, instead. See [EXAMPLES](#) above.

The `Useqq` and `Deparse` flags makes `Dump()` run slower, since the XSUB implementation does not support them.

SCALAR objects have the weirdest looking `bless` workaround.

NAME

DB – programmatic interface to the Perl debugging API (draft, subject to change)

SYNOPSIS

```
package CLIENT;
use DB;
@ISA = qw(DB);

# these (inherited) methods can be called by the client

CLIENT->register()      # register a client package name
CLIENT->done()          # de-register from the debugging API
CLIENT->skippkg('hide::hide') # ask DB not to stop in this package
CLIENT->cont([WHERE])   # run some more (until BREAK or another breakpt)
CLIENT->step()          # single step
CLIENT->next()          # step over
CLIENT->ret()           # return from current subroutine
CLIENT->backtrace()     # return the call stack description
CLIENT->ready()         # call when client setup is done
CLIENT->trace_toggle()  # toggle subroutine call trace mode
CLIENT->subs([SUBS])    # return subroutine information
CLIENT->files()         # return list of all files known to DB
CLIENT->lines()         # return lines in currently loaded file
CLIENT->loadfile(FILE,LINE) # load a file and let other clients know
CLIENT->lineevents()    # return info on lines with actions
CLIENT->set_break([WHERE],[COND])
CLIENT->set_tbreak([WHERE])
CLIENT->clr_breaks([LIST])
CLIENT->set_action(WHERE,ACTION)
CLIENT->clr_actions([LIST])
CLIENT->evalcode(String) # eval STRING in executing code's context
CLIENT->prestop([String]) # execute in code context before stopping
CLIENT->poststop([String]) # execute in code context before resuming

# These methods will be called at the appropriate times.
# Stub versions provided do nothing.
# None of these can block.

CLIENT->init()          # called when debug API inits itself
CLIENT->stop(FILE,LINE) # when execution stops
CLIENT->idle()          # while stopped (can be a client event loop)
CLIENT->cleanup()       # just before exit
CLIENT->output(LIST)    # called to print any output that API must show
```

DESCRIPTION

Perl debug information is frequently required not just by debuggers, but also by modules that need some "special" information to do their job properly, like profilers.

This module abstracts and provides all of the hooks into Perl internal debugging functionality, so that various implementations of Perl debuggers (or packages that want to simply get at the "privileged" debugging data) can all benefit from the development of this common code. Currently used by Swat, the perl/Tk GUI debugger.

Note that multiple "front-ends" can latch into this debugging API simultaneously. This is intended to facilitate things like debugging with a command line and GUI at the same time, debugging debuggers etc. [Sounds nice, but this needs some serious support — GSAR]

In particular, this API does **not** provide the following functions:

- data display
- command processing
- command alias management
- user interface (tty or graphical)

These are intended to be services performed by the clients of this API.

This module attempts to be squeaky clean w.r.t `use strict`; and when warnings are enabled.

Global Variables

The following "public" global names can be read by clients of this API. Beware that these should be considered "readonly".

`$DB::sub`

Name of current executing subroutine.

`%DB::sub`

The keys of this hash are the names of all the known subroutines. Each value is an encoded string that has the `sprintf(3)` format `("%s:%d-%d", filename, fromline, toline)`.

`$DB::single`

Single-step flag. Will be true if the API will stop at the next statement.

`$DB::signal`

Signal flag. Will be set to a true value if a signal was caught. Clients may check for this flag to abort time-consuming operations.

`$DB::trace`

This flag is set to true if the API is tracing through subroutine calls.

`@DB::args`

Contains the arguments of current subroutine, or the `@ARGV` array if in the `toplevel` context.

`@DB::dbline`

List of lines in currently loaded file.

`%DB::dbline`

Actions in current file (keys are line numbers). The values are strings that have the `sprintf(3)` format `("%s\000%s", breakcondition, actioncode)`.

`$DB::package`

Package namespace of currently executing code.

`$DB::filename`

Currently loaded filename.

`$DB::subname`

Fully qualified name of currently executing subroutine.

`$DB::lineno`

Line number that will be executed next.

API Methods

The following are methods in the DB base class. A client must access these methods by inheritance (**not** by calling them directly), since the API keeps track of clients through the inheritance mechanism.

CLIENT-register()

register a client object/package

CLIENT-evalcode(String)

eval String in executing code context

CLIENT-skippkg('D::hide')

ask DB not to stop in these packages

CLIENT-run()

run some more (until a breakpoint is reached)

CLIENT-step()

single step

CLIENT-next()

step over

CLIENT-done()

de-register from the debugging API

Client Callback Methods

The following "virtual" methods can be defined by the client. They will be called by the API at appropriate points. Note that unless specified otherwise, the debug API only defines empty, non-functional default versions of these methods.

CLIENT-init()

Called after debug API inits itself.

CLIENT-prestop([String])

Usually inherited from DB package. If no arguments are passed, returns the prestop action string.

CLIENT-stop()

Called when execution stops (w/ args file, line).

CLIENT-idle()

Called while stopped (can be a client event loop).

CLIENT-poststop([String])

Usually inherited from DB package. If no arguments are passed, returns the poststop action string.

CLIENT-evalcode(String)

Usually inherited from DB package. Ask for a String to be eval-ed in executing code context.

CLIENT-cleanup()

Called just before exit.

CLIENT-output(List)

Called when API must show a message (warnings, errors etc.).

BUGS

The interface defined by this module is missing some of the later additions to perl's debugging functionality. As such, this interface should be considered highly experimental and subject to change.

NAME

DB_File – Perl5 access to Berkeley DB version 1.x

SYNOPSIS

```
use DB_File;

[$X =] tie %hash, 'DB_File', [$filename, $flags, $mode, $DB_HASH] ;
[$X =] tie %hash, 'DB_File', $filename, $flags, $mode, $DB_BTREE ;
[$X =] tie @array, 'DB_File', $filename, $flags, $mode, $DB_RECNO ;

$status = $X->del($key [, $flags]) ;
$status = $X->put($key, $value [, $flags]) ;
$status = $X->get($key, $value [, $flags]) ;
$status = $X->seq($key, $value, $flags) ;
$status = $X->sync([$flags]) ;
$status = $X->fd ;

# BTREE only
$count = $X->get_dup($key) ;
@list = $X->get_dup($key) ;
%list = $X->get_dup($key, 1) ;
$status = $X->find_dup($key, $value) ;
$status = $X->del_dup($key, $value) ;

# RECNO only
$a = $X->length;
$a = $X->pop ;
$X->push(list);
$a = $X->shift;
$X->unshift(list);
@r = $X->splice(offset, length, elements);

# DBM Filters
$old_filter = $db->filter_store_key ( sub { ... } ) ;
$old_filter = $db->filter_store_value( sub { ... } ) ;
$old_filter = $db->filter_fetch_key ( sub { ... } ) ;
$old_filter = $db->filter_fetch_value( sub { ... } ) ;

untie %hash ;
untie @array ;
```

DESCRIPTION

DB_File is a module which allows Perl programs to make use of the facilities provided by Berkeley DB version 1.x (if you have a newer version of DB, see [Using DB_File with Berkeley DB version 2 or greater](#)). It is assumed that you have a copy of the Berkeley DB manual pages at hand when reading this documentation. The interface defined here mirrors the Berkeley DB interface closely.

Berkeley DB is a C library which provides a consistent interface to a number of database formats. **DB_File** provides an interface to all three of the database types currently supported by Berkeley DB.

The file types are:

DB_HASH

This database type allows arbitrary key/value pairs to be stored in data files. This is equivalent to the functionality provided by other hashing packages like DBM, NDBM, ODBM, GDBM, and SDBM. Remember though, the files created using DB_HASH are not compatible with any of the other packages mentioned.

A default hashing algorithm, which will be adequate for most applications, is built into Berkeley DB.

If you do need to use your own hashing algorithm it is possible to write your own in Perl and have **DB_File** use it instead.

DB_BTREE

The btree format allows arbitrary key/value pairs to be stored in a sorted, balanced binary tree.

As with the DB_HASH format, it is possible to provide a user defined Perl routine to perform the comparison of keys. By default, though, the keys are stored in lexical order.

DB_RECNO

DB_RECNO allows both fixed-length and variable-length flat text files to be manipulated using the same key/value pair interface as in DB_HASH and DB_BTREE. In this case the key will consist of a record (line) number.

Using DB_File with Berkeley DB version 2 or greater

Although **DB_File** is intended to be used with Berkeley DB version 1, it can also be used with version 2, 3 or 4. In this case the interface is limited to the functionality provided by Berkeley DB 1.x. Anywhere the version 2 or greater interface differs, **DB_File** arranges for it to work like version 1. This feature allows **DB_File** scripts that were built with version 1 to be migrated to version 2 or greater without any changes.

If you want to make use of the new features available in Berkeley DB 2.x or greater, use the Perl module **BerkeleyDB** instead.

Note: The database file format has changed multiple times in Berkeley DB version 2, 3 and 4. If you cannot recreate your databases, you must dump any existing databases with either the `db_dump` or the `db_dump185` utility that comes with Berkeley DB. Once you have rebuilt DB_File to use Berkeley DB version 2 or greater, your databases can be recreated using `db_load`. Refer to the Berkeley DB documentation for further details.

Please read "[COPYRIGHT](#)" before using version 2.x or greater of Berkeley DB with DB_File.

Interface to Berkeley DB

DB_File allows access to Berkeley DB files using the `tie()` mechanism in Perl 5 (for full details, see [tie\(\)](#)). This facility allows **DB_File** to access Berkeley DB files using either an associative array (for DB_HASH & DB_BTREE file types) or an ordinary array (for the DB_RECNO file type).

In addition to the `tie()` interface, it is also possible to access most of the functions provided in the Berkeley DB API directly. See [THE API INTERFACE](#).

Opening a Berkeley DB Database File

Berkeley DB uses the function `dbopen()` to open or create a database. Here is the C prototype for `dbopen()`:

```
DB*
dbopen (const char* file, int flags, int mode,
        DBTYPE type, const void * openinfo)
```

The parameter `type` is an enumeration which specifies which of the 3 interface methods (DB_HASH, DB_BTREE or DB_RECNO) is to be used. Depending on which of these is actually chosen, the final parameter, `openinfo` points to a data structure which allows tailoring of the specific interface method.

This interface is handled slightly differently in **DB_File**. Here is an equivalent call using **DB_File**:

```
tie %array, 'DB_File', $filename, $flags, $mode, $DB_HASH ;
```

The `filename`, `flags` and `mode` parameters are the direct equivalent of their `dbopen()` counterparts. The final parameter `$DB_HASH` performs the function of both the `type` and `openinfo` parameters in `dbopen()`.

In the example above `$DB_HASH` is actually a pre-defined reference to a hash object. **DB_File** has three of these pre-defined references. Apart from `$DB_HASH`, there is also `$DB_BTREE` and `$DB_RECNO`.

The keys allowed in each of these pre-defined references is limited to the names used in the equivalent C structure. So, for example, the `$DB_HASH` reference will only allow keys called `bsize`, `cachesize`, `ffactor`, `hash`, `lorder` and `nelem`.

To change one of these elements, just assign to it like this:

```
$DB_HASH->{'cachesize'} = 10000 ;
```

The three predefined variables `$DB_HASH`, `$DB_BTREE` and `$DB_RECNO` are usually adequate for most applications. If you do need to create extra instances of these objects, constructors are available for each file type.

Here are examples of the constructors and the valid options available for `DB_HASH`, `DB_BTREE` and `DB_RECNO` respectively.

```
$a = new DB_File::HASHINFO ;
$a->{'bsize'} ;
$a->{'cachesize'} ;
$a->{'ffactor'} ;
$a->{'hash'} ;
$a->{'lorder'} ;
$a->{'nelem'} ;

$b = new DB_File::BTREEINFO ;
$b->{'flags'} ;
$b->{'cachesize'} ;
$b->{'maxkeypage'} ;
$b->{'minkeypage'} ;
$b->{'psize'} ;
$b->{'compare'} ;
$b->{'prefix'} ;
$b->{'lorder'} ;

$c = new DB_File::RECNOINFO ;
$c->{'bval'} ;
$c->{'cachesize'} ;
$c->{'psize'} ;
$c->{'flags'} ;
$c->{'lorder'} ;
$c->{'reclen'} ;
$c->{'bfname'} ;
```

The values stored in the hashes above are mostly the direct equivalent of their C counterpart. Like their C counterparts, all are set to a default values – that means you don't have to set *all* of the values when you only want to change one. Here is an example:

```
$a = new DB_File::HASHINFO ;
$a->{'cachesize'} = 12345 ;
tie %y, 'DB_File', "filename", $flags, 0777, $a ;
```

A few of the options need extra discussion here. When used, the C equivalent of the keys `hash`, `compare` and `prefix` store pointers to C functions. In **DB_File** these keys are used to store references to Perl subs. Below are templates for each of the subs:

```
sub hash
{
    my ($data) = @_ ;
    ...
    # return the hash value for $data
    return $hash ;
}
```

```

    }

    sub compare
    {
        my ($key, $key2) = @_ ;
        ...
        # return 0 if $key1 eq $key2
        #       -1 if $key1 lt $key2
        #       1 if $key1 gt $key2
        return (-1 , 0 or 1) ;
    }

    sub prefix
    {
        my ($key, $key2) = @_ ;
        ...
        # return number of bytes of $key2 which are
        # necessary to determine that it is greater than $key1
        return $bytes ;
    }

```

See [Changing the BTREE sort order](#) for an example of using the compare template.

If you are using the DB_RECNO interface and you intend making use of bval, you should check out [The 'bval' Option](#).

Default Parameters

It is possible to omit some or all of the final 4 parameters in the call to tie and let them take default values. As DB_HASH is the most common file format used, the call:

```
tie %A, "DB_File", "filename" ;
```

is equivalent to:

```
tie %A, "DB_File", "filename", O_CREAT|O_RDWR, 0666, $DB_HASH ;
```

It is also possible to omit the filename parameter as well, so the call:

```
tie %A, "DB_File" ;
```

is equivalent to:

```
tie %A, "DB_File", undef, O_CREAT|O_RDWR, 0666, $DB_HASH ;
```

See [In Memory Databases](#) for a discussion on the use of undef in place of a filename.

In Memory Databases

Berkeley DB allows the creation of in-memory databases by using NULL (that is, a (char *)0 in C) in place of the filename. **DB_File** uses undef instead of NULL to provide this functionality.

DB_HASH

The DB_HASH file format is probably the most commonly used of the three file formats that **DB_File** supports. It is also very straightforward to use.

A Simple Example

This example shows how to create a database, add key/value pairs to the database, delete keys/value pairs and finally how to enumerate the contents of the database.

```

use warnings ;
use strict ;
use DB_File ;
our (%h, $k, $v) ;

```

```

unlink "fruit" ;
tie %h, "DB_File", "fruit", O_RDWR|O_CREAT, 0666, $DB_HASH
    or die "Cannot open file 'fruit': $!\n";

# Add a few key/value pairs to the file
$h{"apple"} = "red" ;
$h{"orange"} = "orange" ;
$h{"banana"} = "yellow" ;
$h{"tomato"} = "red" ;

# Check for existence of a key
print "Banana Exists\n\n" if $h{"banana"} ;

# Delete a key/value pair.
delete $h{"apple"} ;

# print the contents of the file
while (($k, $v) = each %h)
    { print "$k -> $v\n" }

untie %h ;

```

here is the output:

```

Banana Exists

orange -> orange
tomato -> red
banana -> yellow

```

Note that the like ordinary associative arrays, the order of the keys retrieved is in an apparently random order.

DB_BTREE

The DB_BTREE format is useful when you want to store data in a given order. By default the keys will be stored in lexical order, but as you will see from the example shown in the next section, it is very easy to define your own sorting function.

Changing the BTREE sort order

This script shows how to override the default sorting algorithm that BTREE uses. Instead of using the normal lexical ordering, a case insensitive compare function will be used.

```

use warnings ;
use strict ;
use DB_File ;

my %h ;

sub Compare
{
    my ($key1, $key2) = @_ ;
    "\L$key1" cmp "\L$key2" ;
}

# specify the Perl sub that will do the comparison
$db_BTREE->{'compare'} = \&Compare ;

unlink "tree" ;
tie %h, "DB_File", "tree", O_RDWR|O_CREAT, 0666, $DB_BTREE
    or die "Cannot open file 'tree': $!\n" ;

# Add a key/value pair to the file
$h{'Wall'} = 'Larry' ;

```

```

$h{'Smith'} = 'John' ;
$h{'mouse'} = 'mickey' ;
$h{'duck'} = 'donald' ;

# Delete
delete $h{"duck"} ;

# Cycle through the keys printing them in order.
# Note it is not necessary to sort the keys as
# the btree will have kept them in order automatically.
foreach (keys %h)
    { print "$_\n" }

untie %h ;

```

Here is the output from the code above.

```

mouse
Smith
Wall

```

There are a few point to bear in mind if you want to change the ordering in a BTREE database:

1. The new compare function must be specified when you create the database.
2. You cannot change the ordering once the database has been created. Thus you must use the same compare function every time you access the database.
3. Duplicate keys are entirely defined by the comparison function. In the case-insensitive example above, the keys: 'KEY' and 'key' would be considered duplicates, and assigning to the second one would overwrite the first. If duplicates are allowed for (with the R_DUPS flag discussed below), only a single copy of duplicate keys is stored in the database — so (again with example above) assigning three values to the keys: 'KEY', 'Key', and 'key' would leave just the first key: 'KEY' in the database with three values. For some situations this results in information loss, so care should be taken to provide fully qualified comparison functions when necessary. For example, the above comparison routine could be modified to additionally compare case-sensitively if two keys are equal in the case insensitive comparison:

```

sub compare {
    my($key1, $key2) = @_;
    lc $key1 cmp lc $key2 ||
    $key1 cmp $key2;
}

```

And now you will only have duplicates when the keys themselves are truly the same. (note: in versions of the db library prior to about November 1996, such duplicate keys were retained so it was possible to recover the original keys in sets of keys that compared as equal).

Handling Duplicate Keys

The BTREE file type optionally allows a single key to be associated with an arbitrary number of values. This option is enabled by setting the flags element of \$DB_BTREE to R_DUP when creating the database.

There are some difficulties in using the tied hash interface if you want to manipulate a BTREE database with duplicate keys. Consider this code:

```

use warnings ;
use strict ;
use DB_File ;

my ($filename, %h) ;

$filename = "tree" ;

```

```

unlink $filename ;

# Enable duplicate records
$DB_BTREE->{'flags'} = R_DUP ;

tie %h, "DB_File", $filename, O_RDWR|O_CREAT, 0666, $DB_BTREE
    or die "Cannot open $filename: $!\n";

# Add some key/value pairs to the file
$h{'Wall'} = 'Larry' ;
$h{'Wall'} = 'Brick' ; # Note the duplicate key
$h{'Wall'} = 'Brick' ; # Note the duplicate key and value
$h{'Smith'} = 'John' ;
$h{'mouse'} = 'mickey' ;

# iterate through the associative array
# and print each key/value pair.
foreach (sort keys %h)
    { print "$_ -> $h{$_}\n" }

untie %h ;

```

Here is the output:

```

Smith    -> John
Wall     -> Larry
Wall     -> Larry
Wall     -> Larry
mouse    -> mickey

```

As you can see 3 records have been successfully created with key Wall – the only thing is, when they are retrieved from the database they *seem* to have the same value, namely Larry. The problem is caused by the way that the associative array interface works. Basically, when the associative array interface is used to fetch the value associated with a given key, it will only ever retrieve the first value.

Although it may not be immediately obvious from the code above, the associative array interface can be used to write values with duplicate keys, but it cannot be used to read them back from the database.

The way to get around this problem is to use the Berkeley DB API method called `seq`. This method allows sequential access to key/value pairs. See [THE API INTERFACE](#) for details of both the `seq` method and the API in general.

Here is the script above rewritten using the `seq` API method.

```

use warnings ;
use strict ;
use DB_File ;

my ($filename, $x, %h, $status, $key, $value) ;

$filename = "tree" ;
unlink $filename ;

# Enable duplicate records
$DB_BTREE->{'flags'} = R_DUP ;

$x = tie %h, "DB_File", $filename, O_RDWR|O_CREAT, 0666, $DB_BTREE
    or die "Cannot open $filename: $!\n";

# Add some key/value pairs to the file
$h{'Wall'} = 'Larry' ;
$h{'Wall'} = 'Brick' ; # Note the duplicate key
$h{'Wall'} = 'Brick' ; # Note the duplicate key and value

```

```

$h{'Smith'} = 'John' ;
$h{'mouse'} = 'mickey' ;

# iterate through the btree using seq
# and print each key/value pair.
$key = $value = 0 ;
for ($status = $x->seq($key, $value, R_FIRST) ;
    $status == 0 ;
    $status = $x->seq($key, $value, R_NEXT) )
{
    print "$key -> $value\n" ;
}

undef $x ;
untie %h ;

```

that prints:

```

Smith    -> John
Wall     -> Brick
Wall     -> Brick
Wall     -> Larry
mouse    -> mickey

```

This time we have got all the key/value pairs, including the multiple values associated with the key `Wall`.

To make life easier when dealing with duplicate keys, **DB_File** comes with a few utility methods.

The `get_dup()` Method

The `get_dup` method assists in reading duplicate values from BTREE databases. The method can take the following forms:

```

$count = $x->get_dup($key) ;
@list  = $x->get_dup($key) ;
%list  = $x->get_dup($key, 1) ;

```

In a scalar context the method returns the number of values associated with the key, `$key`.

In list context, it returns all the values which match `$key`. Note that the values will be returned in an apparently random order.

In list context, if the second parameter is present and evaluates TRUE, the method returns an associative array. The keys of the associative array correspond to the values that matched in the BTREE and the values of the array are a count of the number of times that particular value occurred in the BTREE.

So assuming the database created above, we can use `get_dup` like this:

```

use warnings ;
use strict ;
use DB_File ;

my ($filename, $x, %h) ;

$filename = "tree" ;

# Enable duplicate records
$DB_BTREE->{'flags'} = R_DUP ;

$x = tie %h, "DB_File", $filename, O_RDWR|O_CREAT, 0666, $DB_BTREE
    or die "Cannot open $filename: $!\n";

my $cnt = $x->get_dup("Wall") ;
print "Wall occurred $cnt times\n" ;

my %hash = $x->get_dup("Wall", 1) ;
print "Larry is there\n" if $hash{'Larry'} ;

```

```

print "There are $hash{'Brick'} Brick Walls\n" ;

my @list = sort $x->get_dup("Wall") ;
print "Wall =>      [@list]\n" ;

@list = $x->get_dup("Smith") ;
print "Smith =>      [@list]\n" ;

@list = $x->get_dup("Dog") ;
print "Dog =>        [@list]\n" ;

```

and it will print:

```

Wall occurred 3 times
Larry is there
There are 2 Brick Walls
Wall =>      [Brick Brick Larry]
Smith =>      [John]
Dog =>        []

```

The `find_dup()` Method

```
$status = $X->find_dup($key, $value) ;
```

This method checks for the existence of a specific key/value pair. If the pair exists, the cursor is left pointing to the pair and the method returns 0. Otherwise the method returns a non-zero value.

Assuming the database from the previous example:

```

use warnings ;
use strict ;
use DB_File ;

my ($filename, $x, %h, $found) ;

$filename = "tree" ;

# Enable duplicate records
$DB_BTREE->{'flags'} = R_DUP ;

$x = tie %h, "DB_File", $filename, O_RDWR|O_CREAT, 0666, $DB_BTREE
    or die "Cannot open $filename: $!\n";

$found = ( $x->find_dup("Wall", "Larry") == 0 ? "" : "not" ) ;
print "Larry Wall is $found there\n" ;

$found = ( $x->find_dup("Wall", "Harry") == 0 ? "" : "not" ) ;
print "Harry Wall is $found there\n" ;

undef $x ;
untie %h ;

```

prints this

```

Larry Wall is  there
Harry Wall is not there

```

The `del_dup()` Method

```
$status = $X->del_dup($key, $value) ;
```

This method deletes a specific key/value pair. It returns 0 if they exist and have been deleted successfully. Otherwise the method returns a non-zero value.

Again assuming the existence of the tree database

```
use warnings ;
```

```

use strict ;
use DB_File ;

my ($filename, $x, %h, $found) ;

$filename = "tree" ;

# Enable duplicate records
$DB_BTREE->{'flags'} = R_DUP ;

$x = tie %h, "DB_File", $filename, O_RDWR|O_CREAT, 0666, $DB_BTREE
    or die "Cannot open $filename: $!\n";

$x->del_dup("Wall", "Larry") ;

$found = ( $x->find_dup("Wall", "Larry") == 0 ? "" : "not") ;
print "Larry Wall is $found there\n" ;

undef $x ;
untie %h ;

prints this

    Larry Wall is not there

```

Matching Partial Keys

The BTREE interface has a feature which allows partial keys to be matched. This functionality is *only* available when the seq method is used along with the R_CURSOR flag.

```
$x->seq($key, $value, R_CURSOR) ;
```

Here is the relevant quote from the dbopen man page where it defines the use of the R_CURSOR flag with seq:

Note, for the DB_BTREE access method, the returned key is not necessarily an exact match for the specified key. The returned key is the smallest key greater than or equal to the specified key, permitting partial key matches and range searches.

In the example script below, the match sub uses this feature to find and print the first matching key/value pair given a partial key.

```

use warnings ;
use strict ;
use DB_File ;
use Fcntl ;

my ($filename, $x, %h, $st, $key, $value) ;

sub match
{
    my $key = shift ;
    my $value = 0 ;
    my $orig_key = $key ;
    $x->seq($key, $value, R_CURSOR) ;
    print "$orig_key\t-> $key\t-> $value\n" ;
}

$filename = "tree" ;
unlink $filename ;

$x = tie %h, "DB_File", $filename, O_RDWR|O_CREAT, 0666, $DB_BTREE
    or die "Cannot open $filename: $!\n";

```

```

# Add some key/value pairs to the file
$h{'mouse'} = 'mickey' ;
$h{'Wall'} = 'Larry' ;
$h{'Walls'} = 'Brick' ;
$h{'Smith'} = 'John' ;

$key = $value = 0 ;
print "IN ORDER\n" ;
for ($st = $x->seq($key, $value, R_FIRST) ;
    $st == 0 ;
    $st = $x->seq($key, $value, R_NEXT) )
    { print "$key    -> $value\n" }

print "\nPARTIAL MATCH\n" ;

match "Wa" ;
match "A" ;
match "a" ;

undef $x ;
untie %h ;

```

Here is the output:

```

IN ORDER
Smith -> John
Wall  -> Larry
Walls -> Brick
mouse -> mickey

PARTIAL MATCH
Wa -> Wall  -> Larry
A  -> Smith -> John
a  -> mouse -> mickey

```

DB_RECNO

DB_RECNO provides an interface to flat text files. Both variable and fixed length records are supported.

In order to make RECNO more compatible with Perl, the array offset for all RECNO arrays begins at 0 rather than 1 as in Berkeley DB.

As with normal Perl arrays, a RECNO array can be accessed using negative indexes. The index -1 refers to the last element of the array, -2 the second last, and so on. Attempting to access an element before the start of the array will raise a fatal run-time error.

The 'bval' Option

The operation of the bval option warrants some discussion. Here is the definition of bval from the Berkeley DB 1.85 recno manual page:

```

The delimiting byte to be used to mark the end of a
record for variable-length records, and the pad charac-
ter for fixed-length records.  If no value is speci-
fied, newlines ('\n') are used to mark the end of
variable-length records and fixed-length records are
padded with spaces.

```

The second sentence is wrong. In actual fact bval will only default to "\n" when the openinfo parameter in dbopen is NULL. If a non-NULL openinfo parameter is used at all, the value that happens to be in bval will be used. That means you always have to specify bval when making use of any of the options in the openinfo parameter. This documentation error will be fixed in the next release of Berkeley DB.

That clarifies the situation with regards Berkeley DB itself. What about **DB_File**? Well, the behavior defined in the quote above is quite useful, so **DB_File** conforms to it.

That means that you can specify other options (e.g. cachesize) and still have bval default to "\n" for variable length records, and space for fixed length records.

Also note that the bval option only allows you to specify a single byte as a delimiter.

A Simple Example

Here is a simple example that uses RECNO (if you are using a version of Perl earlier than 5.004_57 this example won't work — see [Extra RECNO Methods](#) for a workaround).

```
use warnings ;
use strict ;
use DB_File ;

my $filename = "text" ;
unlink $filename ;

my @h ;
tie @h, "DB_File", $filename, O_RDWR|O_CREAT, 0666, $DB_RECNO
    or die "Cannot open file 'text': $!\n" ;

# Add a few key/value pairs to the file
$h[0] = "orange" ;
$h[1] = "blue" ;
$h[2] = "yellow" ;

push @h, "green", "black" ;

my $elements = scalar @h ;
print "The array contains $elements entries\n" ;

my $last = pop @h ;
print "popped $last\n" ;

unshift @h, "white" ;
my $first = shift @h ;
print "shifted $first\n" ;

# Check for existence of a key
print "Element 1 Exists with value $h[1]\n" if $h[1] ;

# use a negative index
print "The last element is $h[-1]\n" ;
print "The 2nd last element is $h[-2]\n" ;

untie @h ;
```

Here is the output from the script:

```
The array contains 5 entries
popped black
shifted white
Element 1 Exists with value blue
The last element is green
The 2nd last element is yellow
```

Extra RECNO Methods

If you are using a version of Perl earlier than 5.004_57, the tied array interface is quite limited. In the example script above push, pop, shift, unshift or determining the array length will not work with a tied array.

To make the interface more useful for older versions of Perl, a number of methods are supplied with **DB_File** to simulate the missing array operations. All these methods are accessed via the object returned from the tie call.

Here are the methods:

`$X->push(list) ;`

Pushes the elements of `list` to the end of the array.

`$value = $X->pop ;`

Removes and returns the last element of the array.

`$X->shift`

Removes and returns the first element of the array.

`$X->unshift(list) ;`

Pushes the elements of `list` to the start of the array.

`$X->length`

Returns the number of elements in the array.

`$X->splice(offset, length, elements);`

Returns a splice of the the array.

Another Example

Here is a more complete example that makes use of some of the methods described above. It also makes use of the API interface directly (see [THE API INTERFACE](#)).

```
use warnings ;
use strict ;
my (@h, $H, $file, $i) ;
use DB_File ;
use Fcntl ;

$file = "text" ;

unlink $file ;

$H = tie @h, "DB_File", $file, O_RDWR|O_CREAT, 0666, $DB_RECNO
    or die "Cannot open file $file: $!\n" ;

# first create a text file to play with
$h[0] = "zero" ;
$h[1] = "one" ;
$h[2] = "two" ;
$h[3] = "three" ;
$h[4] = "four" ;

# Print the records in order.
#
# The length method is needed here because evaluating a tied
# array in a scalar context does not return the number of
# elements in the array.

print "\nORIGINAL\n" ;
foreach $i (0 .. $H->length - 1) {
    print "$i: $h[$i]\n" ;
}

# use the push & pop methods
$a = $H->pop ;
```

```

$H->push("last") ;
print "\nThe last record was [$a]\n" ;

# and the shift & unshift methods
$a = $H->shift ;
$H->unshift("first") ;
print "The first record was [$a]\n" ;

# Use the API to add a new record after record 2.
$i = 2 ;
$H->put($i, "Newbie", R_I AFTER) ;

# and a new record before record 1.
$i = 1 ;
$H->put($i, "New One", R_I BEFORE) ;

# delete record 3
$H->del(3) ;

# now print the records in reverse order
print "\nREVERSE\n" ;
for ($i = $H->length - 1 ; $i >= 0 ; -- $i)
    { print "$i: $h[$i]\n" }

# same again, but use the API functions instead
print "\nREVERSE again\n" ;
my ($s, $k, $v) = (0, 0, 0) ;
for ($s = $H->seq($k, $v, R_LAST) ;
     $s == 0 ;
     $s = $H->seq($k, $v, R_PREV))
    { print "$k: $v\n" }

undef $H ;
untie @h ;

```

and this is what it outputs:

```

ORIGINAL
0: zero
1: one
2: two
3: three
4: four

The last record was [four]
The first record was [zero]

REVERSE
5: last
4: three
3: Newbie
2: one
1: New One
0: first

REVERSE again
5: last
4: three
3: Newbie
2: one

```

```
1: New One
0: first
```

Notes:

1. Rather than iterating through the array, @h like this:

```
foreach $i (@h)
```

it is necessary to use either this:

```
foreach $i (0 .. $H->length - 1)
```

or this:

```
for ($a = $H->get($k, $v, R_FIRST) ;
    $a == 0 ;
    $a = $H->get($k, $v, R_NEXT) )
```

2. Notice that both times the put method was used the record index was specified using a variable, \$i, rather than the literal value itself. This is because put will return the record number of the inserted line via that parameter.

THE API INTERFACE

As well as accessing Berkeley DB using a tied hash or array, it is also possible to make direct use of most of the API functions defined in the Berkeley DB documentation.

To do this you need to store a copy of the object returned from the tie.

```
$db = tie %hash, "DB_File", "filename" ;
```

Once you have done that, you can access the Berkeley DB API functions as **DB_File** methods directly like this:

```
$db->put($key, $value, R_NOOVERWRITE) ;
```

Important: If you have saved a copy of the object returned from tie, the underlying database file will *not* be closed until both the tied variable is untied and all copies of the saved object are destroyed.

```
use DB_File ;
$db = tie %hash, "DB_File", "filename"
    or die "Cannot tie filename: $!" ;
...
undef $db ;
untie %hash ;
```

See [The untie\(\) Gotcha](#) for more details.

All the functions defined in [dbopen](#) are available except for close() and dbopen() itself. The **DB_File** method interface to the supported functions have been implemented to mirror the way Berkeley DB works whenever possible. In particular note that:

- The methods return a status value. All return 0 on success. All return -1 to signify an error and set \$! to the exact error code. The return code 1 generally (but not always) means that the key specified did not exist in the database.

Other return codes are defined. See below and in the Berkeley DB documentation for details. The Berkeley DB documentation should be used as the definitive source.
- Whenever a Berkeley DB function returns data via one of its parameters, the equivalent **DB_File** method does exactly the same.
- If you are careful, it is possible to mix API calls with the tied hash/array interface in the same piece of code. Although only a few of the methods used to implement the tied interface currently make use of the cursor, you should always assume that the cursor has been changed any time the tied

hash/array interface is used. As an example, this code will probably not do what you expect:

```
$X = tie %x, 'DB_File', $filename, O_RDWR|O_CREAT, 0777, $DB_BTREE
    or die "Cannot tie $filename: $!";

# Get the first key/value pair and set the cursor
$X->seq($key, $value, R_FIRST) ;

# this line will modify the cursor
$count = scalar keys %x ;

# Get the second key/value pair.
# oops, it didn't, it got the last key/value pair!
$X->seq($key, $value, R_NEXT) ;
```

The code above can be rearranged to get around the problem, like this:

```
$X = tie %x, 'DB_File', $filename, O_RDWR|O_CREAT, 0777, $DB_BTREE
    or die "Cannot tie $filename: $!";

# this line will modify the cursor
$count = scalar keys %x ;

# Get the first key/value pair and set the cursor
$X->seq($key, $value, R_FIRST) ;

# Get the second key/value pair.
# worked this time.
$X->seq($key, $value, R_NEXT) ;
```

All the constants defined in [dbopen](#) for use in the flags parameters in the methods defined below are also available. Refer to the Berkeley DB documentation for the precise meaning of the flags values.

Below is a list of the methods available.

`$status = $X->get($key, $value [, $flags]) ;`

Given a key (`$key`) this method reads the value associated with it from the database. The value read from the database is returned in the `$value` parameter.

If the key does not exist the method returns 1.

No flags are currently defined for this method.

`$status = $X->put($key, $value [, $flags]) ;`

Stores the key/value pair in the database.

If you use either the `R_IAFTER` or `R_IBEFORE` flags, the `$key` parameter will have the record number of the inserted key/value pair set.

Valid flags are `R_CURSOR`, `R_IAFTER`, `R_IBEFORE`, `R_NOOVERWRITE` and `R_SETCURSOR`.

`$status = $X->del($key [, $flags]) ;`

Removes all key/value pairs with key `$key` from the database.

A return code of 1 means that the requested key was not in the database.

`R_CURSOR` is the only valid flag at present.

`$status = $X->fd ;`

Returns the file descriptor for the underlying database.

See [Locking: The Trouble with fd](#) for an explanation for why you should not use `fd` to lock your database.

```
$status = $X->seq($key, $value, $flags) ;
```

This interface allows sequential retrieval from the database. See [dbopen](#) for full details.

Both the `$key` and `$value` parameters will be set to the key/value pair read from the database.

The flags parameter is mandatory. The valid flag values are `R_CURSOR`, `R_FIRST`, `R_LAST`, `R_NEXT` and `R_PREV`.

```
$status = $X->sync([ $flags ] ) ;
```

Flushes any cached buffers to disk.

`R_RECNO_SYNC` is the only valid flag at present.

DBM FILTERS

A DBM Filter is a piece of code that is be used when you *always* want to make the same transformation to all keys and/or values in a DBM database.

There are four methods associated with DBM Filters. All work identically, and each is used to install (or uninstall) a single DBM Filter. Each expects a single parameter, namely a reference to a sub. The only difference between them is the place that the filter is installed.

To summarise:

filter_store_key

If a filter has been installed with this method, it will be invoked every time you write a key to a DBM database.

filter_store_value

If a filter has been installed with this method, it will be invoked every time you write a value to a DBM database.

filter_fetch_key

If a filter has been installed with this method, it will be invoked every time you read a key from a DBM database.

filter_fetch_value

If a filter has been installed with this method, it will be invoked every time you read a value from a DBM database.

You can use any combination of the methods, from none, to all four.

All filter methods return the existing filter, if present, or `undef` in not.

To delete a filter pass `undef` to it.

The Filter

When each filter is called by Perl, a local copy of `$_` will contain the key or value to be filtered. Filtering is achieved by modifying the contents of `$_`. The return code from the filter is ignored.

An Example — the NULL termination problem.

Consider the following scenario. You have a DBM database that you need to share with a third-party C application. The C application assumes that *all* keys and values are NULL terminated. Unfortunately when Perl writes to DBM databases it doesn't use NULL termination, so your Perl application will have to manage NULL termination itself. When you write to the database you will have to use something like this:

```
$hash{"$key\0"} = "$value\0" ;
```

Similarly the NULL needs to be taken into account when you are considering the length of existing keys/values.

It would be much better if you could ignore the NULL terminations issue in the main application code and have a mechanism that automatically added the terminating NULL to all keys and values whenever you write

to the database and have them removed when you read from the database. As I'm sure you have already guessed, this is a problem that DBM Filters can fix very easily.

```
use warnings ;
use strict ;
use DB_File ;

my %hash ;
my $filename = "/tmp/filt" ;
unlink $filename ;

my $db = tie %hash, 'DB_File', $filename, O_CREAT|O_RDWR, 0666, $DB_HASH
    or die "Cannot open $filename: $!\n" ;

# Install DBM Filters
$db->filter_fetch_key  ( sub { s/\0$//      } ) ;
$db->filter_store_key   ( sub { $_ .= "\0"   } ) ;
$db->filter_fetch_value( sub { s/\0$//      } ) ;
$db->filter_store_value( sub { $_ .= "\0"   } ) ;

$hash{"abc"} = "def" ;
my $a = $hash{"ABC"} ;
# ...
undef $db ;
untie %hash ;
```

Hopefully the contents of each of the filters should be self-explanatory. Both "fetch" filters remove the terminating NULL, and both "store" filters add a terminating NULL.

Another Example — Key is a C int.

Here is another real-life example. By default, whenever Perl writes to a DBM database it always writes the key and value as strings. So when you use this:

```
$hash{12345} = "soemthing" ;
```

the key 12345 will get stored in the DBM database as the 5 byte string "12345". If you actually want the key to be stored in the DBM database as a C int, you will have to use `pack` when writing, and `unpack` when reading.

Here is a DBM Filter that does it:

```
use warnings ;
use strict ;
use DB_File ;
my %hash ;
my $filename = "/tmp/filt" ;
unlink $filename ;

my $db = tie %hash, 'DB_File', $filename, O_CREAT|O_RDWR, 0666, $DB_HASH
    or die "Cannot open $filename: $!\n" ;

$db->filter_fetch_key  ( sub { $_ = unpack("i", $_) } ) ;
$db->filter_store_key   ( sub { $_ = pack ("i", $_) } ) ;
$hash{123} = "def" ;
# ...
undef $db ;
untie %hash ;
```

This time only two filters have been used — we only need to manipulate the contents of the key, so it wasn't necessary to install any value filters.

HINTS AND TIPS

Locking: The Trouble with fd

Until version 1.72 of this module, the recommended technique for locking **DB_File** databases was to flock the filehandle returned from the "fd" function. Unfortunately this technique has been shown to be fundamentally flawed (Kudos to David Harris for tracking this down). Use it at your own peril!

The locking technique went like this.

```
$db = tie(%db, 'DB_File', '/tmp/foo.db', O_CREAT|O_RDWR, 0666)
    || die "dbcreat /tmp/foo.db $!";
$fd = $db->fd;
open(DB_FH, "+<&=$fd") || die "dup $!";
flock (DB_FH, LOCK_EX) || die "flock: $!";
...
$db{"Tom"} = "Jerry" ;
...
flock (DB_FH, LOCK_UN);
undef $db;
untie %db;
close (DB_FH);
```

In simple terms, this is what happens:

1. Use "tie" to open the database.
2. Lock the database with fd & flock.
3. Read & Write to the database.
4. Unlock and close the database.

Here is the crux of the problem. A side-effect of opening the **DB_File** database in step 2 is that an initial block from the database will get read from disk and cached in memory.

To see why this is a problem, consider what can happen when two processes, say "A" and "B", both want to update the same **DB_File** database using the locking steps outlined above. Assume process "A" has already opened the database and has a write lock, but it hasn't actually updated the database yet (it has finished step 2, but not started step 3 yet). Now process "B" tries to open the same database – step 1 will succeed, but it will block on step 2 until process "A" releases the lock. The important thing to notice here is that at this point in time both processes will have cached identical initial blocks from the database.

Now process "A" updates the database and happens to change some of the data held in the initial buffer. Process "A" terminates, flushing all cached data to disk and releasing the database lock. At this point the database on disk will correctly reflect the changes made by process "A".

With the lock released, process "B" can now continue. It also updates the database and unfortunately it too modifies the data that was in its initial buffer. Once that data gets flushed to disk it will overwrite some/all of the changes process "A" made to the database.

The result of this scenario is at best a database that doesn't contain what you expect. At worst the database will corrupt.

The above won't happen every time competing process update the same **DB_File** database, but it does illustrate why the technique should not be used.

Safe ways to lock a database

Starting with version 2.x, Berkeley DB has internal support for locking. The companion module to this one, **BerkeleyDB**, provides an interface to this locking functionality. If you are serious about locking Berkeley DB databases, I strongly recommend using **BerkeleyDB**.

If using **BerkeleyDB** isn't an option, there are a number of modules available on CPAN that can be used to implement locking. Each one implements locking differently and has different goals in mind. It is therefore worth knowing the difference, so that you can pick the right one for your application. Here are the three locking wrappers:

Tie::DB_Lock

A **DB_File** wrapper which creates copies of the database file for read access, so that you have a kind of a multiversioning concurrent read system. However, updates are still serial. Use for databases where reads may be lengthy and consistency problems may occur.

Tie::DB_LockFile

A **DB_File** wrapper that has the ability to lock and unlock the database while it is being used. Avoids the tie-before-flock problem by simply re-tie-ing the database when you get or drop a lock. Because of the flexibility in dropping and re-acquiring the lock in the middle of a session, this can be massaged into a system that will work with long updates and/or reads if the application follows the hints in the POD documentation.

DB_File::Lock

An extremely lightweight **DB_File** wrapper that simply flocks a lockfile before tie-ing the database and drops the lock after the untie. Allows one to use the same lockfile for multiple databases to avoid deadlock problems, if desired. Use for databases where updates are reads are quick and simple flock locking semantics are enough.

Sharing Databases With C Applications

There is no technical reason why a Berkeley DB database cannot be shared by both a Perl and a C application.

The vast majority of problems that are reported in this area boil down to the fact that C strings are NULL terminated, whilst Perl strings are not. See [DBM FILTERS](#) for a generic way to work around this problem.

Here is a real example. Netscape 2.0 keeps a record of the locations you visit along with the time you last visited them in a DB_HASH database. This is usually stored in the file `~/.netscape/history.db`. The key field in the database is the location string and the value field is the time the location was last visited stored as a 4 byte binary value.

If you haven't already guessed, the location string is stored with a terminating NULL. This means you need to be careful when accessing the database.

Here is a snippet of code that is loosely based on Tom Christiansen's *ggh* script (available from your nearest CPAN archive in [authors/id/TOMC/scripts/nshist.gz](#)).

```
use warnings ;
use strict ;
use DB_File ;
use Fcntl ;

my ($dotdir, $HISTORY, %hist_db, $href, $binary_time, $date) ;
$dotdir = $ENV{HOME} || $ENV{LOGNAME};
$HISTORY = "$dotdir/.netscape/history.db";

tie %hist_db, 'DB_File', $HISTORY
    or die "Cannot open $HISTORY: $!\n" ;;

# Dump the complete database
while ( ($href, $binary_time) = each %hist_db ) {
    # remove the terminating NULL
    $href =~ s/\x00$// ;

    # convert the binary time into a user friendly string
```

```

        $date = localtime unpack("V", $binary_time);
        print "$date $href\n" ;
    }

    # check for the existence of a specific key
    # remember to add the NULL
    if ( $binary_time = $hist_db{"http://mox.perl.com/\x00"} ) {
        $date = localtime unpack("V", $binary_time) ;
        print "Last visited mox.perl.com on $date\n" ;
    }
    else {
        print "Never visited mox.perl.com\n"
    }

    untie %hist_db ;

```

The `untie()` Gotcha

If you make use of the Berkeley DB API, it is *very* strongly recommended that you read [The `untie` Gotcha](#).

Even if you don't currently make use of the API interface, it is still worth reading it.

Here is an example which illustrates the problem from a **DB_File** perspective:

```

use DB_File ;
use Fcntl ;

my %x ;
my $X ;

$X = tie %x, 'DB_File', 'tst.fil' , O_RDWR|O_TRUNC
    or die "Cannot tie first time: $!" ;

$x{123} = 456 ;

untie %x ;

tie %x, 'DB_File', 'tst.fil' , O_RDWR|O_CREAT
    or die "Cannot tie second time: $!" ;

untie %x ;

```

When run, the script will produce this error message:

```
Cannot tie second time: Invalid argument at bad.file line 14.
```

Although the error message above refers to the second `tie()` statement in the script, the source of the problem is really with the `untie()` statement that precedes it.

Having read [perl tie](#) you will probably have already guessed that the error is caused by the extra copy of the tied object stored in `$X`. If you haven't, then the problem boils down to the fact that the **DB_File** destructor, `DESTROY`, will not be called until *all* references to the tied object are destroyed. Both the tied variable, `%x`, and `$X` above hold a reference to the object. The call to `untie()` will destroy the first, but `$X` still holds a valid reference, so the destructor will not get called and the database file *tst.fil* will remain open. The fact that Berkeley DB then reports the attempt to open a database that is already open via the catch-all "Invalid argument" doesn't help.

If you run the script with the `-w` flag the error message becomes:

```
untie attempted while 1 inner references still exist at bad.file line 12.
Cannot tie second time: Invalid argument at bad.file line 14.
```

which pinpoints the real problem. Finally the script can now be modified to fix the original problem by destroying the API object before the `untie`:

```
...
$x{123} = 456 ;
undef $X ;
untie %x ;

$X = tie %x, 'DB_File', 'tst.fil' , O_RDWR|O_CREAT
...
```

COMMON QUESTIONS

Why is there Perl source in my database?

If you look at the contents of a database file created by DB_File, there can sometimes be part of a Perl script included in it.

This happens because Berkeley DB uses dynamic memory to allocate buffers which will subsequently be written to the database file. Being dynamic, the memory could have been used for anything before DB malloced it. As Berkeley DB doesn't clear the memory once it has been allocated, the unused portions will contain random junk. In the case where a Perl script gets written to the database, the random junk will correspond to an area of dynamic memory that happened to be used during the compilation of the script.

Unless you don't like the possibility of there being part of your Perl scripts embedded in a database file, this is nothing to worry about.

How do I store complex data structures with DB_File?

Although DB_File cannot do this directly, there is a module which can layer transparently over DB_File to accomplish this feat.

Check out the MLDBM module, available on CPAN in the directory *modules/by-module/MLDBM*.

What does "Invalid Argument" mean?

You will get this error message when one of the parameters in the tie call is wrong. Unfortunately there are quite a few parameters to get wrong, so it can be difficult to figure out which one it is.

Here are a couple of possibilities:

1. Attempting to reopen a database without closing it.
2. Using the O_WRONLY flag.

What does "Bareword 'DB_File' not allowed" mean?

You will encounter this particular error message when you have the strict 'subs' pragma (or the full strict pragma) in your script. Consider this script:

```
use warnings ;
use strict ;
use DB_File ;
my %x ;
tie %x, DB_File, "filename" ;
```

Running it produces the error in question:

```
Bareword "DB_File" not allowed while "strict subs" in use
```

To get around the error, place the word DB_File in either single or double quotes, like this:

```
tie %x, "DB_File", "filename" ;
```

Although it might seem like a real pain, it is really worth the effort of having a use strict in all your scripts.

REFERENCES

Articles that are either about **DB_File** or make use of it.

HISTORY

Moved to the Changes file.

BUGS

Some older versions of Berkeley DB had problems with fixed length records using the RECNO file format. This problem has been fixed since version 1.85 of Berkeley DB.

I am sure there are bugs in the code. If you do find any, or can suggest any enhancements, I would welcome your comments.

AVAILABILITY

DB_File comes with the standard Perl source distribution. Look in the directory *ext/DB_File*. Given the amount of time between releases of Perl the version that ships with Perl is quite likely to be out of date, so the most recent version can always be found on CPAN (see [CPAN](#) for details), in the directory *modules/by-module/DB_File*.

This version of **DB_File** will work with either version 1.x, 2.x or 3.x of Berkeley DB, but is limited to the functionality provided by version 1.

The official web site for Berkeley DB is <http://www.sleepycat.com>. All versions of Berkeley DB are available there.

Alternatively, Berkeley DB version 1 is available at your nearest CPAN archive in *src/misc/db.1.85.tar.gz*.

If you are running IRIX, then get Berkeley DB version 1 from <http://reality.sgi.com/ariel>. It has the patches necessary to compile properly on IRIX 5.3.

COPYRIGHT

Copyright (c) 1995–2002 Paul Marquess. All rights reserved. This program is free software; you can redistribute it and/or modify it under the same terms as Perl itself.

Although **DB_File** is covered by the Perl license, the library it makes use of, namely Berkeley DB, is not. Berkeley DB has its own copyright and its own license. Please take the time to read it.

Here are a few words taken from the Berkeley DB FAQ (at <http://www.sleepycat.com>) regarding the license:

Do I have to license DB to use it in Perl scripts?

No. The Berkeley DB license requires that software that uses Berkeley DB be freely redistributable. In the case of Perl, that software is Perl, and not your scripts. Any Perl scripts that you write are your property, including scripts that make use of Berkeley DB. Neither the Perl license nor the Berkeley DB license place any restriction on what you may do with them.

If you are in any doubt about the license situation, contact either the Berkeley DB authors or the author of **DB_File**. See *"AUTHOR"* for details.

AUTHOR

The DB_File interface was written by Paul Marquess <Paul.Marquess@btinternet.com>. Questions about the DB system itself may be addressed to <db@sleepycat.com>.

NAME

Devel::DProf – a Perl code profiler

SYNOPSIS

```
perl5 -d:DProf test.pl
```

DESCRIPTION

The Devel::DProf package is a Perl code profiler. This will collect information on the execution time of a Perl script and of the subs in that script. This information can be used to determine which subroutines are using the most time and which subroutines are being called most often. This information can also be used to create an execution graph of the script, showing subroutine relationships.

To profile a Perl script run the perl interpreter with the **-d** debugging switch. The profiler uses the debugging hooks. So to profile script *test.pl* the following command should be used:

```
perl5 -d:DProf test.pl
```

When the script terminates (or when the output buffer is filled) the profiler will dump the profile information to a file called *mon.out*. A tool like *dprofpp* can be used to interpret the information which is in that profile.

The following command will print the top 15 subroutines which used the most time:

```
dprofpp
```

To print an execution graph of the subroutines in the script use the following command:

```
dprofpp -T
```

Consult *dprofpp* for other options.

PROFILE FORMAT

The old profile is a text file which looks like this:

```
#fOrTyTwo
$hz=100;
$XS_VERSION='DProf 19970606';
# All values are given in HZ
$rrun_utime=2; $rrun_stime=0; $rrun_rtime=7
PART2
+ 26 28 566822884 DynaLoader::import
- 26 28 566822884 DynaLoader::import
+ 27 28 566822885 main::bar
- 27 28 566822886 main::bar
+ 27 28 566822886 main::baz
+ 27 28 566822887 main::bar
- 27 28 566822888 main::bar
[....]
```

The first line is the magic number. The second line is the hertz value, or clock ticks, of the machine where the profile was collected. The third line is the name and version identifier of the tool which created the profile. The fourth line is a comment. The fifth line contains three variables holding the user time, system time, and realtime of the process while it was being profiled. The sixth line indicates the beginning of the sub entry/exit profile section.

The columns in **PART2** are:

```
sub entry(+)/exit(-) mark
app's user time at sub entry/exit mark, in ticks
app's system time at sub entry/exit mark, in ticks
app's realtime at sub entry/exit mark, in ticks
fully-qualified sub name, when possible
```

With newer perls another format is used, which may look like this:

```
#fOrTyTwoO
$hz=10000;
$XS_VERSION='DProf 19971213';
# All values are given in HZ
$over_untime=5917; $over_stime=0; $over_rtime=5917;
$over_tests=10000;
$rrun_untime=1284; $rrun_stime=0; $rrun_rtime=1284;
$total_marks=6;

PART2
@ 406 0 406
& 2 main bar
+ 2
@ 456 0 456
- 2
@ 1 0 1
& 3 main baz
+ 3
@ 141 0 141
+ 2
@ 141 0 141
- 2
@ 1 0 1
& 4 main foo
+ 4
@ 142 0 142
+ & Devel::DProf::write
@ 5 0 5
- & Devel::DProf::write
```

(with high value of `$ENV{PERL_DPROF_TICKS}`).

New `$over_*` values show the measured overhead of making `$over_tests` calls to the profiler. These values are used by the profiler to subtract the overhead from the runtimes.

The lines starting with `@` mark time passed from the previous `@` line. The lines starting with `&` introduce new subroutine *id* and show the package and the subroutine name of this *id*. Lines starting with `+`, `-` and `*` mark entering and exit of subroutines by *ids*, and `goto &subr`.

The *old-style* `+-` and `--` lines are used to mark the overhead related to writing to profiler-output file.

AUTOLOAD

When `Devel::DProf` finds a call to an `&AUTOLOAD` subroutine it looks at the `$AUTOLOAD` variable to find the real name of the sub being called. See [Autoloading in perlsub](#).

ENVIRONMENT

`PERL_DPROF_BUFFER` sets size of output buffer in words. Defaults to `2*14`.

`PERL_DPROF_TICKS` sets number of ticks per second on some systems where a replacement for `times()` is used. Defaults to the value of `HZ` macro.

`PERL_DPROF_OUT_FILE_NAME` sets the name of the output file. If not set, defaults to `tmon.out`.

BUGS

Builtin functions cannot be measured by `Devel::DProf`.

With a newer Perl `DProf` relies on the fact that the numeric slot of `$DB::sub` contains an address of a subroutine. Excessive manipulation of this variable may overwrite this slot, as in

```
$DB::sub = 'current_sub';  
...  
$addr = $DB::sub + 0;
```

will set this numeric slot to numeric value of the string `current_sub`, i.e., to `.` This will cause a segfault on the exit from this subroutine. Note that the first assignment above does not change the numeric slot (it will *mark* it as invalid, but will not write over it).

Mail bug reports and feature requests to the perl5-porters mailing list at [<perl5-porters@perl.org>](mailto:perl5-porters@perl.org).

NAME

Devel::Peek – A data debugging tool for the XS programmer

SYNOPSIS

```
use Devel::Peek;
Dump( $a );
Dump( $a, 5 );
DumpArray( 5, $a, $b, ... );
mstat "Point 5";

use Devel::Peek ':opd=st';
```

DESCRIPTION

Devel::Peek contains functions which allows raw Perl datatypes to be manipulated from a Perl script. This is used by those who do XS programming to check that the data they are sending from C to Perl looks as they think it should look. The trick, then, is to know what the raw datatype is supposed to look like when it gets to Perl. This document offers some tips and hints to describe good and bad raw data.

It is very possible that this document will fall far short of being useful to the casual reader. The reader is expected to understand the material in the first few sections of [perlguts](#).

Devel::Peek supplies a `Dump()` function which can dump a raw Perl datatype, and `mstat("marker")` function to report on memory usage (if perl is compiled with corresponding option). The function `DeadCode()` provides statistics on the data "frozen" into inactive CV. Devel::Peek also supplies `SvREFCNT()`, `SvREFCNT_inc()`, and `SvREFCNT_dec()` which can query, increment, and decrement reference counts on SVs. This document will take a passive, and safe, approach to data debugging and for that it will describe only the `Dump()` function.

Function `DumpArray()` allows dumping of multiple values (useful when you need to analyze returns of functions).

The global variable `$Devel::Peek::pv_limit` can be set to limit the number of character printed in various string values. Setting it to 0 means no limit.

If use `Devel::Peek` directive has a `:opd=FLAGS` argument, this switches on debugging of opcode dispatch. `FLAGS` should be a combination of `s`, `t`, and `P` (see `-D` flags in [perlrun](#)). `:opd` is a shortcut for `:opd=st`.

Runtime debugging

`CvGV($cv)` return one of the globs associated to a subroutine reference `$cv`.

`debug_flags()` returns a string representation of `$_D` (similar to what is allowed for `-D` flag). When called with a numeric argument, sets `$_D` to the corresponding value. When called with an argument of the form `"flags-flags"`, set on/off bits of `$_D` corresponding to letters before/after `-`. (The returned value is for `$_D` before the modification.)

`runops_debug()` returns true if the current *opcode dispatcher* is the debugging one. When called with an argument, switches to debugging or non-debugging dispatcher depending on the argument (active for newly-entered subs/etc only). (The returned value is for the dispatcher before the modification.)

Memory footprint debugging

When perl is compiled with support for memory footprint debugging (default with Perl's `malloc()`), Devel::Peek provides an access to this API.

Use `mstat()` function to emit a memory state statistic to the terminal. For more information on the format of output of `mstat()` see [Using \\$ENV{PERL_DEBUG_MSTATS}](#).

Three additional functions allow access to this statistic from Perl. First, use `mstats_fillhash(%hash)` to get the information contained in the output of `mstat()` into `%hash`. The field of this hash are

```
minbucket nbuckets sbrk_good sbrk_slack sbrked_remains sbrks start_slack
topbucket topbucket_ev topbucket_odd total total_chain total_sbrk totfree
```

Two additional fields `free`, `used` contain array references which provide per-bucket count of free and used chunks. Two other fields `mem_size`, `available_size` contain array references which provide the information about the allocated size and usable size of chunks in each bucket. Again, see [Using \\$ENV{PERL_DEBUG_MSTATS}](#) for details.

Keep in mind that only the first several "odd-numbered" buckets are used, so the information on size of the "odd-numbered" buckets which are not used is probably meaningless.

The information in

```
mem_size available_size minbucket nbuckets
```

is the property of a particular build of perl, and does not depend on the current process. If you do not provide the optional argument to the functions `mstats_fillhash()`, `fill_mstats()`, `mstats2hash()`, then the information in fields `mem_size`, `available_size` is not updated.

`fill_mstats($buf)` is a much cheaper call (both speedwise and memory-wise) which collects the statistic into `$buf` in machine-readable form. At a later moment you may need to call `mstats2hash($buf, %hash)` to use this information to fill `%hash`.

All three APIs `fill_mstats($buf)`, `mstats_fillhash(%hash)`, and `mstats2hash($buf, %hash)` are designed to allocate no memory if used *the second time* on the same `$buf` and/or `%hash`.

So, if you want to collect memory info in a cycle, you may call

```
$#buf = 999;
fill_mstats($_) for @buf;
mstats_fillhash(%report, 1);           # Static info too

foreach (@buf) {
    # Do something...
    fill_mstats $_;                   # Collect statistic
}
foreach (@buf) {
    mstats2hash($_, %report);         # Preserve static info
    # Do something with %report
}
```

EXAMPLES

The following examples don't attempt to show everything as that would be a monumental task, and, frankly, we don't want this manpage to be an internals document for Perl. The examples do demonstrate some basics of the raw Perl datatypes, and should suffice to get most determined people on their way. There are no guidewires or safety nets, nor blazed trails, so be prepared to travel alone from this point and on and, if at all possible, don't fall into the quicksand (it's bad for business).

Oh, one final bit of advice: take [perlguys](#) with you. When you return we expect to see it well-thumbed.

A simple scalar string

Let's begin by looking a simple scalar which is holding a string.

```
use Devel::Peek;
$a = "hello";
Dump $a;
```

The output:

```
SV = PVIV(0xbc288)
  REFCNT = 1
  FLAGS = (POK,pPOK)
```

```
IV = 0
PV = 0xb2048 "hello"\0
CUR = 5
LEN = 6
```

This says \$a is an SV, a scalar. The scalar is a PVIV, a string. Its reference count is 1. It has the POK flag set, meaning its current PV field is valid. Because POK is set we look at the PV item to see what is in the scalar. The \0 at the end indicate that this PV is properly NUL-terminated. If the FLAGS had been IOK we would look at the IV item. CUR indicates the number of characters in the PV. LEN indicates the number of bytes requested for the PV (one more than CUR, in this case, because LEN includes an extra byte for the end-of-string marker).

A simple scalar number

If the scalar contains a number the raw SV will be leaner.

```
use Devel::Peek;
$a = 42;
Dump $a;
```

The output:

```
SV = IV(0xbc818)
REFCNT = 1
FLAGS = (IOK,pIOK)
IV = 42
```

This says \$a is an SV, a scalar. The scalar is an IV, a number. Its reference count is 1. It has the IOK flag set, meaning it is currently being evaluated as a number. Because IOK is set we look at the IV item to see what is in the scalar.

A simple scalar with an extra reference

If the scalar from the previous example had an extra reference:

```
use Devel::Peek;
$a = 42;
$b = \ $a;
Dump $a;
```

The output:

```
SV = IV(0xbe860)
REFCNT = 2
FLAGS = (IOK,pIOK)
IV = 42
```

Notice that this example differs from the previous example only in its reference count. Compare this to the next example, where we dump \$b instead of \$a.

A reference to a simple scalar

This shows what a reference looks like when it references a simple scalar.

```
use Devel::Peek;
$a = 42;
$b = \ $a;
Dump $b;
```

The output:

```
SV = RV(0xf041c)
REFCNT = 1
FLAGS = (ROK)
```

```

RV = 0xbab08
SV = IV(0xbe860)
REFCNT = 2
FLAGS = (IOK,pIOK)
IV = 42

```

Starting from the top, this says \$b is an SV. The scalar is an RV, a reference. It has the ROK flag set, meaning it is a reference. Because ROK is set we have an RV item rather than an IV or PV. Notice that Dump follows the reference and shows us what \$b was referencing. We see the same \$a that we found in the previous example.

Note that the value of RV coincides with the numbers we see when we stringify \$b. The addresses inside RV() and IV() are addresses of X*** structure which holds the current state of an SV. This address may change during lifetime of an SV.

A reference to an array

This shows what a reference to an array looks like.

```

use Devel::Peek;
$a = [42];
Dump $a;

```

The output:

```

SV = RV(0xf041c)
  REFCNT = 1
  FLAGS = (ROK)
  RV = 0xb2850
SV = PVAV(0xbd448)
  REFCNT = 1
  FLAGS = ( )
  IV = 0
  NV = 0
  ARRAY = 0xb2048
  ALLOC = 0xb2048
  FILL = 0
  MAX = 0
  ARYLEN = 0x0
  FLAGS = (REAL)
Elt No. 0 0xb5658
SV = IV(0xbe860)
  REFCNT = 1
  FLAGS = (IOK,pIOK)
  IV = 42

```

This says \$a is an SV and that it is an RV. That RV points to another SV which is a PVAV, an array. The array has one element, element zero, which is another SV. The field FILL above indicates the last element in the array, similar to \$#\$a.

If \$a pointed to an array of two elements then we would see the following.

```

use Devel::Peek 'Dump';
$a = [42,24];
Dump $a;

```

The output:

```

SV = RV(0xf041c)
  REFCNT = 1
  FLAGS = (ROK)

```

```

RV = 0xb2850
SV = PVAV(0xbd448)
REFCNT = 1
FLAGS = ()
IV = 0
NV = 0
ARRAY = 0xb2048
ALLOC = 0xb2048
FILL = 0
MAX = 0
ARYLEN = 0x0
FLAGS = (REAL)
Elt No. 0 0xb5658
SV = IV(0xbe860)
REFCNT = 1
FLAGS = (IOK,pIOK)
IV = 42
Elt No. 1 0xb5680
SV = IV(0xbe818)
REFCNT = 1
FLAGS = (IOK,pIOK)
IV = 24

```

Note that Dump will not report *all* the elements in the array, only several first (depending on how deep it already went into the report tree).

A reference to a hash

The following shows the raw form of a reference to a hash.

```

use Devel::Peek;
$a = {hello=>42};
Dump $a;

```

The output:

```

SV = RV(0xf041c)
REFCNT = 1
FLAGS = (ROK)
RV = 0xb2850
SV = PVHV(0xbd448)
REFCNT = 1
FLAGS = ()
NV = 0
ARRAY = 0xbd748
KEYS = 1
FILL = 1
MAX = 7
RITER = -1
EITER = 0x0
Elt "hello" => 0xbaaf0
SV = IV(0xbe860)
REFCNT = 1
FLAGS = (IOK,pIOK)
IV = 42

```

This shows `$a` is a reference pointing to an SV. That SV is a PVHV, a hash. Fields RITER and EITER are used by *each*.

Dumping a large array or hash

The `Dump()` function, by default, dumps up to 4 elements from a toplevel array or hash. This number can be increased by supplying a second argument to the function.

```
use Devel::Peek;
$a = [10,11,12,13,14];
Dump $a;
```

Notice that `Dump()` prints only elements 10 through 13 in the above code. The following code will print all of the elements.

```
use Devel::Peek 'Dump';
$a = [10,11,12,13,14];
Dump $a, 5;
```

A reference to an SV which holds a C pointer

This is what you really need to know as an XS programmer, of course. When an XSUB returns a pointer to a C structure that pointer is stored in an SV and a reference to that SV is placed on the XSUB stack. So the output from an XSUB which uses something like the `T_PTROBJ` map might look something like this:

```
SV = RV(0xf381c)
  REFCNT = 1
  FLAGS = (ROK)
  RV = 0xb8ad8
SV = PVMG(0xbb3c8)
  REFCNT = 1
  FLAGS = (OBJECT, IOK, pIOK)
  IV = 729160
  NV = 0
  PV = 0
  STASH = 0xc1d10      "CookBookB::Opaque"
```

This shows that we have an SV which is an RV. That RV points at another SV. In this case that second SV is a PVMG, a blessed scalar. Because it is blessed it has the `OBJECT` flag set. Note that an SV which holds a C pointer also has the `IOK` flag set. The `STASH` is set to the package name which this SV was blessed into.

The output from an XSUB which uses something like the `T_PTRREF` map, which doesn't bless the object, might look something like this:

```
SV = RV(0xf381c)
  REFCNT = 1
  FLAGS = (ROK)
  RV = 0xb8ad8
SV = PVMG(0xbb3c8)
  REFCNT = 1
  FLAGS = (IOK, pIOK)
  IV = 729160
  NV = 0
  PV = 0
```

A reference to a subroutine

Looks like this:

```
SV = RV(0x798ec)
  REFCNT = 1
  FLAGS = (TEMP, ROK)
  RV = 0x1d453c
```

```

SV = PVCV(0x1c768c)
REFCNT = 2
FLAGS = ()
IV = 0
NV = 0
COMP_STASH = 0x31068 "main"
START = 0xb20e0
ROOT = 0xbece0
XSUB = 0x0
XSUBANY = 0
GVGV::GV = 0x1d44e8 "MY" :: "top_targets"
FILE = "(eval 5)"
DEPTH = 0
PADLIST = 0x1c9338

```

This shows that

- the subroutine is not an XSUB (since START and ROOT are non-zero, and XSUB is zero);
- that it was compiled in the package main;
- under the name MY::top_targets;
- inside a 5th eval in the program;
- it is not currently executed (see DEPTH);
- it has no prototype (PROTOTYPE field is missing).

EXPORTS

Dump, mstat, DeadCode, DumpArray, DumpWithOP and DumpProg, fill_mstats, mstats_fillhash, mstats2hash by default. Additionally available SvREFCNT, SvREFCNT_inc and SvREFCNT_dec.

BUGS

Readers have been known to skip important parts of [perlguts](#), causing much frustration for all.

NAME

Perl/Pollution/Portability

SYNOPSIS

```
Devel::PPPort::WriteFile() ; # defaults to ./ppport.h
Devel::PPPort::WriteFile('someheader.h') ;
```

DESCRIPTION

Perl has changed over time, gaining new features, new functions, increasing its flexibility, and reducing the impact on the C namespace environment (reduced pollution). The header file, typically `ppport.h`, written by this module attempts to bring some of the newer Perl features to older versions of Perl, so that you can worry less about keeping track of old releases, but users can still reap the benefit.

Why you should use `ppport.h` in modern code: so that your code will work with the widest range of Perl interpreters possible, without significant additional work.

Why you should attempt older code to fully use `ppport.h`: because the reduced pollution of newer Perl versions is an important thing, so important that the old polluting ways of original Perl modules will not be supported very far into the future, and your module will almost certainly break! By adapting to it now, you'll gained compatibility and a sense of having done the electronic ecology some good.

How to use `ppport.h`: Don't direct the user to download `Devel::PPPort`, and don't make `ppport.h` optional. Rather, just take the most recent copy of `ppport.h` that you can find (probably in `Devel::PPPort` on CPAN), copy it into your project, adjust your project to use it, and distribute the header along with your module.

`Devel::PPPort` contains a single function, called `WriteFile`. It's purpose is to write a 'C' header file that is used when writing XS modules. The file contains a series of macros that allow XS modules to be built using older versions of Perl.

This module is used by `h2xs` to write the file *ppport.h*.

WriteFile

`WriteFile` takes a zero or one parameters. When called with one parameter it expects to be passed a filename. When called with no parameters, it defaults to the filename `./ppport.h`.

The function returns `TRUE` if the file was written successfully. Otherwise it returns `FALSE`.

ppport.h

The file written by this module, typically `ppport.h`, provides access to the following Perl API if not already available (and in some cases [*] even if available, access to a fixed interface):

NAME

Devel::SelfStubber – generate stubs for a SelfLoading module

SYNOPSIS

To generate just the stubs:

```
use Devel::SelfStubber;  
Devel::SelfStubber->stub('MODULENAME', 'MY_LIB_DIR');
```

or to generate the whole module with stubs inserted correctly

```
use Devel::SelfStubber;  
$Devel::SelfStubber::JUST_STUBS=0;  
Devel::SelfStubber->stub('MODULENAME', 'MY_LIB_DIR');
```

MODULENAME is the Perl module name, e.g. Devel::SelfStubber, NOT 'Devel/SelfStubber' or 'Devel/SelfStubber.pm'.

MY_LIB_DIR defaults to '.' if not present.

DESCRIPTION

Devel::SelfStubber prints the stubs you need to put in the module before the `__DATA__` token (or you can get it to print the entire module with stubs correctly placed). The stubs ensure that if a method is called, it will get loaded. They are needed specifically for inherited autoloading methods.

This is best explained using the following example:

Assume four classes, A,B,C & D.

A is the root class, B is a subclass of A, C is a subclass of B, and D is another subclass of A.

If D calls an autoloading method 'foo' which is defined in class A, then the method is loaded into class A, then executed. If C then calls method 'foo', and that method was reimplemented in class B, but set to be autoloading, then the lookup mechanism never gets to the AUTOLOAD mechanism in B because it first finds the method already loaded in A, and so erroneously uses that. If the method foo had been stubbed in B, then the lookup mechanism would have found the stub, and correctly loaded and used the sub from B.

So, for classes and subclasses to have inheritance correctly work with autoloading, you need to ensure stubs are loaded.

The SelfLoader can load stubs automatically at module initialization with the statement

`'SelfLoader->load_stubs()'`; but you may wish to avoid having the stub loading overhead associated with your initialization (though note that the `SelfLoader::load_stubs` method will be called sooner or later – at latest when the first sub is being autoloading). In this case, you can put the sub stubs before the `__DATA__` token. This can be done manually, but this module allows automatic generation of the stubs.

By default it just prints the stubs, but you can set the global `$Devel::SelfStubber::JUST_STUBS` to 0 and it will print out the entire module with the stubs positioned correctly.

At the very least, this is useful to see what the SelfLoader thinks are stubs – in order to ensure future versions of the SelfStubber remain in step with the SelfLoader, the SelfStubber actually uses the SelfLoader to determine which stubs are needed.

NAME

`diagnostics` – Perl compiler pragma to force verbose warning diagnostics

`splain` – standalone program to do the same thing

SYNOPSIS

As a pragma:

```
use diagnostics;
use diagnostics -verbose;

enable diagnostics;
disable diagnostics;
```

As a program:

```
perl program 2>diag.out
splain [-v] [-p] diag.out
```

DESCRIPTION

The `diagnostics` Pragma

This module extends the terse diagnostics normally emitted by both the perl compiler and the perl interpreter, augmenting them with the more explicative and endearing descriptions found in [perl_{ldiag}](#). Like the other pragmata, it affects the compilation phase of your program rather than merely the execution phase.

To use in your program as a pragma, merely invoke

```
use diagnostics;
```

at the start (or near the start) of your program. (Note that this *does* enable perl's `-w` flag.) Your whole compilation will then be subject(ed :-)) to the enhanced diagnostics. These still go out **STDERR**.

Due to the interaction between runtime and compiletime issues, and because it's probably not a very good idea anyway, you may not use `no diagnostics` to turn them off at compiletime. However, you may control their behaviour at runtime using the `disable()` and `enable()` methods to turn them off and on respectively.

The `-verbose` flag first prints out the [perl_{ldiag}](#) introduction before any other diagnostics. The `$diagnostics::PRETTY` variable can generate nicer escape sequences for pagers.

Warnings dispatched from perl itself (or more accurately, those that match descriptions found in [perl_{ldiag}](#)) are only displayed once (no duplicate descriptions). User code generated warnings ala `warn()` are unaffected, allowing duplicate user messages to be displayed.

The `splain` Program

While apparently a whole nuther program, *splain* is actually nothing more than a link to the (executable) *diagnostics.pm* module, as well as a link to the *diagnostics.pod* documentation. The `-v` flag is like the `use diagnostics -verbose` directive. The `-p` flag is like the `$diagnostics::PRETTY` variable. Since you're post-processing with *splain*, there's no sense in being able to `enable()` or `disable()` processing.

Output from *splain* is directed to **STDOUT**, unlike the pragma.

EXAMPLES

The following file is certain to trigger a few errors at both runtime and compiletime:

```
use diagnostics;
print NOWHERE "nothing\n";
print STDERR "\n\tThis message should be unadorned.\n";
warn "\tThis is a user warning";
print "\nDIAGNOSTIC TESTER: Please enter a <CR> here: ";
```

```
my $a, $b = scalar <STDIN>;
print "\n";
print $x/$y;
```

If you prefer to run your program first and look at its problem afterwards, do this:

```
perl -w test.pl 2>test.out
./splain < test.out
```

Note that this is not in general possible in shells of more dubious heritage, as the theoretical

```
(perl -w test.pl >/dev/tty) >& test.out
./splain < test.out
```

Because you just moved the existing **stdout** to somewhere else.

If you don't want to modify your source code, but still have on-the-fly warnings, do this:

```
exec 3>&1; perl -w test.pl 2>&1 1>&3 3>&- | splain 1>&2 3>&-
```

Nifty, eh?

If you want to control warnings on the fly, do something like this. Make sure you do the use first, or you won't be able to get at the `enable()` or `disable()` methods.

```
use diagnostics; # checks entire compilation phase
print "\ntime for 1st bogus diags: SQUAWKINGS\n";
print BOGUS1 'nada';
print "done with 1st bogus\n";

disable diagnostics; # only turns off runtime warnings
print "\ntime for 2nd bogus: (squelched)\n";
print BOGUS2 'nada';
print "done with 2nd bogus\n";

enable diagnostics; # turns back on runtime warnings
print "\ntime for 3rd bogus: SQUAWKINGS\n";
print BOGUS3 'nada';
print "done with 3rd bogus\n";

disable diagnostics;
print "\ntime for 4th bogus: (squelched)\n";
print BOGUS4 'nada';
print "done with 4th bogus\n";
```

INTERNALS

Diagnostic messages derive from the *perl_{diag}.pod* file when available at runtime. Otherwise, they may be embedded in the file itself when the `splain` package is built. See the *Makefile* for details.

If an extant `$SIG{__WARN__}` handler is discovered, it will continue to be honored, but only after the `diagnostics::splainthis()` function (the module's `$SIG{__WARN__}` interceptor) has had its way with your warnings.

There is a `$diagnostics::DEBUG` variable you may set if you're desperately curious what sorts of things are being intercepted.

```
BEGIN { $diagnostics::DEBUG = 1 }
```

BUGS

Not being able to say "no diagnostics" is annoying, but may not be insurmountable.

The `-pretty` directive is called too late to affect matters. You have to do this instead, and *before* you load the module.

```
BEGIN { $diagnostics::PRETTY = 1 }
```

I could start up faster by delaying compilation until it should be needed, but this gets a "panic: top_level" when using the pragma form in Perl 5.001e.

While it's true that this documentation is somewhat subserious, if you use a program named *splain*, you should expect a bit of whimsy.

NAME

Digest:: – Modules that calculate message digests

SYNOPSIS

```
$md2 = Digest->MD2;
$md5 = Digest->MD5;

$sha1 = Digest->SHA1;
$sha1 = Digest->new("SHA-1");

$hmac = Digest->HMAC_MD5($key);
```

DESCRIPTION

The `Digest::` modules calculate digests, also called "fingerprints" or "hashes", of some data, called a message. The digest is (usually) some small/fixed size string. The actual size of the digest depend of the algorithm used. The message is simply a sequence of arbitrary bytes.

An important property of the digest algorithms is that the digest is *likely* to change if the message change in some way. Another property is that digest functions are one-way functions, i.e. it should be *hard* to find a message that correspond to some given digest. Algorithms differ in how "likely" and how "hard", as well as how efficient they are to compute.

All `Digest::` modules provide the same programming interface. A functional interface for simple use, as well as an object oriented interface that can handle messages of arbitrary length and which can read files directly.

The digest can be delivered in three formats:

binary This is the most compact form, but it is not well suited for printing or embedding in places that can't handle arbitrary data.

hex A twice as long string of (lowercase) hexadecimal digits.

base64 A string of portable printable characters. This is the base64 encoded representation of the digest with any trailing padding removed. The string will be about 30% longer than the binary version. [MIME::Base64](#) tells you more about this encoding.

The functional interface is simply importable functions with the same name as the algorithm. The functions take the message as argument and return the digest. Example:

```
use Digest::MD5 qw(md5);
$digest = md5($message);
```

There are also versions of the functions with `"_hex"` or `"_base64"` appended to the name, which returns the digest in the indicated form.

OO INTERFACE

The following methods are available for all `Digest::` modules:

```
$ctx = Digest-XXX($arg, ...)
$ctx = Digest-new(XXX = $arg, ...)
$ctx = Digest::XXX-new($arg, ...)
```

The constructor returns some object that encapsulate the state of the message-digest algorithm. You can add data to the object and finally ask for the digest. The "XXX" should of course be replaced by the proper name of the digest algorithm you want to use.

The two first forms are simply syntactic sugar which automatically load the right module on first use. The second form allow you to use algorithm names which contains letters which are not legal perl identifiers, e.g. "SHA-1".

If `new()` is called as an instance method (i.e. `$ctx->new`) it will just reset the state the object to the state of a newly created object. No new object is created in this case, and the return value is the

reference to the object (i.e. `$ctx`) .

`$ctx-reset`

This is just an alias for `$ctx-new`.

`$ctx-add($data,...)`

The `$data` provided as argument are appended to the message we calculate the digest for. The return value is the `$ctx` object itself.

`$ctx-addfile($io_handle)`

The `$io_handle` is read until EOF and the content is appended to the message we calculate the digest for. The return value is the `$ctx` object itself.

`$ctx-digest`

Return the binary digest for the message.

Note that the `digest` operation is effectively a destructive, read-once operation. Once it has been performed, the `$ctx` object is automatically `reset` and can be used to calculate another digest value.

`$ctx-hexdigest`

Same as `$ctx-digest`, but will return the digest in hexadecimal form.

`$ctx-b64digest`

Same as `$ctx-digest`, but will return the digest as a base64 encoded string.

SEE ALSO

[Digest::MD5](#), [Digest::SHA1](#), [Digest::HMAC](#), [Digest::MD2](#)

[MIME::Base64](#)

AUTHOR

Gisle Aas <gisle@aa.no>

The `Digest::` interface is based on the interface originally developed by Neil Winton for his MD5 module.

NAME

Digest::MD5 – Perl interface to the MD5 Algorithm

SYNOPSIS

```
# Functional style
use Digest::MD5 qw(md5 md5_hex md5_base64);

$digest = md5($data);
$digest = md5_hex($data);
$digest = md5_base64($data);

# OO style
use Digest::MD5;

$ctx = Digest::MD5->new;

$ctx->add($data);
$ctx->addfile(*FILE);

$digest = $ctx->digest;
$digest = $ctx->hexdigest;
$digest = $ctx->b64digest;
```

DESCRIPTION

The Digest::MD5 module allows you to use the RSA Data Security Inc. MD5 Message Digest algorithm from within Perl programs. The algorithm takes as input a message of arbitrary length and produces as output a 128-bit "fingerprint" or "message digest" of the input.

The Digest::MD5 module provide a procedural interface for simple use, as well as an object oriented interface that can handle messages of arbitrary length and which can read files directly.

A binary digest will be 16 bytes long. A hex digest will be 32 characters long. A base64 digest will be 22 characters long.

FUNCTIONS

The following functions can be exported from the Digest::MD5 module. No functions are exported by default.

`md5($data, ...)`

This function will concatenate all arguments, calculate the MD5 digest of this "message", and return it in binary form.

`md5_hex($data, ...)`

Same as `md5()`, but will return the digest in hexadecimal form.

`md5_base64($data, ...)`

Same as `md5()`, but will return the digest as a base64 encoded string.

The base64 encoded string returned is not padded to be a multiple of 4 bytes long. If you want interoperability with other base64 encoded md5 digests you might want to append the string "==" to the result.

METHODS

The following methods are available:

`$md5 = Digest::MD5->new`

The constructor returns a new Digest::MD5 object which encapsulate the state of the MD5 message-digest algorithm. You can add data to the object and finally ask for the digest.

If called as an instance method (i.e. `$md5->new`) it will just reset the state the object to the state of a newly created object. No new object is created in this case.

\$md5-reset

This is just an alias for `$md5-new`.

\$md5-add(\$data,...)

The `$data` provided as argument are appended to the message we calculate the digest for. The return value is the `$md5` object itself.

\$md5-addfile(\$io_handle)

The `$io_handle` is read until EOF and the content is appended to the message we calculate the digest for. The return value is the `$md5` object itself.

In most cases you want to make sure that the `$io_handle` is set up to be in `binmode()`.

\$md5-digest

Return the binary digest for the message.

Note that the `digest` operation is effectively a destructive, read-once operation. Once it has been performed, the `Digest::MD5` object is automatically reset and can be used to calculate another digest value.

\$md5-hexdigest

Same as `$md5-digest`, but will return the digest in hexadecimal form.

\$md5-b64digest

Same as `$md5-digest`, but will return the digest as a base64 encoded string.

The base64 encoded string returned is not padded to be a multiple of 4 bytes long. If you want interoperability with other base64 encoded md5 digests you might want to append the string `"=="` to the result.

EXAMPLES

The simplest way to use this library is to import the `md5_hex()` function (or one of its cousins):

```
use Digest::MD5 qw(md5_hex);
print "Digest is ", md5_hex("foobarbaz"), "\n";
```

The above example would print out the message

```
Digest is 6df23dc03f9b54cc38a0fc1483df6e21
```

provided that the implementation is working correctly. The same checksum can also be calculated in OO style:

```
use Digest::MD5;

$md5 = Digest::MD5->new;
$md5->add('foo', 'bar');
$md5->add('baz');
$digest = $md5->hexdigest;

print "Digest is $digest\n";
```

With OO style you can break the message arbitrary. This means that we are no longer limited to have space for the whole message in memory, i.e. we can handle messages of any size.

This is useful when calculating checksum for files:

```
use Digest::MD5;

my $file = shift || "/etc/passwd";
open(FILE, $file) or die "Can't open '$file': $!";
binmode(FILE);
```

```
$md5 = Digest::MD5->new;
while (<FILE>) {
    $md5->add($_);
}
close(FILE);
print $md5->b64digest, " $file\n";
```

Or we can use the builtin addfile method for more efficient reading of the file:

```
use Digest::MD5;

my $file = shift || "/etc/passwd";
open(FILE, $file) or die "Can't open '$file': $!";
binmode(FILE);

print Digest::MD5->new->addfile(*FILE)->hexdigest, " $file\n";
```

NAME

DirHandle – supply object methods for directory handles

SYNOPSIS

```
use DirHandle;
$d = new DirHandle ".";
if (defined $d) {
    while (defined($_ = $d->read)) { something($_); }
    $d->rewind;
    while (defined($_ = $d->read)) { something_else($_); }
    undef $d;
}
```

DESCRIPTION

The `DirHandle` method provide an alternative interface to the `opendir()`, `closedir()`, `readdir()`, and `rewinddir()` functions.

The only objective benefit to using `DirHandle` is that it avoids namespace pollution by creating globs to hold directory handles.

NOTES

- On Mac OS (Classic), the path separator is `':'`, not `'/'`, and the current directory is denoted as `':'`, not `'.'`. You should be careful about specifying relative pathnames. While a full path always begins with a volume name, a relative pathname should always begin with a `':'`. If specifying a volume name only, a trailing `':'` is required.

NAME

Dumpvalue – provides screen dump of Perl data.

SYNOPSIS

```
use Dumpvalue;
my $dumper = new Dumpvalue;
$dumper->set(globPrint => 1);
$dumper->dumpValue(\*::);
$dumper->dumpvars('main');
my $dump = $dumper->stringify($some_value);
```

DESCRIPTION**Creation**

A new dumper is created by a call

```
$d = new Dumpvalue(option1 => value1, option2 => value2)
```

Recognized options:

`arrayDepth`, `hashDepth`

Print only first N elements of arrays and hashes. If false, prints all the elements.

`compactDump`, `veryCompact`

Change style of array and hash dump. If true, short array may be printed on one line.

`globPrint`

Whether to print contents of globs.

`dumpDBFiles`

Dump arrays holding contents of debugged files.

`dumpPackages`

Dump symbol tables of packages.

`dumpReused`

Dump contents of "reused" addresses.

`tick`, `quoteHighBit`, `printUndef`

Change style of string dump. Default value of `tick` is `auto`, one can enable either double-quotish dump, or single-quotish by setting it to `"` or `'`. By default, characters with high bit set are printed *as is*. If `quoteHighBit` is set, they will be quoted.

`usageOnly`

rudimentally per-package memory usage dump. If set, `dumpvars` calculates total size of strings in variables in the package.

`unctrl`

Changes the style of printout of strings. Possible values are `unctrl` and `quote`.

`subdump`

Whether to try to find the subroutine name given the reference.

`bareStringify`

Whether to write the non-overloaded form of the `stringify`-overloaded objects.

`quoteHighBit`

Whether to print chars with high bit set in binary or "as is".

stopDbSignal

Whether to abort printing if debugger signal flag is raised.

Later in the life of the object the methods may be queried with `get()` method and `set()` method (which accept multiple arguments).

Methods**dumpValue**

```
$dumper->dumpValue($value);
$dumper->dumpValue([$value1, $value2]);
```

Prints a dump to the currently selected filehandle.

dumpValues

```
$dumper->dumpValues($value1, $value2);
```

Same as `$dumper->dumpValue([$value1, $value2]);`.

stringify

```
my $dump = $dumper->stringify($value [, $noticks] );
```

Returns the dump of a single scalar without printing. If the second argument is true, the return value does not contain enclosing ticks. Does not handle data structures.

dumpvars

```
$dumper->dumpvars('my_package');
$dumper->dumpvars('my_package', 'foo', '~bar$', '!.....');
```

The optional arguments are considered as literal strings unless they start with `~` or `!`, in which case they are interpreted as regular expressions (possibly negated).

The second example prints entries with names `foo`, and also entries with names which ends on `bar`, or are shorter than 5 chars.

set_quote

```
$d->set_quote('');
```

Sets `tick` and `unctrl` options to suitable values for printout with the given quote char. Possible values are `auto`, `'` and `"`.

set_unctrl

```
$d->set_unctrl('');
```

Sets `unctrl` option with checking for an invalid argument. Possible values are `unctrl` and `quote`.

compactDump

```
$d->compactDump(1);
```

Sets `compactDump` option. If the value is 1, sets to a reasonable big number.

veryCompact

```
$d->veryCompact(1);
```

Sets `compactDump` and `veryCompact` options simultaneously.

set

```
$d->set(option1 => value1, option2 => value2);
```

get

```
@values = $d->get('option1', 'option2');
```

NAME

Encode::Byte – Single Byte Encodings

SYNOPSIS

```
use Encode qw/encode decode/;
$greek = encode("iso-8859-7", $utf8); # loads Encode::Byte implicitly
$utf8  = decode("iso-8859-7", $greek); # ditto
```

ABSTRACT

This module implements various single byte encodings. For most cases it uses \x80–\xff (upper half) to map non-ASCII characters. Encodings supported are as follows.

Canonical	Alias	Description

# ISO 8859 series		
(iso-8859-1	is in built-in)	
iso-8859-2	latin2	[ISO]
iso-8859-3	latin3	[ISO]

NAME

Encode::CN – China-based Chinese Encodings

SYNOPSIS

```
use Encode qw/encode decode/;
$euc_cn = encode("euc-cn", $utf8); # loads Encode::CN implicitly
$utf8   = decode("euc-cn", $euc_cn); # ditto
```

DESCRIPTION

This module implements China-based Chinese charset encodings. Encodings supported are as follows.

Canonical	Alias	Description

euc-cn	/\beuc.*cn\$/i /\bcn.*euc\$/i /\bGB[-_]?2312(?:\D.*\$ \$/i (see below)	EUC (Extended Unix Character)
gb2312-raw		The raw (low-bit) GB2312 character map
gb12345-raw		Traditional chinese counterpart to GB2312 (raw)
iso-ir-165		GB2312 + GB6345 + GB8565 + additions
MacChineseSimp		GB2312 + Apple Additions
cp936		Code Page 936, also known as GBK (Extended GuoBiao)
hz		7-bit escaped GB2312 encoding

To find how to use this module in detail, see [Encode](#).

NOTES

Due to size concerns, GB 18030 (an extension to GBK) is distributed separately on CPAN, under the name [Encode::HanExtra](#). That module also contains extra Taiwan-based encodings.

BUGS

When you see `charset=gb2312` on mails and web pages, they really mean `euc-cn` encodings. To fix that, `gb2312` is aliased to `euc-cn`. Use `gb2312-raw` when you really mean it.

The ASCII region (0x00–0x7f) is preserved for all encodings, even though this conflicts with mappings by the Unicode Consortium. See

<http://www.debian.or.jp/~kubota/unicode-symbols.html.en>

to find out why it is implemented that way.

NAME

Encode::PerlIO — a detailed document on Encode and PerlIO

Overview

It is very common to want to do encoding transformations when reading or writing files, network connections, pipes etc. If Perl is configured to use the new 'perlio' IO system then Encode provides a "layer" (see [PerlIO](#)) which can transform data as it is read or written.

Here is how the blind poet would modernise the encoding:

```
use Encode;
open(my $iliad, '<:encoding(iso-8859-7)', 'iliad.greek');
open(my $utf8, '>:utf8', 'iliad.utf8');
my @epic = <$iliad>;
print $utf8 @epic;
close($utf8);
close($iliad);
```

In addition, the new IO system can also be configured to read/write UTF-8 encoded characters (as noted above, this is efficient):

```
open(my $fh, '>:utf8', 'anything');
print $fh "Any \x{0021} string \N{SMILEY FACE}\n";
```

Either of the above forms of "layer" specifications can be made the default for a lexical scope with the use open ... pragma. See [open](#).

Once a handle is open, its layers can be altered using binmode.

Without any such configuration, or if Perl itself is built using the system's own IO, then write operations assume that the file handle accepts only *bytes* and will die if a character larger than 255 is written to the handle. When reading, each octet from the handle becomes a byte-in-a-character. Note that this default is the same behaviour as bytes-only languages (including Perl before v5.6) would have, and is sufficient to handle native 8-bit encodings e.g. iso-8859-1, EBCDIC etc. and any legacy mechanisms for handling other encodings and binary data.

In other cases, it is the program's responsibility to transform characters into bytes using the API above before doing writes, and to transform the bytes read from a handle into characters before doing "character operations" (e.g. lc, /\W+/, ...).

You can also use PerlIO to convert larger amounts of data you don't want to bring into memory. For example, to convert between ISO-8859-1 (Latin 1) and UTF-8 (or UTF-EBCDIC in EBCDIC machines):

```
open(F, "<:encoding(iso-8859-1)", "data.txt") or die $!;
open(G, ">:utf8", "data.utf") or die $!;
while (<F>) { print G }

# Could also do "print G <F>" but that would pull
# the whole file into memory just to write it out again.
```

More examples:

```
open(my $f, "<:encoding(cp1252)")
open(my $g, ">:encoding(iso-8859-2)")
open(my $h, ">:encoding(latin9)") # iso-8859-15
```

See also [encoding](#) for how to change the default encoding of the data in your script.

How does it work?

Here is a crude diagram of how filehandle, PerlIO, and Encode interact.

How can I tell whether my encoding fully supports PerlIO ?

As of this writing, any encoding whose class belongs to `Encode::XS` and `Encode::Unicode` works. The `Encode` module has a `perlio_ok` method which you can use before applying PerlIO encoding to the filehandle. Here is an example:

```
my $use_perlio = perlio_ok($enc);
my $layer = $use_perlio ? "<:raw" : "<:encoding($enc)";
open my $fh, $layer, $file or die "$file : $!";
while(<$fh>){
    $_ = decode($enc, $_) unless $use_perlio;
    # ....
}
```

NAME

Encode::Supported — Encodings supported by Encode

DESCRIPTION**Encoding Names**

Encoding names are case insensitive. White space in names is ignored. In addition, an encoding may have aliases. Each encoding has one "canonical" name. The "canonical" name is chosen from the names of the encoding by picking the first in the following sequence (with a few exceptions).

- The name used by the Perl community. That includes 'utf8' and 'ascii'. Unlike aliases, canonical names directly reach the method so such frequently used words like 'utf8' don't need to do alias lookups.
- The MIME name as defined in IETF RFCs. This includes all "iso-"s.
- The name in the IANA registry.
- The name used by the organization that defined it.

In case *de jure* canonical names differ from that of the Encode module, they are always aliased if it ever be implemented. So you can safely tell if a given encoding is implemented or not just by passing the canonical name.

Because of all the alias issues, and because in the general case encodings have state, "Encode" uses an encoding object internally once an operation is in progress.

Supported Encodings

As of Perl 5.8.0, at least the following encodings are recognized. Note that unless otherwise specified, they are all case insensitive (via alias) and all occurrence of spaces are replaced with '-'. In other words, "ISO 8859 1" and "iso-8859-1" are identical.

Encodings are categorized and implemented in several different modules but you don't have to use `Encode:::XX` to make them available for most cases. `Encode.pm` will automatically load those modules on demand.

Built-in Encodings

The following encodings are always available.

Canonical	Aliases	Comments & References
ascii	US-ascii ISO-646-US	[ECMA]
ascii-ctrl		Special Encoding
iso-8859-1	latin1	[ISO]
null		Special Encoding
utf8	UTF-8	[RFC2279]

null and *ascii-ctrl* are special. "null" fails for all character so when you set fallback mode to PERLQQ, HTMLCREF or XMLCREF, ALL CHARACTERS will fall back to character references. Ditto for "ascii-ctrl" except for control characters. For fallback modes, see [Encode](#).

Encode::Unicode — other Unicode encodings

Unicode coding schemes other than native utf8 are supported by `Encode::Unicode`, which will be autoloaded on demand.

UCS-2BE	UCS-2, iso-10646-1	[IANA, UC]
UCS-2LE		[UC]
UTF-16		[UC]
UTF-16BE		[UC]

UTF-16LE		[UC]
UTF-32		[UC]
UTF-32BE	UCS-4	[UC]
UTF-32LE		[UC]

To find how (UCS-2|UTF-(16|32))(LE|BE)? differ from one another, see [Encode::Unicode](#).

Encode::Byte — Extended ASCII

Encode::Byte implements most single-byte encodings except for Symbols and EBCDIC. The following encodings are based on single-byte encodings implemented as extended ASCII. Most of them map \x80–\xff (upper half) to non-ASCII characters.

ISO-8859 and corresponding vendor mappings

Since there are so many, they are presented in table format with languages and corresponding encoding names by vendors. Note that the table is sorted in order of ISO-8859 and the corresponding vendor mappings are slightly different from that of ISO. See <http://czyborra.com/charsets/iso8859.html> for details.

Lang/Regions	ISO/Other Std.	DOS	Windows	Macintosh	Others
N. America	(ASCII)	cp437		AdobeStandardEncoding	
		cp863	(DOSCanadaF)		
W. Europe	iso-8859-1	cp850	cp1252	MacRoman	nextstep hp-roman8
		cp860	(DOSPortuguese)		
Cntrl. Europe	iso-8859-2	cp852	cp1250	MacCentralEurRoman	
				MacCroatian	
				MacRomanian	
				MacRumanian	
Latin3 [1]	iso-8859-3				
Latin4 [2]	iso-8859-4				
Cyrillics	iso-8859-5	cp855	cp1251	MacCyrillic	
(See also next section)		cp866		MacUkrainian	
Arabic	iso-8859-6	cp864	cp1256	MacArabic	
		cp1006		MacFarsi	
Greek	iso-8859-7	cp737	cp1253	MacGreek	
		cp869	(DOSGreek2)		
Hebrew	iso-8859-8	cp862	cp1255	MacHebrew	
Turkish	iso-8859-9	cp857	cp1254	MacTurkish	
Nordics	iso-8859-10	cp865			
		cp861		MacIcelandic	
				MacSami	
Thai	iso-8859-11 [3]	cp874		MacThai	
(iso-8859-12 is nonexistent.	Reserved for Indics?)				
Baltics	iso-8859-13	cp775		cp1257	
Celtics	iso-8859-14				
Latin9 [4]	iso-8859-15				
Latin10	iso-8859-16				
Vietnamese	viscii		cp1258	MacVietnamese	

[1] Esperanto, Maltese, and Turkish. Turkish is now on 8859-9.

[2] Baltics. Now on 8859-10, except for Latvian.

[3] Also known as TIS 620.

[4] Nicknamed Latin0; the Euro sign as well as French and Finnish letters that are missing from 8859-1 were added.

All cp* are also available as ibm-*, ms-*, and windows-*. See also <http://czyborra.com/charsets/codepages.html>.

Macintosh encodings don't seem to be registered in such entities as IANA. "Canonical" names in Encode are based upon Apple's Tech Note 1150. See <http://developer.apple.com/technotes/tn/tn1150.html> for details.

KOI8 – De Facto Standard for the Cyrillic world

Though ISO-8859 does have ISO-8859-5, the KOI8 series is far more popular in the Net. *Encode* comes with the following KOI charsets. For gory details, see <http://czyborra.com/charsets/cyrillic.html>

```
-----
koi8-f
koi8-r cp878 [RFC1489]
koi8-u [RFC2319]
-----
```

gsm0338 – Hentai Latin 1

GSM0338 is for GSM handsets. Though it shares alphanumeric with ASCII, control character ranges and other parts are mapped very differently, presumably to store Greek and Cyrillic alphabets. This is also covered in Encode::Byte even though it is not an "extended ASCII" encoding.

CJK: Chinese, Japanese, Korean (Multibyte)

Note that Vietnamese is listed above. Also read "Encoding vs Charset" below. Also note that these are implemented in distinct modules by countries, due to the size concerns (simplified Chinese is mapped to 'CN', continental China, while traditional Chinese is mapped to 'TW', Taiwan). Please refer to their respective documentataion pages.

Encode::CN — Continental China

Standard	DOS/Win	Macintosh	Comment/Reference
euc-cn [1]		MacChineseSimp	
(gbk)	cp936 [2]		
gb12345-raw		{ GB12345 without CES }	
gb2312-raw		{ GB2312 without CES }	
hz			
iso-ir-165			

[1] GB2312 is aliased to this. See L<Microsoft-related naming mess>

[2] gbk is aliased to this. See L<Microsoft-related naming mess>

Encode::JP — Japan

Standard	DOS/Win	Macintosh	Comment/Reference
euc-jp			
shiftjis	cp932	macJapanese	
7bit-jis			
iso-2022-jp			[RFC1468]
iso-2022-jp-1			[RFC2237]
jis0201-raw	{ JIS X 0201 (roman + halfwidth kana)		without CES }
jis0208-raw	{ JIS X 0208 (Kanji + fullwidth kana)		without CES }
jis0212-raw	{ JIS X 0212 (Extended Kanji)		without CES }

Encode::KR — Korea

Standard	DOS/Win Macintosh	Comment/Reference
euc-kr	MacKorean	[RFC1557]
	cp949 [1]	
iso-2022-kr		[RFC1557]
johab		[KS X 1001:1998, Annex 3]
ksc5601-raw		{ KSC5601 without CES }

[1] ks_c_5601-1987, (x-)?windows-949, and uhc are aliased to this. See below.

Encode::TW — Taiwan

Standard	DOS/Win Macintosh	Comment/Reference
big5-eten	cp950 MacChineseTrad	{big5 aliased to big5-eten}
big5-hkscs		

Encode::HanExtra — More Chinese via CPAN

Due to size concerns, additional Chinese encodings below are distributed separately on CPAN, under the name Encode::HanExtra.

Standard	DOS/Win Macintosh	Comment/Reference
big5ext		CMEX's Big5e Extension
big5plus		CMEX's Big5+ Extension
cccii	Chinese Character Code for Information Interchange	
euc-tw		EUC (Extended Unix Character)
gb18030		GBK with Traditional Characters

Encode::JIS2K — JIS X 0213 encodings via CPAN

Due to size concerns, additional Japanese encodings below are distributed separately on CPAN, under the name Encode::JIS2K.

Standard	DOS/Win Macintosh	Comment/Reference
euc-jisx0213		
shiftjisx0123		
iso-2022-jp-3		
jis0213-1-raw		
jis0213-2-raw		

Miscellaneous encodings

Encode::EBCDIC

See [perlebcdic](#) for details.

```
-----
cp37
cp500
cp875
cp1026
cp1047
posix-bc
```

Encode::Symbols

For symbols and dingbats.

```
symbol
dingbats
MacDingbats
AdobeZdingbat
AdobeSymbol
```

Encode::MIME::Header

Strictly speaking, MIME header encoding documented in RFC 2047 is more of encapsulation than encoding. But included anyway.

MIME-Header	[RFC2047]
MIME-B	[RFC2047]
MIME-Q	[RFC2047]

Encode::Guess

This one is not a name of encoding but a utility that lets you pick up the most appropriate encoding for a data out of given *suspects*. See [Encode::Guess](#) for details.

Unsupported encodings

The following encodings are not supported as yet; some because they are rarely used, some because of technical difficulties. They may be supported by external modules via CPAN in the future, however.

ISO-2022-JP-2 [RFC1554]

Not very popular yet. Needs Unicode Database or equivalent to implement `encode()` (because it includes JIS X 0208/0212, KSC5601, and GB2312 simultaneously, whose code points in Unicode overlap. So you need to lookup the database to determine to what character set a given Unicode character should belong).

ISO-2022-CN [RFC1922]

Not very popular. Needs CNS 11643-1 and -2 which are not available in this module. CNS 11643 is supported (via `eutw`) in `Encode::HanExtra`. Atrijus Tang may add support for this encoding in his module in future.

Various HP-UX encodings

The following are unsupported due to the lack of mapping data.

```
'8' - arabic8, greek8, hebrew8, kana8, thai8, and turkish8
'15' - japanese15, korean15, and roi15
```

Cyrillic encoding ISO-IR-111

Anton Tagunov doubts its usefulness.

ISO-8859-8-1 [Hebrew]

None of the Encode team knows Hebrew enough (ISO-8859-8, `cp1255` and `MacHebrew` are supported because and just because there were mappings available at <http://www.unicode.org/>). Contributions welcome.

ISIRI 3342, Iran System, ISIRI 2900 [Farsi]

Ditto.

Thai encoding TCVN

Ditto.

Vietnamese encodings VPS

Though Jungshik Shin has reported that Mozilla supports this encoding, it was too late before 5.8.0 for us to add it. In the future, it may be available via a separate module. See

<http://lxr.mozilla.org/seamoney/source/intl/uconv/ucvlatin/vps.uf> and

<http://lxr.mozilla.org/seamoney/source/intl/uconv/ucvlatin/vps.ut> if you are interested in helping us.

Various Mac encodings

The following are unsupported due to the lack of mapping data.

MacArmenian, MacBengali, MacBurmese, MacEthiopic
MacExtArabic, MacGeorgian, MacKannada, MacKhmer
MacLaotian, MacMalayalam, MacMongolian, MacOriya
MacSinhalese, MacTamil, MacTelugu, MacTibetan
MacVietnamese

The rest which are already available are based upon the vendor mappings at

<http://www.unicode.org/Public/MAPPINGS/VENDORS/APPLE/>.

(Mac) Indic encodings

The maps for the following are available at <http://www.unicode.org/> but remain unsupported because those encodings need algorithmical approach, currently unsupported by *enc2xs*:

MacDevanagari
MacGurmukhi
MacGujarati

For details, please see Unicode mapping issues and notes: at

<http://www.unicode.org/Public/MAPPINGS/VENDORS/APPLE/DEVANAGA.TXT>.

I believe this issue is prevalent not only for Mac Indic but also in other Indic encodings, but the above were the only Indic encodings maps that I could find at <http://www.unicode.org/>.

Encoding vs. Charset — terminology

We are used to using the term (character) *encoding* and *character set* interchangeably. But just as confusing the terms byte and character is dangerous and the terms should be differentiated when needed, we need to differentiate *encoding* and *character set*.

To understand that, here is a description of how we make computers grok our characters.

- First we start with which characters to include. We call this collection of characters *character repertoire*.
- Then we have to give each character a unique ID so your computer can tell the difference between ‘a’ and ‘A’. This itemized character repertoire is now a *character set*.
- If your computer can grow the character set without further processing, you can go ahead and use it. This is called a *coded character set* (CCS) or *raw character encoding*. ASCII is used this way for most cases.
- But in many cases, especially multi-byte CJK encodings, you have to tweak a little more. Your network connection may not accept any data with the Most Significant Bit set, and your computer may not be able to tell if a given byte is a whole character or just half of it. So you have to *encode* the character set to use it.

A *character encoding scheme* (CES) determines how to encode a given character set, or a set of multiple character sets. 7bit ISO-2022 is an example of a CES. You switch between character sets via *escape sequences*.

Technically, or mathematically, speaking, a character set encoded in such a CES that maps character by character may form a CCS. EUC is such an example. The CES of EUC is as follows:

- Map ASCII unchanged.
- Map such a character set that consists of 94 or 96 powered by N members by adding 0x80 to each byte.
- You can also use 0x8e and 0x8f to indicate that the following sequence of characters belongs to yet another character set. To each following byte is added the value 0x80.

By carefully looking at the encoded byte sequence, you can find that the byte sequence conforms a unique number. In that sense, EUC is a CCS generated by a CES above from up to four CCS (complicated?). UTF-8 falls into this category. See [UTF-8 in perlUnicode](#) to find out how UTF-8 maps Unicode to a byte sequence.

You may also have found out by now why 7bit ISO-2022 cannot comprise a CCS. If you look at a byte sequence `\x21\x21`, you can't tell if it is two `!`'s or IDEOGRAPHIC SPACE. EUC maps the latter to `\xA1\xA1` so you have no trouble differentiating between `!!`, and `" "`.

Encoding Classification (by Anton Tagunov and Dan Kogai)

This section tries to classify the supported encodings by their applicability for information exchange over the Internet and to choose the most suitable aliases to name them in the context of such communication.

- To (en/de)code encodings marked by `(**)`, you need `Encode::HanExtra`, available from CPAN.

Encoding names

US-ASCII	UTF-8	ISO-8859-*	KOI8-R
Shift_JIS	EUC-JP	ISO-2022-JP	ISO-2022-JP-1
EUC-KR	Big5	GB2312	

are registered with IANA as preferred MIME names and may be used over the Internet.

Shift_JIS has been officialized by JIS X 0208:1997. [Microsoft-related naming mess](#) gives details.

GB2312 is the IANA name for EUC-CN. See [Microsoft-related naming mess](#) for details.

GB_2312-80 raw encoding is available as `gb2312-raw` with Encode. See [Encode::CN](#) for details.

EUC-CN	
KOI8-U	[RFC2319]

have not been registered with IANA (as of March 2002) but seem to be supported by major web browsers. The IANA name for EUC-CN is GB2312.

KS_C_5601-1987

is heavily misused. See [Microsoft-related naming mess](#) for details.

KS_C_5601-1987 raw encoding is available as `kcs5601-raw` with Encode. See [Encode::KR](#) for details.

UTF-16 UTF-16BE UTF-16LE

are IANA-registered charsets. See [RFC 2781] for details. Jungshik Shin reports that UTF-16 with a BOM is well accepted by MS IE 5/6 and NS 4/6. Beware however that

- UTF-16 support in any software you're going to be using/interoperating with has probably been less tested than UTF-8 support
- UTF-8 coded data seamlessly passes traditional command piping (`cat`, `more`, etc.) while UTF-16 coded data is likely to cause confusion (with its zero bytes, for example)

- it is beyond the power of words to describe the way HTML browsers encode non-ASCII form data. To get a general impression, visit <http://ppewww.ph.gla.ac.uk/~flavell/charset/form-i18n.html>. While encoding of form data has stabilized for UTF-8 encoded pages (at least IE 5/6, NS 6, and Opera 6 behave consistently), be sure to expect fun (and cross-browser discrepancies) with UTF-16 encoded pages!

The rule of thumb is to use UTF-8 unless you know what you're doing and unless you really benefit from using UTF-16.

```
ISO-IR-165      [RFC1345]
VISCII
GB 12345
GB 18030 (**)   (see links bellow)
EUC-TW         (**)
```

are totally valid encodings but not registered at IANA. The names under which they are listed here are probably the most widely-known names for these encodings and are recommended names.

```
BIG5PLUS (**)

```

is a proprietary name.

Microsoft-related naming mess

Microsoft products misuse the following names:

KS_C_5601-1987

Microsoft extension to EUC-KR.

Proper names: CP949, UHC, x-windows-949 (as used by Mozilla).

See <http://lists.w3.org/Archives/Public/ietf-charsets/2001AprJun/0033.html> for details.

Encode aliases KS_C_5601-1987 to cp949 to reflect this common misuse. *Raw* KS_C_5601-1987 encoding is available as kcs5601-raw.

See [Encode::KR](#) for details.

GB2312

Microsoft extension to EUC-CN.

Proper names: CP936, GBK.

GB2312 has been registered in the EUC-CN meaning at IANA. This has partially repaired the situation: Microsoft's GB2312 has become a superset of the official GB2312.

Encode aliases GB2312 to euc-cn in full agreement with IANA registration. cp936 is supported separately. *Raw* GB_2312-80 encoding is available as gb2312-raw.

See [Encode::CN](#) for details.

Big5

Microsoft extension to Big5.

Proper name: CP950.

Encode separately supports Big5 and cp950.

Shift_JIS

Microsoft's understanding of Shift_JIS.

JIS has not endorsed the full Microsoft standard however. The official Shift_JIS includes only JIS X 0201 and JIS X 0208 character sets, while Microsoft has always used Shift_JIS to encode a wider character repertoire. See IANA registration for Windows-31J.

As a historical predecessor, Microsoft's variant probably has more rights for the name, though it may be objected that Microsoft shouldn't have used JIS as part of the name in the first place.

Unambiguous name: CP932. IANA name (not used?): Windows-31J.

Encode separately supports Shift_JIS and cp932.

Glossary

character repertoire

A collection of unique characters. A *character* set in the strictest sense. At this stage, characters are not numbered.

coded character set (CCS)

A character set that is mapped in a way computers can use directly. Many character encodings, including EUC, fall in this category.

character encoding scheme (CES)

An algorithm to map a character set to a byte sequence. You don't have to be able to tell which character set a given byte sequence belongs. 7-bit ISO-2022 is a CES but it cannot be a CCS. EUC is an example of being both a CCS and CES.

charset (in MIME context)

has long been used in the meaning of encoding, CES.

While the word combination `character set` has lost this meaning in MIME context since [RFC 2130], the `charset` abbreviation has retained it. This is how [RFC 2277] and [RFC 2278] bless `charset`:

This document uses the term "charset" to mean a set of rules for mapping from a sequence of octets to a sequence of characters, such as the combination of a coded character set and a character encoding scheme; this is also what is used as an identifier in MIME "charset=" parameters, and registered in the IANA charset registry ... (Note that this is NOT a term used by other standards bodies, such as ISO).
[RFC 2277]

EUC

Extended Unix Character. See ISO-2022.

ISO-2022

A CES that was carefully designed to coexist with ASCII. There are a 7 bit version and an 8 bit version.

The 7 bit version switches character set via escape sequence so it cannot form a CCS. Since this is more difficult to handle in programs than the 8 bit version, the 7 bit version is not very popular except for iso-2022-jp, the *de facto* standard CES for e-mails.

The 8 bit version can form a CCS. EUC and ISO-8859 are two examples thereof. Pre-5.6 perl could use them as string literals.

UCS

Short for *Universal Character Set*. When you say just UCS, it means *Unicode*.

UCS-2

ISO/IEC 10646 encoding form: Universal Character Set coded in two octets.

Unicode

A character set that aims to include all character repertoires of the world. Many character sets in various national as well as industrial standards have become, in a way, just subsets of Unicode.

UTF

Short for *Unicode Transformation Format*. Determines how to map a Unicode character into a byte sequence.

UTF-16

A UTF in 16-bit encoding. Can either be in big endian or little endian. The big endian version is called UTF-16BE (equal to UCS-2 + surrogate support) and the little endian version is called UTF-16LE.

NAME

Encode – character encodings

SYNOPSIS

```
use Encode;
```

Table of Contents

Encode consists of a collection of modules whose details are too big to fit in one document. This POD itself explains the top-level APIs and general topics at a glance. For other topics and more details, see the PODs below:

Name	Description
Encode::Alias	Alias definitions to encodings
Encode::Encoding	Encode Implementation Base Class
Encode::Supported	List of Supported Encodings
Encode::CN	Simplified Chinese Encodings
Encode::JP	Japanese Encodings
Encode::KR	Korean Encodings
Encode::TW	Traditional Chinese Encodings

DESCRIPTION

The Encode module provides the interfaces between Perl's strings and the rest of the system. Perl strings are sequences of **characters**.

The repertoire of characters that Perl can represent is at least that defined by the Unicode Consortium. On most platforms the ordinal values of the characters (as returned by `ord(ch)`) is the "Unicode codepoint" for the character (the exceptions are those platforms where the legacy encoding is some variant of EBCDIC rather than a super-set of ASCII – see [perlebcdic](#)).

Traditionally, computer data has been moved around in 8-bit chunks often called "bytes". These chunks are also known as "octets" in networking standards. Perl is widely used to manipulate data of many types – not only strings of characters representing human or computer languages but also "binary" data being the machine's representation of numbers, pixels in an image – or just about anything.

When Perl is processing "binary data", the programmer wants Perl to process "sequences of bytes". This is not a problem for Perl – as a byte has 256 possible values, it easily fits in Perl's much larger "logical character".

TERMINOLOGY

- *character*: a character in the range 0..(2**32–1) (or more). (What Perl's strings are made of.)
- *byte*: a character in the range 0..255 (A special case of a Perl character.)
- *octet*: 8 bits of data, with ordinal values 0..255 (Term for bytes passed to or from a non-Perl context, e.g. a disk file.)

PERL ENCODING API

```
$octets = encode(ENCODING, $string [, CHECK])
```

Encodes a string from Perl's internal form into *ENCODING* and returns a sequence of octets. ENCODING can be either a canonical name or an alias. For encoding names and aliases, see [. For CHECK, see \[.\]\(#\)](#)

For example, to convert a string from Perl's internal format to iso-8859-1 (also known as Latin1),

```
$octets = encode("iso-8859-1", $string);
```

CAVEAT: When you run `$octets = encode("utf8", $string)`, then `$octets` **may not be**

equal to `$string`. Though they both contain the same data, the utf8 flag for `$octets` is **always** off. When you encode anything, utf8 flag of the result is always off, even when it contains completely valid utf8 string. See below.

`encode($valid_encoding, undef)` is harmless but warns you for Use of uninitialized value in subroutine entry. `encode($valid_encoding, "")` is harmless and warnless.

`$string = decode(ENCODING, $octets [, CHECK])`

Decodes a sequence of octets assumed to be in *ENCODING* into Perl's internal form and returns the resulting string. As in `encode()`, *ENCODING* can be either a canonical name or an alias. For encoding names and aliases, see . For *CHECK*, see .

For example, to convert ISO-8859-1 data to a string in Perl's internal format:

```
$string = decode("iso-8859-1", $octets);
```

CAVEAT: When you run `$string = decode("utf8", $octets)`, then `$string` **may not be equal to** `$octets`. Though they both contain the same data, the utf8 flag for `$string` is on unless `$octets` entirely consists of ASCII data (or EBCDIC on EBCDIC machines). See below.

`decode($valid_encoding, undef)` is harmless but warns you for Use of uninitialized value in subroutine entry. `decode($valid_encoding, "")` is harmless and warnless.

`[$length =] from_to($octets, FROM_ENC, TO_ENC [, CHECK])`

Converts **in-place** data between two encodings. The data in `$octets` must be encoded as octets and not as characters in Perl's internal format. For example, to convert ISO-8859-1 data to Microsoft's CP1250 encoding:

```
from_to($octets, "iso-8859-1", "cp1250");
```

and to convert it back:

```
from_to($octets, "cp1250", "iso-8859-1");
```

Note that because the conversion happens in place, the data to be converted cannot be a string constant; it must be a scalar variable.

`from_to()` returns the length of the converted string in octets on success, `undef` otherwise.

CAVEAT: The following operations look the same but are not quite so;

```
from_to($data, "iso-8859-1", "utf8"); #1
$data = decode("iso-8859-1", $data); #2
```

Both #1 and #2 make `$data` consist of a completely valid UTF-8 string but only #2 turns utf8 flag on. #1 is equivalent to

```
$data = encode("utf8", decode("iso-8859-1", $data));
```

See below.

`$octets = encode_utf8($string);`

Equivalent to `$octets = encode("utf8", $string)`; The characters that comprise `$string` are encoded in Perl's internal format and the result is returned as a sequence of octets. All possible characters have a UTF-8 representation so this function cannot fail.

`$string = decode_utf8($octets [, CHECK]);`

equivalent to `$string = decode("utf8", $octets [, CHECK])`. The sequence of octets represented by `$octets` is decoded from UTF-8 into a sequence of logical characters. Not all sequences of octets form valid UTF-8 encodings, so it is possible for this call to fail. For *CHECK*, see .

Listing available encodings

```
use Encode;
@list = Encode->encodings();
```

Returns a list of the canonical names of the available encodings that are loaded. To get a list of all available encodings including the ones that are not loaded yet, say

```
@all_encodings = Encode->encodings(":all");
```

Or you can give the name of a specific module.

```
@with_jp = Encode->encodings("Encode::JP");
```

When ":" is not in the name, "Encode:" is assumed.

```
@ebcdic = Encode->encodings("EBCDIC");
```

To find out in detail which encodings are supported by this package, see [Encode::Supported](#).

Defining Aliases

To add a new alias to a given encoding, use:

```
use Encode;
use Encode::Alias;
define_alias(newName => ENCODING);
```

After that, `newName` can be used as an alias for `ENCODING`. `ENCODING` may be either the name of an encoding or an *encoding object*

But before you do so, make sure the alias is nonexistent with `resolve_alias()`, which returns the canonical name thereof. i.e.

```
Encode::resolve_alias("latin1") eq "iso-8859-1" # true
Encode::resolve_alias("iso-8859-12")           # false; nonexistent
Encode::resolve_alias($name) eq $name          # true if $name is canonical
```

`resolve_alias()` does not need `use Encode::Alias`; it can be exported via `use Encode qw(resolve_alias)`.

See [Encode::Alias](#) for details.

Encoding via PerlIO

If your perl supports *PerlIO* (which is the default), you can use a PerlIO layer to decode and encode directly via a filehandle. The following two examples are totally identical in their functionality.

```
# via PerlIO
open my $in, "<:encoding(shiftjis)", $infile or die;
open my $out, ">:encoding(euc-jp)", $outfile or die;
while(<$in){ print $out $_; }

# via from_to
open my $in, "<", $infile or die;
open my $out, ">", $outfile or die;
while(<$in){
    from_to($_, "shiftjis", "euc-jp", 1);
    print $out $_;
}
```

Unfortunately, it may be that encodings are PerlIO-savvy. You can check if your encoding is supported by PerlIO by calling the `perlio_ok` method.

```
Encode::perlio_ok("hz");           # False
find_encoding("euc-cn")->perlio_ok; # True where PerlIO is available
```

```
use Encode qw(perlio_ok);          # exported upon request
perlio_ok("euc-jp")
```

Fortunately, all encodings that come with Encode core are PerlIO-savvy except for hz and ISO-2022-kr. For gory details, see [Encode::Encoding](#) and [Encode::PerlIO](#).

Handling Malformed Data

The *CHECK* argument is used as follows. When you omit it, the behaviour is the same as if you had passed a value of 0 for *CHECK*.

CHECK = Encode::FB_DEFAULT (== 0)

If *CHECK* is 0, (en|de)code will put a *substitution character* in place of a malformed character. For UCM-based encodings, <subchar> will be used. For Unicode, the code point 0xFFFD is used. If the data is supposed to be UTF-8, an optional lexical warning (category utf8) is given.

CHECK = Encode::FB_CROAK (== 1)

If *CHECK* is 1, methods will die on error immediately with an error message. Therefore, when *CHECK* is set to 1, you should trap the fatal error with eval{ } unless you really want to let it die on error.

CHECK = Encode::FB_QUIET

If *CHECK* is set to Encode::FB_QUIET, (en|de)code will immediately return the portion of the data that has been processed so far when an error occurs. The data argument will be overwritten with everything after that point (that is, the unprocessed part of data). This is handy when you have to call decode repeatedly in the case where your source data may contain partial multi-byte character sequences, for example because you are reading with a fixed-width buffer. Here is some sample code that does exactly this:

```
my $data = ''; my $utf8 = '';
while(defined(read $fh, $buffer, 256)){
    # buffer may end in a partial character so we append
    $data .= $buffer;
    $utf8 .= decode($encoding, $data, Encode::FB_QUIET);
    # $data now contains the unprocessed partial character
}
```

CHECK = Encode::FB_WARN

This is the same as above, except that it warns on error. Handy when you are debugging the mode above.

perlqq mode (*CHECK* = Encode::FB_PERLQQ)

HTML charref mode (*CHECK* = Encode::FB_HTMLCREF)

XML charref mode (*CHECK* = Encode::FB_XMLCREF)

For encodings that are implemented by Encode::XS, *CHECK* == Encode::FB_PERLQQ turns (en|de)code into perlqq fallback mode.

When you decode, \xHH will be inserted for a malformed character, where HH is the hex representation of the octet that could not be decoded to utf8. And when you encode, \x{HHHH} will be inserted, where HHHH is the Unicode ID of the character that cannot be found in the character repertoire of the encoding.

HTML/XML character reference modes are about the same, in place of \x{HHHH}, HTML uses &#NNNN; where NNNN is a decimal digit and XML uses &#xHHHH; where HHHH is the hexadecimal digit.

The bitmask

These modes are actually set via a bitmask. Here is how the FB_XX constants are laid out. You can import the FB_XX constants via use Encode qw(:fallbacks); you can import the generic bitmask constants via use Encode qw(:fallback_all).

```
FB_DEFAULT FB_CROAK FB_QUIET FB_WARN FB_PERLQQ
```

DIE_ON_ERR	0x0001	X	
WARN_ON_ERR	0x0002		X
RETURN_ON_ERR	0x0004	X	X
LEAVE_SRC	0x0008		
PERLQQ	0x0100		X
HTMLCREF	0x0200		
XMLCREF	0x0400		

Unimplemented fallback schemes

In the future, you will be able to use a code reference to a callback function for the value of *CHECK* but its API is still undecided.

The fallback scheme does not work on EBCDIC platforms.

Defining Encodings

To define a new encoding, use:

```
use Encode qw(define_encoding);
define_encoding($object, 'canonicalName' [, alias...]);
```

canonicalName will be associated with *\$object*. The object should provide the interface described in [Encode::Encoding](#). If more than two arguments are provided then additional arguments are taken as aliases for *\$object*.

See [Encode::Encoding](#) for more details.

The UTF-8 flag

Before the introduction of utf8 support in perl, The eq operator just compared the strings represented by two scalars. Beginning with perl 5.8, eq compares two strings with simultaneous consideration of *the utf8 flag*. To explain why we made it so, I will quote page 402 of *Programming Perl*, 3rd ed.

Goal #1:

Old byte-oriented programs should not spontaneously break on the old byte-oriented data they used to work on.

Goal #2:

Old byte-oriented programs should magically start working on the new character-oriented data when appropriate.

Goal #3:

Programs should run just as fast in the new character-oriented mode as in the old byte-oriented mode.

Goal #4:

Perl should remain one language, rather than forking into a byte-oriented Perl and a character-oriented Perl.

Back when *Programming Perl*, 3rd ed. was written, not even Perl 5.6.0 was born and many features documented in the book remained unimplemented for a long time. Perl 5.8 corrected this and the introduction of the UTF-8 flag is one of them. You can think of this perl notion as of a byte-oriented mode (utf8 flag off) and a character-oriented mode (utf8 flag on).

Here is how Encode takes care of the utf8 flag.

- When you encode, the resulting utf8 flag is always off.

When you decode, the resulting utf8 flag is on unless you can unambiguously represent data. Here is the definition of dis-ambiguity.

```
After $utf8 = decode('foo', $octet);,
```

```
When $octet is... The utf8 flag in $utf8 is
```

```
-----
```

In ASCII only (or EBCDIC only)	OFF
In ISO-8859-1	ON
In any other Encoding	ON

As you see, there is one exception, In ASCII. That way you can assue Goal #1. And with Encode Goal #2 is assumed but you still have to be careful in such cases mentioned in **CAVEAT** paragraphs.

This utf8 flag is not visible in perl scripts, exactly for the same reason you cannot (or you *don't have to*) see if a scalar contains a string, integer, or floating point number. But you can still peek and poke these if you will. See the section below.

Messing with Perl's Internals

The following API uses parts of Perl's internals in the current implementation. As such, they are efficient but may change.

`is_utf8(String [, CHECK])`

[INTERNAL] Tests whether the UTF-8 flag is turned on in the STRING. If CHECK is true, also checks the data in STRING for being well-formed UTF-8. Returns true if successful, false otherwise.

`_utf8_on(String)`

[INTERNAL] Turns on the UTF-8 flag in STRING. The data in STRING is **not** checked for being well-formed UTF-8. Do not use unless you **know** that the STRING is well-formed UTF-8. Returns the previous state of the UTF-8 flag (so please don't treat the return value as indicating success or failure), or undef if STRING is not a string.

`_utf8_off(String)`

[INTERNAL] Turns off the UTF-8 flag in STRING. Do not use frivolously. Returns the previous state of the UTF-8 flag (so please don't treat the return value as indicating success or failure), or undef if STRING is not a string.

NAME

encoding – allows you to write your script in non-ascii or non-utf8

SYNOPSIS

```
use encoding "greek"; # Perl like Greek to you?
use encoding "euc-jp"; # Jperl!

# or you can even do this if your shell supports your native encoding

perl -Mencoding=latin2 -e '...' # Feeling centrally European?
perl -Mencoding=euc-kr -e '...' # Or Korean?

# more control

# A simple euc-cn => utf-8 converter
use encoding "euc-cn", STDOUT => "utf8"; while(<>){print};

# "no encoding;" supported (but not scoped!)
no encoding;

# an alternate way, Filter
use encoding "euc-jp", Filter=>1;
use utf8;
# now you can use kanji identifiers -- in euc-jp!
```

ABSTRACT

Let's start with a bit of history: Perl 5.6.0 introduced Unicode support. You could apply `substr()` and regexes even to complex CJK characters — so long as the script was written in UTF-8. But back then, text editors that supported UTF-8 were still rare and many users instead chose to write scripts in legacy encodings, giving up a whole new feature of Perl 5.6.

Rewind to the future: starting from perl 5.8.0 with the **encoding** pragma, you can write your script in any encoding you like (so long as the Encode module supports it) and still enjoy Unicode support. You can write code in EUC-JP as follows:

```
my $Rakuda = "\xF1\xD1\xF1\xCC"; # Camel in Kanji
           #<-char-><-char->      # 4 octets
s/\bCamel\b/$Rakuda/;
```

And with `use encoding "euc-jp"` in effect, it is the same thing as the code in UTF-8:

```
my $Rakuda = "\x{99F1}\x{99DD}"; # two Unicode Characters
s/\bCamel\b/$Rakuda/;
```

The **encoding** pragma also modifies the filehandle disciplines of STDIN, STDOUT, and STDERR to the specified encoding. Therefore,

```
use encoding "euc-jp";
my $message = "Camel is the symbol of perl.\n";
my $Rakuda = "\xF1\xD1\xF1\xCC"; # Camel in Kanji
$message =~ s/\bCamel\b/$Rakuda/;
print $message;
```

Will print `"\xF1\xD1\xF1\xCC is the symbol of perl.\n"`, not `"\x{99F1}\x{99DD} is the symbol of perl.\n"`.

You can override this by giving extra arguments; see below.

USAGE

`use encoding [ENCNAME];`

Sets the script encoding to *ENCNAME*. Filehandle disciplines of STDIN and STDOUT are set to `":encoding(ENCNAME)"`. Note that STDERR will not be changed.

If no encoding is specified, the environment variable *PERL_ENCODING* is consulted. If no encoding can be found, the error `Unknown encoding 'ENCNAME'` will be thrown.

Note that non-STD file handles remain unaffected. Use `use open` or `binmode` to change disciplines of those.

`use encoding ENCNAME [STDIN => ENCNAME_IN ...] ;`

You can also individually set encodings of STDIN and STDOUT via the `< STDIN = ENCNAME` form. In this case, you cannot omit the first *ENCNAME*. `< STDIN = undef` turns the IO transcoding completely off.

`no encoding;`

Unsets the script encoding. The disciplines of STDIN, STDOUT are reset to `":raw"` (the default unprocessed raw stream of bytes).

CAVEATS

NOT SCOPED

The pragma is a per script, not a per block lexical. Only the last `use encoding` or `no encoding` matters, and it affects **the whole script**. However, the `<no encoding` pragma is supported and **use encoding** can appear as many times as you want in a given script. The multiple use of this pragma is discouraged.

Because of this nature, the use of this pragma inside the module is strongly discouraged (because the influence of this pragma lasts not only for the module but the script that uses). But if you have to, make sure you say `no encoding` at the end of the module so you contain the influence of the pragma within the module.

DO NOT MIX MULTIPLE ENCODINGS

Notice that only literals (string or regular expression) having only legacy code points are affected: if you mix data like this

```
\xDF\x{100}
```

the data is assumed to be in (Latin 1 and) Unicode, not in your native encoding. In other words, this will match in "greek":

```
"\xDF" =~ /\x{3af}/
```

but this will not

```
"\xDF\x{100}" =~ /\x{3af}\x{100}/
```

since the `\xDF` (ISO 8859-7 GREEK SMALL LETTER IOTA WITH TONOS) on the left will **not** be upgraded to `\x{3af}` (Unicode GREEK SMALL LETTER IOTA WITH TONOS) because of the `\x{100}` on the left. You should not be mixing your legacy data and Unicode in the same string.

This pragma also affects encoding of the 0x80..0xFF code point range: normally characters in that range are left as eight-bit bytes (unless they are combined with characters with code points 0x100 or larger, in which case all characters need to become UTF-8 encoded), but if the `encoding` pragma is present, even the 0x80..0xFF range always gets UTF-8 encoded.

After all, the best thing about this pragma is that you don't have to resort to `\x{....}` just to spell your name in a native encoding. So feel free to put your strings in your encoding in quotes and regexes.

Non-ASCII Identifiers and Filter option

The magic of `use encoding` is not applied to the names of identifiers. In order to make `${"\x{4eba}"}++` (`$human++`, where `human` is a single Han ideograph) work, you still need to write your script in UTF-8 or use a source filter.

In other words, the same restriction as with `Jperl` applies.

If you dare to experiment, however, you can try the `Filter` option.

use encoding *ENCNAME* **Filter=>1**;

This turns the encoding pragma into a source filter. While the default approach just decodes interpolated literals (in `qq()` and `qr()`), this will apply a source filter to the entire source code. In this case, `STDIN` and `STDOUT` remain untouched.

What does this mean? Your source code behaves as if it is written in UTF-8. So even if your editor only supports Shift_JIS, for example, you can still try examples in Chapter 15 of *Programming Perl*, 3rd Ed.. For instance, you can use UTF-8 identifiers.

This option is significantly slower and (as of this writing) non-ASCII identifiers are not very stable WITHOUT this option and with the source code written in UTF-8.

To make your script in legacy encoding work with minimum effort, do not use `Filter=>1`.

EXAMPLE – Greekperl

```
use encoding "iso 8859-7";

# \xDF in ISO 8859-7 (Greek) is \x{3af} in Unicode.

$a = "\xDF";
$b = "\x{100}";

printf "%#x\n", ord($a); # will print 0x3af, not 0xdf

$c = $a . $b;

# $c will be "\x{3af}\x{100}", not "\x{df}\x{100}".
# chr() is affected, and ...

print "mega\n" if ord(chr(0xdf)) == 0x3af;

# ... ord() is affected by the encoding pragma ...

print "tera\n" if ord(pack("C", 0xdf)) == 0x3af;

# ... as are eq and cmp ...

print "peta\n" if "\x{3af}" eq pack("C", 0xdf);
print "exa\n" if "\x{3af}" cmp pack("C", 0xdf) == 0;

# ... but pack/unpack C are not affected, in case you still
# want to go back to your native encoding

print "zetta\n" if unpack("C", (pack("C", 0xdf))) == 0xdf;
```

KNOWN PROBLEMS

For native multibyte encodings (either fixed or variable length), the current implementation of the regular expressions may introduce recoding errors for regular expression literals longer than 127 bytes.

The encoding pragma is not supported on EBCDIC platforms. (Porters who are willing and able to remove this limitation are welcome.)

NAME

Encode::JP – Japanese Encodings

SYNOPSIS

```
use Encode qw/encode decode/;
$euc_jp = encode("euc-jp", $utf8); # loads Encode::JP implicitly
$utf8   = decode("euc-jp", $euc_jp); # ditto
```

ABSTRACT

This module implements Japanese charset encodings. Encodings supported are as follows.

Canonical	Alias	Description
euc-jp	/\beuc.*jp\$/i /\bjp.*euc/i /\bujis\$/i	EUC (Extended Unix Character)
shiftjis	/\bshift.*jis\$/i /\bsjis\$/i	Shift JIS (aka MS Kanji)
7bit-jis	/\bjis\$/i	7bit JIS
iso-2022-jp		ISO-2022-JP [RFC1468] = 7bit JIS with all Halfwidth Kana converted to Fullwidth
iso-2022-jp-1		ISO-2022-JP-1 [RFC2237] = ISO-2022-JP with JIS X 0212-1990 support. See below
MacJapanese cp932		Shift JIS + Apple vendor mappings Code Page 932 = Shift JIS + MS/IBM vendor mappings
jis0201-raw		JIS0201, raw format
jis0208-raw		JIS0201, raw format
jis0212-raw		JIS0201, raw format

DESCRIPTION

To find out how to use this module in detail, see [Encode](#).

Note on ISO-2022-JP(-1)?

ISO-2022-JP-1 (RFC2237) is a superset of ISO-2022-JP (RFC1468) which adds support for JIS X 0212-1990. That means you can use the same code to decode to utf8 but not vice versa.

```
$utf8 = decode('iso-2022-jp-1', $stream);
```

and

```
$utf8 = decode('iso-2022-jp', $stream);
```

yield the same result but

```
$with_0212 = encode('iso-2022-jp-1', $utf8);
```

is now different from

```
$without_0212 = encode('iso-2022-jp', $utf8 );
```

In the latter case, characters that map to 0212 are first converted to U+3013 (0xA2AE in EUC-JP; a white square also known as ‘Tofu’ or ‘geta mark’) then fed to the decoding engine. U+FFFD is not used, in order to preserve text layout as much as possible.

BUGS

The ASCII region (0x00–0x7f) is preserved for all encodings, even though this conflicts with mappings by the Unicode Consortium. See

<http://www.debian.or.jp/~kubota/unicode-symbols.html.en>

to find out why it is implemented that way.

Encode

NAME

Encode::KR – Korean Encodings

SYNOPSIS

```
use Encode qw/encode decode/;
$euc_kr = encode("euc-kr", $utf8); # loads Encode::KR implicitly
$utf8   = decode("euc-kr", $euc_kr); # ditto
```

DESCRIPTION

This module implements Korean charset encodings. Encodings supported are as follows.

Canonical	Alias	Description
euc-kr	/\beuc.*kr\$/i /\bkr.*euc\$/i	EUC (Extended Unix Character)
ksc5601-raw		Korean standard code set (as is)
cp949	/(?:x-)?uhc\$/i /(?:x-)?windows-949\$/i /\bks_c_5601-1987\$/i	Code Page 949 (EUC-KR + 8,822 (additional Hangul syllables)
MacKorean		EUC-KR + Apple Vendor Mappings
johab	JOHAB	A supplementary encoding defined in Annex 3 of KS X 1001:1998
iso-2022-kr		iso-2022-kr [RFC1557]

To find how to use this module in detail, see [Encode](#).

BUGS

When you see charset=ks_c_5601-1987 on mails and web pages, they really mean "cp949" encodings. To fix that, the following aliases are set;

```
qr/(?:x-)?uhc$/i      => ' "cp949" '
qr/(?:x-)?windows-949$/i => ' "cp949" '
qr/ks_c_5601-1987$/i  => ' "cp949" '
```

The ASCII region (0x00–0x7f) is preserved for all encodings, even though this conflicts with mappings by the Unicode Consortium. See

<http://www.debian.or.jp/~kubota/unicode-symbols.html.en>

to find out why it is implemented that way.

NAME

Encode::Alias – alias definitions to encodings

SYNOPSIS

```
use Encode;
use Encode::Alias;
define_alias( newName => ENCODING );
```

DESCRIPTION

Allows *newName* to be used as an alias for *ENCODING*. *ENCODING* may be either the name of an encoding or an encoding object (as described in [Encode](#)).

Currently *newName* can be specified in the following ways:

As a simple string.

As a `qr//` compiled regular expression, e.g.:

```
define_alias( qr/^iso8859-(\d+)$/i => "iso-8859-$1" );
```

In this case, if *ENCODING* is not a reference, it is `eval`-ed in order to allow `$1` etc. to be substituted.

The example is one way to alias names as used in X11 fonts to the MIME names for the iso-8859-* family. Note the double quotes inside the single quotes.

If you are using a regex here, you have to use the quotes as shown or it won't work. Also note that regex handling is tricky even for the experienced. Use it with caution.

As a code reference, e.g.:

```
define_alias( sub { return /^iso8859-(\d+)$/i ? "iso-8859-$1" : undef } , '' );
```

In this case, `$_` will be set to the name that is being looked up and *ENCODING* is passed to the sub as its first argument. The example is another way to alias names as used in X11 fonts to the MIME names for the iso-8859-* family.

Alias overloading

You can override predefined aliases by simply applying `define_alias()`. The new alias is always evaluated first, and when necessary, `define_alias()` flushes the internal cache to make the new definition available.

```
# redirect SHIFT_JIS to MS/IBM Code Page 932, which is a
# superset of SHIFT_JIS

define_alias( qr/shift.*jis$/i   => "cp932" );
define_alias( qr/sjis$/i         => "cp932" );
```

If you want to zap all predefined aliases, you can use

```
Encode::Alias->undef_aliases;
```

to do so. And

```
Encode::Alias->init_aliases;
```

gets the factory settings back.

NAME

Encode::CN::HZ — internally used by Encode::CN

NAME

Encode::Config — internally used by Encode

NAME

Encode::Encoder — Object Oriented Encoder

SYNOPSIS

```
use Encode::Encoder;
# Encode::encode("ISO-8859-1", $data);
Encode::Encoder->new($data)->iso_8859_1; # OOP way
# shortcut
use Encode::Encoder qw(encoder);
encoder($data)->iso_8859_1;
# you can stack them!
encoder($data)->iso_8859_1->base64; # provided base64() is defined
# you can use it as a decoder as well
encoder($base64)->bytes('base64')->latin1;
# stringified
print encoder($data)->utf8->latin1; # prints the string in latin1
# numified
encoder("\x{abcd}\x{ef}g")->utf8 == 6; # true. bytes::length($data)
```

ABSTRACT

Encode::Encoder allows you to use Encode in an object-oriented style. This is not only more intuitive than a functional approach, but also handier when you want to stack encodings. Suppose you want your UTF-8 string converted to Latin1 then Base64: you can simply say

```
my $base64 = encoder($utf8)->latin1->base64;
```

instead of

```
my $latin1 = encode("latin1", $utf8);
my $base64 = encode_base64($utf8);
```

or the lazier and more convoluted

```
my $base64 = encode_base64(encode("latin1", $utf8));
```

Description

Here is how to use this module.

- There are at least two instance variables stored in a hash reference, {data} and {encoding}.
- When there is no method, it takes the method name as the name of the encoding and encodes the instance *data* with *encoding*. If successful, the instance *encoding* is set accordingly.
- You can retrieve the result via `->data` but usually you don't have to because the stringify operator (`""`) is overridden to do exactly that.

Predefined Methods

This module predefines the methods below:

```
$e = Encode::Encoder->new([$data, $encoding]);
```

returns an encoder object. Its data is initialized with *\$data* if present, and its encoding is set to *\$encoding* if present.

When *\$encoding* is omitted, it defaults to `utf8` if *\$data* is already in `utf8` or `""` (empty string) otherwise.

```
encoder()
```

is an alias of `Encode::Encoder->new()`. This one is exported on demand.

`$e->data([$data])`

When `$data` is present, sets the instance data to `$data` and returns the object itself. Otherwise, the current instance data is returned.

`$e->encoding([$encoding])`

When `$encoding` is present, sets the instance encoding to `$encoding` and returns the object itself. Otherwise, the current instance encoding is returned.

`$e->bytes([$encoding])`

decodes instance data from `$encoding`, or the instance encoding if omitted. If the conversion is successful, the instance encoding will be set to `""`.

The name *bytes* was deliberately picked to avoid namespace tainting — this module may be used as a base class so method names that appear in `Encode::Encoding` are avoided.

Example: base64 transcoder

This module is designed to work with [Encode::Encoding](#). To make the Base64 transcoder example above really work, you could write a module like this:

```
package Encode::Base64;
use base 'Encode::Encoding';
__PACKAGE__->Define('base64');
use MIME::Base64;
sub encode{
    my ($obj, $data) = @_;
    return encode_base64($data);
}
sub decode{
    my ($obj, $data) = @_;
    return decode_base64($data);
}
1;
__END__
```

And your caller module would be something like this:

```
use Encode::Encoder;
use Encode::Base64;

# now you can really do the following

encoder($data)->iso_8859_1->base64;
encoder($base64)->bytes('base64')->latin1;
```

Operator Overloading

This module overloads two operators, `stringify ("")` and `numify (0+)`.

`Stringify` dumps the data inside the object.

`Numify` returns the number of bytes in the instance data.

They come in handy when you want to print or find the size of data.

NAME

Encode::Encoding – Encode Implementation Base Class

SYNOPSIS

```
package Encode::MyEncoding;
use base qw(Encode::Encoding);

__PACKAGE__->Define(qw(myCanonical myAlias));
```

DESCRIPTION

As mentioned in [Encode](#), encodings are (in the current implementation at least) defined as objects. The mapping of encoding name to object is via the `%Encode::Encoding` hash. Though you can directly manipulate this hash, it is strongly encouraged to use this base class module and add `encode()` and `decode()` methods.

Methods you should implement

You are strongly encouraged to implement methods below, at least either `encode()` or `decode()`.

`->encode($string[, $check])`

MUST return the octet sequence representing *\$string*.

- If *\$check* is true, it SHOULD modify *\$string* in place to remove the converted part (i.e. the whole string unless there is an error). If `perlio_ok()` is true, SHOULD becomes MUST.
- If an error occurs, it SHOULD return the octet sequence for the fragment of string that has been converted and modify *\$string* in-place to remove the converted part leaving it starting with the problem fragment. If `perlio_ok()` is true, SHOULD becomes MUST.
- If *\$check* is false then `encode` MUST make a "best effort" to convert the string – for example, by using a replacement character.

`->decode($octets[, $check])`

MUST return the string that *\$octets* represents.

- If *\$check* is true, it SHOULD modify *\$octets* in place to remove the converted part (i.e. the whole sequence unless there is an error). If `perlio_ok()` is true, SHOULD becomes MUST.
- If an error occurs, it SHOULD return the fragment of string that has been converted and modify *\$octets* in-place to remove the converted part leaving it starting with the problem fragment. If `perlio_ok()` is true, SHOULD becomes MUST.
- If *\$check* is false then `decode` should make a "best effort" to convert the string – for example by using Unicode's `"\x{FFFD}"` as a replacement character.

Other methods defined in Encode::Encodings

You do not have to override methods shown below unless you have to.

`->name`

Predefined As:

```
sub name { return shift->{'Name'} }
```

MUST return the string representing the canonical name of the encoding.

`->new_sequence`

Predefined As:

```
sub new_sequence { return $_[0] }
```

This is a placeholder for encodings with state. It should return an object which implements this interface. All current implementations return the original object.

`->perlio_ok()`

Predefined As:

```
sub perlio_ok {
    eval{ require PerlIO::encoding };
    return $@ ? 0 : 1;
}
```

If your encoding does not support PerlIO for some reasons, just;

```
sub perlio_ok { 0 }
```

`->needs_lines()`

Predefined As:

```
sub needs_lines { 0 };
```

If your encoding can work with PerlIO but needs line buffering, you **MUST** define this method so it returns true. 7bit ISO-2022 encodings are one example that needs this. When this method is missing, false is assumed.

Example: Encode::ROT13

```
package Encode::ROT13;
use strict;
use base qw(Encode::Encoding);
__PACKAGE__->Define('rot13');

sub encode($$;$){
    my ($obj, $str, $chk) = @_;
    $str =~ tr/A-Za-z/N-ZA-Mn-za-m/;
    $_[1] = '' if $chk; # this is what in-place edit means
    return $str;
}

# Jr pna or ynm1 yvxr guvf;
*decode = \&encode;

1;
```

Why the heck Encode API is different?

It should be noted that the *\$check* behaviour is different from the outer public API. The logic is that the "unchecked" case is useful when the encoding is part of a stream which may be reporting errors (e.g. STDERR). In such cases, it is desirable to get everything through somehow without causing additional errors which obscure the original one. Also, the encoding is best placed to know what the correct replacement character is, so if that is the desired behaviour then letting low level code do it is the most efficient.

By contrast, if *\$check* is true, the scheme above allows the encoding to do as much as it can and tell the layer above how much that was. What is lacking at present is a mechanism to report what went wrong. The most likely interface will be an additional method call to the object, or perhaps (to avoid forcing per-stream objects on otherwise stateless encodings) an additional parameter.

It is also highly desirable that encoding classes inherit from `Encode::Encoding` as a base class. This allows that class to define additional behaviour for all encoding objects.

```
package Encode::MyEncoding;
use base qw(Encode::Encoding);
__PACKAGE__->Define(qw(myCanonical myAlias));
```

to create an object with `< bless {Name = ...}, $class`, and call `define_encoding`. They inherit their name method from `Encode::Encoding`.

Compiled Encodings

For the sake of speed and efficiency, most of the encodings are now supported via a *compiled form*: XS modules generated from UCM files. Encode provides the `enc2xs` tool to achieve that. Please see [enc2xs](#) for more details.

SEE ALSO

[perlmod](#), [enc2xs](#)

=begin future

Scheme 1

The fixup routine gets passed the remaining fragment of string being processed. It modifies it in place to remove bytes/characters it can understand and returns a string used to represent them. For example:

```
sub fixup {
    my $ch = substr($_[0], 0, 1, '');
    return sprintf("\x{%02X}", ord($ch);
}
```

This scheme is close to how the underlying C code for Encode works, but gives the fixup routine very little context.

Scheme 2

The fixup routine gets passed the original string, an index into it of the problem area, and the output string so far. It appends what it wants to the output string and returns a new index into the original string. For example:

```
sub fixup {
    # my ($s,$i,$d) = @_;
    my $ch = substr($_[0], $_[1], 1);
    $_[2] .= sprintf("\x{%02X}", ord($ch);
    return $_[1]+1;
}
```

This scheme gives maximal control to the fixup routine but is more complicated to code, and may require that the internals of Encode be tweaked to keep the original string intact.

Other Schemes

Hybrids of the above.

Multiple return values rather than in-place modifications.

Index into the string could be `pos($str)` allowing `s/\G...//`.

=end future

NAME

Encode::JP::H2Z — internally used by Encode::JP::2022_JP*

NAME

Encode::JP::JIS7 — internally used by Encode::JP

NAME

Encode::KR::2022_KR — internally used by Encode::KR

NAME

Encode::Supported — Encodings supported by Encode

DESCRIPTION**Encoding Names**

Encoding names are case insensitive. White space in names is ignored. In addition, an encoding may have aliases. Each encoding has one "canonical" name. The "canonical" name is chosen from the names of the encoding by picking the first in the following sequence (with a few exceptions).

- The name used by the Perl community. That includes 'utf8' and 'ascii'. Unlike aliases, canonical names directly reach the method so such frequently used words like 'utf8' don't need to do alias lookups.
- The MIME name as defined in IETF RFCs. This includes all "iso-"s.
- The name in the IANA registry.
- The name used by the organization that defined it.

In case *de jure* canonical names differ from that of the Encode module, they are always aliased if it ever be implemented. So you can safely tell if a given encoding is implemented or not just by passing the canonical name.

Because of all the alias issues, and because in the general case encodings have state, "Encode" uses an encoding object internally once an operation is in progress.

Supported Encodings

As of Perl 5.8.0, at least the following encodings are recognized. Note that unless otherwise specified, they are all case insensitive (via alias) and all occurrence of spaces are replaced with '-'. In other words, "ISO 8859 1" and "iso-8859-1" are identical.

Encodings are categorized and implemented in several different modules but you don't have to use `Encode:::XX` to make them available for most cases. `Encode.pm` will automatically load those modules on demand.

Built-in Encodings

The following encodings are always available.

Canonical	Aliases	Comments & References
ascii	US-ascii ISO-646-US	[ECMA]
ascii-ctrl		Special Encoding
iso-8859-1	latin1	[ISO]
null		Special Encoding
utf8	UTF-8	[RFC2279]

null and *ascii-ctrl* are special. "null" fails for all character so when you set fallback mode to PERLQQ, HTMLCREF or XMLCREF, ALL CHARACTERS will fall back to character references. Ditto for "ascii-ctrl" except for control characters. For fallback modes, see [Encode](#).

Encode::Unicode — other Unicode encodings

Unicode coding schemes other than native utf8 are supported by `Encode::Unicode`, which will be autoloaded on demand.

UCS-2BE	UCS-2, iso-10646-1	[IANA, UC]
UCS-2LE		[UC]
UTF-16		[UC]
UTF-16BE		[UC]

UTF-16LE		[UC]
UTF-32		[UC]
UTF-32BE	UCS-4	[UC]
UTF-32LE		[UC]

To find how (UCS-2|UTF-(16|32))(LE|BE)? differ from one another, see [Encode::Unicode](#).

Encode::Byte — Extended ASCII

Encode::Byte implements most single-byte encodings except for Symbols and EBCDIC. The following encodings are based on single-byte encodings implemented as extended ASCII. Most of them map \x80-\xff (upper half) to non-ASCII characters.

ISO-8859 and corresponding vendor mappings

Since there are so many, they are presented in table format with languages and corresponding encoding names by vendors. Note that the table is sorted in order of ISO-8859 and the corresponding vendor mappings are slightly different from that of ISO. See <http://czyborra.com/charsets/iso8859.html> for details.

Lang/Regions	ISO/Other Std.	DOS	Windows	Macintosh	Others

Nordics	iso-8859-10	cp865			
		cp861		MacIcelandic	
				MacSami	
Thai	iso-8859-11 [3]	cp874		MacThai	
(iso-8859-12 is nonexistent.	Reserved for Indics?)				
Baltics	iso-8859-13	cp775		cp1257	
Celtics	iso-8859-14				
Latin9 [4]	iso-8859-15				
Latin10	iso-8859-16				
Vietnamese	viscii		cp1258	MacVietnamese	

[1] Esperanto, Maltese, and Turkish. Turkish is now on 8859-9.

[2] Baltics. Now on 8859-10, except for Latvian.

[3] Also known as TIS 620.

[4] Nicknamed Latin0; the Euro sign as well as French and Finnish letters that are missing from 8859-1 were added.

All cp* are also available as ibm-*, ms-*, and windows-*. See also <http://czyborra.com/charsets/codepages.html>.

Macintosh encodings don't seem to be registered in such entities as IANA. "Canonical" names in Encode are based upon Apple's Tech Note 1150. See <http://developer.apple.com/technotes/tn/tn1150.html> for details.

KOI8 – De Facto Standard for the Cyrillic world

Though ISO-8859 does have ISO-8859-5, the KOI8 series is far more popular in the Net. [Encode](#) comes with the following KOI charsets. For gory details, see <http://czyborra.com/charsets/cyrillic.html>

```
-----
koi8-f
koi8-r cp878 [RFC1489]
koi8-u [RFC2319]
-----
```

gsm0338 – Hentai Latin 1

GSM0338 is for GSM handsets. Though it shares alphanumeric with ASCII, control character ranges and other parts are mapped very differently, presumably to store Greek and Cyrillic alphabets. This is also covered in Encode::Byte even though it is not an "extended ASCII" encoding.

CJK: Chinese, Japanese, Korean (Multibyte)

Note that Vietnamese is listed above. Also read "Encoding vs Charset" below. Also note that these are implemented in distinct modules by countries, due to the size concerns (simplified Chinese is mapped to 'CN', continental China, while traditional Chinese is mapped to 'TW', Taiwan). Please refer to their respective documentataion pages.

[2] gbk is aliased to this. See L<Microsoft-related naming mess>

Encode::JP — Japan

Standard	DOS/Win	Macintosh	Comment/Reference
euc-jp			
shiftjis	cp932	macJapanese	
7bit-jis			
iso-2022-jp			[RFC1468]
iso-2022-jp-1			[RFC2237]
jis0201-raw	{ JIS X 0201 (roman + halfwidth kana)		without CES }
jis0208-raw	{ JIS X 0208 (Kanji + fullwidth kana)		without CES }
jis0212-raw	{ JIS X 0212 (Extended Kanji)		without CES }

Encode::KR — Korea

Standard	DOS/Win Macintosh	Comment/Reference
euc-kr	MacKorean	[RFC1557]
	cp949 [1]	
iso-2022-kr		[RFC1557]
johab		[KS X 1001:1998, Annex 3]
ksc5601-raw		{ KSC5601 without CES }

[1] ks_c_5601-1987, (x-)?windows-949, and uhc are aliased to this. See below.

Encode::TW — Taiwan

Standard	DOS/Win Macintosh	Comment/Reference
big5-eten	cp950 MacChineseTrad	{big5 aliased to big5-eten}
big5-hkscs		

Encode::HanExtra — More Chinese via CPAN

Due to size concerns, additional Chinese encodings below are distributed separately on CPAN, under the name Encode::HanExtra.

Standard	DOS/Win Macintosh	Comment/Reference
big5ext		CMEX's Big5e Extension
big5plus		CMEX's Big5+ Extension
cccii	Chinese Character Code for Information Interchange	
euc-tw		EUC (Extended Unix Character)
gb18030		GBK with Traditional Characters

Encode::JIS2K — JIS X 0213 encodings via CPAN

Due to size concerns, additional Japanese encodings below are distributed separately on CPAN, under the name Encode::JIS2K.

Standard	DOS/Win Macintosh	Comment/Reference
euc-jisx0213		
shiftjisx0123		
iso-2022-jp-3		
jis0213-1-raw		
jis0213-2-raw		

Miscellaneous encodings

Encode::EBCDIC

See [perlebcdic](#) for details.

```
-----
cp37
cp500
cp875
cp1026
cp1047
posix-bc
```

Encode::Symbols

For symbols and dingbats.

```
symbol
dingbats
MacDingbats
AdobeZdingbat
AdobeSymbol
```

Encode::MIME::Header

Strictly speaking, MIME header encoding documented in RFC 2047 is more of encapsulation than encoding. But included anyway.

MIME-Header	[RFC2047]
MIME-B	[RFC2047]
MIME-Q	[RFC2047]

Encode::Guess

This one is not a name of encoding but a utility that lets you pick up the most appropriate encoding for a data out of given *suspects*. See [Encode::Guess](#) for details.

Unsupported encodings

The following encodings are not supported as yet; some because they are rarely used, some because of technical difficulties. They may be supported by external modules via CPAN in the future, however.

ISO-2022-JP-2 [RFC1554]

Not very popular yet. Needs Unicode Database or equivalent to implement `encode()` (because it includes JIS X 0208/0212, KSC5601, and GB2312 simultaneously, whose code points in Unicode overlap. So you need to lookup the database to determine to what character set a given Unicode character should belong).

ISO-2022-CN [RFC1922]

Not very popular. Needs CNS 11643-1 and -2 which are not available in this module. CNS 11643 is supported (via `euc-tw`) in `Encode::HanExtra`. Atrijus Tang may add support for this encoding in his module in future.

Various HP-UX encodings

The following are unsupported due to the lack of mapping data.

```
'8' - arabic8, greek8, hebrew8, kana8, thai8, and turkish8
'15' - japanese15, korean15, and roi15
```

Cyrillic encoding ISO-IR-111

Anton Tagunov doubts its usefulness.

ISO-8859-8-1 [Hebrew]

None of the Encode team knows Hebrew enough (ISO-8859-8, `cp1255` and `MacHebrew` are supported because and just because there were mappings available at <http://www.unicode.org/>). Contributions welcome.

ISIRI 3342, Iran System, ISIRI 2900 [Farsi]

Ditto.

Thai encoding TCVN

Ditto.

Vietnamese encodings VPS

Though Jungshik Shin has reported that Mozilla supports this encoding, it was too late before 5.8.0 for us to add it. In the future, it may be available via a separate module. See

<http://lxr.mozilla.org/seamoney/source/intl/uconv/ucvlatin/vps.uf> and

<http://lxr.mozilla.org/seamoney/source/intl/uconv/ucvlatin/vps.ut> if you are interested in helping us.

Various Mac encodings

The following are unsupported due to the lack of mapping data.

MacArmenian, MacBengali, MacBurmese, MacEthiopic
MacExtArabic, MacGeorgian, MacKannada, MacKhmer
MacLaotian, MacMalayalam, MacMongolian, MacOriya
MacSinhalese, MacTamil, MacTelugu, MacTibetan
MacVietnamese

The rest which are already available are based upon the vendor mappings at

<http://www.unicode.org/Public/MAPPINGS/VENDORS/APPLE/>.

(Mac) Indic encodings

The maps for the following are available at <http://www.unicode.org/> but remain unsupported because those encodings need algorithmical approach, currently unsupported by *enc2xs*:

MacDevanagari
MacGurmukhi
MacGujarati

For details, please see Unicode mapping issues and notes: at

<http://www.unicode.org/Public/MAPPINGS/VENDORS/APPLE/DEVANAGA.TXT>.

I believe this issue is prevalent not only for Mac Indic but also in other Indic encodings, but the above were the only Indic encodings maps that I could find at <http://www.unicode.org/>.

Encoding vs. Charset — terminology

We are used to using the term (character) *encoding* and *character set* interchangeably. But just as confusing the terms byte and character is dangerous and the terms should be differentiated when needed, we need to differentiate *encoding* and *character set*.

To understand that, here is a description of how we make computers grok our characters.

- First we start with which characters to include. We call this collection of characters *character repertoire*.
- Then we have to give each character a unique ID so your computer can tell the difference between ‘a’ and ‘A’. This itemized character repertoire is now a *character set*.
- If your computer can grow the character set without further processing, you can go ahead and use it. This is called a *coded character set* (CCS) or *raw character encoding*. ASCII is used this way for most cases.
- But in many cases, especially multi-byte CJK encodings, you have to tweak a little more. Your network connection may not accept any data with the Most Significant Bit set, and your computer may not be able to tell if a given byte is a whole character or just half of it. So you have to *encode* the character set to use it.

A *character encoding scheme* (CES) determines how to encode a given character set, or a set of multiple character sets. 7bit ISO-2022 is an example of a CES. You switch between character sets via *escape sequences*.

Technically, or mathematically, speaking, a character set encoded in such a CES that maps character by character may form a CCS. EUC is such an example. The CES of EUC is as follows:

- Map ASCII unchanged.
- Map such a character set that consists of 94 or 96 powered by N members by adding 0x80 to each byte.
- You can also use 0x8e and 0x8f to indicate that the following sequence of characters belongs to yet another character set. To each following byte is added the value 0x80.

By carefully looking at the encoded byte sequence, you can find that the byte sequence conforms a unique number. In that sense, EUC is a CCS generated by a CES above from up to four CCS (complicated?). UTF-8 falls into this category. See [UTF-8 in perlUnicode](#) to find out how UTF-8 maps Unicode to a byte sequence.

You may also have found out by now why 7bit ISO-2022 cannot comprise a CCS. If you look at a byte sequence `\x21\x21`, you can't tell if it is two `!`'s or IDEOGRAPHIC SPACE. EUC maps the latter to `\xA1\xA1` so you have no trouble differentiating between `!!` and `" "`.

Encoding Classification (by Anton Tagunov and Dan Kogai)

This section tries to classify the supported encodings by their applicability for information exchange over the Internet and to choose the most suitable aliases to name them in the context of such communication.

- To (en/de)code encodings marked by `(**)`, you need `Encode::HanExtra`, available from CPAN.

Encoding names

US-ASCII	UTF-8	ISO-8859-*	KOI8-R
Shift_JIS	EUC-JP	ISO-2022-JP	ISO-2022-JP-1
EUC-KR	Big5	GB2312	

are registered with IANA as preferred MIME names and may be used over the Internet.

Shift_JIS has been officialized by JIS X 0208:1997. [Microsoft-related naming mess](#) gives details.

GB2312 is the IANA name for EUC-CN. See [Microsoft-related naming mess](#) for details.

GB_2312-80 raw encoding is available as `gb2312-raw` with Encode. See [Encode::CN](#) for details.

EUC-CN	
KOI8-U	[RFC2319]

have not been registered with IANA (as of March 2002) but seem to be supported by major web browsers. The IANA name for EUC-CN is GB2312.

KS_C_5601-1987

is heavily misused. See [Microsoft-related naming mess](#) for details.

KS_C_5601-1987 raw encoding is available as `kcs5601-raw` with Encode. See [Encode::KR](#) for details.

UTF-16 UTF-16BE UTF-16LE

are IANA-registered charsets. See [RFC 2781] for details. Jungshik Shin reports that UTF-16 with a BOM is well accepted by MS IE 5/6 and NS 4/6. Beware however that

- UTF-16 support in any software you're going to be using/interoperating with has probably been less tested than UTF-8 support
- UTF-8 coded data seamlessly passes traditional command piping (`cat`, `more`, etc.) while UTF-16 coded data is likely to cause confusion (with its zero bytes, for example)

- it is beyond the power of words to describe the way HTML browsers encode non-ASCII form data. To get a general impression, visit <http://ppewww.ph.gla.ac.uk/~flavell/charset/form-i18n.html>. While encoding of form data has stabilized for UTF-8 encoded pages (at least IE 5/6, NS 6, and Opera 6 behave consistently), be sure to expect fun (and cross-browser discrepancies) with UTF-16 encoded pages!

The rule of thumb is to use UTF-8 unless you know what you're doing and unless you really benefit from using UTF-16.

```
ISO-IR-165      [RFC1345]
VISCII
GB 12345
GB 18030 (**)   (see links bellow)
EUC-TW         (**)
```

are totally valid encodings but not registered at IANA. The names under which they are listed here are probably the most widely-known names for these encodings and are recommended names.

```
BIG5PLUS (**)

```

is a proprietary name.

Microsoft-related naming mess

Microsoft products misuse the following names:

KS_C_5601-1987

Microsoft extension to EUC-KR.

Proper names: CP949, UHC, x-windows-949 (as used by Mozilla).

See <http://lists.w3.org/Archives/Public/ietf-charsets/2001AprJun/0033.html> for details.

Encode aliases KS_C_5601-1987 to cp949 to reflect this common misuse. *Raw* KS_C_5601-1987 encoding is available as kcs5601-raw.

See [Encode::KR](#) for details.

GB2312

Microsoft extension to EUC-CN.

Proper names: CP936, GBK.

GB2312 has been registered in the EUC-CN meaning at IANA. This has partially repaired the situation: Microsoft's GB2312 has become a superset of the official GB2312.

Encode aliases GB2312 to euc-cn in full agreement with IANA registration. cp936 is supported separately. *Raw* GB_2312-80 encoding is available as gb2312-raw.

See [Encode::CN](#) for details.

Big5

Microsoft extension to Big5.

Proper name: CP950.

Encode separately supports Big5 and cp950.

Shift_JIS

Microsoft's understanding of Shift_JIS.

JIS has not endorsed the full Microsoft standard however. The official Shift_JIS includes only JIS X 0201 and JIS X 0208 character sets, while Microsoft has always used Shift_JIS to encode a wider character repertoire. See IANA registration for Windows-31J.

As a historical predecessor, Microsoft's variant probably has more rights for the name, though it may be objected that Microsoft shouldn't have used JIS as part of the name in the first place.

Unambiguous name: CP932. IANA name (not used?): Windows-31J.

Encode separately supports Shift_JIS and cp932.

Glossary

character repertoire

A collection of unique characters. A *character* set in the strictest sense. At this stage, characters are not numbered.

coded character set (CCS)

A character set that is mapped in a way computers can use directly. Many character encodings, including EUC, fall in this category.

character encoding scheme (CES)

An algorithm to map a character set to a byte sequence. You don't have to be able to tell which character set a given byte sequence belongs to. 7-bit ISO-2022 is a CES but it cannot be a CCS. EUC is an example of being both a CCS and CES.

charset (in MIME context)

has long been used in the meaning of encoding, CES.

While the word combination `character set` has lost this meaning in MIME context since [RFC 2130], the `charset` abbreviation has retained it. This is how [RFC 2277] and [RFC 2278] bless `charset`:

This document uses the term "charset" to mean a set of rules for mapping from a sequence of octets to a sequence of characters, such as the combination of a coded character set and a character encoding scheme; this is also what is used as an identifier in MIME "charset=" parameters, and registered in the IANA charset registry ... (Note that this is NOT a term used by other standards bodies, such as ISO).
[RFC 2277]

EUC

Extended Unix Character. See ISO-2022.

ISO-2022

A CES that was carefully designed to coexist with ASCII. There are a 7 bit version and an 8 bit version.

The 7 bit version switches character set via escape sequence so it cannot form a CCS. Since this is more difficult to handle in programs than the 8 bit version, the 7 bit version is not very popular except for iso-2022-jp, the *de facto* standard CES for e-mails.

The 8 bit version can form a CCS. EUC and ISO-8859 are two examples thereof. Pre-5.6 perl could use them as string literals.

UCS

Short for *Universal Character Set*. When you say just UCS, it means *Unicode*.

UCS-2

ISO/IEC 10646 encoding form: Universal Character Set coded in two octets.

Unicode

A character set that aims to include all character repertoires of the world. Many character sets in various national as well as industrial standards have become, in a way, just subsets of Unicode.

UTF

Short for *Unicode Transformation Format*. Determines how to map a Unicode character into a byte sequence.

UTF-16

A UTF in 16-bit encoding. Can either be in big endian or little endian. The big endian version is called UTF-16BE (equal to UCS-2 + surrogate support) and the little endian version is called UTF-16LE.

NAME

Encode::Symbol – Symbol Encodings

SYNOPSIS

```
use Encode qw/encode decode/;
$symbol = encode("symbol", $utf8); # loads Encode::Symbol implicitly
$utf8 = decode("", $symbol);      # ditto
```

ABSTRACT

This module implements symbol and dingbats encodings. Encodings supported are as follows.

Canonical	Alias	Description
-----------	-------	-------------

symbol		
dingbats		
AdobeZDingbat		
AdobeSymbol		
MacDingbats		

DESCRIPTION

To find out how to use this module in detail, see [Encode](#).

SEE ALSO

[Encode](#)

NAME

Encode::TW – Taiwan-based Chinese Encodings

SYNOPSIS

```
use Encode qw/encode decode/;
$big5 = encode("big5", $utf8); # loads Encode::TW implicitly
$utf8 = decode("big5", $big5); # ditto
```

DESCRIPTION

This module implements tradition Chinese charset encodings as used in Taiwan and Hong Kong. Encodings supported are as follows.

Canonical	Alias	Description

big5-eten	/\bbig-?5\$/i /\bbig5-?et(en)?\$/i /\btca-?big5\$/i	Big5 encoding (with ETen extensions)
big5-hkscs	/\bbig5-?hk(scs)?\$/i /\bhk(scs)?-?big5\$/i	Big5 + Cantonese characters in Hong Kong
MacChineseTrad		Big5 + Apple Vendor Mappings
cp950		Code Page 950 = Big5 + Microsoft vendor mappings

To find out how to use this module in detail, see [Encode](#).

NOTES

Due to size concerns, EUC-TW (Extended Unix Character), CCCII (Chinese Character Code for Information Interchange), BIG5PLUS (CMEX's Big5+) and BIG5EXT (CMEX's Big5e) are distributed separately on CPAN, under the name [Encode::HanExtra](#). That module also contains extra China-based encodings.

BUGS

Since the original big5 encoding (1984) is not supported anywhere (glibc and DOS-based systems uses big5 to mean big5-eten; Microsoft uses big5 to mean cp950), a conscious decision was made to alias big5 to big5-eten, which is the de facto superset of the original big5.

The CNS11643 encoding files are not complete. For common CNS11643 manipulation, please use EUC-TW in [Encode::HanExtra](#), which contains planes 1–7.

The ASCII region (0x00–0x7f) is preserved for all encodings, even though this conflicts with mappings by the Unicode Consortium. See

<http://www.debian.or.jp/~kubota/unicode-symbols.html.en>

to find out why it is implemented that way.

[Encode](#)

NAME

English – use nice English (or awk) names for ugly punctuation variables

SYNOPSIS

```
use English qw( -no_match_vars ) ; # Avoids regex performance penalty
use English;
...
if ( $ERRNO =~ /denied/ ) { ... }
```

DESCRIPTION

This module provides aliases for the built-in variables whose names no one seems to like to read. Variables with side-effects which get triggered just by accessing them (like `$0`) will still be affected.

For those variables that have an **awk** version, both long and short English alternatives are provided. For example, the `$/` variable can be referred to either `$RS` or `$INPUT_RECORD_SEPARATOR` if you are using the English module.

See [perlvar](#) for a complete list of these.

PERFORMANCE

This module can provoke sizeable inefficiencies for regular expressions, due to unfortunate implementation details. If performance matters in your application and you don't need `$PREMATCH`, `$MATCH`, or `$POSTMATCH`, try doing

```
use English qw( -no_match_vars ) ;
```

. **It is especially important to do this in modules to avoid penalizing all applications which use them.**

NAME

Env – perl module that imports environment variables as scalars or arrays

SYNOPSIS

```
use Env;
use Env qw(PATH HOME TERM);
use Env qw($SHELL @LD_LIBRARY_PATH);
```

DESCRIPTION

Perl maintains environment variables in a special hash named %ENV. For when this access method is inconvenient, the Perl module Env allows environment variables to be treated as scalar or array variables.

The `Env::import()` function ties environment variables with suitable names to global Perl variables with the same names. By default it ties all existing environment variables (`keys %ENV`) to scalars. If the `import` function receives arguments, it takes them to be a list of variables to tie; it's okay if they don't yet exist. The scalar type prefix '\$' is inferred for any element of this list not prefixed by '\$' or '@'. Arrays are implemented in terms of `split` and `join`, using `$Config::Config{path_sep}` as the delimiter.

After an environment variable is tied, merely use it like a normal variable. You may access its value

```
@path = split(/:/, $PATH);
print join("\n", @LD_LIBRARY_PATH), "\n";
```

or modify it

```
$PATH .= " . ";
push @LD_LIBRARY_PATH, $dir;
```

however you'd like. Bear in mind, however, that each access to a tied array variable requires splitting the environment variable's string anew.

The code:

```
use Env qw(@PATH);
push @PATH, ' . ';
```

is equivalent to:

```
use Env qw(PATH);
$PATH .= " . ";
```

except that if `$ENV{PATH}` started out empty, the second approach leaves it with the (odd) value `" . "`, but the first approach leaves it with `" . "`.

To remove a tied environment variable from the environment, assign it the undefined value

```
undef $PATH;
undef @LD_LIBRARY_PATH;
```

LIMITATIONS

On VMS systems, arrays tied to environment variables are read-only. Attempting to change anything will cause a warning.

AUTHOR

Chip Salzenberg <chip@fin.uucp> and Gregor N. Purdy <gregor@focusresearch.com>

NAME

Exporter – Implements default import method for modules

SYNOPSIS

In module YourModule.pm:

```
package YourModule;
require Exporter;
@ISA = qw(Exporter);
@EXPORT_OK = qw(munge frobnicate); # symbols to export on request
```

In other files which wish to use YourModule:

```
use ModuleName qw(frobnicate);      # import listed symbols
frobnicate ($left, $right)          # calls YourModule::frobnicate
```

DESCRIPTION

The Exporter module implements an import method which allows a module to export functions and variables to its users' namespaces. Many modules use Exporter rather than implementing their own import method because Exporter provides a highly flexible interface, with an implementation optimised for the common case.

Perl automatically calls the import method when processing a use statement for a module. Modules and use are documented in [perlfunc](#) and [perlmod](#). Understanding the concept of modules and how the use statement operates is important to understanding the Exporter.

How to Export

The arrays @EXPORT and @EXPORT_OK in a module hold lists of symbols that are going to be exported into the users name space by default, or which they can request to be exported, respectively. The symbols can represent functions, scalars, arrays, hashes, or typeglobs. The symbols must be given by full name with the exception that the ampersand in front of a function is optional, e.g.

```
@EXPORT      = qw(afunc $scalar @array); # afunc is a function
@EXPORT_OK   = qw(&bfunc %hash *typeglob); # explicit prefix on &bfunc
```

If you are only exporting function names it is recommended to omit the ampersand, as the implementation is faster this way.

Selecting What To Export

Do **not** export method names!

Do **not** export anything else by default without a good reason!

Exports pollute the namespace of the module user. If you must export try to use @EXPORT_OK in preference to @EXPORT and avoid short or common symbol names to reduce the risk of name clashes.

Generally anything not exported is still accessible from outside the module using the ModuleName::item_name (or \$blessed_ref->method) syntax. By convention you can use a leading underscore on names to informally indicate that they are 'internal' and not for public use.

(It is actually possible to get private functions by saying:

```
my $subref = sub { ... };
$subref->(@args);          # Call it as a function
$obj->$subref(@args);      # Use it as a method
```

However if you use them for methods it is up to you to figure out how to make inheritance work.)

As a general rule, if the module is trying to be object oriented then export nothing. If it's just a collection of functions then @EXPORT_OK anything but use @EXPORT with caution. For function and method names use barewords in preference to names prefixed with ampersands for the export lists.

Other module design guidelines can be found in [perlmod](#).

How to Import

In other files which wish to use your module there are three basic ways for them to load your module and import its symbols:

```
use ModuleName;
```

This imports all the symbols from ModuleName's @EXPORT into the namespace of the use statement.

```
use ModuleName ();
```

This causes perl to load your module but does not import any symbols.

```
use ModuleName qw(...);
```

This imports only the symbols listed by the caller into their namespace. All listed symbols must be in your @EXPORT or @EXPORT_OK, else an error occurs. The advanced export features of Exporter are accessed like this, but with list entries that are syntactically distinct from symbol names.

Unless you want to use its advanced features, this is probably all you need to know to use Exporter.

Advanced features

Specialised Import Lists

If the first entry in an import list begins with !, : or / then the list is treated as a series of specifications which either add to or delete from the list of names to import. They are processed left to right. Specifications are in the form:

[!]name	This name only
[!]:DEFAULT	All names in @EXPORT
[!]:tag	All names in \$EXPORT_TAGS{tag} anonymous list
[!]/pattern/	All names in @EXPORT and @EXPORT_OK which match

A leading ! indicates that matching names should be deleted from the list of names to import. If the first specification is a deletion it is treated as though preceded by :DEFAULT. If you just want to import extra names in addition to the default set you will still need to include :DEFAULT explicitly.

e.g., Module.pm defines:

```
@EXPORT      = qw(A1 A2 A3 A4 A5);
@EXPORT_OK   = qw(B1 B2 B3 B4 B5);
%EXPORT_TAGS = (T1 => [qw(A1 A2 B1 B2)], T2 => [qw(A1 A2 B3 B4)]);
```

Note that you cannot use tags in @EXPORT or @EXPORT_OK.

Names in EXPORT_TAGS must also appear in @EXPORT or @EXPORT_OK.

An application using Module can say something like:

```
use Module qw(:DEFAULT :T2 !B3 A3);
```

Other examples include:

```
use Socket qw(!/^ [AP] F_ / !SOMAXCONN !SOL_SOCKET);
use POSIX  qw(:errno_h :termios_h !TCSADRAIN !/^EXIT/);
```

Remember that most patterns (using //) will need to be anchored with a leading ^, e.g., /^EXIT/ rather than /EXIT/.

You can say BEGIN { \$Exporter::Verbose=1 } to see how the specifications are being processed and what is actually being imported into modules.

Exporting without using Exporter's import method

Exporter has a special method, 'export_to_level' which is used in situations where you can't directly call Exporter's import method. The export_to_level method looks like:

```
MyPackage->export_to_level($where_to_export, $package, @what_to_export);
```

where \$where_to_export is an integer telling how far up the calling stack to export your symbols, and @what_to_export is an array telling what symbols *to* export (usually this is @_). The \$package argument is currently unused.

For example, suppose that you have a module, A, which already has an import function:

```
package A;

@ISA = qw(Exporter);
@EXPORT_OK = qw ($b);

sub import
{
    $A::b = 1;      # not a very useful import method
}
```

and you want to Export symbol \$A::b back to the module that called package A. Since Exporter relies on the import method to work, via inheritance, as it stands Exporter::import() will never get called. Instead, say the following:

```
package A;
@ISA = qw(Exporter);
@EXPORT_OK = qw ($b);

sub import
{
    $A::b = 1;
    A->export_to_level(1, @_);
}
```

This will export the symbols one level 'above' the current package – ie: to the program or module that used package A.

Note: Be careful not to modify '@_' at all before you call export_to_level – or people using your package will get very unexplained results!

Module Version Checking

The Exporter module will convert an attempt to import a number from a module into a call to \$module_name->require_version(\$value). This can be used to validate that the version of the module being used is greater than or equal to the required version.

The Exporter module supplies a default require_version method which checks the value of \$VERSION in the exporting module.

Since the default require_version method treats the \$VERSION number as a simple numeric value it will regard version 1.10 as lower than 1.9. For this reason it is strongly recommended that you use numbers with at least two decimal places, e.g., 1.09.

Managing Unknown Symbols

In some situations you may want to prevent certain symbols from being exported. Typically this applies to extensions which have functions or constants that may not exist on some systems.

The names of any symbols that cannot be exported should be listed in the @EXPORT_FAIL array.

If a module attempts to import any of these symbols the Exporter will give the module an opportunity to handle the situation before generating an error. The Exporter will call an export_fail method with a list of the

failed symbols:

```
@failed_symbols = $module_name->export_fail(@failed_symbols);
```

If the `export_fail` method returns an empty list then no error is recorded and all the requested symbols are exported. If the returned list is not empty then an error is generated for each symbol and the export fails. The Exporter provides a default `export_fail` method which simply returns the list unchanged.

Uses for the `export_fail` method include giving better error messages for some symbols and performing lazy architectural checks (put more symbols into `@EXPORT_FAIL` by default and then take them out if someone actually tries to use them and an expensive check shows that they are usable on that platform).

Tag Handling Utility Functions

Since the symbols listed within `%EXPORT_TAGS` must also appear in either `@EXPORT` or `@EXPORT_OK`, two utility functions are provided which allow you to easily add tagged sets of symbols to `@EXPORT` or `@EXPORT_OK`:

```
%EXPORT_TAGS = (foo => [qw(aa bb cc)], bar => [qw(aa cc dd)]);

Exporter::export_tags('foo');      # add aa, bb and cc to @EXPORT
Exporter::export_ok_tags('bar');    # add aa, cc and dd to @EXPORT_OK
```

Any names which are not tags are added to `@EXPORT` or `@EXPORT_OK` unchanged but will trigger a warning (with `-w`) to avoid misspelt tags names being silently added to `@EXPORT` or `@EXPORT_OK`. Future versions may make this a fatal error.

Generating combined tags

If several symbol categories exist in `%EXPORT_TAGS`, it's usually useful to create the utility `":all"` to simplify `"use"` statements.

The simplest way to do this is:

```
%EXPORT_TAGS = (foo => [qw(aa bb cc)], bar => [qw(aa cc dd)]);

# add all the other ":class" tags to the ":all" class,
# deleting duplicates
{
    my %seen;

    push @{$EXPORT_TAGS{all}},
        grep {!$seen{$_}++} @{$EXPORT_TAGS{$_}} foreach keys %EXPORT_TAGS;
}
```

`CGI.pm` creates an `":all"` tag which contains some (but not really all) of its categories. That could be done with one small change:

```
# add some of the other ":class" tags to the ":all" class,
# deleting duplicates
{
    my %seen;

    push @{$EXPORT_TAGS{all}},
        grep {!$seen{$_}++} @{$EXPORT_TAGS{$_}}
            foreach qw/html2 html3 netscape form cgi internal/;
}
```

Note that the tag names in `%EXPORT_TAGS` don't have the leading `':'`.

AUTOLOADED Constants

Many modules make use of `AUTOLOADING` for constant subroutines to avoid having to compile and waste memory on rarely used values (see [perlsyn](#) for details on constant subroutines). Calls to such constant subroutines are not optimized away at compile time because they can't be checked at compile time for

constancy.

Even if a prototype is available at compile time, the body of the subroutine is not (it hasn't been AUTOLOADED yet). perl needs to examine both the () prototype and the body of a subroutine at compile time to detect that it can safely replace calls to that subroutine with the constant value.

A workaround for this is to call the constants once in a BEGIN block:

```
package My ;  
use Socket ;  
  
foo( SO_LINGER );      ## SO_LINGER NOT optimized away; called at runtime  
BEGIN { SO_LINGER }  
foo( SO_LINGER );      ## SO_LINGER optimized away at compile time.
```

This forces the AUTOLOAD for SO_LINGER to take place before SO_LINGER is encountered later in My package.

If you are writing a package that AUTOLOADs, consider forcing an AUTOLOAD for any constants explicitly imported by other packages or which are usually used when your package is used.

NAME

Exporter::Heavy – Exporter guts

SYNOPSIS

(internal use only)

DESCRIPTION

No user-serviceable parts inside.

NAME

ExtUtils::Command – utilities to replace common UNIX commands in Makefiles etc.

SYNOPSIS

```
perl -MExtUtils::Command -e cat files... > destination
perl -MExtUtils::Command -e mv source... destination
perl -MExtUtils::Command -e cp source... destination
perl -MExtUtils::Command -e touch files...
perl -MExtUtils::Command -e rm_f file...
perl -MExtUtils::Command -e rm_rf directories...
perl -MExtUtils::Command -e mkpath directories...
perl -MExtUtils::Command -e eqtime source destination
perl -MExtUtils::Command -e chmod mode files...
perl -MExtUtils::Command -e test_f file
```

DESCRIPTION

The module is used to replace common UNIX commands. In all cases the functions work from @ARGV rather than taking arguments. This makes them easier to deal with in Makefiles.

```
perl -MExtUtils::Command -e some_command some files to work on
```

NOT

```
perl -MExtUtils::Command -e 'some_command qw(some files to work on)'
```

Filenames with * and ? will be glob expanded.

cat Concatenates all files mentioned on command line to STDOUT.

eqtime src dst

Sets modified time of dst to that of src

rm_rf files....

Removes directories – recursively (even if readonly)

rm_f files....

Removes files (even if readonly)

touch files ...

Makes files exist, with current timestamp

mv source... destination

Moves source to destination. Multiple sources are allowed if destination is an existing directory.

cp source... destination

Copies source to destination. Multiple sources are allowed if destination is an existing directory.

chmod mode files...

Sets UNIX like permissions ‘mode’ on all the files.

mkpath directory...

Creates directory, including any parent directories.

test_f file

Tests if a file exists

BUGS

Should probably be Auto/Self loaded.

SEE ALSO

ExtUtils::MakeMaker, ExtUtils::MM_Unix, ExtUtils::MM_Win32

AUTHOR

Nick Ing-Simmons <*nick@ni-s.u-net.com*>.

NAME

ExtUtils::Command::MM – Commands for the MM's to use in Makefiles

SYNOPSIS

```
perl -MExtUtils::Command::MM -e "function" files...
```

DESCRIPTION

FOR INTERNAL USE ONLY! The interface is not stable.

ExtUtils::Command::MM encapsulates code which would otherwise have to be done with large "one" liners.

They all read their input from @ARGV unless otherwise noted.

Any \$(FOO) used in the examples are make variables, not Perl.

test_harness

```
test_harness($verbose, @test_libs);
```

Runs the tests on @ARGV via Test::Harness passing through the \$verbose flag. Any @test_libs will be unshifted onto the test's @INC.

@test_libs are run in alphabetical order.

NAME

ExtUtils::Constant – generate XS code to import C header constants

SYNOPSIS

```
use ExtUtils::Constant qw (WriteConstants);
WriteConstants(
    NAME => 'Foo',
    NAMES => [qw(FOO BAR BAZ)],
);
# Generates wrapper code to make the values of the constants FOO BAR BAZ
# available to perl
```

DESCRIPTION

ExtUtils::Constant facilitates generating C and XS wrapper code to allow perl modules to AUTOLOAD constants defined in C library header files. It is principally used by the h2xs utility, on which this code is based. It doesn't contain the routines to scan header files to extract these constants.

USAGE

Generally one only needs to call the WriteConstants function, and then

```
#include "const-c.inc"
```

in the C section of Foo.xs

```
INCLUDE const-xs.inc
```

in the XS section of Foo.xs.

For greater flexibility use constant_types(), C_constant and XS_constant, with which WriteConstants is implemented.

Currently this module understands the following types. h2xs may only know a subset. The sizes of the numeric types are chosen by the Configure script at compile time.

IV signed integer, at least 32 bits.

UV unsigned integer, the same size as IV

NV floating point type, probably double, possibly long double

PV NUL terminated string, length will be determined with strlen

PVN

A fixed length thing, given as a [pointer, length] pair. If you know the length of a string at compile time you may use this instead of PV

SV A mortal SV.

YES

Truth. (PL_sv_yes) The value is not needed (and ignored).

NO Defined Falsehood. (PL_sv_no) The value is not needed (and ignored).

UNDEF

undef. The value of the macro is not needed.

FUNCTIONS

C_stringify NAME

A function which returns a 7 bit ASCII correctly \ escaped version of the string passed suitable for C's "" or ". It will die if passed Unicode characters.

perl_stringify NAME

A function which returns a 7 bit ASCII correctly \ escaped version of the string passed suitable for a perl "" string.

constant_types

A function returning a single scalar with #define definitions for the constants used internally between the generated C and XS functions.

memEQ_clause NAME, CHECKED_AT, INDENT

A function to return a suitable C if statement to check whether *NAME* is equal to the C variable name. If *CHECKED_AT* is defined, then it is used to avoid memEQ for short names, or to generate a comment to highlight the position of the character in the switch statement.

assign INDENT, TYPE, PRE, POST, VALUE...

A function to return a suitable assignment clause. If *TYPE* is aggregate (eg *PVN* expects both pointer and length) then there should be multiple *VALUES* for the components. *PRE* and *POST* if defined give snippets of C code to proceed and follow the assignment. *PRE* will be at the start of a block, so variables may be defined in it.

return_clause

return_clause ITEM, INDENT

A function to return a suitable #ifdef clause. *ITEM* is a hashref (as passed to C_constant and match_clause. *INDENT* is the number of spaces to indent, defaulting to 6.

XXX document me

switch_clause INDENT, NAMELEN, ITEMHASH, ITEM...

An internal function to generate a suitable switch clause, called by C_constant *ITEMs* are in the hash ref format as given in the description of C_constant, and must all have the names of the same length, given by *NAMELEN* (This is not checked). *ITEMHASH* is a reference to a hash, keyed by name, values being the hashrefs in the *ITEM* list. (No parameters are modified, and there can be keys in the *ITEMHASH* that are not in the list of *ITEMs* without causing problems).

params WHAT

An internal function. *WHAT* should be a hashref of types the constant function will return. *params* returns a hashref keyed IV NV PV SV to show which combination of pointers will be needed in the C argument list.

dump_names

dump_names DEFAULT_TYPE, TYPES, INDENT, OPTIONS, ITEM...

An internal function to generate the embedded perl code that will regenerate the constant subroutines. *DEFAULT_TYPE*, *TYPES* and *ITEMs* are the same as for C_constant. *INDENT* is treated as number of spaces to indent by. *OPTIONS* is a hashref of options. Currently only declare_types is recognised. If the value is true a \$types is always declared in the perl code generated, if defined and false never declared, and if undefined \$types is only declared if the values in *TYPES* as passed in cannot be inferred from *DEFAULT_TYPES* and the *ITEMs*.

dogfood

dogfood PACKAGE, SUBNAME, DEFAULT_TYPE, TYPES, INDENT, BREAKOUT, ITEM...

An internal function to generate the embedded perl code that will regenerate the constant subroutines. Parameters are the same as for C_constant.

C_constant

C_constant PACKAGE, SUBNAME, DEFAULT_TYPE, TYPES, INDENT, BREAKOUT, ITEM...

A function that returns a **list** of C subroutine definitions that return the value and type of constants

when passed the name by the XS wrapper. *ITEM...* gives a list of constant names. Each can either be a string, which is taken as a C macro name, or a reference to a hash with the following keys

name	The name of the constant, as seen by the perl code.
type	The type of the constant (<i>IV</i> , <i>NV</i> etc)
value	A C expression for the value of the constant, or a list of C expressions if the type is aggregate. This defaults to the <i>name</i> if not given.
macro	The C pre-processor macro to use in the <code>#ifdef</code> . This defaults to the <i>name</i> , and is mainly used if <i>value</i> is an enum. If a reference an array is passed then the first element is used in place of the <code>#ifdef</code> line, and the second element in place of the <code>#endif</code> . This allows pre-processor constructions such as

```
#if defined (foo)
#if !defined (bar)
...
#endif
#endif
```

to be used to determine if a constant is to be defined.

A "macro" 1 signals that the constant is always defined, so the `#if/#endif` test is omitted.

default	Default value to use (instead of croaking with "your vendor has not defined...") to return if the macro isn't defined. Specify a reference to an array with type followed by value(s).
pre	C code to use before the assignment of the value of the constant. This allows you to use temporary variables to extract a value from part of a <code>struct</code> and return this as <i>value</i> . This C code is places at the start of a block, so you can declare variables in it.
post	C code to place between the assignment of value (to a temporary) and the return from the function. This allows you to clear up anything in <i>pre</i> . Rarely needed.
def_pre	
def_post	Equivalents of <i>pre</i> and <i>post</i> for the default value.

utf8 Generated internally. Is zero or undefined if name is 7 bit ASCII, "no" if the name is 8 bit (and so should only match if `SvUTF8()` is false), "yes" if the name is utf8 encoded.

The internals automatically clone any name with characters 128–255 but none 256+ (ie one that could be either in bytes or utf8) into a second entry which is utf8 encoded.

PACKAGE is the name of the package, and is only used in comments inside the generated C code.

The next 5 arguments can safely be given as `undef`, and are mainly used for recursion. *SUBNAME* defaults to `constant` if undefined.

DEFAULT_TYPE is the type returned by *ITEMs* that don't specify their type. In turn it defaults to *IV*. *TYPES* should be given either as a comma separated list of types that the C subroutine `constant` will generate or as a reference to a hash. *DEFAULT_TYPE* will be added to the list if not present, as will any types given in the list of *ITEMs*. The resultant list should be the same list of types that `XS_constant` is given. [Otherwise `XS_constant` and `C_constant` may differ in the number of parameters to the constant function. *INDENT* is currently unused and ignored. In future it may be used to pass in information used to change the C indentation style used.] The best way to maintain consistency is to pass in a hash reference and let this function update it.

BREAKOUT governs when child functions of *SUBNAME* are generated. If there are *BREAKOUT* or more *ITEMs* with the same length of name, then the code to switch between them is placed into a function named *SUBNAME_LEN*, for example `constant_5` for names 5 characters long. The default *BREAKOUT* is 3. A single *ITEM* is always inlined.

XS_constant PACKAGE, TYPES, SUBNAME, C_SUBNAME

A function to generate the XS code to implement the perl subroutine *PACKAGE::constant* used by *PACKAGE::AUTOLOAD* to load constants. This XS code is a wrapper around a C subroutine usually generated by *C_constant*, and usually named *constant*.

TYPES should be given either as a comma separated list of types that the C subroutine *constant* will generate or as a reference to a hash. It should be the same list of types as *C_constant* was given. [Otherwise *XS_constant* and *C_constant* may have different ideas about the number of parameters passed to the C function *constant*]

You can call the perl visible subroutine something other than *constant* if you give the parameter *SUBNAME*. The C subroutine it calls defaults to the name of the perl visible subroutine, unless you give the parameter *C_SUBNAME*.

autoload PACKAGE, VERSION, AUTOLOADER

A function to generate the AUTOLOAD subroutine for the module *PACKAGE VERSION* is the perl version the code should be backwards compatible with. It defaults to the version of perl running the subroutine. If *AUTOLOADER* is true, the AUTOLOAD subroutine falls back on *AutoLoader::AUTOLOAD* for all names that the *constant()* routine doesn't recognise.

WriteMakefileSnippet

WriteMakefileSnippet ATTRIBUTE => VALUE [, ...]

A function to generate perl code for *Makefile.PL* that will regenerate the constant subroutines. Parameters are named as passed to *WriteConstants*, with the addition of *INDENT* to specify the number of leading spaces (default 2).

Currently only *INDENT*, *NAME*, *DEFAULT_TYPE*, *NAMES*, *C_FILE* and *XS_FILE* are recognised.

WriteConstants ATTRIBUTE => VALUE [, ...]

Writes a file of C code and a file of XS code which you should *#include* and *INCLUDE* in the C and XS sections respectively of your module's XS code. You probably want to do this in your *Makefile.PL*, so that you can easily edit the list of constants without touching the rest of your module. The attributes supported are

NAME

Name of the module. This must be specified

DEFAULT_TYPE

The default type for the constants. If not specified IV is assumed.

BREAKOUT_AT

The names of the constants are grouped by length. Generate child subroutines for each group with this number or more names in.

NAMES

An array of constants' names, either scalars containing names, or hashrefs as detailed in *"C_constant"*.

C_FILE

The name of the file to write containing the C code. The default is *const-c.inc*. The *-* in the name ensures that the file can't be mistaken for anything related to a legitimate perl package name, and not naming the file *.c* avoids having to override *Makefile.PL*'s *.xs* to *.c* rules.

XS_FILE

The name of the file to write containing the XS code. The default is *const-xs.inc*.

SUBNAME

The perl visible name of the XS subroutine generated which will return the constants. The default is `constant`.

C_SUBNAME

The name of the C subroutine generated which will return the constants. The default is *SUBNAME*. Child subroutines have `_` and the name length appended, so constants with 10 character names would be in `constant_10` with the default *XS_SUBNAME*.

NAME

ExtUtils::Embed – Utilities for embedding Perl in C/C++ applications

SYNOPSIS

```
perl -MExtUtils::Embed -e xsinit
perl -MExtUtils::Embed -e ccopts
perl -MExtUtils::Embed -e ldopts
```

DESCRIPTION

ExtUtils::Embed provides utility functions for embedding a Perl interpreter and extensions in your C/C++ applications. Typically, an application **Makefile** will invoke ExtUtils::Embed functions while building your application.

@EXPORT

ExtUtils::Embed exports the following functions:

```
xsinit(), ldopts(), ccopts(), perl_inc(), ccflags(), ccdlflags(), xsi_header(),
xsi_protos(), xsi_body()
```

FUNCTIONS

`xsinit()`

Generate C/C++ code for the XS initializer function.

When invoked as ``perl -MExtUtils::Embed -e xsinit -`` the following options are recognized:

`-o <output filename>` (Defaults to **perlxsi.c**)

`-o STDOUT` will print to STDOUT.

`-std` (Write code for extensions that are linked with the current Perl.)

Any additional arguments are expected to be names of modules to generate code for.

When invoked with parameters the following are accepted and optional:

```
xsinit($filename, $std, [@modules])
```

Where,

\$filename is equivalent to the `-o` option.

\$std is boolean, equivalent to the `-std` option.

[@modules] is an array ref, same as additional arguments mentioned above.

Examples

```
perl -MExtUtils::Embed -e xsinit -- -o xsinit.c Socket
```

This will generate code with an **xs_init** function that glues the perl **Socket::bootstrap** function to the C **boot_Socket** function and writes it to a file named **xsinit.c**.

Note that **DynaLoader** is a special case where it must call **boot_DynaLoader** directly.

```
perl -MExtUtils::Embed -e xsinit
```

This will generate code for linking with **DynaLoader** and each static extension found in **\$Config{static_ext}**. The code is written to the default file name **perlxsi.c**.

```
perl -MExtUtils::Embed -e xsinit -- -o xsinit.c -std DBI DBD::Oracle
```

Here, code is written for all the currently linked extensions along with code for **DBI** and **DBD::Oracle**.

If you have a working **DynaLoader** then there is rarely any need to statically link in any other extensions.

`ldopts()`

Output arguments for linking the Perl library and extensions to your application.

When invoked as `'perl -MExtUtils::Embed -e ldopts -'` the following options are recognized:

-std

Output arguments for linking the Perl library and any extensions linked with the current Perl.

-I <path1:path2>

Search path for ModuleName.a archives. Default path is **@INC**. Library archives are expected to be found as `/some/path/auto/ModuleName/ModuleName.a`. For example, when looking for **Socket.a** relative to a search path, we should find `auto/Socket/Socket.a`.

When looking for **DBD::Oracle** relative to a search path, we should find `auto/DBD/Oracle/Oracle.a`.

Keep in mind that you can always supply `/my/own/path/ModuleName.a` as an additional linker argument.

— <list of linker args>

Additional linker arguments to be considered.

Any additional arguments found before the — token are expected to be names of modules to generate code for.

When invoked with parameters the following are accepted and optional:

`ldopts($std, [@modules], [@link_args], $path)`

Where:

\$std is boolean, equivalent to the **-std** option.

[@modules] is equivalent to additional arguments found before the — token.

[@link_args] is equivalent to arguments found after the — token.

\$path is equivalent to the **-I** option.

In addition, when `ldopts` is called with parameters, it will return the argument string rather than print it to STDOUT.

Examples

```
perl -MExtUtils::Embed -e ldopts
```

This will print arguments for linking with **libperl.a**, **DynaLoader** and extensions found in `$Config{static_ext}`. This includes libraries found in `$Config{libs}` and the first ModuleName.a library for each extension that is found by searching **@INC** or the path specified by the **-I** option. In addition, when ModuleName.a is found, additional linker arguments are picked up from the `extralibs.ld` file in the same directory.

```
perl -MExtUtils::Embed -e ldopts -- -std Socket
```

This will do the same as the above example, along with printing additional arguments for linking with the **Socket** extension.

```
perl -MExtUtils::Embed -e ldopts -- DynaLoader
```

This will print arguments for linking with just the **DynaLoader** extension and **libperl.a**.

```
perl -MExtUtils::Embed -e ldopts -- -std Mysql -- -L/usr/mysql/lib -lmysql
```

Any arguments after the second ‘—’ token are additional linker arguments that will be examined for potential conflict. If there is no conflict, the additional arguments will be part of the output.

`perl_inc()`

For including perl header files this function simply prints:

```
-I$Config{archlibexp}/CORE
```

So, rather than having to say:

```
perl -MConfig -e 'print "-I$Config{archlibexp}/CORE"'
```

Just say:

```
perl -MExtUtils::Embed -e perl_inc
```

`ccflags()`, `ccdlflags()`

These functions simply print `$Config{ccflags}` and `$Config{ccdlflags}`

`ccopts()`

This function combines `perl_inc()`, `ccflags()` and `ccdlflags()` into one.

`xsi_header()`

This function simply returns a string defining the same **EXTERN_C** macro as **perlmain.c** along with #including **perl.h** and **EXTERN.h**.

`xsi_protos(@modules)`

This function returns a string of **boot_**`$ModuleName` prototypes for each @modules.

`xsi_body(@modules)`

This function returns a string of calls to **newXS()** that glue the module **bootstrap** function to **boot_**`ModuleName` for each @modules.

xsinit() uses the `xsi_*` functions to generate most of its code.

EXAMPLES

For examples on how to use **ExtUtils::Embed** for building C/C++ applications with embedded perl, see [perlembed](#).

NAME

ExtUtils::Install – install files from here to there

SYNOPSIS

```
use ExtUtils::Install;

install($hashref, $verbose, $nonono) ;

uninstall($packlistfile, $verbose, $nonono) ;

pm_to_blib($hashref) ;
```

DESCRIPTION

Both `install()` and `uninstall()` are specific to the way ExtUtils::MakeMaker handles the installation and deinstallation of perl modules. They are not designed as general purpose tools.

`install()` takes three arguments. A reference to a hash, a verbose switch and a don't-really-do-it switch. The hash ref contains a mapping of directories: each key/value pair is a combination of directories to be copied. Key is a directory to copy from, value is a directory to copy to. The whole tree below the "from" directory will be copied preserving timestamps and permissions.

There are two keys with a special meaning in the hash: "read" and "write". After the copying is done, `install` will write the list of target files to the file named by `$hashref->{write}`. If there is another file named by `$hashref->{read}`, the contents of this file will be merged into the written file. The read and the written file may be identical, but on AFS it is quite likely that people are installing to a different directory than the one where the files later appear.

`install_default()` takes one or less arguments. If no arguments are specified, it takes `$ARGV[0]` as if it was specified as an argument. The argument is the value of MakeMaker's FULLEXT key, like *Tk/Canvas*. This function calls `install()` with the same arguments as the defaults the MakeMaker would use.

The argument-less form is convenient for install scripts like

```
perl -MExtUtils::Install -e install_default Tk/Canvas
```

Assuming this command is executed in a directory with a populated *blib* directory, it will proceed as if the *blib* was build by MakeMaker on this machine. This is useful for binary distributions.

`uninstall()` takes as first argument a file containing filenames to be unlinked. The second argument is a verbose switch, the third is a no-don't-really-do-it-now switch.

`pm_to_blib()` takes a hashref as the first argument and copies all keys of the hash to the corresponding values efficiently. Filenames with the extension pm are autosplit. Second argument is the autosplit directory. If third argument is not empty, it is taken as a filter command to be ran on each .pm file, the output of the command being what is finally copied, and the source for auto-splitting.

You can have an environment variable PERL_INSTALL_ROOT set which will be prepended as a directory to each installed file (and directory).

NAME

ExtUtils::Installed – Inventory management of installed modules

SYNOPSIS

```
use ExtUtils::Installed;
my ($inst) = ExtUtils::Installed->new();
my (@modules) = $inst->modules();
my (@missing) = $inst->validate("DBI");
my $all_files = $inst->files("DBI");
my $files_below_usr_local = $inst->files("DBI", "all", "/usr/local");
my $all_dirs = $inst->directories("DBI");
my $dirs_below_usr_local = $inst->directory_tree("DBI", "prog");
my $packlist = $inst->packlist("DBI");
```

DESCRIPTION

ExtUtils::Installed provides a standard way to find out what core and module files have been installed. It uses the information stored in .packlist files created during installation to provide this information. In addition it provides facilities to classify the installed files and to extract directory information from the .packlist files.

USAGE

The new() function searches for all the installed .packlists on the system, and stores their contents. The .packlists can be queried with the functions described below.

FUNCTIONS

new()

This takes no parameters, and searches for all the installed .packlists on the system. The packlists are read using the ExtUtils::packlist module.

modules()

This returns a list of the names of all the installed modules. The perl 'core' is given the special name 'Perl'.

files()

This takes one mandatory parameter, the name of a module. It returns a list of all the filenames from the package. To obtain a list of core perl files, use the module name 'Perl'. Additional parameters are allowed. The first is one of the strings "prog", "doc" or "all", to select either just program files, just manual files or all files. The remaining parameters are a list of directories. The filenames returned will be restricted to those under the specified directories.

directories()

This takes one mandatory parameter, the name of a module. It returns a list of all the directories from the package. Additional parameters are allowed. The first is one of the strings "prog", "doc" or "all", to select either just program directories, just manual directories or all directories. The remaining parameters are a list of directories. The directories returned will be restricted to those under the specified directories. This method returns only the leaf directories that contain files from the specified module.

directory_tree()

This is identical in operation to directories(), except that it includes all the intermediate directories back up to the specified directories.

validate()

This takes one mandatory parameter, the name of a module. It checks that all the files listed in the modules .packlist actually exist, and returns a list of any missing files. If an optional second argument which evaluates to true is given any missing files will be removed from the .packlist

packlist()

This returns the ExtUtils::Packlist object for the specified module.

version()

This returns the version number for the specified module.

EXAMPLE

See the example in [ExtUtils::Packlist](#).

AUTHOR

Alan Burlison <Alan.Burlison@uk.sun.com>

NAME

ExtUtils::Liblist – determine libraries to use and how to use them

SYNOPSIS

```
require ExtUtils::Liblist;

ExtUtils::Liblist::ext($self, $potential_libs, $verbose, $need_names);
```

DESCRIPTION

This utility takes a list of libraries in the form `-llib1 -llib2 -llib3` and returns lines suitable for inclusion in an extension Makefile. Extra library paths may be included with the form `-L/another/path` this will affect the searches for all subsequent libraries.

It returns an array of four or five scalar values: `EXTRALIBS`, `BSLOADLIBS`, `LDLOADLIBS`, `LD_RUN_PATH`, and, optionally, a reference to the array of the filenames of actual libraries. Some of these don't mean anything unless on Unix. See the details about those platform specifics below. The list of the filenames is returned only if `$need_names` argument is true.

Dependent libraries can be linked in one of three ways:

- For static extensions
by the `ld` command when the perl binary is linked with the extension library. See `EXTRALIBS` below.
- For dynamic extensions at build/link time
by the `ld` command when the shared object is built/linked. See `LDLOADLIBS` below.
- For dynamic extensions at load time
by the DynaLoader when the shared object is loaded. See `BSLOADLIBS` below.

EXTRALIBS

List of libraries that need to be linked with when linking a perl binary which includes this extension. Only those libraries that actually exist are included. These are written to a file and used when linking perl.

LDLOADLIBS and LD_RUN_PATH

List of those libraries which can or must be linked into the shared library when created using `ld`. These may be static or dynamic libraries. `LD_RUN_PATH` is a colon separated list of the directories in `LDLOADLIBS`. It is passed as an environment variable to the process that links the shared library.

BSLOADLIBS

List of those libraries that are needed but can be linked in dynamically at run time on this platform. SunOS/Solaris does not need this because `ld` records the information (from `LDLOADLIBS`) into the object file. This list is used to create a `.bs` (bootstrap) file.

PORTABILITY

This module deals with a lot of system dependencies and has quite a few architecture specific `ifs` in the code.

VMS implementation

The version of `ext()` which is executed under VMS differs from the Unix-OS/2 version in several respects:

- Input library and path specifications are accepted with or without the `-l` and `-L` prefixes used by Unix linkers. If neither prefix is present, a token is considered a directory to search if it is in fact a directory, and a library to search for otherwise. Authors who wish their extensions to be portable to Unix or OS/2 should use the Unix prefixes, since the Unix-OS/2 version of `ext()` requires them.
- Wherever possible, shareable images are preferred to object libraries, and object libraries to plain object files. In accordance with VMS naming conventions, `ext()` looks for files named `libshr` and `librtl`; it also looks for `liblib` and `liblib` to accommodate Unix conventions used in some ported software.

- For each library that is found, an appropriate directive for a linker options file is generated. The return values are space-separated strings of these directives, rather than elements used on the linker command line.
- LDLOADLIBS contains both the libraries found based on `$potential_libs` and the CRTs, if any, specified in `Config.pm`. EXTRALIBS contains just those libraries found based on `$potential_libs`. BSLOADLIBS and LD_RUN_PATH are always empty.

In addition, an attempt is made to recognize several common Unix library names, and filter them out or convert them to their VMS equivalents, as appropriate.

In general, the VMS version of `ext()` should properly handle input from extensions originally designed for a Unix or VMS environment. If you encounter problems, or discover cases where the search could be improved, please let us know.

Win32 implementation

The version of `ext()` which is executed under Win32 differs from the Unix-OS/2 version in several respects:

- If `$potential_libs` is empty, the return value will be empty. Otherwise, the libraries specified by `$Config{perllibs}` (see `Config.pm`) will be appended to the list of `$potential_libs`. The libraries will be searched for in the directories specified in `$potential_libs`, `$Config{libpth}`, and in `$Config{installarchlib}/CORE`. For each library that is found, a space-separated list of fully qualified library pathnames is generated.
- Input library and path specifications are accepted with or without the `-l` and `-L` prefixes used by Unix linkers.

An entry of the form `-La:\foo` specifies the `a:\foo` directory to look for the libraries that follow.

An entry of the form `-lfoo` specifies the library `foo`, which may be spelled differently depending on what kind of compiler you are using. If you are using GCC, it gets translated to `libfoo.a`, but for other win32 compilers, it becomes `foo.lib`. If no files are found by those translated names, one more attempt is made to find them using either `foo.a` or `libfoo.lib`, depending on whether GCC or some other win32 compiler is being used, respectively.

If neither the `-L` or `-l` prefix is present in an entry, the entry is considered a directory to search if it is in fact a directory, and a library to search for otherwise. The `$Config{lib_ext}` suffix will be appended to any entries that are not directories and don't already have the suffix.

Note that the `-L` and `-l` prefixes are **not required**, but authors who wish their extensions to be portable to Unix or OS/2 should use the prefixes, since the Unix-OS/2 version of `ext()` requires them.

- Entries cannot be plain object files, as many Win32 compilers will not handle object files in the place of libraries.
- Entries in `$potential_libs` beginning with a colon and followed by alphanumeric characters are treated as flags. Unknown flags will be ignored.

An entry that matches `/:nodefault/i` disables the appending of default libraries found in `$Config{perllibs}` (this should be only needed very rarely).

An entry that matches `/:nosearch/i` disables all searching for the libraries specified after it. Translation of `-Lfoo` and `-lfoo` still happens as appropriate (depending on compiler being used, as reflected by `$Config{cc}`), but the entries are not verified to be valid files or directories.

An entry that matches `/:search/i` reenables searching for the libraries specified after it. You can put it at the end to enable searching for default libraries specified by `$Config{perllibs}`.

- The libraries specified may be a mixture of static libraries and import libraries (to link with DLLs). Since both kinds are used pretty transparently on the Win32 platform, we do not attempt to distinguish between them.

- LDLOADLIBS and EXTRALIBS are always identical under Win32, and BSLOADLIBS and LD_RUN_PATH are always empty (this may change in future).
- You must make sure that any paths and path components are properly surrounded with double-quotes if they contain spaces. For example, `$potential_libs` could be (literally):

```
"-Lc:\Program Files\vc\lib" msvcrt.lib "la test\foo bar.lib"
```

Note how the first and last entries are protected by quotes in order to protect the spaces.

- Since this module is most often used only indirectly from extension `Makefile.PL` files, here is an example `Makefile.PL` entry to add a library to the build process for an extension:

```
LIBS => ['-lg1']
```

When using GCC, that entry specifies that MakeMaker should first look for `libg1.a` (followed by `g1.a`) in all the locations specified by `$Config{libpth}`.

When using a compiler other than GCC, the above entry will search for `g1.lib` (followed by `libg1.lib`).

If the library happens to be in a location not in `$Config{libpth}`, you need:

```
LIBS => ['-Lc:\gllibs -lg1']
```

Here is a less often used example:

```
LIBS => ['-lg1', ':nosearch -Ld:\mesalibs -lmesa -luser32']
```

This specifies a search for library `g1` as before. If that search fails to find the library, it looks at the next item in the list. The `:nosearch` flag will prevent searching for the libraries that follow, so it simply returns the value as `-Ld:\mesalibs -lmesa -luser32`, since GCC can use that value as is with its linker.

When using the Visual C compiler, the second item is returned as `-libpath:d:\mesalibs mesa.lib user32.lib`.

When using the Borland compiler, the second item is returned as `-Ld:\mesalibs mesa.lib user32.lib`, and MakeMaker takes care of moving the `-Ld:\mesalibs` to the correct place in the linker command line.

NAME

ExtUtils::MakeMaker – create an extension Makefile

SYNOPSIS

```
use ExtUtils::MakeMaker;

WriteMakefile( ATTRIBUTE => VALUE [, ...] );
```

DESCRIPTION

This utility is designed to write a Makefile for an extension module from a Makefile.PL. It is based on the Makefile.SH model provided by Andy Dougherty and the perl5-porters.

It splits the task of generating the Makefile into several subroutines that can be individually overridden. Each subroutine returns the text it wishes to have written to the Makefile.

MakeMaker is object oriented. Each directory below the current directory that contains a Makefile.PL is treated as a separate object. This makes it possible to write an unlimited number of Makefiles with a single invocation of `WriteMakefile()`.

How To Write A Makefile.PL

The short answer is: Don't.

```
Always begin with h2xs.
Always begin with h2xs!
ALWAYS BEGIN WITH H2XS!
```

even if you're not building around a header file, and even if you don't have an XS component.

Run `h2xs(1)` before you start thinking about writing a module. For so called pm-only modules that consist of *.pm files only, `h2xs` has the `-X` switch. This will generate dummy files of all kinds that are useful for the module developer.

The medium answer is:

```
use ExtUtils::MakeMaker;
WriteMakefile( NAME => "Foo::Bar" );
```

The long answer is the rest of the manpage :-)

Default Makefile Behaviour

The generated Makefile enables the user of the extension to invoke

```
perl Makefile.PL # optionally "perl Makefile.PL verbose"
make
make test        # optionally set TEST_VERBOSE=1
make install     # See below
```

The Makefile to be produced may be altered by adding arguments of the form `KEY=VALUE`. E.g.

```
perl Makefile.PL PREFIX=/tmp/myperl5
```

Other interesting targets in the generated Makefile are

```
make config      # to check if the Makefile is up-to-date
make clean       # delete local temp files (Makefile gets renamed)
make realclean   # delete derived files (including ./blib)
make ci          # check in all the files in the MANIFEST file
make dist        # see below the Distribution Support section
```

make test

MakeMaker checks for the existence of a file named *test.pl* in the current directory and if it exists it execute the script with the proper set of `perl -I` options.

MakeMaker also checks for any files matching `glob("t/*.t")`. It will execute all matching files in alphabetical order via the [Test::Harness](#) module with the `-I` switches set correctly.

If you'd like to see the raw output of your tests, set the `TEST_VERBOSE` variable to true.

```
make test TEST_VERBOSE=1
```

make testdb

A useful variation of the above is the target `testdb`. It runs the test under the Perl debugger (see [perldebug](#)). If the file *test.pl* exists in the current directory, it is used for the test.

If you want to debug some other testfile, set the `TEST_FILE` variable thusly:

```
make testdb TEST_FILE=t/mytest.t
```

By default the debugger is called using `-d` option to perl. If you want to specify some other option, set the `TESTDB_SW` variable:

```
make testdb TESTDB_SW=-Dx
```

make install

`make` alone puts all relevant files into directories that are named by the macros `INST_LIB`, `INST_ARCHLIB`, `INST_SCRIPT`, `INST_MAN1DIR` and `INST_MAN3DIR`. All these default to something below `./lib` if you are *not* building below the perl source directory. If you *are* building below the perl source, `INST_LIB` and `INST_ARCHLIB` default to `../lib`, and `INST_SCRIPT` is not defined.

The *install* target of the generated Makefile copies the files found below each of the `INST_*` directories to their `INSTALL*` counterparts. Which counterparts are chosen depends on the setting of `INSTALLDIRS` according to the following table:

		INSTALLDIRS set to	
		perl	site vendor
	PREFIX	SITEPREFIX	VENDORPREFIX
<code>INST_ARCHLIB</code>	<code>INSTALLARCHLIB</code>	<code>INSTALLSITEARCH</code>	<code>INSTALLVENDORARCH</code>
<code>INST_LIB</code>	<code>INSTALLPRIVLIB</code>	<code>INSTALLSITELIB</code>	<code>INSTALLVENDORLIB</code>
<code>INST_BIN</code>	<code>INSTALLBIN</code>	<code>INSTALLSITEBIN</code>	<code>INSTALLVENDORBIN</code>
<code>INST_SCRIPT</code>	<code>INSTALLSCRIPT</code>	<code>INSTALLSCRIPT</code>	<code>INSTALLSCRIPT</code>
<code>INST_MAN1DIR</code>	<code>INSTALLMAN1DIR</code>	<code>INSTALLSITEMAN1DIR</code>	<code>INSTALLVENDORMAN1DIR</code>
<code>INST_MAN3DIR</code>	<code>INSTALLMAN3DIR</code>	<code>INSTALLSITEMAN3DIR</code>	<code>INSTALLVENDORMAN3DIR</code>

The `INSTALL...` macros in turn default to their `%Config` (`$Config{installprivlib}`, `$Config{installarchlib}`, etc.) counterparts.

You can check the values of these variables on your system with

```
perl '-V:install.*'
```

And to check the sequence in which the library directories are searched by perl, run

```
perl -le 'print join $/, @INC'
```

PREFIX and LIB attribute

`PREFIX` and `LIB` can be used to set several `INSTALL*` attributes in one go. The quickest way to install a module in a non-standard place might be

```
perl Makefile.PL PREFIX=~
```

This will install all files in the module under your home directory, with man pages and libraries going into an appropriate place (usually `~/man` and `~/lib`).

Another way to specify many `INSTALL` directories with a single parameter is `LIB`.

```
perl Makefile.PL LIB=~lib
```

This will install the module's architecture-independent files into `~/lib`, the architecture-dependent files into `~/lib/$archname`.

Note, that in both cases the tilde expansion is done by MakeMaker, not by perl by default, nor by make.

Conflicts between parameters LIB, PREFIX and the various INSTALL* arguments are resolved so that:

- setting LIB overrides any setting of INSTALLPRIVLIB, INSTALLARCHLIB, INSTALLSITELIB, INSTALLSITEARCH (and they are not affected by PREFIX);
- without LIB, setting PREFIX replaces the initial `$Config{prefix}` part of those INSTALL* arguments, even if the latter are explicitly set (but are set to still start with `$Config{prefix}`).

If the user has superuser privileges, and is not working on AFS or relatives, then the defaults for INSTALLPRIVLIB, INSTALLARCHLIB, INSTALLSCRIPT, etc. will be appropriate, and this incantation will be the best:

```
perl Makefile.PL;
make;
make test
make install
```

make install per default writes some documentation of what has been done into the file `$(INSTALLARCHLIB)/perllocal.pod`. This feature can be bypassed by calling `make pure_install`.

AFS users

will have to specify the installation directories as these most probably have changed since perl itself has been installed. They will have to do this by calling

```
perl Makefile.PL INSTALLSITELIB=/afs/here/today \
    INSTALLSCRIPT=/afs/there/now INSTALLMAN3DIR=/afs/for/manpages
make
```

Be careful to repeat this procedure every time you recompile an extension, unless you are sure the AFS installation directories are still valid.

Static Linking of a new Perl Binary

An extension that is built with the above steps is ready to use on systems supporting dynamic loading. On systems that do not support dynamic loading, any newly created extension has to be linked together with the available resources. MakeMaker supports the linking process by creating appropriate targets in the Makefile whenever an extension is built. You can invoke the corresponding section of the makefile with

```
make perl
```

That produces a new perl binary in the current directory with all extensions linked in that can be found in INST_ARCHLIB, SITELIBEXP, and PERL_ARCHLIB. To do that, MakeMaker writes a new Makefile, on UNIX, this is called `Makefile.aperl` (may be system dependent). If you want to force the creation of a new perl, it is recommended, that you delete this `Makefile.aperl`, so the directories are searched-through for linkable libraries again.

The binary can be installed into the directory where perl normally resides on your machine with

```
make inst_perl
```

To produce a perl binary with a different name than `perl`, either say

```
perl Makefile.PL MAP_TARGET=myperl
make myperl
make inst_perl
```

or say

```
perl Makefile.PL
make myperl MAP_TARGET=myperl
```

```
make inst_perl MAP_TARGET=myperl
```

In any case you will be prompted with the correct invocation of the `inst_perl` target that installs the new binary into `INSTALLBIN`.

`make inst_perl` per default writes some documentation of what has been done into the file `$(INSTALLARCHLIB)/perllocal.pod`. This can be bypassed by calling `make pure_inst_perl`.

Warning: the `inst_perl` target will most probably overwrite your existing perl binary. Use with care!

Sometimes you might want to build a statically linked perl although your system supports dynamic loading. In this case you may explicitly set the `linktype` with the invocation of the `Makefile.PL` or `make`:

```
perl Makefile.PL LINKTYPE=static      # recommended
```

or

```
make LINKTYPE=static                  # works on most systems
```

Determination of Perl Library and Installation Locations

MakeMaker needs to know, or to guess, where certain things are located. Especially `INST_LIB` and `INST_ARCHLIB` (where to put the files during the `make(1)` run), `PERL_LIB` and `PERL_ARCHLIB` (where to read existing modules from), and `PERL_INC` (header files and `libperl*.*`).

Extensions may be built either using the contents of the perl source directory tree or from the installed perl library. The recommended way is to build extensions after you have run ‘`make install`’ on perl itself. You can do that in any directory on your hard disk that is not below the perl source tree. The support for extensions below the `ext` directory of the perl distribution is only good for the standard extensions that come with perl.

If an extension is being built below the `ext/` directory of the perl source then MakeMaker will set `PERL_SRC` automatically (e.g., `../..`). If `PERL_SRC` is defined and the extension is recognized as a standard extension, then other variables default to the following:

```
PERL_INC      = PERL_SRC
PERL_LIB      = PERL_SRC/lib
PERL_ARCHLIB  = PERL_SRC/lib
INST_LIB      = PERL_LIB
INST_ARCHLIB  = PERL_ARCHLIB
```

If an extension is being built away from the perl source then MakeMaker will leave `PERL_SRC` undefined and default to using the installed copy of the perl library. The other variables default to the following:

```
PERL_INC      = $archlibexp/CORE
PERL_LIB      = $privlibexp
PERL_ARCHLIB  = $archlibexp
INST_LIB      = ./blib/lib
INST_ARCHLIB  = ./blib/arch
```

If perl has not yet been installed then `PERL_SRC` can be defined on the command line as shown in the previous section.

Which architecture dependent directory?

If you don’t want to keep the defaults for the `INSTALL*` macros, MakeMaker helps you to minimize the typing needed: the usual relationship between `INSTALLPRIVLIB` and `INSTALLARCHLIB` is determined by `Configure` at perl compilation time. MakeMaker supports the user who sets `INSTALLPRIVLIB`. If `INSTALLPRIVLIB` is set, but `INSTALLARCHLIB` not, then MakeMaker defaults the latter to be the same subdirectory of `INSTALLPRIVLIB` as `Configure` decided for the counterparts in `%Config`, otherwise it defaults to `INSTALLPRIVLIB`. The same relationship holds for `INSTALLSITELIB` and `INSTALLSITEARCH`.

MakeMaker gives you much more freedom than needed to configure internal variables and get different results. It is worth to mention, that `make(1)` also lets you configure most of the variables that are used in the

Makefile. But in the majority of situations this will not be necessary, and should only be done if the author of a package recommends it (or you know what you're doing).

Using Attributes and Parameters

The following attributes may be specified as arguments to `WriteMakefile()` or as `NAME=VALUE` pairs on the command line.

ABSTRACT

One line description of the module. Will be included in PPD file.

ABSTRACT_FROM

Name of the file that contains the package description. MakeMaker looks for a line in the POD matching `/($\$package$ \s-\s)(.*)/`. This is typically the first line in the `"=head1 NAME"` section. `$2` becomes the abstract.

AUTHOR

String containing name (and email address) of package author(s). Is used in PPD (Perl Package Description) files for PPM (Perl Package Manager).

BINARY_LOCATION

Used when creating PPD files for binary packages. It can be set to a full or relative path or URL to the binary archive for a particular architecture. For example:

```
perl Makefile.PL BINARY_LOCATION=x86/Agent.tar.gz
```

builds a PPD package that references a binary of the `Agent` package, located in the `x86` directory relative to the PPD itself.

C Ref to array of *.c file names. Initialised from a directory scan and the values portion of the XS attribute hash. This is not currently used by MakeMaker but may be handy in Makefile.PLs.

CCFLAGS

String that will be included in the compiler call command line between the arguments `INC` and `OPTIMIZE`.

CONFIG

Arrayref. E.g. `[qw(archname manext)]` defines `ARCHNAME` & `MANEXT` from `config.sh`. MakeMaker will add to `CONFIG` the following values anyway: `ar cc ccldflags ccldflags dlexit dlsrc ld ldldflags ldflags libc lib_ext obj_ext ranlib sitelibexp sitearchexp` so

CONFIGURE

CODE reference. The subroutine should return a hash reference. The hash may contain further attributes, e.g. `{LIBS => ...}`, that have to be determined by some evaluation method.

DEFINE

Something like `"-DHAVE_UNISTD_H"`

DIR

Ref to array of subdirectories containing Makefile.PLs e.g. `['sdbm']` in `ext/SDBM_File`

DISTNAME

Your name for distributing the package (by tar file). This defaults to `NAME` above.

DL_FUNCS

Hashref of symbol names for routines to be made available as universal symbols. Each key/value pair consists of the package name and an array of routine names in that package. Used only under AIX, OS/2, VMS and Win32 at present. The routine names supplied will be expanded in the same way as XSUB names are expanded by the `XS()` macro. Defaults to

```
{ "$ (NAME) " => [ "boot_$ (NAME) " ] }
```

e.g.

```
{ "RPC" => [qw( boot_rpcb rpcb_gettime getnetconfignt )],
  "NetconfigPtr" => [ 'DESTROY' ] }
```

Please see the [ExtUtils::Mksymlists](#) documentation for more information about the DL_FUNCS, DL_VARS and FUNCLIST attributes.

DL_VARS

Array of symbol names for variables to be made available as universal symbols. Used only under AIX, OS/2, VMS and Win32 at present. Defaults to []. (e.g. [qw(Foo_version Foo_numstreams Foo_tree)])

EXCLUDE_EXT

Array of extension names to exclude when doing a static build. This is ignored if INCLUDE_EXT is present. Consult INCLUDE_EXT for more details. (e.g. [qw(Socket POSIX)])

This attribute may be most useful when specified as a string on the command line: perl Makefile.PL EXCLUDE_EXT='Socket Safe'

EXE_FILES

Ref to array of executable files. The files will be copied to the INST_SCRIPT directory. Make realclean will delete them from there again.

FIRST_MAKEFILE

The name of the Makefile to be produced. Defaults to the contents of MAKEFILE, but can be overridden. This is used for the second Makefile that will be produced for the MAP_TARGET.

FULLPERL

Perl binary able to run this extension, load XS modules, etc...

FULLPERLRUN

Like PERLRUN, except it uses FULLPERL.

FULLPERLRUNINST

Like PERLRUNINST, except it uses FULLPERL.

FUNCLIST

This provides an alternate means to specify function names to be exported from the extension. Its value is a reference to an array of function names to be exported by the extension. These names are passed through unaltered to the linker options file.

H Ref to array of *.h file names. Similar to C.

IMPORTS

This attribute is used to specify names to be imported into the extension. Takes a hash ref.

It is only used on OS/2 and Win32.

INC

Include file dirs eg: "-I/usr/5include -I/path/to/inc"

INCLUDE_EXT

Array of extension names to be included when doing a static build. MakeMaker will normally build with all of the installed extensions when doing a static build, and that is usually the desired behavior. If INCLUDE_EXT is present then MakeMaker will build only with those extensions which are explicitly mentioned. (e.g. [qw(Socket POSIX)])

It is not necessary to mention DynaLoader or the current extension when filling in INCLUDE_EXT. If the INCLUDE_EXT is mentioned but is empty then only DynaLoader and the current extension will be included in the build.

This attribute may be most useful when specified as a string on the command line: `perl Makefile.PL INCLUDE_EXT='POSIX Socket Devel::Peek'`

INSTALLARCHLIB

Used by 'make install', which copies files from INST_ARCHLIB to this directory if INSTALLDIRS is set to perl.

INSTALLBIN

Directory to install binary files (e.g. tkperl) into if INSTALLDIRS=perl.

INSTALLDIRS

Determines which of the sets of installation directories to choose: perl, site or vendor. Defaults to site.

INSTALLMAN1DIR

INSTALLMAN3DIR

These directories get the man pages at 'make install' time if INSTALLDIRS=perl. Defaults to `$Config{installman*dir}`.

If set to 'none', no man pages will be installed.

INSTALLPRIVLIB

Used by 'make install', which copies files from INST_LIB to this directory if INSTALLDIRS is set to perl.

Defaults to `$Config{installprivlib}`.

INSTALLSCRIPT

Used by 'make install' which copies files from INST_SCRIPT to this directory.

INSTALLSITEARCH

Used by 'make install', which copies files from INST_ARCHLIB to this directory if INSTALLDIRS is set to site (default).

INSTALLSITEBIN

Used by 'make install', which copies files from INST_BIN to this directory if INSTALLDIRS is set to site (default).

INSTALLSITELIB

Used by 'make install', which copies files from INST_LIB to this directory if INSTALLDIRS is set to site (default).

INSTALLSITEMAN1DIR

INSTALLSITEMAN3DIR

These directories get the man pages at 'make install' time if INSTALLDIRS=site (default). Defaults to `$(SITEPREFIX)/man/man$(MAN*EXT)`.

If set to 'none', no man pages will be installed.

INSTALLVENDORARCH

Used by 'make install', which copies files from INST_ARCHLIB to this directory if INSTALLDIRS is set to vendor.

INSTALLVENDORBIN

Used by 'make install', which copies files from INST_BIN to this directory if INSTALLDIRS is set to vendor.

INSTALLVENDORLIB

Used by 'make install', which copies files from INST_LIB to this directory if INSTALLDIRS is set to vendor.

INSTALLVENDORMAN1DIR

INSTALLVENDORMAN3DIR

These directories get the man pages at 'make install' time if `INSTALLDIRS=vendor`. Defaults to `$(VENDORPREFIX) /man/man$(MAN*EXT)`.

If set to 'none', no man pages will be installed.

INST_ARCHLIB

Same as `INST_LIB` for architecture dependent files.

INST_BIN

Directory to put real binary files during 'make'. These will be copied to `INSTALLBIN` during 'make install'

INST_LIB

Directory where we put library files of this extension while building it.

INST_MAN1DIR

Directory to hold the man pages at 'make' time

INST_MAN3DIR

Directory to hold the man pages at 'make' time

INST_SCRIPT

Directory, where executable files should be installed during 'make'. Defaults to `"/blib/script"`, just to have a dummy location during testing. `make install` will copy the files in `INST_SCRIPT` to `INSTALLSCRIPT`.

LDDLFLAGS

Any special flags that might need to be passed to `ld` to create a shared library suitable for dynamic loading. It is up to the makefile to use it. (See [lddlflags](#))

Defaults to `$Config{lddlflags}`.

LDFROM

Defaults to `"$(OBJECT) "` and is used in the `ld` command to specify what files to link/load from (also see `dynamic_lib` below for how to specify `ld` flags)

LIB

`LIB` should only be set at `perl Makefile.PL` time but is allowed as a `MakeMaker` argument. It has the effect of setting both `INSTALLPRIVLIB` and `INSTALLSITELIB` to that value regardless any explicit setting of those arguments (or of `PREFIX`). `INSTALLARCHLIB` and `INSTALLSITEARCH` are set to the corresponding architecture subdirectory.

LIBPERL_A

The filename of the perl library that will be used together with this extension. Defaults to `libperl.a`.

LIBS

An anonymous array of alternative library specifications to be searched for (in order) until at least one library is found. E.g.

```
'LIBS' => ["-lgdbm", "-ldbm -lfoo", "-L/path -ldbm.nfs"]
```

Mind, that any element of the array contains a complete set of arguments for the `ld` command. So do not specify

```
'LIBS' => ["-ltcl", "-ltk", "-lX11"]
```

See `ODBM_File/Makefile.PL` for an example, where an array is needed. If you specify a scalar as in

```
'LIBS' => "-ltcl -ltk -lX11"
```

MakeMaker will turn it into an array with one element.

LINKTYPE

'static' or 'dynamic' (default unless `usedl=undef` in `config.sh`). Should only be used to force static linking (also see `linkext` below).

MAKEAPERL

Boolean which tells MakeMaker, that it should include the rules to make a perl. This is handled automatically as a switch by MakeMaker. The user normally does not need it.

MAKEFILE

The name of the Makefile to be produced.

MAN1PODS

Hashref of pod-containing files. MakeMaker will default this to all `EXE_FILES` files that include POD directives. The files listed here will be converted to man pages and installed as was requested at Configure time.

MAN3PODS

Hashref that assigns to *.pm and *.pod files the files into which the manpages are to be written. MakeMaker parses all *.pod and *.pm files for POD directives. Files that contain POD will be the default keys of the MAN3PODS hashref. These will then be converted to man pages during make and will be installed during `make install`.

MAP_TARGET

If it is intended, that a new perl binary be produced, this variable may hold a name for that binary. Defaults to perl

MYEXTLIB

If the extension links to a library that it builds set this to the name of the library (see `SDBM_File`)

NAME

Perl module name for this extension (`DBD::Oracle`). This will default to the directory name but should be explicitly defined in the `Makefile.PL`.

NEEDS_LINKING

MakeMaker will figure out if an extension contains linkable code anywhere down the directory tree, and will set this variable accordingly, but you can speed it up a very little bit if you define this boolean variable yourself.

NOECHO

Defaults to @. By setting it to an empty string you can generate a Makefile that echos all commands. Mainly used in debugging MakeMaker itself.

NORECURS

Boolean. Attribute to inhibit descending into subdirectories.

NO_VC

In general, any generated Makefile checks for the current version of MakeMaker and the version the Makefile was built under. If `NO_VC` is set, the version check is neglected. Do not write this into your `Makefile.PL`, use it interactively instead.

OBJECT

List of object files, defaults to `'$(BASEEXT) $(OBJ_EXT) '`, but can be a long string containing all object files, e.g. `"tkpBind.o tkpButton.o tkpCanvas.o"`

(Where `BASEEXT` is the last component of `NAME`, and `OBJ_EXT` is `$Config{obj_ext}`.)

OPTIMIZE

Defaults to `-O`. Set it to `-g` to turn debugging on. The flag is passed to subdirectory makes.

PERL

Perl binary for tasks that can be done by `miniperl`

PERL_CORE

Set only when MakeMaker is building the extensions of the Perl core distribution.

PERLMAINCC

The call to the program that is able to compile `perlmain.c`. Defaults to `$(CC)`.

PERL_ARCHLIB

Same as for `PERL_LIB`, but for architecture dependent files.

Used only when MakeMaker is building the extensions of the Perl core distribution (because normally `$(PERL_ARCHLIB)` is automatically in `@INC`, and adding it would get in the way of `PERL5LIB`).

PERL_LIB

Directory containing the Perl library to use.

Used only when MakeMaker is building the extensions of the Perl core distribution (because normally `$(PERL_LIB)` is automatically in `@INC`, and adding it would get in the way of `PERL5LIB`).

PERL_MALLOC_OK

defaults to 0. Should be set to `TRUE` if the extension can work with the memory allocation routines substituted by the Perl `malloc()` subsystem. This should be applicable to most extensions with exceptions of those

- with bugs in memory allocations which are caught by Perl's `malloc()`;
- which interact with the memory allocator in other ways than via `malloc()`, `realloc()`, `free()`, `calloc()`, `sbrk()` and `brk()`;
- which rely on special alignment which is not provided by Perl's `malloc()`.

NOTE. Negligence to set this flag in *any one* of loaded extension nullifies many advantages of Perl's `malloc()`, such as better usage of system resources, error detection, memory usage reporting, catchable failure of memory allocations, etc.

PERLRUN

Use this instead of `$(PERL)` when you wish to run `perl`. It will set up extra necessary flags for you.

PERLRUNINST

Use this instead of `$(PERL)` when you wish to run `perl` to work with modules. It will add things like `-I$(INST_ARCH)` and other necessary flags so `perl` can see the modules you're about to install.

PERL_SRC

Directory containing the Perl source code (use of this should be avoided, it may be undefined)

PERM_RW

Desired permission for read/writable files. Defaults to `644`. See also [perm_rw](#).

PERM_RWX

Desired permission for executable files. Defaults to `755`. See also [perm_rwx](#).

PL_FILES

Ref to hash of files to be processed as perl programs. MakeMaker will default to any found `*.PL` file (except `Makefile.PL`) being keys and the basename of the file being the value. E.g.

```
{ 'foobar.PL' => 'foobar' }
```

The *.PL files are expected to produce output to the target files themselves. If multiple files can be generated from the same *.PL file then the value in the hash can be a reference to an array of target file names. E.g.

```
{ 'foobar.PL' => ['foobar1', 'foobar2'] }
```

PM

Hashref of .pm files and *.pl files to be installed. e.g.

```
{ 'name_of_file.pm' => '$(INST_LIBDIR)/install_as.pm' }
```

By default this will include *.pm and *.pl and the files found in the PMLIBDIRS directories. Defining PM in the Makefile.PL will override PMLIBDIRS.

PMLIBDIRS

Ref to array of subdirectories containing library files. Defaults to ['lib', \$(BASEEXT)]. The directories will be scanned and *any* files they contain will be installed in the corresponding location in the library. A `libscan()` method can be used to alter the behaviour. Defining PM in the Makefile.PL will override PMLIBDIRS.

(Where BASEEXT is the last component of NAME.)

PM_FILTER

A filter program, in the traditional Unix sense (input from stdin, output to stdout) that is passed on each .pm file during the build (in the `pm_to_blib()` phase). It is empty by default, meaning no filtering is done.

Great care is necessary when defining the command if quoting needs to be done. For instance, you would need to say:

```
{ 'PM_FILTER' => 'grep -v \\"^\\#\\\"' }
```

to remove all the leading comments on the fly during the build. The extra `\\` are necessary, unfortunately, because this variable is interpolated within the context of a Perl program built on the command line, and double quotes are what is used with the `-e` switch to build that command line. The `#` is escaped for the Makefile, since what is going to be generated will then be:

```
PM_FILTER = grep -v \\"^\\#\\\"
```

Without the `\\` before the `#`, we'd have the start of a Makefile comment, and the macro would be incorrectly defined.

POLLUTE

Release 5.005 grandfathered old global symbol names by providing preprocessor macros for extension source compatibility. As of release 5.6, these preprocessor definitions are not available by default. The POLLUTE flag specifies that the old names should still be defined:

```
perl Makefile.PL POLLUTE=1
```

Please inform the module author if this is necessary to successfully install a module under 5.6 or later.

PPM_INSTALL_EXEC

Name of the executable used to run PPM_INSTALL_SCRIPT below. (e.g. perl)

PPM_INSTALL_SCRIPT

Name of the script that gets executed by the Perl Package Manager after the installation of a package.

PREFIX

This overrides all the default install locations. Man pages, libraries, scripts, etc... MakeMaker will try to make an educated guess about where to place things under the new PREFIX based on your Config defaults. Failing that, it will fall back to a structure which should be sensible for your platform.

If you specify LIB or any INSTALL* variables they will not be effected by the PREFIX.

Defaults to `$Config{installprefixexp}`.

PREREQ_FATAL

Bool. If this parameter is true, failing to have the required modules (or the right versions thereof) will be fatal. perl Makefile.PL will die with the proper message.

Note: see [Test::Harness](#) for a shortcut for stopping tests early if you are missing dependencies.

Do *not* use this parameter for simple requirements, which could be resolved at a later time, e.g. after an unsuccessful **make test** of your module.

It is *extremely* rare to have to use PREREQ_FATAL at all!

PREREQ_PM

Hashref: Names of modules that need to be available to run this extension (e.g. Fcntl for SDBM_File) are the keys of the hash and the desired version is the value. If the required version number is 0, we only check if any version is installed already.

PREREQ_PRINT

Bool. If this parameter is true, the prerequisites will be printed to stdout and MakeMaker will exit. The output format is

```
$PREREQ_PM = {
    'A::B' = Vers1,
    'C::D' = Vers2,
    ...
};
```

PRINT_PREREQ

RedHatism for PREREQ_PRINT. The output format is different, though:

```
perl (A::B) >=Vers1 perl (C::D) >=Vers2 ...
```

SITEPREFIX

Like PREFIX, but only for the site install locations.

Defaults to PREFIX (if set) or `$Config{siteprefixexp}`. Perls prior to 5.6.0 didn't have an explicit siteprefix in the Config. In those cases `$Config{installprefix}` will be used.

SKIP

Arrayref. E.g. `[qw(name1 name2)]` skip (do not write) sections of the Makefile. Caution! Do not use the SKIP attribute for the negligible speedup. It may seriously damage the resulting Makefile. Only use it if you really need it.

TYPEMAPS

Ref to array of typemap file names. Use this when the typemaps are in some directory other than the current directory or when they are not named **typemap**. The last typemap in the list takes precedence. A typemap in the current directory has highest precedence, even if it isn't listed in TYPEMAPS. The default system typemap has lowest precedence.

VENDORPREFIX

Like PREFIX, but only for the vendor install locations.

Defaults to PREFIX (if set) or `$Config{vendorprefixexp}`

VERBINST

If true, make install will be verbose

VERSION

Your version number for distributing the package. This defaults to 0.1.

VERSION_FROM

Instead of specifying the VERSION in the Makefile.PL you can let MakeMaker parse a file to determine the version number. The parsing routine requires that the file named by VERSION_FROM contains one single line to compute the version number. The first line in the file that contains the regular expression

```
/([\$*])(([\w\:\']*)\bVERSION)\b.*\s=/
```

will be evaluated with `eval()` and the value of the named variable **after** the `eval()` will be assigned to the VERSION attribute of the MakeMaker object. The following lines will be parsed o.k.:

```
$VERSION = '1.00';
*VERSION = \ '1.01';
( $VERSION ) = '$Revision: 1.63 $' =~ /\$Revision:\s+([^\s]+)/;
$FOO::VERSION = '1.10';
*FOO::VERSION = \ '1.11';
our $VERSION = 1.2.3;          # new for perl5.6.0
```

but these will fail:

```
my $VERSION = '1.01';
local $VERSION = '1.02';
local $FOO::VERSION = '1.30';
```

(Putting `my` or `local` on the preceding line will work o.k.)

The file named in VERSION_FROM is not added as a dependency to Makefile. This is not really correct, but it would be a major pain during development to have to rewrite the Makefile for any smallish change in that file. If you want to make sure that the Makefile contains the correct VERSION macro after any change of the file, you would have to do something like

```
depend => { Makefile => '$(VERSION_FROM)' }
```

See attribute `depend` below.

XS

Hashref of .xs files. MakeMaker will default this. e.g.

```
{ 'name_of_file.xs' => 'name_of_file.c' }
```

The .c files will automatically be included in the list of files deleted by a `make clean`.

XSOPT

String of options to pass to `xsubpp`. This might include `-C++` or `-extern`. Do not include `typemaps` here; the `TYPEMAP` parameter exists for that purpose.

XSPROTOARG

May be set to an empty string, which is identical to `-prototypes`, or `-noprotoypes`. See the `xsubpp` documentation for details. MakeMaker defaults to the empty string.

XS_VERSION

Your version number for the .xs file of this package. This defaults to the value of the VERSION attribute.

Additional lowercase attributes

can be used to pass parameters to the methods which implement that part of the Makefile.

clean

```
{FILES => "*.xyz foo"}
```

depend

```
{ANY_TARGET => ANY_DEPENDENCY, ...}
```

(ANY_TARGET must not be given a double-colon rule by MakeMaker.)

dist

```
{TARFLAGS => 'cvfF', COMPRESS => 'gzip', SUFFIX => '.gz',
SHAR => 'shar -m', DIST_CP => 'ln', ZIP => '/bin/zip',
ZIPFLAGS => '-rl', DIST_DEFAULT => 'private tardist' }
```

If you specify COMPRESS, then SUFFIX should also be altered, as it is needed to tell make the target file of the compression. Setting DIST_CP to ln can be useful, if you need to preserve the timestamps on your files. DIST_CP can take the values 'cp', which copies the file, 'ln', which links the file, and 'best' which copies symbolic links and links the rest. Default is 'best'.

dynamic_lib

```
{ARMAYBE => 'ar', OTHERLDFLAGS => '...', INST_DYNAMIC_DEP => '...'}
```

linkext

```
{LINKTYPE => 'static', 'dynamic' or ''}
```

NB: Extensions that have nothing but *.pm files had to say

```
{LINKTYPE => ''}
```

with Pre-5.0 MakeMakers. Since version 5.00 of MakeMaker such a line can be deleted safely. MakeMaker recognizes when there's nothing to be linked.

macro

```
{ANY_MACRO => ANY_VALUE, ...}
```

realclean

```
{FILES => '$(INST_ARCHAUTODIR)/*.xyz'}
```

test

```
{TESTS => 't/*.t'}
```

tool_autosplit

```
{MAXLEN => 8}
```

Overriding MakeMaker Methods

If you cannot achieve the desired Makefile behaviour by specifying attributes you may define private subroutines in the Makefile.PL. Each subroutine returns the text it wishes to have written to the Makefile. To override a section of the Makefile you can either say:

```
sub MY::c_o { "new literal text" }
```

or you can edit the default by saying something like:

```
package MY; # so that "SUPER" works right
sub c_o {
    my $inherited = shift->SUPER::c_o(@_);
    $inherited =~ s/old text/new text/;
    $inherited;
}
```

If you are running experiments with embedding perl as a library into other applications, you might find MakeMaker is not sufficient. You'd better have a look at ExtUtils::Embed which is a collection of utilities

for embedding.

If you still need a different solution, try to develop another subroutine that fits your needs and submit the diffs to makemaker@perl.org

For a complete description of all MakeMaker methods see [ExtUtils::MM_Unix](#).

Here is a simple example of how to add a new target to the generated Makefile:

```
sub MY::postamble {
    return <<'MAKE_FRAG';
    $(MYEXTLIB): sdbm/Makefile
        cd sdbm && $(MAKE) all

    MAKE_FRAG
}
```

The End Of Cargo Cult Programming

`WriteMakefile()` now does some basic sanity checks on its parameters to protect against typos and malformed values. This means some things which happened to work in the past will now throw warnings and possibly produce internal errors.

Some of the most common mistakes:

```
<MAN3PODS = ''
```

This is commonly used to suppress the creation of man pages. `MAN3PODS` takes a hash ref not a string, but the above worked by accident in old versions of MakeMaker.

The correct code is `<MAN3PODS = { }.`

Hintsfile support

`MakeMaker.pm` uses the architecture specific information from `Config.pm`. In addition it evaluates architecture specific hints files in a `hints/` directory. The hints files are expected to be named like their counterparts in `PERL_SRC/hints`, but with an `.pl` file name extension (eg. `next_3_2.pl`). They are simply eval'd by MakeMaker within the `WriteMakefile()` subroutine, and can be used to execute commands as well as to include special variables. The rules which hintsfile is chosen are the same as in `Configure`.

The hintsfile is `eval()`ed immediately after the arguments given to `WriteMakefile` are stuffed into a hash reference `$self` but before this reference becomes blessed. So if you want to do the equivalent to override or create an attribute you would say something like

```
$self->{LIBS} = ['-ldbm -lucb -lc'];
```

Distribution Support

For authors of extensions MakeMaker provides several Makefile targets. Most of the support comes from the `ExtUtils::Manifest` module, where additional documentation can be found.

make distcheck

reports which files are below the build directory but not in the MANIFEST file and vice versa. (See `ExtUtils::Manifest::fullcheck()` for details)

make skipcheck

reports which files are skipped due to the entries in the MANIFEST.SKIP file (See `ExtUtils::Manifest::skipcheck()` for details)

make distclean

does a `realclean` first and then the `distcheck`. Note that this is not needed to build a new distribution as long as you are sure that the MANIFEST file is ok.

make manifest

rewrites the MANIFEST file, adding all remaining files found (See `ExtUtils::Manifest::mkmanifest()` for details)

make distdir

Copies all the files that are in the MANIFEST file to a newly created directory with the name `$(DISTNAME) - $(VERSION)`. If that directory exists, it will be removed first.

make disttest

Makes a distdir first, and runs a `perl Makefile.PL`, a `make`, and a `make test` in that directory.

make tardist

First does a `distdir`. Then a command `$(PREOP)` which defaults to a null command, followed by `$(TOUNIX)`, which defaults to a null command under UNIX, and will convert files in distribution directory to UNIX format otherwise. Next it runs `tar` on that directory into a tarfile and deletes the directory. Finishes with a command `$(POSTOP)` which defaults to a null command.

make dist

Defaults to `$(DIST_DEFAULT)` which in turn defaults to `tardist`.

make uutardist

Runs a `tardist` first and `uuencodes` the tarfile.

make shdist

First does a `distdir`. Then a command `$(PREOP)` which defaults to a null command. Next it runs `shar` on that directory into a sharfile and deletes the intermediate directory again. Finishes with a command `$(POSTOP)` which defaults to a null command. Note: For `shdist` to work properly a `shar` program that can handle directories is mandatory.

make zipdist

First does a `distdir`. Then a command `$(PREOP)` which defaults to a null command. Runs `$(ZIP)` `$(ZIPFLAGS)` on that directory into a zipfile. Then deletes that directory. Finishes with a command `$(POSTOP)` which defaults to a null command.

make ci

Does a `$(CI)` and a `$(RCS_LABEL)` on all files in the MANIFEST file.

Customization of the dist targets can be done by specifying a hash reference to the `dist` attribute of the `WriteMakefile` call. The following parameters are recognized:

<code>CI</code>	<code>('ci -u')</code>
<code>COMPRESS</code>	<code>('gzip --best')</code>
<code>POSTOP</code>	<code>('@ :')</code>
<code>PREOP</code>	<code>('@ :')</code>
<code>TO_UNIX</code>	<code>(depends on the system)</code>
<code>RCS_LABEL</code>	<code>('rcs -q -Nv\$(VERSION_SYM) :')</code>
<code>SHAR</code>	<code>('shar')</code>
<code>SUFFIX</code>	<code>('gz')</code>
<code>TAR</code>	<code>('tar')</code>
<code>TARFLAGS</code>	<code>('cvf')</code>
<code>ZIP</code>	<code>('zip')</code>
<code>ZIPFLAGS</code>	<code>('r')</code>

An example:

```
WriteMakefile( 'dist' => { COMPRESS=>"bzip2", SUFFIX=>".bz2" } )
```

Disabling an extension

If some events detected in *Makefile.PL* imply that there is no way to create the Module, but this is a normal state of things, then you can create a *Makefile* which does nothing, but succeeds on all the "usual" build targets. To do so, use

```
ExtUtils::MakeMaker::WriteEmptyMakefile();
```

instead of `WriteMakefile()`.

This may be useful if other modules expect this module to be *built* OK, as opposed to *work* OK (say, this system-dependent module builds in a subdirectory of some other distribution, or is listed as a dependency in a CPAN::Bundle, but the functionality is supported by different means on the current architecture).

ENVIRONMENT

PERL_MM_OPT

Command line options used by `MakeMaker->new()`, and thus by `WriteMakefile()`. The string is split on whitespace, and the result is processed before any actual command line arguments are processed.

PERL_MM_USE_DEFAULT

If set to a true value then MakeMaker's prompt function will always return the default without waiting for user input.

NAME

ExtUtils::Manifest – utilities to write and check a MANIFEST file

SYNOPSIS

```
require ExtUtils::Manifest;

ExtUtils::Manifest::mkmanifest;

ExtUtils::Manifest::manicheck;

ExtUtils::Manifest::filecheck;

ExtUtils::Manifest::fullcheck;

ExtUtils::Manifest::skipcheck;

ExtUtils::Manifest::manifind();

ExtUtils::Manifest::maniread($file);

ExtUtils::Manifest::manicopy($read,$target,$show);
```

DESCRIPTION

`mkmanifest()` writes all files in and below the current directory to a file named in the global variable `$ExtUtils::Manifest::MANIFEST` (which defaults to `MANIFEST`) in the current directory. It works similar to

```
find . -print
```

but in doing so checks each line in an existing `MANIFEST` file and includes any comments that are found in the existing `MANIFEST` file in the new one. Anything between white space and an end of line within a `MANIFEST` file is considered to be a comment. Filenames and comments are separated by one or more `TAB` characters in the output. All files that match any regular expression in a file `MANIFEST.SKIP` (if such a file exists) are ignored.

`manicheck()` checks if all the files within a `MANIFEST` in the current directory really do exist. If `MANIFEST` and the tree below the current directory are in sync it exits silently, returning an empty list. Otherwise it returns a list of files which are listed in the `MANIFEST` but missing from the directory, and by default also outputs these names to `STDERR`.

`filecheck()` finds files below the current directory that are not mentioned in the `MANIFEST` file. An optional file `MANIFEST.SKIP` will be consulted. Any file matching a regular expression in such a file will not be reported as missing in the `MANIFEST` file. The list of any extraneous files found is returned, and by default also reported to `STDERR`.

`fullcheck()` does both a `manicheck()` and a `filecheck()`, returning references to two arrays, the first for files `manicheck()` found to be missing, the second for unexpected files found by `filecheck()`.

`skipcheck()` lists all the files that are skipped due to your `MANIFEST.SKIP` file.

`manifind()` returns a hash reference. The keys of the hash are the files found below the current directory.

`maniread($file)` reads a named `MANIFEST` file (defaults to `MANIFEST` in the current directory) and returns a `HASH` reference with files being the keys and comments being the values of the `HASH`. Blank lines and lines which start with `#` in the `MANIFEST` file are discarded.

`manicopy($read,$target,$show)` copies the files that are the keys in the `HASH` `$_$read` to the named target directory. The `HASH` reference `$read` is typically returned by the `maniread()` function. This function is useful for producing a directory tree identical to the intended distribution tree. The third parameter `$show` can be used to specify a different methods of "copying". Valid values are `cp`, which actually copies the files, `ln` which creates hard links, and `best` which mostly links the files but copies any symbolic link to make a tree without any symbolic link. `Best` is the default.

MANIFEST.SKIP

The file MANIFEST.SKIP may contain regular expressions of files that should be ignored by `mkmanifest()` and `filecheck()`. The regular expressions should appear one on each line. Blank lines and lines which start with `#` are skipped. Use `\#` if you need a regular expression to start with a sharp character. A typical example:

```
# Version control files and dirs.
\bRCS\b
\bCVS\b
,v$

# Makemaker generated files and dirs.
^MANIFEST\.
^Makefile$
^blib/
^MakeMaker-\d

# Temp, old and emacs backup files.
~$
\old$
^#.*#$
^\.#
```

If no MANIFEST.SKIP file is found, a default set of skips will be used, similar to the example above. If you want nothing skipped, simply make an empty MANIFEST.SKIP file.

EXPORT_OK

`&mkmanifest`, `&manicheck`, `&filecheck`, `&fullcheck`, `&maniread`, and `&manicopy` are exportable.

GLOBAL VARIABLES

`$ExtUtils::Manifest::MANIFEST` defaults to MANIFEST. Changing it results in both a different MANIFEST and a different MANIFEST.SKIP file. This is useful if you want to maintain different distributions for different audiences (say a user version and a developer version including RCS).

`$ExtUtils::Manifest::Quiet` defaults to 0. If set to a true value, all functions act silently.

`$ExtUtils::Manifest::Debug` defaults to 0. If set to a true value, or if `PERL_MM_MANIFEST_DEBUG` is true, debugging output will be produced.

DIAGNOSTICS

All diagnostic output is sent to STDERR.

Not in MANIFEST: *file*

is reported if a file is found which is not in MANIFEST.

Skipping *file*

is reported if a file is skipped due to an entry in MANIFEST.SKIP.

No such file: *file*

is reported if a file mentioned in a MANIFEST file does not exist.

MANIFEST: *\$!*

is reported if MANIFEST could not be opened.

Added to MANIFEST: *file*

is reported by `mkmanifest()` if `$Verbose` is set and a file is added to MANIFEST. `$Verbose` is set to 1 by default.

ENVIRONMENT**PERL_MM_MANIFEST_DEBUG**

Turns on debugging

NAME

ExtUtils::Mkbootstrap – make a bootstrap file for use by DynaLoader

SYNOPSIS

Mkbootstrap

DESCRIPTION

Mkbootstrap typically gets called from an extension Makefile.

There is no *.bs file supplied with the extension. Instead, there may be a *_BS file which has code for the special cases, like posix for berkeley db on the NeXT.

This file will get parsed, and produce a maybe empty @DynaLoader::dl_resolve_using array for the current architecture. That will be extended by \$BSLOADLIBS, which was computed by ExtUtils::Liblist::ext(). If this array still is empty, we do nothing, else we write a .bs file with an @DynaLoader::dl_resolve_using array.

The *_BS file can put some code into the generated *.bs file by placing it in \$bscode. This is a handy ‘escape’ mechanism that may prove useful in complex situations.

If @DynaLoader::dl_resolve_using contains -L* or -l* entries then Mkbootstrap will automatically add a dl_findfile() call to the generated *.bs file.

NAME

ExtUtils::Mksymlists – write linker options files for dynamic extension

SYNOPSIS

```
use ExtUtils::Mksymlists;
Mksymlists({ NAME      => $name ,
             DL_VARS   => [ $var1, $var2, $var3 ],
             DL_FUNCS => { $pkg1 => [ $func1, $func2 ],
                           $pkg2 => [ $func3 ] } });
```

DESCRIPTION

ExtUtils::Mksymlists produces files used by the linker under some OSs during the creation of shared libraries for dynamic extensions. It is normally called from a MakeMaker-generated Makefile when the extension is built. The linker option file is generated by calling the function `Mksymlists`, which is exported by default from `ExtUtils::Mksymlists`. It takes one argument, a list of key–value pairs, in which the following keys are recognized:

DLBASE

This item specifies the name by which the linker knows the extension, which may be different from the name of the extension itself (for instance, some linkers add an ‘_’ to the name of the extension). If it is not specified, it is derived from the `NAME` attribute. It is presently used only by OS2 and Win32.

DL_FUNCS

This is identical to the `DL_FUNCS` attribute available via MakeMaker, from which it is usually taken. Its value is a reference to an associative array, in which each key is the name of a package, and each value is an a reference to an array of function names which should be exported by the extension. For instance, one might say `DL_FUNCS => { Homer::Iliad => [qw(trojans greeks)], Homer::Odyssey => [qw(travellers family suitors)] }`. The function names should be identical to those in the `XSUB` code; `Mksymlists` will alter the names written to the linker option file to match the changes made by `xsubpp`. In addition, if none of the functions in a list begin with the string `boot_`, `Mksymlists` will add a bootstrap function for that package, just as `xsubpp` does. (If a `boot_<pkg>` function is present in the list, it is passed through unchanged.) If `DL_FUNCS` is not specified, it defaults to the bootstrap function for the extension specified in `NAME`.

DL_VARS

This is identical to the `DL_VARS` attribute available via MakeMaker, and, like `DL_FUNCS`, it is usually specified via MakeMaker. Its value is a reference to an array of variable names which should be exported by the extension.

FILE

This key can be used to specify the name of the linker option file (minus the OS–specific extension), if for some reason you do not want to use the default value, which is the last word of the `NAME` attribute (*e.g.* for `Tk::Canvas`, `FILE` defaults to `Canvas`).

FUNCLIST

This provides an alternate means to specify function names to be exported from the extension. Its value is a reference to an array of function names to be exported by the extension. These names are passed through unaltered to the linker options file. Specifying a value for the `FUNCLIST` attribute suppresses automatic generation of the bootstrap function for the package. To still create the bootstrap name you have to specify the package name in the `DL_FUNCS` hash:

```
Mksymlists({ NAME      => $name ,
             FUNCLIST => [ $func1, $func2 ],
             DL_FUNCS => { $pkg => [ ] } });
```

IMPORTS

This attribute is used to specify names to be imported into the extension. It is currently only used by OS/2 and Win32.

NAME

This gives the name of the extension (*e.g.* Tk : : Canvas) for which the linker option file will be produced.

When calling `Mksymlists`, one should always specify the `NAME` attribute. In most cases, this is all that's necessary. In the case of unusual extensions, however, the other attributes can be used to provide additional information to the linker.

AUTHOR

Charles Bailey <*bailey@newman.upenn.edu*>

REVISION

Last revised 14-Feb-1996, for Perl 5.002.

NAME

ExtUtils::MM – OS adjusted ExtUtils::MakeMaker subclass

SYNOPSIS

```
require ExtUtils::MM;  
my $mm = MM->new(...);
```

DESCRIPTION**FOR INTERNAL USE ONLY**

ExtUtils::MM is a subclass of ExtUtils::MakeMaker which automatically chooses the appropriate OS specific subclass for you (ie. ExtUils::MM_Unix, etc...).

It also provides a convenient alias via the MM class (I didn't want MakeMaker modules outside of ExtUtils/).

This class might turn out to be a temporary solution, but MM won't go away.

NAME

ExtUtils::MM_Any – Platform agnostic MM methods

SYNOPSIS

```
FOR INTERNAL USE ONLY!

package ExtUtils::MM_SomeOS;

# Temporarily, you have to subclass both.  Put MM_Any first.
require ExtUtils::MM_Any;
require ExtUtils::MM_Unix;
@ISA = qw(ExtUtils::MM_Any ExtUtils::Unix);
```

DESCRIPTION**FOR INTERNAL USE ONLY!**

ExtUtils::MM_Any is a superclass for the ExtUtils::MM_* set of modules. It contains methods which are either inherently cross-platform or are written in a cross-platform manner.

Subclass off of ExtUtils::MM_Any *and* ExtUtils::MM_Unix. This is a temporary solution.

THIS MAY BE TEMPORARY!**Inherently Cross-Platform Methods**

These are methods which are by their nature cross-platform and should always be cross-platform.

File::Spec wrappers DEPRECATED

The following methods are deprecated wrappers around File::Spec functions. They exist from before File::Spec did and in fact are from which File::Spec sprang.

They are all deprecated. Please use File::Spec directly.

```
canonpath
catdir
catfile
curdir
file_name_is_absolute
path
rootdir
updir
```

Thought To Be Cross-Platform Methods

These are methods which are thought to be cross-platform by virtue of having been written in a way to avoid incompatibilities.

test_via_harness

```
my $command = $mm->test_via_harness($perl, $tests);
```

Returns a \$command line which runs the given set of \$tests with Test::Harness and the given \$perl.

Used on the t/*.t files.

test_via_script

```
my $command = $mm->test_via_script($perl, $script);
```

Returns a \$command line which just runs a single test without Test::Harness. No checks are done on the results, they're just printed.

Used for test.pl, since they don't always follow Test::Harness formatting.

NAME

ExtUtils::MM_BeOS – methods to override UN*X behaviour in ExtUtils::MakeMaker

SYNOPSIS

```
use ExtUtils::MM_BeOS; # Done internally by ExtUtils::MakeMaker if needed
```

DESCRIPTION

See ExtUtils::MM_Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

perl_archive

This is internal method that returns path to libperl.a equivalent to be linked to dynamic extensions. UNIX does not have one, but at least BeOS has one.

```
1; __END__
```

NAME

ExtUtils::MM_Cygwin – methods to override UN*X behaviour in ExtUtils::MakeMaker

SYNOPSIS

```
use ExtUtils::MM_Cygwin; # Done internally by ExtUtils::MakeMaker if needed
```

DESCRIPTION

See ExtUtils::MM_Unix for a documentation of the methods provided there.

canonpath

replaces backslashes with forward ones. then acts as *nixish.

cflags

if configured for dynamic loading, triggers #define EXT in EXTERN.h

manifypods

replaces strings '::' with '.' in man page names

perl_archive

points to libperl.a

NAME

ExtUtils::MM_DOS – DOS specific subclass of ExtUtils::MM_Unix

SYNOPSIS

Don't use this module directly.
Use ExtUtils::MM and let it choose.

DESCRIPTION

This is a subclass of ExtUtils::MM_Unix which contains functionality for DOS.

Unless otherwise stated, it works just like ExtUtils::MM_Unix

Overridden methods

replace_manpage_separator

AUTHOR

Michael G Schwern <schwern@pobox.com with code from ExtUtils::MM_Unix

ExtUtils::MM_Unix, ExtUtils::MakeMaker

NAME

ExtUtils::MM_NW5 – methods to override UN*X behaviour in ExtUtils::MakeMaker

SYNOPSIS

```
use ExtUtils::MM_NW5; # Done internally by ExtUtils::MakeMaker if needed
```

DESCRIPTION

See ExtUtils::MM_Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

constants (o)

Initializes lots of constants and .SUFFIXES and .PHONY

static_lib (o)

dynamic_lib (o)

Defines how to produce the *.so (or equivalent) files.

NAME

ExtUtils::MM_OS2 – methods to override UN*X behaviour in ExtUtils::MakeMaker

SYNOPSIS

```
use ExtUtils::MM_OS2; # Done internally by ExtUtils::MakeMaker if needed
```

DESCRIPTION

See ExtUtils::MM_Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

METHODS**perl_archive_after**

This is an internal method that returns path to a library which should be put on the linker command line *after* the external libraries to be linked to dynamic extensions. This may be needed if the linker is one-pass, and Perl includes some overrides for C RTL functions, such as `malloc()`.

NAME

ExtUtils::MM_Unix – methods used by ExtUtils::MakeMaker

SYNOPSIS

```
require ExtUtils::MM_Unix;
```

DESCRIPTION

The methods provided by this package are designed to be used in conjunction with ExtUtils::MakeMaker. When MakeMaker writes a Makefile, it creates one or more objects that inherit their methods from a package MM. MM itself doesn't provide any methods, but it ISA ExtUtils::MM_Unix class. The inheritance tree of MM lets operating specific packages take the responsibility for all the methods provided by MM_Unix. We are trying to reduce the number of the necessary overrides by defining rather primitive operations within ExtUtils::MM_Unix.

If you are going to write a platform specific MM package, please try to limit the necessary overrides to primitive methods, and if it is not possible to do so, let's work out how to achieve that gain.

If you are overriding any of these methods in your Makefile.PL (in the MY class), please report that to the makemaker mailing list. We are trying to minimize the necessary method overrides and switch to data driven Makefile.PLs wherever possible. In the long run less methods will be overridable via the MY class.

METHODS

The following description of methods is still under development. Please refer to the code for not suitably documented sections and complain loudly to the makemaker mailing list.

Not all of the methods below are overridable in a Makefile.PL. Overridable methods are marked as (o). All methods are overridable by a platform specific MM_*.pm file (See [ExtUtils::MM_VMS](#)) and [ExtUtils::MM_OS2](#)).

SelfLoaded methods

`c_o` (o)

Defines the suffix rules to compile different flavors of C files to object files.

`cflags` (o)

Does very much the same as the cflags script in the perl distribution. It doesn't return the whole compiler command line, but initializes all of its parts. The `const_cccmd` method then actually returns the definition of the CCCMD macro which uses these parts.

`clean` (o)

Defines the clean target.

`const_cccmd` (o)

Returns the full compiler call for C programs and stores the definition in `CONST_CCCMD`.

`const_config` (o)

Defines a couple of constants in the Makefile that are imported from `%Config`.

`const_loadlibs` (o)

Defines `EXTRALIBS`, `LDLOADLIBS`, `BSLOADLIBS`, `LD_RUN_PATH`. See [ExtUtils::Liblist](#) for details.

`constants` (o)

Initializes lots of constants and `.SUFFIXES` and `.PHONY`

`depend` (o)

Same as macro for the depend attribute.

dir_target (o)

Takes an array of directories that need to exist and returns a Makefile entry for a .exists file in these directories. Returns nothing, if the entry has already been processed. We're helpless though, if the same directory comes as \$ (FOO) _and_ as "bar". Both of them get an entry, that's why we use "::<".

dist (o)

Defines a lot of macros for distribution support.

dist_basics (o)

Defines the targets distclean, distcheck, skipcheck, manifest, veryclean.

dist_ci (o)

Defines a check in target for RCS.

dist_core (o)

Defines the targets dist, tardist, zipdist, uutardist, shdist

dist_dir

Defines the scratch directory target that will hold the distribution before tar-ing (or shar-ing).

dist_test

Defines a target that produces the distribution in the scratchdirectory, and runs 'perl Makefile.PL; make ;make test' in that subdirectory.

dlsyms (o)

Used by AIX and VMS to define DL_FUNCS and DL_VARS and write the *.exp files.

dynamic (o)

Defines the dynamic target.

dynamic_bs (o)

Defines targets for bootstrap files.

dynamic_lib (o)

Defines how to produce the *.so (or equivalent) files.

exescan

Deprecated method. Use libscan instead.

extliblist

Called by init_others, and calls ext ExtUtils::Liblist. See [ExtUtils::Liblist](#) for details.

find_perl

Finds the executables PERL and FULLPERL

find_tests

```
my $test = $mm->find_tests;
```

Returns a string suitable for feeding to the shell to return all tests in t/*.t.

Methods to actually produce chunks of text for the Makefile

The methods here are called for each MakeMaker object in the order specified by @ExtUtils::MakeMaker::MM_Sections.

fixin

```
$mm->fixin(@files);
```

Inserts the sharpbang or equivalent magic number to a set of @files.

force (o)

Just writes FORCE:

guess_name

Guess the name of this package by examining the working directory's name. MakeMaker calls this only if the developer has not supplied a NAME attribute.

has_link_code

Returns true if C, XS, MYEXTLIB or similar objects exist within this object that need a compiler. Does not descend into subdirectories as `needs_linking()` does.

init_dirscan

Initializes DIR, XS, PM, C, O_FILES, H, PL_FILES, MAN*PODS, EXE_FILES.

init_main

Initializes AR, AR_STATIC_ARGS, BASEEXT, CONFIG, DISTNAME, DLBASE, EXE_EXT, FULLEXT, FULLPERL, FULLPERLRUN, FULLPERLRUNINST, INST_*, INSTALL*, INSTALLDIRS, LD, LIB_EXT, LIBPERL_A, MAP_TARGET, NAME, OBJ_EXT, PARENT_NAME, PERL, PERL_ARCHLIB, PERL_INC, PERL_LIB, PERL_SRC, PERLRUN, PERLRUNINST, PREFIX, VERSION, VERSION_FROM, VERSION_SYM, XS_VERSION.

init_others

Initializes EXTRALIBS, BSLOADLIBS, LDLOADLIBS, LIBS, LD_RUN_PATH, OBJECT, BOOTDEP, PERLMAINCC, LDFROM, LINKTYPE, NOOP, FIRST_MAKEFILE, MAKEFILE, NOECHO, RM_F, RM_RF, TEST_F, TOUCH, CP, MV, CHMOD, UMASK_NULL

init_INST

```
$mm->init_INST;
```

Called by `init_main`. Sets up all `INST_*` variables.

init_INSTALL

```
$mm->init_INSTALL;
```

Called by `init_main`. Sets up all `INSTALL_*` variables (except `INSTALLDIRS`) and `PREFIX`.

init_lib2arch

```
$mm->init_lib2arch
```

```
=end _protected
```

init_PERL

```
$mm->init_PERL;
```

Called by `init_main`. Sets up `ABSPERL`, `PERL`, `FULLPERL` and all the `*PERLRUN*` permutations.

PERL is allowed to be `miniperl`

FULLPERL must be a complete perl

ABSPERL is PERL converted to an absolute path

`*PERLRUN` contains everything necessary to run perl, find it's libraries, etc...

`*PERLRUNINST` is `*PERLRUN` + everything necessary to find the modules being built.

init_PERM

```
$mm->init_PERM
```

Called by `init_main`. Initializes `PERL_*`

install (o)

Defines the install target.

installbin (o)

Defines targets to make and to install EXE_FILES.

libscan (o)

Takes a path to a file that is found by `init_dirscan` and returns false if we don't want to include this file in the library. Mainly used to exclude RCS, CVS, and SCCS directories from installation.

linkext (o)

Defines the linkext target which in turn defines the LINKTYPE.

lsdir

Takes as arguments a directory name and a regular expression. Returns all entries in the directory that match the regular expression.

macro (o)

Simple subroutine to insert the macros defined by the macro attribute into the Makefile.

makeaperl (o)

Called by `staticmake`. Defines how to write the Makefile to produce a static new perl.

By default the Makefile produced includes all the static extensions in the perl library. (Purified versions of library files, e.g., `DynaLoader_pure_p1_c0_032.a` are automatically ignored to avoid link errors.)

makefile (o)

Defines how to rewrite the Makefile.

manifypods (o)

Defines targets and routines to translate the pods into manpages and put them into the `INST_*` directories.

maybe_command

Returns true, if the argument is likely to be a command.

maybe_command_in_dirs

method under development. Not yet used. Ask Ilya :-)

needs_linking (o)

Does this module need linking? Looks into subdirectory objects (see also `has_link_code()`)

nicetext

misnamed method (will have to be changed). The MM_Unix method just returns the argument without further processing.

On VMS used to insure that colons marking targets are preceded by space – most Unix Makes don't need this, but it's necessary under VMS to distinguish the target delimiter from a colon appearing as part of a filespec.

parse_abstract

parse a file and return what you think is the ABSTRACT

parse_version

parse a file and return what you think is `$VERSION` in this file set to. It will return the string "undef" if it can't figure out what `$VERSION` is. `$VERSION` should be for all to see, so our `$VERSION` or plain `$VERSION` are okay, but my `$VERSION` is not.

pasthru (o)

Defines the string that is passed to recursive make calls in subdirectories.

perl_script

Takes one argument, a file name, and returns the file name, if the argument is likely to be a perl script. On MM_Unix this is true for any ordinary, readable file.

perldepend (o)

Defines the dependency from all *.h files that come with the perl distribution.

perm_rw (o)

Returns the attribute PERM_RW or the string 644. Used as the string that is passed to the chmod command to set the permissions for read/writeable files. MakeMaker chooses 644 because it has turned out in the past that relying on the umask provokes hard-to-track bug reports. When the return value is used by the perl function chmod, it is interpreted as an octal value.

perm_rwx (o)

Returns the attribute PERM_RWX or the string 755, i.e. the string that is passed to the chmod command to set the permissions for executable files. See also perl_rw.

pm_to_blib

Defines target that copies all files in the hash PM to their destination and autosplits them. See [ExtUtils::Install/DESCRIPTION](#)

post_constants (o)

Returns an empty string per default. Dedicated to overrides from within Makefile.PL after all constants have been defined.

post_initialize (o)

Returns an empty string per default. Used in Makefile.PLs to add some chunk of text to the Makefile after the object is initialized.

postamble (o)

Returns an empty string. Can be used in Makefile.PLs to write some text to the Makefile at the end.

ppd

Defines target that creates a PPD (Perl Package Description) file for a binary distribution.

prefixify

```
$MM->prefixify($var, $prefix, $new_prefix, $default);
```

Using either \$MM-{uc \$var} || \$Config{lc \$var}, it will attempt to replace it's \$prefix with a \$new_prefix. Should the \$prefix fail to match it sill simply set it to the \$new_prefix + \$default.

This is for heuristics which attempt to create directory structures that mirror those of the installed perl.

For example:

```
$MM->prefixify('installman1dir', '/usr', '/home/foo', 'man/man1');
```

this will attempt to remove '/usr' from the front of the \$MM-{INSTALLMAN1DIR} path (initializing it to \$Config{installman1dir} if necessary) and replace it with '/home/foo'. If this fails it will simply use '/home/foo/man/man1'.

processPL (o)

Defines targets to run *.PL files.

quote_paren

Backslashes parentheses () in command line arguments. Doesn't handle recursive Makefile \$(...) constructs, but handles simple ones.

realclean (o)

Defines the realclean target.

replace_manpage_separator

```
my $man_name = $MM->replace_manpage_separator($file_path);
```

Takes the name of a package, which may be a nested package, in the form 'Foo/Bar.pm' and replaces the slash with : : or something else safe for a man page file name. Returns the replacement.

static (o)

Defines the static target.

static_lib (o)

Defines how to produce the *.a (or equivalent) files.

staticmake (o)

Calls makeaperl.

subdir_x (o)

Helper subroutine for subdirs

subdirs (o)

Defines targets to process subdirectories.

test (o)

Defines the test targets.

test_via_harness (override)

For some reason which I forget, Unix machines like to have PERL_DL_NONLAZY set for tests.

test_via_script (override)

Again, the PERL_DL_NONLAZY thing.

tool_autosplit (o)

Defines a simple perl call that runs autosplit. May be deprecated by pm_to_blib soon.

tools_other (o)

Defines SHELL, LD, TOUCH, CP, MV, RM_F, RM_RF, CHMOD, UMASK_NULL in the Makefile. Also defines the perl programs MKPATH, WARN_IF_OLD_PACKLIST, MOD_INSTALL, DOC_INSTALL, and UNINSTALL.

tool_xsubpp (o)

Determines typemaps, xsubpp version, prototype behaviour.

top_targets (o)

Defines the targets all, subdirs, config, and O_FILES

writedoc

Obsolete, deprecated method. Not used since Version 5.21.

xs_c (o)

Defines the suffix rules to compile XS files to C.

xs_cpp (o)

Defines the suffix rules to compile XS files to C++.

xs_o (o)

Defines suffix rules to go from XS to object files directly. This is only intended for broken make implementations.

perl_archive

This is internal method that returns path to libperl.a equivalent to be linked to dynamic extensions. UNIX does not have one but other OSs might have one.

perl_archive_after

This is an internal method that returns path to a library which should be put on the linker command line *after* the external libraries to be linked to dynamic extensions. This may be needed if the linker is one-pass, and Perl includes some overrides for C RTL functions, such as `malloc()`.

export_list

This is internal method that returns name of a file that is passed to linker to define symbols to be exported. UNIX does not have one but OS2 and Win32 do.

NAME

ExtUtils::MM_VMS – methods to override UN*X behaviour in ExtUtils::MakeMaker

SYNOPSIS

Do not use this directly.
Instead, use ExtUtils::MM and it will figure out which MM_*
class to use for you.

DESCRIPTION

See ExtUtils::MM_Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

Methods always loaded

wraplist

Converts a list into a string wrapped at approximately 80 columns.

Methods

Those methods which override default MM_Unix methods are marked "(override)", while methods unique to MM_VMS are marked "(specific)". For overridden methods, documentation is limited to an explanation of why this method overrides the MM_Unix method; see the ExtUtils::MM_Unix documentation for more details.

guess_name (override)

Try to determine name of extension being built. We begin with the name of the current directory. Since VMS filenames are case-insensitive, however, we look for a *.pm* file whose name matches that of the current directory (presumably the 'main' *.pm* file for this extension), and try to find a package statement from which to obtain the Mixed::Case package name.

find_perl (override)

Use VMS file specification syntax and CLI commands to find and invoke Perl images.

maybe_command (override)

Follows VMS naming conventions for executable files. If the name passed in doesn't exactly match an executable file, appends *.Exe* (or equivalent) to check for executable image, and *.Com* to check for DCL procedure. If this fails, checks directories in DCL\$PATH and finally *Sys\$System:* for an executable file having the name specified, with or without the *.Exe*-equivalent suffix.

maybe_command_in_dirs (override)

Uses DCL argument quoting on test command line.

perl_script (override)

If name passed in doesn't specify a readable file, appends *.com* or *.pl* and tries again, since it's customary to have file types on all files under VMS.

replace_manpage_separator

Use as separator a character which is legal in a VMS-syntax file name.

init_main (override)

Override DISTVNAME so it uses VERSION_SYM to avoid getting too many dots in the name.

init_others (override)

Provide VMS-specific forms of various utility commands, then hand off to the default MM_Unix method.

constants (override)

Fixes up numerous file and directory macros to insure VMS syntax regardless of input syntax. Also adds a few VMS-specific macros and makes lists of files comma-separated.

cflags (override)

Bypass shell script and produce qualifiers for CC directly (but warn user if a shell script for this extension exists). Fold multiple /Defines into one, since some C compilers pay attention to only one instance of this qualifier on the command line.

const_cccmd (override)

Adds directives to point C preprocessor to the right place when handling `#include <sys/foo.h>` directives. Also constructs CC command line a bit differently than MM_Unix method.

pm_to_blib (override)

DCL *still* accepts a maximum of 255 characters on a command line, so we write the (potentially) long list of file names to a temp file, then persuade Perl to read it instead of the command line to find args.

tool_autosplit (override)

Use VMS-style quoting on command line.

tool_ssubpp (override)

Use VMS-style quoting on xsubpp command line.

xsubpp_version (override)

Test xsubpp exit status according to VMS rules (`$sts & 1 ==> good`) rather than Unix rules (`$sts == 0 ==> good`).

tools_other (override)

Adds a few MM[SK] macros, and shortens some the installatin commands, in order to stay under DCL's 255-character limit. Also changes EQUALIZE_TIMESTAMP to set revision date of target file to one second later than source file, since MMK interprets precisely equal revision dates for a source and target file as a sign that the target needs to be updated.

dist (override)

Provide VMSish defaults for some values, then hand off to default MM_Unix method.

c_o (override)

Use VMS syntax on command line. In particular, `$(DEFINE)` and `$(PERL_INC)` have been pulled into `$(CCCMD)`. Also use MM[SK] macros.

xs_c (override)

Use MM[SK] macros.

xs_o (override)

Use MM[SK] macros, and VMS command line for C compiler.

top_targets (override)

Path separator differences.

dlsyms (override)

Create VMS linker options files specifying universal symbols for this extension's shareable image, and listing other shareable images or libraries to which it should be linked.

dynamic_lib (override)

Use VMS Link command.

dynamic_bs (override)

Use VMS-style quoting on Mkbootstrap command line.

static_lib (override)

Use VMS commands to manipulate object library.

manifypods (override)

Use VMS-style quoting on command line, and VMS logical name to specify fallback location at build time if we can't find pod2man.

processPL (override)

Use VMS-style quoting on command line.

installbin (override)

Stay under DCL's 255 character command line limit once again by splitting potentially long list of files across multiple lines in `realclean` target.

subdir_x (override)

Use VMS commands to change default directory.

clean (override)

Split potentially long list of files across multiple commands (in order to stay under the magic command line limit). Also use MM[SK] commands for handling subdirectories.

realclean (override)

Guess what we're working around? Also, use MM[SK] for subdirectories.

dist_core (override)

Syntax for invoking *VMS_Share* differs from that for Unix *shar*, so `shdist` target actions are VMS-specific.

dist_test (override)

Use VMS commands to change default directory, and use VMS-style quoting on command line.

install (override)

Work around DCL's 255 character limit several times, and use VMS-style command line quoting in a few cases.

perldepend (override)

Use VMS-style syntax for files; it's cheaper to just do it directly here than to have the MM_Unix method call `catfile` repeatedly. Also, if we have to rebuild `Config.pm`, use MM[SK] to do it.

makefile (override)

Use VMS commands and quoting.

find_tests (override)**test (override)**

Use VMS commands for handling subdirectories.

makeaperl (override)

Undertake to build a new set of Perl images using VMS commands. Since VMS does dynamic loading, it's not necessary to statically link each extension into the Perl image, so this isn't the normal build path. Consequently, it hasn't really been tested, and may well be incomplete.

nicetext (override)

Insure that colons marking targets are preceded by space, in order to distinguish the target delimiter from a colon appearing as part of a filespec.

prefixify (override)

prefixifying on VMS is simple. Each should simply be:

```
perl_root:[some.dir]
```

which can just be converted to:

volume: [your.prefix.some.dir]

otherwise you get the default layout.

In effect, your search prefix is ignored and `$Config{vms_prefix}` is used instead.

NAME

ExtUtils::MM_Win32 – methods to override UN*X behaviour in ExtUtils::MakeMaker

SYNOPSIS

```
use ExtUtils::MM_Win32; # Done internally by ExtUtils::MakeMaker if needed
```

DESCRIPTION

See ExtUtils::MM_Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

constants (o)

Initializes lots of constants and .SUFFIXES and .PHONY

static_lib (o)

Defines how to produce the *.a (or equivalent) files.

dynamic_bs (o)

Defines targets for bootstrap files.

dynamic_lib (o)

Defines how to produce the *.so (or equivalent) files.

perl_script

Takes one argument, a file name, and returns the file name, if the argument is likely to be a perl script. On MM_Unix this is true for any ordinary, readable file.

pm_to_blib

Defines target that copies all files in the hash PM to their destination and autosplits them. See [ExtUtils::Install/DESCRIPTION](#)

tool_autosplit (override)

Use Win32 quoting on command line.

tools_other (o)

Win32 overrides.

Defines SHELL, LD, TOUCH, CP, MV, RM_F, RM_RF, CHMOD, UMASK_NULL in the Makefile. Also defines the perl programs MKPATH, WARN_IF_OLD_PACKLIST, MOD_INSTALL, DOC_INSTALL, and UNINSTALL.

xs_o (o)

Defines suffix rules to go from XS to object files directly. This is only intended for broken make implementations.

top_targets (o)

Defines the targets all, subdirs, config, and O_FILES

manifypods (o)

We don't want manpage process.

dist_ci (o)

Same as MM_Unix version (changes command-line quoting).

dist_core (o)

Same as MM_Unix version (changes command-line quoting).

pasthru (o)

Defines the string that is passed to recursive make calls in subdirectories.

NAME

ExtUtils::MM_Win95 – method to customize MakeMaker for Win9X

SYNOPSIS

You should not be using this module directly.

DESCRIPTION

This is a subclass of ExtUtils::MM_Win32 containing changes necessary to get MakeMaker playing nice with command.com and other Win9Xisms.

NAME

ExtUtils::MY – ExtUtils::MakeMaker subclass for customization

SYNOPSIS

```
# in your Makefile.PL
sub MY::whatever {
    ...
}
```

DESCRIPTION**FOR INTERNAL USE ONLY**

ExtUtils::MY is a subclass of ExtUtils::MM. Its provided in your Makefile.PL for you to add and override MakeMaker functionality.

It also provides a convenient alias via the MY class.

ExtUtils::MY might turn out to be a temporary solution, but MY won't go away.

NAME

ExtUtils::Packlist – manage .packlist files

SYNOPSIS

```
use ExtUtils::Packlist;
my ($pl) = ExtUtils::Packlist->new('.packlist');
$pl->read('/an/old/.packlist');
my @missing_files = $pl->validate();
$pl->write('/a/new/.packlist');

$pl->{'/some/file/name'}++;
    or
$pl->{'/some/other/file/name'} = { type => 'file',
                                   from => '/some/file' };
```

DESCRIPTION

ExtUtils::Packlist provides a standard way to manage .packlist files. Functions are provided to read and write .packlist files. The original .packlist format is a simple list of absolute pathnames, one per line. In addition, this package supports an extended format, where as well as a filename each line may contain a list of attributes in the form of a space separated list of key=value pairs. This is used by the installperl script to differentiate between files and links, for example.

USAGE

The hash reference returned by the `new()` function can be used to examine and modify the contents of the .packlist. Items may be added/deleted from the .packlist by modifying the hash. If the value associated with a hash key is a scalar, the entry written to the .packlist by any subsequent `write()` will be a simple filename. If the value is a hash, the entry written will be the filename followed by the key=value pairs from the hash. Reading back the .packlist will recreate the original entries.

FUNCTIONS

`new()`

This takes an optional parameter, the name of a .packlist. If the file exists, it will be opened and the contents of the file will be read. The `new()` method returns a reference to a hash. This hash holds an entry for each line in the .packlist. In the case of old-style .packlists, the value associated with each key is undef. In the case of new-style .packlists, the value associated with each key is a hash containing the key=value pairs following the filename in the .packlist.

`read()`

This takes an optional parameter, the name of the .packlist to be read. If no file is specified, the .packlist specified to `new()` will be read. If the .packlist does not exist, `Carp::croak` will be called.

`write()`

This takes an optional parameter, the name of the .packlist to be written. If no file is specified, the .packlist specified to `new()` will be overwritten.

`validate()`

This checks that every file listed in the .packlist actually exists. If an argument which evaluates to true is given, any missing files will be removed from the internal hash. The return value is a list of the missing files, which will be empty if they all exist.

`packlist_file()`

This returns the name of the associated .packlist file

EXAMPLE

Here's `modrm`, a little utility to cleanly remove an installed module.

```
#!/usr/local/bin/perl -w
```

```

use strict;
use IO::Dir;
use ExtUtils::Packlist;
use ExtUtils::Installed;

sub emptydir($) {
    my ($dir) = @_ ;
    my $dh = IO::Dir->new($dir) || return(0);
    my @count = $dh->read();
    $dh->close();
    return(@count == 2 ? 1 : 0);
}

# Find all the installed packages
print("Finding all installed modules...\n");
my $installed = ExtUtils::Installed->new();

foreach my $module (grep(!/^Perl$/, $installed->modules())) {
    my $version = $installed->version($module) || "???" ;
    print("Found module $module Version $version\n");
    print("Do you want to delete $module? [n] ");
    my $r = <STDIN>; chomp($r);
    if ($r && $r =~ /^y/i) {
        # Remove all the files
        foreach my $file (sort($installed->files($module))) {
            print("rm $file\n");
            unlink($file);
        }
        my $pf = $installed->packlist($module)->packlist_file();
        print("rm $pf\n");
        unlink($pf);
        foreach my $dir (sort($installed->directory_tree($module))) {
            if (emptydir($dir)) {
                print("rmdir $dir\n");
                rmdir($dir);
            }
        }
    }
}

```

NAME

ExtUtils::testlib – add blib/* directories to @INC

SYNOPSIS

```
use ExtUtils::testlib;
```

DESCRIPTION

After an extension has been built and before it is installed it may be desirable to test it bypassing make test. By adding

```
use ExtUtils::testlib;
```

to a test program the intermediate directories used by make are added to @INC.

NAME

Fatal – replace functions with equivalents which succeed or die

SYNOPSIS

```
use Fatal qw(open close);

sub juggle { . . . }

import Fatal 'juggle';
```

DESCRIPTION

Fatal provides a way to conveniently replace functions which normally return a false value when they fail with equivalents which raise exceptions if they are not successful. This lets you use these functions without having to test their return values explicitly on each call. Exceptions can be caught using `eval{}`. See [perlfunc](#) and [perlvar](#) for details.

The do-or-die equivalents are set up simply by calling Fatal's `import` routine, passing it the names of the functions to be replaced. You may wrap both user-defined functions and overridable CORE operators (except `exec`, `system` which cannot be expressed via prototypes) in this way.

If the symbol `:void` appears in the import list, then functions named later in that import list raise an exception only when these are called in void context—that is, when their return values are ignored. For example

```
use Fatal qw/:void open close/;

# properly checked, so no exception raised on error
if(open(FH, "< /bogotic") {
    warn "bogo file, dude: $!";
}

# not checked, so error raises an exception
close FH;
```

NAME

Fcntl – load the C Fcntl.h defines

SYNOPSIS

```
use Fcntl;  
use Fcntl qw(:DEFAULT :flock);
```

DESCRIPTION

This module is just a translation of the C *fcntl.h* file. Unlike the old mechanism of requiring a translated *fcntl.ph* file, this uses the **h2xs** program (see the Perl source distribution) and your native C compiler. This means that it has a far more likely chance of getting the numbers right.

NOTE

Only `#define` symbols get translated; you must still correctly pack up your own arguments to pass as args for locking functions, etc.

EXPORTED SYMBOLS

By default your system's `F_*` and `O_*` constants (eg, `F_DUPFD` and `O_CREAT`) and the `FD_CLOEXEC` constant are exported into your namespace.

You can request that the `flock()` constants (`LOCK_SH`, `LOCK_EX`, `LOCK_NB` and `LOCK_UN`) be provided by using the tag `:flock`. See [Exporter](#).

You can request that the old constants (`FAPPEND`, `FASYNC`, `FCREAT`, `FDEFER`, `FEXCL`, `FNDELAY`, `FNONBLOCK`, `FSYNC`, `FTRUNC`) be provided for compatibility reasons by using the tag `:Fcompat`. For new applications the newer versions of these constants are suggested (`O_APPEND`, `O_ASYNC`, `O_CREAT`, `O_DEFER`, `O_EXCL`, `O_NDELAY`, `O_NONBLOCK`, `O_SYNC`, `O_TRUNC`).

For ease of use also the `SEEK_*` constants (for `seek()` and `sysseek()`, e.g. `SEEK_END`) and the `S_I*` constants (for `chmod()` and `stat()`) are available for import. They can be imported either separately or using the tags `:seek` and `:mode`.

Please refer to your native `fcntl(2)`, `open(2)`, `fseek(3)`, `lseek(2)` (equal to Perl's `seek()` and `sysseek()`, respectively), and `chmod(2)` documentation to see what constants are implemented in your system.

See [perlopentut](#) to learn about the uses of the `O_*` constants with `sysopen()`.

See [seek](#) and [sysseek](#) about the `SEEK_*` constants.

See [stat](#) about the `S_I*` constants.

NAME

fields – compile-time class fields

SYNOPSIS

```
{
    package Foo;
    use fields qw(foo bar _Foo_private);
    sub new {
        my Foo $self = shift;
        unless (ref $self) {
            $self = fields::new($self);
            $self->{_Foo_private} = "this is Foo's secret";
        }
        $self->{foo} = 10;
        $self->{bar} = 20;
        return $self;
    }
}

my Foo $var = Foo::->new;
$var->{foo} = 42;

# this will generate a compile-time error
$var->{zap} = 42;

# subclassing
{
    package Bar;
    use base 'Foo';
    use fields qw(baz _Bar_private);          # not shared with Foo
    sub new {
        my $class = shift;
        my $self = fields::new($class);
        $self->SUPER::new();                  # init base fields
        $self->{baz} = 10;                    # init own fields
        $self->{_Bar_private} = "this is Bar's secret";
        return $self;
    }
}
```

DESCRIPTION

The `fields` pragma enables compile-time verified class fields.

NOTE: The current implementation keeps the declared fields in the `%FIELDS` hash of the calling package, but this may change in future versions. Do **not** update the `%FIELDS` hash directly, because it must be created at compile-time for it to be fully useful, as is done by this pragma.

If a typed lexical variable holding a reference is used to access a hash element and a package with the same name as the type has declared class fields using this pragma, then the operation is turned into an array access at compile time.

The related `base` pragma will combine fields from base classes and any fields declared using the `fields` pragma. This enables field inheritance to work properly.

Field names that start with an underscore character are made private to the class and are not visible to subclasses. Inherited fields can be overridden but will generate a warning if used together with the `-w` switch.

The effect of all this is that you can have objects with named fields which are as compact and as fast arrays to access. This only works as long as the objects are accessed through properly typed variables. If the objects are not typed, access is only checked at run time.

The following functions are supported:

new `fields::new()` creates and blesses a pseudo-hash comprised of the fields declared using the `fields` pragma into the specified class. This makes it possible to write a constructor like this:

```
package Critter::Sounds;
use fields qw(cat dog bird);

sub new {
    my Critter::Sounds $self = shift;
    $self = fields::new($self) unless ref $self;
    $self->{cat} = 'meow';                # scalar element
    @$self{'dog','bird'} = ('bark','tweet'); # slice
    return $self;
}
```

phash `fields::phash()` can be used to create and initialize a plain (unblessed) pseudo-hash. This function should always be used instead of creating pseudo-hashes directly.

If the first argument is a reference to an array, the pseudo-hash will be created with keys from that array. If a second argument is supplied, it must also be a reference to an array whose elements will be used as the values. If the second array contains less elements than the first, the trailing elements of the pseudo-hash will not be initialized. This makes it particularly useful for creating a pseudo-hash from subroutine arguments:

```
sub dogtag {
    my $tag = fields::phash([qw(name rank ser_num)], [ @_ ]);
}
```

`fields::phash()` also accepts a list of key-value pairs that will be used to construct the pseudo hash. Examples:

```
my $tag = fields::phash(name => "Joe",
                        rank => "captain",
                        ser_num => 42);

my $pseudohash = fields::phash(%args);
```

NAME

`fileparse` – split a pathname into pieces

`basename` – extract just the filename from a path

`dirname` – extract just the directory from a path

SYNOPSIS

```
use File::Basename;

($name,$path,$suffix) = fileparse($fullname,@suffixlist);
fileparse_set_fstype($os_string);
$basename = basename($fullname,@suffixlist);
$dirname = dirname($fullname);

($name,$path,$suffix) = fileparse("lib/File/Basename.pm",qr{\.pm});
fileparse_set_fstype("VMS");
$basename = basename("lib/File/Basename.pm",qr{\.pm});
$dirname = dirname("lib/File/Basename.pm");
```

DESCRIPTION

These routines allow you to parse file specifications into useful pieces using the syntax of different operating systems.

`fileparse_set_fstype`

You select the syntax via the routine `fileparse_set_fstype()`.

If the argument passed to it contains one of the substrings "VMS", "MSDOS", "MacOS", "AmigaOS" or "MSWin32", the file specification syntax of that operating system is used in future calls to `fileparse()`, `basename()`, and `dirname()`. If it contains none of these substrings, Unix syntax is used. This pattern matching is case-insensitive. If you've selected VMS syntax, and the file specification you pass to one of these routines contains a "/", they assume you are using Unix emulation and apply the Unix syntax rules instead, for that function call only.

If the argument passed to it contains one of the substrings "VMS", "MSDOS", "MacOS", "AmigaOS", "os2", "MSWin32" or "RISCOS", then the pattern matching for suffix removal is performed without regard for case, since those systems are not case-sensitive when opening existing files (though some of them preserve case on file creation).

If you haven't called `fileparse_set_fstype()`, the syntax is chosen by examining the builtin variable `$^O` according to these rules.

`fileparse`

The `fileparse()` routine divides a file specification into three parts: a leading **path**, a file **name**, and a **suffix**. The **path** contains everything up to and including the last directory separator in the input file specification. The remainder of the input file specification is then divided into **name** and **suffix** based on the optional patterns you specify in `@suffixlist`. Each element of this list can be a `qr`-quoted pattern (or a string which is interpreted as a regular expression), and is matched against the end of **name**. If this succeeds, the matching portion of **name** is removed and prepended to **suffix**. By proper use of `@suffixlist`, you can remove file types or versions for examination.

You are guaranteed that if you concatenate **path**, **name**, and **suffix** together in that order, the result will denote the same file as the input file specification.

EXAMPLES

Using Unix file syntax:

```
($base,$path,$type) = fileparse('/virgil/aeneid/draft.book7',
                                qr{\.book\d+});
```

would yield

```
$base eq 'draft'
$path eq '/virgil/aeneid/',
$type eq '.book7'
```

Similarly, using VMS syntax:

```
($name,$dir,$type) = fileparse('Doc_Root:[Help]Rhetoric.Rnh',
                                qr{\.*});
```

would yield

```
$name eq 'Rhetoric'
$dir  eq 'Doc_Root:[Help]'
$type eq '.Rnh'
```

basename

The `basename()` routine returns the first element of the list produced by calling `fileparse()` with the same arguments, except that it always quotes metacharacters in the given suffixes. It is provided for programmer compatibility with the Unix shell command `basename(1)`.

dirname

The `dirname()` routine returns the directory portion of the input file specification. When using VMS or MacOS syntax, this is identical to the second element of the list produced by calling `fileparse()` with the same input file specification. (Under VMS, if there is no directory information in the input file specification, then the current default device and directory are returned.) When using Unix or MSDOS syntax, the return value conforms to the behavior of the Unix shell command `dirname(1)`. This is usually the same as the behavior of `fileparse()`, but differs in some cases. For example, for the input file specification *lib/*, `fileparse()` considers the directory name to be *lib/*, while `dirname()` considers the directory name to be *.*).

NAME

validate – run many filetest checks on a tree

SYNOPSIS

```
use File::CheckTree;

$num_warnings = validate( q{
    /vmunix          -e || die
    /boot             -e || die
    /bin              cd
        csh           -ex
        csh           !-ug
        sh            -ex
        sh            !-ug
    /usr              -d || warn "What happened to $file?\n"
});
```

DESCRIPTION

The `validate()` routine takes a single multiline string consisting of directives, each containing a filename plus a file test to try on it. (The file test may also be a "cd", causing subsequent relative filenames to be interpreted relative to that directory.) After the file test you may put `|| die` to make it a fatal error if the file test fails. The default is `|| warn`. The file test may optionally have a "!" prepended to test for the opposite condition. If you do a `cd` and then list some relative filenames, you may want to indent them slightly for readability. If you supply your own `die()` or `warn()` message, you can use `$file` to interpolate the filename.

Filetests may be bunched: `"-rwx"` tests for all of `-r`, `-w`, and `-x`. Only the first failed test of the bunch will produce a warning.

The routine returns the number of warnings issued.

AUTHOR

Unknown. Revised by Paul Grassie <grassie@perl.com> in 2002.

HISTORY

`File::CheckTree` used to not display fatal error messages. It used to count only those warnings produced by a generic `|| warn` (and not those in which the user supplied the message). In addition, the `validate()` routine would leave the user program in whatever directory was last entered through the use of "cd" directives. These bugs were fixed during the development of perl 5.8. The first fixed version of `File::CheckTree` was 4.2.

NAME

File::Compare – Compare files or filehandles

SYNOPSIS

```
use File::Compare;

if (compare("file1","file2") == 0) {
    print "They're equal\n";
}
```

DESCRIPTION

The File::Compare::compare function compares the contents of two sources, each of which can be a file or a file handle. It is exported from File::Compare by default.

File::Compare::cmp is a synonym for File::Compare::compare. It is exported from File::Compare only by request.

File::Compare::compare_text does a line by line comparison of the two files. It stops as soon as a difference is detected. compare_text() accepts an optional third argument: This must be a CODE reference to a line comparison function, which returns 0 when both lines are considered equal. For example:

```
compare_text($file1, $file2)
```

is basically equivalent to

```
compare_text($file1, $file2, sub {$_[0] ne $_[1]} )
```

RETURN

File::Compare::compare and its sibling functions return 0 if the files are equal, 1 if the files are unequal, or -1 if an error was encountered.

AUTHOR

File::Compare was written by Nick Ing-Simmons. Its original documentation was written by Chip Salzenberg.

NAME

File::Copy – Copy files or filehandles

SYNOPSIS

```
use File::Copy;

copy("file1", "file2");
copy("Copy.pm", \*STDOUT);
move("/dev1/fileA", "/dev2/fileB");

use POSIX;
use File::Copy cp;

$n = FileHandle->new("/a/file", "r");
cp($n, "x");
```

DESCRIPTION

The File::Copy module provides two basic functions, `copy` and `move`, which are useful for getting the contents of a file from one place to another.

- The `copy` function takes two parameters: a file to copy from and a file to copy to. Either argument may be a string, a FileHandle reference or a FileHandle glob. Obviously, if the first argument is a filehandle of some sort, it will be read from, and if it is a file *name* it will be opened for reading. Likewise, the second argument will be written to (and created if need be). Trying to copy a file on top of itself is a fatal error.

Note that passing in files as handles instead of names may lead to loss of information on some operating systems; it is recommended that you use file names whenever possible. Files are opened in binary mode where applicable. To get a consistent behaviour when copying from a filehandle to a file, use `binmode` on the filehandle.

An optional third parameter can be used to specify the buffer size used for copying. This is the number of bytes from the first file, that will be held in memory at any given time, before being written to the second file. The default buffer size depends upon the file, but will generally be the whole file (up to 2Mb), or 1k for filehandles that do not reference files (eg. sockets).

You may use the syntax `use File::Copy "cp"` to get at the "cp" alias for this function. The syntax is *exactly* the same.

- The `move` function also takes two parameters: the current name and the intended name of the file to be moved. If the destination already exists and is a directory, and the source is not a directory, then the source file will be renamed into the directory specified by the destination.

If possible, `move()` will simply rename the file. Otherwise, it copies the file to the new location and deletes the original. If an error occurs during this copy-and-delete process, you may be left with a (possibly partial) copy of the file under the destination name.

You may use the "mv" alias for this function in the same way that you may use the "cp" alias for `copy`.

File::Copy also provides the `syscopy` routine, which copies the file specified in the first parameter to the file specified in the second parameter, preserving OS-specific attributes and file structure. For Unix systems, this is equivalent to the simple `copy` routine, which doesn't preserve OS-specific attributes. For VMS systems, this calls the `rmscopy` routine (see below). For OS/2 systems, this calls the `syscopy` XSUB directly. For Win32 systems, this calls `Win32::CopyFile`.

On Mac OS (Classic), `syscopy` calls `Mac::MoreFiles::FSpFileCopy`, if available.

Special behaviour if `syscopy` is defined (OS/2, VMS and Win32)

If both arguments to `copy` are not file handles, then `copy` will perform a "system copy" of the input file to a new output file, in order to preserve file attributes, indexed file structure, *etc.* The buffer size parameter is ignored. If either argument to `copy` is a handle to an opened file, then data is copied using Perl operators, and no effort is made to preserve file attributes or record structure.

The system copy routine may also be called directly under VMS and OS/2 as `File::Copy::syscopy` (or under VMS as `File::Copy::rmscopy`, which is the routine that does the actual work for `syscopy`).

`rmscopy($from, $to[, $date_flag])`

The first and second arguments may be strings, typeglobs, typeglob references, or objects inheriting from `IO::Handle`; they are used in all cases to obtain the *filespec* of the input and output files, respectively. The name and type of the input file are used as defaults for the output file, if necessary.

A new version of the output file is always created, which inherits the structure and RMS attributes of the input file, except for owner and protections (and possibly timestamps; see below). All data from the input file is copied to the output file; if either of the first two parameters to `rmscopy` is a file handle, its position is unchanged. (Note that this means a file handle pointing to the output file will be associated with an old version of that file after `rmscopy` returns, not the newly created version.)

The third parameter is an integer flag, which tells `rmscopy` how to handle timestamps. If it is `< 0`, none of the input file's timestamps are propagated to the output file. If it is `> 0`, then it is interpreted as a bitmask: if bit 0 (the LSB) is set, then timestamps other than the revision date are propagated; if bit 1 is set, the revision date is propagated. If the third parameter to `rmscopy` is 0, then it behaves much like the DCL COPY command: if the name or type of the output file was explicitly specified, then no timestamps are propagated, but if they were taken implicitly from the input filespec, then all timestamps other than the revision date are propagated. If this parameter is not supplied, it defaults to 0.

Like `copy`, `rmscopy` returns 1 on success. If an error occurs, it sets `$!`, deletes the output file, and returns 0.

RETURN

All functions return 1 on success, 0 on failure. `$!` will be set if an error was encountered.

NOTES

- On Mac OS (Classic), the path separator is `':'`, not `'/'`, and the current directory is denoted as `':'`, not `'.'`. You should be careful about specifying relative pathnames. While a full path always begins with a volume name, a relative pathname should always begin with a `':'`. If specifying a volume name only, a trailing `':'` is required.

E.g.

```
copy("file1", "tmp");           # creates the file 'tmp' in the current directory
copy("file1", ":tmp:");         # creates :tmp:file1
copy("file1", ":tmp");          # same as above
copy("file1", "tmp");           # same as above, if 'tmp' is a directory (but don't
                                # that, since it may cause confusion, see example
copy("file1", "tmp:file1");     # error, since 'tmp:' is not a volume
copy("file1", ":tmp:file1");    # ok, partial path
copy("file1", "DataHD:");       # creates DataHD:file1

move("MacintoshHD:fileA", "DataHD:fileB"); # moves (don't copies) files from on
                                           # volume to another
```

AUTHOR

File::Copy was written by Aaron Sherman <*ajs@ajs.com*> in 1995, and updated by Charles Bailey <*bailey@newman.upenn.edu*> in 1996.

NAME

File::DosGlob – DOS like globbing and then some

SYNOPSIS

```
require 5.004;

# override CORE::glob in current package
use File::DosGlob 'glob';

# override CORE::glob in ALL packages (use with extreme caution!)
use File::DosGlob 'GLOBAL_glob';

@perlfiles = glob "..\\pe?l/*.p?";
print <..\\pe?l/*.p?>;

# from the command line (overrides only in main::)
> perl -MFile::DosGlob=glob -e "print <../pe*/*p?>"
```

DESCRIPTION

A module that implements DOS-like globbing with a few enhancements. It is largely compatible with `perlglob.exe` (the M\$ `setargv.obj` version) in all but one respect—it understands wildcards in directory components.

For example, `<..\\l*b\\file/*glob.p?>` will work as expected (in that it will find something like `'..\\lib\\File\\DosGlob.pm'` alright). Note that all path components are case-insensitive, and that backslashes and forward slashes are both accepted, and preserved. You may have to double the backslashes if you are putting them in literally, due to double-quotish parsing of the pattern by perl.

Spaces in the argument delimit distinct patterns, so `glob('*.*exe *.dll')` globs all filenames that end in `.exe` or `.dll`. If you want to put in literal spaces in the glob pattern, you can escape them with either double quotes, or backslashes. e.g. `glob('c:/"Program Files"/*/*.dll')`, or `glob('c:/Program\ Files/*/*.dll')`. The argument is tokenized using `Text::ParseWords::parse_line()`, so see [Text::ParseWords](#) for details of the quoting rules used.

Extending it to csh patterns is left as an exercise to the reader.

NOTES

- Mac OS (Classic) users should note a few differences. The specification of pathnames in glob patterns adheres to the usual Mac OS conventions: The path separator is a colon `:`, not a slash `/` or backslash `\`. A full path always begins with a volume name. A relative pathname on Mac OS must always begin with a `:`, except when specifying a file or directory name in the current working directory, where the leading colon is optional. If specifying a volume name only, a trailing `:` is required. Due to these rules, a glob like `<*>` will find all mounted volumes, while a glob like `<*>` or `<:*>` will find all files and directories in the current directory.

Note that updirs in the glob pattern are resolved before the matching begins, i.e. a pattern like `"*HD:t?p::a"` will be matched as `"*HD:a"`. Note also, that a single trailing `:` in the pattern is ignored (unless it's a volume name pattern like `"*HD:"`), i.e. a glob like `<:*>` will find both directories and files (and not, as one might expect, only directories).

The metachars `*`, `?` and the escape char `\` are valid characters in volume, directory and file names on Mac OS. Hence, if you want to match a `*`, `?` or `\` literally, you have to escape these characters. Due to perl's quoting rules, things may get a bit complicated, when you want to match a string like `*` literally, or when you want to match `\` literally, but treat the immediately following character `*` as metachar. So, here's a rule of thumb (applies to both single- and double-quoted strings): escape each `*` or `?` or `\` with a backslash, if you want to treat them literally, and then double each backslash and you are done. E.g.

– Match `*` literally

```
escape both '\ ' and '*' : '\\\\*'
double the backslashes   : '\\\\\\\\*'

```

(Internally, the glob routine sees a '*', which means that both '\ ' and '*' are escaped.)

– Match '\ ' literally, treat '*' as metachar

```
escape '\ ' but not '*'   : '\\\\*'
double the backslashes    : '\\\\\\\\*'

```

(Internally, the glob routine sees a '*', which means that '\ ' is escaped and '*' is not.)

Note that you also have to quote literal spaces in the glob pattern, as described above.

EXPORTS (by request only)

`glob()`

BUGS

Should probably be built into the core, and needs to stop pandering to DOS habits. Needs a dose of optimizium too.

AUTHOR

Gurusamy Sarathy <gsar@activestate.com>

HISTORY

- Support for globally overriding `glob()` (GSAR 3–JUN–98)
- Scalar context, independent iterator context fixes (GSAR 15–SEP–97)
- A few dir-vs-file optimizations result in glob importation being 10 times faster than using `perlglob.exe`, and using `perlglob.bat` is only twice as slow as `perlglob.exe` (GSAR 28–MAY–97)
- Several cleanups prompted by lack of compatible `perlglob.exe` under Borland (GSAR 27–MAY–97)
- Initial version (GSAR 20–FEB–97)

NAME

File::Find – Traverse a directory tree.

SYNOPSIS

```
use File::Find;
find(\&wanted, @directories_to_search);
sub wanted { ... }

use File::Find;
finddepth(\&wanted, @directories_to_search);
sub wanted { ... }

use File::Find;
find({ wanted => \&process, follow => 1 }, '.');
```

DESCRIPTION

These are functions for searching through directory trees doing work on each file found similar to the Unix *find* command. File::Find exports two functions, *find* and *finddepth*. They work similarly but have subtle differences.

find

```
find(\&wanted, @directories);
find(\%options, @directories);
```

find() does a breadth-first search over the given @directories in the order they are given. In essence, it works from the top down.

For each file or directory found the *&wanted* subroutine is called (see below for details). Additionally, for each directory found it will go into that directory and continue the search.

finddepth

```
finddepth(\&wanted, @directories);
finddepth(\%options, @directories);
```

finddepth() works just like *find()* except it does a depth-first search. It works from the bottom of the directory tree up.

%options

The first argument to *find()* is either a hash reference describing the operations to be performed for each file, or a code reference. The code reference is described in [The wanted function](#) below.

Here are the possible keys for the hash:

wanted

The value should be a code reference. This code reference is described in [The wanted function](#) below.

bydepth

Reports the name of a directory only AFTER all its entries have been reported. Entry point *finddepth()* is a shortcut for specifying { *bydepth* => 1 } in the first argument of *find()*.

preprocess

The value should be a code reference. This code reference is used to preprocess the current directory. The name of currently processed directory is in `$File::Find::dir`. Your preprocessing function is called after *readdir()* but before the loop that calls the *wanted()* function. It is called with a list of strings (actually file/directory names) and is expected to return a list of strings. The code can be used to sort the file/directory names alphabetically, numerically, or to filter out directory entries based on their name alone. When *follow* or *follow_fast* are in effect, *preprocess* is a no-op.

postprocess

The value should be a code reference. It is invoked just before leaving the currently processed directory. It is called in void context with no arguments. The name of the current directory is in `$File::Find::dir`. This hook is handy for summarizing a directory, such as calculating its disk usage. When *follow* or *follow_fast* are in effect, *postprocess* is a no-op.

follow

Causes symbolic links to be followed. Since directory trees with symbolic links (followed) may contain files more than once and may even have cycles, a hash has to be built up with an entry for each file. This might be expensive both in space and time for a large directory tree. See *follow_fast* and *follow_skip* below. If either *follow* or *follow_fast* is in effect:

- It is guaranteed that an *lstat* has been called before the user's *wanted()* function is called. This enables fast file checks involving `_`.
- There is a variable `$File::Find::fullname` which holds the absolute pathname of the file with all symbolic links resolved

follow_fast

This is similar to *follow* except that it may report some files more than once. It does detect cycles, however. Since only symbolic links have to be hashed, this is much cheaper both in space and time. If processing a file more than once (by the user's *wanted()* function) is worse than just taking time, the option *follow* should be used.

follow_skip

`follow_skip=1`, which is the default, causes all files which are neither directories nor symbolic links to be ignored if they are about to be processed a second time. If a directory or a symbolic link are about to be processed a second time, `File::Find` dies. `follow_skip==0` causes `File::Find` to die if any file is about to be processed a second time. `follow_skip==2` causes `File::Find` to ignore any duplicate files and directories but to proceed normally otherwise.

dangling_symlinks

If true and a code reference, will be called with the symbolic link name and the directory it lives in as arguments. Otherwise, if true and warnings are on, warning "symbolic_link_name is a dangling symbolic link\n" will be issued. If false, the dangling symbolic link will be silently ignored.

no_chdir

Does not `chdir()` to each directory as it recurses. The *wanted()* function will need to be aware of this, of course. In this case, `$_` will be the same as `$File::Find::name`.

untaint

If *find* is used in taint-mode (`-T` command line switch or if `EUID != UID` or if `EGID != GID`) then internally directory names have to be untainted before they can be `chdir`'ed to. Therefore they are checked against a regular expression *untaint_pattern*. Note that all names passed to the user's *wanted()* function are still tainted. If this option is used while not in taint-mode, *untaint* is a no-op.

untaint_pattern

See above. This should be set using the `qr` quoting operator. The default is set to `qr|^([-+@\\w. /] +) $|`. Note that the parentheses are vital.

untaint_skip

If set, a directory which fails the *untaint_pattern* is skipped, including all its sub-directories. The default is to 'die' in such a case.

The wanted function

The `wanted()` function does whatever verifications you want on each file and directory. It takes no arguments but rather does its work through a collection of variables.

`$File::Find::dir` is the current directory name,

`$_` is the current filename within that directory

`$File::Find::name` is the complete pathname to the file.

Don't modify these variables.

For example, when examining the file `/some/path/foo.ext` you will have:

```
$File::Find::dir = /some/path/
$_              = foo.ext
$File::Find::name = /some/path/foo.ext
```

You are `chdir()`d to `$File::Find::dir` when the function is called, unless `no_chdir` was specified. Note that when changing to directories is in effect the root directory (`/`) is a somewhat special case inasmuch as the concatenation of `$File::Find::dir`, `'/'` and `$_` is not literally equal to `$File::Find::name`. The table below summarizes all variants:

	<code>\$File::Find::name</code>	<code>\$File::Find::dir</code>	<code>\$_</code>
default	<code>/</code>	<code>/</code>	<code>.</code>
<code>no_chdir=>0</code>	<code>/etc</code> <code>/etc/x</code>	<code>/</code> <code>/etc</code>	<code>etc</code> <code>x</code>
<code>no_chdir=>1</code>	<code>/</code> <code>/etc</code> <code>/etc/x</code>	<code>/</code> <code>/</code> <code>/etc</code>	<code>/</code> <code>/etc</code> <code>/etc/x</code>

When `<follow` or `<follow_fast` are in effect, there is also a `$File::Find::fullname`. The function may set `$File::Find::prune` to prune the tree unless `bydepth` was specified. Unless `follow` or `follow_fast` is specified, for compatibility reasons (`find.pl`, `find2perl`) there are in addition the following globals available: `$File::Find::topdir`, `$File::Find::topdev`, `$File::Find::topino`, `$File::Find::topmode` and `$File::Find::topnlink`.

This library is useful for the `find2perl` tool, which when fed,

```
find2perl / -name .nfs\* -mtime +7 \
    -exec rm -f {} \; -o -fstype nfs -prune
```

produces something like:

```
sub wanted {
    /^\.nfs.*\z/s &&
    (($dev, $ino, $mode, $nlink, $uid, $gid) = lstat($_)) &&
    int(-M _) > 7 &&
    unlink($_)
    ||
    ($nlink || (($dev, $ino, $mode, $nlink, $uid, $gid) = lstat($_)) &&
    $dev < 0 &&
    ($File::Find::prune = 1);
}
```

Notice the `_` in the above `int(-M _)`: the `_` is a magical filehandle that caches the information from the preceding `stat()`, `lstat()`, or `filetest`.

Here's another interesting wanted function. It will find all symbolic links that don't resolve:

```
sub wanted {
    -l && !-e && print "bogus link: $File::Find::name\n";
}
```

```
}
```

See also the script `pfind` on CPAN for a nice application of this module.

WARNINGS

If you run your program with the `-w` switch, or if you use the `warnings` pragma, `File::Find` will report warnings for several weird situations. You can disable these warnings by putting the statement

```
no warnings 'File::Find';
```

in the appropriate scope. See [perllexwarn](#) for more info about lexical warnings.

CAVEAT

`$dont_use_nlink`

You can set the variable `$File::Find::dont_use_nlink` to 1, if you want to force `File::Find` to always stat directories. This was used for file systems that do not have an `nlink` count matching the number of sub-directories. Examples are ISO-9660 (CD-ROM), AFS, HPFS (OS/2 file system), FAT (DOS file system) and a couple of others.

You shouldn't need to set this variable, since `File::Find` should now detect such file systems on-the-fly and switch itself to using `stat`. This works even for parts of your file system, like a mounted CD-ROM.

If you do set `$File::Find::dont_use_nlink` to 1, you will notice slow-downs.

symlinks

Be aware that the option to follow symbolic links can be dangerous. Depending on the structure of the directory tree (including symbolic links to directories) you might traverse a given (physical) directory more than once (only if `follow_fast` is in effect). Furthermore, deleting or changing files in a symbolically linked directory might cause very unpleasant surprises, since you delete or change files in an unknown directory.

NOTES

- Mac OS (Classic) users should note a few differences:
 - The path separator is `':'`, not `'/'`, and the current directory is denoted as `':'`, not `'.'`. You should be careful about specifying relative pathnames. While a full path always begins with a volume name, a relative pathname should always begin with a `':'`. If specifying a volume name only, a trailing `':'` is required.
 - `$File::Find::dir` is guaranteed to end with a `':'`. If `$_` contains the name of a directory, that name may or may not end with a `':'`. Likewise, `$File::Find::name`, which contains the complete pathname to that directory, and `$File::Find::fullname`, which holds the absolute pathname of that directory with all symbolic links resolved, may or may not end with a `':'`.
 - The default `untaint_pattern` (see above) on Mac OS is set to `qr|^(.+)$|`. Note that the parentheses are vital.
 - The invisible system file "Icon\015" is ignored. While this file may appear in every directory, there are some more invisible system files on every volume, which are all located at the volume root level (i.e. "MacintoshHD:"). These system files are **not** excluded automatically. Your filter may use the following code to recognize invisible files or directories (requires `Mac::Files`):

```
use Mac::Files;

# invisible() -- returns 1 if file/directory is invisible,
# 0 if it's visible or undef if an error occurred

sub invisible($) {
    my $file = shift;
    my ($fileCat, $fileInfo);
```

```
my $invisible_flag = 1 << 14;

if ( $fileCat = FSpGetCatInfo($file) ) {
    if ($fileInfo = $fileCat->ioFlFndrInfo() ) {
        return (($fileInfo->fdFlags & $invisible_flag) && 1);
    }
}
return undef;
}
```

Generally, invisible files are system files, unless an odd application decides to use invisible files for its own purposes. To distinguish such files from system files, you have to look at the **type** and **creator** file attributes. The MacPerl built-in functions `GetFileInfo(FILE)` and `SetFileInfo(CREATOR, TYPE, FILES)` offer access to these attributes (see `MacPerl.pm` for details).

Files that appear on the desktop actually reside in an (hidden) directory named "Desktop Folder" on the particular disk volume. Note that, although all desktop files appear to be on the same "virtual" desktop, each disk volume actually maintains its own "Desktop Folder" directory.

HISTORY

`File::Find` used to produce incorrect results if called recursively. During the development of perl 5.8 this bug was fixed. The first fixed version of `File::Find` was 1.01.

NAME

File::Glob – Perl extension for BSD glob routine

SYNOPSIS

```
use File::Glob ':glob';
@list = bsd_glob('*. [ch]');
$homedir = bsd_glob('~gnat', GLOB_TILDE | GLOB_ERR);
if (GLOB_ERROR) {
    # an error occurred reading $homedir
}

## override the core glob (CORE::glob() does this automatically
## by default anyway, since v5.6.0)
use File::Glob ':globally';
my @sources = <*. {c,h,y}>

## override the core glob, forcing case sensitivity
use File::Glob qw(:globally :case);
my @sources = <*. {c,h,y}>

## override the core glob forcing case insensitivity
use File::Glob qw(:globally :nocase);
my @sources = <*. {c,h,y}>
```

DESCRIPTION

File::Glob::bsd_glob() implements the FreeBSD glob(3) routine, which is a superset of the POSIX glob() (described in IEEE Std 1003.2 "POSIX.2"). bsd_glob() takes a mandatory pattern argument, and an optional flags argument, and returns a list of filenames matching the pattern, with interpretation of the pattern modified by the flags variable.

Since v5.6.0, Perl's CORE::glob() is implemented in terms of bsd_glob(). Note that they don't share the same prototype—CORE::glob() only accepts a single argument. Due to historical reasons, CORE::glob() will also split its argument on whitespace, treating it as multiple patterns, whereas bsd_glob() considers them as one pattern.

The POSIX defined flags for bsd_glob() are:

GLOB_ERR

Force bsd_glob() to return an error when it encounters a directory it cannot open or read. Ordinarily bsd_glob() continues to find matches.

GLOB_LIMIT

Make bsd_glob() return an error (GLOB_NOSPACE) when the pattern expands to a size bigger than the system constant ARG_MAX (usually found in limits.h). If your system does not define this constant, bsd_glob() uses sysconf(_SC_ARG_MAX) or _POSIX_ARG_MAX where available (in that order). You can inspect these values using the standard POSIX extension.

GLOB_MARK

Each pathname that is a directory that matches the pattern has a slash appended.

GLOB_NOCASE

By default, file names are assumed to be case sensitive; this flag makes bsd_glob() treat case differences as not significant.

GLOB_NOCHECK

If the pattern does not match any pathname, then bsd_glob() returns a list consisting of only the pattern. If GLOB_QUOTE is set, its effect is present in the pattern returned.

GLOB_NOSORT

By default, the pathnames are sorted in ascending ASCII order; this flag prevents that sorting (speeding up `bsd_glob()`).

The FreeBSD extensions to the POSIX standard are the following flags:

GLOB_BRACE

Pre-process the string to expand `{pat,pat,...}` strings like `csh(1)`. The pattern `'{'` is left unexpanded for historical reasons (and `csh(1)` does the same thing to ease typing of `find(1)` patterns).

GLOB_NOMAGIC

Same as **GLOB_NOCHECK** but it only returns the pattern if it does not contain any of the special characters `"*`, `"?"` or `"["`. **NOMAGIC** is provided to simplify implementing the historic `csh(1)` globbing behaviour and should probably not be used anywhere else.

GLOB_QUOTE

Use the backslash (`'\'`) character for quoting: every occurrence of a backslash followed by a character in the pattern is replaced by that character, avoiding any special interpretation of the character. (But see below for exceptions on DOSISH systems).

GLOB_TILDE

Expand patterns that start with `'~'` to user name home directories.

GLOB_CSH

For convenience, **GLOB_CSH** is a synonym for **GLOB_BRACE** | **GLOB_NOMAGIC** | **GLOB_QUOTE** | **GLOB_TILDE** | **GLOB_ALPHASORT**.

The POSIX provided **GLOB_APPEND**, **GLOB_DOOFFS**, and the FreeBSD extensions **GLOB_ALTDIRFUNC**, and **GLOB_MAGCHAR** flags have not been implemented in the Perl version because they involve more complex interaction with the underlying C structures.

The following flag has been added in the Perl implementation for `csh` compatibility:

GLOB_ALPHASORT

If **GLOB_NOSORT** is not in effect, sort filenames in alphabetical order (case does not matter) rather than in ASCII order.

DIAGNOSTICS

`bsd_glob()` returns a list of matching paths, possibly zero length. If an error occurred, `&File::Glob::GLOB_ERROR` will be non-zero and `$!` will be set. `&File::Glob::GLOB_ERROR` is guaranteed to be zero if no error occurred, or one of the following values otherwise:

GLOB_NOSPACE

An attempt to allocate memory failed.

GLOB_ABEND

The glob was stopped because an error was encountered.

In the case where `bsd_glob()` has found some matching paths, but is interrupted by an error, it will return a list of filenames **and** set `&File::Glob::ERROR`.

Note that `bsd_glob()` deviates from POSIX and FreeBSD `glob(3)` behaviour by not considering `ENOENT` and `ENOTDIR` as errors – `bsd_glob()` will continue processing despite those errors, unless the **GLOB_ERR** flag is set.

Be aware that all filenames returned from `File::Glob` are tainted.

NOTES

- If you want to use multiple patterns, e.g. `bsd_glob "a* b*"`, you should probably throw them in a set as in `bsd_glob "{a*,b*}"`. This is because the argument to `bsd_glob()` isn't subjected to parsing by the C shell. Remember that you can use a backslash to escape things.
- On DOSISH systems, backslash is a valid directory separator character. In this case, use of backslash as a quoting character (via `GLOB_QUOTE`) interferes with the use of backslash as a directory separator. The best (simplest, most portable) solution is to use forward slashes for directory separators, and backslashes for quoting. However, this does not match "normal practice" on these systems. As a concession to user expectation, therefore, backslashes (under `GLOB_QUOTE`) only quote the glob metacharacters `['', ']', '{', '}', '-', '~'`, and backslash itself. All other backslashes are passed through unchanged.
- Win32 users should use the real slash. If you really want to use backslashes, consider using Sarathy's `File::DosGlob`, which comes with the standard Perl distribution.
- Mac OS (Classic) users should note a few differences. Since Mac OS is not Unix, when the glob code encounters a tilde glob (e.g. `~user`) and the `GLOB_TILDE` flag is used, it simply returns that pattern without doing any expansion.

Glob on Mac OS is case-insensitive by default (if you don't use any flags). If you specify any flags at all and still want glob to be case-insensitive, you must include `GLOB_NOCASE` in the flags.

The path separator is `':'` (aka colon), not `'/'` (aka slash). Mac OS users should be careful about specifying relative pathnames. While a full path always begins with a volume name, a relative pathname should always begin with a `':'`. If specifying a volume name only, a trailing `':'` is required.

The specification of pathnames in glob patterns adheres to the usual Mac OS conventions: The path separator is a colon `':'`, not a slash `'/'`. A full path always begins with a volume name. A relative pathname on Mac OS must always begin with a `':'`, except when specifying a file or directory name in the current working directory, where the leading colon is optional. If specifying a volume name only, a trailing `':'` is required. Due to these rules, a glob like `<*:>` will find all mounted volumes, while a glob like `<*>` or `<:*>` will find all files and directories in the current directory.

Note that updirs in the glob pattern are resolved before the matching begins, i.e. a pattern like `"*HD:t?p::a*"` will be matched as `"*HD:a*"`. Note also, that a single trailing `':'` in the pattern is ignored (unless it's a volume name pattern like `"*HD:"`), i.e. a glob like `<*:*>` will find both directories *and* files (and not, as one might expect, only directories). You can, however, use the `GLOB_MARK` flag to distinguish (without a file test) directory names from file names.

If the `GLOB_MARK` flag is set, all directory paths will have a `':'` appended. Since a directory like `'lib:'` is *not* a valid *relative* path on Mac OS, both a leading and a trailing colon will be added, when the directory name in question doesn't contain any colons (e.g. `'lib'` becomes `':lib:'`).

NAME

File::Path – create or remove directory trees

SYNOPSIS

```
use File::Path;

mkpath(['foo/bar/baz', 'blurfl/quux'], 1, 0711);
rmtree(['foo/bar/baz', 'blurfl/quux'], 1, 1);
```

DESCRIPTION

The `mkpath` function provides a convenient way to create directories, even if your `mkdir` kernel call won't create more than one level of directory at a time. `mkpath` takes three arguments:

- the name of the path to create, or a reference to a list of paths to create,
- a boolean value, which if `TRUE` will cause `mkpath` to print the name of each directory as it is created (defaults to `FALSE`), and
- the numeric mode to use when creating the directories (defaults to `0777`)

It returns a list of all directories (including intermediates, determined using the Unix `'/'` separator) created.

If a system error prevents a directory from being created, then the `mkpath` function throws a fatal error with `Carp::croak`. This error can be trapped with an `eval` block:

```
eval { mkpath($dir) };
if ($@) {
    print "Couldn't create $dir: $@";
}
```

Similarly, the `rmtree` function provides a convenient way to delete a subtree from the directory structure, much like the Unix command `rm -r`. `rmtree` takes three arguments:

- the root of the subtree to delete, or a reference to a list of roots. All of the files and directories below each root, as well as the roots themselves, will be deleted.
- a boolean value, which if `TRUE` will cause `rmtree` to print a message each time it examines a file, giving the name of the file, and indicating whether it's using `rmdir` or `unlink` to remove it, or that it's skipping it. (defaults to `FALSE`)
- a boolean value, which if `TRUE` will cause `rmtree` to skip any files to which you do not have delete access (if running under VMS) or write access (if running under another OS). This will change in the future when a criterion for 'delete permission' under OSs other than VMS is settled. (defaults to `FALSE`)

It returns the number of files successfully deleted. Symlinks are simply deleted and not followed.

NOTE: If the third parameter is not `TRUE`, `rmtree` is **unsecure** in the face of failure or interruption. Files and directories which were not deleted may be left with permissions reset to allow world read and write access. Note also that the occurrence of errors in `rmtree` can be determined *only* by trapping diagnostic messages using `$SIG{__WARN__}`; it is not apparent from the return value. Therefore, you must be extremely careful about using `rmtree($foo, $bar, 0` in situations where security is an issue.

NAME

File::Spec – portably perform operations on file names

SYNOPSIS

```
use File::Spec;

$x=File::Spec->catfile('a', 'b', 'c');
```

which returns 'a/b/c' under Unix. Or:

```
use File::Spec::Functions;

$x = catfile('a', 'b', 'c');
```

DESCRIPTION

This module is designed to support operations commonly performed on file specifications (usually called "file names", but not to be confused with the contents of a file, or Perl's file handles), such as concatenating several directory and file names into a single path, or determining whether a path is rooted. It is based on code directly taken from MakeMaker 5.17, code written by Andreas König, Andy Dougherty, Charles Bailey, Ilya Zakharevich, Paul Schinder, and others.

Since these functions are different for most operating systems, each set of OS specific routines is available in a separate module, including:

```
File::Spec::Unix
File::Spec::Mac
File::Spec::OS2
File::Spec::Win32
File::Spec::VMS
```

The module appropriate for the current OS is automatically loaded by File::Spec. Since some modules (like VMS) make use of facilities available only under that OS, it may not be possible to load all modules under all operating systems.

Since File::Spec is object oriented, subroutines should not be called directly, as in:

```
File::Spec::catfile('a', 'b');
```

but rather as class methods:

```
File::Spec->catfile('a', 'b');
```

For simple uses, *File::Spec::Functions* provides convenient functional forms of these methods.

METHODS

canonpath

No physical check on the filesystem, but a logical cleanup of a path.

```
$cpath = File::Spec->canonpath( $path );
```

catdir

Concatenate two or more directory names to form a complete path ending with a directory. But remove the trailing slash from the resulting string, because it doesn't look good, isn't necessary and confuses OS2. Of course, if this is the root directory, don't cut off the trailing slash :-)

```
$path = File::Spec->catdir( @directories );
```

catfile

Concatenate one or more directory names and a filename to form a complete path ending with a filename

```
$path = File::Spec->catfile( @directories, $filename );
```

curdir

Returns a string representation of the current directory.

```
$curdir = File::Spec->curdir();
```

devnull

Returns a string representation of the null device.

```
$devnull = File::Spec->devnull();
```

rootdir

Returns a string representation of the root directory.

```
$rootdir = File::Spec->rootdir();
```

tmpdir

Returns a string representation of the first writable directory from a list of possible temporary directories. Returns "" if no writable temporary directories are found. The list of directories checked depends on the platform; e.g. `File::Spec::Unix` checks `$ENV{TMPDIR}` and `/tmp`.

```
$tmpdir = File::Spec->tmpdir();
```

updir

Returns a string representation of the parent directory.

```
$updir = File::Spec->updir();
```

no_upwards

Given a list of file names, strip out those that refer to a parent directory. (Does not strip symlinks, only `'.'`, `'..'`, and equivalents.)

```
@paths = File::Spec->no_upwards( @paths );
```

case_tolerant

Returns a true or false value indicating, respectively, that alphabetic is not or is significant when comparing file specifications.

```
$is_case_tolerant = File::Spec->case_tolerant();
```

file_name_is_absolute

Takes as argument a path and returns true if it is an absolute path.

```
$is_absolute = File::Spec->file_name_is_absolute( $path );
```

This does not consult the local filesystem on Unix, Win32, OS/2, or Mac OS (Classic). It does consult the working environment for VMS (see [File::Spec::VMS/file_name_is_absolute](#)).

path

Takes no argument, returns the environment variable `PATH` as an array.

```
@PATH = File::Spec->path();
```

join

join is the same as `catfile`.

splitpath

Splits a path in to volume, directory, and filename portions. On systems with no concept of volume, returns undef for volume.

```
($volume,$directories,$file) = File::Spec->splitpath( $path );  
($volume,$directories,$file) = File::Spec->splitpath( $path, $no_file );
```

For systems with no syntax differentiating filenames from directories, assumes that the last file is a path unless `$no_file` is true or a trailing separator or `/.` or `./.` is present. On Unix this means that `$no_file` true makes this return (`"", $path, ""`).

The directory portion may or may not be returned with a trailing `'/'`.

The results can be passed to `/catpath()` to get back a path equivalent to (usually identical to) the original path.

splitdir

The opposite of `/catdir()`.

```
@dirs = File::Spec->splitdir( $directories );
```

`$directories` must be only the directory portion of the path on systems that have the concept of a volume or that have path syntax that differentiates files from directories.

Unlike just splitting the directories on the separator, empty directory names (`' '`) can be returned, because these are significant on some OSs.

catpath()

Takes volume, directory and file portions and returns an entire path. Under Unix, `$volume` is ignored, and directory and file are catenated. A `'/'` is inserted if need be. On other OSs, `$volume` is significant.

```
$full_path = File::Spec->catpath( $volume, $directory, $file );
```

abs2rel

Takes a destination path and an optional base path returns a relative path from the base path to the destination path:

```
$rel_path = File::Spec->abs2rel( $path ) ;
$rel_path = File::Spec->abs2rel( $path, $base ) ;
```

If `$base` is not present or `"`, then `cwd()` | Cwd is used. If `$base` is relative, then it is converted to absolute form using `/rel2abs()`. This means that it is taken to be relative to `cwd()` | Cwd.

On systems with the concept of a volume, this assumes that both paths are on the `$destination` volume, and ignores the `$base` volume.

On systems that have a grammar that indicates filenames, this ignores the `$base` filename as well. Otherwise all path components are assumed to be directories.

If `$path` is relative, it is converted to absolute form using `/rel2abs()`. This means that it is taken to be relative to `cwd()` | Cwd.

No checks against the filesystem are made. On VMS, there is interaction with the working environment, as logicals and macros are expanded.

Based on code written by Shigio Yamaguchi.

rel2abs()

Converts a relative path to an absolute path.

```
$abs_path = File::Spec->rel2abs( $path ) ;
$abs_path = File::Spec->rel2abs( $path, $base ) ;
```

If `$base` is not present or `"`, then `cwd()` | Cwd is used. If `$base` is relative, then it is converted to absolute form using `/rel2abs()`. This means that it is taken to be relative to `cwd()` | Cwd.

On systems with the concept of a volume, this assumes that both paths are on the `$base` volume, and ignores the `$path` volume.

On systems that have a grammar that indicates filenames, this ignores the `$base` filename as well. Otherwise all path components are assumed to be directories.

If `$path` is absolute, it is cleaned up and returned using `/canonpath()`.

No checks against the filesystem are made. On VMS, there is interaction with the working environment, as logicals and macros are expanded.

Based on code written by Shigio Yamaguchi.

NAME

File::Spec::Cygwin – methods for Cygwin file specs

SYNOPSIS

```
require File::Spec::Cygwin; # Done internally by File::Spec if needed
```

DESCRIPTION

See File::Spec::Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

This module is still in beta. Cygwin-knowledgeable folks are invited to offer patches and suggestions.

NAME

File::Spec::Epoc – methods for Epoc file specs

SYNOPSIS

```
require File::Spec::Epoc; # Done internally by File::Spec if needed
```

DESCRIPTION

See File::Spec::Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

This package is still work in progress ;-) o.flebbe@gmx.de

```
sub case_tolerant {  
    return 1;  
}
```

```
canonpath()
```

No physical check on the filesystem, but a logical cleanup of a path. On UNIX eliminated successive slashes and successive "/.".

NAME

File::Spec::Functions – portably perform operations on file names

SYNOPSIS

```
use File::Spec::Functions;
$x = catfile('a', 'b');
```

DESCRIPTION

This module exports convenience functions for all of the class methods provided by File::Spec.

For a reference of available functions, please consult [File::Spec::Unix](#), which contains the entire set, and which is inherited by the modules for other platforms. For further information, please see [File::Spec::Mac](#), [File::Spec::OS2](#), [File::Spec::Win32](#), or [File::Spec::VMS](#).

Exports

The following functions are exported by default.

```
canonpath
catdir
catfile
curdir
rootdir
updir
no_upwards
file_name_is_absolute
path
```

The following functions are exported only by request.

```
devnull
tmpdir
splitpath
splitdir
catpath
abs2rel
rel2abs
```

All the functions may be imported using the `:ALL` tag.

NAME

File::Spec::Mac – File::Spec for Mac OS (Classic)

SYNOPSIS

```
require File::Spec::Mac; # Done internally by File::Spec if needed
```

DESCRIPTION

Methods for manipulating file specifications.

METHODS**canonpath**

On Mac OS, there's nothing to be done. Returns what it's given.

catdir()

Concatenate two or more directory names to form a path separated by colons (":") ending with a directory. Resulting paths are **relative** by default, but can be forced to be absolute (but avoid this, see below). Automatically puts a trailing ":" on the end of the complete path, because that's what's done in MacPerl's environment and helps to distinguish a file path from a directory path.

IMPORTANT NOTE: Beginning with version 1.3 of this module, the resulting path is relative by default and *not* absolute. This decision was made due to portability reasons. Since `File::Spec->catdir()` returns relative paths on all other operating systems, it will now also follow this convention on Mac OS. Note that this may break some existing scripts.

The intended purpose of this routine is to concatenate *directory names*. But because of the nature of Macintosh paths, some additional possibilities are allowed to make using this routine give reasonable results for some common situations. In other words, you are also allowed to concatenate *paths* instead of directory names (strictly speaking, a string like ":a" is a path, but not a name, since it contains a punctuation character ":").

So, beside calls like

```
catdir("a") = ":a:"
catdir("a","b") = ":a:b:"
catdir() = ""                (special case)
```

calls like the following

```
catdir(":a:") = ":a:"
catdir(":a","b") = ":a:b:"
catdir(":a:", "b") = ":a:b:"
catdir(":a:", ":b:") = ":a:b:"
catdir(":") = ":"
```

are allowed.

Here are the rules that are used in `catdir()`; note that we try to be as compatible as possible to Unix:

1. The resulting path is relative by default, i.e. the resulting path will have a leading colon.
2. A trailing colon is added automatically to the resulting path, to denote a directory.
3. Generally, each argument has one leading ":" and one trailing ":" removed (if any). They are then joined together by a ":". Special treatment applies for arguments denoting updir paths like "::lib:", see (4), or arguments consisting solely of colons ("colon paths"), see (5).

4.

When an updir path like ":::lib::" is passed as argument, the number of directories to climb up is handled correctly, not removing leading or trailing colons when necessary. E.g.

```
catdir(":::a", ":::b", "c")    = ":::a::b:c:"
catdir(":::a::", ":::b", "c")  = ":::a:::b:c:"
```

5.

Adding a colon ":" or empty string "" to a path at *any* position doesn't alter the path, i.e. these arguments are ignored. (When a "" is passed as the first argument, it has a special meaning, see (6)). This way, a colon ":" is handled like a "." (curdir) on Unix, while an empty string "" is generally ignored (see `Unix->canonpath()`). Likewise, a "::" is handled like a ".." (updir), and a ":::" is handled like a ".../" etc. E.g.

```
catdir("a", ":", ":", "b")     = ":a:b:"
catdir("a", ":", ":", "b")    = ":a::b:"
```

6.

If the first argument is an empty string "" or is a volume name, i.e. matches the pattern `/^[^:]+/`, the resulting path is **absolute**.

7.

Passing an empty string "" as the first argument to `catdir()` is like passing `File::Spec->rootdir()` as the first argument, i.e.

```
catdir("", "a", "b")           is the same as
catdir(rootdir(), "a", "b").
```

This is true on Unix, where `catdir("", "a", "b")` yields `/a/b` and `rootdir()` is `/`. Note that `rootdir()` on Mac OS is the startup volume, which is the closest in concept to Unix' `/`. This should help to run existing scripts originally written for Unix.

8.

For absolute paths, some cleanup is done, to ensure that the volume name isn't immediately followed by updirs. This is invalid, because this would go beyond "root". Generally, these cases are handled like their Unix counterparts:

Unix:

```
Unix->catdir("", "")           = "/"
Unix->catdir("", ".")          = "/"
Unix->catdir("", "..")         = "/" # can't go beyond root
Unix->catdir("", ".", "..", "..", "a") = "/a"
```

Mac:

```
Mac->catdir("", "")           = rootdir()      # (e.g. "HD:")
Mac->catdir("", ":")          = rootdir()
Mac->catdir("", "::")          = rootdir()      # can't go beyond root
Mac->catdir("", ":", ":", "a") = rootdir() . "a:" # (e.g. "HD:a:")
```

However, this approach is limited to the first arguments following "root" (again, see `Unix->canonpath()`). If there are more arguments that move up the directory tree, an invalid path going beyond root can be created.

As you've seen, you can force `catdir()` to create an absolute path by passing either an empty string or a path that begins with a volume name as the first argument. However, you are strongly encouraged not to do so, since this is done only for backward compatibility. Newer versions of `File::Spec` come with a method called `catpath()` (see below), that is designed to offer a portable solution for the creation of absolute paths. It takes volume, directory and file portions and returns an entire path. While `catdir()` is still suitable for the concatenation of *directory names*, you are encouraged to use `catpath()` to

concatenate *volume names* and *directory paths*. E.g.

```
$dir      = File::Spec->catdir("tmp", "sources");
$abs_path = File::Spec->catpath("MacintoshHD:", $dir, "");
```

yields

```
"MacintoshHD:tmp:sources:" .
```

catfile

Concatenate one or more directory names and a filename to form a complete path ending with a filename. Resulting paths are **relative** by default, but can be forced to be absolute (but avoid this).

IMPORTANT NOTE: Beginning with version 1.3 of this module, the resulting path is relative by default and *not* absolute. This decision was made due to portability reasons. Since `File::Spec->catfile()` returns relative paths on all other operating systems, it will now also follow this convention on Mac OS. Note that this may break some existing scripts.

The last argument is always considered to be the file portion. Since `catfile()` uses `catdir()` (see above) for the concatenation of the directory portions (if any), the following with regard to relative and absolute paths is true:

```
catfile("")      = ""
catfile("file") = "file"
```

but

```
catfile("", "")      = rootdir()      # (e.g. "HD:")
catfile("", "file")  = rootdir() . file # (e.g. "HD:file")
catfile("HD:", "file") = "HD:file"
```

This means that `catdir()` is called only when there are two or more arguments, as one might expect.

Note that the leading ":" is removed from the filename, so that

```
catfile("a", "b", "file") = ":a:b:file"    and
catfile("a", "b", ":file") = ":a:b:file"
```

give the same answer.

To concatenate *volume names*, *directory paths* and *filenames*, you are encouraged to use `catpath()` (see below).

curdir

Returns a string representing the current directory. On Mac OS, this is ":".

devnull

Returns a string representing the null device. On Mac OS, this is "Dev:Null".

rootdir

Returns a string representing the root directory. Under MacPerl, returns the name of the startup volume, since that's the closest in concept, although other volumes aren't rooted there. The name has a trailing ":", because that's the correct specification for a volume name on Mac OS.

If `Mac::Files` could not be loaded, the empty string is returned.

tmpdir

Returns the contents of `$ENV{TMPDIR}`, if that directory exists or the current working directory otherwise. Under MacPerl, `$ENV{TMPDIR}` will contain a path like "MacintoshHD:Temporary Items:", which is a hidden directory on your startup volume.

updir

Returns a string representing the parent directory. On Mac OS, this is ":".

file_name_is_absolute

Takes as argument a path and returns true, if it is an absolute path. If the path has a leading ":", it's a relative path. Otherwise, it's an absolute path, unless the path doesn't contain any colons, i.e. it's a name like "a". In this particular case, the path is considered to be relative (i.e. it is considered to be a filename). Use ":" in the appropriate place in the path if you want to distinguish unambiguously. As a special case, the filename "" is always considered to be absolute. Note that with version 1.2 of File::Spec::Mac, this does no longer consult the local filesystem.

E.g.

```
File::Spec->file_name_is_absolute("a");           # false (relative)
File::Spec->file_name_is_absolute(":a:b:");       # false (relative)
File::Spec->file_name_is_absolute("MacintoshHD:"); # true (absolute)
File::Spec->file_name_is_absolute("");           # true (absolute)
```

path

Returns the null list for the MacPerl application, since the concept is usually meaningless under Mac OS. But if you're using the MacPerl tool under MPW, it gives back \$ENV{Commands} suitably split, as is done in :lib:ExtUtils:MM_Mac.pm.

splitpath

```
($volume,$directories,$file) = File::Spec->splitpath( $path );
($volume,$directories,$file) = File::Spec->splitpath( $path, $no_file );
```

Splits a path in to volume, directory, and filename portions.

On Mac OS, assumes that the last part of the path is a filename unless \$no_file is true or a trailing separator ":" is present.

The volume portion is always returned with a trailing ":". The directory portion is always returned with a leading (to denote a relative path) and a trailing ":" (to denote a directory). The file portion is always returned *without* a leading ":". Empty portions are returned as empty string "".

The results can be passed to catpath() to get back a path equivalent to (usually identical to) the original path.

splitdir

The opposite of catdir().

```
@dirs = File::Spec->splitdir( $directories );
```

\$directories should be only the directory portion of the path on systems that have the concept of a volume or that have path syntax that differentiates files from directories. Consider using splitpath() otherwise.

Unlike just splitting the directories on the separator, empty directory names ("") can be returned. Since catdir() on Mac OS always appends a trailing colon to distinguish a directory path from a file path, a single trailing colon will be ignored, i.e. there's no empty directory name after it.

Hence, on Mac OS, both

```
File::Spec->splitdir( ":a:b::c:" );    and
File::Spec->splitdir( ":a:b::c" );
```

yield:

```
( "a", "b", ":", "c")
```

while

```
File::Spec->splitdir( ":a:b::c:" );
```

yields:

```
( "a", "b", ":", "c", ":")
```

catpath

```
$path = File::Spec->catpath($volume,$directory,$file);
```

Takes volume, directory and file portions and returns an entire path. On Mac OS, \$volume, \$directory and \$file are concatenated. A ‘.’ is inserted if need be. You may pass an empty string for each portion. If all portions are empty, the empty string is returned. If \$volume is empty, the result will be a relative path, beginning with a ‘.’. If \$volume and \$directory are empty, a leading ":" (if any) is removed from \$file and the remainder is returned. If \$file is empty, the resulting path will have a trailing ‘.’.

abs2rel

Takes a destination path and an optional base path and returns a relative path from the base path to the destination path:

```
$rel_path = File::Spec->abs2rel( $path ) ;
$rel_path = File::Spec->abs2rel( $path, $base ) ;
```

Note that both paths are assumed to have a notation that distinguishes a directory path (with trailing ‘.’) from a file path (without trailing ‘.’).

If \$base is not present or ‘’, then the current working directory is used. If \$base is relative, then it is converted to absolute form using `rel2abs()`. This means that it is taken to be relative to the current working directory.

Since Mac OS has the concept of volumes, this assumes that both paths are on the \$destination volume, and ignores the \$base volume (!).

If \$base doesn’t have a trailing colon, the last element of \$base is assumed to be a filename. This filename is ignored (!). Otherwise all path components are assumed to be directories.

If \$path is relative, it is converted to absolute form using `rel2abs()`. This means that it is taken to be relative to the current working directory.

Based on code written by Shigio Yamaguchi.

rel2abs

Converts a relative path to an absolute path:

```
$abs_path = File::Spec->rel2abs( $path ) ;
$abs_path = File::Spec->rel2abs( $path, $base ) ;
```

Note that both paths are assumed to have a notation that distinguishes a directory path (with trailing ‘.’) from a file path (without trailing ‘.’).

If \$base is not present or ‘’, then \$base is set to the current working directory. If \$base is relative, then it is converted to absolute form using `rel2abs()`. This means that it is taken to be relative to the current working directory.

If \$base doesn’t have a trailing colon, the last element of \$base is assumed to be a filename. This filename is ignored (!). Otherwise all path components are assumed to be directories.

If \$path is already absolute, it is returned and \$base is ignored.

Based on code written by Shigio Yamaguchi.

AUTHORS

See the authors list in *File::Spec*. Mac OS support by Paul Schinder <schinder@pobox.com> and Thomas Wegner <wegner_thomas@yahoo.com>.

SEE ALSO

File::Spec

canonpath

No physical check on the filesystem, but a logical cleanup of a path. On UNIX eliminated successive slashes and successive "/".

splitpath

```
($volume,$directories,$file) = File::Spec->splitpath( $path );
($volume,$directories,$file) = File::Spec->splitpath( $path, $no_file );
```

Splits a path in to volume, directory, and filename portions. Assumes that the last file is a path unless the path ends in '/', './', or '..' or `$no_file` is true. On Win32 this means that `$no_file` true makes this return (`$volume, $path, undef`).

Separators accepted are \ and /.

Volumes can be drive letters or UNC sharenames (\\server\share).

The results can be passed to [/catpath](#) to get back a path equivalent to (usually identical to) the original path.

splitdir

The opposite of [catdir\(\)](#).

```
@dirs = File::Spec->splitdir( $directories );
```

`$directories` must be only the directory portion of the path on systems that have the concept of a volume or that have path syntax that differentiates files from directories.

Unlike just splitting the directories on the separator, leading empty and trailing directory entries can be returned, because these are significant on some OSs. So,

```
File::Spec->splitdir( "/a/b//c/" );
```

Yields:

```
( '', 'a', 'b', '', 'c', '' )
```

catpath

Takes volume, directory and file portions and returns an entire path. Under Unix, `$volume` is ignored, and this is just like `catfile()`. On other OSs, the `$volume` become significant.

NAME

File::Spec::OS2 – methods for OS/2 file specs

SYNOPSIS

```
require File::Spec::OS2; # Done internally by File::Spec if needed
```

DESCRIPTION

See `File::Spec::Unix` for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

NAME

File::Spec::Unix – File::Spec for Unix, base for other File::Spec modules

SYNOPSIS

```
require File::Spec::Unix; # Done automatically by File::Spec
```

DESCRIPTION

Methods for manipulating file specifications. Other File::Spec modules, such as File::Spec::Mac, inherit from File::Spec::Unix and override specific methods.

METHODS

`canonpath()`

No physical check on the filesystem, but a logical cleanup of a path. On UNIX eliminates successive slashes and successive `"/."`.

```
$cpath = File::Spec->canonpath( $path ) ;
```

`catdir()`

Concatenate two or more directory names to form a complete path ending with a directory. But remove the trailing slash from the resulting string, because it doesn't look good, isn't necessary and confuses OS2. Of course, if this is the root directory, don't cut off the trailing slash :-)

`catfile`

Concatenate one or more directory names and a filename to form a complete path ending with a filename

`curdir`

Returns a string representation of the current directory. `"/."` on UNIX.

`devnull`

Returns a string representation of the null device. `"/dev/null"` on UNIX.

`rootdir`

Returns a string representation of the root directory. `"/"` on UNIX.

`tmpdir`

Returns a string representation of the first writable directory from the following list or `""` if none are writable:

```
$ENV{TMPDIR}  
/tmp
```

Since perl 5.8.0, if running under taint mode, and if `$ENV{TMPDIR}` is tainted, it is not used.

`updir`

Returns a string representation of the parent directory. `"/.."` on UNIX.

`no_upwards`

Given a list of file names, strip out those that refer to a parent directory. (Does not strip symlinks, only `'.'`, `'..'`, and equivalents.)

`case_tolerant`

Returns a true or false value indicating, respectively, that alphabetic is not or is significant when comparing file specifications.

`file_name_is_absolute`

Takes as argument a path and returns true if it is an absolute path.

This does not consult the local filesystem on Unix, Win32, OS/2 or Mac OS (Classic). It does consult the working environment for VMS (see [File::Spec::VMS/file_name_is_absolute](#)).

path

Takes no argument, returns the environment variable `PATH` as an array.

join

`join` is the same as `catfile`.

splitpath

```
($volume,$directories,$file) = File::Spec->splitpath( $path );
($volume,$directories,$file) = File::Spec->splitpath( $path, $no_file );
```

Splits a path in to volume, directory, and filename portions. On systems with no concept of volume, returns `undef` for volume.

For systems with no syntax differentiating filenames from directories, assumes that the last file is a path unless `$no_file` is true or a trailing separator or `/.` or `./.` is present. On Unix this means that `$no_file` true makes this return `("", $path, "")`.

The directory portion may or may not be returned with a trailing `'/'`.

The results can be passed to `/catpath()` to get back a path equivalent to (usually identical to) the original path.

splitdir

The opposite of `/catdir()`.

```
@dirs = File::Spec->splitdir( $directories );
```

`$directories` must be only the directory portion of the path on systems that have the concept of a volume or that have path syntax that differentiates files from directories.

Unlike just splitting the directories on the separator, empty directory names `('')` can be returned, because these are significant on some OSs.

On Unix,

```
File::Spec->splitdir( "/a/b//c/" );
```

Yields:

```
( '', 'a', 'b', '', 'c', '' )
```

catpath()

Takes volume, directory and file portions and returns an entire path. Under Unix, `$volume` is ignored, and directory and file are catenated. A `'/'` is inserted if needed (though if the directory portion doesn't start with `'/'` it is not added). On other OSs, `$volume` is significant.

abs2rel

Takes a destination path and an optional base path returns a relative path from the base path to the destination path:

```
$rel_path = File::Spec->abs2rel( $path );
$rel_path = File::Spec->abs2rel( $path, $base );
```

If `$base` is not present or `""`, then `cwd()` | `Cwd` is used. If `$base` is relative, then it is converted to absolute form using `/rel2abs()`. This means that it is taken to be relative to `cwd()` | `Cwd`.

On systems with the concept of a volume, this assumes that both paths are on the `$destination` volume, and ignores the `$base` volume.

On systems that have a grammar that indicates filenames, this ignores the `$base` filename as well. Otherwise all path components are assumed to be directories.

If `$path` is relative, it is converted to absolute form using `/rel2abs()`. This means that it is taken to

be relative to [cwd\(\)](#) | Cwd.

No checks against the filesystem are made. On VMS, there is interaction with the working environment, as logicals and macros are expanded.

Based on code written by Shigio Yamaguchi.

`rel2abs()`

Converts a relative path to an absolute path.

```
$abs_path = File::Spec->rel2abs( $path ) ;  
$abs_path = File::Spec->rel2abs( $path, $base ) ;
```

If `$base` is not present or `''`, then [cwd\(\)](#) | Cwd is used. If `$base` is relative, then it is converted to absolute form using [/rel2abs\(\)](#). This means that it is taken to be relative to [cwd\(\)](#) | Cwd.

On systems with the concept of a volume, this assumes that both paths are on the `$base` volume, and ignores the `$path` volume.

On systems that have a grammar that indicates filenames, this ignores the `$base` filename as well. Otherwise all path components are assumed to be directories.

If `$path` is absolute, it is cleaned up and returned using [/canonpath\(\)](#).

No checks against the filesystem are made. On VMS, there is interaction with the working environment, as logicals and macros are expanded.

Based on code written by Shigio Yamaguchi.

NAME

File::Spec::VMS – methods for VMS file specs

SYNOPSIS

```
require File::Spec::VMS; # Done internally by File::Spec if needed
```

DESCRIPTION

See File::Spec::Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

eliminate_macros

Expands MM[KS]/Make macros in a text string, using the contents of identically named elements of `$_$self`, and returns the result as a file specification in Unix syntax.

fixpath

Catchall routine to clean up problem MM[SK]/Make macros. Expands macros in any directory specification, in order to avoid juxtaposing two VMS-syntax directories when MM[SK] is run. Also expands expressions which are all macro, so that we can tell how long the expansion is, and avoid overrunning DCL's command buffer when MM[KS] is running.

If optional second argument has a TRUE value, then the return string is a VMS-syntax directory specification, if it is FALSE, the return string is a VMS-syntax file specification, and if it is not specified, `fixpath()` checks to see whether it matches the name of a directory in the current default directory, and returns a directory or file specification accordingly.

Methods always loaded**canonpath (override)**

Removes redundant portions of file specifications according to VMS syntax.

catdir

Concatenates a list of file specifications, and returns the result as a VMS-syntax directory specification. No check is made for "impossible" cases (e.g. elements other than the first being absolute filespecs).

catfile

Concatenates a list of file specifications, and returns the result as a VMS-syntax file specification.

curdir (override)

Returns a string representation of the current directory: `[']`

devnull (override)

Returns a string representation of the null device: `['_NLA0:']`

rootdir (override)

Returns a string representation of the root directory: `['SYS$DISK: [000000]']`

tmpdir (override)

Returns a string representation of the first writable directory from the following list or `''` if none are writable:

```
sys$scratch:
$ENV{TMPDIR}
```

Since perl 5.8.0, if running under taint mode, and if `$ENV{TMPDIR}` is tainted, it is not used.

updir (override)

Returns a string representation of the parent directory: `['-']`

`case_tolerant` (override)

VMS file specification syntax is case-tolerant.

`path` (override)

Translate logical name `DCL$PATH` as a searchlist, rather than trying to `split` string value of `$ENV{ 'PATH' }`.

`file_name_is_absolute` (override)

Checks for VMS directory spec as well as Unix separators.

`splitpath` (override)

Splits using VMS syntax.

`splitdir` (override)

Split dirs spec using VMS syntax.

`catpath` (override)

Construct a complete filespec using VMS syntax

`abs2rel` (override)

Use VMS syntax when converting filespecs.

`rel2abs` (override)

Use VMS syntax when converting filespecs.

[File::Spec](#)

NAME

File::Spec::Win32 – methods for Win32 file specs

SYNOPSIS

```
require File::Spec::Win32; # Done internally by File::Spec if needed
```

DESCRIPTION

See File::Spec::Unix for a documentation of the methods provided there. This package overrides the implementation of these methods, not the semantics.

devnull

Returns a string representation of the null device.

tmpdir

Returns a string representation of the first existing directory from the following list:

```
$ENV{TMPDIR}
$ENV{TEMP}
$ENV{TMP}
SYS:/temp
C:/temp
/tmp
/
```

The SYS:/temp is preferred in Novell NetWare.

Since Perl 5.8.0, if running under taint mode, and if the environment variables are tainted, they are not used.

catfile

Concatenate one or more directory names and a filename to form a complete path ending with a filename

canonpath

No physical check on the filesystem, but a logical cleanup of a path. On UNIX eliminated successive slashes and successive "/.".

splitpath

```
($volume,$directories,$file) = File::Spec->splitpath( $path );
($volume,$directories,$file) = File::Spec->splitpath( $path, $no_file );
```

Splits a path in to volume, directory, and filename portions. Assumes that the last file is a path unless the path ends in '\\', '\\.', '\\..' or \$no_file is true. On Win32 this means that \$no_file true makes this return (\$volume, \$path, undef).

Separators accepted are \ and /.

Volumes can be drive letters or UNC sharenames (\\server\share).

The results can be passed to [/catpath](#) to get back a path equivalent to (usually identical to) the original path.

splitdir

The opposite of [catdir\(\)](#).

```
@dirs = File::Spec->splitdir( $directories );
```

\$directories must be only the directory portion of the path on systems that have the concept of a volume or that have path syntax that differentiates files from directories.

Unlike just splitting the directories on the separator, leading empty and trailing directory entries can

be returned, because these are significant on some OSs. So,

```
File::Spec->splitdir( "/a/b/c" );
```

Yields:

```
( ' ', 'a', 'b', ' ', 'c', ' ' )
```

`catpath`

Takes volume, directory and file portions and returns an entire path. Under Unix, `$volume` is ignored, and this is just like `catfile()`. On other OSs, the `$volume` become significant.

Note For File::Spec::Win32 Maintainers

Novell NetWare inherits its `File::Spec` behaviour from `File::Spec::Win32`.

NAME

File::stat – by-name interface to Perl's built-in `stat()` functions

SYNOPSIS

```
use File::stat;
$st = stat($file) or die "No $file: $!";
if ( ($st->mode & 0111) && $st->nlink > 1 ) {
    print "$file is executable with lotsa links\n";
}

use File::stat qw(:FIELDS);
stat($file) or die "No $file: $!";
if ( ($st_mode & 0111) && $st_nlink > 1 ) {
    print "$file is executable with lotsa links\n";
}
```

DESCRIPTION

This module's default exports override the core `stat()` and `lstat()` functions, replacing them with versions that return "File::stat" objects. This object has methods that return the similarly named structure field name from the `stat(2)` function; namely, `dev`, `ino`, `mode`, `nlink`, `uid`, `gid`, `rdev`, `size`, `atime`, `mtime`, `ctime`, `blksize`, and `blocks`.

You may also import all the structure fields directly into your namespace as regular variables using the `:FIELDS` import tag. (Note that this still overrides your `stat()` and `lstat()` functions.) Access these fields as variables named with a preceding `st_` in front their method names. Thus, `$stat_obj->dev()` corresponds to `$st_dev` if you import the fields.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. On the other hand, the built-ins are still available via the `CORE::pseudo-package`.

BUGS

As of Perl 5.8.0 after using this module you cannot use the implicit `$_` or the special filehandle `_` with `stat()` or `lstat()`, trying to do so leads into strange errors. The workaround is for `$_` to be explicit

```
my $stat_obj = stat $_;
```

and for `_` to explicitly populate the object using the unexported and undocumented `populate()` function with `CORE::stat()`:

```
my $stat_obj = File::stat::populate(CORE::stat(_));
```

NOTE

While this class is currently implemented using the `Class::Struct` module to build a struct-like class, you shouldn't rely upon this.

Tom Christiansen

NAME

File::Temp – return name and handle of a temporary file safely

=begin __INTERNALS

PORTABILITY

This module is designed to be portable across operating systems and it currently supports Unix, VMS, DOS, OS/2, Windows and Mac OS (Classic). When porting to a new OS there are generally three main issues that have to be solved:

- Can the OS unlink an open file? If it can not then the `_can_unlink_opened_file` method should be modified.
- Are the return values from `stat` reliable? By default all the return values from `stat` are compared when unlinking a temporary file using the filename and the handle. Operating systems other than unix do not always have valid entries in all fields. If `unlink0` fails then the `stat` comparison should be modified accordingly.
- Security. Systems that can not support a test for the sticky bit on a directory can not use the MEDIUM and HIGH security tests. The `_can_do_level` method should be modified accordingly.

=end __INTERNALS

SYNOPSIS

```
use File::Temp qw/ tempfile tempdir /;

$dir = tempdir( CLEANUP => 1 );
($fh, $filename) = tempfile( DIR => $dir );

($fh, $filename) = tempfile( $template, DIR => $dir );
($fh, $filename) = tempfile( $template, SUFFIX => '.dat' );

$fh = tempfile();
```

MkTemp family:

```
use File::Temp qw/ :mktemp /;

($fh, $file) = mkstemp( "tmpfileXXXXXX" );
($fh, $file) = mkstemp( "tmpfileXXXXXX", $suffix );

$tmpdir = mkdtemp( $template );

$unopened_file = mktemp( $template );
```

POSIX functions:

```
use File::Temp qw/ :POSIX /;

$file = tmpnam();
$fh = tmpfile();

($fh, $file) = tmpnam();
($fh, $file) = tmpfile();
```

Compatibility functions:

```
$unopened_file = File::Temp::tempnam( $dir, $pfx );
```

=begin later

Objects (NOT YET IMPLEMENTED):

```
require File::Temp;
```

```
$fh = new File::Temp($template);
$fname = $fh->filename;

=end later
```

DESCRIPTION

`File::Temp` can be used to create and open temporary files in a safe way. The `tempfile()` function can be used to return the name and the open filehandle of a temporary file. The `tmpdir()` function can be used to create a temporary directory.

The security aspect of temporary file creation is emphasized such that a filehandle and filename are returned together. This helps guarantee that a race condition can not occur where the temporary file is created by another process between checking for the existence of the file and its opening. Additional security levels are provided to check, for example, that the sticky bit is set on world writable directories. See *"safe_level"* for more information.

For compatibility with popular C library functions, Perl implementations of the `mkstemp()` family of functions are provided. These are, `mkstemp()`, `mkstemps()`, `mkdtemp()` and `mktemp()`.

Additionally, implementations of the standard *POSIX/POSIX* `tmpnam()` and `tmpfile()` functions are provided if required.

Implementations of `mktemp()`, `tmpnam()`, and `tempnam()` are provided, but should be used with caution since they return only a filename that was valid when function was called, so cannot guarantee that the file will not exist by the time the caller opens the filename.

FUNCTIONS

This section describes the recommended interface for generating temporary files and directories.

tempfile

This is the basic function to generate temporary files. The behaviour of the file can be changed using various options:

```
($fh, $filename) = tempfile();
```

Create a temporary file in the directory specified for temporary files, as specified by the `tmpdir()` function in *File::Spec*.

```
($fh, $filename) = tempfile($template);
```

Create a temporary file in the current directory using the supplied template. Trailing 'X' characters are replaced with random letters to generate the filename. At least four 'X' characters must be present in the template.

```
($fh, $filename) = tempfile($template, SUFFIX => $suffix)
```

Same as previously, except that a suffix is added to the template after the 'X' translation. Useful for ensuring that a temporary filename has a particular extension when needed by other applications. But see the WARNING at the end.

```
($fh, $filename) = tempfile($template, DIR => $dir);
```

Translates the template as before except that a directory name is specified.

```
($fh, $filename) = tempfile($template, UNLINK => 1);
```

Return the filename and filehandle as before except that the file is automatically removed when the program exits. Default is for the file to be removed if a file handle is requested and to be kept if the filename is requested. In a scalar context (where no filename is returned) the file is always deleted either on exit or when it is closed.

If the template is not specified, a template is always automatically generated. This temporary file is placed in `tmpdir()` (*File::Spec*) unless a directory is specified explicitly with the `DIR` option.

```
$fh = tempfile( $template, DIR => $dir );
```

If called in scalar context, only the filehandle is returned and the file will automatically be deleted when closed (see the description of `tempfile()` elsewhere in this document). This is the preferred mode of operation, as if you only have a filehandle, you can never create a race condition by fumbling with the filename. On systems that can not unlink an open file or can not mark a file as temporary when it is opened (for example, Windows NT uses the `O_TEMPORARY` flag)) the file is marked for deletion when the program ends (equivalent to setting `UNLINK` to 1). The `UNLINK` flag is ignored if present.

```
(undef, $filename) = tempfile($template, OPEN => 0);
```

This will return the filename based on the template but will not open this file. Cannot be used in conjunction with `UNLINK` set to true. Default is to always open the file to protect from possible race conditions. A warning is issued if warnings are turned on. Consider using the `tmpnam()` and `mktemp()` functions described elsewhere in this document if opening the file is not required.

Options can be combined as required.

tmpdir

This is the recommended interface for creation of temporary directories. The behaviour of the function depends on the arguments:

```
$tmpdir = tmpdir();
```

Create a directory in `tmpdir()` (see [File::Spec/File::Spec](#)).

```
$tmpdir = tmpdir( $template );
```

Create a directory from the supplied template. This template is similar to that described for `tempfile()`. 'X' characters at the end of the template are replaced with random letters to construct the directory name. At least four 'X' characters must be in the template.

```
$tmpdir = tmpdir ( DIR => $dir );
```

Specifies the directory to use for the temporary directory. The temporary directory name is derived from an internal template.

```
$tmpdir = tmpdir ( $template, DIR => $dir );
```

Prepend the supplied directory name to the template. The template should not include parent directory specifications itself. Any parent directory specifications are removed from the template before prepending the supplied directory.

```
$tmpdir = tmpdir ( $template, TMPDIR => 1 );
```

Using the supplied template, create the temporary directory in a standard location for temporary files. Equivalent to doing

```
$tmpdir = tmpdir ( $template, DIR => File::Spec->tmpdir);
```

but shorter. Parent directory specifications are stripped from the template itself. The `TMPDIR` option is ignored if `DIR` is set explicitly. Additionally, `TMPDIR` is implied if neither a template nor a directory are supplied.

```
$tmpdir = tmpdir( $template, CLEANUP => 1);
```

Create a temporary directory using the supplied template, but attempt to remove it (and all files inside it) when the program exits. Note that an attempt will be made to remove all files from the directory even if they were not created by this module (otherwise why ask to clean it up?). The directory removal is made with the `rmtree()` function from the [File::Path/File::Path](#) module. Of course, if the template is not specified, the temporary directory will be created in `tmpdir()` and will also be removed at program exit.

MKTEMP FUNCTIONS

The following functions are Perl implementations of the `mktemp()` family of temp file generation system calls.

mkstemp

Given a template, returns a filehandle to the temporary file and the name of the file.

```
($fh, $name) = mkstemp( $template );
```

In scalar context, just the filehandle is returned.

The template may be any filename with some number of X's appended to it, for example */tmp/temp.XXXX*. The trailing X's are replaced with unique alphanumeric combinations.

mkstemps

Similar to `mkstemp()`, except that an extra argument can be supplied with a suffix to be appended to the template.

```
($fh, $name) = mkstemps( $template, $suffix );
```

For example a template of `testXXXXXX` and suffix of `.dat` would generate a file similar to *testhGji_w.dat*.

Returns just the filehandle alone when called in scalar context.

mkdtemp

Create a directory from a template. The template must end in X's that are replaced by the routine.

```
$tmpdir_name = mkdtemp($template);
```

Returns the name of the temporary directory created. Returns undef on failure.

Directory must be removed by the caller.

mktemp

Returns a valid temporary filename but does not guarantee that the file will not be opened by someone else.

```
$unopened_file = mktemp($template);
```

Template is the same as that required by `mkstemp()`.

POSIX FUNCTIONS

This section describes the re-implementation of the `tmpnam()` and `tmpfile()` functions described in [POSIX](#) using the `mkstemp()` from this module.

Unlike the [POSIX/POSIX](#) implementations, the directory used for the temporary file is not specified in a system include file (`P_tmpdir`) but simply depends on the choice of `tmpdir()` returned by [File::Spec/File::Spec](#). On some implementations this location can be set using the `TMPDIR` environment variable, which may not be secure. If this is a problem, simply use `mkstemp()` and specify a template.

tmpnam

When called in scalar context, returns the full name (including path) of a temporary file (uses `mktemp()`). The only check is that the file does not already exist, but there is no guarantee that that condition will continue to apply.

```
$file = tmpnam();
```

When called in list context, a filehandle to the open file and a filename are returned. This is achieved by calling `mkstemp()` after constructing a suitable template.

```
($fh, $file) = tmpnam();
```

If possible, this form should be used to prevent possible race conditions.

See [File::Spec/tmpdir](#) for information on the choice of temporary directory for a particular operating system.

tmpfile

In scalar context, returns the filehandle of a temporary file.

```
$fh = tmpfile();
```

The file is removed when the filehandle is closed or when the program exits. No access to the filename is provided.

If the temporary file can not be created undef is returned. Currently this command will probably not work when the temporary directory is on an NFS file system.

ADDITIONAL FUNCTIONS

These functions are provided for backwards compatibility with common tempfile generation C library functions.

They are not exported and must be addressed using the full package name.

tempnam

Return the name of a temporary file in the specified directory using a prefix. The file is guaranteed not to exist at the time the function was called, but such guarantees are good for one clock tick only. Always use the proper form of `sysopen` with `O_CREAT | O_EXCL` if you must open such a filename.

```
$filename = File::Temp::tempnam( $dir, $prefix );
```

Equivalent to running `mktemp()` with `$dir/$prefixXXXXXXXX` (using unix file convention as an example)

Because this function uses `mktemp()`, it can suffer from race conditions.

UTILITY FUNCTIONS

Useful functions for dealing with the filehandle and filename.

unlink0

Given an open filehandle and the associated filename, make a safe unlink. This is achieved by first checking that the filename and filehandle initially point to the same file and that the number of links to the file is 1 (all fields returned by `stat()` are compared). Then the filename is unlinked and the filehandle checked once again to verify that the number of links on that file is now 0. This is the closest you can come to making sure that the filename unlinked was the same as the file whose descriptor you hold.

```
unlink0($fh, $path) or die "Error unlinking file $path safely";
```

Returns false on error. The filehandle is not closed since on some occasions this is not required.

On some platforms, for example Windows NT, it is not possible to unlink an open file (the file must be closed first). On those platforms, the actual unlinking is deferred until the program ends and good status is returned. A check is still performed to make sure that the filehandle and filename are pointing to the same thing (but not at the time the end block is executed since the deferred removal may not have access to the filehandle).

Additionally, on Windows NT not all the fields returned by `stat()` can be compared. For example, the `dev` and `rdev` fields seem to be different. Also, it seems that the size of the file returned by `stat()` does not always agree, with `stat(FH)` being more accurate than `stat(filename)`, presumably because of caching issues even when using `autoflush` (this is usually overcome by waiting a while after writing to the tempfile before attempting to `unlink0` it).

Finally, on NFS file systems the link count of the file handle does not always go to zero immediately after unlinking. Currently, this command is expected to fail on NFS disks.

PACKAGE VARIABLES

These functions control the global state of the package.

safe_level

Controls the lengths to which the module will go to check the safety of the temporary file or directory before proceeding. Options are:

STANDARD

Do the basic security measures to ensure the directory exists and is writable, that the `umask()` is fixed before opening of the file, that temporary files are opened only if they do not already exist, and that possible race conditions are avoided. Finally the `unlink0/unlink0` function is used to remove files safely.

MEDIUM In addition to the STANDARD security, the output directory is checked to make sure that it is owned either by root or the user running the program. If the directory is writable by group or by other, it is then checked to make sure that the sticky bit is set.

Will not work on platforms that do not support the `-k` test for sticky bit.

HIGH In addition to the MEDIUM security checks, also check for the possibility of ```chown()` giveaway'' using the *POSIX/POSIX* `sysconf()` function. If this is a possibility, each directory in the path is checked in turn for safeness, recursively walking back to the root directory.

For platforms that do not support the *POSIX/POSIX* `_PC_CHOWN_RESTRICTED` symbol (for example, Windows NT) it is assumed that ```chown()` giveaway'' is possible and the recursive test is performed.

The level can be changed as follows:

```
File::Temp->safe_level( File::Temp::HIGH );
```

The level constants are not exported by the module.

Currently, you must be running at least perl v5.6.0 in order to run with MEDIUM or HIGH security. This is simply because the safety tests use functions from *Fcntl/Fcntl* that are not available in older versions of perl. The problem is that the version number for Fcntl is the same in perl 5.6.0 and in 5.005_03 even though they are different versions.

On systems that do not support the HIGH or MEDIUM safety levels (for example Win NT or OS/2) any attempt to change the level will be ignored. The decision to ignore rather than raise an exception allows portable programs to be written with high security in mind for the systems that can support this without those programs failing on systems where the extra tests are irrelevant.

If you really need to see whether the change has been accepted simply examine the return value of `safe_level`.

```
$newlevel = File::Temp->safe_level( File::Temp::HIGH );
die "Could not change to high security"
    if $newlevel != File::Temp::HIGH;
```

TopSystemUID

This is the highest UID on the current system that refers to a root UID. This is used to make sure that the temporary directory is owned by a system UID (`root`, `bin`, `sys` etc) rather than simply by root.

This is required since on many unix systems `/tmp` is not owned by root.

Default is to assume that any UID less than or equal to 10 is a root UID.

```
File::Temp->top_system_uid(10);  
my $topid = File::Temp->top_system_uid;
```

This value can be adjusted to reduce security checking if required. The value is only relevant when `safe_level` is set to `MEDIUM` or higher.

WARNING

For maximum security, endeavour always to avoid ever looking at, touching, or even imputing the existence of the filename. You do not know that that filename is connected to the same file as the handle you have, and attempts to check this can only trigger more race conditions. It's far more secure to use the filehandle alone and dispense with the filename altogether.

If you need to pass the handle to something that expects a filename then, on a unix system, use `"/dev/fd/" . fileno($fh)` for arbitrary programs, or more generally `< "+<=&" . fileno($fh)` for Perl programs. You will have to clear the close-on-exec bit on that file descriptor before passing it to another process.

```
use Fcntl qw/F_SETFD F_GETFD/;  
fcntl($tmpfh, F_SETFD, 0)  
    or die "Can't clear close-on-exec flag on temp fh: $!\n";
```

Temporary files and NFS

Some problems are associated with using temporary files that reside on NFS file systems and it is recommended that a local filesystem is used whenever possible. Some of the security tests will most probably fail when the temp file is not local. Additionally, be aware that the performance of I/O operations over NFS will not be as good as for a local disk.

HISTORY

Originally began life in May 1999 as an XS interface to the system `mkstemp()` function. In March 2000, the OpenBSD `mkstemp()` code was translated to Perl for total control of the code's security checking, to ensure the presence of the function regardless of operating system and to help with portability.

SEE ALSO

NAME

FileCache – keep more files open than the system permits

SYNOPSIS

```
use FileCache;
# or
use FileCache maxopen => 16;

cacheout $path;
print $path @data;

cacheout $mode, $path;
print $path @data;
```

DESCRIPTION

The `cacheout` function will make sure that there's a filehandle open for reading or writing available as the pathname you give it. It automatically closes and re-opens files if you exceed your system's maximum number of file descriptors, or the suggested maximum.

`cacheout` *EXPR*

The 1-argument form of `cacheout` will open a file for writing (`< ''`) on it's first use, and appending (`<< ''`) thereafter.

`cacheout` *MODE*, *EXPR*

The 2-argument form of `cacheout` will use the supplied mode for the initial and subsequent openings. Most valid modes for 3-argument `open` are supported namely; `< ''`, `< '+'`, `< '<'`, `< '<+'`, `<< ''`, `'|-'` and `'-|'`

CAVEATS

If you use `cacheout` with `'|-'` or `'-|'` you should catch `SIGPIPE` and explicitly close the filehandle., when it is closed from the other end some cleanup needs to be done.

While it is permissible to close a FileCache managed file, do not do so if you are calling `FileCache::cacheout` from a package other than which it was imported, or with another module which overrides `close`. If you must, use `FileCache::cacheout_close`.

BUGS

sys/param.h lies with its `NOFILE` define on some systems, so you may have to set `maxopen` (`$FileCache::cacheout_maxopen`) yourself.

NAME

FileHandle – supply object methods for filehandles

SYNOPSIS

```
use FileHandle;

$fh = new FileHandle;
if ($fh->open("< file")) {
    print <$fh>;
    $fh->close;
}

$fh = new FileHandle "> FOO";
if (defined $fh) {
    print $fh "bar\n";
    $fh->close;
}

$fh = new FileHandle "file", "r";
if (defined $fh) {
    print <$fh>;
    undef $fh;          # automatically closes the file
}

$fh = new FileHandle "file", O_WRONLY|O_APPEND;
if (defined $fh) {
    print $fh "corge\n";
    undef $fh;          # automatically closes the file
}

$pos = $fh->getpos;
$fh->setpos($pos);

$fh->setvbuf($buffer_var, _IOLBF, 1024);

($readfh, $writefh) = FileHandle::pipe;

autoflush STDOUT 1;
```

DESCRIPTION

NOTE: This class is now a front-end to the IO::* classes.

`FileHandle::new` creates a `FileHandle`, which is a reference to a newly created symbol (see the `Symbol` package). If it receives any parameters, they are passed to `FileHandle::open`; if the open fails, the `FileHandle` object is destroyed. Otherwise, it is returned to the caller.

`FileHandle::new_from_fd` creates a `FileHandle` like `new` does. It requires two parameters, which are passed to `FileHandle::fdopen`; if the `fdopen` fails, the `FileHandle` object is destroyed. Otherwise, it is returned to the caller.

`FileHandle::open` accepts one parameter or two. With one parameter, it is just a front end for the built-in `open` function. With two parameters, the first parameter is a filename that may include whitespace or other special characters, and the second parameter is the open mode, optionally followed by a file permission value.

If `FileHandle::open` receives a Perl mode string ("`"`", "`+`<", etc.) or a POSIX `fopen()` mode string ("`w`", "`r+`", etc.), it uses the basic Perl `open` operator.

If `FileHandle::open` is given a numeric mode, it passes that mode and the optional permissions value to the Perl `sysopen` operator. For convenience, `FileHandle::import` tries to import the `O_XXX` constants from the `Fcntl` module. If dynamic loading is not available, this may fail, but the rest of

FileHandle will still work.

`FileHandle::fdopen` is like `open` except that its first parameter is not a filename but rather a file handle name, a FileHandle object, or a file descriptor number.

If the C functions `fgetpos()` and `fsetpos()` are available, then `FileHandle::getpos` returns an opaque value that represents the current position of the FileHandle, and `FileHandle::setpos` uses that value to return to a previously visited position.

If the C function `setvbuf()` is available, then `FileHandle::setvbuf` sets the buffering policy for the FileHandle. The calling sequence for the Perl function is the same as its C counterpart, including the macros `_IOFBF`, `_IOLBF`, and `_IONBF`, except that the buffer parameter specifies a scalar variable to use as a buffer. **WARNING:** A variable used as a buffer by `FileHandle::setvbuf` must not be modified in any way until the FileHandle is closed or until `FileHandle::setvbuf` is called again, or memory corruption may result!

See [perlfunc](#) for complete descriptions of each of the following supported FileHandle methods, which are just front ends for the corresponding built-in functions:

```
close
fileno
getc
gets
eof
clearerr
seek
tell
```

See [perlvar](#) for complete descriptions of each of the following supported FileHandle methods:

```
autoflush
output_field_separator
output_record_separator
input_record_separator
input_line_number
format_page_number
format_lines_per_page
format_lines_left
format_name
format_top_name
format_line_break_characters
format_formfeed
```

Furthermore, for doing normal I/O you might need these:

`$fh->print`

See [print](#).

`$fh->printf`

See [printf](#).

`$fh->getline`

This works like `<$fh` described in [I/O Operators in perlop](#) except that it's more readable and can be safely called in a list context but still returns just one line.

`$fh->getlines`

This works like `<$fh` when called in a list context to read all the remaining lines in a file, except that it's more readable. It will also `croak()` if accidentally called in a scalar context.

There are many other functions available since FileHandle is descended from `IO::File`, `IO::Seekable`, and

IO::Handle. Please see those respective pages for documentation on more functions.

NAME

filetest – Perl pragma to control the filetest permission operators

SYNOPSIS

```
$scan_perhaps_read = -r "file";      # use the mode bits
{
    use filetest 'access';           # intuit harder
    $scan_really_read = -r "file";
}
$scan_perhaps_read = -r "file";      # use the mode bits again
```

DESCRIPTION

This pragma tells the compiler to change the behaviour of the filetest permissions operators, the `-r -w -x -R -W -X` (see [perlfunc](#)).

The default behaviour to use the mode bits as returned by the `stat()` family of calls. This, however, may not be the right thing to do if for example various ACL (access control lists) schemes are in use. For such environments, `use filetest` may help the permission operators to return results more consistent with other tools.

Each "use filetest" or "no filetest" affects statements to the end of the enclosing block.

There may be a slight performance decrease in the filetests when `use filetest` is in effect, because in some systems the extended functionality needs to be emulated.

NOTE: using the file tests for security purposes is a lost cause from the start: there is a window open for race conditions (who is to say that the permissions will not change between the test and the real operation?). Therefore if you are serious about security, just try the real operation and test for its success. Think atomicity.

subpragma access

Currently only one subpragma, `access` is implemented. It enables (or disables) the use of `access()` or similar system calls. This extended filetest functionality is used only when the argument of the operators is a filename, not when it is a filehandle.

NAME

Filter::Simple – Simplified source filtering

SYNOPSIS

```
# in MyFilter.pm:

package MyFilter;

use Filter::Simple;

FILTER { ... };

# or just:
#
# use Filter::Simple sub { ... };

# in user's code:

use MyFilter;

# this code is filtered

no MyFilter;

# this code is not
```

DESCRIPTION**The Problem**

Source filtering is an immensely powerful feature of recent versions of Perl. It allows one to extend the language itself (e.g. the Switch module), to simplify the language (e.g. Language::Pythonesque), or to completely recast the language (e.g. Lingua::Romana::Perligata). Effectively, it allows one to use the full power of Perl as its own, recursively applied, macro language.

The excellent Filter::Util::Call module (by Paul Marquess) provides a usable Perl interface to source filtering, but it is often too powerful and not nearly as simple as it could be.

To use the module it is necessary to do the following:

1. Download, build, and install the Filter::Util::Call module. (If you have Perl 5.7.1 or later, this is already done for you.)
2. Set up a module that does a `use Filter::Util::Call`.
3. Within that module, create an `import` subroutine.
4. Within the `import` subroutine do a call to `filter_add`, passing it either a subroutine reference.
5. Within the subroutine reference, call `filter_read` or `filter_read_exact` to "prime" `$_` with source code data from the source file that will use your module. Check the status value returned to see if any source code was actually read in.
6. Process the contents of `$_` to change the source code in the desired manner.
7. Return the status value.
8. If the act of unimporting your module (via a `no`) should cause source code filtering to cease, create an `unimport` subroutine, and have it call `filter_del`. Make sure that the call to `filter_read` or `filter_read_exact` in step 5 will not accidentally read past the `no`. Effectively this limits source code filters to line-by-line operation, unless the `import` subroutine does some fancy pre-pre-parsing of the source code it's filtering.

For example, here is a minimal source code filter in a module named BANG.pm. It simply converts every occurrence of the sequence `BANG\s+BANG` to the sequence `die 'BANG' if $BANG` in any piece of code following a `use BANG;` statement (until the next `no BANG;` statement, if any):

```

package BANG;

use Filter::Util::Call ;

sub import {
    filter_add( sub {
        my $caller = caller;
        my ($status, $no_seen, $data);
        while ($status = filter_read()) {
            if (/^\s*no\s+$caller\s*;\s*?$/ ) {
                $no_seen=1;
                last;
            }
            $data .= $_;
            $_ = "";
        }
        $_ = $data;
        s/BANG\s+BANG/die 'BANG' if \xBANG/g
        unless $status < 0;
        $_ .= "no $class;\n" if $no_seen;
        return 1;
    })
}

sub unimport {
    filter_del();
}

1 ;

```

This level of sophistication puts filtering out of the reach of many programmers.

A Solution

The `Filter::Simple` module provides a simplified interface to `Filter::Util::Call`; one that is sufficient for most common cases.

Instead of the above process, with `Filter::Simple` the task of setting up a source code filter is reduced to:

1. Download and install the `Filter::Simple` module. (If you have Perl 5.7.1 or later, this is already done for you.)
2. Set up a module that does a `use Filter::Simple` and then calls `FILTER { ... }`.
3. Within the anonymous subroutine or block that is passed to `FILTER`, process the contents of `$_` to change the source code in the desired manner.

In other words, the previous example, would become:

```

package BANG;
use Filter::Simple;

FILTER {
    s/BANG\s+BANG/die 'BANG' if \xBANG/g;
};

1 ;

```

Note that the source code is passed as a single string, so any regex that uses `^` or `$` to detect line boundaries will need the `/m` flag.

Disabling or changing <no behaviour

By default, the installed filter only filters up to a line consisting of one of the three standard source "terminators":

```
no ModuleName;  # optional comment
```

or:

```
__END__
```

or:

```
__DATA__
```

but this can be altered by passing a second argument to use `Filter::Simple` or `FILTER` (just remember: there's *no* comma after the initial block when you use `FILTER`).

That second argument may be either a qr'd regular expression (which is then used to match the terminator line), or a defined false value (which indicates that no terminator line should be looked for), or a reference to a hash (in which case the terminator is the value associated with the key 'terminator').

For example, to cause the previous filter to filter only up to a line of the form:

```
GNAB esu;
```

you would write:

```
package BANG;
use Filter::Simple;

FILTER {
    s/BANG\s+BANG/die 'BANG' if \$BANG/g;
}
qr/^\s*GNAB\s+esu\s*;\s*?$/;
```

or:

```
FILTER {
    s/BANG\s+BANG/die 'BANG' if \$BANG/g;
}
{ terminator => qr/^\s*GNAB\s+esu\s*;\s*?$/ };
```

and to prevent the filter's being turned off in any way:

```
package BANG;
use Filter::Simple;

FILTER {
    s/BANG\s+BANG/die 'BANG' if \$BANG/g;
}
";    # or: 0
```

or:

```
FILTER {
    s/BANG\s+BANG/die 'BANG' if \$BANG/g;
}
{ terminator => "" };
```

Note that, no matter what you set the terminator pattern to, the actual terminator itself *must* be contained on a single source line.

All-in-one interface

Separating the loading of `Filter::Simple`:

```
use Filter::Simple;
```

from the setting up of the filtering:

```
FILTER { ... };
```

is useful because it allows other code (typically parser support code or caching variables) to be defined before the filter is invoked. However, there is often no need for such a separation.

In those cases, it is easier to just append the filtering subroutine and any terminator specification directly to the `use` statement that loads `Filter::Simple`, like so:

```
use Filter::Simple sub {
    s/BANG\s+BANG/die 'BANG' if \xBANG/g;
};
```

This is exactly the same as:

```
use Filter::Simple;
BEGIN {
    Filter::Simple::FILTER {
        s/BANG\s+BANG/die 'BANG' if \xBANG/g;
    };
}
```

except that the `FILTER` subroutine is not exported by `Filter::Simple`.

Filtering only specific components of source code

One of the problems with a filter like:

```
use Filter::Simple;

FILTER { s/BANG\s+BANG/die 'BANG' if \xBANG/g };
```

is that it indiscriminately applies the specified transformation to the entire text of your source program. So something like:

```
warn 'BANG BANG, YOU'RE DEAD';
BANG BANG;
```

will become:

```
warn 'die 'BANG' if $BANG, YOU'RE DEAD';
die 'BANG' if $BANG;
```

It is very common when filtering source to only want to apply the filter to the non-character-string parts of the code, or alternatively to *only* the character strings.

`Filter::Simple` supports this type of filtering by automatically exporting the `FILTER_ONLY` subroutine.

`FILTER_ONLY` takes a sequence of specifiers that install separate (and possibly multiple) filters that act on only parts of the source code. For example:

```
use Filter::Simple;

FILTER_ONLY
    code      => sub { s/BANG\s+BANG/die 'BANG' if \xBANG/g },
    quotelike => sub { s/BANG\s+BANG/CHITTY CHITTY/g };
```

The "code" subroutine will only be used to filter parts of the source code that are not quotelikes, POD, or `__DATA__`. The `quotelike` subroutine only filters Perl quotelikes (including here documents).

The full list of alternatives is:

"code"

Filters only those sections of the source code that are not quotelikes, POD, or `__DATA__`.

"executable"

Filters only those sections of the source code that are not POD or `__DATA__`.

"quotelike"

Filters only Perl quotelikes (as interpreted by `&Text::Balanced::extract_quotelike`).

"string"

Filters only the string literal parts of a Perl quotelike (i.e. the contents of a string literal, either half of a `tr///`, the second half of an `s///`).

"regex"

Filters only the pattern literal parts of a Perl quotelike (i.e. the contents of a `qr//` or an `m//`, the first half of an `s///`).

"all"

Filters everything. Identical in effect to `FILTER`.

Except for `< FILTER_ONLY code = sub { ... }`, each of the component filters is called repeatedly, once for each component found in the source code.

Note that you can also apply two or more of the same type of filter in a single `FILTER_ONLY`. For example, here's a simple macro-preprocessor that is only applied within regexes, with a final debugging pass that prints the resulting source code:

```
use Regexp::Common;
FILTER_ONLY
    regex => sub { s/!\[/[^\]/g },
    regex => sub { s/%d/$RE{num}{int}/g },
    regex => sub { s/%f/$RE{num}{real}/g },
    all   => sub { print if $::DEBUG };
```

Filtering only the code parts of source code

Most source code ceases to be grammatically correct when it is broken up into the pieces between string literals and regexes. So the 'code' component filter behaves slightly differently from the other partial filters described in the previous section.

Rather than calling the specified processor on each individual piece of code (i.e. on the bits between quotelikes), the 'code' partial filter operates on the entire source code, but with the quotelike bits "blanked out".

That is, a 'code' filter *replaces* each quoted string, quotelike, regex, POD, and `__DATA__` section with a placeholder. The delimiters of this placeholder are the contents of the `$;` variable at the time the filter is applied (normally `"\034"`). The remaining four bytes are a unique identifier for the component being replaced.

This approach makes it comparatively easy to write code preprocessors without worrying about the form or contents of strings, regexes, etc. For convenience, during a 'code' filtering operation, `Filter::Simple` provides a package variable (`$Filter::Simple::placeholder`) that contains a pre-compiled regex that matches any placeholder. Placeholders can be moved and re-ordered within the source code as needed.

Once the filtering has been applied, the original strings, regexes, POD, etc. are re-inserted into the code, by replacing each placeholder with the corresponding original component.

For example, the following filter detects concatenated pairs of strings/quotelikes and reverses the order in which they are concatenated:

```
package DemoRevCat;
use Filter::Simple;

FILTER_ONLY code => sub { my $ph = $Filter::Simple::placeholder;
                          s{ ($ph) \s* [.] \s* ($ph) }{ $2.$1 }gx
                        };

```

Thus, the following code:

```
use DemoRevCat;

my $str = "abc" . q(def);

print "$str\n";

```

would become:

```
my $str = q(def). "abc";

print "$str\n";

```

and hence print:

```
defabc

```

Using Filter::Simple with an explicit import subroutine

Filter::Simple generates a special import subroutine for your module (see ["How it works"](#)) which would normally replace any import subroutine you might have explicitly declared.

However, Filter::Simple is smart enough to notice your existing import and Do The Right Thing with it. That is, if you explicitly define an import subroutine in a package that's using Filter::Simple, that import subroutine will still be invoked immediately after any filter you install.

The only thing you have to remember is that the import subroutine *must* be declared *before* the filter is installed. If you use FILTER to install the filter:

```
package Filter::TurnItUpTo11;
use Filter::Simple;

FILTER { s/(\w+)/\U$1/ };

```

that will almost never be a problem, but if you install a filtering subroutine by passing it directly to the use Filter::Simple statement:

```
package Filter::TurnItUpTo11;
use Filter::Simple sub{ s/(\w+)/\U$1/ };

```

then you must make sure that your import subroutine appears before that use statement.

Using Filter::Simple and Exporter together

Likewise, Filter::Simple is also smart enough to Do The Right Thing if you use Exporter:

```
package Switch;
use base Exporter;
use Filter::Simple;

@EXPORT      = qw(switch case);
@EXPORT_OK   = qw(given when);

FILTER { $_ = magic_Perl_filter($_) }

```

Immediately after the filter has been applied to the source, Filter::Simple will pass control to Exporter, so it can do its magic too.

Of course, here too, Filter::Simple has to know you're using Exporter before it applies the filter. That's

almost never a problem, but if you're nervous about it, you can guarantee that things will work correctly by ensuring that your `use base Exporter` always precedes your `use Filter::Simple`.

How it works

The `Filter::Simple` module exports into the package that calls `FILTER` (or uses it directly) — such as package "BANG" in the above example — two automatically constructed subroutines — `import` and `unimport` — which take care of all the nasty details.

In addition, the generated `import` subroutine passes its own argument list to the filtering subroutine, so the BANG.pm filter could easily be made parametric:

```
package BANG;

use Filter::Simple;

FILTER {
    my ($die_msg, $var_name) = @_;
    s/BANG\s+BANG/die '$die_msg' if \${$var_name}/g;
};

# and in some user code:

use BANG "BOOM", "BAM"; # "BANG BANG" becomes: die 'BOOM' if $BAM
```

The specified filtering subroutine is called every time a `use BANG` is encountered, and passed all the source code following that call, up to either the next `no BANG;` (or whatever terminator you've set) or the end of the source file, whichever occurs first. By default, any `no BANG;` call must appear by itself on a separate line, or it is ignored.

NAME

Filter::Util::Call – Perl Source Filter Utility Module

SYNOPSIS

```
use Filter::Util::Call ;
```

DESCRIPTION

This module provides you with the framework to write *Source Filters* in Perl.

An alternate interface to Filter::Util::Call is now available. See [Filter::Simple](#) for more details.

A *Perl Source Filter* is implemented as a Perl module. The structure of the module can take one of two broadly similar formats. To distinguish between them, the first will be referred to as *method filter* and the second as *closure filter*.

Here is a skeleton for the *method filter*:

```
package MyFilter ;
use Filter::Util::Call ;
sub import
{
    my($type, @arguments) = @_ ;
    filter_add([]) ;
}
sub filter
{
    my($self) = @_ ;
    my($status) ;

    $status = filter_read() ;
    $status ;
}
1 ;
```

and this is the equivalent skeleton for the *closure filter*:

```
package MyFilter ;
use Filter::Util::Call ;
sub import
{
    my($type, @arguments) = @_ ;
    filter_add(
        sub
        {
            my($status) ;
            $status = filter_read() ;
            $status ;
        } )
}
1 ;
```

To make use of either of the two filter modules above, place the line below in a Perl source file.

```
use MyFilter;
```

In fact, the skeleton modules shown above are fully functional *Source Filters*, albeit fairly useless ones. All they do is filter the source stream without modifying it at all.

As you can see both modules have a broadly similar structure. They both make use of the `Filter::Util::Call` module and both have an `import` method. The difference between them is that the *method filter* requires a *filter* method, whereas the *closure filter* gets the equivalent of a *filter* method with the anonymous sub passed to *filter_add*.

To make proper use of the *closure filter* shown above you need to have a good understanding of the concept of a *closure*. See [perlref](#) for more details on the mechanics of *closures*.

use Filter::Util::Call

The following functions are exported by `Filter::Util::Call`:

```
filter_add()
filter_read()
filter_read_exact()
filter_del()
```

import()

The `import` method is used to create an instance of the filter. It is called indirectly by Perl when it encounters the `use MyFilter` line in a source file (See [import](#) for more details on `import`).

It will always have at least one parameter automatically passed by Perl – this corresponds to the name of the package. In the example above it will be `"MyFilter"`.

Apart from the first parameter, `import` can accept an optional list of parameters. These can be used to pass parameters to the filter. For example:

```
use MyFilter qw(a b c) ;
```

will result in the `@_` array having the following values:

```
@_ [0] => "MyFilter"
@_ [1] => "a"
@_ [2] => "b"
@_ [3] => "c"
```

Before terminating, the `import` function must explicitly install the filter by calling *filter_add*.

filter_add()

The function, *filter_add*, actually installs the filter. It takes one parameter which should be a reference. The kind of reference used will dictate which of the two filter types will be used.

If a CODE reference is used then a *closure filter* will be assumed.

If a CODE reference is not used, a *method filter* will be assumed. In a *method filter*, the reference can be used to store context information. The reference will be *blessed* into the package by *filter_add*.

See the filters at the end of this document for examples of using context information using both *method filters* and *closure filters*.

filter() and anonymous sub

Both the *filter* method used with a *method filter* and the anonymous sub used with a *closure filter* is where the main processing for the filter is done.

The big difference between the two types of filter is that the *method filter* uses the object passed to the method to store any context data, whereas the *closure filter* uses the lexical variables that are maintained by the closure.

Note that the single parameter passed to the *method filter*, `$self`, is the same reference that was passed to *filter_add* blessed into the filter's package. See the example filters later on for details of using `$self`.

Here is a list of the common features of the anonymous sub and the `filter()` method.

\$_ Although `$_` doesn't actually appear explicitly in the sample filters above, it is implicitly used in a number of places.

Firstly, when either `filter` or the anonymous sub are called, a local copy of `$_` will automatically be created. It will always contain the empty string at this point.

Next, both `filter_read` and `filter_read_exact` will append any source data that is read to the end of `$_`.

Finally, when `filter` or the anonymous sub are finished processing, they are expected to return the filtered source using `$_`.

This implicit use of `$_` greatly simplifies the filter.

\$status

The status value that is returned by the user's `filter` method or anonymous sub and the `filter_read` and `read_exact` functions take the same set of values, namely:

```
< 0  Error
= 0  EOF
> 0  OK
```

filter_read and filter_read_exact

These functions are used by the filter to obtain either a line or block from the next filter in the chain or the actual source file if there aren't any other filters.

The function `filter_read` takes two forms:

```
$status = filter_read() ;
$status = filter_read($size) ;
```

The first form is used to request a *line*, the second requests a *block*.

In line mode, `filter_read` will append the next source line to the end of the `$_` scalar.

In block mode, `filter_read` will append a block of data which is `<= $size` to the end of the `$_` scalar. It is important to emphasise that `filter_read` will not necessarily read a block which is *precisely* `$size` bytes.

If you need to be able to read a block which has an exact size, you can use the function `filter_read_exact`. It works identically to `filter_read` in block mode, except it will try to read a block which is exactly `$size` bytes in length. The only circumstances when it will not return a block which is `$size` bytes long is on EOF or error.

It is *very* important to check the value of `$status` after *every* call to `filter_read` or `filter_read_exact`.

filter_del

The function, `filter_del`, is used to disable the current filter. It does not affect the running of the filter. All it does is tell Perl not to call filter any more.

See [Example 4: Using filter_del](#) for details.

EXAMPLES

Here are a few examples which illustrate the key concepts – as such most of them are of little practical use.

The `examples` sub-directory has copies of all these filters implemented both as *method filters* and as *closure filters*.

Example 1: A simple filter.

Below is a *method filter* which is hard-wired to replace all occurrences of the string "Joe" to "Jim". Not particularly Useful, but it is the first example and I wanted to keep it simple.

```
package Joe2Jim ;
use Filter::Util::Call ;
sub import
{
    my($type) = @_ ;
    filter_add(bless []) ;
}
sub filter
{
    my($self) = @_ ;
    my($status) ;
    s/Joe/Jim/g
    if ($status = filter_read()) > 0 ;
    $status ;
}
1 ;
```

Here is an example of using the filter:

```
use Joe2Jim ;
print "Where is Joe?\n" ;
```

And this is what the script above will print:

```
Where is Jim?
```

Example 2: Using the context

The previous example was not particularly useful. To make it more general purpose we will make use of the context data and allow any arbitrary *from* and *to* strings to be used. This time we will use a *closure filter*. To reflect its enhanced role, the filter is called Subst.

```
package Subst ;
use Filter::Util::Call ;
use Carp ;
sub import
{
    croak("usage: use Subst qw(from to)")
    unless @_ == 3 ;
    my ($self, $from, $to) = @_ ;
    filter_add(
        sub
        {
            my ($status) ;
            s/$from/$to/
            if ($status = filter_read()) > 0 ;
            $status ;
        })
}
1 ;
```

and is used like this:

```
use Subst qw(Joe Jim) ;
print "Where is Joe?\n" ;
```

Example 3: Using the context within the filter

Here is a filter which a variation of the `Joe2Jim` filter. As well as substituting all occurrences of "Joe" to "Jim" it keeps a count of the number of substitutions made in the context object.

Once EOF is detected (`$status` is zero) the filter will insert an extra line into the source stream. When this extra line is executed it will print a count of the number of substitutions actually made. Note that `$status` is set to 1 in this case.

```
package Count ;
use Filter::Util::Call ;
sub filter
{
    my ($self) = @_ ;
    my ($status) ;

    if (($status = filter_read()) > 0 ) {
        s/Joe/Jim/g ;
        ++ $$self ;
    }
    elsif ($$self >= 0) { # EOF
        $_ = "print q[Made ${$self} substitutions\n]" ;
        $status = 1 ;
        $$self = -1 ;
    }

    $status ;
}

sub import
{
    my ($self) = @_ ;
    my ($count) = 0 ;
    filter_add(\$count) ;
}

1 ;
```

Here is a script which uses it:

```
use Count ;
print "Hello Joe\n" ;
print "Where is Joe\n" ;
```

Outputs:

```
Hello Jim
Where is Jim
Made 2 substitutions
```

Example 4: Using `filter_del`

Another variation on a theme. This time we will modify the `Subst` filter to allow a starting and stopping pattern to be specified as well as the *from* and *to* patterns. If you know the *vi* editor, it is the equivalent of this command:

```
:/start/,/stop/s/from/to/
```

When used as a filter we want to invoke it like this:

```
use NewSubst qw(start stop from to) ;
```

Here is the module.

```
package NewSubst ;
use Filter::Util::Call ;
use Carp ;
sub import
{
    my ($self, $start, $stop, $from, $to) = @_ ;
    my ($found) = 0 ;
    croak("usage: use Subst qw(start stop from to)")
        unless @_ == 5 ;

    filter_add(
        sub
        {
            my ($status) ;
            if (($status = filter_read()) > 0) {
                $found = 1
                if $found == 0 and /$start/ ;

                if ($found) {
                    s/$from/$to/ ;
                    filter_del() if /$stop/ ;
                }
            }
            $status ;
        } )
    }
    1 ;
}
```

Filter::Simple

If you intend using the Filter::Call functionality, I would strongly recommend that you check out Damian Conway's excellent Filter::Simple module. This module provides a much cleaner interface than Filter::Util::Call. Although it doesn't allow the fine control that Filter::Util::Call does, it should be adequate for the majority of applications. It's available at

http://www.cpan.org/modules/by-author/Damian_Conway/Filter-Simple.tar.gz
<http://www.csse.monash.edu.au/~damian/CPAN/Filter-Simple.tar.gz>

NAME

FindBin – Locate directory of original perl script

SYNOPSIS

```
use FindBin;
use lib "$FindBin::Bin/./lib";

or

use FindBin qw($Bin);
use lib "$Bin/./lib";
```

DESCRIPTION

Locates the full path to the script bin directory to allow the use of paths relative to the bin directory.

This allows a user to setup a directory tree for some software with directories <root>/bin and <root>/lib and then the above example will allow the use of modules in the lib directory without knowing where the software tree is installed.

If perl is invoked using the `-e` option or the perl script is read from STDIN then FindBin sets both `$Bin` and `$RealBin` to the current directory.

EXPORTABLE VARIABLES

<code>\$Bin</code>	- path to bin directory from where script was invoked
<code>\$Script</code>	- basename of script from which perl was invoked
<code>\$RealBin</code>	- <code>\$Bin</code> with all links resolved
<code>\$RealScript</code>	- <code>\$Script</code> with all links resolved

KNOWN ISSUES

If there are two modules using FindBin from different directories under the same interpreter, this won't work. Since FindBin uses BEGIN block, it'll be executed only once, and only the first caller will get it right. This is a problem under mod_perl and other persistent Perl environments, where you shouldn't use this module. Which also means that you should avoid using FindBin in modules that you plan to put on CPAN. The only way to make sure that FindBin will work is to force the BEGIN block to be executed again:

```
delete $INC{'FindBin.pm'};
require FindBin;
```

KNOWN BUGS

If perl is invoked as

```
perl filename
```

and *filename* does not have executable rights and a program called *filename* exists in the users `$ENV{PATH}` which satisfies both `-x` and `-T` then FindBin assumes that it was invoked via the `$ENV{PATH}`.

Workaround is to invoke perl as

```
perl ./filename
```

AUTHORS

FindBin is supported as part of the core perl distribution. Please send bug reports to [<perlbug@perl.org>](mailto:perlbug@perl.org) using the perlbug program included with perl.

NAME

Getopt::Long – Extended processing of command line options

SYNOPSIS

```
use Getopt::Long;
my $data    = "file.dat";
my $length  = 24;
my $verbose;
$result = GetOptions ("length=i" => \$length,    # numeric
                     "file=s"   => \$data,       # string
                     "verbose"  => \$verbose);    # flag
```

DESCRIPTION

The Getopt::Long module implements an extended getopt function called `GetOptions()`. This function adheres to the POSIX syntax for command line options, with GNU extensions. In general, this means that options have long names instead of single letters, and are introduced with a double dash "`--`". Support for bundling of command line options, as was the case with the more traditional single-letter approach, is provided but not enabled by default.

Command Line Options, an Introduction

Command line operated programs traditionally take their arguments from the command line, for example filenames or other information that the program needs to know. Besides arguments, these programs often take command line *options* as well. Options are not necessary for the program to work, hence the name 'option', but are used to modify its default behaviour. For example, a program could do its job quietly, but with a suitable option it could provide verbose information about what it did.

Command line options come in several flavours. Historically, they are preceded by a single dash `-`, and consist of a single letter.

```
-l -a -c
```

Usually, these single-character options can be bundled:

```
-lac
```

Options can have values, the value is placed after the option character. Sometimes with whitespace in between, sometimes not:

```
-s 24 -s24
```

Due to the very cryptic nature of these options, another style was developed that used long names. So instead of a cryptic `-l` one could use the more descriptive `--long`. To distinguish between a bundle of single-character options and a long one, two dashes are used to precede the option name. Early implementations of long options used a plus `+` instead. Also, option values could be specified either like

```
--size=24
```

or

```
--size 24
```

The `+` form is now obsolete and strongly deprecated.

Getting Started with Getopt::Long

Getopt::Long is the Perl5 successor of `newgetopt.pl`. This was the first Perl module that provided support for handling the new style of command line options, hence the name Getopt::Long. This module also supports single-character options and bundling. In this case, the options are restricted to alphabetic characters only, and the characters `?` and `-`.

To use Getopt::Long from a Perl program, you must include the following line in your Perl program:

```
use Getopt::Long;
```

This will load the core of the `Getopt::Long` module and prepare your program for using it. Most of the actual `Getopt::Long` code is not loaded until you really call one of its functions.

In the default configuration, options names may be abbreviated to uniqueness, case does not matter, and a single dash is sufficient, even for long option names. Also, options may be placed between non-option arguments. See [Configuring Getopt::Long](#) for more details on how to configure `Getopt::Long`.

Simple options

The most simple options are the ones that take no values. Their mere presence on the command line enables the option. Popular examples are:

```
--all --verbose --quiet --debug
```

Handling simple options is straightforward:

```
my $verbose = ''; # option variable with default value (false)
my $all = '';    # option variable with default value (false)
GetOptions ('verbose' => \$verbose, 'all' => \$all);
```

The call to `GetOptions()` parses the command line arguments that are present in `@ARGV` and sets the option variable to the value 1 if the option did occur on the command line. Otherwise, the option variable is not touched. Setting the option value to true is often called *enabling* the option.

The option name as specified to the `GetOptions()` function is called the option *specification*. Later we'll see that this specification can contain more than just the option name. The reference to the variable is called the option *destination*.

`GetOptions()` will return a true value if the command line could be processed successfully. Otherwise, it will write error messages to `STDERR`, and return a false result.

A little bit less simple options

`Getopt::Long` supports two useful variants of simple options: *negatable* options and *incremental* options.

A negatable option is specified with an exclamation mark `!` after the option name:

```
my $verbose = ''; # option variable with default value (false)
GetOptions ('verbose!' => \$verbose);
```

Now, using `--verbose` on the command line will enable `$verbose`, as expected. But it is also allowed to use `--noverbose`, which will disable `$verbose` by setting its value to `.` Using a suitable default value, the program can find out whether `$verbose` is false by default, or disabled by using `--noverbose`.

An incremental option is specified with a plus `+` after the option name:

```
my $verbose = ''; # option variable with default value (false)
GetOptions ('verbose+' => \$verbose);
```

Using `--verbose` on the command line will increment the value of `$verbose`. This way the program can keep track of how many times the option occurred on the command line. For example, each occurrence of `--verbose` could increase the verbosity level of the program.

Mixing command line option with other arguments

Usually programs take command line options as well as other arguments, for example, file names. It is good practice to always specify the options first, and the other arguments last. `Getopt::Long` will, however, allow the options and arguments to be mixed and 'filter out' all the options before passing the rest of the arguments to the program. To stop `Getopt::Long` from processing further arguments, insert a double dash `--` on the command line:

```
--size 24 -- --all
```

In this example, `--all` will *not* be treated as an option, but passed to the program unharmed, in `@ARGV`.

Options with values

For options that take values it must be specified whether the option value is required or not, and what kind of value the option expects.

Three kinds of values are supported: integer numbers, floating point numbers, and strings.

If the option value is required, `Getopt::Long` will take the command line argument that follows the option and assign this to the option variable. If, however, the option value is specified as optional, this will only be done if that value does not look like a valid command line option itself.

```
my $tag = '';          # option variable with default value
GetOptions ('tag=s' => \$tag);
```

In the option specification, the option name is followed by an equals sign `=` and the letter `s`. The equals sign indicates that this option requires a value. The letter `s` indicates that this value is an arbitrary string. Other possible value types are `i` for integer values, and `f` for floating point values. Using a colon `:` instead of the equals sign indicates that the option value is optional. In this case, if no suitable value is supplied, string valued options get an empty string `''` assigned, while numeric options are set to `.`

Options with multiple values

Options sometimes take several values. For example, a program could use multiple directories to search for library files:

```
--library lib/stdlib --library lib/extlib
```

To accomplish this behaviour, simply specify an array reference as the destination for the option:

```
my @libfiles = ();
GetOptions ("library=s" => \@libfiles);
```

Used with the example above, `@libfiles` would contain two strings upon completion: `"lib/stdlib"` and `"lib/extlib"`, in that order. It is also possible to specify that only integer or floating point numbers are acceptable values.

Often it is useful to allow comma-separated lists of values as well as multiple occurrences of the options. This is easy using Perl's `split()` and `join()` operators:

```
my @libfiles = ();
GetOptions ("library=s" => \@libfiles);
@libfiles = split(/,/ , join(',', @libfiles));
```

Of course, it is important to choose the right separator string for each purpose.

Options with hash values

If the option destination is a reference to a hash, the option will take, as value, strings of the form *key=value*. The value will be stored with the specified key in the hash.

```
my %defines = ();
GetOptions ("define=s" => \%defines);
```

When used with command line options:

```
--define os=linux --define vendor=redhat
```

the hash `%defines` will contain two keys, `"os"` with value `"linux"` and `"vendor"` with value `"redhat"`. It is also possible to specify that only integer or floating point numbers are acceptable values. The keys are always taken to be strings.

User-defined subroutines to handle options

Ultimate control over what should be done when (actually: each time) an option is encountered on the command line can be achieved by designating a reference to a subroutine (or an anonymous subroutine) as the option destination. When `GetOptions()` encounters the option, it will call the subroutine with two or

three arguments. The first argument is the name of the option. For a scalar or array destination, the second argument is the value to be stored. For a hash destination, the second arguments is the key to the hash, and the third argument the value to be stored. It is up to the subroutine to store the value, or do whatever it thinks is appropriate.

A trivial application of this mechanism is to implement options that are related to each other. For example:

```
my $verbose = ''; # option variable with default value (false)
GetOptions ('verbose' => \$verbose,
           'quiet'    => sub { $verbose = 0 });
```

Here `--verbose` and `--quiet` control the same variable `$verbose`, but with opposite values.

If the subroutine needs to signal an error, it should call `die()` with the desired error message as its argument. `GetOptions()` will catch the `die()`, issue the error message, and record that an error result must be returned upon completion.

If the text of the error message starts with an exclamation mark `!` it is interpreted specially by `GetOptions()`. There is currently one special command implemented: `die("!FINISH")` will cause `GetOptions()` to stop processing options, as if it encountered a double dash `--`.

Options with multiple names

Often it is user friendly to supply alternate mnemonic names for options. For example `--height` could be an alternate name for `--length`. Alternate names can be included in the option specification, separated by vertical bar `|` characters. To implement the above example:

```
GetOptions ('length|height=f' => \$length);
```

The first name is called the *primary* name, the other names are called *aliases*.

Multiple alternate names are possible.

Case and abbreviations

Without additional configuration, `GetOptions()` will ignore the case of option names, and allow the options to be abbreviated to uniqueness.

```
GetOptions ('length|height=f' => \$length, "head" => \$head);
```

This call will allow `-l` and `-L` for the length option, but requires a least `-hea` and `-hei` for the head and height options.

Summary of Option Specifications

Each option specifier consists of two parts: the name specification and the argument specification.

The name specification contains the name of the option, optionally followed by a list of alternative names separated by vertical bar characters.

```
length          option name is "length"
length|size|l   name is "length", aliases are "size" and "l"
```

The argument specification is optional. If omitted, the option is considered boolean, a value of 1 will be assigned when the option is used on the command line.

The argument specification can be

- ! The option does not take an argument and may be negated, i.e. prefixed by "no". E.g. `"foo!"` will allow `--foo` (a value of 1 will be assigned) and `--nofoo` (a value of 0 will be assigned). If the option has aliases, this applies to the aliases as well.

Using negation on a single letter option when bundling is in effect is pointless and will result in a warning.

- + The option does not take an argument and will be incremented by 1 every time it appears on the command line. E.g. "more+", when used with `--more --more --more`, will increment the value three times, resulting in a value of 3 (provided it was 0 or undefined at first).

The + specifier is ignored if the option destination is not a scalar.

`= type [desttype]`

The option requires an argument of the given type. Supported types are:

- s String. An arbitrary sequence of characters. It is valid for the argument to start with `-` or `--`.
- i Integer. An optional leading plus or minus sign, followed by a sequence of digits.
- o Extended integer, Perl style. This can be either an optional leading plus or minus sign, followed by a sequence of digits, or an octal string (a zero, optionally followed by '0', '1', .. '7'), or a hexadecimal string (0x followed by '0' .. '9', 'a' .. 'f', case insensitive), or a binary string (0b followed by a series of '0' and '1').
- f Real number. For example 3.14, -6.23E24 and so on.

The *desttype* can be @ or % to specify that the option is list or a hash valued. This is only needed when the destination for the option value is not otherwise specified. It should be omitted when not needed.

`: type [desttype]`

Like `=`, but designates the argument as optional. If omitted, an empty string will be assigned to string values options, and the value zero to numeric options.

Note that if a string argument starts with `-` or `--`, it will be considered an option on itself.

`: number [desttype]`

Like `:i`, but if the value is omitted, the *number* will be assigned.

`: + [desttype]`

Like `:i`, but if the value is omitted, the current value for the option will be incremented.

Advanced Possibilities

Object oriented interface

Getopt::Long can be used in an object oriented way as well:

```
use Getopt::Long;
$p = new Getopt::Long::Parser;
$p->configure(...configuration options...);
if ($p->getoptions(...options descriptions...)) ...
```

Configuration options can be passed to the constructor:

```
$p = new Getopt::Long::Parser
    config => [...configuration options...];
```

Thread Safety

Getopt::Long is thread safe when using `ithreads` as of Perl 5.8. It is *not* thread safe when using the older (experimental and now obsolete) `threads` implementation that was added to Perl 5.005.

Documentation and help texts

Getopt::Long encourages the use of Pod::Usage to produce help messages. For example:

```
use Getopt::Long;
use Pod::Usage;

my $man = 0;
my $help = 0;
```

```

GetOptions('help|?' => \$help, man => \$man) or pod2usage(2);
pod2usage(1) if $help;
pod2usage(-exitstatus => 0, -verbose => 2) if $man;

__END__

=head1 NAME

sample - Using GetOpt::Long and Pod::Usage

=head1 SYNOPSIS

sample [options] [file ...]

    Options:
        -help             brief help message
        -man              full documentation

=head1 OPTIONS

=over 8

=item B<-help>

Print a brief help message and exits.

=item B<-man>

Prints the manual page and exits.

=back

=head1 DESCRIPTION

B<This program> will read the given input file(s) and do something
useful with the contents thereof.

=cut

```

See [Pod::Usage](#) for details.

Storing options in a hash

Sometimes, for example when there are a lot of options, having a separate variable for each of them can be cumbersome. `GetOptions()` supports, as an alternative mechanism, storing options in a hash.

To obtain this, a reference to a hash must be passed *as the first argument* to `GetOptions()`. For each option that is specified on the command line, the option value will be stored in the hash with the option name as key. Options that are not actually used on the command line will not be put in the hash, on other words, `exists($h{option})` (or `defined()`) can be used to test if an option was used. The drawback is that warnings will be issued if the program runs under `use strict` and uses `$h{option}` without testing with `exists()` or `defined()` first.

```

my %h = ();
GetOptions (\%h, 'length=i');      # will store in $h{length}

```

For options that take list or hash values, it is necessary to indicate this by appending an `@` or `%` sign after the type:

```

GetOptions (\%h, 'colours=s@');    # will push to @{$h{colours}}

```

To make things more complicated, the hash may contain references to the actual destinations, for example:

```

my $len = 0;
my %h = ('length' => \$len);
GetOptions (\%h, 'length=i');      # will store in $len

```

This example is fully equivalent with:

```
my $len = 0;
GetOptions ('length=i' => \$len); # will store in $len
```

Any mixture is possible. For example, the most frequently used options could be stored in variables while all other options get stored in the hash:

```
my $verbose = 0; # frequently referred
my $debug = 0; # frequently referred
my %h = ('verbose' => \$verbose, 'debug' => \$debug);
GetOptions (\%h, 'verbose', 'debug', 'filter', 'size=i');
if ( $verbose ) { ... }
if ( exists $h{filter} ) { ... option 'filter' was specified ... }
```

Bundling

With bundling it is possible to set several single-character options at once. For example if a, v and x are all valid options,

```
-vax
```

would set all three.

Getopt::Long supports two levels of bundling. To enable bundling, a call to Getopt::Long::Configure is required.

The first level of bundling can be enabled with:

```
Getopt::Long::Configure ("bundling");
```

Configured this way, single-character options can be bundled but long options **must** always start with a double dash – to avoid ambiguity. For example, when vax, a, v and x are all valid options,

```
-vax
```

would set a, v and x, but

```
--vax
```

would set vax.

The second level of bundling lifts this restriction. It can be enabled with:

```
Getopt::Long::Configure ("bundling_override");
```

Now, -vax would set the option vax.

When any level of bundling is enabled, option values may be inserted in the bundle. For example:

```
-h24w80
```

is equivalent to

```
-h 24 -w 80
```

When configured for bundling, single-character options are matched case sensitive while long options are matched case insensitive. To have the single-character options matched case insensitive as well, use:

```
Getopt::Long::Configure ("bundling", "ignorecase_always");
```

It goes without saying that bundling can be quite confusing.

The lonesome dash

Normally, a lone dash – on the command line will not be considered an option. Option processing will terminate (unless "permute" is configured) and the dash will be left in @ARGV.

It is possible to get special treatment for a lone dash. This can be achieved by adding an option specification

with an empty name, for example:

```
GetOptions ('' => \$stdio);
```

A lone dash on the command line will now be a legal option, and using it will set variable `$stdio`.

Argument callback

A special option `'name' <` can be used to designate a subroutine to handle non-option arguments. When `GetOptions()` encounters an argument that does not look like an option, it will immediately call this subroutine and passes it one parameter: the argument name.

For example:

```
my $width = 80;
sub process { ... }
GetOptions ('width=i' => \$width, '<>' => \&process);
```

When applied to the following command line:

```
arg1 --width=72 arg2 --width=60 arg3
```

This will call `process("arg1")` while `$width` is 80, `process("arg2")` while `$width` is 72, and `process("arg3")` while `$width` is 60.

This feature requires configuration option **permute**, see section [Configuring Getopt::Long](#).

Configuring Getopt::Long

`Getopt::Long` can be configured by calling subroutine `Getopt::Long::Configure()`. This subroutine takes a list of quoted strings, each specifying a configuration option to be enabled, e.g. `ignore_case`, or disabled, e.g. `no_ignore_case`. Case does not matter. Multiple calls to `Configure()` are possible.

Alternatively, as of version 2.24, the configuration options may be passed together with the `use` statement:

```
use Getopt::Long qw(:config no_ignore_case bundling);
```

The following options are available:

default	This option causes all configuration options to be reset to their default values.
posix_default	This option causes all configuration options to be reset to their default values as if the environment variable <code>POSIXLY_CORRECT</code> had been set.
auto_abbrev	Allow option names to be abbreviated to uniqueness. Default is enabled unless environment variable <code>POSIXLY_CORRECT</code> has been set, in which case <code>auto_abbrev</code> is disabled.
getopt_compat	Allow <code>+</code> to start options. Default is enabled unless environment variable <code>POSIXLY_CORRECT</code> has been set, in which case <code>getopt_compat</code> is disabled.
gnu_compat	<code>gnu_compat</code> controls whether <code>--opt=</code> is allowed, and what it should do. Without <code>gnu_compat</code> , <code>--opt=</code> gives an error. With <code>gnu_compat</code> , <code>--opt=</code> will give option <code>opt</code> and empty value. This is the way GNU <code>getopt_long()</code> does it.
gnu_getopt	This is a short way of setting <code>gnu_compat bundling permute no_getopt_compat</code> . With <code>gnu_getopt</code> , command line handling should be fully compatible with GNU <code>getopt_long()</code> .
require_order	Whether command line arguments are allowed to be mixed with options. Default is disabled unless environment variable <code>POSIXLY_CORRECT</code> has been set, in which case <code>require_order</code> is enabled.

See also `permute`, which is the opposite of `require_order`.

permute Whether command line arguments are allowed to be mixed with options. Default is enabled unless environment variable `POSIXLY_CORRECT` has been set, in which case `permute` is disabled. Note that `permute` is the opposite of `require_order`.

If `permute` is enabled, this means that

```
--foo arg1 --bar arg2 arg3
```

is equivalent to

```
--foo --bar arg1 arg2 arg3
```

If an argument callback routine is specified, `@ARGV` will always be empty upon successful return of `GetOptions()` since all options have been processed. The only exception is when `-` is used:

```
--foo arg1 --bar arg2 -- arg3
```

This will call the callback routine for `arg1` and `arg2`, and then terminate `GetOptions()` leaving "arg2" in `@ARGV`.

If `require_order` is enabled, options processing terminates when the first non-option is encountered.

```
--foo arg1 --bar arg2 arg3
```

is equivalent to

```
--foo -- arg1 --bar arg2 arg3
```

If `pass_through` is also enabled, options processing will terminate at the first unrecognized option, or non-option, whichever comes first.

bundling (default: disabled)

Enabling this option will allow single-character options to be bundled. To distinguish bundles from long option names, long options *must* be introduced with `-` and bundles with `.`.

Note that, if you have options `a`, `l` and `all`, and `auto_abbrev` enabled, possible arguments and option settings are:

using argument	sets option(s)
-----	-----
-a, --a	a
-l, --l	l
-al, -la, -ala, -all, ...	a, l
--al, --all	all

The suprising part is that `-a` sets option `a` (due to auto completion), not `all`.

Note: disabling `bundling` also disables `bundling_override`.

bundling_override (default: disabled)

If `bundling_override` is enabled, `bundling` is enabled as with `bundling` but now long option names override option bundles.

Note: disabling `bundling_override` also disables `bundling`.

Note: Using option bundling can easily lead to unexpected results, especially when mixing long options and bundles. Caveat emptor.

ignore_case (default: enabled)

If enabled, case is ignored when matching long option names. If, however, `bundling` is enabled as well, single character options will be treated case-sensitive.

With `ignore_case`, option specifications for options that only differ in case, e.g., `"foo"` and `"Foo"`, will be flagged as duplicates.

Note: disabling `ignore_case` also disables `ignore_case_always`.

`ignore_case_always` (default: disabled)

When bundling is in effect, case is ignored on single-character options also.

Note: disabling `ignore_case_always` also disables `ignore_case`.

`pass_through` (default: disabled)

Options that are unknown, ambiguous or supplied with an invalid option value are passed through in `@ARGV` instead of being flagged as errors. This makes it possible to write wrapper scripts that process only part of the user supplied command line arguments, and pass the remaining options to some other program.

If `require_order` is enabled, options processing will terminate at the first unrecognized option, or non-option, whichever comes first. However, if `permute` is enabled instead, results can become confusing.

`prefix` The string that starts options. If a constant string is not sufficient, see `prefix_pattern`.

`prefix_pattern` A Perl pattern that identifies the strings that introduce options. Default is `(-|\-|\+)` unless environment variable `POSIXLY_CORRECT` has been set, in which case it is `(-|-)`.

`debug` (default: disabled)

Enable debugging output.

Return values and Errors

Configuration errors and errors in the option definitions are signalled using `die()` and will terminate the calling program unless the call to `Getopt::Long::GetOptions()` was embedded in `eval { ... }`, or `die()` was trapped using `$SIG{__DIE__}`.

`GetOptions` returns true to indicate success. It returns false when the function detected one or more errors during option parsing. These errors are signalled using `warn()` and can be trapped with `$SIG{__WARN__}`.

Errors that can't happen are signalled using `Carp::croak()`.

Legacy

The earliest development of `newgetopt.pl` started in 1990, with Perl version 4. As a result, its development, and the development of `Getopt::Long`, has gone through several stages. Since backward compatibility has always been extremely important, the current version of `Getopt::Long` still supports a lot of constructs that nowadays are no longer necessary or otherwise unwanted. This section describes briefly some of these 'features'.

Default destinations

When no destination is specified for an option, `GetOptions` will store the resultant value in a global variable named `opt_XXX`, where `XXX` is the primary name of this option. When a program executes under `use strict` (recommended), these variables must be pre-declared with `our()` or `use vars`.

```
our $opt_length = 0;
GetOptions ('length=i');    # will store in $opt_length
```

To yield a usable Perl variable, characters that are not part of the syntax for variables are translated to underscores. For example, `-fpp-struct-return` will set the variable `$opt_fpp_struct_return`. Note that this variable resides in the namespace of the calling program, not necessarily `main`. For example:

```
GetOptions ("size=i", "sizes=i@");
```

with command line "`--size 10 --sizes 24 --sizes 48`" will perform the equivalent of the assignments

```
$opt_size = 10;
@opt_sizes = (24, 48);
```

Alternative option starters

A string of alternative option starter characters may be passed as the first argument (or the first argument after a leading hash reference argument).

```
my $len = 0;
GetOptions ('/', 'length=i' => $len);
```

Now the command line may look like:

```
/length 24 -- arg
```

Note that to terminate options processing still requires a double dash `--`.

`GetOptions()` will not interpret a leading `< "<"` as option starters if the next argument is a reference. To force `< "<"` and `< ""` as option starters, use `< "<"`. Confusing? Well, **using a starter argument is strongly deprecated** anyway.

Configuration variables

Previous versions of `Getopt::Long` used variables for the purpose of configuring. Although manipulating these variables still work, it is strongly encouraged to use the `Configure` routine that was introduced in version 2.17. Besides, it is much easier.

Trouble Shooting

Warning: Ignoring '!' modifier for short option

This warning is issued when the `!` modifier is applied to a short (one-character) option and bundling is in effect. E.g.,

```
Getopt::Long::Configure("bundling");
GetOptions("foo|f!" => \$foo);
```

Note that older `Getopt::Long` versions did not issue a warning, because the `!` modifier was applied to the first name only. This bug was fixed in 2.22.

Solution: separate the long and short names and apply the `!` to the long names only, e.g.,

```
GetOptions("foo!" => \$foo, "f" => \$foo);
```

GetOptions does not return a false result when an option is not supplied

That's why they're called 'options'.

GetOptions does not split the command line correctly

The command line is not split by `GetOptions`, but by the command line interpreter (CLI). On Unix, this is the shell. On Windows, it is `COMMAND.COM` or `CMD.EXE`. Other operating systems have other CLIs.

It is important to know that these CLIs may behave different when the command line contains special characters, in particular quotes or backslashes. For example, with Unix shells you can use single quotes (`'`) and double quotes (`"`) to group words together. The following alternatives are equivalent on Unix:

```
"two words"
'two words'
two\ words
```

In case of doubt, insert the following statement in front of your Perl program:

```
print STDERR (join(" | ", @ARGV), "\n");
```

to verify how your CLI passes the arguments to the program.

How do I put a "-?" option into a Getopt::Long?

You can only obtain this using an alias, and Getopt::Long of at least version 2.13.

```
use Getopt::Long;  
GetOptions ("help|?");    # -help and -? will both set $opt_help
```

NAME

`getopt` – Process single-character switches with switch clustering

`getopts` – Process single-character switches with switch clustering

SYNOPSIS

```
use Getopt::Std;

getopt('oDI');    # -o, -D & -I take arg.  Sets $opt_* as a side effect.
getopt('oDI', \%opts);    # -o, -D & -I take arg.  Values in %opts
getopts('oif:');  # -o & -i are boolean flags, -f takes an argument
                  # Sets $opt_* as a side effect.
getopts('oif:', \%opts); # options as above. Values in %opts
```

DESCRIPTION

The `getopt()` function processes single-character switches with switch clustering. Pass one argument which is a string containing all switches that take an argument. For each switch found, sets `$opt_x` (where `x` is the switch name) to the value of the argument if an argument is expected, or 1 otherwise. Switches which take an argument don't care whether there is a space between the switch and the argument.

The `getopts()` function is similar, but you should pass to it the list of all switches to be recognized. If unspecified switches are found on the command-line, the user will be warned that an unknown option was given.

Note that, if your code is running under the recommended `use strict 'vars'` pragma, you will need to declare these package variables with "our":

```
our($opt_x, $opt_y);
```

For those of you who don't like additional global variables being created, `getopt()` and `getopts()` will also accept a hash reference as an optional second argument. Hash keys will be `x` (where `x` is the switch name) with key values the value of the argument or 1 if no argument is specified.

To allow programs to process arguments that look like switches, but aren't, both functions will stop processing switches when they see the argument `—`. The `—` will be removed from `@ARGV`.

NAME

Hash::Util – A selection of general-utility hash subroutines

SYNOPSIS

```
use Hash::Util qw(lock_keys  unlock_keys
                  lock_value  unlock_value
                  lock_hash   unlock_hash);

%hash = (foo => 42, bar => 23);
lock_keys(%hash);
lock_keys(%hash, @keyset);
unlock_keys(%hash);

lock_value(%hash, 'foo');
unlock_value(%hash, 'foo');

lock_hash(%hash);
unlock_hash(%hash);
```

DESCRIPTION

Hash::Util contains special functions for manipulating hashes that don't really warrant a keyword.

By default Hash::Util does not export anything.

Restricted hashes

5.8.0 introduces the ability to restrict a hash to a certain set of keys. No keys outside of this set can be added.

It also introduces the ability to lock an individual key so it cannot be deleted and the value cannot be changed.

This is intended to largely replace the deprecated pseudo-hashes.

lock_keys**unlock_keys**

```
lock_keys(%hash);
lock_keys(%hash, @keys);
```

Restricts the given %hash's set of keys to @keys. If @keys is not given it restricts it to its current keyset. No more keys can be added. `delete()` and `exists()` will still work, but it does not effect the set of allowed keys.

```
unlock_keys(%hash);
```

Removes the restriction on the %hash's keyset.

lock_value**unlock_value**

```
lock_key(%hash, $key);
unlock_key(%hash, $key);
```

Locks and unlocks an individual key of a hash. The value of a locked key cannot be changed.

%hash must have already been locked for this to have useful effect.

lock_hash**unlock_hash**

```
lock_hash(%hash);
```

`lock_hash()` locks an entire hash, making all keys and values readonly. No value can be changed, no keys can be added or deleted.

```
unlock_hash(%hash);
```

`unlock_hash()` does the opposite of `lock_hash()`. All keys and values are made read/write. All values can be changed and keys can be added and deleted.

NAME

I18N::Collate – compare 8-bit scalar data according to the current locale

SYNOPSIS

```
use I18N::Collate;
setlocale(LC_COLLATE, 'locale-of-your-choice');
$s1 = new I18N::Collate "scalar_data_1";
$s2 = new I18N::Collate "scalar_data_2";
```

DESCRIPTION

WARNING: starting from the Perl version 5.003_06
the I18N::Collate interface for comparing 8-bit scalar data
according to the current locale

HAS BEEN DEPRECATED

That is, please do not use it anymore for any new applications
and please migrate the old applications away from it because its
functionality was integrated into the Perl core language in the
release 5.003_06.

See the perllocale manual page for further information.

This module provides you with objects that will collate according to your national character set, provided
that the POSIX `setlocale()` function is supported on your system.

You can compare `$s1` and `$s2` above with

```
$s1 le $s2
```

to extract the data itself, you'll need a dereference: `$$s1`

This module uses `POSIX::setlocale()`. The basic collation conversion is done by `strxfrm()` which
terminates at NUL characters being a decent C routine. `collate_xfrm()` handles embedded NUL
characters gracefully.

The available locales depend on your operating system; try whether `locale -a` shows them or man pages
for "locale" or "nlsinfo" or the direct approach `ls /usr/lib/nls/loc` or `ls /usr/lib/nls` or `ls /usr/lib/locale`. Not all the locales that your vendor supports are necessarily installed: please consult
your operating system's documentation and possibly your local system administration. The locale names are
probably something like `xx_XX.(ISO)?8859-N` or `xx_XX.(ISO)?8859N`, for example
`fr_CH.ISO8859-1` is the Swiss (CH) variant of French (fr), ISO Latin (8859) 1 (-1) which is the Western
European character set.

NAME

I18N::Langinfo – query locale information

SYNOPSIS

```
use I18N::Langinfo;
```

DESCRIPTION

The `langinfo()` function queries various locale information that can be used to localize output and user interfaces. The `langinfo()` requires one numeric argument that identifies the locale constant to query: if no argument is supplied, `$_` is used. The numeric constants appropriate to be used as arguments are exportable from `I18N::Langinfo`.

The following example will import the `langinfo()` function itself and three constants to be used as arguments to `langinfo()`: a constant for the abbreviated first day of the week (the numbering starts from Sunday = 1) and two more constants for the affirmative and negative answers for a yes/no question in the current locale.

```
use I18N::Langinfo qw(langinfo ABDAY_1 YESSTR NOSTR);
my ($abday_1, $yesstr, $nostr) = map { langinfo } qw(ABDAY_1 YESSTR NOSTR);
print "$abday_1? [$yesstr/$nostr] ";
```

In other words, in the "C" (or English) locale the above will probably print something like:

```
Sun? [yes/no]
```

but under a French locale

```
dim? [oui/non]
```

The usually available constants are

```
ABDAY_1 ABDAY_2 ABDAY_3 ABDAY_4 ABDAY_5 ABDAY_6 ABDAY_7
ABMON_1 ABMON_2 ABMON_3 ABMON_4 ABMON_5 ABMON_6
ABMON_7 ABMON_8 ABMON_9 ABMON_10 ABMON_11 ABMON_12
DAY_1 DAY_2 DAY_3 DAY_4 DAY_5 DAY_6 DAY_7
MON_1 MON_2 MON_3 MON_4 MON_5 MON_6
MON_7 MON_8 MON_9 MON_10 MON_11 MON_12
```

for abbreviated and full length days of the week and months of the year,

```
D_T_FMT D_FMT T_FMT
```

for the date–time, date, and time formats used by the `strftime()` function (see [POSIX](#))

```
AM_STR PM_STR T_FMT_AMPM
```

for the locales for which it makes sense to have ante meridiem and post meridiem time formats,

```
CODESET CRNCYSTR RADIXCHAR
```

for the character code set being used (such as "ISO8859-1", "cp850", "koi8-r", "sjis", "utf8", etc.), for the currency string, for the radix character used between the integer and the fractional part of decimal numbers (yes, this is redundant with `POSIX::localeconv()`)

```
YESSTR YESEXPR NOSTR NOEXPR
```

for the affirmative and negative responses and expressions, and

```
ERA ERA_D_FMT ERA_D_T_FMT ERA_T_FMT
```

for the Japanese Emperor eras (naturally only defined under Japanese locales).

See your [langinfo\(3\)](#) for more information about the available constants. (Often this means having to look

directly at the *langinfo.h* C header file.)

Note that unfortunately none of the above constants are guaranteed to be available on a particular platform. To be on the safe side you can wrap the import in an eval like this:

```
eval {  
    require I18N::Langinfo;  
    I18N::Langinfo->import(qw(langinfo CODESET));  
    $codeset = langinfo(CODESET()); # note the ()  
};  
if (!$?) { ... failed ... }
```

EXPORT

Nothing is exported by default.

SEE ALSO

[perllocale](#), [localeconv](#), [setlocale](#), [nl_langinfo\(3\)](#).

The `langinfo()` is just a wrapper for the C `nl_langinfo()` interface.

NAME

I18N::LangTags – functions for dealing with RFC3066–style language tags

SYNOPSIS

```
use I18N::LangTags qw(is_language_tag same_language_tag
                      extract_language_tags super_languages
                      similarity_language_tag is_dialect_of
                      locale2language_tag alternate_language_tags
                      encode_language_tag panic_languages
                      );
```

...or whatever of those functions you want to import. Those are all the exportable functions — you're free to import only some, or none at all. By default, none are imported. If you say:

```
use I18N::LangTags qw(:ALL)
```

...then all are exported. (This saves you from having to use something less obvious like `use I18N::LangTags qw(/./)`.)

If you don't import any of these functions, assume a `&I18N::LangTags::` in front of all the function names in the following examples.

DESCRIPTION

Language tags are a formalism, described in RFC 3066 (obsoleting 1766), for declaring what language form (language and possibly dialect) a given chunk of information is in.

This library provides functions for common tasks involving language tags as they are needed in a variety of protocols and applications.

Please see the "See Also" references for a thorough explanation of how to correctly use language tags.

- the function `is_language_tag($lang1)`

Returns true iff `$lang1` is a formally valid language tag.

```
is_language_tag("fr")           is TRUE
is_language_tag("x-jicarilla")  is FALSE
    (Subtags can be 8 chars long at most -- 'jicarilla' is 9)

is_language_tag("sgn-US")       is TRUE
    (That's American Sign Language)

is_language_tag("i-Klikitat")   is TRUE
    (True without regard to the fact noone has actually
    registered Klikitat -- it's a formally valid tag)

is_language_tag("fr-patois")    is TRUE
    (Formally valid -- altho descriptively weak!)

is_language_tag("Spanish")      is FALSE
is_language_tag("french-patois") is FALSE
    (No good -- first subtag has to match
    /^[xXiI]|[a-zA-Z]{2,3}$/ -- see RFC3066)

is_language_tag("x-borg-prot2532") is TRUE
    (Yes, subtags can contain digits, as of RFC3066)
```

- the function `extract_language_tags($whatever)`

Returns a list of whatever looks like formally valid language tags in `$whatever`. Not very smart, so don't get too creative with what you want to feed it.

```
extract_language_tags("fr, fr-ca, i-mingo")
returns: ('fr', 'fr-ca', 'i-mingo')
```

```
extract_language_tags("It's like this: I'm in fr -- French!")
returns:    ('It', 'in', 'fr')
(So don't just feed it any old thing.)
```

The output is untainted. If you don't know what tainting is, don't worry about it.

- the function `same_language_tag($lang1, $lang2)`

Returns true iff `$lang1` and `$lang2` are acceptable variant tags representing the same language-form.

```
same_language_tag('x-kadara', 'i-kadara')  is TRUE
(The x/i- alternation doesn't matter)
same_language_tag('X-KADARA', 'i-kadara')  is TRUE
(...and neither does case)
same_language_tag('en', 'en-US')           is FALSE
(all-English is not the SAME as US English)
same_language_tag('x-kadara', 'x-kadar')   is FALSE
(these are totally unrelated tags)
same_language_tag('no-bok', 'nb')          is TRUE
(no-bok is a legacy tag for nb (Norwegian Bokmal))
```

`same_language_tag` works by just seeing whether `encode_language_tag($lang1)` is the same as `encode_language_tag($lang2)`.

(Yes, I know this function is named a bit oddly. Call it historic reasons.)

- the function `similarity_language_tag($lang1, $lang2)`

Returns an integer representing the degree of similarity between tags `$lang1` and `$lang2` (the order of which does not matter), where similarity is the number of common elements on the left, without regard to case and to x/i- alternation.

```
similarity_language_tag('fr', 'fr-ca')      is 1
(one element in common)
similarity_language_tag('fr-ca', 'fr-FR')   is 1
(one element in common)
similarity_language_tag('fr-CA-joual',
                        'fr-CA-PEI')        is 2
similarity_language_tag('fr-CA-joual', 'fr-CA') is 2
(two elements in common)
similarity_language_tag('x-kadara', 'i-kadara') is 1
(x/i- doesn't matter)
similarity_language_tag('en', 'x-kadar')    is 0
similarity_language_tag('x-kadara', 'x-kadar') is 0
(unrelated tags -- no similarity)
similarity_language_tag('i-cree-syllabic',
                        'i-cherokee-syllabic') is 0
(no B<leftmost> elements in common!)
```

- the function `is_dialect_of($lang1, $lang2)`

Returns true iff language tag `$lang1` represents a subform of language tag `$lang2`.

Get the order right! It doesn't work the other way around!

```
is_dialect_of('en-US', 'en')                is TRUE
(American English IS a dialect of all-English)
is_dialect_of('fr-CA-joual', 'fr-CA')       is TRUE
```

```

is_dialect_of('fr-CA-joual', 'fr')      is TRUE
    (Joual is a dialect of (a dialect of) French)

is_dialect_of('en', 'en-US')            is FALSE
    (all-English is a NOT dialect of American English)

is_dialect_of('fr', 'en-CA')            is FALSE

is_dialect_of('en', 'en')                is TRUE
is_dialect_of('en-US', 'en-US')         is TRUE
    (B<Note:> these are degenerate cases)

is_dialect_of('i-mingo-tom', 'x-Mingo') is TRUE
    (the x/i thing doesn't matter, nor does case)

is_dialect_of('nn', 'no')                is TRUE
    (because 'nn' (New Norse) is aliased to 'no-nyn',
     as a special legacy case, and 'no-nyn' is a
     subform of 'no' (Norwegian))

```

- the function `super_languages($lang1)`

Returns a list of language tags that are superordinate tags to `$lang1` — it gets this by removing subtags from the end of `$lang1` until nothing (or just "i" or "x") is left.

```

super_languages("fr-CA-joual") is ("fr-CA", "fr")
super_languages("en-AU")      is ("en")
super_languages("en")         is empty-list, ()
super_languages("i-cherokee") is empty-list, ()
...not ("i"), which would be illegal as well as pointless.

```

If `$lang1` is not a valid language tag, returns empty-list in a list context, undef in a scalar context.

A notable and rather unavoidable problem with this method: "x-mingo-tom" has an "x" because the whole tag isn't an IANA-registered tag — but `super_languages('x-mingo-tom')` is ('x-mingo') — which isn't really right, since 'i-mingo' is registered. But this module has no way of knowing that. (But note that `same_language_tag('x-mingo', 'i-mingo')` is TRUE.)

More importantly, you assume *at your peril* that superordinates of `$lang1` are mutually intelligible with `$lang1`. Consider this carefully.

- the function `locale2language_tag($locale_identifier)`

This takes a locale name (like "en", "en-US", or "en-US.ISO8859-1") and maps it to a language tag. If it's not mappable (as with, notably, "C" and "POSIX"), this returns empty-list in a list context, or undef in a scalar context.

```

locale2language_tag("en") is "en"
locale2language_tag("en-US") is "en-US"
locale2language_tag("en-US.ISO8859-1") is "en-US"
locale2language_tag("C") is undef or ()
locale2language_tag("POSIX") is undef or ()
locale2language_tag("POSIX") is undef or ()

```

I'm not totally sure that locale names map satisfactorily to language tags. Think REAL hard about how you use this. YOU HAVE BEEN WARNED.

The output is untainted. If you don't know what tainting is, don't worry about it.

- the function `encode_language_tag($lang1)`

This function, if given a language tag, returns an encoding of it such that:

- * tags representing different languages never get the same encoding.
- * tags representing the same language always get the same encoding.
- * an encoding of a formally valid language tag always is a string value that is defined, has length, and is true if considered as a boolean.

Note that the encoding itself is **not** a formally valid language tag. Note also that you cannot, currently, go from an encoding back to a language tag that it's an encoding of.

Note also that you **must** consider the encoded value as atomic; i.e., you should not consider it as anything but an opaque, unanalysable string value. (The internals of the encoding method may change in future versions, as the language tagging standard changes over time.)

`encode_language_tag` returns undef if given anything other than a formally valid language tag.

The reason `encode_language_tag` exists is because different language tags may represent the same language; this is normally treatable with `same_language_tag`, but consider this situation:

You have a data file that expresses greetings in different languages. Its format is "[language tag]=[how to say 'Hello']", like:

```
en-US=Hiho
fr=Bonjour
i-mingo=Hau'
```

And suppose you write a program that reads that file and then runs as a daemon, answering client requests that specify a language tag and then expect the string that says how to greet in that language. So an interaction looks like:

```
greeting-client asks:   fr
greeting-server answers: Bonjour
```

So far so good. But suppose the way you're implementing this is:

```
my %greetings;
die unless open(IN, "<in.dat");
while(<IN>) {
    chomp;
    next unless /^([^=]+)=(.+)$/s;
    my($lang, $expr) = ($1, $2);
    $greetings{$lang} = $expr;
}
close(IN);
```

at which point `%greetings` has the contents:

```
"en-US"    => "Hiho"
"fr"        => "Bonjour"
"i-mingo"   => "Hau' "
```

And suppose then that you answer client requests for language `$wanted` by just looking up `$greetings{$wanted}`.

If the client asks for "fr", that will look up successfully in `%greetings`, to the value "Bonjour". And if the client asks for "i-mingo", that will look up successfully in `%greetings`, to the value "Hau'".

But if the client asks for "i-Mingo" or "x-mingo", or "Fr", then the lookup in `%greetings` fails. That's the Wrong Thing.

You could instead do lookups on `$wanted` with:

```
use I18N::LangTags qw(same_language_tag);
my $response = '';
foreach my $l2 (keys %greetings) {
    if(same_language_tag($wanted, $l2)) {
        $response = $greetings{$l2};
        last;
    }
}
```

But that's rather inefficient. A better way to do it is to start your program with:

```
use I18N::LangTags qw(encode_language_tag);
my %greetings;
die unless open(IN, "<in.dat");
while(<IN>) {
    chomp;
    next unless /^(^[^=]+)=(.+)$/s;
    my($lang, $expr) = ($1, $2);
    $greetings{
        encode_language_tag($lang)
    } = $expr;
}
close(IN);
```

and then just answer client requests for language `$wanted` by just looking up

```
$greetings{encode_language_tag($wanted)}
```

And that does the Right Thing.

- the function `alternate_language_tags($lang1)`

This function, if given a language tag, returns all language tags that are alternate forms of this language tag. (I.e., tags which refer to the same language.) This is meant to handle legacy tags caused by the minor changes in language tag standards over the years; and the `x-/i-` alternation is also dealt with.

Note that this function does *not* try to equate new (and never-used, and unusable) ISO639-2 three-letter tags to old (and still in use) ISO639-1 two-letter equivalents — like "ara" — "ar" — because "ara" has *never* been in use as an Internet language tag, and RFC 3066 stipulates that it never should be, since a shorter tag ("ar") exists.

Examples:

```
alternate_language_tags('no-bok')    is ('nb')
alternate_language_tags('nb')        is ('no-bok')
alternate_language_tags('he')        is ('iw')
alternate_language_tags('iw')        is ('he')
alternate_language_tags('i-hakka')    is ('zh-hakka', 'x-hakka')
alternate_language_tags('zh-hakka')   is ('i-hakka', 'x-hakka')
alternate_language_tags('en')         is ()
alternate_language_tags('x-mingo-tom') is ('i-mingo-tom')
alternate_language_tags('x-klikitat') is ('i-klikitat')
alternate_language_tags('i-klikitat') is ('x-klikitat')
```

This function returns empty-list if given anything other than a formally valid language tag.

- the function `@langs = panic_languages(@accept_languages)`

This function takes a list of 0 or more language tags that constitute a given user's Accept-Language list, and returns a list of tags for *other* (non-super) languages that are probably acceptable to the user,

to be used *if all else fails*.

For example, if a user accepts only 'ca' (Catalan) and 'es' (Spanish), and the documents/interfaces you have available are just in German, Italian, and Chinese, then the user will most likely want the Italian one (and not the Chinese or German one!), instead of getting nothing. So `panic_languages('ca', 'es')` returns a list containing 'it' (Italian).

English ('en') is *always* in the return list, but whether it's at the very end or not depends on the input languages. This function works by consulting an internal table that stipulates what common languages are "close" to each other.

A useful construct you might consider using is:

```
@fallbacks = super_languages(@accept_languages);
push @fallbacks, panic_languages(
    @accept_languages, @fallbacks,
);
```

ABOUT LOWERCASING

I've considered making all the above functions that output language tags return all those tags strictly in lowercase. Having all your language tags in lowercase does make some things easier. But you might as well just lowercase as you like, or call `encode_language_tag($lang1)` where appropriate.

ABOUT UNICODE PLAINTEXT LANGUAGE TAGS

In some future version of I18N::LangTags, I plan to include support for RFC2482-style language tags — which are basically just normal language tags with their ASCII characters shifted into Plane 14.

NAME

I18N::LangTags::List — tags and names for human languages

SYNOPSIS

```
use I18N::LangTags::List;
print "Parlez-vous... ", join(' ',
    I18N::LangTags::List::name('elx') || 'unknown_language',
    I18N::LangTags::List::name('ar-Kw') || 'unknown_language',
    I18N::LangTags::List::name('en') || 'unknown_language',
    I18N::LangTags::List::name('en-CA') || 'unknown_language',
), "?\n";
```

prints:

```
Parlez-vous... Elamite, Kuwait Arabic, English, Canadian English?
```

DESCRIPTION

This module provides a function `I18N::LangTags::List::name(langtag)` that takes a language tag (see [I18N::LangTags/I18N::LangTags](#)) and returns the best attempt at an English name for it, or undef if it can't make sense of the tag.

The function `I18N::LangTags::List::name(...)` is not exported.

The map of tags-to-names that it uses is accessible as `%I18N::LangTags::List::Name`, and it's the same as the list that follows in this documentation, which should be useful to you even if you don't use this module.

ABOUT LANGUAGE TAGS

Internet language tags, as defined in RFC 3066, are a formalism for denoting human languages. The two-letter ISO 639-1 language codes are well known (as "en" for English), as are their forms when qualified by a country code ("en-US"). Less well-known are the arbitrary-length non-ISO codes (like "i-mingo"), and the recently (in 2001) introduced three-letter ISO-639-2 codes.

Remember these important facts:

- Language tags are not locale IDs. A locale ID is written with a "_" instead of a "-", (almost?) always matches `m/^\w\w_\w\w\b/`, and *means* something different than a language tag. A language tag denotes a language. A locale ID denotes a language *as used in* a particular place, in combination with non-linguistic location-specific information such as what currency is used there. Locales *also* often denote character set information, as in "en_US.ISO8859-1".
- Language tags are not for computer languages.
- "Dialect" is not a useful term, since there is no objective criterion for establishing when two language-forms are dialects of eachother, or are separate languages.
- Language tags are not case-sensitive. en-US, en-us, En-U_s, etc., are all the same tag, and denote the same language.
- Not every language tag really refers to a single language. Some language tags refer to conditions: i-default (system-message text in English plus maybe other languages), und (undetermined language). Others (notably lots of the three-letter codes) are bibliographic tags that classify whole groups of languages, as with cus "Cushitic (Other)" (i.e., a language that has been classed as Cushtic, but which has no more specific code) or the even less linguistically coherent sai for "South American Indian (Other)". Though useful in bibliography, **SUCH TAGS ARE NOT FOR GENERAL USE**. For further guidance, email me.
- Language tags are not country codes. In fact, they are often distinct codes, as with language tag ja for Japanese, and ISO 3166 country code .jp for Japan.

LIST OF LANGUAGES

The first part of each item is the language tag, between {...}. It is followed by an English name for the language or language-group. Language tags that I judge to be not for general use, are bracketed.

This list is in alphabetical order by English name of the language.

=for reminder

The name in the =item line MUST NOT have 's in it!!

 eq Sard.

{sas} : Sasak
{sco} : Scots
 NOT Scots Gaelic!

{sel} : Selkup
[sem] : Semitic (Other)
{sr} : Serbian
 eq Serb. NOT Sorbian.

{srr} : Serer
{shn} : Shan
{sn} : Shona
{sid} : Sidamo
{sgn-...} : Sign Languages
 Always use with a subtag. Notable forms: {sgn-gb} British Sign Language (BSL); {sgn-ie} Irish
 Sign Language (ESL); {sgn-ni} Nicaraguan Sign Language (ISN); {sgn-us} American Sign
 Language (ASL).

{bla} : Siksika
 eq Blackfoot. eq Pikanii.

{sd} : Sindhi
{si} : Sinhalese
 eq Sinhala.

[sit] : Sino-Tibetan (Other)
[sio] : Siouan languages
{den} : Slave (Athapaskan)
 ("Slavey" is a subform.)

[sla] : Slavic (Other)
{sk} : Slovak
 eq Slovakian.

{sl} : Slovenian
 eq Slovene.

{sog} : Sogdian
{so} : Somali
{son} : Songhai
{snk} : Soninke
{wen} : Sorbian languages
 eq Wendish. eq Sorb. eq Lusatian. eq Wend. NOT Venda! NOT Serbian!

{nso} : Northern Sotho
{st} : Southern Sotho
 eq Sutu. eq Sesotho.

[{sai} : South American Indian (Other)]

{es} : Spanish

Notable forms: {es-ar} Argentine Spanish; {es-bo} Bolivian Spanish; {es-cl} Chilean Spanish; {es-co} Colombian Spanish; {es-do} Dominican Spanish; {es-ec} Ecuadorian Spanish; {es-es} Spain Spanish; {es-gt} Guatemalan Spanish; {es-hn} Honduran Spanish; {es-mx} Mexican Spanish; {es-pa} Panamanian Spanish; {es-pe} Peruvian Spanish; {es-pr} Puerto Rican Spanish; {es-py} Paraguay Spanish; {es-sv} Salvadoran Spanish; {es-us} US Spanish; {es-uy} Uruguayan Spanish; {es-ve} Venezuelan Spanish.

{suk} : Sukuma

{sux} : Sumerian

(Historical)

{su} : Sundanese

{sus} : Susu

{sw} : Swahili

eq Kiswahili

{ss} : Swati

{sv} : Swedish

Notable forms: {sv-se} Sweden Swedish; {sv-fi} Finland Swedish.

{syr} : Syriac

{tl} : Tagalog

{ty} : Tahitian

[{tai} : Tai (Other)]

NOT Thai!

{tg} : Tajik

{tmh} : Tamashek

{ta} : Tamil

{i-tao} : Tao

eq Yami.

{tt} : Tatar

{i-tay} : Tayal

eq Atayal. eq Atayan.

{te} : Telugu

{ter} : Tereno

{tet} : Tetum

{th} : Thai

NOT Tai!

{bo} : Tibetan

{tig} : Tigre

{ti} : Tigrinya

{tem} : Timne

eq Themne. eq Timene.

{tiv} : Tiv

{tli} : Tlingit

{tpi} : Tok Pisin

{tkl} : Tokelau

{tog} : Tonga (Nyasa)

NOT Tsonga!

{to} : Tonga (Tonga Islands)
(Pronounced "Tong-a", not "Tong-ga")
NOT Tsonga!

{tsi} : Tsimshian
eq Sm'algyax

{ts} : Tsonga
NOT Tonga!

{i-tsu} : Tsou

{tn} : Tswana
Same as Setswana.

NAME

if – use a Perl module if a condition holds

SYNOPSIS

```
use if CONDITION, MODULE => ARGUMENTS;
```

DESCRIPTION

The construct

```
use if CONDITION, MODULE => ARGUMENTS;
```

has no effect unless `CONDITION` is true. In this case the effect is the same as of

```
use MODULE ARGUMENTS;
```

BUGS

The current implementation does not allow specification of the required version of the module.

Ilya Zakharevich <mailto:perl-module-if@ilyaz.org>.

NAME

integer – Perl pragma to use integer arithmetic instead of floating point

SYNOPSIS

```
use integer;
$x = 10/3;
# $x is now 3, not 3.3333333333333333
```

DESCRIPTION

This tells the compiler to use integer operations from here to the end of the enclosing BLOCK. On many machines, this doesn't matter a great deal for most computations, but on those without floating point hardware, it can make a big difference in performance.

Note that this only affects how most of the arithmetic and relational **operators** handle their operands and results, and **not** how all numbers everywhere are treated. Specifically, `use integer;` has the effect that before computing the results of the arithmetic operators (+, −, *, /, %, +=, −=, *=, /=, %=, and unary minus), the comparison operators (<, <=, =, ==, !=, <=), and the bitwise operators (&, ^, <<, >>, &=, ^=, <<=, >>=), the operands have their fractional portions truncated (or floored), and the result will have its fractional portion truncated as well. In addition, the range of operands and results is restricted to that of familiar two's complement integers, i.e., $-(2^{**31}) .. (2^{**31}-1)$ on 32-bit architectures, and $-(2^{**63}) .. (2^{**63}-1)$ on 64-bit architectures. For example, this code

```
use integer;
$x = 5.8;
$y = 2.5;
$z = 2.7;
$a = 2**31 - 1; # Largest positive integer on 32-bit machines
$, = ", ";
print $x, -$x, $x + $y, $x - $y, $x / $y, $x * $y, $y == $z, $a, $a + 1;
```

will print: 5.8, −5, 7, 3, 2, 10, 1, 2147483647, −2147483648

Note that `$x` is still printed as having its true non-integer value of 5.8 since it wasn't operated on. And note too the wrap-around from the largest positive integer to the largest negative one. Also, arguments passed to functions and the values returned by them are **not** affected by `use integer;`. E.g.,

```
srand(1.5);
$, = ", ";
print sin(.5), cos(.5), atan2(1,2), sqrt(2), rand(10);
```

will give the same result with or without `use integer;` The power operator `**` is also not affected, so that `2**.5` is always the square root of 2. Now, it so happens that the pre- and post- increment and decrement operators, `++` and `--`, are not affected by `use integer;` either. Some may rightly consider this to be a bug — but at least it's a long-standing one.

Finally, `use integer;` also has an additional affect on the bitwise operators. Normally, the operands and results are treated as **unsigned** integers, but with `use integer;` the operands and results are **signed**. This means, among other things, that `~0` is `−1`, and `−2 & −5` is `−6`.

Internally, native integer arithmetic (as provided by your C compiler) is used. This means that Perl's own semantics for arithmetic operations may not be preserved. One common source of trouble is the modulus of negative numbers, which Perl does one way, but your hardware may do another.

```
% perl -le 'print (4 % -3)'
-2
% perl -Minteger -le 'print (4 % -3)'
1
```

See [Pragmatic Modules in perlmodlib](#), [Integer Arithmetic in perlop](#)

NAME

IO – load various IO modules

SYNOPSIS

```
use IO;
```

DESCRIPTION

IO provides a simple mechanism to load some of the IO modules at one go. Currently this includes:

```
IO::Handle  
IO::Seekable  
IO::File  
IO::Pipe  
IO::Socket  
IO::Dir
```

For more information on any of these modules, please see its respective documentation.

NAME

IO::Dir – supply object methods for directory handles

SYNOPSIS

```
use IO::Dir;
$d = new IO::Dir ".";
if (defined $d) {
    while (defined($_ = $d->read)) { something($_); }
    $d->rewind;
    while (defined($_ = $d->read)) { something_else($_); }
    undef $d;
}

tie %dir, IO::Dir, ".";
foreach (keys %dir) {
    print $_, " " , $dir{$_}->size, "\n";
}
```

DESCRIPTION

The IO::Dir package provides two interfaces to perl's directory reading routines.

The first interface is an object approach. IO::Dir provides an object constructor and methods, which are just wrappers around perl's built in directory reading routines.

`new ([DIRNAME])`

`new` is the constructor for IO::Dir objects. It accepts one optional argument which, if given, `new` will pass to `open`

The following methods are wrappers for the directory related functions built into perl (the trailing 'dir' has been removed from the names). See [perlfunc](#) for details of these functions.

`open (DIRNAME)`

`read ()`

`seek (POS)`

`tell ()`

`rewind ()`

`close ()`

IO::Dir also provides an interface to reading directories via a tied HASH. The tied HASH extends the interface beyond just the directory reading routines by the use of `lstat`, from the `File::stat` package, `unlink`, `rmdir` and `utime`.

`tie %hash, IO::Dir, DIRNAME [, OPTIONS]`

The keys of the HASH will be the names of the entries in the directory. Reading a value from the hash will be the result of calling `File::stat::lstat`. Deleting an element from the hash will call `unlink` providing that `DIR_UNLINK` is passed in the `OPTIONS`.

Assigning to an entry in the HASH will cause the time stamps of the file to be modified. If the file does not exist then it will be created. Assigning a single integer to a HASH element will cause both the access and modification times to be changed to that value. Alternatively a reference to an array of two values can be passed. The first array element will be used to set the access time and the second element will be used to set the modification time.

NAME

IO::File – supply object methods for filehandles

SYNOPSIS

```
use IO::File;

$fh = new IO::File;
if ($fh->open("< file")) {
    print <$fh>;
    $fh->close;
}

$fh = new IO::File "> file";
if (defined $fh) {
    print $fh "bar\n";
    $fh->close;
}

$fh = new IO::File "file", "r";
if (defined $fh) {
    print <$fh>;
    undef $fh;          # automatically closes the file
}

$fh = new IO::File "file", O_WRONLY|O_APPEND;
if (defined $fh) {
    print $fh "corge\n";

    $pos = $fh->getpos;
    $fh->setpos($pos);

    undef $fh;          # automatically closes the file
}

autoflush STDOUT 1;
```

DESCRIPTION

IO::File inherits from IO::Handle and IO::Seekable. It extends these classes with methods that are specific to file handles.

CONSTRUCTOR

`new (FILENAME [,MODE [,PERMS]])`

Creates an IO::File. If it receives any parameters, they are passed to the method `open`; if the open fails, the object is destroyed. Otherwise, it is returned to the caller.

`new_tmpfile`

Creates an IO::File opened for read/write on a newly created temporary file. On systems where this is possible, the temporary file is anonymous (i.e. it is unlinked after creation, but held open). If the temporary file cannot be created or opened, the IO::File object is destroyed. Otherwise, it is returned to the caller.

METHODS

`open(FILENAME [,MODE [,PERMS]])`

`open` accepts one, two or three parameters. With one parameter, it is just a front end for the built-in `open` function. With two or three parameters, the first parameter is a filename that may include whitespace or other special characters, and the second parameter is the open mode, optionally followed by a file permission value.

If `IO::File::open` receives a Perl mode string ("`>`", "`+<`", etc.) or an ANSI C `fopen()` mode string ("`w`", "`r+`", etc.), it uses the basic Perl `open` operator (but protects any special characters).

If `IO::File::open` is given a numeric mode, it passes that mode and the optional permissions value to the Perl `sysopen` operator. The permissions default to 0666.

For convenience, `IO::File` exports the `O_XXX` constants from the `Fcntl` module, if this module is available.

NAME

IO::Handle – supply object methods for I/O handles

SYNOPSIS

```
use IO::Handle;

$io = new IO::Handle;
if ($io->fdopen(fileno(STDIN), "r")) {
    print $io->getline;
    $io->close;
}

$io = new IO::Handle;
if ($io->fdopen(fileno(STDOUT), "w")) {
    $io->print("Some text\n");
}

use IO::Handle '_IOLBF';
$io->setvbuf($buffer_var, _IOLBF, 1024);

undef $io;          # automatically closes the file if it's open

autoflush STDOUT 1;
```

DESCRIPTION

IO::Handle is the base class for all other IO handle classes. It is not intended that objects of IO::Handle would be created directly, but instead IO::Handle is inherited from by several other classes in the IO hierarchy.

If you are reading this documentation, looking for a replacement for the FileHandle package, then I suggest you read the documentation for IO::File too.

CONSTRUCTOR

`new ()`

Creates a new IO::Handle object.

`new_from_fd (FD, MODE)`

Creates an IO::Handle like new does. It requires two parameters, which are passed to the method `fdopen`; if the `fdopen` fails, the object is destroyed. Otherwise, it is returned to the caller.

METHODS

See [perlfunc](#) for complete descriptions of each of the following supported IO::Handle methods, which are just front ends for the corresponding built-in functions:

```
$io->close
$io->eof
$io->fileno
$io->format_write( [FORMAT_NAME] )
$io->getc
$io->read ( BUF, LEN, [OFFSET] )
$io->print ( ARGS )
$io->printf ( FMT, [ARGS] )
$io->stat
$io->sysread ( BUF, LEN, [OFFSET] )
$io->syswrite ( BUF, [LEN, [OFFSET]] )
$io->truncate ( LEN )
```

See [perlvar](#) for complete descriptions of each of the following supported IO::Handle methods. All of them return the previous value of the attribute and takes an optional single argument that when given will set

the value. If no argument is given the previous value is unchanged (except for `$io->autoflush` will actually turn ON autoflush by default).

```

$io->autoflush ( [BOOL] )           $|
$io->format_page_number( [NUM] )     $%
$io->format_lines_per_page( [NUM] )  $=
$io->format_lines_left( [NUM] )      $-
$io->format_name( [STR] )            $~
$io->format_top_name( [STR] )        $^
$io->input_line_number( [NUM] )      $.

```

The following methods are not supported on a per-filehandle basis.

```

IO::Handle->format_line_break_characters( [STR] ) $:
IO::Handle->format_formfeed( [STR] )             $^L
IO::Handle->output_field_separator( [STR] )       $,
IO::Handle->output_record_separator( [STR] )      $\
IO::Handle->input_record_separator( [STR] )        $/

```

Furthermore, for doing normal I/O you might need these:

`$io->fdopen (FD, MODE)`

`fdopen` is like an ordinary `open` except that its first parameter is not a filename but rather a file handle name, an `IO::Handle` object, or a file descriptor number.

`$io->opened`

Returns true if the object is currently a valid file descriptor, false otherwise.

`$io->getline`

This works like `<$io` described in *[I/O Operators in perlop](#)* except that it's more readable and can be safely called in a list context but still returns just one line.

`$io->getlines`

This works like `<$io` when called in a list context to read all the remaining lines in a file, except that it's more readable. It will also `croak()` if accidentally called in a scalar context.

`$io->ungetc (ORD)`

Pushes a character with the given ordinal value back onto the given handle's input stream. Only one character of pushback per handle is guaranteed.

`$io->write (BUF, LEN [, OFFSET])`

This `write` is like `write` found in C, that is it is the opposite of `read`. The wrapper for the perl `write` function is called `format_write`.

`$io->error`

Returns a true value if the given handle has experienced any errors since it was opened or since the last call to `clearerr`, or if the handle is invalid. It only returns false for a valid handle with no outstanding errors.

`$io->clearerr`

Clear the given handle's error indicator. Returns `-1` if the handle is invalid, `0` otherwise.

`$io->sync`

`sync` synchronizes a file's in-memory state with that on the physical medium. `sync` does not operate at the `perlio` api level, but operates on the file descriptor (similar to `sysread`, `sysseek` and `system`). This means that any data held at the `perlio` api level will not be synchronized. To synchronize data that is buffered at the `perlio` api level you must use the `flush` method. `sync` is not implemented on all platforms. Returns "0 but true" on success, `undef` on error, `undef` for an invalid handle. See *[fsync\(3c\)](#)*.

`$io-flush`

`flush` causes perl to flush any buffered data at the `perlio` api level. Any unread data in the buffer will be discarded, and any unwritten data will be written to the underlying file descriptor. Returns "0 but true" on success, `undef` on error.

`$io-printflush (ARGS)`

Turns on autoflush, print `ARGS` and then restores the autoflush status of the `IO::Handle` object. Returns the return value from `print`.

`$io-blocking ([BOOL])`

If called with an argument `blocking` will turn on non-blocking IO if `BOOL` is false, and turn it off if `BOOL` is true.

`blocking` will return the value of the previous setting, or the current setting if `BOOL` is not given.

If an error occurs `blocking` will return `undef` and `$!` will be set.

If the C functions `setbuf()` and/or `setvbuf()` are available, then `IO::Handle::setbuf` and `IO::Handle::setvbuf` set the buffering policy for an `IO::Handle`. The calling sequences for the Perl functions are the same as their C counterparts—including the constants `_IOFBF`, `_IOLBF`, and `_IONBF` for `setvbuf()`—except that the buffer parameter specifies a scalar variable to use as a buffer. You should only change the buffer before any I/O, or immediately after calling `flush`.

WARNING: A variable used as a buffer by `setbuf` or `setvbuf` **must not be modified** in any way until the `IO::Handle` is closed or `setbuf` or `setvbuf` is called again, or memory corruption may result! Remember that the order of global destruction is undefined, so even if your buffer variable remains in scope until program termination, it may be undefined before the file `IO::Handle` is closed. Note that you need to import the constants `_IOFBF`, `_IOLBF`, and `_IONBF` explicitly. Like C, `setbuf` returns nothing. `setvbuf` returns "0 but true", on success, `undef` on failure.

Lastly, there is a special method for working under `-T` and `setuid/gid` scripts:

`$io-untaint`

Marks the object as taint-clean, and as such data read from it will also be considered taint-clean. Note that this is a very trusting action to take, and appropriate consideration for the data source and potential vulnerability should be kept in mind. Returns 0 on success, -1 if setting the taint-clean flag failed. (eg invalid handle)

NOTE

An `IO::Handle` object is a reference to a symbol/GLOB reference (see the `Symbol` package). Some modules that inherit from `IO::Handle` may want to keep object related variables in the hash table part of the GLOB. In an attempt to prevent modules trampling on each other I propose that any such module should prefix its variables with its own name separated by `_`'s. For example the `IO::Socket` module keeps a `timeout` variable in `'io_socket_timeout'`.

SEE ALSO

[perlfunc](#), [I/O Operators in perlop](#), [IO::File](#)

BUGS

Due to backwards compatibility, all filehandles resemble objects of class `IO::Handle`, or actually classes derived from that class. They actually aren't. Which means you can't derive your own class from `IO::Handle` and inherit those methods.

HISTORY

Derived from `FileHandle.pm` by Graham Barr <gbarr@pobox.com>

NAME

IO::Pipe – supply object methods for pipes

SYNOPSIS

```
use IO::Pipe;

$pipe = new IO::Pipe;

if($pid = fork()) { # Parent
    $pipe->reader();

    while(<$pipe>) {
        ...
    }
}

elsif(defined $pid) { # Child
    $pipe->writer();

    print $pipe ...
}

or

$pipe = new IO::Pipe;
$pipe->reader(qw(ls -l));

while(<$pipe>) {
    ...
}
```

DESCRIPTION

IO::Pipe provides an interface to creating pipes between processes.

CONSTRUCTOR

`new ([READER, WRITER])`

Creates an `IO::Pipe`, which is a reference to a newly created symbol (see the `Symbol` package). `IO::Pipe::new` optionally takes two arguments, which should be objects blessed into `IO::Handle`, or a subclass thereof. These two objects will be used for the system call to `pipe`. If no arguments are given then `method handles` is called on the new `IO::Pipe` object.

These two handles are held in the array part of the GLOB until either `reader` or `writer` is called.

METHODS

`reader ([ARGS])`

The object is re-blessed into a sub-class of `IO::Handle`, and becomes a handle at the reading end of the pipe. If `ARGS` are given then `fork` is called and `ARGS` are passed to `exec`.

`writer ([ARGS])`

The object is re-blessed into a sub-class of `IO::Handle`, and becomes a handle at the writing end of the pipe. If `ARGS` are given then `fork` is called and `ARGS` are passed to `exec`.

`handles ()`

This method is called during construction by `IO::Pipe::new` on the newly created `IO::Pipe` object. It returns an array of two objects blessed into `IO::Pipe::End`, or a subclass thereof.

NAME

IO::Poll – Object interface to system poll call

SYNOPSIS

```
use IO::Poll qw(POLLRDNORM POLLWRNORM POLLIN POLLHUP);

$poll = new IO::Poll;

$poll->mask($input_handle => POLLIN);
$poll->mask($output_handle => POLLOUT);

$poll->poll($timeout);

$ev = $poll->events($input);
```

DESCRIPTION

IO::Poll is a simple interface to the system level poll routine.

METHODS

mask (IO [, EVENT_MASK])

If EVENT_MASK is given, then, if EVENT_MASK is non-zero, IO is added to the list of file descriptors and the next call to poll will check for any event specified in EVENT_MASK. If EVENT_MASK is zero then IO will be removed from the list of file descriptors.

If EVENT_MASK is not given then the return value will be the current event mask value for IO.

poll ([TIMEOUT])

Call the system level poll routine. If TIMEOUT is not specified then the call will block. Returns the number of handles which had events happen, or -1 on error.

events (IO)

Returns the event mask which represents the events that happen on IO during the last call to poll.

remove (IO)

Remove IO from the list of file descriptors for the next poll.

handles([EVENT_MASK])

Returns a list of handles. If EVENT_MASK is not given then a list of all handles known will be returned. If EVENT_MASK is given then a list of handles will be returned which had one of the events specified by EVENT_MASK happen during the last call to poll.

NAME

IO::Seekable – supply seek based methods for I/O objects

SYNOPSIS

```
use IO::Seekable;
package IO::Something;
@ISA = qw(IO::Seekable);
```

DESCRIPTION

IO::Seekable does not have a constructor of its own as it is intended to be inherited by other IO::Handle based objects. It provides methods which allow seeking of the file descriptors.

\$io-getpos

Returns an opaque value that represents the current position of the IO::File, or undef if this is not possible (eg an unseekable stream such as a terminal, pipe or socket). If the `fgetpos()` function is available in your C library it is used to implements `getpos`, else perl emulates `getpos` using C's `ftell()` function.

\$io-setpos

Uses the value of a previous `getpos` call to return to a previously visited position. Returns "0 but true" on success, undef on failure.

See [perlfunc](#) for complete descriptions of each of the following supported IO::Seekable methods, which are just front ends for the corresponding built-in functions:

\$io-seek (POS, WHENCE)

Seek the IO::File to position POS, relative to WHENCE:

WHENCE=0 (SEEK_SET)

POS is absolute position. (Seek relative to the start of the file)

WHENCE=1 (SEEK_CUR)

POS is an offset from the current position. (Seek relative to current)

WHENCE=2 (SEEK_END)

POS is an offset from the end of the file. (Seek relative to end)

The SEEK_* constants can be imported from the `Fcntl` module if you don't wish to use the numbers 1 or 2 in your code.

Returns 1 upon success, otherwise.

\$io-sysseek(POS, WHENCE)

Similar to `$io-seek`, but sets the IO::File's position using the system call `lseek(2)` directly, so will confuse most perl IO operators except `sysread` and `syswrite` (see [perlfunc](#) for full details)

Returns the new position, or undef on failure. A position of zero is returned as the string "0 but true"

\$io-tell

Returns the IO::File's current position, or -1 on error.

HISTORY

Derived from FileHandle.pm by Graham Barr <gbarr@pobox.com>

NAME

IO::Select – OO interface to the select system call

SYNOPSIS

```
use IO::Select;

$s = IO::Select->new();

$s->add(\*STDIN);
$s->add($some_handle);

@ready = $s->can_read($timeout);

@ready = IO::Select->new(@handles)->read(0);
```

DESCRIPTION

The `IO::Select` package implements an object approach to the system `select` function call. It allows the user to see what IO handles, see [IO::Handle](#), are ready for reading, writing or have an error condition pending.

CONSTRUCTOR

`new ([HANDLES])`

The constructor creates a new object and optionally initialises it with a set of handles.

METHODS

`add (HANDLES)`

Add the list of handles to the `IO::Select` object. It is these values that will be returned when an event occurs. `IO::Select` keeps these values in a cache which is indexed by the `fileno` of the handle, so if more than one handle with the same `fileno` is specified then only the last one is cached.

Each handle can be an `IO::Handle` object, an integer or an array reference where the first element is an `IO::Handle` or an integer.

`remove (HANDLES)`

Remove all the given handles from the object. This method also works by the `fileno` of the handles. So the exact handles that were added need not be passed, just handles that have an equivalent `fileno`

`exists (HANDLE)`

Returns a true value (actually the handle itself) if it is present. Returns `undef` otherwise.

`handles`

Return an array of all registered handles.

`can_read ([TIMEOUT])`

Return an array of handles that are ready for reading. `TIMEOUT` is the maximum amount of time to wait before returning an empty list, in seconds, possibly fractional. If `TIMEOUT` is not given and any handles are registered then the call will block.

`can_write ([TIMEOUT])`

Same as `can_read` except check for handles that can be written to.

`has_exception ([TIMEOUT])`

Same as `can_read` except check for handles that have an exception condition, for example pending out-of-band data.

`count ()`

Returns the number of handles that the object will check for when one of the `can_` methods is called or the object is passed to the `select` static method.

bits()

Return the bit string suitable as argument to the core `select()` call.

select (READ, WRITE, ERROR [, TIMEOUT])

`select` is a static method, that is you call it with the package name like `new`. `READ`, `WRITE` and `ERROR` are either `undef` or `IO::Select` objects. `TIMEOUT` is optional and has the same effect as for the core `select` call.

The result will be an array of 3 elements, each a reference to an array which will hold the handles that are ready for reading, writing and have error conditions respectively. Upon error an empty array is returned.

EXAMPLE

Here is a short example which shows how `IO::Select` could be used to write a server which communicates with several sockets while also listening for more connections on a listen socket

```
use IO::Select;
use IO::Socket;

$lsn = new IO::Socket::INET(Listen => 1, LocalPort => 8080);
$sel = new IO::Select( $lsn );

while(@ready = $sel->can_read) {
    foreach $fh (@ready) {
        if($fh == $lsn) {
            # Create a new socket
            $new = $lsn->accept;
            $sel->add($new);
        }
        else {
            # Process socket

            # Maybe we have finished with the socket
            $sel->remove($fh);
            $fh->close;
        }
    }
}
```

NAME

IO::Socket – Object interface to socket communications

SYNOPSIS

```
use IO::Socket;
```

DESCRIPTION

IO::Socket provides an object interface to creating and using sockets. It is built upon the [IO::Handle](#) interface and inherits all the methods defined by [IO::Handle](#).

IO::Socket only defines methods for those operations which are common to all types of socket. Operations which are specified to a socket in a particular domain have methods defined in sub classes of IO::Socket

IO::Socket will export all functions (and constants) defined by [Socket](#).

CONSTRUCTOR

```
new ( [ARGS] )
```

Creates an IO::Socket, which is a reference to a newly created symbol (see the Symbol package). new optionally takes arguments, these arguments are in key–value pairs. new only looks for one key Domain which tells new which domain the socket will be in. All other arguments will be passed to the configuration method of the package for that domain, See below.

NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE

As of VERSION 1.18 all IO::Socket objects have autoflush turned on by default. This was not the case with earlier releases.

NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE

METHODS

See [perlfunc](#) for complete descriptions of each of the following supported IO::Socket methods, which are just front ends for the corresponding built–in functions:

```
socket
socketpair
bind
listen
accept
send
recv
peername (getpeername)
sockname (getsockname)
shutdown
```

Some methods take slightly different arguments to those defined in [perlfunc](#) in attempt to make the interface more flexible. These are

```
accept([PKG])
```

perform the system call `accept` on the socket and return a new object. The new object will be created in the same class as the listen socket, unless PKG is specified. This object can be used to communicate with the client that was trying to connect.

In a scalar context the new socket is returned, or undef upon failure. In a list context a two–element array is returned containing the new socket and the peer address; the list will be empty upon failure.

The timeout in the [PKG] can be specified as zero to effect a "poll", but you shouldn't do that because a new IO::Select object will be created behind the scenes just to do the single poll. This is horrendously inefficient. Use rather `true select()` with a zero timeout on the handle, or

non-blocking IO.

socketpair(DOMAIN, TYPE, PROTOCOL)

Call `socketpair` and return a list of two sockets created, or an empty list on failure.

Additional methods that are provided are:

atmark

True if the socket is currently positioned at the urgent data mark, false otherwise.

```
use IO::Socket;

my $sock = IO::Socket::INET->new('some_server');
$sock->read(1024,$data) until $sock->atmark;
```

Note: this is a reasonably new addition to the family of socket functions, so all systems may not support this yet. If it is unsupported by the system, an attempt to use this method will abort the program.

The `atmark()` functionality is also exportable as `socketatmark()` function:

```
use IO::Socket 'socketatmark';
```

This allows for a more traditional use of `socketatmark()` as a procedural socket function. If your system does not support `socketatmark()`, the use declaration will fail at compile time.

connected

If the socket is in a connected state the peer address is returned. If the socket is not in a connected state then `undef` will be returned.

protocol

Returns the numerical number for the protocol being used on the socket, if known. If the protocol is unknown, as with an `AF_UNIX` socket, zero is returned.

sockdomain

Returns the numerical number for the socket domain type. For example, for an `AF_INET` socket the value of `&AF_INET` will be returned.

sockopt(OPT [, VAL])

Unified method to both set and get options in the `SOL_SOCKET` level. If called with one argument then `getsockopt` is called, otherwise `setsockopt` is called.

socktype

Returns the numerical number for the socket type. For example, for a `SOCK_STREAM` socket the value of `&SOCK_STREAM` will be returned.

timeout([VAL])

Set or get the timeout value associated with this socket. If called without any arguments then the current setting is returned. If called with an argument the current setting is changed and the previous value returned.

NAME

IO::Socket::INET – Object interface for AF_INET domain sockets

SYNOPSIS

```
use IO::Socket::INET;
```

DESCRIPTION

IO::Socket::INET provides an object interface to creating and using sockets in the AF_INET domain. It is built upon the *IO::Socket* interface and inherits all the methods defined by *IO::Socket*.

CONSTRUCTOR

```
new ( [ARGS] )
```

Creates an IO::Socket::INET object, which is a reference to a newly created symbol (see the Symbol package). new optionally takes arguments, these arguments are in key–value pairs.

In addition to the key–value pairs accepted by *IO::Socket*, IO::Socket::INET provides.

PeerAddr	Remote host address	<hostname>[:<port>]
PeerHost	Synonym for PeerAddr	
PeerPort	Remote port or service	<service>[(<no>)] <no>
LocalAddr	Local host bind address	hostname[:port]
LocalHost	Synonym for LocalAddr	
LocalPort	Local host bind port	<service>[(<no>)] <no>
Proto	Protocol name (or number)	"tcp" "udp" ...
Type	Socket type	SOCK_STREAM SOCK_DGRAM ...
Listen	Queue size for listen	
ReuseAddr	Set SO_REUSEADDR before binding	
Reuse	Set SO_REUSEADDR before binding (deprecated, prefer ReuseAddr)	
ReusePort	Set SO_REUSEPORT before binding	
Broadcast	Set SO_BROADCAST before binding	
Timeout	Timeout value for various operations	
MultiHomed	Try all addresses for multi-homed hosts	
Blocking	Determine if connection will be blocking mode	

If Listen is defined then a listen socket is created, else if the socket type, which is derived from the protocol, is SOCK_STREAM then connect () is called.

Although it is not illegal, the use of MultiHomed on a socket which is in non–blocking mode is of little use. This is because the first connect will never fail with a timeout as the connect call will not block.

The PeerAddr can be a hostname or the IP–address on the "xx.xx.xx.xx" form. The PeerPort can be a number or a symbolic service name. The service name might be followed by a number in parenthesis which is used if the service is not known by the system. The PeerPort specification can also be embedded in the PeerAddr by preceding it with a ":".

If Proto is not given and you specify a symbolic PeerPort port, then the constructor will try to derive Proto from the service name. As a last resort Proto "tcp" is assumed. The Type parameter will be deduced from Proto if not specified.

If the constructor is only passed a single argument, it is assumed to be a PeerAddr specification.

If Blocking is set to 0, the connection will be in nonblocking mode. If not specified it defaults to 1 (blocking mode).

Examples:

```
$sock = IO::Socket::INET->new (PeerAddr => 'www.perl.org',
                               PeerPort => 'http(80)',
```

```

                                Proto    => 'tcp');
$sock = IO::Socket::INET->new(PeerAddr => 'localhost:smtp(25)');
$sock = IO::Socket::INET->new(Listen    => 5,
                                LocalAddr => 'localhost',
                                LocalPort => 9000,
                                Proto     => 'tcp');

$sock = IO::Socket::INET->new('127.0.0.1:25');
$sock = IO::Socket::INET->new(PeerPort  => 9999,
                                PeerAddr  => inet_ntoa(INADDR_BROADCAST),
                                Proto     => udp,
                                LocalAddr => 'localhost',
                                Broadcast => 1 )
                                or die "Can't bind : $@\n";

```

NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE

As of VERSION 1.18 all IO::Socket objects have autoflush turned on by default. This was not the case with earlier releases.

NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE

METHODS

`sockaddr ()`

Return the address part of the sockaddr structure for the socket

`sockport ()`

Return the port number that the socket is using on the local host

`sockhost ()`

Return the address part of the sockaddr structure for the socket in a text form xx.xx.xx.xx

`peeraddr ()`

Return the address part of the sockaddr structure for the socket on the peer host

`peerport ()`

Return the port number for the socket on the peer host.

`peerhost ()`

Return the address part of the sockaddr structure for the socket on the peer host in a text form xx.xx.xx.xx

NAME

IO::Socket::UNIX – Object interface for AF_UNIX domain sockets

SYNOPSIS

```
use IO::Socket::UNIX;
```

DESCRIPTION

IO::Socket::UNIX provides an object interface to creating and using sockets in the AF_UNIX domain. It is built upon the *IO::Socket* interface and inherits all the methods defined by *IO::Socket*.

CONSTRUCTOR

```
new ( [ARGS] )
```

Creates an IO::Socket::UNIX object, which is a reference to a newly created symbol (see the Symbol package). new optionally takes arguments, these arguments are in key–value pairs.

In addition to the key–value pairs accepted by *IO::Socket*, IO::Socket::UNIX provides.

Type	Type of socket (eg SOCK_STREAM or SOCK_DGRAM)
Local	Path to local fifo
Peer	Path to peer fifo
Listen	Create a listen socket

If the constructor is only passed a single argument, it is assumed to be a Peer specification.

NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE

As of VERSION 1.18 all IO::Socket objects have autoflush turned on by default. This was not the case with earlier releases.

NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE NOTE

METHODS

```
hostpath()
```

Returns the pathname to the fifo at the local end

```
peerpath()
```

Returns the pathanme to the fifo at the peer end

NAME

IPC::Open2, open2 – open a process for both reading and writing

SYNOPSIS

```
use IPC::Open2;

$pid = open2(\*RDRFH, \*WTRFH, 'some cmd and args');
# or without using the shell
$pid = open2(\*RDRFH, \*WTRFH, 'some', 'cmd', 'and', 'args');

# or with handle autovivification
my($rdrfh, $wtrfh);
$pid = open2($rdrfh, $wtrfh, 'some cmd and args');
# or without using the shell
$pid = open2($rdrfh, $wtrfh, 'some', 'cmd', 'and', 'args');
```

DESCRIPTION

The `open2()` function runs the given `$cmd` and connects `$rdrfh` for reading and `$wtrfh` for writing. It's what you think should work when you try

```
$pid = open(HANDLE, "|cmd args|");
```

The write filehandle will have autoflush turned on.

If `$rdrfh` is a string (that is, a bareword filehandle rather than a glob or a reference) and it begins with `< &`, then the child will send output directly to that file handle. If `$wtrfh` is a string that begins with `< <&`, then `$wtrfh` will be closed in the parent, and the child will read from it directly. In both cases, there will be a `dup(2)` instead of a `pipe(2)` made.

If either reader or writer is the null string, this will be replaced by an autogenerated filehandle. If so, you must pass a valid `lvalue` in the parameter slot so it can be overwritten in the caller, or an exception will be raised.

`open2()` returns the process ID of the child process. It doesn't return on failure: it just raises an exception matching `^open2:/.` . However, `exec` failures in the child are not detected. You'll have to trap `SIGPIPE` yourself.

`open2()` does not wait for and reap the child process after it exits. Except for short programs where it's acceptable to let the operating system take care of this, you need to do this yourself. This is normally as simple as calling `waitpid $pid, 0` when you're done with the process. Failing to do this can result in an accumulation of defunct or "zombie" processes. See [waitpid](#) for more information.

This whole affair is quite dangerous, as you may block forever. It assumes it's going to talk to something like `bc`, both writing to it and reading from it. This is presumably safe because you "know" that commands like `bc` will read a line at a time and output a line at a time. Programs like `sort` that read their entire input stream first, however, are quite apt to cause deadlock.

The big problem with this approach is that if you don't have control over source code being run in the child process, you can't control what it does with pipe buffering. Thus you can't just open a pipe to `cat -v` and continually read and write a line from it.

The `IO::Pty` and `Expect` modules from CPAN can help with this, as they provide a real tty (well, a pseudo-tty, actually), which gets you back to line buffering in the invoked command again.

WARNING

The order of arguments differs from that of `open3()`.

SEE ALSO

See [IPC::Open3](#) for an alternative that handles `STDERR` as well. This function is really just a wrapper around `open3()`.

NAME

IPC::Open3, open3 – open a process for reading, writing, and error handling

SYNOPSIS

```
$pid = open3(\*WTRFH, \*RDRFH, \*ERRFH,  
            'some cmd and args', 'optarg', ...);  
  
my($wtr, $rdr, $err);  
$pid = open3($wtr, $rdr, $err,  
            'some cmd and args', 'optarg', ...);
```

DESCRIPTION

Extremely similar to `open2()`, `open3()` spawns the given `$cmd` and connects `RDRFH` for reading, `WTRFH` for writing, and `ERRFH` for errors. If `ERRFH` is false, or the same file descriptor as `RDRFH`, then `STDOUT` and `STDERR` of the child are on the same filehandle. The `WTRFH` will have autoflush turned on.

If `WTRFH` begins with `< &`, then `WTRFH` will be closed in the parent, and the child will read from it directly. If `RDRFH` or `ERRFH` begins with `< &`, then the child will send output directly to that filehandle. In both cases, there will be a `dup(2)` instead of a `pipe(2)` made.

If either reader or writer is the null string, this will be replaced by an autogenerated filehandle. If so, you must pass a valid lvalue in the parameter slot so it can be overwritten in the caller, or an exception will be raised.

The filehandles may also be integers, in which case they are understood as file descriptors.

`open3()` returns the process ID of the child process. It doesn't return on failure: it just raises an exception matching `/^open3:/. However, exec failures in the child are not detected. You'll have to trap SIGPIPE yourself.`

`open3()` does not wait for and reap the child process after it exits. Except for short programs where it's acceptable to let the operating system take care of this, you need to do this yourself. This is normally as simple as calling `waitpid $pid, 0` when you're done with the process. Failing to do this can result in an accumulation of defunct or "zombie" processes. See [waitpid](#) for more information.

If you try to read from the child's stdout writer and their stderr writer, you'll have problems with blocking, which means you'll want to use `select()` or the `IO::Select`, which means you'd best use `sysread()` instead of `readline()` for normal stuff.

This is very dangerous, as you may block forever. It assumes it's going to talk to something like **bc**, both writing to it and reading from it. This is presumably safe because you "know" that commands like **bc** will read a line at a time and output a line at a time. Programs like **sort** that read their entire input stream first, however, are quite apt to cause deadlock.

The big problem with this approach is that if you don't have control over source code being run in the child process, you can't control what it does with pipe buffering. Thus you can't just open a pipe to `cat -v` and continually read and write a line from it.

WARNING

The order of arguments differs from that of `open2()`.

NAME

IPC::Msg – SysV Msg IPC object class

SYNOPSIS

```
use IPC::SysV qw(IPC_PRIVATE S_IRWXU);
use IPC::Msg;

$msg = new IPC::Msg(IPC_PRIVATE, S_IRWXU);
$msg->snd(pack("l! a*", $msgtype, $msg));
$msg->rcv($buf, 256);

$ds = $msg->stat;

$msg->remove;
```

DESCRIPTION

A class providing an object based interface to SysV IPC message queues.

METHODS

new (KEY , FLAGS)

Creates a new message queue associated with KEY. A new queue is created if

- KEY is equal to IPC_PRIVATE
- KEY does not already have a message queue associated with it, and *FLAGS* & IPC_CREAT is true.

On creation of a new message queue *FLAGS* is used to set the permissions.

id Returns the system message queue identifier.

rcv (BUF, LEN [, TYPE [, FLAGS]])

Read a message from the queue. Returns the type of the message read. See [msgrcv](#). The BUF becomes tainted.

remove

Remove and destroy the message queue from the system.

set (STAT)

set (NAME = VALUE [, NAME = VALUE ...])

set will set the following values of the stat structure associated with the message queue.

```
uid
gid
mode (oly the permission bits)
qbytes
```

set accepts either a stat object, as returned by the stat method, or a list of *name–value* pairs.

snd (TYPE, MSG [, FLAGS])

Place a message on the queue with the data from MSG and with type TYPE. See [msgsnd](#).

stat Returns an object of type IPC::Msg::stat which is a sub-class of Class::Struct. It provides the following fields. For a description of these fields see you system documentation.

```
uid
gid
cuid
cgid
mode
```

qnum
qbytes
lspid
lrpid
stime
rtime
ctime

SEE ALSO

[IPC::SysV Class::Struct](#)

NAME

IPC::Semaphore – SysV Semaphore IPC object class

SYNOPSIS

```
use IPC::SysV qw(IPC_PRIVATE S_IRWXU IPC_CREAT);
use IPC::Semaphore;

$sem = new IPC::Semaphore(IPC_PRIVATE, 10, S_IRWXU | IPC_CREAT);
$sem->setall( (0) x 10);
@sem = $sem->getall;
$ncnt = $sem->getncnt;
$zcnt = $sem->getzcnt;
$ds = $sem->stat;
$sem->remove;
```

DESCRIPTION

A class providing an object based interface to SysV IPC semaphores.

METHODS

new (KEY , NSEMS , FLAGS)

Create a new semaphore set associated with KEY. NSEMS is the number of semaphores in the set. A new set is created if

- KEY is equal to IPC_PRIVATE
- KEY does not already have a semaphore identifier associated with it, and *FLAGS* & IPC_CREAT is true.

On creation of a new semaphore set *FLAGS* is used to set the permissions.

getall

Returns the values of the semaphore set as an array.

getncnt (SEM)

Returns the number of processes waiting for the semaphore SEM to become greater than its current value

getpid (SEM)

Returns the process id of the last process that performed an operation on the semaphore SEM.

getval (SEM)

Returns the current value of the semaphore SEM.

getzcnt (SEM)

Returns the number of processes waiting for the semaphore SEM to become zero.

id Returns the system identifier for the semaphore set.

op (OPLIST)

OPLIST is a list of operations to pass to *semop*. OPLIST is a concatenation of smaller lists, each which has three values. The first is the semaphore number, the second is the operation and the last is a flags value. See [semop](#) for more details. For example

```
$sem->op(
    0, -1, IPC_NOWAIT,
    1,  1, IPC_NOWAIT
```

```
) ;
```

remove

Remove and destroy the semaphore set from the system.

set (STAT)

set (NAME = VALUE [, NAME = VALUE ...])

set will set the following values of the stat structure associated with the semaphore set.

```
uid
gid
mode (only the permission bits)
```

set accepts either a stat object, as returned by the stat method, or a list of *name-value* pairs.

setall (VALUES)

Sets all values in the semaphore set to those given on the VALUES list. VALUES must contain the correct number of values.

setval (N , VALUE)

Set the Nth value in the semaphore set to VALUE

stat Returns an object of type `IPC::Semaphore::stat` which is a sub-class of `Class::Struct`. It provides the following fields. For a description of these fields see your system documentation.

```
uid
gid
cuid
cgid
mode
ctime
otime
nsems
```

IPC::SysV – SysV IPC constants

SYNOPSIS

```
use IPC::SysV qw(IPC_STAT IPC_PRIVATE);
```

DESCRIPTION

IPC::SysV defines and conditionally exports all the constants defined in your system include files which are needed by the SysV IPC calls.

ftok(PATH, ID)

Return a key based on PATH and ID, which can be used as a key for msgget, semget and shmget.

See *ftok*

NAME

less – perl pragma to request less of something from the compiler

SYNOPSIS

```
use less;  # unimplemented
```

DESCRIPTION

Currently unimplemented, this may someday be a compiler directive to make certain trade-offs, such as perhaps

```
use less 'memory';
use less 'CPU';
use less 'fat';
```

NAME

List::Util – A selection of general-utility list subroutines

SYNOPSIS

```
use List::Util qw(first max maxstr min minstr reduce shuffle sum);
```

DESCRIPTION

List::Util contains a selection of subroutines that people have expressed would be nice to have in the perl core, but the usage would not really be high enough to warrant the use of a keyword, and the size so small such that being individual extensions would be wasteful.

By default List::Util does not export any subroutines. The subroutines defined are

first BLOCK LIST

Similar to `grep` in that it evaluates `BLOCK` setting `$_` to each element of `LIST` in turn. `first` returns the first element where the result from `BLOCK` is a true value. If `BLOCK` never returns true or `LIST` was empty then `undef` is returned.

```
$foo = first { defined($_) } @list      # first defined value in @list
$foo = first { $_ > $value } @list      # first value in @list which
                                         # is greater than $value
```

This function could be implemented using `reduce` like this

```
$foo = reduce { defined($a) ? $a : wanted($b) ? $b : undef } undef, @list
```

for example `wanted()` could be `defined()` which would return the first defined value in `@list`

max LIST

Returns the entry in the list with the highest numerical value. If the list is empty then `undef` is returned.

```
$foo = max 1..10                # 10
$foo = max 3,9,12               # 12
$foo = max @bar, @baz           # whatever
```

This function could be implemented using `reduce` like this

```
$foo = reduce { $a > $b ? $a : $b } 1..10
```

maxstr LIST

Similar to `max`, but treats all the entries in the list as strings and returns the highest string as defined by the `gt` operator. If the list is empty then `undef` is returned.

```
$foo = maxstr 'A'..'Z'          # 'Z'
$foo = maxstr "hello","world"   # "world"
$foo = maxstr @bar, @baz        # whatever
```

This function could be implemented using `reduce` like this

```
$foo = reduce { $a gt $b ? $a : $b } 'A'..'Z'
```

min LIST

Similar to `max` but returns the entry in the list with the lowest numerical value. If the list is empty then `undef` is returned.

```
$foo = min 1..10                # 1
$foo = min 3,9,12               # 3
$foo = min @bar, @baz           # whatever
```

This function could be implemented using `reduce` like this

```
$foo = reduce { $a < $b ? $a : $b } 1..10
```

minstr LIST

Similar to min, but treats all the entries in the list as strings and returns the lowest string as defined by the lt operator. If the list is empty then undef is returned.

```
$foo = minstr 'A'..'Z'           # 'A'
$foo = minstr "hello","world"    # "hello"
$foo = minstr @bar, @baz         # whatever
```

This function could be implemented using reduce like this

```
$foo = reduce { $a lt $b ? $a : $b } 'A'..'Z'
```

reduce BLOCK LIST

Reduces LIST by calling BLOCK multiple times, setting \$a and \$b each time. The first call will be with \$a and \$b set to the first two elements of the list, subsequent calls will be done by setting \$a to the result of the previous call and \$b to the next element in the list.

Returns the result of the last call to BLOCK. If LIST is empty then undef is returned. If LIST only contains one element then that element is returned and BLOCK is not executed.

```
$foo = reduce { $a < $b ? $a : $b } 1..10      # min
$foo = reduce { $a lt $b ? $a : $b } 'aa'..'zz' # minstr
$foo = reduce { $a + $b } 1 .. 10              # sum
$foo = reduce { $a . $b } @bar                 # concat
```

shuffle LIST

Returns the elements of LIST in a random order

```
@cards = shuffle 0..51          # 0..51 in a random order
```

sum LIST

Returns the sum of all the elements in LIST.

```
$foo = sum 1..10                # 55
$foo = sum 3,9,12               # 24
$foo = sum @bar, @baz           # whatever
```

This function could be implemented using reduce like this

```
$foo = reduce { $a + $b } 1..10
```

KNOWN BUGS

With perl versions prior to 5.005 there are some cases where reduce will return an incorrect result. This will show up as test 7 of reduce.t failing.

SUGGESTED ADDITIONS

The following are additions that have been requested, but I have been reluctant to add due to them being very simple to implement in perl

```
# One argument is true
sub any { $_ && return 1 for @_; 0 }

# All arguments are true
sub all { $_ || return 0 for @_; 1 }

# All arguments are false
sub none { $_ && return 0 for @_; 1 }

# One argument is false
```

```
sub notall { $_ || return 1 for @_; 0 }  
# How many elements are true  
sub true { scalar grep { $_ } @_ }  
# How many elements are false  
sub false { scalar grep { !$_ } @_ }
```

NAME

Scalar::Util – A selection of general-utility scalar subroutines

SYNOPSIS

```
use Scalar::Util qw(blessed dualvar isweak readonly reftype tainted weaken);
```

DESCRIPTION

Scalar::Util contains a selection of subroutines that people have expressed would be nice to have in the perl core, but the usage would not really be high enough to warrant the use of a keyword, and the size so small such that being individual extensions would be wasteful.

By default Scalar::Util does not export any subroutines. The subroutines defined are

blessed EXPR

If EXPR evaluates to a blessed reference the name of the package that it is blessed into is returned. Otherwise undef is returned.

```
$scalar = "foo";
$class  = blessed $scalar;           # undef

$ref    = [];
$class  = blessed $ref;              # undef

$obj    = bless [], "Foo";
$class  = blessed $obj;              # "Foo"
```

dualvar NUM, STRING

Returns a scalar that has the value NUM in a numeric context and the value STRING in a string context.

```
$foo = dualvar 10, "Hello";
$num = $foo + 2;           # 12
$str = $foo . " world";    # Hello world
```

isweak EXPR

If EXPR is a scalar which is a weak reference the result is true.

```
$ref = \ $foo;
$weak = isweak($ref);      # false
weaken($ref);
$weak = isweak($ref);      # true
```

openhandle FH

Returns FH if FH may be used as a filehandle and is open, or FH is a tied handle. Otherwise undef is returned.

```
$fh = openhandle(*STDIN);      # \*STDIN
$fh = openhandle(\*STDIN);    # \*STDIN
$fh = openhandle(*NOTOPEN);   # undef
$fh = openhandle("scalar");    # undef
```

readonly SCALAR

Returns true if SCALAR is readonly.

```
sub foo { readonly($_[0]) }

$readonly = foo($bar);        # false
$readonly = foo(0);           # true
```

reftype EXPR

If EXPR evaluates to a reference the type of the variable referenced is returned. Otherwise undef is returned.

```
$type = reftype "string";           # undef
$type = reftype \ $var;             # SCALAR
$type = reftype [];                # ARRAY

$obj = bless {}, "Foo";
$type = reftype $obj;               # HASH
```

tainted EXPR

Return true if the result of EXPR is tainted

```
$taint = tainted("constant");       # false
$taint = tainted($ENV{PWD});        # true if running under -T
```

weaken REF

REF will be turned into a weak reference. This means that it will not hold a reference count on the object it references. Also when the reference count on that object reaches zero, REF will be set to undef.

This is useful for keeping copies of references , but you don't want to prevent the object being DESTROY-ed at its usual time.

```
{
    my $var;
    $ref = \ $var;
    weaken($ref);                  # Make $ref a weak reference
}
# $ref is now undef
```

KNOWN BUGS

There is a bug in perl5.6.0 with UV's that are = 1<<31. This will show up as tests 8 and 9 of dualvar.t failing

COPYRIGHT

BLATANT PLUG

The weaken and isweak subroutines in this module and the patch to the core Perl were written in connection with the APress book 'Tuomas J. Lukka's Definitive Guide to Object-Oriented Programming in Perl', to avoid explaining why certain things would have to be done in cumbersome ways.

NAME

locale – Perl pragma to use and avoid POSIX locales for built-in operations

SYNOPSIS

```
@x = sort @y;      # ASCII sorting order
{
    use locale;
    @x = sort @y;   # Locale-defined sorting order
}
@x = sort @y;      # ASCII sorting order again
```

DESCRIPTION

This pragma tells the compiler to enable (or disable) the use of POSIX locales for built-in operations (LC_CTYPE for regular expressions, and LC_COLLATE for string comparison). Each "use locale" or "no locale" affects statements to the end of the enclosing BLOCK.

See [perllocale](#) for more detailed information on how Perl supports locales.

NAME

Locale::Constants – constants for Locale codes

SYNOPSIS

```
use Locale::Constants;  
  
$codeset = LOCALE_CODE_ALPHA_2;
```

DESCRIPTION

Locale::Constants defines symbols which are used in the four modules from the Locale–Codes distribution:

```
Locale::Language  
Locale::Country  
Locale::Currency  
Locale::Script
```

Note: at the moment only `Locale::Country` and `Locale::Script` support more than one code set.

The symbols defined are used to specify which codes you want to be used:

```
LOCALE_CODE_ALPHA_2  
LOCALE_CODE_ALPHA_3  
LOCALE_CODE_NUMERIC
```

You shouldn't have to use this module directly yourself – it is used by the three Locale modules, which in turn export the symbols.

KNOWN BUGS AND LIMITATIONS

None at the moment.

SEE ALSO

`Locale::Language`
Codes for identification of languages.

`Locale::Country`
Codes for identification of countries.

`Locale::Script`
Codes for identification of scripts.

`Locale::Currency`
Codes for identification of currencies and funds.

NAME

Locale::Country – ISO codes for country identification (ISO 3166)

SYNOPSIS

```
use Locale::Country;

$country = code2country('jp');      # $country gets 'Japan'
$code    = country2code('Norway');  # $code gets 'no'

@codes    = all_country_codes();
@names    = all_country_names();

# semi-private routines
Locale::Country::alias_code('uk' => 'gb');
Locale::Country::rename_country('gb' => 'Great Britain');
```

DESCRIPTION

The `Locale::Country` module provides access to the ISO codes for identifying countries, as defined in ISO 3166-1. You can either access the codes via the [conversion routines](#) (described below), or with the two functions which return lists of all country codes or all country names.

There are three different code sets you can use for identifying countries:

alpha-2

Two letter codes, such as 'tv' for Tuvalu. This code set is identified with the symbol `LOCALE_CODE_ALPHA_2`.

alpha-3

Three letter codes, such as 'brb' for Barbados. This code set is identified with the symbol `LOCALE_CODE_ALPHA_3`.

numeric

Numeric codes, such as 064 for Bhutan. This code set is identified with the symbol `LOCALE_CODE_NUMERIC`.

All of the routines take an optional additional argument which specifies the code set to use. If not specified, it defaults to the two-letter codes. This is partly for backwards compatibility (previous versions of this module only supported the alpha-2 codes), and partly because they are the most widely used codes.

The alpha-2 and alpha-3 codes are not case-dependent, so you can use 'BO', 'Bo', 'bo' or 'bo' for Bolivia. When a code is returned by one of the functions in this module, it will always be lower-case.

As of version 2.00, `Locale::Country` supports variant names for countries. So, for example, the country code for "United States" is "us", so `country2code('United States')` returns 'us'. Now the following will also return 'us':

```
country2code('United States of America')
country2code('USA')
```

CONVERSION ROUTINES

There are three conversion routines: `code2country()`, `country2code()`, and `country_code2code()`.

`code2country(CODE, [CODESET])`

This function takes a country code and returns a string which contains the name of the country identified. If the code is not a valid country code, as defined by ISO 3166, then `undef` will be returned:

```
$country = code2country('fi');
```

`country2code(STRING, [CODESET])`

This function takes a country name and returns the corresponding country code, if such exists. If the argument could not be identified as a country name, then `undef` will be returned:

```
$code = country2code('Norway', LOCALE_CODE_ALPHA_3);
# $code will now be 'nor'
```

The case of the country name is not important. See the section [KNOWN BUGS AND LIMITATIONS](#) below.

`country_code2code(CODE, CODESET, CODESET)`

This function takes a country code from one code set, and returns the corresponding code from another code set.

```
$alpha2 = country_code2code('fin',
                             LOCALE_CODE_ALPHA_3, LOCALE_CODE_ALPHA_2);
# $alpha2 will now be 'fi'
```

If the code passed is not a valid country code in the first code set, or if there isn't a code for the corresponding country in the second code set, then `undef` will be returned.

QUERY ROUTINES

There are two function which can be used to obtain a list of all codes, or all country names:

`all_country_codes([CODESET])`

Returns a list of all two-letter country codes. The codes are guaranteed to be all lower-case, and not in any particular order.

`all_country_names([CODESET])`

Returns a list of all country names for which there is a corresponding country code in the specified code set. The names are capitalised, and not returned in any particular order.

Not all countries have alpha-3 and numeric codes – some just have an alpha-2 code, so you'll get a different number of countries depending on which code set you specify.

SEMI-PRIVATE ROUTINES

`Locale::Country` provides two semi-private routines for modifying the internal data. Given their status, they aren't exported by default, and so need to be called by prefixing the function name with the package name.

`alias_code`

Define a new code as an alias for an existing code:

```
Locale::Country::alias_code( ALIAS => CODE [, CODESET ] )
```

This feature was added as a mechanism for handling a "uk" code. The ISO standard says that the two-letter code for "United Kingdom" is "gb", whereas domain names are all .uk.

By default the module does not understand "uk", since it is implementing an ISO standard. If you would like 'uk' to work as the two-letter code for United Kingdom, use the following:

```
Locale::Country::alias_code('uk' => 'gb');
```

With this code, both "uk" and "gb" are valid codes for United Kingdom, with the reverse lookup returning "uk" rather than the usual "gb".

Note: this function was previously called `_alias_code`, but the leading underscore has been dropped. The old name will be supported for all 2.X releases for backwards compatibility.

`rename_country`

If the official country name just isn't good enough for you, you can rename a country. For example, the official country name for code 'gb' is 'United Kingdom'. If you want to change that, you might call:

```
Locale::Country::rename_country('gb' => 'Great Britain');
```

This means that calling `code2country('gb')` will now return 'Great Britain' instead of 'United Kingdom'. The original country name is retained as an alias, so for the above example, `country2code('United Kingdom')` will still return 'gb'.

EXAMPLES

The following example illustrates use of the `code2country()` function. The user is prompted for a country code, and then told the corresponding country name:

```
$| = 1;    # turn off buffering

print "Enter country code: ";
chop($code = <STDIN>);
$country = code2country($code, LOCALE_CODE_ALPHA_2);
if (defined $country)
{
    print "$code = $country\n";
}
else
{
    print "'$code' is not a valid country code!\n";
}
```

DOMAIN NAMES

Most top-level domain names are based on these codes, but there are certain codes which aren't. If you are using this module to identify country from hostname, your best bet is to preprocess the country code.

For example, **edu**, **com**, **gov** and friends would map to **us**; **uk** would map to **gb**. Any others?

KNOWN BUGS AND LIMITATIONS

- When using `country2code()`, the country name must currently appear exactly as it does in the source of the module. The module now supports a small number of variants.
Possible extensions to this are: an interface for getting at the list of variant names, and regular expression matches.
- In the current implementation, all data is read in when the module is loaded, and then held in memory. A lazy implementation would be more memory friendly.
- Support for country names in different languages.

NAME

Locale::Currency – ISO three letter codes for currency identification (ISO 4217)

SYNOPSIS

```
use Locale::Currency;

$curr = code2currency('usd');    # $curr gets 'US Dollar'
$code = currency2code('Euro');   # $code gets 'eur'

@codes = all_currency_codes();
@names = all_currency_names();
```

DESCRIPTION

The `Locale::Currency` module provides access to the ISO three-letter codes for identifying currencies and funds, as defined in ISO 4217. You can either access the codes via the [conversion routines](#) (described below), or with the two functions which return lists of all currency codes or all currency names.

There are two special codes defined by the standard which aren't understood by this module:

XTS

Specifically reserved for testing purposes.

XXX

For transactions where no currency is involved.

CONVERSION ROUTINES

There are two conversion routines: `code2currency()` and `currency2code()`.

`code2currency()`

This function takes a three letter currency code and returns a string which contains the name of the currency identified. If the code is not a valid currency code, as defined by ISO 4217, then `undef` will be returned.

```
$curr = code2currency($code);
```

`currency2code()`

This function takes a currency name and returns the corresponding three letter currency code, if such exists. If the argument could not be identified as a currency name, then `undef` will be returned.

```
$code = currency2code('French Franc');
```

The case of the currency name is not important. See the section [KNOWN BUGS AND LIMITATIONS](#) below.

QUERY ROUTINES

There are two function which can be used to obtain a list of all currency codes, or all currency names:

`all_currency_codes()`

Returns a list of all three-letter currency codes. The codes are guaranteed to be all lower-case, and not in any particular order.

`all_currency_names()`

Returns a list of all currency names for which there is a corresponding three-letter currency code. The names are capitalised, and not returned in any particular order.

EXAMPLES

The following example illustrates use of the `code2currency()` function. The user is prompted for a currency code, and then told the corresponding currency name:

```
$| = 1;    # turn off buffering
```

```
print "Enter currency code: ";
chop($code = <STDIN>);
$curr = code2currency($code);
if (defined $curr)
{
    print "$code = $curr\n";
}
else
{
    print "'$code' is not a valid currency code!\n";
}
```

KNOWN BUGS AND LIMITATIONS

- In the current implementation, all data is read in when the module is loaded, and then held in memory. A lazy implementation would be more memory friendly.
- This module also includes the special codes which are not for a currency, such as Gold, Platinum, etc. This might cause a problem if you're using this module to display a list of currencies. Let Neil know if this does cause a problem, and we can do something about it.
- ISO 4217 also defines a numeric code for each currency. Currency codes are not currently supported by this module, in the same way Locale::Country supports multiple codesets.
- There are three cases where there is more than one code for the same currency name. Kwacha has two codes: mwk for Malawi, and zmk for Zambia. The Russian Ruble has two codes: rub and rur. The Belarussian Ruble has two codes: byr and byb. The `currency2code()` function only returns one code, so you might not get back the code you expected.

NAME

Locale::Language – ISO two letter codes for language identification (ISO 639)

SYNOPSIS

```
use Locale::Language;

$lang = code2language('en');      # $lang gets 'English'
$code = language2code('French');  # $code gets 'fr'

@codes = all_language_codes();
@names = all_language_names();
```

DESCRIPTION

The `Locale::Language` module provides access to the ISO two-letter codes for identifying languages, as defined in ISO 639. You can either access the codes via the *conversion routines* (described below), or via the two functions which return lists of all language codes or all language names.

CONVERSION ROUTINES

There are two conversion routines: `code2language()` and `language2code()`.

`code2language()`

This function takes a two letter language code and returns a string which contains the name of the language identified. If the code is not a valid language code, as defined by ISO 639, then `undef` will be returned.

```
$lang = code2language($code);
```

`language2code()`

This function takes a language name and returns the corresponding two letter language code, if such exists. If the argument could not be identified as a language name, then `undef` will be returned.

```
$code = language2code('French');
```

The case of the language name is not important. See the section *KNOWN BUGS AND LIMITATIONS* below.

QUERY ROUTINES

There are two function which can be used to obtain a list of all language codes, or all language names:

`all_language_codes()`

Returns a list of all two-letter language codes. The codes are guaranteed to be all lower-case, and not in any particular order.

`all_language_names()`

Returns a list of all language names for which there is a corresponding two-letter language code. The names are capitalised, and not returned in any particular order.

EXAMPLES

The following example illustrates use of the `code2language()` function. The user is prompted for a language code, and then told the corresponding language name:

```
$| = 1;      # turn off buffering

print "Enter language code: ";
chop($code = <STDIN>);
$lang = code2language($code);
if (defined $lang)
{
    print "$code = $lang\n";
}
```

```
else
{
    print "'$code' is not a valid language code!\n";
}
```

KNOWN BUGS AND LIMITATIONS

- In the current implementation, all data is read in when the module is loaded, and then held in memory. A lazy implementation would be more memory friendly.
- Currently just supports the two letter language codes – there are also three-letter codes, and numbers. Would these be of any use to anyone?

SEE ALSO

Locale::Country

ISO codes for identification of country (ISO 3166). Supports 2-letter, 3-letter, and numeric country codes.

NAME

Locale::Maketext — framework for localization

SYNOPSIS

```
package MyProgram;
use strict;
use MyProgram::L10N;
# ...which inherits from Locale::Maketext
my $lh = MyProgram::L10N->get_handle() || die "What language?";
...
# And then any messages your program emits, like:
warn $lh->maketext( "Can't open file [_1]: [_2]\n", $f, $! );
...
```

DESCRIPTION

It is a common feature of applications (whether run directly, or via the Web) for them to be "localized" — i.e., for them to present an English interface to an English-speaker, a German interface to a German-speaker, and so on for all languages it's programmed with. `Locale::Maketext` is a framework for software localization; it provides you with the tools for organizing and accessing the bits of text and text-processing code that you need for producing localized applications.

In order to make sense of `Maketext` and how all its components fit together, you should probably go read [Locale::Maketext::TPJ13](#)/[Locale::Maketext::TPJ13](#), and then read the following documentation.

You may also want to read over the source for `File::Findgrep` and its constituent modules — they are a complete (if small) example application that uses `Maketext`.

QUICK OVERVIEW

The basic design of `Locale::Maketext` is object-oriented, and `Locale::Maketext` is an abstract base class, from which you derive a "project class". The project class (with a name like `"TkBocciBall::Localize"`, which you then use in your module) is in turn the base class for all the "language classes" for your project (with names `"TkBocciBall::Localize::it"`, `"TkBocciBall::Localize::en"`, `"TkBocciBall::Localize::fr"`, etc.).

A language class is a class containing a lexicon of phrases as class data, and possibly also some methods that are of use in interpreting phrases in the lexicon, or otherwise dealing with text in that language.

An object belonging to a language class is called a "language handle"; it's typically a flyweight object.

The normal course of action is to call:

```
use TkBocciBall::Localize; # the localization project class
$lh = TkBocciBall::Localize->get_handle();
# Depending on the user's locale, etc., this will
# make a language handle from among the classes available,
# and any defaults that you declare.
die "Couldn't make a language handle?" unless $lh;
```

From then on, you use the `maketext` function to access entries in whatever lexicon(s) belong to the language handle you got. So, this:

```
print $lh->maketext("You won!"), "\n";
```

...emits the right text for this language. If the object in `$lh` belongs to class `"TkBocciBall::Localize::fr"` and `%TkBocciBall::Localize::fr::Lexicon` contains `("You won!" => "Tu as gagné!")`, then the above code happily tells the user "Tu as gagné!".

METHODS

`Locale::Maketext` offers a variety of methods, which fall into three categories:

- Methods to do with constructing language handles.
- maketext and other methods to do with accessing %Lexicon data for a given language handle.
- Methods that you may find it handy to use, from routines of yours that you put in %Lexicon entries.

These are covered in the following section.

Construction Methods

These are to do with constructing a language handle:

- `$lh = YourProjClass->get_handle(...langtags...) || die "lg-handle?"`;

This tries loading classes based on the language-tags you give (like ("en-US", "sk", "kon", "es-MX", "ja", "i-klingon")), and for the first class that succeeds, returns `YourProjClass::language-new()`.

It runs thru the entire given list of language-tags, and finds no classes for those exact terms, it then tries "superordinate" language classes. So if no "en-US" class (i.e., `YourProjClass::en_us`) was found, nor classes for anything else in that list, we then try its superordinate, "en" (i.e., `YourProjClass::en`), and so on thru the other language-tags in the given list: "es". (The other language-tags in our example list: happen to have no superordinates.)

If none of those language-tags leads to loadable classes, we then try classes derived from `YourProjClass->fallback_languages()` and then if nothing comes of that, we use classes named by `YourProjClass->fallback_language_classes()`. Then in the (probably quite unlikely) event that that fails, we just return undef.

- `$lh = YourProjClass->get_handle() || die "lg-handle?"`;

When `get_handle` is called with an empty parameter list, magic happens:

If `get_handle` senses that it's running in program that was invoked as a CGI, then it tries to get language-tags out of the environment variable "HTTP_ACCEPT_LANGUAGE", and it pretends that those were the languages passed as parameters to `get_handle`.

Otherwise (i.e., if not a CGI), this tries various OS-specific ways to get the language-tags for the current locale/language, and then pretends that those were the value(s) passed to `get_handle`.

Currently this OS-specific stuff consists of looking in the environment variables "LANG" and "LANGUAGE"; and on MSWin machines (where those variables are typically unused), this also tries using the module `Win32::Locale` to get a language-tag for whatever language/locale is currently selected in the "Regional Settings" (or "International"?) Control Panel. I welcome further suggestions for making this do the Right Thing under other operating systems that support localization.

If you're using localization in an application that keeps a configuration file, you might consider something like this in your project class:

```
sub get_handle_via_config {
    my $class = $_[0];
    my $preferred_language = $Config_settings{'language'};
    my $lh;
    if($preferred_language) {
        $lh = $class->get_handle($chosen_language)
        || die "No language handle for \"$chosen_language\" or the like";
    } else {
        # Config file missing, maybe?
        $lh = $class->get_handle()
        || die "Can't get a language handle";
    }
    return $lh;
}
```

```
}
```

- `$lh = YourProjClass::langname-new();`

This constructs a language handle. You usually **don't** call this directly, but instead let `get_handle` find a language class to use and to then call `-new` on.

- `$lh-init();`

This is called by `-new` to initialize newly-constructed language handles. If you define an `init` method in your class, remember that it's usually considered a good idea to call `$lh-SUPER::init` in it (presumably at the beginning), so that all classes get a chance to initialize a new object however they see fit.

- `YourProjClass-fallback_languages()`

`get_handle` appends the return value of this to the end of whatever list of languages you pass `get_handle`. Unless you override this method, your project class will inherit `Locale::Maketext's fallback_languages`, which currently returns `('i-default', 'en', 'en-US')`. ("i-default" is defined in RFC 2277).

This method (by having it return the name of a language-tag that has an existing language class) can be used for making sure that `get_handle` will always manage to construct a language handle (assuming your language classes are in an appropriate `@INC` directory). Or you can use the next method:

- `YourProjClass-fallback_language_classes()`

`get_handle` appends the return value of this to the end of the list of classes it will try using. Unless you override this method, your project class will inherit `Locale::Maketext's fallback_language_classes`, which currently returns an empty list, `()`. By setting this to some value (namely, the name of a loadable language class), you can be sure that `get_handle` will always manage to construct a language handle.

The "maketext" Method

This is the most important method in `Locale::Maketext`:

```
$text = $lh-maketext(key, ...parameters for this phrase...);
```

This looks in the `%Lexicon` of the language handle `$lh` and all its superclasses, looking for an entry whose key is the string `key`. Assuming such an entry is found, various things then happen, depending on the value found:

If the value is a scalarref, the scalar is dereferenced and returned (and any parameters are ignored). If the value is a coderef, we return `&$value($lh, ...parameters...)`. If the value is a string that *doesn't* look like it's in Bracket Notation, we return it (after replacing it with a scalarref, in its `%Lexicon`). If the value *does* look like it's in Bracket Notation, then we compile it into a sub, replace the string in the `%Lexicon` with the new coderef, and then we return `&$new_sub($lh, ...parameters...)`.

Bracket Notation is discussed in a later section. Note that trying to compile a string into Bracket Notation can throw an exception if the string is not syntactically valid (say, by not balancing brackets right.)

Also, calling `&$coderef($lh, ...parameters...)` can throw any sort of exception (if, say, code in that sub tries to divide by zero). But a very common exception occurs when you have Bracket Notation text that says to call a method "foo", but there is no such method. (E.g., "You have [quatn,1,ball]." will throw an exception on trying to call `$lh-quatn($_[1], 'ball')` — you presumably meant "quant".) `maketext` catches these exceptions, but only to make the error message more readable, at which point it rethrows the exception.

An exception *may* be thrown if `key` is not found in any of `$lh's %Lexicon` hashes. What happens if a key is not found, is discussed in a later section, "Controlling Lookup Failure".

Note that you might find it useful in some cases to override the `maketext` method with an "after method", if you want to translate encodings, or even scripts:

```
package YrProj::zh_cn; # Chinese with PRC-style glyphs
use base ('YrProj::zh_tw'); # Taiwan-style
sub maketext {
    my $self = shift(@_);
    my $value = $self->maketext(@_);
    return Chineeze::taiwan2mainland($value);
}
```

Or you may want to override it with something that traps any exceptions, if that's critical to your program:

```
sub maketext {
    my($lh, @stuff) = @_;
    my $out;
    eval { $out = $lh->SUPER::maketext(@stuff) };
    return $out unless $@;
    ...otherwise deal with the exception...
}
```

Other than those two situations, I don't imagine that it's useful to override the `maketext` method. (If you run into a situation where it is useful, I'd be interested in hearing about it.)

`$lh-fail_with` or `$lh-fail_with(PARAM)`
`$lh-failure_handler_auto`

These two methods are discussed in the section "Controlling Lookup Failure".

Utility Methods

These are methods that you may find it handy to use, generally from %Lexicon routines of yours (whether expressed as Bracket Notation or not).

```
$language-quant($number, $singular)
$language-quant($number, $singular, $plural)
$language-quant($number, $singular, $plural, $negative)
```

This is generally meant to be called from inside Bracket Notation (which is discussed later), as in

```
"Your search matched [quant,_1,document]!"
```

It's for *quantifying* a noun (i.e., saying how much of it there is, while giving the current form of it). The behavior of this method is handy for English and a few other Western European languages, and you should override it for languages where it's not suitable. You can feel free to read the source, but the current implementation is basically as this pseudocode describes:

```
if $number is 0 and there's a $negative,
    return $negative;
elsif $number is 1,
    return "1 $singular";
elsif there's a $plural,
    return "$number $plural";
else
    return "$number " . $singular . "s";
#
# ...except that we actually call numf to
# stringify $number before returning it.
```

So for English (with Bracket Notation) "...[quant,_1,file]..." is fine (for 0 it returns "0 files", for 1 it returns "1 file", and for more it returns "2 files", etc.)

But for "directory", you'd want "[quant,_1,direcory,directories]" so that our elementary quant method doesn't think that the plural of "directory" is "directorys". And you might find that the output may sound better if you specify a negative form, as in:

```
"[quant,_1,file,files,No files] matched your query.\n"
```

Remember to keep in mind verb agreement (or adjectives too, in other languages), as in:

```
"[quant,_1,document] were matched.\n"
```

Because if _1 is one, you get "1 document **were** matched". An acceptable hack here is to do something like this:

```
"[quant,_1,document was, documents were] matched.\n"
```

`$language-numf($number)`

This returns the given number formatted nicely according to this language's conventions. Maketext's default method is mostly to just take the normal string form of the number (applying `sprintf "%G"` for only very large numbers), and then to add commas as necessary. (Except that we apply `tr/,./././` if `$language-{numf_comma}` is true; that's a bit of a hack that's useful for languages that express two million as "2.000.000" and not as "2,000,000").

If you want anything fancier, consider overriding this with something that uses [Number::Format/Number::Format](#), or does something else entirely.

Note that `numf` is called by `quant` for stringifying all quantifying numbers.

`$language-sprintf($format, @items)`

This is just a wrapper around Perl's normal `sprintf` function. It's provided so that you can use "sprintf" in Bracket Notation:

```
"Couldn't access datanode [sprintf,%10x=~[%s~],_1,_2]!\n"
```

returning...

```
Couldn't access datanode          Stuff=[thangamabob]!
```

`$language-language_tag()`

Currently this just takes the last bit of `ref($language)`, turns underscores to dashes, and returns it. So if `$language` is an object of class `Hee::HOO::Haw::en_us`, `$language-language_tag()` returns "en-us". (Yes, the usual representation for that language tag is "en-US", but case is *never* considered meaningful in language-tag comparison.)

You may override this as you like; Maketext doesn't use it for anything.

`$language-encoding()`

Currently this isn't used for anything, but it's provided (with default value of `(ref($language) && $language->{'encoding'})` or "iso-8859-1") as a sort of suggestion that it may be useful/necessary to associate encodings with your language handles (whether on a per-class or even per-handle basis.)

Language Handle Attributes and Internals

A language handle is a flyweight object — i.e., it doesn't (necessarily) carry any data of interest, other than just being a member of whatever class it belongs to.

A language handle is implemented as a blessed hash. Subclasses of yours can store whatever data you want in the hash. Currently the only hash entry used by any crucial Maketext method is "fail", so feel free to use anything else as you like.

Remember: Don't be afraid to read the Maketext source if there's any point on which this documentation is unclear. This documentation is vastly longer than the module source itself.

LANGUAGE CLASS HIERARCHIES

These are Locale::Maketext's assumptions about the class hierarchy formed by all your language classes:

- You must have a project base class, which you load, and which you then use as the first argument in the call to `YourProjClass->get_handle(...)`. It should derive (whether directly or indirectly) from `Locale::Maketext`. It **doesn't matter** how you name this class, altho assuming this is the localization component of your Super Mega Program, good names for your project class might be `SuperMegaProgram::Localization`, `SuperMegaProgram::L10N`, `SuperMegaProgram::I18N`, `SuperMegaProgram::International`, or even `SuperMegaProgram::Languages` or `SuperMegaProgram::Messages`.
- Language classes are what `YourProjClass->get_handle` will try to load. It will look for them by taking each language-tag (**skipping** it if it doesn't look like a language-tag or locale-tag!), turning it to all lowercase, turning and dashes to underscores, and appending it to `YourProjClass . "::"`. So this:

```
$lh = YourProjClass->get_handle(
    'en-US', 'fr', 'kon', 'i-klingon', 'i-klingon-romanized'
);
```

will try loading the classes `YourProjClass::en_us` (note lowercase!), `YourProjClass::fr`, `YourProjClass::kon`, `YourProjClass::i_klingon` and `YourProjClass::i_klingon_romanized`. (And it'll stop at the first one that actually loads.)

- I assume that each language class derives (directly or indirectly) from your project class, and also defines its `@ISA`, its `%Lexicon`, or both. But I anticipate no dire consequences if these assumptions do not hold.
- Language classes may derive from other language classes (altho they should have "use *Thatclassname*" or "use base qw(...*classes*...)"). They may derive from the project class. They may derive from some other class altogether. Or via multiple inheritance, it may derive from any mixture of these.
- I foresee no problems with having multiple inheritance in your hierarchy of language classes. (As usual, however, Perl will complain bitterly if you have a cycle in the hierarchy: i.e., if any class is its own ancestor.)

ENTRIES IN EACH LEXICON

A typical `%Lexicon` entry is meant to signify a phrase, taking some number (0 or more) of parameters. An entry is meant to be accessed by via a string *key* in `$lh->maketext(key, ...parameters...)`, which should return a string that is generally meant for be used for "output" to the user — regardless of whether this actually means printing to STDOUT, writing to a file, or putting into a GUI widget.

While the key must be a string value (since that's a basic restriction that Perl places on hash keys), the value in the lexicon can currently be of several types: a defined scalar, `scalarref`, or `coderef`. The use of these is explained above, in the section "The "maketext" Method", and Bracket Notation for strings is discussed in the next section.

While you can use arbitrary unique IDs for lexicon keys (like `"_min_larger_max_error"`), it is often useful for if an entry's key is itself a valid value, like this example error message:

```
"Minimum ([_1]) is larger than maximum ([_2])!\n",
```

Compare this code that uses an arbitrary ID...

```
die $lh->maketext( "_min_larger_max_error", $min, $max )
    if $min > $max;
```

...to this code that uses a key-as-value:

```
die $lh->maketext(
    "Minimum ([_1]) is larger than maximum ([_2])!\n",
    $min, $max
```

```
) if $min > $max;
```

The second is, in short, more readable. In particular, it's obvious that the number of parameters you're feeding to that phrase (two) is the number of parameters that it *wants* to be fed. (Since you see `_1` and a `_2` being used in the key there.)

Also, once a project is otherwise complete and you start to localize it, you can scrape together all the various keys you use, and pass it to a translator; and then the translator's work will go faster if what he's presented is this:

```
"Minimum ([_1]) is larger than maximum ([_2])!\n",
=> "",    # fill in something here, Jacques!
```

rather than this more cryptic mess:

```
"_min_larger_max_error"
=> "",    # fill in something here, Jacques
```

I think that keys as lexicon values makes the completed lexicon entries more readable:

```
"Minimum ([_1]) is larger than maximum ([_2])!\n",
=> "Le minimum ([_1]) est plus grand que le maximum ([_2])!\n",
```

Also, having valid values as keys becomes very useful if you set up an `_AUTO` lexicon. `_AUTO` lexicons are discussed in a later section.

I almost always use keys that are themselves valid lexicon values. One notable exception is when the value is quite long. For example, to get the screenful of data that a command-line program might return when given an unknown switch, I often just use a key `"_USAGE_MESSAGE"`. At that point I then go and immediately to define that lexicon entry in the `ProjectClass::L10N::en` lexicon (since English is always my "project language"):

```
'_USAGE_MESSAGE' => <<'EOSTUFF',
...long long message...
EOSTUFF
```

and then I can use it as:

```
getopt('oDI', \%opts) or die $lh->maketext('_USAGE_MESSAGE');
```

Incidentally, note that each class's `%Lexicon` inherits—and—extends the lexicons in its superclasses. This is not because these are special hashes *per se*, but because you access them via the `maketext` method, which looks for entries across all the `%Lexicon`'s in a language class *and* all its ancestor classes. (This is because the idea of "class data" isn't directly implemented in Perl, but is instead left to individual class-systems to implement as they see fit..)

Note that you may have things stored in a lexicon besides just phrases for output: for example, if your program takes input from the keyboard, asking a "(Y/N)" question, you probably need to know what equivalent of "Y[es]/N[o]" is in whatever language. You probably also need to know what the equivalents of the answers "y" and "n" are. You can store that information in the lexicon (say, under the keys `"~answer_y"` and `"~answer_n"`, and the long forms as `"~answer_yes"` and `"~answer_no"`, where `"~"` is just an ad-hoc character meant to indicate to programmers/translators that these are not phrases for output).

Or instead of storing this in the language class's lexicon, you can (and, in some cases, really should) represent the same bit of knowledge as code is a method in the language class. (That leaves a tidy distinction between the lexicon as the things we know how to *say*, and the rest of the things in the lexicon class as things that we know how to *do*.) Consider this example of a processor for responses to French "oui/non" questions:

```
sub y_or_n {
    return undef unless defined $_[1] and length $_[1];
    my $answer = lc $_[1]; # smash case
```

```

    return 1 if $answer eq 'o' or $answer eq 'oui';
    return 0 if $answer eq 'n' or $answer eq 'non';
    return undef;
}

```

...which you'd then call in a construct like this:

```

my $response;
until(defined $response) {
    print $lh->maketext("Open the pod bay door (y/n)? ");
    $response = $lh->y_or_n( get_input_from_keyboard_somewhat() );
}
if($response) { $pod_bay_door->open() }
else          { $pod_bay_door->leave_closed() }

```

Other data worth storing in a lexicon might be things like filenames for language-targeted resources:

```

...
"_main_splash_png"
=> "/styles/en_us/main_splash.png",
"_main_splash_imagemap"
=> "/styles/en_us/main_splash.incl",
"_general_graphics_path"
=> "/styles/en_us/",
"_alert_sound"
=> "/styles/en_us/hey_there.wav",
"_forward_icon"
=> "left_arrow.png",
"_backward_icon"
=> "right_arrow.png",
# In some other languages, left equals
# BACKwards, and right is FOREwards.
...

```

You might want to do the same thing for expressing key bindings or the like (since hardwiring "q" as the binding for the function that quits a screen/menu/program is useful only if your language happens to associate "q" with "quit"!)

BRACKET NOTATION

Bracket Notation is a crucial feature of `Locale::Maketext`. I mean Bracket Notation to provide a replacement for `sprintf` formatting. Everything you do with Bracket Notation could be done with a sub block, but bracket notation is meant to be much more concise.

Bracket Notation is like a miniature "template" system (in the sense of [Text::Template/Text::Template](#), not in the sense of C++ templates), where normal text is passed thru basically as is, but text in special regions is specially interpreted. In Bracket Notation, you use brackets ("[...] — not "{...}"!) to note sections that are specially interpreted.

For example, here all the areas that are taken literally are underlined with a "^", and all the in-bracket special regions are underlined with an X:

```

"Minimum ([_1]) is larger than maximum ([_2])!\n",
^^^^^^^^^ XX ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^ XX ^^^^^

```

When that string is compiled from bracket notation into a real Perl sub, it's basically turned into:

```

sub {
    my $lh = $_[0];
    my @params = @_;
    return join ' ',

```

```

    "Minimum (",
    ...some code here...
    ") is larger than maximum (",
    ...some code here...
    ")!\n",
}
# to be called by $lh->maketext(KEY, params...)

```

In other words, text outside bracket groups is turned into string literals. Text in brackets is rather more complex, and currently follows these rules:

- Bracket groups that are empty, or which consist only of whitespace, are ignored. (Examples: "[]", "[]", or a [and a] with returns and/or tabs and/or spaces between them.
Otherwise, each group is taken to be a comma-separated group of items, and each item is interpreted as follows:
- An item that is "*_digits*" or "*_*-*digits*" is interpreted as `$_[value]`. I.e., "`_1`" becomes with `$_[1]`, and "`_-3`" is interpreted as `$_[-3]` (in which case `@_` should have at least three elements in it). Note that `$_[0]` is the language handle, and is typically not named directly.
- An item "`_*`" is interpreted to mean "all of `@_` except `$_[0]`". I.e., `@_[1..$#_]`. Note that this is an empty list in the case of calls like `$lh->maketext(key)` where there are no parameters (except `$_[0]`, the language handle).
- Otherwise, each item is interpreted as a string literal.

The group as a whole is interpreted as follows:

- If the first item in a bracket group looks like a method name, then that group is interpreted like this:

```

    $lh->that_method_name(
        ...rest of items in this group...
    ),

```
- If the first item in a bracket group is "`*`", it's taken as shorthand for the so commonly called "quant" method. Similarly, if the first item in a bracket group is "`#`", it's taken to be shorthand for "numf".
- If the first item in a bracket group is empty-string, or "`_*`" or "*_digits*" or "*_*-*digits*", then that group is interpreted as just the interpolation of all its items:

```

    join('',
        ...rest of items in this group...
    ),

```

Examples: "`[_1]`" and "`[,_1]`", which are synonymous; and "`[ID-(,_4,-,_2,)]`", which compiles as `join "", "ID-(", $_[4], "-", $_[2], ")"`.
- Otherwise this bracket group is invalid. For example, in the group "`[!@#,whatever]`", the first item "`!@#`" is neither empty-string, "*_number*", "*_*-*number*", "`_*`", nor a valid method name; and so Locale::Maketext will throw an exception of you try compiling an expression containing this bracket group.

Note, incidentally, that items in each group are comma-separated, not `/\s*, \s*/`-separated. That is, you might expect that this bracket group:

```
"Hoohah [foo, _1 , bar ,baz]!"
```

would compile to this:

```

sub {
    my $lh = $_[0];
    return join ' ',

```

```

    "Hoohah ",
    $lh->foo( $_[1], "bar", "baz"),
    "!",
}

```

But it actually compiles as this:

```

sub {
    my $lh = $_[0];
    return join '',
        "Hoohah ",
        $lh->foo(" _1 ", " bar ", "baz"),    #!!!
        "!",
}

```

In the notation discussed so far, the characters "[" and "]" are given special meaning, for opening and closing bracket groups, and "," has a special meaning inside bracket groups, where it separates items in the group. This begs the question of how you'd express a literal "[" or "]" in a Bracket Notation string, and how you'd express a literal comma inside a bracket group. For this purpose I've adopted "~" (tilde) as an escape character: "~[" means a literal '[' character anywhere in Bracket Notation (i.e., regardless of whether you're in a bracket group or not), and ditto for "~]" meaning a literal ']', and "~," meaning a literal comma. (Altho "~," means a literal comma outside of bracket groups — it's only inside bracket groups that commas are special.)

And on the off chance you need a literal tilde in a bracket expression, you get it with "~~".

Currently, an unescaped "~" before a character other than a bracket or a comma is taken to mean just a "~" and that character. I.e., "~X" means the same as "~~X" — i.e., one literal tilde, and then one literal "X". However, by using "~X", you are assuming that no future version of Maketext will use "~X" as a magic escape sequence. In practice this is not a great problem, since first off you can just write "~~X" and not worry about it; second off, I doubt I'll add lots of new magic characters to bracket notation; and third off, you aren't likely to want literal "~" characters in your messages anyway, since it's not a character with wide use in natural language text.

Brackets must be balanced — every openbracket must have one matching closebracket, and vice versa. So these are all **invalid**:

```

"I ate [quant,_1,rhubarb pie."
"I ate [quant,_1,rhubarb pie[."
"I ate quant,_1,rhubarb pie] ."
"I ate quant,_1,rhubarb pie[."

```

Currently, bracket groups do not nest. That is, you **cannot** say:

```

"Foo [bar,baz,[quux,quuux]]\n";

```

If you need a notation that's that powerful, use normal Perl:

```

%Lexicon = (
    ...
    "some_key" => sub {
        my $lh = $_[0];
        join '',
            "Foo ",
            $lh->bar('baz', $lh->quux('quuux')),
            "\n",
        },
    ...
);

```

Or write the "bar" method so you don't need to pass it the output from calling quux.

I do not anticipate that you will need (or particularly want) to nest bracket groups, but you are welcome to email me with convincing (real-life) arguments to the contrary.

AUTO LEXICONS

If maketext goes to look in an individual %Lexicon for an entry for *key* (where *key* does not start with an underscore), and sees none, **but does see** an entry of "_AUTO" = *some_true_value*, then we actually define `$Lexicon{key} = key` right then and there, and then use that value as if it had been there all along. This happens before we even look in any superclass %Lexicons!

(This is meant to be somewhat like the AUTOLOAD mechanism in Perl's function call system — or, looked at another way, like the [AutoLoader/AutoLoader](#) module.)

I can picture all sorts of circumstances where you just do not want lookup to be able to fail (since failing normally means that maketext throws a die, altho see the next section for greater control over that). But here's one circumstance where _AUTO lexicons are meant to be *especially* useful:

As you're writing an application, you decide as you go what messages you need to emit. Normally you'd go to write this:

```
if(-e $filename) {
    go_process_file($filename)
} else {
    print "Couldn't find file \"$filename\"!\n";
}
```

but since you anticipate localizing this, you write:

```
use ThisProject::I18N;
my $lh = ThisProject::I18N->get_handle();
# For the moment, assume that things are set up so
# that we load class ThisProject::I18N::en
# and that's the class that $lh belongs to.
...
if(-e $filename) {
    go_process_file($filename)
} else {
    print $lh->maketext(
        "Couldn't find file \"[_1]\"!\n", $filename
    );
}
```

Now, right after you've just written the above lines, you'd normally have to go open the file `ThisProject/I18N/en.pm`, and immediately add an entry:

```
"Couldn't find file \"[_1]\"!\n"
=> "Couldn't find file \"[_1]\"!\n",
```

But I consider that somewhat of a distraction from the work of getting the main code working — to say nothing of the fact that I often have to play with the program a few times before I can decide exactly what wording I want in the messages (which in this case would require me to go changing three lines of code: the call to maketext with that key, and then the two lines in `ThisProject/I18N/en.pm`).

However, if you set "_AUTO = 1" in the %Lexicon in, `ThisProject/I18N/en.pm` (assuming that English (en) is the language that all your programmers will be using for this project's internal message keys), then you don't ever have to go adding lines like this

```
"Couldn't find file \"[_1]\"!\n"
=> "Couldn't find file \"[_1]\"!\n",
```

to ThisProject/I18N/en.pm, because if `_AUTO` is true there, then just looking for an entry with the key "Couldn't find file \"[_1]\"!\n" in that lexicon will cause it to be added, with that value!

Note that the reason that keys that start with `"_"` are immune to `_AUTO` isn't anything generally magical about the underscore character — I just wanted a way to have most lexicon keys be autoable, except for possibly a few, and I arbitrarily decided to use a leading underscore as a signal to distinguish those few.

CONTROLLING LOOKUP FAILURE

If you call `$lh->maketext(key, ...parameters...)`, and there's no entry *key* in `$lh`'s class's `%Lexicon`, nor in the superclass `%Lexicon` hash, *and* if we can't auto-make *key* (because either it starts with a `"_"`, or because none of its lexicons have `_AUTO => 1`), then we have failed to find a normal way to maketext *key*. What then happens in these failure conditions, depends on the `$lh` object "fail" attribute.

If the language handle has no "fail" attribute, maketext will simply throw an exception (i.e., it calls `die`, mentioning the *key* whose lookup failed, and naming the line number where the calling `$lh->maketext(key,...)` was.

If the language handle has a "fail" attribute whose value is a coderef, then `$lh->maketext(key,...params...)` gives up and calls:

```
return &{$that_subref}($lh, $key, @params);
```

Otherwise, the "fail" attribute's value should be a string denoting a method name, so that `$lh->maketext(key,...params...)` can give up with:

```
return $lh->$that_method_name($phrase, @params);
```

The "fail" attribute can be accessed with the `fail_with` method:

```
# Set to a coderef:
$lh->fail_with( \&failure_handler );

# Set to a method name:
$lh->fail_with( 'failure_method' );

# Set to nothing (i.e., so failure throws a plain exception)
$lh->fail_with( undef );

# Simply read:
$handler = $lh->fail_with();
```

Now, as to what you may want to do with these handlers: Maybe you'd want to log what key failed for what class, and then die. Maybe you don't like `die` and instead you want to send the error message to `STDOUT` (or wherever) and then merely `exit()`.

Or maybe you don't want to die at all! Maybe you could use a handler like this:

```
# Make all lookups fall back onto an English value,
# but after we log it for later fingerprinting.
my $lh_backup = ThisProject->get_handle('en');
open(LEX_FAIL_LOG, ">>wherever/lex.log") || die "GNAARGH $!";
sub lex_fail {
    my($failing_lh, $key, $params) = @_;
    print LEX_FAIL_LOG scalar(localtime), "\t",
        ref($failing_lh), "\t", $key, "\n";
    return $lh_backup->maketext($key,@params);
}
```

Some users have expressed that they think this whole mechanism of having a "fail" attribute at all, seems a rather pointless complication. But I want `Locale::Maketext` to be usable for software projects of *any* scale and type; and different software projects have different ideas of what the right thing is to do in failure conditions. I could simply say that failure always throws an exception, and that if you want to be careful,

you'll just have to wrap every call to `$lh->maketext` in an `eval { }`. However, I want programmers to reserve the right (via the "fail" attribute) to treat lookup failure as something other than an exception of the same level of severity as a config file being unreadable, or some essential resource being inaccessible.

One possibly useful value for the "fail" attribute is the method name `failure_handler_auto`. This is a method defined in class `Locale::Maketext` itself. You set it with:

```
$lh->fail_with('failure_handler_auto');
```

Then when you call `$lh->maketext(key, ...parameters...)` and there's no *key* in any of those lexicons, `maketext` gives up with

```
return $lh->failure_handler_auto($key, @params);
```

But `failure_handler_auto`, instead of dying or anything, compiles `$key`, caching it in `$lh->{'failure_lex'}{$key} = $compiled`, and then calls the compiled value, and returns that. (I.e., if `$key` looks like bracket notation, `$compiled` is a sub, and we return `&{$compiled}(@params)`; but if `$key` is just a plain string, we just return that.)

The effect of using `failure_handler_auto` is like an AUTO lexicon, except that it 1) compiles `$key` even if it starts with `"_"`, and 2) you have a record in the new hashref `$lh->{'failure_lex'}` of all the keys that have failed for this object. This should avoid your program dying — as long as your keys aren't actually invalid as bracket code, and as long as they don't try calling methods that don't exist.

`failure_handler_auto` may not be exactly what you want, but I hope it at least shows you that `maketext` failure can be mitigated in any number of very flexible ways. If you can formalize exactly what you want, you should be able to express that as a failure handler. You can even make it default for every object of a given class, by setting it in that class's `init`:

```
sub init {
    my $lh = $_[0]; # a newborn handle
    $lh->SUPER::init();
    $lh->fail_with('my_clever_failure_handler');
    return;
}
sub my_clever_failure_handler {
    ...you clever things here...
}
```

HOW TO USE MAKETEXT

Here is a brief checklist on how to use `Maketext` to localize applications:

- Decide what system you'll use for lexicon keys. If you insist, you can use opaque IDs (if you're nostalgic for `catgets`), but I have better suggestions in the section "Entries in Each Lexicon", above. Assuming you opt for meaningful keys that double as values (like "Minimum ([_1]) is larger than maximum ([_2])!n"), you'll have to settle on what language those should be in. For the sake of argument, I'll call this English, specifically American English, "en-US".
- Create a class for your localization project. This is the name of the class that you'll use in the idiom:

```
use Projname::L10N;
my $lh = Projname::L10N->get_handle(...) || die "Language?";
```

Assuming you call your class `Projname::L10N`, create a class consisting minimally of:

```
package Projname::L10N;
use base qw(Locale::Maketext);
...any methods you might want all your languages to share...

# And, assuming you want the base class to be an _AUTO lexicon,
# as is discussed a few sections up:
```

```
1;
```

- Create a class for the language your internal keys are in. Name the class after the language-tag for that language, in lowercase, with dashes changed to underscores. Assuming your project's first language is US English, you should call this `Projname::L10N::en_us`. It should consist minimally of:

```
package Projname::L10N::en_us;
use base qw(Projname::L10N);
%Lexicon = (
    '_AUTO' => 1,
);
1;
```

(For the rest of this section, I'll assume that this "first language class" of `Projname::L10N::en_us` has `_AUTO` lexicon.)

- Go and write your program. Everywhere in your program where you would say:

```
print "Foobar $thing stuff\n";
```

instead do it thru `maketext`, using no variable interpolation in the key:

```
print $lh->maketext("Foobar [_1] stuff\n", $thing);
```

If you get tired of constantly saying `print $lh->maketext`, consider making a functional wrapper for it, like so:

```
use Projname::L10N;
use vars qw($lh);
$lh = Projname::L10N->get_handle(...) || die "Language?";
sub pmt (@) { print( $lh->maketext(@_)) }
# "pmt" is short for "Print MakeText"
$Carp::Verbose = 1;
# so if maketext fails, we see made the call to pmt
```

Besides whole phrases meant for output, anything language-dependent should be put into the class `Projname::L10N::en_us`, whether as methods, or as lexicon entries — this is discussed in the section "Entries in Each Lexicon", above.

- Once the program is otherwise done, and once its localization for the first language works right (via the data and methods in `Projname::L10N::en_us`), you can get together the data for translation. If your first language lexicon isn't an `_AUTO` lexicon, then you already have all the messages explicitly in the lexicon (or else you'd be getting exceptions thrown when you call `$lh->maketext` to get messages that aren't in there). But if you were (advisedly) lazy and are using an `_AUTO` lexicon, then you've got to make a list of all the phrases that you've so far been letting `_AUTO` generate for you. There are very many ways to assemble such a list. The most straightforward is to simply `grep` the source for every occurrence of "maketext" (or calls to wrappers around it, like the above `pmt` function), and to log the following phrase.
- You may at this point want to consider whether the your base class (`Projname::L10N`) that all lexicons inherit from (`Projname::L10N::en`, `Projname::L10N::es`, etc.) should be an `_AUTO` lexicon. It may be true that in theory, all needed messages will be in each language class; but in the presumably unlikely or "impossible" case of lookup failure, you should consider whether your program should throw an exception, emit text in English (or whatever your project's first language is), or some more complex solution as described in the section "Controlling Lookup Failure", above.
- Submit all messages/phrases/etc. to translators.

(You may, in fact, want to start with localizing to *one* other language at first, if you're not sure that you've property abstracted the language-dependent parts of your code.)

Translators may request clarification of the situation in which a particular phrase is found. For example, in English we are entirely happy saying "*n* files found", regardless of whether we mean "I looked for files, and found *n* of them" or the rather distinct situation of "I looked for something else (like lines in files), and along the way I saw *n* files." This may involve rethinking things that you thought quite clear: should "Edit" on a toolbar be a noun ("editing") or a verb ("to edit")? Is there already a conventionalized way to express that menu option, separate from the target language's normal word for "to edit"?

In all cases where the very common phenomenon of quantification (saying "*N* files", for **any** value of *N*) is involved, each translator should make clear what dependencies the number causes in the sentence. In many cases, dependency is limited to words adjacent to the number, in places where you might expect them ("I found the-?PLURAL *N* empty-?PLURAL directory-?PLURAL"), but in some cases there are unexpected dependencies ("I found-?PLURAL ...") as well as long-distance dependencies "The *N* directory-?PLURAL could not be deleted-?PLURAL").

Remind the translators to consider the case where *N* is 0: "0 files found" isn't exactly natural-sounding in any language, but it may be unacceptable in many — or it may condition special kinds of agreement (similar to English "I didN'T find ANY files").

Remember to ask your translators about numeral formatting in their language, so that you can override the `numf` method as appropriate. Typical variables in number formatting are: what to use as a decimal point (comma? period?); what to use as a thousands separator (space? nonbreaking space? comma? period? small middot? prime? apostrophe?); and even whether the so-called "thousands separator" is actually for every third digit — I've heard reports of two hundred thousand being expressible as "2,00,000" for some Indian (Subcontinental) languages, besides the less surprising "200 000", "200.000", "200,000", and "200'000". Also, using a set of numeral glyphs other than the usual ASCII "0"–"9" might be appreciated, as via `tr/0-9/\x{0966}-\x{096F}/` for getting digits in Devanagari script (for Hindi, Konkani, others).

The basic `quant` method that `Locale::Maketext` provides should be good for many languages. For some languages, it might be useful to modify it (or its constituent `numerate` method) to take a plural form in the two-argument call to `quant` (as in "[quant,_1,files]") if it's all-around easier to infer the singular form from the plural, than to infer the plural form from the singular.

But for other languages (as is discussed at length in

[Locale::Maketext::TPJ13/Locale::Maketext::TPJ13](#)), simple `quant/numerify` is not enough. For the particularly problematic Slavic languages, what you may need is a method which you provide with the number, the citation form of the noun to quantify, and the case and gender that the sentence's syntax projects onto that noun slot. The method would then be responsible for determining what grammatical number that numeral projects onto its noun phrase, and what case and gender it may override the normal case and gender with; and then it would look up the noun in a lexicon providing all needed inflected forms.

- You may also wish to discuss with the translators the question of how to relate different subforms of the same language tag, considering how this reacts with `get_handle`'s treatment of these. For example, if a user accepts interfaces in "en, fr", and you have interfaces available in "en-US" and "fr", what should they get? You may wish to resolve this by establishing that "en" and "en-US" are effectively synonymous, by having one class zero-derive from the other.

For some languages this issue may never come up (Danish is rarely expressed as "da-DK", but instead is just "da"). And for other languages, the whole concept of a "generic" form may verge on being uselessly vague, particularly for interfaces involving voice media in forms of Arabic or Chinese.

- Once you've localized your program/site/etc. for all desired languages, be sure to show the result (whether live, or via screenshots) to the translators. Once they approve, make every effort to have it then checked by at least one other speaker of that language. This holds true even when (or especially when) the translation is done by one of your own programmers. Some kinds of systems may be harder to find testers for than others, depending on the amount of domain-specific jargon and concepts

involved — it's easier to find people who can tell you whether they approve of your translation for "delete this message" in an email-via-Web interface, than to find people who can give you an informed opinion on your translation for "attribute value" in an XML query tool's interface.

SEE ALSO

I recommend reading all of these:

[Locale::Maketext::TPJ13/Locale::Maketext::TPJ13](#) — my *The Perl Journal* article about Maketext. It explains many important concepts underlying Locale::Maketext's design, and some insight into why Maketext is better than the plain old approach of just having message catalogs that are just databases of printf formats.

[File::Findgrep/File::Findgrep](#) is a sample application/module that uses Locale::Maketext to localize its messages.

[I18N::LangTags/I18N::LangTags](#).

[Win32::Locale/Win32::Locale](#).

RFC 3066, *Tags for the Identification of Languages*, as at <http://sunsite.dk/RFC/rfc/rfc3066.html>

RFC 2277, *IETF Policy on Character Sets and Languages* is at <http://sunsite.dk/RFC/rfc/rfc2277.html> — much of it is just things of interest to protocol designers, but it explains some basic concepts, like the distinction between locales and language-tags.

The manual for GNU gettext. The gettext dist is available in <ftp://prep.ai.mit.edu/pub/gnu/> — get a recent gettext tarball and look in its "doc/" directory, there's an easily browsable HTML version in there. The gettext documentation asks lots of questions worth thinking about, even if some of their answers are sometimes wonky, particularly where they start talking about pluralization.

The Locale/Maketext.pm source. Observe that the module is much shorter than its documentation!

NAME

Locale::Maketext::TPJ13 — article about software localization

SYNOPSIS

```
# This an article, not a module.
```

DESCRIPTION

The following article by Sean M. Burke and Jordan Lachler first appeared in *The Perl Journal* #13 and is copyright 1999 The Perl Journal. It appears courtesy of Jon Orwant and The Perl Journal. This document may be distributed under the same terms as Perl itself.

Localization and Perl: gettext breaks, Maketext fixes

by Sean M. Burke and Jordan Lachler

This article points out cases where gettext (a common system for localizing software interfaces — i.e., making them work in the user's language of choice) fails because of basic differences between human languages. This article then describes Maketext, a new system capable of correctly treating these differences.

A Localization Horror Story: It Could Happen To You

"There are a number of languages spoken by human beings in this world."

— Harald Tveit Alvestrand, in RFC 1766, "Tags for the Identification of Languages"

Imagine that your task for the day is to localize a piece of software — and luckily for you, the only output the program emits is two messages, like this:

```
I scanned 12 directories.
```

```
Your query matched 10 files in 4 directories.
```

So how hard could that be? You look at the code that produces the first item, and it reads:

```
printf("I scanned %g directories.",
      $directory_count);
```

You think about that, and realize that it doesn't even work right for English, as it can produce this output:

```
I scanned 1 directories.
```

So you rewrite it to read:

```
printf("I scanned %g %s.",
      $directory_count,
      $directory_count == 1 ?
        "directory" : "directories",
    );
```

...which does the Right Thing. (In case you don't recall, "%g" is for locale-specific number interpolation, and "%s" is for string interpolation.)

But you still have to localize it for all the languages you're producing this software for, so you pull Locale::gettext off of CPAN so you can access the gettext C functions you've heard are standard for localization tasks.

And you write:

```
printf(gettext("I scanned %g %s."),
      $dir_scan_count,
      $dir_scan_count == 1 ?
        gettext("directory") : gettext("directories"),
    );
```

But you then read in the gettext manual (Drepper, Miller, and Pinard 1995) that this is not a good idea, since how a single word like "directory" or "directories" is translated may depend on context — and this is true, since in a case language like German or Russian, you'd may need these words with a different case ending in the first instance (where the word is the object of a verb) than in the second instance, which you haven't even gotten to yet (where the word is the object of a preposition, "in %g directories") — assuming these keep the same syntax when translated into those languages.

So, on the advice of the gettext manual, you rewrite:

```
printf( $dir_scan_count == 1 ?
        gettext("I scanned %g directory.") :
        gettext("I scanned %g directories."),
        $dir_scan_count );
```

So, you email your various translators (the boss decides that the languages du jour are Chinese, Arabic, Russian, and Italian, so you have one translator for each), asking for translations for "I scanned %g directory." and "I scanned %g directories.". When they reply, you'll put that in the lexicons for gettext to use when it localizes your software, so that when the user is running under the "zh" (Chinese) locale, gettext("I scanned %g directory.") will return the appropriate Chinese text, with a "%g" in there where printf can then interpolate \$dir_scan.

Your Chinese translator emails right back — he says both of these phrases translate to the same thing in Chinese, because, in linguistic jargon, Chinese "doesn't have number as a grammatical category" — whereas English does. That is, English has grammatical rules that refer to "number", i.e., whether something is grammatically singular or plural; and one of these rules is the one that forces nouns to take a plural suffix (generally "s") when in a plural context, as they are when they follow a number other than "one" (including, oddly enough, "zero"). Chinese has no such rules, and so has just the one phrase where English has two. But, no problem, you can have this one Chinese phrase appear as the translation for the two English phrases in the "zh" gettext lexicon for your program.

Emboldened by this, you dive into the second phrase that your software needs to output: "Your query matched 10 files in 4 directories.". You notice that if you want to treat phrases as indivisible, as the gettext manual wisely advises, you need four cases now, instead of two, to cover the permutations of singular and plural on the two items, \$dir_count and \$file_count. So you try this:

```
printf( $file_count == 1 ?
        ( $directory_count == 1 ?
          gettext("Your query matched %g file in %g directory.") :
          gettext("Your query matched %g file in %g directories.") ) :
        ( $directory_count == 1 ?
          gettext("Your query matched %g files in %g directory.") :
          gettext("Your query matched %g files in %g directories.") ),
        $file_count, $directory_count,
        );
```

(The case of "1 file in 2 [or more] directories" could, I suppose, occur in the case of symlinking or something of the sort.)

It occurs to you that this is not the prettiest code you've ever written, but this seems the way to go. You mail off to the translators asking for translations for these four cases. The Chinese guy replies with the one phrase that these all translate to in Chinese, and that phrase has two "%g"s in it, as it should — but there's a problem. He translates it word-for-word back: "In %g directories contains %g files match your query." The %g slots are in an order reverse to what they are in English. You wonder how you'll get gettext to handle that.

But you put it aside for the moment, and optimistically hope that the other translators won't have this problem, and that their languages will be better behaved — i.e., that they will be just like English.

But the Arabic translator is the next to write back. First off, your code for "I scanned %g directory." or "I

scanned %g directories." assumes there's only singular or plural. But, to use linguistic jargon again, Arabic has grammatical number, like English (but unlike Chinese), but it's a three-term category: singular, dual, and plural. In other words, the way you say "directory" depends on whether there's one directory, or *two* of them, or *more than two* of them. Your test of (`$directory == 1`) no longer does the job. And it means that where English's grammatical category of number necessitates only the two permutations of the first sentence based on "directory [singular]" and "directories [plural]", Arabic has three — and, worse, in the second sentence ("Your query matched %g file in %g directory."), where English has four, Arabic has nine. You sense an unwelcome, exponential trend taking shape.

Your Italian translator emails you back and says that "I searched 0 directories" (a possible English output of your program) is stilted, and if you think that's fine English, that's your problem, but that *just will not do* in the language of Dante. He insists that where `$directory_count` is 0, your program should produce the Italian text for "I *didn't* scan *any* directories.". And ditto for "I didn't match any files in any directories", although he says the last part about "in any directories" should probably just be left off.

You wonder how you'll get `gettext` to handle this; to accomodate the ways Arabic, Chinese, and Italian deal with numbers in just these few very simple phrases, you need to write code that will ask `gettext` for different queries depending on whether the numerical values in question are 1, 2, more than 2, or in some cases 0, and you still haven't figured out the problem with the different word order in Chinese.

Then your Russian translator calls on the phone, to *personally* tell you the bad news about how really unpleasant your life is about to become:

Russian, like German or Latin, is an inflectional language; that is, nouns and adjectives have to take endings that depend on their case (i.e., nominative, accusative, genitive, etc...) — which is roughly a matter of what role they have in syntax of the sentence — as well as on the grammatical gender (i.e., masculine, feminine, neuter) and number (i.e., singular or plural) of the noun, as well as on the declension class of the noun. But unlike with most other inflected languages, putting a number-phrase (like "ten" or "forty-three", or their Arabic numeral equivalents) in front of noun in Russian can change the case and number that noun is, and therefore the endings you have to put on it.

He elaborates: In "I scanned %g directories", you'd *expect* "directories" to be in the accusative case (since it is the direct object in the sentence) and the plural number, except where `$directory_count` is 1, then you'd expect the singular, of course. Just like Latin or German. *But!* Where `$directory_count % 10` is 1 ("`%`" for modulo, remember), assuming `$directory_count` is an integer, and except where `$directory_count % 100` is 11, "directories" is forced to become grammatically singular, which means it gets the ending for the accusative singular... You begin to visualize the code it'd take to test for the problem so far, *and still work for Chinese and Arabic and Italian*, and how many `gettext` items that'd take, but he keeps going... But where `$directory_count % 10` is 2, 3, or 4 (except where `$directory_count % 100` is 12, 13, or 14), the word for "directories" is forced to be genitive singular — which means another ending... The room begins to spin around you, slowly at first... But with *all other* integer values, since "directory" is an inanimate noun, when preceded by a number and in the nominative or accusative cases (as it is here, just your luck!), it does stay plural, but it is forced into the genitive case — yet another ending... And you never hear him get to the part about how you're going to run into similar (but maybe subtly different) problems with other Slavic languages like Polish, because the floor comes up to meet you, and you fade into unconsciousness.

The above cautionary tale relates how an attempt at localization can lead from programmer consternation, to program obfuscation, to a need for sedation. But careful evaluation shows that your choice of tools merely needed further consideration.

The Linguistic View

"It is more complicated than you think."

— The Eighth Networking Truth, from RFC 1925

The field of Linguistics has expended a great deal of effort over the past century trying to find grammatical patterns which hold across languages; it's been a constant process of people making generalizations that should apply to all languages, only to find out that, all too often, these generalizations fail — sometimes

failing for just a few languages, sometimes whole classes of languages, and sometimes nearly every language in the world except English. Broad statistical trends are evident in what the "average language" is like as far as what its rules can look like, must look like, and cannot look like. But the "average language" is just as unreal a concept as the "average person" — it runs up against the fact no language (or person) is, in fact, average. The wisdom of past experience leads us to believe that any given language can do whatever it wants, in any order, with appeal to any kind of grammatical categories wants — case, number, tense, real or metaphoric characteristics of the things that words refer to, arbitrary or predictable classifications of words based on what endings or prefixes they can take, degree or means of certainty about the truth of statements expressed, and so on, ad infinitum.

Mercifully, most localization tasks are a matter of finding ways to translate whole phrases, generally sentences, where the context is relatively set, and where the only variation in content is *usually* in a number being expressed — as in the example sentences above. Translating specific, fully-formed sentences is, in practice, fairly foolproof — which is good, because that's what's in the phrasebooks that so many tourists rely on. Now, a given phrase (whether in a phrasebook or in a gettext lexicon) in one language *might* have a greater or lesser applicability than that phrase's translation into another language — for example, strictly speaking, in Arabic, the "your" in "Your query matched..." would take a different form depending on whether the user is male or female; so the Arabic translation "your[feminine] query" is applicable in fewer cases than the corresponding English phrase, which doesn't distinguish the user's gender. (In practice, it's not feasible to have a program know the user's gender, so the masculine "you" in Arabic is usually used, by default.)

But in general, such surprises are rare when entire sentences are being translated, especially when the functional context is restricted to that of a computer interacting with a user either to convey a fact or to prompt for a piece of information. So, for purposes of localization, translation by phrase (generally by sentence) is both the simplest and the least problematic.

Breaking gettext

"It Has To Work."

— First Networking Truth, RFC 1925

Consider that sentences in a tourist phrasebook are of two types: ones like "How do I get to the marketplace?" that don't have any blanks to fill in, and ones like "How much do these ___ cost?", where there's one or more blanks to fill in (and these are usually linked to a list of words that you can put in that blank: "fish", "potatoes", "tomatoes", etc.) The ones with no blanks are no problem, but the fill-in-the-blank ones may not be really straightforward. If it's a Swahili phrasebook, for example, the authors probably didn't bother to tell you the complicated ways that the verb "cost" changes its inflectional prefix depending on the noun you're putting in the blank. The trader in the marketplace will still understand what you're saying if you say "how much do these potatoes cost?" with the wrong inflectional prefix on "cost". After all, *you* can't speak proper Swahili, *you're* just a tourist. But while tourists can be stupid, computers are supposed to be smart; the computer should be able to fill in the blank, and still have the results be grammatical.

In other words, a phrasebook entry takes some values as parameters (the things that you fill in the blank or blanks), and provides a value based on these parameters, where the way you get that final value from the given values can, properly speaking, involve an arbitrarily complex series of operations. (In the case of Chinese, it'd be not at all complex, at least in cases like the examples at the beginning of this article; whereas in the case of Russian it'd be a rather complex series of operations. And in some languages, the complexity could be spread around differently: while the act of putting a number-expression in front of a noun phrase might not be complex by itself, it may change how you have to, for example, inflect a verb elsewhere in the sentence. This is what in syntax is called "long-distance dependencies".)

This talk of parameters and arbitrary complexity is just another way to say that an entry in a phrasebook is what in a programming language would be called a "function". Just so you don't miss it, this is the crux of this article: *A phrase is a function; a phrasebook is a bunch of functions.*

The reason that using gettext runs into walls (as in the above second-person horror story) is that you're

trying to use a string (or worse, a choice among a bunch of strings) to do what you really need a function for — which is futile. Preforming (s)printf interpolation on the strings which you get back from gettext does allow you to do *some* common things passably well... sometimes... sort of; but, to paraphrase what some people say about `csh` script programming, "it fools you into thinking you can use it for real things, but you can't, and you don't discover this until you've already spent too much time trying, and by then it's too late."

Replacing gettext

So, what needs to replace gettext is a system that supports lexicons of functions instead of lexicons of strings. An entry in a lexicon from such a system should *not* look like this:

```
"J'ai trouv\xE9 %g fichiers dans %g r\xE9pertoires"
```

[`\xE9` is e-acute in Latin-1. Some pod renderers would scream if I used the actual character here. — SB]

but instead like this, bearing in mind that this is just a first stab:

```
sub I_found_X1_files_in_X2_directories {
    my( $files, $dirs ) = @_ [0,1];
    $files = sprintf("%g %s", $files,
        $files == 1 ? 'fichier' : 'fichiers');
    $dirs = sprintf("%g %s", $dirs,
        $dirs == 1 ? "r\xE9pertoire" : "r\xE9pertoires");
    return "J'ai trouv\xE9 $files dans $dirs.";
}
```

Now, there's no particularly obvious way to store anything but strings in a gettext lexicon; so it looks like we just have to start over and make something better, from scratch. I call my shot at a gettext-replacement system "Maketext", or, in CPAN terms, `Locale::Maketext`.

When designing Maketext, I chose to plan its main features in terms of "buzzword compliance". And here are the buzzwords:

Buzzwords: Abstraction and Encapsulation

The complexity of the language you're trying to output a phrase in is entirely abstracted inside (and encapsulated within) the Maketext module for that interface. When you call:

```
print $lang->maketext("You have [quant,_1,piece] of new mail.",
    scalar(@messages));
```

you don't know (and in fact can't easily find out) whether this will involve lots of figuring, as in Russian (if `$lang` is a handle to the Russian module), or relatively little, as in Chinese. That kind of abstraction and encapsulation may encourage other pleasant buzzwords like modularization and stratification, depending on what design decisions you make.

Buzzword: Isomorphism

"Isomorphism" means "having the same structure or form"; in discussions of program design, the word takes on the special, specific meaning that your implementation of a solution to a problem *has the same structure* as, say, an informal verbal description of the solution, or maybe of the problem itself. Isomorphism is, all things considered, a good thing — it's what problem-solving (and solution-implementing) should look like.

What's wrong the with gettext—using code like this...

```
printf( $file_count == 1 ?
    ( $directory_count == 1 ?
        "Your query matched %g file in %g directory." :
        "Your query matched %g file in %g directories." ) :
    ( $directory_count == 1 ?
        "Your query matched %g files in %g directory." :
        "Your query matched %g files in %g directories." ),
    $file_count, $directory_count,
```

);

is first off that it's not well abstracted — these ways of testing for grammatical number (as in the expressions like `foo == 1 ? singular_form : plural_form`) should be abstracted to each language module, since how you get grammatical number is language-specific.

But second off, it's not isomorphic — the "solution" (i.e., the phrasebook entries) for Chinese maps from these four English phrases to the one Chinese phrase that fits for all of them. In other words, the informal solution would be "The way to say what you want in Chinese is with the one phrase 'For your question, in Y directories you would find X files'" — and so the implemented solution should be, isomorphically, just a straightforward way to spit out that one phrase, with numerals properly interpolated. It shouldn't have to map from the complexity of other languages to the simplicity of this one.

Buzzword: Inheritance

There's a great deal of reuse possible for sharing of phrases between modules for related dialects, or for sharing of auxiliary functions between related languages. (By "auxiliary functions", I mean functions that don't produce phrase-text, but which, say, return an answer to "does this number require a plural noun after it?". Such auxiliary functions would be used in the internal logic of functions that actually do produce phrase-text.)

In the case of sharing phrases, consider that you have an interface already localized for American English (probably by having been written with that as the native locale, but that's incidental). Localizing it for UK English should, in practical terms, be just a matter of running it past a British person with the instructions to indicate what few phrases would benefit from a change in spelling or possibly minor rewording. In that case, you should be able to put in the UK English localization module *only* those phrases that are UK-specific, and for all the rest, *inherit* from the American English module. (And I expect this same situation would apply with Brazilian and Continental Portuguese, possibly with some *very* closely related languages like Czech and Slovak, and possibly with the slightly different "versions" of written Mandarin Chinese, as I hear exist in Taiwan and mainland China.)

As to sharing of auxiliary functions, consider the problem of Russian numbers from the beginning of this article; obviously, you'd want to write only once the hairy code that, given a numeric value, would return some specification of which case and number a given quantified noun should use. But suppose that you discover, while localizing an interface for, say, Ukrainian (a Slavic language related to Russian, spoken by several million people, many of whom would be relieved to find that your Web site's or software's interface is available in their language), that the rules in Ukrainian are the same as in Russian for quantification, and probably for many other grammatical functions. While there may well be no phrases in common between Russian and Ukrainian, you could still choose to have the Ukrainian module inherit from the Russian module, just for the sake of inheriting all the various grammatical methods. Or, probably better organizationally, you could move those functions to a module called `_E_Slavic` or something, which Russian and Ukrainian could inherit useful functions from, but which would (presumably) provide no lexicon.

Buzzword: Concision

Okay, concision isn't a buzzword. But it should be, so I decree that as a new buzzword, "concision" means that simple common things should be expressible in very few lines (or maybe even just a few characters) of code — call it a special case of "making simple things easy and hard things possible", and see also the role it played in the MIDI::Simple language, discussed elsewhere in this issue [TPJ#13].

Consider our first stab at an entry in our "phrasebook of functions":

```
sub I_found_X1_files_in_X2_directories {
    my( $files, $dirs ) = @_ [0,1];
    $files = sprintf("%g %s", $files,
        $files == 1 ? 'fichier' : 'fichiers');
    $dirs = sprintf("%g %s", $dirs,
        $dirs == 1 ? "r\xE9pertoire" : "r\xE9pertoires");
    return "J'ai trouv\xE9 $files dans $dirs.";
}
```

You may sense that a lexicon (to use a non-committal catch-all term for a collection of things you know how to say, regardless of whether they're phrases or words) consisting of functions *expressed* as above would make for rather long-winded and repetitive code — even if you wisely rewrote this to have quantification (as we call adding a number expression to a noun phrase) be a function called like:

```
sub I_found_X1_files_in_X2_directories {
    my( $files, $dirs ) = @_ [0,1];
    $files = quant($files, "fichier");
    $dirs = quant($dirs, "r\xE9pertoire");
    return "J'ai trouv\xE9 $files dans $dirs.";
}
```

And you may also sense that you do not want to bother your translators with having to write Perl code — you'd much rather that they spend their *very costly time* on just translation. And this is to say nothing of the near impossibility of finding a commercial translator who would know even simple Perl.

In a first-hack implementation of Maketext, each language-module's lexicon looked like this:

```
%Lexicon = (
    "I found %g files in %g directories"
    => sub {
        my( $files, $dirs ) = @_ [0,1];
        $files = quant($files, "fichier");
        $dirs = quant($dirs, "r\xE9pertoire");
        return "J'ai trouv\xE9 $files dans $dirs.";
    },
    ... and so on with other phrase => sub mappings ...
);
```

but I immediately went looking for some more concise way to basically denote the same phrase-function — a way that would also serve to concisely denote *most* phrase-functions in the lexicon for *most* languages. After much time and even some actual thought, I decided on this system:

- * Where a value in a %Lexicon hash is a contentful string instead of an anonymous sub (or, conceivably, a coderef), it would be interpreted as a sort of shorthand expression of what the sub does. When accessed for the first time in a session, it is parsed, turned into Perl code, and then eval'd into an anonymous sub; then that sub replaces the original string in that lexicon. (That way, the work of parsing and evaluating the shorthand form for a given phrase is done no more than once per session.)

- * Calls to maketext (as Maketext's main function is called) happen thru a "language session handle", notionally very much like an IO handle, in that you open one at the start of the session, and use it for "sending signals" to an object in order to have it return the text you want.

So, this:

```
$lang->maketext("You have [quant,_1,piece] of new mail.",
               scalar(@messages));
```

basically means this: look in the lexicon for \$lang (which may inherit from any number of other lexicons), and find the function that we happen to associate with the string "You have [quant,_1,piece] of new mail" (which is, and should be, a functioning "shorthand" for this function in the native locale — English in this case). If you find such a function, call it with \$lang as its first parameter (as if it were a method), and then a copy of scalar(@messages) as its second, and then return that value. If that function was found, but was in string shorthand instead of being a fully specified function, parse it and make it into a function before calling it the first time.

- * The shorthand uses code in brackets to indicate method calls that should be performed. A full explanation is not in order here, but a few examples will suffice:

```
"You have [quant,_1,piece] of new mail."
```

The above code is shorthand for, and will be interpreted as, this:

```
sub {
    my $handle = $_[0];
    my(@params) = @_;
    return join '',
        "You have ",
        $handle->quant($params[1], 'piece'),
        "of new mail.";
}
```

where "quant" is the name of a method you're using to quantify the noun "piece" with the number \$params[0].

A string with no bracket calls, like this:

```
"Your search expression was malformed."
```

is somewhat of a degerate case, and just gets turned into:

```
sub { return "Your search expression was malformed." }
```

However, not everything you can write in Perl code can be written in the above shorthand system — not by a long shot. For example, consider the Italian translator from the beginning of this article, who wanted the Italian for "I didn't find any files" as a special case, instead of "I found 0 files". That couldn't be specified (at least not easily or simply) in our shorthand system, and it would have to be written out in full, like this:

```
sub { # pretend the English strings are in Italian
    my($handle, $files, $dirs) = @_[0,1,2];
    return "I didn't find any files" unless $files;
    return join '',
        "I found ",
        $handle->quant($files, 'file'),
        " in ",
        $handle->quant($dirs, 'directory'),
        ".";
}
```

Next to a lexicon full of shorthand code, that sort of sticks out like a sore thumb — but this *is* a special case, after all; and at least it's possible, if not as concise as usual.

As to how you'd implement the Russian example from the beginning of the article, well, There's More Than One Way To Do It, but it could be something like this (using English words for Russian, just so you know what's going on):

```
"I [quant,_1,directory,accusative] scanned."
```

This shifts the burden of complexity off to the quant method. That method's parameters are: the numeric value it's going to use to quantify something; the Russian word it's going to quantify; and the parameter "accusative", which you're using to mean that this sentence's syntax wants a noun in the accusative case there, although that quantification method may have to overrule, for grammatical reasons you may recall from the beginning of this article.

Now, the Russian quant method here is responsible not only for implementing the strange logic necessary for figuring out how Russian number-phrases impose case and number on their noun-phrases, but also for inflecting the Russian word for "directory". How that inflection is to be carried out is no small issue, and among the solutions I've seen, some (like variations on a simple lookup in a hash where all possible forms are provided for all necessary words) are straightforward but *can* become cumbersome when you need to inflect more than a few dozen words; and other solutions (like using algorithms to model the inflections, storing only root forms and irregularities) *can* involve more overhead than is justifiable for all but the largest lexicons.

Mercifully, this design decision becomes crucial only in the hairiest of inflected languages, of which Russian is by no means the *worst* case scenario, but is worse than most. Most languages have simpler inflection systems; for example, in English or Swahili, there are generally no more than two possible inflected forms for a given noun ("error/errors"; "kosa/makosa"), and the rules for producing these forms are fairly simple — or at least, simple rules can be formulated that work for most words, and you can then treat the exceptions as just "irregular", at least relative to your ad hoc rules. A simpler inflection system (simpler rules, fewer forms) means that design decisions are less crucial to maintaining sanity, whereas the same decisions could incur overhead—versus—scalability problems in languages like Russian. It may *also* be likely that code (possibly in Perl, as with `Lingua::EN::Inflect`, for English nouns) has already been written for the language in question, whether simple or complex.

Moreover, a third possibility may even be simpler than anything discussed above: "Just require that all possible (or at least applicable) forms be provided in the call to the given language's `quant` method, as in:"

```
"I found [quant,_1,file,files]."
```

That way, `quant` just has to choose which form it needs, without having to look up or generate anything. While possibly not optimal for Russian, this should work well for most other languages, where quantification is not as complicated an operation.

The Devil in the Details

There's plenty more to `Maketext` than described above — for example, there's the details of how language tags ("en-US", "i-pwn", "fi", etc.) or locale IDs ("en_US") interact with actual module naming ("BogoQuery/Locale/en_us.pm"), and what magic can ensue; there's the details of how to record (and possibly negotiate) what character encoding `Maketext` will return text in (UTF8? Latin-1? KOI8?). There's the interesting fact that `Maketext` is for localization, but nowhere actually has a `"use locale;"` anywhere in it. For the curious, there's the somewhat frightening details of how I actually implement something like data inheritance so that searches across modules' `%Lexicon` hashes can parallel how Perl implements method inheritance.

And, most importantly, there's all the practical details of how to actually go about deriving from `Maketext` so you can use it for your interfaces, and the various tools and conventions for starting out and maintaining individual language modules.

That is all covered in the documentation for `Locale::Maketext` and the modules that come with it, available in CPAN. After having read this article, which covers the why's of `Maketext`, the documentation, which covers the how's of it, should be quite straightforward.

The Proof in the Pudding: Localizing Web Sites

`Maketext` and `gettext` have a notable difference: `gettext` is in C, accessible thru C library calls, whereas `Maketext` is in Perl, and really can't work without a Perl interpreter (although I suppose something like it could be written for C). Accidents of history (and not necessarily lucky ones) have made C++ the most common language for the implementation of applications like word processors, Web browsers, and even many in-house applications like custom query systems. Current conditions make it somewhat unlikely that the next one of any of these kinds of applications will be written in Perl, albeit clearly more for reasons of custom and inertia than out of consideration of what is the right tool for the job.

However, other accidents of history have made Perl a well-accepted language for design of server-side programs (generally in CGI form) for Web site interfaces. Localization of static pages in Web sites is trivial, feasible either with simple language-negotiation features in servers like Apache, or with some kind of server-side inclusions of language-appropriate text into layout templates. However, I think that the localization of Perl-based search systems (or other kinds of dynamic content) in Web sites, be they public or access-restricted, is where `Maketext` will see the greatest use.

I presume that it would be only the exceptional Web site that gets localized for English *and* Chinese *and* Italian *and* Arabic *and* Russian, to recall the languages from the beginning of this article — to say nothing of German, Spanish, French, Japanese, Finnish, and Hindi, to name a few languages that benefit from large numbers of programmers or Web viewers or both.

However, the ever-increasing internationalization of the Web (whether measured in terms of amount of content, of numbers of content writers or programmers, or of size of content audiences) makes it increasingly likely that the interface to the average Web-based dynamic content service will be localized for two or maybe three languages. It is my hope that Maketext will make that task as simple as possible, and will remove previous barriers to localization for languages dissimilar to English.

NAME

Locale::Script – ISO codes for script identification (ISO 15924)

SYNOPSIS

```
use Locale::Script;
use Locale::Constants;

$script = code2script('ph');           # 'Phoenician'
$code   = script2code('Tibetan');      # 'bo'
$code3  = script2code('Tibetan',
                      LOCALE_CODE_ALPHA_3); # 'bod'
$codeN  = script2code('Tibetan',
                      LOCALE_CODE_ALPHA_NUMERIC); # 330

@codes  = all_script_codes();
@scripts = all_script_names();
```

DESCRIPTION

The `Locale::Script` module provides access to the ISO codes for identifying scripts, as defined in ISO 15924. For example, Egyptian hieroglyphs are denoted by the two-letter code 'eg', the three-letter code 'egy', and the numeric code 050.

You can either access the codes via the conversion routines (described below), or with the two functions which return lists of all script codes or all script names.

There are three different code sets you can use for identifying scripts:

alpha-2

Two letter codes, such as 'bo' for Tibetan. This code set is identified with the symbol `LOCALE_CODE_ALPHA_2`.

alpha-3

Three letter codes, such as 'ell' for Greek. This code set is identified with the symbol `LOCALE_CODE_ALPHA_3`.

numeric

Numeric codes, such as 410 for Hiragana. This code set is identified with the symbol `LOCALE_CODE_NUMERIC`.

All of the routines take an optional additional argument which specifies the code set to use. If not specified, it defaults to the two-letter codes. This is partly for backwards compatibility (previous versions of `Locale` modules only supported the alpha-2 codes), and partly because they are the most widely used codes.

The alpha-2 and alpha-3 codes are not case-dependent, so you can use 'BO', 'Bo', 'bO' or 'bo' for Tibetan. When a code is returned by one of the functions in this module, it will always be lower-case.

SPECIAL CODES

The standard defines various special codes.

- The standard reserves codes in the ranges **qa – qt**, **qaa – qat**, and **900 – 919**, for private use.
- **zx**, **zxx**, and **997**, are the codes for unwritten languages.
- **zy**, **zyy**, and **998**, are the codes for an undetermined script.
- **zz**, **zzz**, and **999**, are the codes for an uncoded script.

The private codes are not recognised by `Locale::Script`, but the others are.

CONVERSION ROUTINES

There are three conversion routines: `code2script()`, `script2code()`, and `script_code2code()`.

`code2script(CODE, [CODESET])`

This function takes a script code and returns a string which contains the name of the script identified. If the code is not a valid script code, as defined by ISO 15924, then `undef` will be returned:

```
$script = code2script('cy');    # Cyrillic
```

`script2code(STRING, [CODESET])`

This function takes a script name and returns the corresponding script code, if such exists. If the argument could not be identified as a script name, then `undef` will be returned:

```
$code = script2code('Gothic', LOCALE_CODE_ALPHA_3);
# $code will now be 'gth'
```

The case of the script name is not important. See the section [KNOWN BUGS AND LIMITATIONS](#) below.

`script_code2code(CODE, CODESET, CODESET)`

This function takes a script code from one code set, and returns the corresponding code from another code set.

```
$alpha2 = script_code2code('jwi',
                           LOCALE_CODE_ALPHA_3 => LOCALE_CODE_ALPHA_2);
# $alpha2 will now be 'jw' (Javanese)
```

If the code passed is not a valid script code in the first code set, or if there isn't a code for the corresponding script in the second code set, then `undef` will be returned.

QUERY ROUTINES

There are two function which can be used to obtain a list of all codes, or all script names:

`all_script_codes ([CODESET])`

Returns a list of all two-letter script codes. The codes are guaranteed to be all lower-case, and not in any particular order.

`all_script_names ([CODESET])`

Returns a list of all script names for which there is a corresponding script code in the specified code set. The names are capitalised, and not returned in any particular order.

EXAMPLES

The following example illustrates use of the `code2script()` function. The user is prompted for a script code, and then told the corresponding script name:

```
$| = 1;    # turn off buffering

print "Enter script code: ";
chop($code = <STDIN>);
$script = code2script($code, LOCALE_CODE_ALPHA_2);
if (defined $script)
{
    print "$code = $script\n";
}
else
{
    print "'$code' is not a valid script code!\n";
}
```

KNOWN BUGS AND LIMITATIONS

- When using `script2code()`, the script name must currently appear exactly as it does in the source of the module. For example,

```
script2code('Egyptian hieroglyphs')
```

will return **eg**, as expected. But the following will all return `undef`:

```
script2code('hieroglyphs')
script2code('Egyptian Hieroglyphics')
```

If there's need for it, a future version could have variants for script names.

- In the current implementation, all data is read in when the module is loaded, and then held in memory. A lazy implementation would be more memory friendly.

SEE ALSO

`Locale::Language`

ISO two letter codes for identification of language (ISO 639).

`Locale::Currency`

ISO three letter codes for identification of currencies and funds (ISO 4217).

`Locale::Country`

ISO three letter codes for identification of countries (ISO 3166)

ISO 15924

The ISO standard which defines these codes.

NAME

Math::BigFloat – Arbitrary size floating point math package

SYNOPSIS

```
use Math::BigFloat;

# Number creation
$x = Math::BigFloat->new($str);           # defaults to 0
$nan = Math::BigFloat->bnan();             # create a NaN
$zero = Math::BigFloat->bzero();           # create a +0
$inf = Math::BigFloat->binf();             # create a +inf
$inf = Math::BigFloat->binf('-');          # create a -inf
$one = Math::BigFloat->bone();              # create a +1
$one = Math::BigFloat->bone('-');          # create a -1

# Testing
$x->is_zero();                             # true if arg is +0
$x->is_nan();                              # true if arg is NaN
$x->is_one();                              # true if arg is +1
$x->is_one('-');                           # true if arg is -1
$x->is_odd();                              # true if odd, false for even
$x->is_even();                             # true if even, false for odd
$x->is_positive();                         # true if >= 0
$x->is_negative();                        # true if < 0
$x->is_inf(sign);                         # true if +inf, or -inf (default is '+')

$x->bcmp($y);                             # compare numbers (undef,<0,=0,>0)
$x->bacmp($y);                            # compare absolutely (undef,<0,=0,>0)
$x->sign();                               # return the sign, either +, - or NaN
$x->digit($n);                           # return the nth digit, counting from right
$x->digit(-$n);                          # return the nth digit, counting from left

# The following all modify their first argument:

# set
$x->bzero();                             # set $i to 0
$x->bnan();                              # set $i to NaN
$x->bone();                               # set $x to +1
$x->bone('-');                            # set $x to -1
$x->binf();                              # set $x to inf
$x->binf('-');                           # set $x to -inf

$x->bneg();                               # negation
$x->babs();                               # absolute value
$x->bnorm();                              # normalize (no-op)
$x->bnot();                               # two's complement (bit wise not)
$x->binc();                               # increment x by 1
$x->bdec();                               # decrement x by 1

$x->badd($y);                             # addition (add $y to $x)
$x->bsub($y);                             # subtraction (subtract $y from $x)
$x->bmul($y);                             # multiplication (multiply $x by $y)
$x->bdiv($y);                             # divide, set $i to quotient
                                           # return (quo,rem) or quo if scalar

$x->bmod($y);                             # modulus
$x->bpow($y);                             # power of arguments (a**b)
$x->blsft($y);                            # left shift
```

```

$x->brsft($y);      # right shift
                    # return (quo,rem) or quo if scalar

$x->blog($base);    # logarithm of $x, base defaults to e
                    # (other bases than e not supported yet)

$x->band($y);        # bit-wise and
$x->bior($y);        # bit-wise inclusive or
$x->bxor($y);        # bit-wise exclusive or
$x->bnot();           # bit-wise not (two's complement)

$x->bsqrt();         # calculate square-root
$x->bfac();           # factorial of $x (1*2*3*4*...*x)

$x->bround($N);      # accuracy: preserver $N digits
$x->bfround($N);     # precision: round to the $Nth digit

# The following do not modify their arguments:
bgcd(@values);      # greatest common divisor
blcm(@values);      # lowest common multiplier

$x->bstr();           # return string
$x->bsstr();          # return string in scientific notation

$x->bfloor();         # return integer less or equal than $x
$x->bceil();          # return integer greater or equal than $x

$x->exponent();       # return exponent as BigInt
$x->mantissa();       # return mantissa as BigInt
$x->parts();          # return (mantissa,exponent) as BigInt

$x->length();         # number of digits (w/o sign and '.')
($l,$f) = $x->length(); # number of digits, and length of fraction

$x->precision();      # return P of $x (or global, if P of $x undef)
$x->precision($n);    # set P of $x to $n
$x->accuracy();       # return A of $x (or global, if A of $x undef)
$x->accuracy($n);     # set A $x to $n

Math::BigFloat->precision(); # get/set global P for all BigFloat objects
Math::BigFloat->accuracy();  # get/set global A for all BigFloat objects

```

DESCRIPTION

All operators (including basic math operations) are overloaded if you declare your big floating point numbers as

```
$i = new Math::BigFloat '12_3.456_789_123_456_789E-2';
```

Operations with overloaded operators preserve the arguments, which is exactly what you expect.

Canonical notation

Input to these routines are either BigFloat objects, or strings of the following four forms:

- `/^[+-]\d+$/`
- `/^[+-]\d+\.\d*$/`
- `/^[+-]\d+E[+-]?\d+$/`
- `/^[+-]\d*\.\d+E[+-]?\d+$/`

all with optional leading and trailing zeros and/or spaces. Additionally, numbers are allowed to have an underscore between any two digits.

Empty strings as well as other illegal numbers results in 'NaN'.

`bnorm()` on a BigFloat object is now effectively a no-op, since the numbers are always stored in normalized form. On a string, it creates a BigFloat object.

Output

Output values are BigFloat objects (normalized), except for `bstr()` and `bsstr()`.

The string output will always have leading and trailing zeros stripped and drop a plus sign. `bstr()` will give you always the form with a decimal point, while `bsstr()` (for scientific) gives you the scientific notation.

Input	<code>bstr()</code>	<code>bsstr()</code>
'-0'	'0'	'0E1'
' -123 123 123 '	'-123123123'	'-123123123E0'
'00.0123'	'0.0123'	'123E-4'
'123.45E-2'	'1.2345'	'12345E-4'
'10E+3'	'10000'	'1E4'

Some routines (`is_odd()`, `is_even()`, `is_zero()`, `is_one()`, `is_nan()`) return true or false, while others (`bcmp()`, `bacmp()`) return either undef, <0, 0 or 0 and are suited for sort.

Actual math is done by using BigInts to represent the mantissa and exponent. The sign `/^[+-]$/` is stored separately. The string 'NaN' is used to represent the result when input arguments are not numbers, as well as the result of dividing by zero.

`mantissa()`, `exponent()` and `parts()`

`mantissa()` and `exponent()` return the said parts of the BigFloat as BigInts such that:

```
$m = $x->mantissa();
$e = $x->exponent();
$y = $m * ( 10 ** $e );
print "ok\n" if $x == $y;
```

`< ($m,$e) = $x->parts();` is just a shortcut giving you both of them.

A zero is represented and returned as 0E1, **not** 0E0 (after Knuth).

Currently the mantissa is reduced as much as possible, favouring higher exponents over lower ones (e.g. returning 1e7 instead of 10e6 or 10000000e0). This might change in the future, so do not depend on it.

Accuracy vs. Precision

See also: [Rounding/Rounding](#).

Math::BigFloat supports both precision and accuracy. For a full documentation, examples and tips on these topics please see the large section in [Math::BigInt](#).

Since things like `sqrt(2)` or `1/3` must be presented with a limited precision lest an operation consumes all resources, each operation produces no more than `Math::BigFloat::precision()` digits.

In case the result of one operation has more precision than specified, it is rounded. The rounding mode taken is either the default mode, or the one supplied to the operation after the *scale*:

```
$x = Math::BigFloat->new(2);
Math::BigFloat::precision(5);           # 5 digits max
$y = $x->copy()->bdiv(3);                 # will give 0.66666
$y = $x->copy()->bdiv(3,6);               # will give 0.666666
$y = $x->copy()->bdiv(3,6,'odd');         # will give 0.666667
Math::BigFloat::round_mode('zero');
$y = $x->copy()->bdiv(3,6);               # will give 0.666666
```

Rounding

`ffround (+$scale)`

Rounds to the `$scale`'th place left from the '.', counting from the dot. The first digit is numbered 1.

`ffround (-$scale)`

Rounds to the `$scale`'th place right from the '.', counting from the dot.

`ffround (0)`

Rounds to an integer.

`fround (+$scale)`

Preserves accuracy to `$scale` digits from the left (aka significant digits) and pads the rest with zeros. If the number is between 1 and -1, the significant digits count from the first non-zero after the '.'.

`fround (-$scale)` and `fround (0)`

These are effectively no-ops.

All rounding functions take as a second parameter a rounding mode from one of the following: 'even', 'odd', '+inf', '-inf', 'zero' or 'trunc'.

The default rounding mode is 'even'. By using <

`Math::BigFloat::round_mode($round_mode);` you can get and set the default mode for subsequent rounding. The usage of `Math::BigFloat::$round_mode` is no longer supported. The second parameter to the round functions then overrides the default temporarily.

The `< as_number()` function returns a `BigInt` from a `Math::BigFloat`. It uses 'trunc' as rounding mode to make it equivalent to:

```
$x = 2.5;
$y = int($x) + 2;
```

You can override this by passing the desired rounding mode as parameter to `as_number()`:

```
$x = Math::BigFloat->new(2.5);
$y = $x->as_number('odd');      # $y = 3
```

EXAMPLES

```
# not ready yet
```

Autocreating constants

After use `Math::BigFloat ':constant'` all the floating point constants in the given scope are converted to `Math::BigFloat`. This conversion happens at compile time.

In particular

```
perl -MMath::BigFloat=:constant -e 'print 2E-100, "\n"'
```

prints the value of 2E-100. Note that without conversion of constants the expression 2E-100 will be calculated as normal floating point number.

Please note that ':constant' does not affect integer constants, nor binary nor hexadecimal constants. Use [bignum](#) or [Math::BigInt](#) to get this to work.

Math library

Math with the numbers is done (by default) by a module called `Math::BigInt::Calc`. This is equivalent to saying:

```
use Math::BigFloat lib => 'Calc';
```

You can change this by using:

```
use Math::BigFloat lib => 'BitVect';
```

The following would first try to find `Math::BigInt::Foo`, then `Math::BigInt::Bar`, and when this also fails, revert to `Math::BigInt::Calc`:

```
use Math::BigFloat lib => 'Foo,Math::BigInt::Bar';
```

`Calc.pm` uses as internal format an array of elements of some decimal base (usually `1e7`, but this might be different for some systems) with the least significant digit first, while `BitVect.pm` uses a bit vector of base 2, most significant bit first. Other modules might use even different means of representing the numbers. See the respective module documentation for further details.

Please note that `Math::BigFloat` does **not** use the denoted library itself, but it merely passes the `lib` argument to `Math::BigInt`. So, instead of the need to do:

```
use Math::BigInt lib => 'GMP';
use Math::BigFloat;
```

you can roll it all into one line:

```
use Math::BigFloat lib => 'GMP';
```

Use the `lib`, Luke! And see [Using Math::BigInt::Lite](#) for more details.

Using Math::BigInt::Lite

It is possible to use [Math::BigInt::Lite](#) with `Math::BigFloat`:

```
# 1
use Math::BigFloat with => 'Math::BigInt::Lite';
```

There is no need to "use `Math::BigInt`" or "use `Math::BigInt::Lite`", but you can combine these if you want. For instance, you may want to use `Math::BigInt` objects in your main script, too.

```
# 2
use Math::BigInt;
use Math::BigFloat with => 'Math::BigInt::Lite';
```

Of course, you can combine this with the `lib` parameter.

```
# 3
use Math::BigFloat with => 'Math::BigInt::Lite', lib => 'GMP,Pari';
```

If you want to use `Math::BigInt`'s, too, simple add a `Math::BigInt` **before**:

```
# 4
use Math::BigInt;
use Math::BigFloat with => 'Math::BigInt::Lite', lib => 'GMP,Pari';
```

Notice that the module with the last `lib` will "win" and thus its `lib` will be used if the `lib` is available:

```
# 5
use Math::BigInt lib => 'Bar,Baz';
use Math::BigFloat with => 'Math::BigInt::Lite', lib => 'Foo';
```

That would try to load `Foo`, `Bar`, `Baz` and `Calc` (in that order). Or in other words, `Math::BigFloat` will try to retain previously loaded `libs` when you don't specify it one.

Actually, the `lib` loading order would be "`Bar,Baz,Calc`", and then "`Foo,Bar,Baz,Calc`", but independent of which `lib` exists, the result is the same as trying the latter load alone, except for the fact that `Bar` or `Baz` might be loaded needlessly in an intermediate step

The old way still works though:

```
# 6
use Math::BigInt lib => 'Bar,Baz';
```

```
use Math::BigFloat;
```

But **examples #3 and #4 are recommended** for usage.

BUGS

- The following does not work yet:

```
$m = $x->mantissa();
$e = $x->exponent();
$y = $m * ( 10 ** $e );
print "ok\n" if $x == $y;
```

- There is no `fmod()` function yet.

CAVEAT

`stringify`, `bstr()`

Both `stringify` and `bstr()` now drop the leading '+'. The old code would return '+1.23', the new returns '1.23'. See the documentation in [Math::BigInt](#) for reasoning and details.

`bdiv`

The following will probably not do what you expect:

```
print $c->bdiv(123.456), "\n";
```

It prints both quotient and remainder since `print` works in list context. Also, `bdiv()` will modify `$c`, so be carefull. You probably want to use

```
print $c / 123.456, "\n";
print scalar $c->bdiv(123.456), "\n"; # or if you want to modify $c
```

instead.

Modifying and =

Beware of:

```
$x = Math::BigFloat->new(5);
$y = $x;
```

It will not do what you think, e.g. making a copy of `$x`. Instead it just makes a second reference to the **same** object and stores it in `$y`. Thus anything that modifies `$x` will modify `$y`, and vice versa.

```
$x->bmul(2);
print "$x, $y\n";          # prints '10, 10'
```

If you want a true copy of `$x`, use:

```
$y = $x->copy();
```

See also the documentation in [overload](#) regarding `=`.

`bpow`

`bpow()` now modifies the first argument, unlike the old code which left it alone and only returned the result. This is to be consistent with `badd()` etc. The first will modify `$x`, the second one won't:

```
print bpow($x, $i), "\n";          # modify $x
print $x->bpow($i), "\n";          # ditto
print $x ** $i, "\n";              # leave $x alone
```

NAME

Math::BigInt – Arbitrary size integer math package

SYNOPSIS

```
use Math::BigInt;

# Number creation
$x = Math::BigInt->new($str);           # defaults to 0
$nan = Math::BigInt->bnan();             # create a NotANumber
$zero = Math::BigInt->bzero();           # create a +0
$inf = Math::BigInt->binf();             # create a +inf
$inf = Math::BigInt->binf('-');          # create a -inf
$one = Math::BigInt->bone();             # create a +1
$one = Math::BigInt->bone('-');          # create a -1

# Testing
$x->is_zero();                          # true if arg is +0
$x->is_nan();                           # true if arg is NaN
$x->is_one();                           # true if arg is +1
$x->is_one('-');                        # true if arg is -1
$x->is_odd();                           # true if odd, false for even
$x->is_even();                          # true if even, false for odd
$x->is_positive();                      # true if >= 0
$x->is_negative();                     # true if < 0
$x->is_inf(sign);                      # true if +inf, or -inf (sign is default '+')
$x->is_int();                           # true if $x is an integer (not a float)

$x->bcmp($y);                           # compare numbers (undef,<0,=0,>0)
$x->bacmp($y);                          # compare absolutely (undef,<0,=0,>0)
$x->sign();                             # return the sign, either +, - or NaN
$x->digit($n);                          # return the nth digit, counting from right
$x->digit(-$n);                         # return the nth digit, counting from left

# The following all modify their first argument:

# set
$x->bzero();                             # set $x to 0
$x->bnan();                              # set $x to NaN
$x->bone();                               # set $x to +1
$x->bone('-');                           # set $x to -1
$x->binf();                              # set $x to inf
$x->binf('-');                           # set $x to -inf

$x->bneg();                              # negation
$x->babs();                              # absolute value
$x->bnorm();                             # normalize (no-op)
$x->bnot();                              # two's complement (bit wise not)
$x->binc();                              # increment x by 1
$x->bdec();                              # decrement x by 1

$x->badd($y);                            # addition (add $y to $x)
$x->bsub($y);                            # subtraction (subtract $y from $x)
$x->bmul($y);                            # multiplication (multiply $x by $y)
$x->bdiv($y);                            # divide, set $x to quotient
                                           # return (quo,rem) or quo if scalar

$x->bmod($y);                            # modulus (x % y)
$x->bmodpow($exp,$mod);                  # modular exponentiation (($num**$exp) % $mod)
```

```

$x->bmodinv($mod);          # the inverse of $x in the given modulus $mod
$x->bpow($y);               # power of arguments (x ** y)
$x->blsft($y);              # left shift
$x->brsft($y);              # right shift
$x->blsft($y,$n);           # left shift, by base $n (like 10)
$x->brsft($y,$n);           # right shift, by base $n (like 10)

$x->band($y);               # bitwise and
$x->bior($y);               # bitwise inclusive or
$x->bxor($y);               # bitwise exclusive or
$x->bnot();                 # bitwise not (two's complement)

$x->bsqrt();                # calculate square-root
$x->bfac();                 # factorial of $x (1*2*3*4*...*x)

$x->round($A,$P,$round_mode); # round to accuracy or precision using mode $r
$x->bround($N);              # accuracy: preserve $N digits
$x->bfround($N);             # round to $Nth digit, no-op for BigInts

# The following do not modify their arguments in BigInt, but do in BigFloat:
$x->bfloor();                # return integer less or equal than $x
$x->bceil();                 # return integer greater or equal than $x

# The following do not modify their arguments:
bgcd(@values);              # greatest common divisor (no OO style)
blcm(@values);              # lowest common multiplier (no OO style)

$x->length();               # return number of digits in number
($x,$f) = $x->length();     # length of number and length of fraction part,
                           # latter is always 0 digits long for BigInt's

$x->exponent();              # return exponent as BigInt
$x->mantissa();              # return (signed) mantissa as BigInt
$x->parts();                 # return (mantissa,exponent) as BigInt
$x->copy();                  # make a true copy of $x (unlike $y = $x;)
$x->as_number();             # return as BigInt (in BigInt: same as copy())

# conversation to string
$x->bstr();                  # normalized string
$x->bsstr();                 # normalized string in scientific notation
$x->as_hex();                # as signed hexadecimal string with prefixed 0x
$x->as_bin();                # as signed binary string with prefixed 0b

Math::BigInt->config();      # return hash containing configuration/version

# precision and accuracy (see section about rounding for more)
$x->precision();             # return P of $x (or global, if P of $x undef)
$x->precision($n);          # set P of $x to $n
$x->accuracy();              # return A of $x (or global, if A of $x undef)
$x->accuracy($n);           # set A $x to $n

Math::BigInt->precision();   # get/set global P for all BigInt objects
Math::BigInt->accuracy();    # get/set global A for all BigInt objects

```

DESCRIPTION

All operators (including basic math operations) are overloaded if you declare your big integers as

```
$i = new Math::BigInt '123_456_789_123_456_789';
```

Operations with overloaded operators preserve the arguments which is exactly what you expect.

Canonical notation

Big integer values are strings of the form `/^[+-]\d+$/` with leading zeros suppressed.

<code>'-0'</code>	canonical value <code>'-0'</code> , normalized <code>'0'</code>
<code>'-123_123_123'</code>	canonical value <code>'-123123123'</code>
<code>'1_23_456_7890'</code>	canonical value <code>'1234567890'</code>

Input

Input values to these routines may be either `Math::BigInt` objects or strings of the form `/^[+-]?[\d]+\.[\d]*E?[+-]?[\d]*$/`.

You can include one underscore between any two digits. The input string may have leading and trailing whitespace, which will be ignored. In later versions, a more strict (no whitespace at all) or more lax (whitespace allowed everywhere) input checking will also be possible.

This means integer values like 1.01E2 or even 1000E-2 are also accepted. Non integer values result in NaN.

`Math::BigInt::new()` defaults to 0, while `Math::BigInt::new('')` results in 'NaN'.

`bnorm()` on a `BigInt` object is now effectively a no-op, since the numbers are always stored in normalized form. On a string, it creates a `BigInt` object.

Output

Output values are `BigInt` objects (normalized), except for `bstr()`, which returns a string in normalized form. Some routines (`is_odd()`, `is_even()`, `is_zero()`, `is_one()`, `is_nan()`) return true or false, while others (`bcmp()`, `bacmp()`) return either undef, <0, 0 or 0 and are suited for sort.

METHODS

Each of the methods below accepts three additional parameters. These arguments `$A`, `$P` and `$R` are accuracy, precision and round_mode. Please see more in the section about [ACCURACY](#) and [ROUNDIND](#).

config

```
use Data::Dumper;

print Dumper ( Math::BigInt->config() );
```

Returns a hash containing the configuration, e.g. the version number, lib loaded etc.

accuracy

```
$x->accuracy(5);           # local for $x
$class->accuracy(5);       # global for all members of $class
```

Set or get the global or local accuracy, aka how many significant digits the results have. Please see the section about [ACCURACY AND PRECISION](#) for further details.

Value must be greater than zero. Pass an undef value to disable it:

```
$x->accuracy(undef);
Math::BigInt->accuracy(undef);
```

Returns the current accuracy. For `$x->accuracy()` it will return either the local accuracy, or if not defined, the global. This means the return value represents the accuracy that will be in effect for `$x`:

```
$y = Math::BigInt->new(1234567);           # unrounded
print Math::BigInt->accuracy(4), "\n";      # set 4, print 4
$x = Math::BigInt->new(123456);             # will be automatically rounded
print "$x $y\n";                           # '123500 1234567'
print $x->accuracy(), "\n";                 # will be 4
print $y->accuracy(), "\n";                 # also 4, since global is 4
print Math::BigInt->accuracy(5), "\n";      # set to 5, print 5
```

```
print $x->accuracy(), "\n";      # still 4
print $y->accuracy(), "\n";      # 5, since global is 5
```

brsft

```
$x->brsft($y, $n);
```

Shifts x right by y in base n . Default is base 2, used are usually 10 and 2, but others work, too.

Right shifting usually amounts to dividing x by $n^{**}y$ and truncating the result:

```
$x = Math::BigInt->new(10);
$x->brsft(1);                      # same as $x >> 1: 5
$x = Math::BigInt->new(1234);
$x->brsft(2, 10);                  # result 12
```

There is one exception, and that is base 2 with negative x :

```
$x = Math::BigInt->new(-5);
print $x->brsft(1);
```

This will print -3 , not -2 (as it would if you divide -5 by 2 and truncate the result).

new

```
$x = Math::BigInt->new($str, $A, $P, $R);
```

Creates a new BigInt object from a string or another BigInt object. The input is accepted as decimal, hex (with leading '0x') or binary (with leading '0b').

bnan

```
$x = Math::BigInt->bnan();
```

Creates a new BigInt object representing NaN (Not A Number). If used on an object, it will set it to NaN:

```
$x->bnan();
```

bzero

```
$x = Math::BigInt->bzero();
```

Creates a new BigInt object representing zero. If used on an object, it will set it to zero:

```
$x->bzero();
```

binf

```
$x = Math::BigInt->binf($sign);
```

Creates a new BigInt object representing infinity. The optional argument is either '-' or '+', indicating whether you want infinity or minus infinity. If used on an object, it will set it to infinity:

```
$x->binf();
$x->binf('-');
```

bone

```
$x = Math::BigInt->binf($sign);
```

Creates a new BigInt object representing one. The optional argument is either '-' or '+', indicating whether you want one or minus one. If used on an object, it will set it to one:

```
$x->bone();                      # +1
$x->bone('-');                   # -1
```

is_one()/is_zero()/is_nan()/is_inf()

```
$x->is_zero();                   # true if arg is +0
$x->is_nan();                    # true if arg is NaN
$x->is_one();                    # true if arg is +1
```

```

$x->is_one('-');          # true if arg is -1
$x->is_inf();             # true if +inf
$x->is_inf('-');          # true if -inf (sign is default '+')

```

These methods all test the BigInt for being one specific value and return true or false depending on the input. These are faster than doing something like:

```
if ($x == 0)
```

is_positive()/is_negative()

```

$x->is_positive();        # true if >= 0
$x->is_negative();        # true if < 0

```

The methods return true if the argument is positive or negative, respectively. NaN is neither positive nor negative, while +inf counts as positive, and -inf is negative. A zero is positive.

These methods are only testing the sign, and not the value.

is_odd()/is_even()/is_int()

```

$x->is_odd();             # true if odd, false for even
$x->is_even();            # true if even, false for odd
$x->is_int();             # true if $x is an integer

```

The return true when the argument satisfies the condition. NaN, +inf, -inf are not integers and are neither odd nor even.

bcmp

```
$x->bcmp($y);
```

Compares \$x with \$y and takes the sign into account. Returns -1, 0, 1 or undef.

bacmp

```
$x->bacmp($y);
```

Compares \$x with \$y while ignoring their. Returns -1, 0, 1 or undef.

sign

```
$x->sign();
```

Return the sign, of \$x, meaning either +, -, -inf, +inf or NaN.

bcmp

```
$x->digit($n);           # return the nth digit, counting from right
```

bneg

```
$x->bneg();
```

Negate the number, e.g. change the sign between '+' and '-', or between '+inf' and '-inf', respectively. Does nothing for NaN or zero.

babs

```
$x->babs();
```

Set the number to it's absolute value, e.g. change the sign from '-' to '+' and from '-inf' to '+inf', respectively. Does nothing for NaN or positive numbers.

bnorm

```
$x->bnorm();             # normalize (no-op)
```

bnot

```
$x->bnot();              # two's complement (bit wise not)
```

binc

```
$x->binc();           # increment x by 1
```

bdec

```
$x->bdec();           # decrement x by 1
```

badd

```
$x->badd($y);          # addition (add $y to $x)
```

```
$x->bsub($y);          # subtraction (subtract $y from $x)
```

bmul

```
$x->bmul($y);          # multiplication (multiply $x by $y)
```

bdiv

```
$x->bdiv($y);          # divide, set $x to quotient
                        # return (quo,rem) or quo if scalar
```

bmod

```
$x->bmod($y);           # modulus (x % y)
```

bmodinv

```
$num->bmodinv($mod);    # modular inverse
```

Returns the inverse of \$num in the given modulus \$mod. ‘NaN’ is returned unless \$num is relatively prime to \$mod, i.e. unless `bgcd($num, $mod) == 1`.

bmodpow

```
$num->bmodpow($exp, $mod); # modular exponentation ($num**$exp % $mod)
```

Returns the value of \$num taken to the power \$exp in the modulus \$mod using binary exponentation. `bmodpow` is far superior to writing

```
$num ** $exp % $mod
```

because `bmodpow` is much faster—it reduces internal variables into the modulus whenever possible, so it operates on smaller numbers.

`bmodpow` also supports negative exponents.

```
bmodpow($num, -1, $mod)
```

is exactly equivalent to

```
bmodinv($num, $mod)
```

bpow

```
$x->bpow($y);           # power of arguments (x ** y)
```

blsft

```
$x->blsft($y);           # left shift
$x->blsft($y, $n);        # left shift, by base $n (like 10)
```

brsft

```
$x->brsft($y);           # right shift
$x->brsft($y, $n);        # right shift, by base $n (like 10)
```

band

```
$x->band($y);           # bitwise and
```

bior

```
$x->bior($y); # bitwise inclusive or
```

bxor

```
$x->bxor($y); # bitwise exclusive or
```

bnot

```
$x->bnot(); # bitwise not (two's complement)
```

bsqrt

```
$x->bsqrt(); # calculate square-root
```

bfac

```
$x->bfac(); # factorial of $x (1*2*3*4*...$x)
```

round

```
$x->round($A,$P,$round_mode); # round to accuracy or precision using mode $r
```

bround

```
$x->bround($N); # accuracy: preserve $N digits
```

bfround

```
$x->bfround($N); # round to $Nth digit, no-op for BigInts
```

bfloor

```
$x->bfloor();
```

Set `$x` to the integer less or equal than `$x`. This is a no-op in `BigInt`, but does change `$x` in `BigFloat`.

bceil

```
$x->bceil();
```

Set `$x` to the integer greater or equal than `$x`. This is a no-op in `BigInt`, but does change `$x` in `BigFloat`.

bgcd

```
bgcd(@values); # greatest common divisor (no OO style)
```

blcm

```
blcm(@values); # lowest common multiplier (no OO style)
```

head2 length

```
$x->length();
($x1,$f1) = $x->length();
```

Returns the number of digits in the decimal representation of the number. In list context, returns the length of the integer and fraction part. For `BigInt`'s, the length of the fraction part will always be 0.

exponent

```
$x->exponent();
```

Return the exponent of `$x` as `BigInt`.

mantissa

```
$x->mantissa();
```

Return the signed mantissa of `$x` as `BigInt`.

parts

```
$x->parts(); # return (mantissa,exponent) as BigInt
```

copy

```
$x->copy();
```

make a true copy of \$x (unlike \$y = \$x;)

as_number

```
$x->as_number();
```

return as BigInt (in BigInt: same as copy())

bsrt

```
$x->bstr();
```

normalized string

bsstr

```
$x->bsstr();
```

normalized string in scientific notation

as_hex

```
$x->as_hex();
```

as signed hexadecimal string with prefixed 0x

as_bin

```
$x->as_bin();
```

as signed binary string with prefixed 0b

ACCURACY and PRECISION

Since version v1.33, Math::BigInt and Math::BigFloat have full support for accuracy and precision based rounding, both automatically after every operation as well as manually.

This section describes the accuracy/precision handling in Math::Big* as it used to be and as it is now, complete with an explanation of all terms and abbreviations.

Not yet implemented things (but with correct description) are marked with ‘!’, things that need to be answered are marked with ‘?’.

In the next paragraph follows a short description of terms used here (because these may differ from terms used by others people or documentation).

During the rest of this document, the shortcuts A (for accuracy), P (for precision), F (fallback) and R (rounding mode) will be used.

Precision P

A fixed number of digits before (positive) or after (negative) the decimal point. For example, 123.45 has a precision of -2. 0 means an integer like 123 (or 120). A precision of 2 means two digits to the left of the decimal point are zero, so 123 with P = 1 becomes 120. Note that numbers with zeros before the decimal point may have different precisions, because 1200 can have p = 0, 1 or 2 (depending on what the initial value was). It could also have p < 0, when the digits after the decimal point are zero.

The string output (of floating point numbers) will be padded with zeros:

Initial value	P	A	Result	String
1234.01	-3		1000	1000
1234	-2		1200	1200
1234.5	-1		1230	1230
1234.001	1		1234	1234.0
1234.01	0		1234	1234
1234.01	2		1234.01	1234.01
1234.01	5		1234.01	1234.01000

For BigInts, no padding occurs.

Accuracy A

Number of significant digits. Leading zeros are not counted. A number may have an accuracy greater than the non-zero digits when there are zeros in it or trailing zeros. For example, 123.456 has A of 6, 10203 has 5, 123.0506 has 7, 123.450000 has 8 and 0.000123 has 3.

The string output (of floating point numbers) will be padded with zeros:

Initial value	P	A	Result	String
1234.01		3	1230	1230
1234.01		6	1234.01	1234.01
1234.1		8	1234.1	1234.1000

For BigInts, no padding occurs.

Fallback F

When both A and P are undefined, this is used as a fallback accuracy when dividing numbers.

Rounding mode R

When rounding a number, different ‘styles’ or ‘kinds’ of rounding are possible. (Note that random rounding, as in `Math::Round`, is not implemented.)

‘trunc’

truncation invariably removes all digits following the rounding place, replacing them with zeros. Thus, 987.65 rounded to tens ($P=1$) becomes 980, and rounded to the fourth sigdig becomes 987.6 ($A=4$). 123.456 rounded to the second place after the decimal point ($P=-2$) becomes 123.46.

All other implemented styles of rounding attempt to round to the "nearest digit." If the digit D immediately to the right of the rounding place (skipping the decimal point) is greater than 5, the number is incremented at the rounding place (possibly causing a cascade of incrementation): e.g. when rounding to units, 0.9 rounds to 1, and -19.9 rounds to -20 . If $D < 5$, the number is similarly truncated at the rounding place: e.g. when rounding to units, 0.4 rounds to 0, and -19.4 rounds to -19 .

However the results of other styles of rounding differ if the digit immediately to the right of the rounding place (skipping the decimal point) is 5 and if there are no digits, or no digits other than 0, after that 5. In such cases:

‘even’

rounds the digit at the rounding place to 0, 2, 4, 6, or 8 if it is not already. E.g., when rounding to the first sigdig, 0.45 becomes 0.4, -0.55 becomes -0.6 , but 0.4501 becomes 0.5.

‘odd’

rounds the digit at the rounding place to 1, 3, 5, 7, or 9 if it is not already. E.g., when rounding to the first sigdig, 0.45 becomes 0.5, -0.55 becomes -0.5 , but 0.5501 becomes 0.6.

‘+inf’

round to plus infinity, i.e. always round up. E.g., when rounding to the first sigdig, 0.45 becomes 0.5, -0.55 becomes -0.5 , and 0.4501 also becomes 0.5.

‘-inf’

round to minus infinity, i.e. always round down. E.g., when rounding to the first sigdig, 0.45 becomes 0.4, -0.55 becomes -0.6 , but 0.4501 becomes 0.5.

‘zero’

round to zero, i.e. positive numbers down, negative ones up. E.g., when rounding to the first sigdig, 0.45 becomes 0.4, -0.55 becomes -0.5 , but 0.4501 becomes 0.5.

The handling of A & P in MBI/MBF (the old core code shipped with Perl versions $\leq 5.7.2$) is like this:

Precision

- * `ffround($p)` is able to round to \$p number of digits after the decimal point
- * otherwise P is unused

Accuracy (significant digits)

- * `fround($a)` rounds to \$a significant digits
 - * only `fdiv()` and `fsqrt()` take A as (optional) parameter
 - + other operations simply create the same number (`fneg` etc), or more (`fmul`) of digits
 - + rounding/truncating is only done when explicitly calling one of `fround` or `ffround`, and never for `BigInt` (not implemented)
 - * `fsqrt()` simply hands its accuracy argument over to `fdiv`.
 - * the documentation and the comment in the code indicate two different ways on how `fdiv()` determines the maximum number of digits it should calculate, and the actual code does yet another thing
- POD:
- ```
max($Math::BigFloat::div_scale,length(dividend)+length(divisor))
```
- Comment:
- ```
result has at most max(scale, length(dividend), length(divisor)) digits
```
- Actual code:
- ```
scale = max(scale, length(dividend)-1,length(divisor)-1);
scale += length(divisor) - length(dividend);
```
- So for `lx = 3`, `ly = 9`, `scale = 10`, `scale` will actually be 16 (`10+9-3`). Actually, the 'difference' added to the scale is calculated from the number of "significant digits" in dividend and divisor, which is derived by looking at the length of the mantissa. Which is wrong, since it includes the + sign (oops) and actually gets 2 for `'+100'` and 4 for `'+101'`. Oups again. Thus `124/3` with `div_scale=1` will get you `'41.3'` based on the strange assumption that 124 has 3 significant digits, while `120/7` will get you `'17'`, not `'17.1'` since 120 is thought to have 2 significant digits. The rounding after the division then uses the remainder and `$y` to determine whether it must round up or down.
- ? I have no idea which is the right way. That's why I used a slightly more
- ? simple scheme and tweaked the few failing testcases to match it.

This is how it works now:

### Setting/Accessing

- \* You can set the A global via `Math::BigInt->accuracy()` or `Math::BigFloat->accuracy()` or whatever class you are using.
- \* You can also set P globally by using `Math::SomeClass->precision()` likewise.
- \* Globals are classwide, and not inherited by subclasses.
- \* to undefine A, use `Math::SomeClass->accuracy(undef);`
- \* to undefine P, use `Math::SomeClass->precision(undef);`
- \* Setting `Math::SomeClass->accuracy()` clears automatically `Math::SomeClass->precision()`, and vice versa.
- \* To be valid, A must be `> 0`, P can have any value.
- \* If P is negative, this means round to the P'th place to the right of the decimal point; positive values mean to the left of the decimal point. P of 0 means round to integer.
- \* to find out the current global A, take `Math::SomeClass->accuracy()`
- \* to find out the current global P, take `Math::SomeClass->precision()`
- \* use `$x->accuracy()` respective `$x->precision()` for the local setting of `$x`.
- \* Please note that `$x->accuracy()` respective `$x->precision()` fall back to the defined globals, when `$x's` A or P is not set.

### Creating numbers

- \* When you create a number, you can give it's desired A or P via:
 

```
$x = Math::BigInt->new($number,$A,$P);
```

- \* Only one of A or P can be defined, otherwise the result is NaN
- \* If no A or P is give (`$x = Math::BigInt->new($number)` form), then the globals (if set) will be used. Thus changing the global defaults later on will not change the A or P of previously created numbers (i.e., A and P of \$x will be what was in effect when \$x was created)
- \* If given undef for A and P, B<no> rounding will occur, and the globals will B<not> be used. This is used by subclasses to create numbers without suffering rounding in the parent. Thus a subclass is able to have it's own globals enforced upon creation of a number by using  
`$x = Math::BigInt->new($number,undef,undef) :`

```

 use Math::BigInt::SomeSubclass;
 use Math::BigInt;

 Math::BigInt->accuracy(2);
 Math::BigInt::SomeSubClass->accuracy(3);
 $x = Math::BigInt::SomeSubClass->new(1234);

```

\$x is now 1230, and not 1200. A subclass might choose to implement this otherwise, e.g. falling back to the parent's A and P.

### Usage

- \* If A or P are enabled/defined, they are used to round the result of each operation according to the rules below
- \* Negative P is ignored in Math::BigInt, since BigInts never have digits after the decimal point
- \* Math::BigFloat uses Math::BigInts internally, but setting A or P inside Math::BigInt as globals should not tamper with the parts of a BigFloat. Thus a flag is used to mark all Math::BigFloat numbers as 'never round'

### Precedence

- \* It only makes sense that a number has only one of A or P at a time. Since you can set/get both A and P, there is a rule that will practically enforce only A or P to be in effect at a time, even if both are set. This is called precedence.
- \* If two objects are involved in an operation, and one of them has A in effect, and the other P, this results in an error (NaN).
- \* A takes precedence over P (Hint: A comes before P). If A is defined, it is used, otherwise P is used. If neither of them is defined, nothing is used, i.e. the result will have as many digits as it can (with an exception for fdiv/fsqrt) and will not be rounded.
- \* There is another setting for fdiv() (and thus for fsqrt()). If neither of A or P is defined, fdiv() will use a fallback (F) of \$div\_scale digits. If either the dividend's or the divisor's mantissa has more digits than the value of F, the higher value will be used instead of F. This is to limit the digits (A) of the result (just consider what would happen with unlimited A and P in the case of 1/3 :-)
- \* fdiv will calculate (at least) 4 more digits than required (determined by A, P or F), and, if F is not used, round the result (this will still fail in the case of a result like 0.12345000000001 with A or P of 5, but this can not be helped - or can it?)
- \* Thus you can have the math done by on Math::Big\* class in three modes:
  - + never round (this is the default):  
 This is done by setting A and P to undef. No math operation will round the result, with fdiv() and fsqrt() as exceptions to guard against overflows. You must explicitly call bround(), bround() or round() (the latter with parameters).

Note: Once you have rounded a number, the settings will 'stick' on it and 'infect' all other numbers engaged in math operations with it, since local settings have the highest precedence. So, to get `SafeRound[tm]`, use a `copy()` before rounding like this:

```
$x = Math::BigFloat->new(12.34);
$y = Math::BigFloat->new(98.76);
$z = $x * $y; # 1218.6984
print $x->copy()->fround(3); # 12.3 (but A is now 3!)
$z = $x * $y; # still 1218.6984, without
 # copy would have been 1210!
```

+ round after each op:

After each single operation (except for testing like `is_zero()`), the method `round()` is called and the result is rounded appropriately. By setting proper values for A and P, you can have all-the-same-A or all-the-same-P modes. For example, `Math::Currency` might set A to undef, and P to -2, globally.

?Maybe an extra option that forbids local A & P settings would be in order, ?so that intermediate rounding does not 'poison' further math?

### Overriding globals

- \* you will be able to give A, P and R as an argument to all the calculation routines; the second parameter is A, the third one is P, and the fourth is R (shift right by one for binary operations like `badd`). P is used only if the first parameter (A) is undefined. These three parameters override the globals in the order detailed as follows, i.e. the first defined value wins:
  - (local: per object, global: global default, parameter: argument to sub)
  - + parameter A
  - + parameter P
  - + local A (if defined on both of the operands: smaller one is taken)
  - + local P (if defined on both of the operands: bigger one is taken)
  - + global A
  - + global P
  - + global F
- \* `fsqrt()` will hand its arguments to `fdiv()`, as it used to, only now for two arguments (A and P) instead of one

### Local settings

- \* You can set A and P locally by using `$x->accuracy()` and `$x->precision()` and thus force different A and P for different objects/numbers.
- \* Setting A or P this way immediately rounds `$x` to the new value.
- \* `$x->accuracy()` clears `$x->precision()`, and vice versa.

### Rounding

- \* the rounding routines will use the respective global or local settings. `fround()/bround()` is for accuracy rounding, while `ffround()/bfround()` is for precision
- \* the two rounding functions take as the second parameter one of the following rounding modes (R):
  - 'even', 'odd', '+inf', '-inf', 'zero', 'trunc'
- \* you can set and get the global R by using `Math::SomeClass->round_mode()` or by setting `$Math::SomeClass::round_mode`
- \* after each operation, `$result->round()` is called, and the result may eventually be rounded (that is, if A or P were set either locally,

- globally or as parameter to the operation)
- \* to manually round a number, call `$x->round($A,$P,$round_mode)`; this will round the number by using the appropriate rounding function and then normalize it.
- \* rounding modifies the local settings of the number:

```
$x = Math::BigFloat->new(123.456);
$x->accuracy(5);
$x->bround(4);
```

Here 4 takes precedence over 5, so 123.5 is the result and `$x->accuracy()` will be 4 from now on.

#### Default values

- \* R: 'even'
- \* F: 40
- \* A: undef
- \* P: undef

#### Remarks

- \* The defaults are set up so that the new code gives the same results as the old code (except in a few cases on `fdiv`):
- + Both A and P are undefined and thus will not be used for rounding after each operation.
- + `round()` is thus a no-op, unless given extra parameters A and P

## INTERNALS

The actual numbers are stored as unsigned big integers (with separate sign). You should neither care about nor depend on the internal representation; it might change without notice. Use only method calls like `< $x->sign()`; instead relying on the internal hash keys like in `< $x-{sign}`;

## MATH LIBRARY

Math with the numbers is done (by default) by a module called `Math::BigInt::Calc`. This is equivalent to saying:

```
use Math::BigInt lib => 'Calc';
```

You can change this by using:

```
use Math::BigInt lib => 'BitVect';
```

The following would first try to find `Math::BigInt::Foo`, then `Math::BigInt::Bar`, and when this also fails, revert to `Math::BigInt::Calc`:

```
use Math::BigInt lib => 'Foo,Math::BigInt::Bar';
```

`Calc.pm` uses as internal format an array of elements of some decimal base (usually 1e5 or 1e7) with the least significant digit first, while `BitVect.pm` uses a bit vector of base 2, most significant bit first. Other modules might use even different means of representing the numbers. See the respective module documentation for further details.

## SIGN

The sign is either '+', '-', 'NaN', '+inf' or '-inf' and stored separately.

A sign of 'NaN' is used to represent the result when input arguments are not numbers or as a result of 0/0. '+inf' and '-inf' represent plus respectively minus infinity. You will get '+inf' when dividing a positive number by 0, and '-inf' when dividing any negative number by 0.

**mantissa(), exponent() and parts()**

`mantissa()` and `exponent()` return the said parts of the `BigInt` such that:

```
$m = $x->mantissa();
$e = $x->exponent();
$y = $m * (10 ** $e);
print "ok\n" if $x == $y;
```

`< ($m,$e) = $x->parts()` is just a shortcut that gives you both of them in one go. Both the returned mantissa and exponent have a sign.

Currently, for `BigInts` `$e` will be always 0, except for NaN, +inf and -inf, where it will be NaN; and for `$x == 0`, where it will be 1 (to be compatible with `Math::BigFloat`'s internal representation of a zero as 0E1).

`$m` will always be a copy of the original number. The relation between `$e` and `$m` might change in the future, but will always be equivalent in a numerical sense, e.g. `$m` might get minimized.

**EXAMPLES**

```
use Math::BigInt;

sub bint { Math::BigInt->new(shift); }

$x = Math::BigInt->bstr("1234") # string "1234"
$x = "$x"; # same as bstr()
$x = Math::BigInt->bneg("1234"); # BigInt "-1234"
$x = Math::BigInt->babs("-12345"); # BigInt "12345"
$x = Math::BigInt->bnorm("-0 00"); # BigInt "0"
$x = bint(1) + bint(2); # BigInt "3"
$x = bint(1) + "2"; # ditto (auto-BigIntify of "2")
$x = bint(1); # BigInt "1"
$x = $x + 5 / 2; # BigInt "3"
$x = $x ** 3; # BigInt "27"
$x *= 2; # BigInt "54"
$x = Math::BigInt->new(0); # BigInt "0"
$x--; # BigInt "-1"
$x = Math::BigInt->badd(4,5) # BigInt "9"
print $x->bsstr(); # 9e+0
```

Examples for rounding:

```
use Math::BigFloat;
use Test;

$x = Math::BigFloat->new(123.4567);
$y = Math::BigFloat->new(123.456789);
Math::BigFloat->accuracy(4); # no more A than 4

ok ($x->copy()->fround(),123.4); # even rounding
print $x->copy()->fround(),"\n"; # 123.4
Math::BigFloat->round_mode('odd'); # round to odd
print $x->copy()->fround(),"\n"; # 123.5
Math::BigFloat->accuracy(5); # no more A than 5
Math::BigFloat->round_mode('odd'); # round to odd
print $x->copy()->fround(),"\n"; # 123.46
$y = $x->copy()->fround(4)," \n"; # A = 4: 123.4
print "$y, ", $y->accuracy()," \n"; # 123.4, 4

Math::BigFloat->accuracy(undef); # A not important now
Math::BigFloat->precision(2); # P important
print $x->copy()->bnorm(),"\n"; # 123.46
```

```
print $x->copy()->fround(),"\n#;123.46
```

Examples for converting:

```
my $x = Math::BigInt->new('0b1'.'01' x 123);
print "bin: ",$x->as_bin()," hex: ",$x->as_hex()," dec: ",$x,"\n";
```

### Autocreating constants

After use `Math::BigInt ':constant'` all the **integer** decimal, hexadecimal and binary constants in the given scope are converted to `Math::BigInt`. This conversion happens at compile time.

In particular,

```
perl -MMath::BigInt=:constant -e 'print 2**100,"\n"'
```

prints the integer value of `2**100`. Note that without conversion of constants the expression `2**100` will be calculated as perl scalar.

Please note that strings and floating point constants are not affected, so that

```
use Math::BigInt qw/:constant/;

$x = 1234567890123456789012345678901234567890
 + 123456789123456789;
$y = '1234567890123456789012345678901234567890'
 + '123456789123456789';
```

do not work. You need an explicit `Math::BigInt-new()` around one of the operands. You should also quote large constants to protect loss of precision:

```
use Math::BigInt;

$x = Math::BigInt->new('1234567889123456789123456789123456789');
```

Without the quotes Perl would convert the large number to a floating point constant at compile time and then hand the result to `BigInt`, which results in an truncated result or a NaN.

This also applies to integers that look like floating point constants:

```
use Math::BigInt ':constant';

print ref(123e2),"\n";
print ref(123.2e2),"\n";
```

will print nothing but newlines. Use either *bignum* or *Math::BigFloat* to get this to work.

### PERFORMANCE

Using the form `$x += $y`; etc over `$x = $x + $y` is faster, since a copy of `$x` must be made in the second case. For long numbers, the copy can eat up to 20% of the work (in the case of addition/subtraction, less for multiplication/division). If `$y` is very small compared to `$x`, the form `$x += $y` is MUCH faster than `$x = $x + $y` since making the copy of `$x` takes more time then the actual addition.

With a technique called copy-on-write, the cost of copying with overload could be minimized or even completely avoided. A test implementation of COW did show performance gains for overloaded math, but introduced a performance loss due to a constant overhead for all other operations.

The rewritten version of this module is slower on certain operations, like `new()`, `bstr()` and `numify()`. The reason are that it does now more work and handles more cases. The time spent in these operations is usually gained in the other operations so that programs on the average should get faster. If they don't, please contact the author.

Some operations may be slower for small numbers, but are significantly faster for big numbers. Other operations are now constant (O(1), like `bneg()`, `babs()` etc), instead of O(N) and thus nearly always take much less time. These optimizations were done on purpose.

If you find the Calc module to slow, try to install any of the replacement modules and see if they help you.

### Alternative math libraries

You can use an alternative library to drive Math::BigInt via:

```
use Math::BigInt lib => 'Module';
```

See [MATH LIBRARY](#) for more information.

For more benchmark results see <http://bloodgate.com/perl/benchmarks.html>.

## SUBCLASSING

### Subclassing Math::BigInt

The basic design of Math::BigInt allows simple subclasses with very little work, as long as a few simple rules are followed:

- The public API must remain consistent, i.e. if a sub-class is overloading addition, the sub-class must use the same name, in this case `badd()`. The reason for this is that Math::BigInt is optimized to call the object methods directly.
- The private object hash keys like `$x-{sign}` may not be changed, but additional keys can be added, like `$x-{_custom}`.
- Accessor functions are available for all existing object hash keys and should be used instead of directly accessing the internal hash keys. The reason for this is that Math::BigInt itself has a pluggable interface which permits it to support different storage methods.

More complex sub-classes may have to replicate more of the logic internal of Math::BigInt if they need to change more basic behaviors. A subclass that needs to merely change the output only needs to overload `bstr()`.

All other object methods and overloaded functions can be directly inherited from the parent class.

At the very minimum, any subclass will need to provide it's own `new()` and can store additional hash keys in the object. There are also some package globals that must be defined, e.g.:

```
Globals
$accuracy = undef;
$precision = -2; # round to 2 decimal places
$round_mode = 'even';
$div_scale = 40;
```

Additionally, you might want to provide the following two globals to allow auto-upgrading and auto-downgrading to work correctly:

```
$upgrade = undef;
$downgrade = undef;
```

This allows Math::BigInt to correctly retrieve package globals from the subclass, like `$SubClass::precision`. See `t/Math/BigInt/Subclass.pm` or `t/Math/BigFloat/SubClass.pm` completely functional subclass examples.

Don't forget to

```
use overload;
```

in your subclass to automatically inherit the overloading from the parent. If you like, you can change part of the overloading, look at Math::String for an example.

## UPGRADING

When used like this:

```
use Math::BigInt upgrade => 'Foo::Bar';
```

certain operations will ‘upgrade’ their calculation and thus the result to the class `Foo::Bar`. Usually this is used in conjunction with `Math::BigFloat`:

```
use Math::BigInt upgrade => 'Math::BigFloat';
```

As a shortcut, you can use the module `bignum`:

```
use bignum;
```

Also good for oneliners:

```
perl -mbignum -le 'print 2 ** 255'
```

This makes it possible to mix arguments of different classes (as in  $2.5 + 2$ ) as well as preserve accuracy (as in `sqrt(3)`).

Beware: This feature is not fully implemented yet.

### Auto-upgrade

The following methods upgrade themselves unconditionally; that is if upgrade is in effect, they will always hand up their work:

```
bsqrt()
div()
blog()
```

Beware: This list is not complete.

All other methods upgrade themselves only when one (or all) of their arguments are of the class mentioned in `$upgrade` (This might change in later versions to a more sophisticated scheme):

### BUGS

#### Out of Memory!

Under Perl prior to 5.6.0 having an `use Math::BigInt ':constant';` and `eval()` in your code will crash with "Out of memory". This is probably an overload/exporter bug. You can workaround by not having `eval()` and `:constant` at the same time or upgrade your Perl to a newer version.

#### Fails to load Calc on Perl prior 5.6.0

Since `eval('use ...')` can not be used in conjunction with `:constant`, `BigInt` will fall back to `eval { require ... }` when loading the math lib on Perls prior to 5.6.0. This simple replaces `::` with `/` and thus might fail on filesystems using a different separator.

### CAVEATS

Some things might not work as you expect them. Below is documented what is known to be troublesome:

#### `stringify`, `bstr()`, `bsstr()` and `'cmp'`

Both `stringify` and `bstr()` now drop the leading `+`. The old code would return `+3`, the new returns `3`. This is to be consistent with Perl and to make `cmp` (especially with overloading) to work as you expect. It also solves problems with `Test.pm`, it's `ok()` uses `'eq'` internally.

Mark said, when asked about to drop the `+` altogether, or make only `cmp` work:

```
I agree (with the first alternative), don't add the '+' on positive
numbers. It's not as important anymore with the new internal
form for numbers. It made doing things like abs and neg easier,
but those have to be done differently now anyway.
```

So, the following examples will now work all as expected:

```
use Test;
BEGIN { plan tests => 1 }
use Math::BigInt;
```

```

my $x = new Math::BigInt 3*3;
my $y = new Math::BigInt 3*3;

ok ($x,3*3);
print "$x eq 9" if $x eq $y;
print "$x eq 9" if $x eq '9';
print "$x eq 9" if $x eq 3*3;

```

Additionally, the following still works:

```

print "$x == 9" if $x == $y;
print "$x == 9" if $x == 9;
print "$x == 9" if $x == 3*3;

```

There is now a `bsstr()` method to get the string in scientific notation aka `1e+2` instead of `100`. Be advised that overloaded `'eq'` always uses `bstr()` for comparison, but Perl will represent some numbers as `100` and others as `1e+308`. If in doubt, convert both arguments to `Math::BigInt` before doing `eq`:

```

use Test;
BEGIN { plan tests => 3 }
use Math::BigInt;

$x = Math::BigInt->new('1e56'); $y = 1e56;
ok ($x,$y); # will fail
ok ($x->bsstr(),$y); # okay
$y = Math::BigInt->new($y);
ok ($x,$y); # okay

```

Alternatively, simply use `<=` for comparisons, that will get it always right. There is not yet a way to get a number automatically represented as a string that matches exactly the way Perl represents it.

`int()`

`int()` will return (at least for Perl v5.7.1 and up) another `BigInt`, not a Perl scalar:

```

$x = Math::BigInt->new(123);
$y = int($x); # BigInt 123
$x = Math::BigFloat->new(123.45);
$y = int($x); # BigInt 123

```

In all Perl versions you can use `as_number()` for the same effect:

```

$x = Math::BigFloat->new(123.45);
$y = $x->as_number(); # BigInt 123

```

This also works for other subclasses, like `Math::String`.

It is yet unclear whether overloaded `int()` should return a scalar or a `BigInt`.

`length`

The following will probably not do what you expect:

```

$c = Math::BigInt->new(123);
print $c->length(), "\n"; # prints 30

```

It prints both the number of digits in the number and in the fraction part since `print` calls `length()` in list context. Use something like:

```

print scalar $c->length(), "\n"; # prints 3

```

`bdiv`

The following will probably not do what you expect:

```

print $c->bdiv(10000), "\n";

```

It prints both quotient and remainder since `print` calls `bdiv()` in list context. Also, `bdiv()` will modify `$c`, so be carefull. You probably want to use

```
print $c / 10000, "\n";
print scalar $c->bdiv(10000), "\n"; # or if you want to modify $c
```

instead.

The quotient is always the greatest integer less than or equal to the real-valued quotient of the two operands, and the remainder (when it is nonzero) always has the same sign as the second operand; so, for example,

```
1 / 4 => (0, 1)
1 / -4 => (-1, -3)
-3 / 4 => (-1, 1)
-3 / -4 => (0, -3)
-11 / 2 => (-5, 1)
11 / -2 => (-5, -1)
```

As a consequence, the behavior of the operator `%` agrees with the behavior of Perl's built-in `%` operator (as documented in the `perlop` manpage), and the equation

$$\$x == (\$x / \$y) * \$y + (\$x \% \$y)$$

holds true for any `$x` and `$y`, which justifies calling the two return values of `bdiv()` the quotient and remainder. The only exception to this rule are when `$y == 0` and `$x` is negative, then the remainder will also be negative. See below under "infinity handling" for the reasoning behind this.

Perl's 'use integer;' changes the behaviour of `%` and `/` for scalars, but will not change `BigInt`'s way to do things. This is because under 'use integer' Perl will do what the underlying C thinks is right and this is different for each system. If you need `BigInt`'s behaving exactly like Perl's 'use integer', bug the author to implement it ;)

### infinity handling

Here are some examples that explain the reasons why certain results occur while handling infinity:

The following table shows the result of the division and the remainder, so that the equation above holds true. Some "ordinary" cases are strewn in to show more clearly the reasoning:

| A / B = C,       | R  | so that C * B + R = A |
|------------------|----|-----------------------|
| =====            |    |                       |
| 5 / 8 = 0,       | 5  | 0 * 8 + 5 = 5         |
| 0 / 8 = 0,       | 0  | 0 * 8 + 0 = 0         |
| 0 / inf = 0,     | 0  | 0 * inf + 0 = 0       |
| 0 / -inf = 0,    | 0  | 0 * -inf + 0 = 0      |
| 5 / inf = 0,     | 5  | 0 * inf + 5 = 5       |
| 5 / -inf = 0,    | 5  | 0 * -inf + 5 = 5      |
| -5 / inf = 0,    | -5 | 0 * inf + -5 = -5     |
| -5 / -inf = 0,   | -5 | 0 * -inf + -5 = -5    |
| inf / 5 = inf,   | 0  | inf * 5 + 0 = inf     |
| -inf / 5 = -inf, | 0  | -inf * 5 + 0 = -inf   |
| inf / -5 = -inf, | 0  | -inf * -5 + 0 = inf   |
| -inf / -5 = inf, | 0  | inf * -5 + 0 = -inf   |
| 5 / 5 = 1,       | 0  | 1 * 5 + 0 = 5         |
| -5 / -5 = 1,     | 0  | 1 * -5 + 0 = -5       |
| inf / inf = 1,   | 0  | 1 * inf + 0 = inf     |
| -inf / -inf = 1, | 0  | 1 * -inf + 0 = -inf   |
| inf / -inf = -1, | 0  | -1 * -inf + 0 = inf   |
| -inf / inf = -1, | 0  | 1 * -inf + 0 = -inf   |
| 8 / 0 = inf,     | 8  | inf * 0 + 8 = 8       |

```

inf/ 0 = inf, inf inf * 0 + inf = inf
0/ 0 = NaN

```

These cases below violate the "remainder has the sign of the second of the two arguments", since they wouldn't match up otherwise.

```

 A / B = C, R so that C * B + R = A
=====
-inf/ 0 = -inf, -inf -inf * 0 + inf = -inf
-8/ 0 = -inf, -8 -inf * 0 + 8 = -8

```

### Modifying and =

Beware of:

```

$x = Math::BigFloat->new(5);
$y = $x;

```

It will not do what you think, e.g. making a copy of `$x`. Instead it just makes a second reference to the **same** object and stores it in `$y`. Thus anything that modifies `$x` (except overloaded operators) will modify `$y`, and vice versa. Or in other words, `=` is only safe if you modify your BigInts only via overloaded math. As soon as you use a method call it breaks:

```

$x->bmul(2);
print "$x, $y\n"; # prints '10, 10'

```

If you want a true copy of `$x`, use:

```

$y = $x->copy();

```

You can also chain the calls like this, this will make first a copy and then multiply it by 2:

```

$y = $x->copy()->bmul(2);

```

See also the documentation for `overload.pm` regarding `=`.

### bpow

`bpow()` (and the rounding functions) now modifies the first argument and returns it, unlike the old code which left it alone and only returned the result. This is to be consistent with `badd()` etc. The first three will modify `$x`, the last one won't:

```

print bpow($x,$i), "\n"; # modify $x
print $x->bpow($i), "\n"; # ditto
print $x **= $i, "\n"; # the same
print $x ** $i, "\n"; # leave $x alone

```

The form `$x **= $y` is faster than `$x = $x ** $y`, though.

### Overloading -\$x

The following:

```

$x = -$x;

```

is slower than

```

$x->bneg();

```

since `overload` calls `sub($x, 0, 1)`; instead of `neg($x)`. The first variant needs to preserve `$x` since it does not know that it later will get overwritten. This makes a copy of `$x` and takes  $O(N)$ , but `$x->bneg()` is  $O(1)$ .

With Copy-On-Write, this issue would be gone, but C-o-W is not implemented since it is slower for all other things.

### Mixing different object types

In Perl you will get a floating point value if you do one of the following:

```
$float = 5.0 + 2;
$float = 2 + 5.0;
$float = 5 / 2;
```

With overloaded math, only the first two variants will result in a BigInt:

```
use Math::BigInt;
use Math::BigFloat;

$mbf = Math::BigFloat->new(5);
$mbi2 = Math::BigInteger->new(5);
$mbi = Math::BigInteger->new(2);

what actually gets called:
$float = $mbf + $mbi; # $mbf->badd()
$float = $mbf / $mbi; # $mbf->bdiv()
$integer = $mbi + $mbf; # $mbi->badd()
$integer = $mbi2 / $mbi; # $mbi2->bdiv()
$integer = $mbi2 / $mbf; # $mbi2->bdiv()
```

This is because math with overloaded operators follows the first (dominating) operand, and the operation of that is called and returns thus the result. So, `Math::BigInt::bdiv()` will always return a `Math::BigInt`, regardless whether the result should be a `Math::BigFloat` or the second operand is one.

To get a `Math::BigFloat` you either need to call the operation manually, make sure the operands are already of the proper type or casted to that type via `Math::BigFloat->new()`:

```
$float = Math::BigFloat->new($mbi2) / $mbi; # = 2.5
```

Beware of simple "casting" the entire expression, this would only convert the already computed result:

```
$float = Math::BigFloat->new($mbi2 / $mbi); # = 2.0 thus wrong!
```

Beware also of the order of more complicated expressions like:

```
$integer = ($mbi2 + $mbi) / $mbf; # int / float => int
$integer = $mbi2 / Math::BigFloat->new($mbi); # ditto
```

If in doubt, break the expression into simpler terms, or cast all operands to the desired resulting type.

Scalar values are a bit different, since:

```
$float = 2 + $mbf;
$float = $mbf + 2;
```

will both result in the proper type due to the way the overloaded math works.

This section also applies to other overloaded math packages, like `Math::String`.

One solution to your problem might be [autoupgrading/upgrading](#).

### `bsqrt()`

`bsqrt()` works only good if the result is a big integer, e.g. the square root of 144 is 12, but from 12 the square root is 3, regardless of rounding mode.

If you want a better approximation of the square root, then use:

```
$x = Math::BigFloat->new(12);
Math::BigFloat->precision(0);
Math::BigFloat->round_mode('even');
print $x->copy->bsqrt(), "\n"; # 4
```

```
Math::BigFloat->precision(2);
print $x->bsqrt(), "\n"; # 3.46
print $x->bsqrt(3), "\n"; # 3.464

brsft()
```

For negative numbers in base see also [brsft/brsft](#).

## AUTHORS

Original code by Mark Biggar, overloaded interface by Ilya Zakharevich. Completely rewritten by Tels <http://bloodgate.com> in late 2000, 2001.

**NAME**

Math::BigInt::Calc – Pure Perl module to support Math::BigInt

**SYNOPSIS**

Provides support for big integer calculations. Not intended to be used by other modules (except Math::BigInt::Cached). Other modules which sport the same functions can also be used to support Math::BigInt, like Math::BigInt::Pari.

**DESCRIPTION**

In order to allow for multiple big integer libraries, Math::BigInt was rewritten to use library modules for core math routines. Any module which follows the same API as this can be used instead by using the following:

```
use Math::BigInt lib => 'libname';
```

'libname' is either the long name ('Math::BigInt::Pari'), or only the short version like 'Pari'.

**EXPORT**

The following functions **MUST** be defined in order to support the use by Math::BigInt:

|                             |                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_new(string)</code>   | return ref to new object from ref to decimal string                                                                                                          |
| <code>_zero()</code>        | return a new object with value 0                                                                                                                             |
| <code>_one()</code>         | return a new object with value 1                                                                                                                             |
| <code>_str(obj)</code>      | return ref to a string representing the object                                                                                                               |
| <code>_num(obj)</code>      | returns a Perl integer/floating point number                                                                                                                 |
|                             | NOTE: because of Perl numeric notation defaults, the <code>_num</code> 'ified obj may lose accuracy due to machine-dependend floating point size limitations |
| <code>_add(obj,obj)</code>  | Simple addition of two objects                                                                                                                               |
| <code>_mul(obj,obj)</code>  | Multiplication of two objects                                                                                                                                |
| <code>_div(obj,obj)</code>  | Division of the 1st object by the 2nd                                                                                                                        |
|                             | In list context, returns (result,remainder).                                                                                                                 |
|                             | NOTE: this is integer math, so no fractional part will be returned.                                                                                          |
| <code>_sub(obj,obj)</code>  | Simple subtraction of 1 object from another                                                                                                                  |
|                             | a third, optional parameter indicates that the params are swapped. In this case, the first param needs to be preserved, while you can destroy the second.    |
|                             | sub (x,y,1) => return x - y and keep x intact!                                                                                                               |
| <code>_dec(obj)</code>      | decrement object by one (input is garant. to be > 0)                                                                                                         |
| <code>_inc(obj)</code>      | increment object by one                                                                                                                                      |
| <code>_acmp(obj,obj)</code> | <=> operator for objects (return -1, 0 or 1)                                                                                                                 |
| <code>_len(obj)</code>      | returns count of the decimal digits of the object                                                                                                            |
| <code>_digit(obj,n)</code>  | returns the n'th decimal digit of object                                                                                                                     |
| <code>_is_one(obj)</code>   | return true if argument is +1                                                                                                                                |
| <code>_is_zero(obj)</code>  | return true if argument is 0                                                                                                                                 |
| <code>_is_even(obj)</code>  | return true if argument is even (0,2,4,6..)                                                                                                                  |
| <code>_is_odd(obj)</code>   | return true if argument is odd (1,3,5,7..)                                                                                                                   |
| <code>_copy</code>          | return a ref to a true copy of the object                                                                                                                    |
| <code>_check(obj)</code>    | check whether internal representation is still intact                                                                                                        |
|                             | return 0 for ok, otherwise error message as string                                                                                                           |

The following functions are optional, and can be defined if the underlying lib has a fast way to do them. If undefined, Math::BigInt will use pure Perl (hence slow) fallback routines to emulate these:

|                              |                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_from_hex(str)</code>  | return ref to new object from ref to hexadecimal string                                                                                        |
| <code>_from_bin(str)</code>  | return ref to new object from ref to binary string                                                                                             |
| <code>_as_hex(str)</code>    | return ref to scalar string containing the value as unsigned hex string, with the '0x' prepended. Leading zeros must be stripped.              |
| <code>_as_bin(str)</code>    | Like <code>_as_hex</code> , only as binary string containing only zeros and ones. Leading zeros must be stripped and a '0b' must be prepended. |
| <code>_rsft(obj,N,B)</code>  | shift object in base B by N 'digits' right<br>For unsupported bases B, return undef to signal failure                                          |
| <code>_lsft(obj,N,B)</code>  | shift object in base B by N 'digits' left<br>For unsupported bases B, return undef to signal failure                                           |
| <code>_xor(obj1,obj2)</code> | XOR (bit-wise) object 1 with object 2<br>Note: XOR, AND and OR pad with zeros if size mismatches                                               |
| <code>_and(obj1,obj2)</code> | AND (bit-wise) object 1 with object 2                                                                                                          |
| <code>_or(obj1,obj2)</code>  | OR (bit-wise) object 1 with object 2                                                                                                           |
| <code>_mod(obj,obj)</code>   | Return remainder of div of the 1st by the 2nd object                                                                                           |
| <code>_sqrt(obj)</code>      | return the square root of object (truncate to int)                                                                                             |
| <code>_fac(obj)</code>       | return factorial of object 1 (1*2*3*4..)                                                                                                       |
| <code>_pow(obj,obj)</code>   | return object 1 to the power of object 2                                                                                                       |
| <code>_gcd(obj,obj)</code>   | return Greatest Common Divisor of two objects                                                                                                  |
| <code>_zeros(obj)</code>     | return number of trailing decimal zeros                                                                                                        |
| <code>_modinv</code>         | return inverse modulus                                                                                                                         |
| <code>_modpow</code>         | return modulus of power (\$x ** \$y) % \$z                                                                                                     |

Input strings come in as unsigned but with prefix (i.e. as '123', '0xabc' or '0b1101').

Testing of input parameter validity is done by the caller, so you need not worry about underflow (f.i. in `_sub()`, `_dec()`) nor about division by zero or similar cases.

The first parameter can be modified, that includes the possibility that you return a reference to a completely different object instead. Although keeping the reference and just changing it's contents is preferred over creating and returning a different reference.

Return values are always references to objects or strings. Exceptions are `_lsft()` and `_rsft()`, which return undef if they can not shift the argument. This is used to delegate shifting of bases different than the one you can support back to `Math::BigInt`, which will use some generic code to calculate the result.

## WRAP YOUR OWN

If you want to port your own favourite c-lib for big numbers to the `Math::BigInt` interface, you can take any of the already existing modules as a rough guideline. You should really wrap up the latest `BigInt` and `BigFloat` testsuites with your module, and replace in them any of the following:

```
use Math::BigInt;
```

by this:

```
use Math::BigInt lib => 'yourlib';
```

This way you ensure that your library really works 100% within `Math::BigInt`.

**NAME**

Math::BigRat – arbitrarily big rationals

**SYNOPSIS**

```
use Math::BigRat;

$x = Math::BigRat->new('3/7');

print $x->bstr(), "\n";
```

**DESCRIPTION**

This is just a placeholder until the real thing is up and running. Watch this space...

**MATH LIBRARY**

Math with the numbers is done (by default) by a module called Math::BigInt::Calc. This is equivalent to saying:

```
use Math::BigRat lib => 'Calc';
```

You can change this by using:

```
use Math::BigRat lib => 'BitVect';
```

The following would first try to find Math::BigInt::Foo, then Math::BigInt::Bar, and when this also fails, revert to Math::BigInt::Calc:

```
use Math::BigRat lib => 'Foo,Math::BigInt::Bar';
```

Calc.pm uses as internal format an array of elements of some decimal base (usually 1e7, but this might be different for some systems) with the least significant digit first, while BitVect.pm uses a bit vector of base 2, most significant bit first. Other modules might use even different means of representing the numbers. See the respective module documentation for further details.

**METHODS**

Any method not listed here is derived from Math::BigFloat (or Math::BigInt), so make sure you check these two modules for further information.

**new()**

```
$x = Math::BigRat->new('1/3');
```

Create a new Math::BigRat object. Input can come in various forms:

```
$x = Math::BigRat->new('1/3'); # simple string
$x = Math::BigRat->new('1 / 3'); # spaced
$x = Math::BigRat->new('1 / 0.1'); # w/ floats
$x = Math::BigRat->new(Math::BigInt->new(3)); # BigInt
$x = Math::BigRat->new(Math::BigFloat->new('3.1')); # BigFloat
$x = Math::BigRat->new(Math::BigInt::Lite->new('2')); # BigLite
```

**numerator()**

```
$n = $x->numerator();
```

Returns a copy of the numerator (the part above the line) as signed BigInt.

**denominator()**

```
$d = $x->denominator();
```

Returns a copy of the denominator (the part under the line) as positive BigInt.

**parts()**

```
($n,$d) = $x->parts();
```

Return a list consisting of (signed) numerator and (unsigned) denominator as BigInts.

**as\_number()**

Returns a copy of the object as BigInt by truncating it to integer.

**bfac()**

```
$x->bfac();
```

Calculates the factorial of \$x. For instance:

```
print Math::BigRat->new('3/1')->bfac(), "\n"; # 1*2*3
print Math::BigRat->new('5/1')->bfac(), "\n"; # 1*2*3*4*5
```

Only works for integers for now.

**blog()**

Is not yet implemented.

**bound()/round()/bround()**

Are not yet implemented.

**BUGS**

Some things are not yet implemented, or only implemented half-way.

(C) by Tels <http://bloodgate.com/> 2001–2002.

**NAME**

Math::Complex – complex numbers and associated mathematical functions

**SYNOPSIS**

```
use Math::Complex;

$z = Math::Complex->make(5, 6);
$t = 4 - 3*i + $z;
$j = cplx(1, 2*pi/3);
```

**DESCRIPTION**

This package lets you create and manipulate complex numbers. By default, *Perl* limits itself to real numbers, but an extra `use` statement brings full complex support, along with a full set of mathematical functions typically associated with and/or extended to complex numbers.

If you wonder what complex numbers are, they were invented to be able to solve the following equation:

$$x^2 = -1$$

and by definition, the solution is noted *i* (engineers use *j* instead since *i* usually denotes an intensity, but the name does not matter). The number *i* is a pure *imaginary* number.

The arithmetics with pure imaginary numbers works just like you would expect it with real numbers... you just have to remember that

$$i*i = -1$$

so you have:

$$\begin{aligned} 5i + 7i &= i * (5 + 7) = 12i \\ 4i - 3i &= i * (4 - 3) = i \\ 4i * 2i &= -8 \\ 6i / 2i &= 3 \\ 1 / i &= -i \end{aligned}$$

Complex numbers are numbers that have both a real part and an imaginary part, and are usually noted:

$$a + bi$$

where *a* is the *real* part and *b* is the *imaginary* part. The arithmetic with complex numbers is straightforward. You have to keep track of the real and the imaginary parts, but otherwise the rules used for real numbers just apply:

$$\begin{aligned} (4 + 3i) + (5 - 2i) &= (4 + 5) + i(3 - 2) = 9 + i \\ (2 + i) * (4 - i) &= 2*4 + 4i - 2i - i*i = 8 + 2i + 1 = 9 + 2i \end{aligned}$$

A graphical representation of complex numbers is possible in a plane (also called the *complex plane*, but it's really a 2D plane). The number

$$z = a + bi$$

is the point whose coordinates are (a, b). Actually, it would be the vector originating from (0, 0) to (a, b). It follows that the addition of two complex numbers is a vectorial addition.

Since there is a bijection between a point in the 2D plane and a complex number (i.e. the mapping is unique and reciprocal), a complex number can also be uniquely identified with polar coordinates:

$$[\text{rho}, \text{theta}]$$

where *rho* is the distance to the origin, and *theta* the angle between the vector and the *x* axis. There is a notation for this using the exponential form, which is:

$$\text{rho} * \exp(i * \text{theta})$$

where  $i$  is the famous imaginary number introduced above. Conversion between this form and the cartesian form  $a + bi$  is immediate:

```
a = rho * cos(theta)
b = rho * sin(theta)
```

which is also expressed by this formula:

```
z = rho * exp(i * theta) = rho * (cos theta + i * sin theta)
```

In other words, it's the projection of the vector onto the  $x$  and  $y$  axes. Mathematicians call *rho* the *norm* or *modulus* and *theta* the *argument* of the complex number. The *norm* of  $z$  will be noted `abs(z)`.

The polar notation (also known as the trigonometric representation) is much more handy for performing multiplications and divisions of complex numbers, whilst the cartesian notation is better suited for additions and subtractions. Real numbers are on the  $x$  axis, and therefore *theta* is zero or  $\pi$ .

All the common operations that can be performed on a real number have been defined to work on complex numbers as well, and are merely *extensions* of the operations defined on real numbers. This means they keep their natural meaning when there is no imaginary part, provided the number is within their definition set.

For instance, the `sqrt` routine which computes the square root of its argument is only defined for non-negative real numbers and yields a non-negative real number (it is an application from  $\mathbf{R}^+$  to  $\mathbf{R}^+$ ). If we allow it to return a complex number, then it can be extended to negative real numbers to become an application from  $\mathbf{R}$  to  $\mathbf{C}$  (the set of complex numbers):

```
sqrt(x) = x >= 0 ? sqrt(x) : sqrt(-x)*i
```

It can also be extended to be an application from  $\mathbf{C}$  to  $\mathbf{C}$ , whilst its restriction to  $\mathbf{R}$  behaves as defined above by using the following definition:

```
sqrt(z = [r,t]) = sqrt(r) * exp(i * t/2)
```

Indeed, a negative real number can be noted  $[x, \pi]$  (the modulus  $x$  is always non-negative, so  $[x, \pi]$  is really  $-x$ , a negative number) and the above definition states that

```
sqrt([x,pi]) = sqrt(x) * exp(i*pi/2) = [sqrt(x),pi/2] = sqrt(x)*i
```

which is exactly what we had defined for negative real numbers above. The `sqrt` returns only one of the solutions: if you want the both, use the `root` function.

All the common mathematical functions defined on real numbers that are extended to complex numbers share that same property of working *as usual* when the imaginary part is zero (otherwise, it would not be called an extension, would it?).

A *new* operation possible on a complex number that is the identity for real numbers is called the *conjugate*, and is noted with a horizontal bar above the number, or  $\sim z$  here.

```
z = a + bi
~z = a - bi
```

Simple... Now look:

```
z * ~z = (a + bi) * (a - bi) = a*a + b*b
```

We saw that the norm of  $z$  was noted `abs(z)` and was defined as the distance to the origin, also known as:

```
rho = abs(z) = sqrt(a*a + b*b)
```

so

```
z * ~z = abs(z) ** 2
```

If  $z$  is a pure real number (i.e.  $b == 0$ ), then the above yields:

```
a * a = abs(a) ** 2
```

which is true (abs has the regular meaning for real number, i.e. stands for the absolute value). This example explains why the norm of  $z$  is noted `abs(z)`: it extends the `abs` function to complex numbers, yet is the regular `abs` we know when the complex number actually has no imaginary part... This justifies *a posteriori* our use of the `abs` notation for the norm.

## OPERATIONS

Given the following notations:

```
z1 = a + bi = r1 * exp(i * t1)
z2 = c + di = r2 * exp(i * t2)
z = <any complex or real number>
```

the following (overloaded) operations are supported on complex numbers:

```
z1 + z2 = (a + c) + i(b + d)
z1 - z2 = (a - c) + i(b - d)
z1 * z2 = (r1 * r2) * exp(i * (t1 + t2))
z1 / z2 = (r1 / r2) * exp(i * (t1 - t2))
z1 ** z2 = exp(z2 * log z1)
~z = a - bi
abs(z) = r1 = sqrt(a*a + b*b)
sqrt(z) = sqrt(r1) * exp(i * t/2)
exp(z) = exp(a) * exp(i * b)
log(z) = log(r1) + i*t
sin(z) = 1/2i (exp(i * z1) - exp(-i * z))
cos(z) = 1/2 (exp(i * z1) + exp(-i * z))
atan2(z1, z2) = atan(z1/z2)
```

The following extra operations are supported on both real and complex numbers:

```
Re(z) = a
Im(z) = b
arg(z) = t
abs(z) = r

cbrt(z) = z ** (1/3)
log10(z) = log(z) / log(10)
logn(z, n) = log(z) / log(n)

tan(z) = sin(z) / cos(z)

csc(z) = 1 / sin(z)
sec(z) = 1 / cos(z)
cot(z) = 1 / tan(z)

asin(z) = -i * log(i*z + sqrt(1-z*z))
acos(z) = -i * log(z + i*sqrt(1-z*z))
atan(z) = i/2 * log((i+z) / (i-z))

acsc(z) = asin(1 / z)
asec(z) = acos(1 / z)
acot(z) = atan(1 / z) = -i/2 * log((i+z) / (z-i))

sinh(z) = 1/2 (exp(z) - exp(-z))
cosh(z) = 1/2 (exp(z) + exp(-z))
tanh(z) = sinh(z) / cosh(z) = (exp(z) - exp(-z)) / (exp(z) + exp(-z))

csch(z) = 1 / sinh(z)
sech(z) = 1 / cosh(z)
coth(z) = 1 / tanh(z)
```

```

asinh(z) = log(z + sqrt(z*z+1))
acosh(z) = log(z + sqrt(z*z-1))
atanh(z) = 1/2 * log((1+z) / (1-z))

acsch(z) = asinh(1 / z)
asech(z) = acosh(1 / z)
acoth(z) = atanh(1 / z) = 1/2 * log((1+z) / (z-1))

```

*arg*, *abs*, *log*, *csc*, *cot*, *acsc*, *acot*, *csch*, *coth*, *acosech*, *acotanh*, have aliases *rho*, *theta*, *ln*, *cosec*, *cotan*, *acosec*, *acotan*, *cosech*, *cotanh*, *acosech*, *acotanh*, respectively. *Re*, *Im*, *arg*, *abs*, *rho*, and *theta* can be used also as mutators. The *cbrt* returns only one of the solutions: if you want all three, use the *root* function.

The *root* function is available to compute all the *n* roots of some complex, where *n* is a strictly positive integer. There are exactly *n* such roots, returned as a list. Getting the number mathematicians call *j* such that:

```
1 + j + j*j = 0;
```

is a simple matter of writing:

```
$j = ((root(1, 3))[1]);
```

The *k*th root for *z* = [*r*,*t*] is given by:

```
(root(z, n))[k] = r**(1/n) * exp(i * (t + 2*k*pi)/n)
```

The *spaceship* comparison operator, *<=>*, is also defined. In order to ensure its restriction to real numbers is conform to what you would expect, the comparison is run on the real part of the complex number first, and imaginary parts are compared only when the real parts match.

## CREATION

To create a complex number, use either:

```
$z = Math::Complex->make(3, 4);
$z = cplx(3, 4);
```

if you know the cartesian form of the number, or

```
$z = 3 + 4*i;
```

if you like. To create a number using the polar form, use either:

```
$z = Math::Complex->emake(5, pi/3);
$x = cplx(5, pi/3);
```

instead. The first argument is the modulus, the second is the angle (in radians, the full circle is *2\*pi*). (Mnemonic: *e* is used as a notation for complex numbers in the polar form).

It is possible to write:

```
$x = cplx(-3, pi/4);
```

but that will be silently converted into [*3*, *-3pi/4*], since the modulus must be non-negative (it represents the distance to the origin in the complex plane).

It is also possible to have a complex number as either argument of the *make*, *emake*, *cplx*, and *cplx**e*: the appropriate component of the argument will be used.

```
$z1 = cplx(-2, 1);
$z2 = cplx($z1, 4);
```

The new, *make*, *emake*, *cplx*, and *cplx**e* will also understand a single (string) argument of the forms

```
2-3i
-3i
```

```
[2, 3]
[2]
```

in which case the appropriate cartesian and exponential components will be parsed from the string and used to create new complex numbers. The imaginary component and the theta, respectively, will default to zero.

## STRINGIFICATION

When printed, a complex number is usually shown under its cartesian style  $a+bi$ , but there are legitimate cases where the polar style  $[r,t]$  is more appropriate.

By calling the class method `Math::Complex::display_format` and supplying either "polar" or "cartesian" as an argument, you override the default display style, which is "cartesian". Not supplying any argument returns the current settings.

This default can be overridden on a per-number basis by calling the `display_format` method instead. As before, not supplying any argument returns the current display style for this number. Otherwise whatever you specify will be the new display style for *this* particular number.

For instance:

```
use Math::Complex;

Math::Complex::display_format('polar');
$j = (root(1, 3))[1];
print "j = $j\n"; # Prints "j = [1,2pi/3]"
$j->display_format('cartesian');
print "j = $j\n"; # Prints "j = -0.5+0.866025403784439i"
```

The polar style attempts to emphasize arguments like  $k\pi/n$  (where  $n$  is a positive integer and  $k$  an integer within  $[-9, +9]$ ), this is called *polar pretty-printing*.

## CHANGED IN PERL 5.6

The `display_format` class method and the corresponding `display_format` object method can now be called using a parameter hash instead of just a one parameter.

The old display format style, which can have values "cartesian" or "polar", can be changed using the "style" parameter.

```
$j->display_format(style => "polar");
```

The one parameter calling convention also still works.

```
$j->display_format("polar");
```

There are two new display parameters.

The first one is "format", which is a `sprintf()`-style format string to be used for both numeric parts of the complex number(s). The is somewhat system-dependent but most often it corresponds to "%.15g". You can revert to the default by setting the format to undef.

```
the $j from the above example

$j->display_format('format' => '%.5f');
print "j = $j\n"; # Prints "j = -0.50000+0.86603i"
$j->display_format('format' => undef);
print "j = $j\n"; # Prints "j = -0.5+0.86603i"
```

Notice that this affects also the return values of the `display_format` methods: in list context the whole parameter hash will be returned, as opposed to only the style parameter value. This is a potential incompatibility with earlier versions if you have been calling the `display_format` method in list context.

The second new display parameter is "polar\_pretty\_print", which can be set to true or false, the default being true. See the previous section for what this means.

**USAGE**

Thanks to overloading, the handling of arithmetics with complex numbers is simple and almost transparent.

Here are some examples:

```
use Math::Complex;

$j = cplx(1, 2*pi/3); # $j ** 3 == 1
print "j = $j, j**3 = ", $j ** 3, "\n";
print "1 + j + j**2 = ", 1 + $j + $j**2, "\n";

$z = -16 + 0*i; # Force it to be a complex
print "sqrt($z) = ", sqrt($z), "\n";

$k = exp(i * 2*pi/3);
print "$j - $k = ", $j - $k, "\n";

$z->Re(3); # Re, Im, arg, abs,
$j->arg(2); # (the last two aka rho, theta)
 # can be used also as mutators.
```

**ERRORS DUE TO DIVISION BY ZERO OR LOGARITHM OF ZERO**

The division (/) and the following functions

|       |       |       |       |
|-------|-------|-------|-------|
| log   | ln    | log10 | logn  |
| tan   | sec   | csc   | cot   |
| atan  | asec  | acsc  | acot  |
| tanh  | sech  | csch  | coth  |
| atanh | asech | acsch | acoth |

cannot be computed for all arguments because that would mean dividing by zero or taking logarithm of zero. These situations cause fatal runtime errors looking like this

```
cot(0): Division by zero.
(Because in the definition of cot(0), the divisor sin(0) is 0)
Died at ...
```

or

```
atanh(-1): Logarithm of zero.
Died at...
```

For the *csc*, *cot*, *asec*, *acsc*, *acot*, *csch*, *coth*, *asech*, *acsch*, the argument cannot be (zero). For the logarithmic functions and the *atanh*, *acoth*, the argument cannot be 1 (one). For the *atanh*, *acoth*, the argument cannot be -1 (minus one). For the *atan*, *acot*, the argument cannot be *i* (the imaginary unit). For the *atan*, *acoth*, the argument cannot be -*i* (the negative imaginary unit). For the *tan*, *sec*, *tanh*, the argument cannot be  $\pi/2 + k * \pi$ , where *k* is any integer.

Note that because we are operating on approximations of real numbers, these errors can happen when merely 'too close' to the singularities listed above.

**ERRORS DUE TO INDIGESTIBLE ARGUMENTS**

The *make* and *emake* accept both real and complex arguments. When they cannot recognize the arguments they will die with error messages like the following

```
Math::Complex::make: Cannot take real part of ...
Math::Complex::make: Cannot take real part of ...
Math::Complex::emake: Cannot take rho of ...
Math::Complex::emake: Cannot take theta of ...
```

## BUGS

Saying `use Math::Complex;` exports many mathematical routines in the caller environment and even overrides some (`sqrt`, `log`). This is construed as a feature by the Authors, actually... :-)

All routines expect to be given real or complex numbers. Don't attempt to use `BigFloat`, since Perl has currently no rule to disambiguate a '+' operation (for instance) between two overloaded entities.

In Cray UNICOS there is some strange numerical instability that results in `root()`, `cos()`, `sin()`, `cosh()`, `sinh()`, losing accuracy fast. Beware. The bug may be in UNICOS math libs, in UNICOS C compiler, in `Math::Complex`. Whatever it is, it does not manifest itself anywhere else where Perl runs.

**NAME**

Math::Trig – trigonometric functions

**SYNOPSIS**

```
use Math::Trig;

$x = tan(0.9);
$y = acos(3.7);
$z = asin(2.4);

$halfpi = pi/2;

$rad = deg2rad(120);
```

**DESCRIPTION**

Math::Trig defines many trigonometric functions not defined by the core Perl which defines only the `sin()` and `cos()`. The constant **pi** is also defined as are a few convenience functions for angle conversions.

**TRIGONOMETRIC FUNCTIONS**

The tangent

**tan**

The cofunctions of the sine, cosine, and tangent (`cosec/csc` and `cotan/cot` are aliases)

**csc, cosec, sec, sec, cot, cotan**

The arcus (also known as the inverse) functions of the sine, cosine, and tangent

**asin, acos, atan**

The principal value of the arc tangent of y/x

**atan2(y, x)**

The arcus cofunctions of the sine, cosine, and tangent (`acosec/acsc` and `acotan/acot` are aliases)

**acsc, acosec, asec, acot, acotan**

The hyperbolic sine, cosine, and tangent

**sinh, cosh, tanh**

The cofunctions of the hyperbolic sine, cosine, and tangent (`cosech/csch` and `cotanh/coth` are aliases)

**csch, cosech, sech, coth, cotanh**

The arcus (also known as the inverse) functions of the hyperbolic sine, cosine, and tangent

**asinh, acosh, atanh**

The arcus cofunctions of the hyperbolic sine, cosine, and tangent (`acsch/acosech` and `acoth/acotanh` are aliases)

**acsch, acosech, asech, acoth, acotanh**

The trigonometric constant **pi** is also defined.

```
$pi2 = 2 * pi;
```

**ERRORS DUE TO DIVISION BY ZERO**

The following functions

```
acoth
acsc
acsch
```

```

asec
asech
atanh
cot
coth
csc
csch
sec
sech
tan
tanh

```

cannot be computed for all arguments because that would mean dividing by zero or taking logarithm of zero. These situations cause fatal runtime errors looking like this

```

cot(0): Division by zero.
(Because in the definition of cot(0), the divisor sin(0) is 0)
Died at ...

```

or

```

atanh(-1): Logarithm of zero.
Died at...

```

For the `csc`, `cot`, `asec`, `acsc`, `acot`, `csch`, `coth`, `asech`, `acsch`, the argument cannot be (zero). For the `atanh`, `acoth`, the argument cannot be 1 (one). For the `atanh`, `acoth`, the argument cannot be -1 (minus one). For the `tan`, `sec`, `tanh`, `sech`, the argument cannot be  $\pi/2 + k * \pi$ , where  $k$  is any integer.

## SIMPLE (REAL) ARGUMENTS, COMPLEX RESULTS

Please note that some of the trigonometric functions can break out from the **real axis** into the **complex plane**. For example `asin(2)` has no definition for plain real numbers but it has definition for complex numbers.

In Perl terms this means that supplying the usual Perl numbers (also known as scalars, please see [perldata](#)) as input for the trigonometric functions might produce as output results that no more are simple real numbers: instead they are complex numbers.

The `Math::Trig` handles this by using the `Math::Complex` package which knows how to handle complex numbers, please see [Math::Complex](#) for more information. In practice you need not to worry about getting complex numbers as results because the `Math::Complex` takes care of details like for example how to display complex numbers. For example:

```
print asin(2), "\n";
```

should produce something like this (take or leave few last decimals):

```
1.5707963267949-1.31695789692482i
```

That is, a complex number with the real part of approximately 1.571 and the imaginary part of approximately -1.317.

## PLANE ANGLE CONVERSIONS

(Plane, 2-dimensional) angles may be converted with the following functions.

```

$radians = deg2rad($degrees);
$radians = grad2rad($gradians);

$degrees = rad2deg($radians);
$degrees = grad2deg($gradians);

$gradians = deg2grad($degrees);

```

```
$gradians = rad2grad($radians);
```

The full circle is  $2\pi$  radians or 360 degrees or 400 gradians. The result is by default wrapped to be inside the  $[0, [2\pi, 360, 400]]$  circle. If you don't want this, supply a true second argument:

```
$zillions_of_radians = deg2rad($zillions_of_degrees, 1);
$negative_degrees = rad2deg($negative_radians, 1);
```

You can also do the wrapping explicitly by `rad2rad()`, `deg2deg()`, and `grad2grad()`.

## RADIAL COORDINATE CONVERSIONS

**Radial coordinate systems** are the **spherical** and the **cylindrical** systems, explained shortly in more detail.

You can import radial coordinate conversion functions by using the `:radial` tag:

```
use Math::Trig ':radial';

($rho, $theta, $z) = cartesian_to_cylindrical($x, $y, $z);
($rho, $theta, $phi) = cartesian_to_spherical($x, $y, $z);
($x, $y, $z) = cylindrical_to_cartesian($rho, $theta, $z);
($rho_s, $theta, $phi) = cylindrical_to_spherical($rho_c, $theta, $z);
($x, $y, $z) = spherical_to_cartesian($rho, $theta, $phi);
($rho_c, $theta, $z) = spherical_to_cylindrical($rho_s, $theta, $phi);
```

**All angles are in radians.**

## COORDINATE SYSTEMS

**Cartesian** coordinates are the usual rectangular  $(x, y, z)$ -coordinates.

Spherical coordinates,  $(rho, theta, pi)$ , are three-dimensional coordinates which define a point in three-dimensional space. They are based on a sphere surface. The radius of the sphere is **rho**, also known as the *radial* coordinate. The angle in the  $xy$ -plane (around the  $z$ -axis) is **theta**, also known as the *azimuthal* coordinate. The angle from the  $z$ -axis is **phi**, also known as the *polar* coordinate. The 'North Pole' is therefore  $0, 0, rho$ , and the 'Bay of Guinea' (think of the missing big chunk of Africa)  $0, \pi/2, rho$ . In geographical terms  $phi$  is latitude (northward positive, southward negative) and  $theta$  is longitude (eastward positive, westward negative).

**BEWARE:** some texts define *theta* and *phi* the other way round, some texts define the *phi* to start from the horizontal plane, some texts use  $r$  in place of  $rho$ .

Cylindrical coordinates,  $(rho, theta, z)$ , are three-dimensional coordinates which define a point in three-dimensional space. They are based on a cylinder surface. The radius of the cylinder is **rho**, also known as the *radial* coordinate. The angle in the  $xy$ -plane (around the  $z$ -axis) is **theta**, also known as the *azimuthal* coordinate. The third coordinate is the  $z$ , pointing up from the **theta**-plane.

## 3-D ANGLE CONVERSIONS

Conversions to and from spherical and cylindrical coordinates are available. Please notice that the conversions are not necessarily reversible because of the equalities like  $\pi$  angles being equal to  $-\pi$  angles.

**cartesian\_to\_cylindrical**

```
($rho, $theta, $z) = cartesian_to_cylindrical($x, $y, $z);
```

**cartesian\_to\_spherical**

```
($rho, $theta, $phi) = cartesian_to_spherical($x, $y, $z);
```

**cylindrical\_to\_cartesian**

```
($x, $y, $z) = cylindrical_to_cartesian($rho, $theta, $z);
```

**cylindrical\_to\_spherical**

```
($rho_s, $theta, $phi) = cylindrical_to_spherical($rho_c, $theta, $z);
```

Notice that when  $z$  is not 0  $\rho_s$  is not equal to  $\rho_c$ .

spherical\_to\_cartesian

```
($x, $y, $z) = spherical_to_cartesian($rho, $theta, $phi);
```

spherical\_to\_cylindrical

```
($rho_c, $theta, $z) = spherical_to_cylindrical($rho_s, $theta, $phi);
```

Notice that when \$z is not 0 \$rho\_c is not equal to \$rho\_s.

## GREAT CIRCLE DISTANCES AND DIRECTIONS

You can compute spherical distances, called **great circle distances**, by importing the `great_circle_distance()` function:

```
use Math::Trig 'great_circle_distance';

$distance = great_circle_distance($theta0, $phi0, $theta1, $phi1, [, $rho]);
```

The *great circle distance* is the shortest distance between two points on a sphere. The distance is in \$rho units. The \$rho is optional, it defaults to 1 (the unit sphere), therefore the distance defaults to radians.

If you think geographically the *theta* are longitudes: zero at the Greenwich meridian, eastward positive, westward negative—and the *phi* are latitudes: zero at the North Pole, northward positive, southward negative. **NOTE:** this formula thinks in mathematics, not geographically: the *phi* zero is at the North Pole, not at the Equator on the west coast of Africa (Bay of Guinea). You need to subtract your geographical coordinates from  $\pi/2$  (also known as 90 degrees).

```
$distance = great_circle_distance($lon0, pi/2 - $lat0,
 $lon1, pi/2 - $lat1, $rho);
```

The direction you must follow the great circle can be computed by the `great_circle_direction()` function:

```
use Math::Trig 'great_circle_direction';

$direction = great_circle_direction($theta0, $phi0, $theta1, $phi1);
```

The result is in radians, zero indicating straight north,  $\pi$  or  $-\pi$  straight south,  $\pi/2$  straight west, and  $-\pi/2$  straight east.

Notice that the resulting directions might be somewhat surprising if you are looking at a flat worldmap: in such map projections the great circles quite often do not look like the shortest routes—but for example the shortest possible routes from Europe or North America to Asia do often cross the polar regions.

## EXAMPLES

To calculate the distance between London (51.3N 0.5W) and Tokyo (35.7N 139.8E) in kilometers:

```
use Math::Trig qw(great_circle_distance deg2rad);

Notice the 90 - latitude: phi zero is at the North Pole.
@L = (deg2rad(-0.5), deg2rad(90 - 51.3));
@T = (deg2rad(139.8), deg2rad(90 - 35.7));

$km = great_circle_distance(@L, @T, 6378);
```

The direction you would have to go from London to Tokyo

```
use Math::Trig qw(great_circle_direction);

$rad = great_circle_direction(@L, @T);
```

## CAVEAT FOR GREAT CIRCLE FORMULAS

The answers may be off by few percentages because of the irregular (slightly aspherical) form of the Earth. The formula used for great circle distances

```
lat0 = 90 degrees - phi0
```

```
lat1 = 90 degrees - phi1
d = R * arccos(cos(lat0) * cos(lat1) * cos(lon1 - lon01) +
 sin(lat0) * sin(lat1))
```

is also somewhat unreliable for small distances (for locations separated less than about five degrees) because it uses arc cosine which is rather ill-conditioned for values close to zero.

## BUGS

Saying `use Math::Trig;` exports many mathematical routines in the caller environment and even overrides some (`sin`, `cos`). This is construed as a feature by the Authors, actually...;-)

The code is not optimized for speed, especially because we use `Math::Complex` and thus go quite near complex numbers while doing the computations even when the arguments are not. This, however, cannot be completely avoided if we want things like `asin(2)` to give an answer instead of giving a fatal runtime error.

## NAME

Memoize – Make functions faster by trading space for time

## SYNOPSIS

```
This is the documentation for Memoize 1.01
use Memoize;
memoize('slow_function');
slow_function(arguments); # Is faster than it was before
```

This is normally all you need to know. However, many options are available:

```
memoize(function, options...);
```

Options include:

```
NORMALIZER => function
INSTALL => new_name

SCALAR_CACHE => 'MEMORY'
SCALAR_CACHE => ['HASH', \%cache_hash]
SCALAR_CACHE => 'FAULT'
SCALAR_CACHE => 'MERGE'

LIST_CACHE => 'MEMORY'
LIST_CACHE => ['HASH', \%cache_hash]
LIST_CACHE => 'FAULT'
LIST_CACHE => 'MERGE'
```

## DESCRIPTION

'Memoizing' a function makes it faster by trading space for time. It does this by caching the return values of the function in a table. If you call the function again with the same arguments, memoize jumps in and gives you the value out of the table, instead of letting the function compute the value all over again.

Here is an extreme example. Consider the Fibonacci sequence, defined by the following function:

```
Compute Fibonacci numbers
sub fib {
 my $n = shift;
 return $n if $n < 2;
 fib($n-1) + fib($n-2);
}
```

This function is very slow. Why? To compute fib(14), it first wants to compute fib(13) and fib(12), and add the results. But to compute fib(13), it first has to compute fib(12) and fib(11), and then it comes back and computes fib(12) all over again even though the answer is the same. And both of the times that it wants to compute fib(12), it has to compute fib(11) from scratch, and then it has to do it again each time it wants to compute fib(13). This function does so much recomputing of old results that it takes a really long time to run—fib(14) makes 1,200 extra recursive calls to itself, to compute and recompute things that it already computed.

This function is a good candidate for memoization. If you memoize the 'fib' function above, it will compute fib(14) exactly once, the first time it needs to, and then save the result in a table. Then if you ask for fib(14) again, it gives you the result out of the table. While computing fib(14), instead of computing fib(12) twice, it does it once; the second time it needs the value it gets it from the table. It doesn't compute fib(11) four times; it computes it once, getting it from the table the next three times. Instead of making 1,200 recursive calls to 'fib', it makes 15. This makes the function about 150 times faster.

You could do the memoization yourself, by rewriting the function, like this:

```
Compute Fibonacci numbers, memoized version
```

```

{ my @fib;
 sub fib {
 my $n = shift;
 return $fib[$n] if defined $fib[$n];
 return $fib[$n] = $n if $n < 2;
 $fib[$n] = fib($n-1) + fib($n-2);
 }
}

```

Or you could use this module, like this:

```

use Memoize;
memoize('fib');

Rest of the fib function just like the original version.

```

This makes it easy to turn memoizing on and off.

Here's an even simpler example: I wrote a simple ray tracer; the program would look in a certain direction, figure out what it was looking at, and then convert the 'color' value (typically a string like 'red') of that object to a red, green, and blue pixel value, like this:

```

for ($direction = 0; $direction < 300; $direction++) {
 # Figure out which object is in direction $direction
 $color = $object->{color};
 ($r, $g, $b) = @{&ColorToRGB($color)};
 ...
}

```

Since there are relatively few objects in a picture, there are only a few colors, which get looked up over and over again. Memoizing ColorToRGB sped up the program by several percent.

## DETAILS

This module exports exactly one function, `memoize`. The rest of the functions in this package are None of Your Business.

You should say

```
memoize(function)
```

where `function` is the name of the function you want to memoize, or a reference to it. `memoize` returns a reference to the new, memoized version of the function, or `undef` on a non-fatal error. At present, there are no non-fatal errors, but there might be some in the future.

If `function` was the name of a function, then `memoize` hides the old version and installs the new memoized version under the old name, so that `&function(...)` actually invokes the memoized version.

## OPTIONS

There are some optional options you can pass to `memoize` to change the way it behaves a little. To supply options, invoke `memoize` like this:

```

memoize(function, NORMALIZER => function,
 INSTALL => newname,
 SCALAR_CACHE => option,
 LIST_CACHE => option
);

```

Each of these options is optional; you can include some, all, or none of them.

## INSTALL

If you supply a function name with `INSTALL`, `memoize` will install the new, memoized version of the function under the name you give. For example,

```
memoize('fib', INSTALL => 'fastfib')
```

installs the memoized version of `fib` as `fastfib`; without the `INSTALL` option it would have replaced the old `fib` with the memoized version.

To prevent `memoize` from installing the memoized version anywhere, use `INSTALL => undef`.

## NORMALIZER

Suppose your function looks like this:

```
Typical call: f('aha!', A => 11, B => 12);
sub f {
 my $a = shift;
 my %hash = @_;
 $hash{B} ||= 2; # B defaults to 2
 $hash{C} ||= 7; # C defaults to 7

 # Do something with $a, %hash
}
```

Now, the following calls to your function are all completely equivalent:

```
f(OUCH);
f(OUCH, B => 2);
f(OUCH, C => 7);
f(OUCH, B => 2, C => 7);
f(OUCH, C => 7, B => 2);
(etc.)
```

However, unless you tell `Memoize` that these calls are equivalent, it will not know that, and it will compute the values for these invocations of your function separately, and store them separately.

To prevent this, supply a `NORMALIZER` function that turns the program arguments into a string in a way that equivalent arguments turn into the same string. A `NORMALIZER` function for `f` above might look like this:

```
sub normalize_f {
 my $a = shift;
 my %hash = @_;
 $hash{B} ||= 2;
 $hash{C} ||= 7;

 join(',', $a, map ($_ => $hash{$_}) sort keys %hash);
}
```

Each of the argument lists above comes out of the `normalize_f` function looking exactly the same, like this:

```
OUCH,B,2,C,7
```

You would tell `Memoize` to use this normalizer this way:

```
memoize('f', NORMALIZER => 'normalize_f');
```

`memoize` knows that if the normalized version of the arguments is the same for two argument lists, then it can safely look up the value that it computed for one argument list and return it as the result of calling the function with the other argument list, even if the argument lists look different.

The default normalizer just concatenates the arguments with character 28 in between. (In ASCII, this is called FS or control-\.) This always works correctly for functions with only one string argument, and also when the arguments never contain character 28. However, it can confuse certain argument lists:

```
normalizer("a\034", "b")
normalizer("a", "\034b")
```

```
normalizer("a\034\034b")
```

for example.

Since hash keys are strings, the default normalizer will not distinguish between `undef` and the empty string. It also won't work when the function's arguments are references. For example, consider a function `g` which gets two arguments: A number, and a reference to an array of numbers:

```
g(13, [1,2,3,4,5,6,7]);
```

The default normalizer will turn this into something like `"13\034ARRAY(0x436c1f)"`. That would be all right, except that a subsequent array of numbers might be stored at a different location even though it contains the same data. If this happens, Memoize will think that the arguments are different, even though they are equivalent. In this case, a normalizer like this is appropriate:

```
sub normalize { join ' ', $_[0], @{$_[1]} }
```

For the example above, this produces the key `"13 1 2 3 4 5 6 7"`.

Another use for normalizers is when the function depends on data other than those in its arguments. Suppose you have a function which returns a value which depends on the current hour of the day:

```
sub on_duty {
 my ($problem_type) = @_;
 my $hour = (localtime)[2];
 open my $fh, "$DIR/$problem_type" or die...;
 my $line;
 while ($hour-- > 0)
 $line = <$fh>;
 }
 return $line;
}
```

At 10:23, this function generates the 10th line of a data file; at 3:45 PM it generates the 15th line instead. By default, Memoize will only see the `$problem_type` argument. To fix this, include the current hour in the normalizer:

```
sub normalize { join ' ', (localtime)[2], @_ }
```

The calling context of the function (scalar or list context) is propagated to the normalizer. This means that if the memoized function will treat its arguments differently in list context than it would in scalar context, you can have the normalizer function select its behavior based on the results of `wantarray`. Even if called in a list context, a normalizer should still return a single string.

### SCALAR\_CACHE, LIST\_CACHE

Normally, Memoize caches your function's return values into an ordinary Perl hash variable. However, you might like to have the values cached on the disk, so that they persist from one run of your program to the next, or you might like to associate some other interesting semantics with the cached values.

There's a slight complication under the hood of Memoize: There are actually *two* caches, one for scalar values and one for list values. When your function is called in scalar context, its return value is cached in one hash, and when your function is called in list context, its value is cached in the other hash. You can control the caching behavior of both contexts independently with these options.

The argument to `LIST_CACHE` or `SCALAR_CACHE` must either be one of the following four strings:

```
MEMORY
FAULT
MERGE
HASH
```

or else it must be a reference to a list whose first element is one of these four strings, such as `[HASH,`

arguments...].

#### MEMORY

MEMORY means that return values from the function will be cached in an ordinary Perl hash variable. The hash variable will not persist after the program exits. This is the default.

#### HASH

HASH allows you to specify that a particular hash that you supply will be used as the cache. You can tie this hash beforehand to give it any behavior you want.

A tied hash can have any semantics at all. It is typically tied to an on-disk database, so that cached values are stored in the database and retrieved from it again when needed, and the disk file typically persists after your program has exited. See `perltie` for more complete details about `tie`.

A typical example is:

```
use DB_File;
tie my %cache => 'DB_File', $filename, O_RDWR|O_CREAT, 0666;
memoize 'function', SCALAR_CACHE => [HASH => \%cache];
```

This has the effect of storing the cache in a `DB_File` database whose name is in `$filename`. The cache will persist after the program has exited. Next time the program runs, it will find the cache already populated from the previous run of the program. Or you can forcibly populate the cache by constructing a batch program that runs in the background and populates the cache file. Then when you come to run your real program the memoized function will be fast because all its results have been precomputed.

**TIE** This option is no longer supported. It is still documented only to aid in the debugging of old programs that use it. Old programs should be converted to use the **HASH** option instead.

```
memoize ... [TIE, PACKAGE, ARGS...]
```

is merely a shortcut for

```
require PACKAGE;
{ my %cache;
 tie %cache, PACKAGE, ARGS...;
}
memoize ... [HASH => \%cache];
```

#### FAULT

**FAULT** means that you never expect to call the function in scalar (or list) context, and that if Memoize detects such a call, it should abort the program. The error message is one of

```
'foo' function called in forbidden list context at line ...
'foo' function called in forbidden scalar context at line ...
```

#### MERGE

**MERGE** normally means the function does not distinguish between list and scalar context, and that return values in both contexts should be stored together. `LIST_CACHE => MERGE` means that list context return values should be stored in the same hash that is used for scalar context returns, and `SCALAR_CACHE => MERGE` means the same, mutatis mutandis. It is an error to specify **MERGE** for both, but it probably does something useful.

Consider this function:

```
sub pi { 3; }
```

Normally, the following code will result in two calls to `pi`:

```
$x = pi();
($y) = pi();
```

```
$z = pi();
```

The first call caches the value 3 in the scalar cache; the second caches the list (3) in the list cache. The third call doesn't call the real `pi` function; it gets the value from the scalar cache.

Obviously, the second call to `pi` is a waste of time, and storing its return value is a waste of space. Specifying `LIST_CACHE => MERGE` will make `memoize` use the same cache for scalar and list context return values, so that the second call uses the scalar cache that was populated by the first call. `pi` ends up being called only once, and both subsequent calls return 3 from the cache, regardless of the calling context.

Another use for `MERGE` is when you want both kinds of return values stored in the same disk file; this saves you from having to deal with two disk files instead of one. You can use a normalizer function to keep the two sets of return values separate. For example:

```
tie my %cache => 'MLDBM', 'DB_File', $filename, ...;

memoize 'myfunc',
 NORMALIZER => 'n',
 SCALAR_CACHE => [HASH => \%cache],
 LIST_CACHE => MERGE,
;

sub n {
 my $context = wantarray() ? 'L' : 'S';
 # ... now compute the hash key from the arguments ...
 $hashkey = "$context:$hashkey";
}
```

This normalizer function will store scalar context return values in the disk file under keys that begin with `S:`, and list context return values under keys that begin with `L:`.

## OTHER FACILITIES

### `unmemoize`

There's an `unmemoize` function that you can import if you want to. Why would you want to? Here's an example: Suppose you have your cache tied to a DBM file, and you want to make sure that the cache is written out to disk if someone interrupts the program. If the program exits normally, this will happen anyway, but if someone types control-C or something then the program will terminate immediately without synchronizing the database. So what you can do instead is

```
$SIG{INT} = sub { unmemoize 'function' };
```

`unmemoize` accepts a reference to, or the name of a previously memoized function, and undoes whatever it did to provide the memoized version in the first place, including making the name refer to the unmemoized version if appropriate. It returns a reference to the unmemoized version of the function.

If you ask it to `unmemoize` a function that was never memoized, it croaks.

### `flush_cache`

`flush_cache(function)` will flush out the caches, discarding *all* the cached data. The argument may be a function name or a reference to a function. For finer control over when data is discarded or expired, see the documentation for `Memoize::Expire`, included in this package.

Note that if the cache is a tied hash, `flush_cache` will attempt to invoke the `CLEAR` method on the hash. If there is no `CLEAR` method, this will cause a run-time error.

An alternative approach to cache flushing is to use the `HASH` option (see above) to request that `Memoize` use a particular hash variable as its cache. Then you can examine or modify the hash at any time in any way you desire. You may flush the cache by using `%hash = ()`.

**CAVEATS**

Memoization is not a cure-all:

- Do not memoize a function whose behavior depends on program state other than its own arguments, such as global variables, the time of day, or file input. These functions will not produce correct results when memoized. For a particularly easy example:

```
sub f {
 time;
}
```

This function takes no arguments, and as far as Memoize is concerned, it always returns the same result. Memoize is wrong, of course, and the memoized version of this function will call `time` once to get the current time, and it will return that same time every time you call it after that.

- Do not memoize a function with side effects.

```
sub f {
 my ($a, $b) = @_;
 my $s = $a + $b;
 print "$a + $b = $s.\n";
}
```

This function accepts two arguments, adds them, and prints their sum. Its return value is the number of characters it printed, but you probably didn't care about that. But Memoize doesn't understand that. If you memoize this function, you will get the result you expect the first time you ask it to print the sum of 2 and 3, but subsequent calls will return 1 (the return value of `print`) without actually printing anything.

- Do not memoize a function that returns a data structure that is modified by its caller.

Consider these functions: `getusers` returns a list of users somehow, and then `main` throws away the first user on the list and prints the rest:

```
sub main {
 my $userlist = getusers();
 shift @$userlist;
 foreach $u (@$userlist) {
 print "User $u\n";
 }
}

sub getusers {
 my @users;
 # Do something to get a list of users;
 \@users; # Return reference to list.
}
```

If you memoize `getusers` here, it will work right exactly once. The reference to the users list will be stored in the memo table. `main` will discard the first element from the referenced list. The next time you invoke `main`, Memoize will not call `getusers`; it will just return the same reference to the same list it got last time. But this time the list has already had its head removed; `main` will erroneously remove another element from it. The list will get shorter and shorter every time you call `main`.

Similarly, this:

```
$u1 = getusers();
$u2 = getusers();
pop @$u1;
```

will modify `$u2` as well as `$u1`, because both variables are references to the same array. Had `getusers` not been memoized, `$u1` and `$u2` would have referred to different arrays.

- Do not memoize a very simple function.

Recently someone mentioned to me that the Memoize module made his program run slower instead of faster. It turned out that he was memoizing the following function:

```
sub square {
 $_[0] * $_[0];
}
```

I pointed out that Memoize uses a hash, and that looking up a number in the hash is necessarily going to take a lot longer than a single multiplication. There really is no way to speed up the square function.

Memoization is not magical.

## PERSISTENT CACHE SUPPORT

You can tie the cache tables to any sort of tied hash that you want to, as long as it supports `TIEHASH`, `FETCH`, `STORE`, and `EXISTS`. For example,

```
tie my %cache => 'GDBM_File', $filename, O_RDWR|O_CREAT, 0666;
memoize 'function', SCALAR_CACHE => [HASH => \%cache];
```

works just fine. For some storage methods, you need a little glue.

`SDBM_File` doesn't supply an `EXISTS` method, so included in this package is a glue module called `Memoize::SDBM_File` which does provide one. Use this instead of plain `SDBM_File` to store your cache table on disk in an `SDBM_File` database:

```
tie my %cache => 'Memoize::SDBM_File', $filename, O_RDWR|O_CREAT, 0666;
memoize 'function', SCALAR_CACHE => [HASH => \%cache];
```

`NDBM_File` has the same problem and the same solution. (Use `Memoize::NDBM_File` instead of plain `NDBM_File`.)

`Storable` isn't a tied hash class at all. You can use it to store a hash to disk and retrieve it again, but you can't modify the hash while it's on the disk. So if you want to store your cache table in a `Storable` database, use `Memoize::Storable`, which puts a hashlike front-end onto `Storable`. The hash table is actually kept in memory, and is loaded from your `Storable` file at the time you memoize the function, and stored back at the time you unmemoize the function (or when your program exits):

```
tie my %cache => 'Memoize::Storable', $filename;
memoize 'function', SCALAR_CACHE => [HASH => \%cache];

tie my %cache => 'Memoize::Storable', $filename, 'nstore';
memoize 'function', SCALAR_CACHE => [HASH => \%cache];
```

Include the `'nstore'` option to have the `Storable` database written in 'network order'. (See [Storable](#) for more details about this.)

The `flush_cache()` function will raise a run-time error unless the tied package provides a `CLEAR` method.

## EXPIRATION SUPPORT

See `Memoize::Expire`, which is a plug-in module that adds expiration functionality to Memoize. If you don't like the kinds of policies that `Memoize::Expire` implements, it is easy to write your own plug-in module to implement whatever policy you desire. Memoize comes with several examples. An expiration manager that implements a LRU policy is available on CPAN as `Memoize::ExpireLRU`.

## BUGS

The test suite is much better, but always needs improvement.

There is some problem with the way `goto &f` works under threaded Perl, perhaps because of the lexical scoping of `@_`. This is a bug in Perl, and until it is resolved, memoized functions will see a slightly different `caller()` and will perform a little more slowly on threaded perls than unthreaded perls.

Some versions of `DB_File` won't let you store data under a key of length 0. That means that if you have a function `f` which you memoized and the cache is in a `DB_File` database, then the value of `f()` (`f` called with no arguments) will not be memoized. If this is a big problem, you can supply a normalizer function that prepends "x" to every key.

## MAILING LIST

To join a very low-traffic mailing list for announcements about Memoize, send an empty note to `mjd-perl-memoize-request@plover.com`.

## AUTHOR

Mark-Jason Dominus (`mjd-perl-memoize+@plover.com`), Plover Systems co.

See the `Memoize.pm` Page at <http://www.plover.com/~mjd/perl/Memoize/> for news and upgrades. Near this page, at <http://www.plover.com/~mjd/perl/MiniMemoize/> there is an article about memoization and about the internals of Memoize that appeared in The Perl Journal, issue #13. (This article is also included in the Memoize distribution as 'article.html'.)

My upcoming book will discuss memoization (and many other fascinating topics) in tremendous detail. It will be published by Morgan Kaufmann in 2002, possibly under the title *Perl Advanced Techniques Handbook*. It will also be available on-line for free. For more information, visit <http://perl.plover.com/book/>.

To join a mailing list for announcements about Memoize, send an empty message to `mjd-perl-memoize-request@plover.com`. This mailing list is for announcements only and has extremely low traffic—about two messages per year.

## THANK YOU

Many thanks to Jonathan Roy for bug reports and suggestions, to Michael Schwern for other bug reports and patches, to Mike Cariaso for helping me to figure out the Right Thing to Do About Expiration, to Joshua Gerth, Joshua Chamas, Jonathan Roy (again), Mark D. Anderson, and Andrew Johnson for more suggestions about expiration, to Brent Powers for the `Memoize::ExpireLRU` module, to Ariel Scolnicov for delightful messages about the Fibonacci function, to Dion Almaer for thought-provoking suggestions about the default normalizer, to Walt Mankowski and Kurt Starsinic for much help investigating problems under threaded Perl, to Alex Dudkevich for reporting the bug in prototyped functions and for checking my patch, to Tony Bass for many helpful suggestions, to Jonathan Roy (again) for finding a use for `unmemoize()`, to Philippe Verdret for enlightening discussion of `Hook::PrePostCall`, to Nat Torkington for advice I ignored, to Chris Nandor for portability advice, to Randal Schwartz for suggesting the 'flush\_cache' function, and to Jenda Krynicky for being a light in the world.

Special thanks to Jarkko Hietaniemi, the 5.8.0 pumpking, for including this module in the core and for his patient and helpful guidance during the integration process.

**NAME**

Memoize::AnyDBM\_File – glue to provide EXISTS for AnyDBM\_File for Storable use

**DESCRIPTION**

See [Memoize](#).

**NAME**

Memoize::Expire – Plug-in module for automatic expiration of memoized values

**SYNOPSIS**

```
use Memoize;
use Memoize::Expire;
tie my %cache => 'Memoize::Expire',
 LIFETIME => $lifetime, # In seconds
 NUM_USES => $n_uses;

memoize 'function', SCALAR_CACHE => [HASH => \%cache];
```

**DESCRIPTION**

Memoize::Expire is a plug-in module for Memoize. It allows the cached values for memoized functions to expire automatically. This manual assumes you are already familiar with the Memoize module. If not, you should study that manual carefully first, paying particular attention to the HASH feature.

Memoize::Expire is a layer of software that you can insert in between Memoize itself and whatever underlying package implements the cache. The layer presents a hash variable whose values expire whenever they get too old, have been used too often, or both. You tell Memoize to use this forgetful hash as its cache instead of the default, which is an ordinary hash.

To specify a real-time timeout, supply the LIFETIME option with a numeric value. Cached data will expire after this many seconds, and will be looked up afresh when it expires. When a data item is looked up afresh, its lifetime is reset.

If you specify NUM\_USES with an argument of *n*, then each cached data item will be discarded and looked up afresh after the *n*th time you access it. When a data item is looked up afresh, its number of uses is reset.

If you specify both arguments, data will be discarded from the cache when either expiration condition holds.

Memoize::Expire uses a real hash internally to store the cached data. You can use the HASH option to Memoize::Expire to supply a tied hash in place of the ordinary hash that Memoize::Expire will normally use. You can use this feature to add Memoize::Expire as a layer in between a persistent disk hash and Memoize. If you do this, you get a persistent disk cache whose entries expire automatically. For example:

```
Memoize
|
Memoize::Expire enforces data expiration policy
|
DB_File implements persistence of data in a disk file
|
Disk file

use Memoize;
use Memoize::Expire;
use DB_File;

Set up persistence
tie my %disk_cache => 'DB_File', $filename, O_CREAT|O_RDWR, 0666];

Set up expiration policy, supplying persistent hash as a target
tie my %cache => 'Memoize::Expire',
 LIFETIME => $lifetime, # In seconds
 NUM_USES => $n_uses,
 HASH => \%disk_cache;

Set up memoization, supplying expiring persistent hash for cache
memoize 'function', SCALAR_CACHE => [HASH => \%cache];
```

## INTERFACE

There is nothing special about Memoize::Expire. It is just an example. If you don't like the policy that it implements, you are free to write your own expiration policy module that implements whatever policy you desire. Here is how to do that. Let us suppose that your module will be named MyExpirePolicy.

Short summary: You need to create a package that defines four methods:

### TIEHASH

Construct and return cache object.

### EXISTS

Given a function argument, is the corresponding function value in the cache, and if so, is it fresh enough to use?

### FETCH

Given a function argument, look up the corresponding function value in the cache and return it.

### STORE

Given a function argument and the corresponding function value, store them into the cache.

### CLEAR

(Optional.) Flush the cache completely.

The user who wants the memoization cache to be expired according to your policy will say so by writing

```
tie my %cache => 'MyExpirePolicy', args...;
memoize 'function', SCALAR_CACHE => [HASH => \%cache];
```

This will invoke `< MyExpirePolicy-TIEHASH(args) . MyExpirePolicy::TIEHASH` should do whatever is appropriate to set up the cache, and it should return the cache object to the caller.

For example, MyExpirePolicy::TIEHASH might create an object that contains a regular Perl hash (which it will to store the cached values) and some extra information about the arguments and how old the data is and things like that. Let us call this object 'C'.

When Memoize needs to check to see if an entry is in the cache already, it will invoke `< C-EXISTS(key) . key` is the normalized function argument. MyExpirePolicy::EXISTS should return 0 if the key is not in the cache, or if it has expired, and 1 if an unexpired value is in the cache. It should *not* return undef, because there is a bug in some versions of Perl that will cause a spurious FETCH if the EXISTS method returns undef.

If your EXISTS function returns true, Memoize will try to fetch the cached value by invoking `< C-FETCH(key) . MyExpirePolicy::FETCH` should return the cached value. Otherwise, Memoize will call the memoized function to compute the appropriate value, and will store it into the cache by calling `< C-STORE(key, value) .`

Here is a very brief example of a policy module that expires each cache item after ten seconds.

```
package Memoize::TenSecondExpire;

sub TIEHASH {
 my ($package, %args) = @_;
 my $cache = $args{HASH} || {};
 bless $cache => $package;
}

sub EXISTS {
 my ($cache, $key) = @_;
 if (exists $cache->{$key} &&
```

```

 $cache->{$key}{EXPIRE_TIME} > time) {
 return 1
 } else {
 return 0; # Do NOT return 'undef' here.
 }
 }

 sub FETCH {
 my ($cache, $key) = @_;
 return $cache->{$key}{VALUE};
 }

 sub STORE {
 my ($cache, $key, $newvalue) = @_;
 $cache->{$key}{VALUE} = $newvalue;
 $cache->{$key}{EXPIRE_TIME} = time + 10;
 }

```

To use this expiration policy, the user would say

```

use Memoize;
tie my %cache10sec => 'Memoize::TenSecondExpire';
memoize 'function', SCALAR_CACHE => [HASH => \%cache10sec];

```

Memoize would then call function whenever a cached value was entirely absent or was older than ten seconds.

You should always support a HASH argument to TIEHASH that ties the underlying cache so that the user can specify that the cache is also persistent or that it has some other interesting semantics. The example above demonstrates how to do this, as does Memoize::Expire.

## ALTERNATIVES

Brent Powers has a Memoize::ExpireLRU module that was designed to work with Memoize and provides expiration of least-recently-used data. The cache is held at a fixed number of entries, and when new data comes in, the least-recently used data is expired. See <http://search.cpan.org/search?mode=module&query=ExpireLRU>.

Joshua Chamas's Tie::Cache module may be useful as an expiration manager. (If you try this, let me know how it works out.)

If you develop any useful expiration managers that you think should be distributed with Memoize, please let me know.

## CAVEATS

This module is experimental, and may contain bugs. Please report bugs to the address below.

Number-of-uses is stored as a 16-bit unsigned integer, so can't exceed 65535.

Because of clock granularity, expiration times may occur up to one second sooner than you expect. For example, suppose you store a value with a lifetime of ten seconds, and you store it at 12:00:00.998 on a certain day. Memoize will look at the clock and see 12:00:00. Then 9.01 seconds later, at 12:00:10.008 you try to read it back. Memoize will look at the clock and see 12:00:10 and conclude that the value has expired. This will probably not occur if you have Time::HiRes installed.

## AUTHOR

Mark-Jason Dominus (mjd-perl-memoize+@plover.com)

Mike Carias provided valuable insight into the best way to solve this problem.

**NAME**

MIME::Base64 – Encoding and decoding of base64 strings

**SYNOPSIS**

```
use MIME::Base64;

$encoded = encode_base64('Aladdin:open sesame');
$decoded = decode_base64($encoded);
```

**DESCRIPTION**

This module provides functions to encode and decode strings into the Base64 encoding specified in RFC 2045 – *MIME (Multipurpose Internet Mail Extensions)*. The Base64 encoding is designed to represent arbitrary sequences of octets in a form that need not be humanly readable. A 65-character subset ([A–Za–z0–9+/=]) of US–ASCII is used, enabling 6 bits to be represented per printable character.

The following functions are provided:

`encode_base64($str, [$eol])`

Encode data by calling the `encode_base64()` function. The first argument is the string to encode. The second argument is the line ending sequence to use (it is optional and defaults to `"\n"`). The returned encoded string is broken into lines of no more than 76 characters each and it will end with `$eol` unless it is empty. Pass an empty string as second argument if you do not want the encoded string broken into lines.

`decode_base64($str)`

Decode a base64 string by calling the `decode_base64()` function. This function takes a single argument which is the string to decode and returns the decoded data.

Any character not part of the 65-character base64 subset set is silently ignored. Characters occurring after a '=' padding character are never decoded.

If the length of the string to decode (after ignoring non-base64 chars) is not a multiple of 4 or padding occurs too early, then a warning is generated if perl is running under `-w`.

If you prefer not to import these routines into your namespace you can call them as:

```
use MIME::Base64 ();
$encoded = MIME::Base64::encode($decoded);
$decoded = MIME::Base64::decode($encoded);
```

**DIAGNOSTICS**

The following warnings might be generated if perl is invoked with the `-w` switch:

**Premature end of base64 data**

The number of characters to decode is not a multiple of 4. Legal base64 data should be padded with one or two "=" characters to make its length a multiple of 4. The decoded result will anyway be as if the padding was there.

**Premature padding of base64 data**

The '=' padding character occurs as the first or second character in a base64 quartet.

**EXAMPLES**

If you want to encode a large file, you should encode it in chunks that are a multiple of 57 bytes. This ensures that the base64 lines line up and that you do not end up with padding in the middle. 57 bytes of data fills one complete base64 line ( $76 == 57 * 4 / 3$ ):

```
use MIME::Base64 qw(encode_base64);

open(FILE, "/var/log/wtmp") or die "$!";
while (read(FILE, $buf, 60*57)) {
```

```
 print encode_base64($buf);
}
```

or if you know you have enough memory

```
use MIME::Base64 qw(encode_base64);
local($/) = undef; # slurp
print encode_base64(<STDIN>);
```

The same approach as a command line:

```
perl -MMIME::Base64 -0777 -ne 'print encode_base64($_)' <file
```

Decoding does not need slurp mode if all the lines contains a multiple of 4 base64 chars:

```
perl -MMIME::Base64 -ne 'print decode_base64($_)' <file
```

**NAME**

MIME::QuotedPrint – Encoding and decoding of quoted–printable strings

**SYNOPSIS**

```
use MIME::QuotedPrint;

$encoded = encode_qp($decoded);
$decoded = decode_qp($encoded);
```

**DESCRIPTION**

This module provides functions to encode and decode strings into the Quoted–Printable encoding specified in RFC 2045 – *MIME (Multipurpose Internet Mail Extensions)*. The Quoted–Printable encoding is intended to represent data that largely consists of bytes that correspond to printable characters in the ASCII character set. Non–printable characters (as defined by english americans) are represented by a triplet consisting of the character "=" followed by two hexadecimal digits.

The following functions are provided:

`encode_qp($str)`

This function will return an encoded version of the string given as argument.

Note that `encode_qp()` does not change newlines "\n" to the CRLF sequence even though this might be considered the right thing to do (RFC 2045 (Q–P Rule #4)).

`decode_qp($str);`

This function will return the plain text version of the string given as argument.

If you prefer not to import these routines into your namespace you can call them as:

```
use MIME::QuotedPrint ();
$encoded = MIME::QuotedPrint::encode($decoded);
$decoded = MIME::QuotedPrint::decode($encoded);
```

**NAME**

Net::Cmd – Network Command class (as used by FTP, SMTP etc)

**SYNOPSIS**

```
use Net::Cmd;

@ISA = qw(Net::Cmd);
```

**DESCRIPTION**

Net::Cmd is a collection of methods that can be inherited by a sub class of IO::Handle. These methods implement the functionality required for a command based protocol, for example FTP and SMTP.

**USER METHODS**

These methods provide a user interface to the Net::Cmd object.

**debug ( VALUE )**

Set the level of debug information for this object. If VALUE is not given then the current state is returned. Otherwise the state is changed to VALUE and the previous state returned.

Different packages may implement different levels of debug but a non-zero value results in copies of all commands and responses also being sent to STDERR.

If VALUE is undef then the debug level will be set to the default debug level for the class.

This method can also be called as a *static* method to set/get the default debug level for a given class.

**message ( )**

Returns the text message returned from the last command

**code ( )**

Returns the 3-digit code from the last command. If a command is pending then the value 0 is returned

**ok ( )**

Returns non-zero if the last code value was greater than zero and less than 400. This holds true for most command servers. Servers where this does not hold may override this method.

**status ( )**

Returns the most significant digit of the current status code. If a command is pending then CMD\_PENDING is returned.

**datasend ( DATA )**

Send data to the remote server, converting LF to CRLF. Any line starting with a '.' will be prefixed with another '.'. DATA may be an array or a reference to an array.

**dataend ( )**

End the sending of data to the remote server. This is done by ensuring that the data already sent ends with CRLF then sending '.CRLF' to end the transmission. Once this data has been sent dataend calls response and returns true if response returns CMD\_OK.

**CLASS METHODS**

These methods are not intended to be called by the user, but used or over-ridden by a sub-class of Net::Cmd

**debug\_print ( DIR, TEXT )**

Print debugging information. DIR denotes the direction *true* being data being sent to the server. Calls debug\_text before printing to STDERR.

**debug\_text ( TEXT )**

This method is called to print debugging information. TEXT is the text being sent. The method should return the text to be printed

This is primarily meant for the use of modules such as FTP where passwords are sent, but we do not want to display them in the debugging information.

**command** ( CMD [, ARGS, ... ] )

Send a command to the command server. All arguments are first joined with a space character and CRLF is appended, this string is then sent to the command server.

Returns undef upon failure

**unsupported** ( )

Sets the status code to 580 and the response text to 'Unsupported command'. Returns zero.

**response** ( )

Obtain a response from the server. Upon success the most significant digit of the status code is returned. Upon failure, timeout etc., *undef* is returned.

**parse\_response** ( TEXT )

This method is called by *response* as a method with one argument. It should return an array of 2 values, the 3-digit status code and a flag which is true when this is part of a multi-line response and this line is not the last.

**getline** ( )

Retrieve one line, delimited by CRLF, from the remote server. Returns *undef* upon failure.

**NOTE:** If you do use this method for any reason, please remember to add some *debug\_print* calls into your method.

**ungetline** ( TEXT )

Unget a line of text from the server.

**read\_until\_dot** ( )

Read data from the remote server until a line consisting of a single '.'. Any lines starting with '.' will have one of the '.'s removed.

Returns a reference to a list containing the lines, or *undef* upon failure.

**tied\_fh** ( )

Returns a filehandle tied to the Net::Cmd object. After issuing a command, you may read from this filehandle using *read()* or *<*. The filehandle will return EOF when the final dot is encountered. Similarly, you may write to the filehandle in order to send data to the server after issuing a command that expects data to be written.

See the Net::POP3 and Net::SMTP modules for examples of this.

## EXPORTS

Net::Cmd exports six subroutines, five of these, CMD\_INFO, CMD\_OK, CMD\_MORE, CMD\_REJECT and CMD\_ERROR, correspond to possible results of response and status. The sixth is CMD\_PENDING.

\$Id: //depot/libnet/Net/Cmd.pm#28 \$

**NAME**

Net::Config – Local configuration data for libnet

**SYNOPSIS**

```
use Net::Config qw(%NetConfig);
```

**DESCRIPTION**

Net::Config holds configuration data for the modules in the libnet distribuion. During installation you will be asked for these values.

The configuration data is held globally in a file in the perl installation tree, but a user may override any of these values by providing their own. This can be done by having a `.libnetrc` file in their home directory. This file should return a reference to a HASH containing the keys described below. For example

```
.libnetrc
{
 nntp_hosts => ["my_prefered_host"],
 ph_hosts => ["my_ph_server"],
}
__END__
```

**METHODS**

Net::Config defines the following methods. They are methods as they are invoked as class methods. This is because Net::Config inherits from Net::LocalCfg so you can override these methods if you want.

**requires\_firewall HOST**

Attempts to determine if a given host is outside your firewall. Possible return values are.

```
-1 Cannot lookup hostname
0 Host is inside firewall (or there is no ftp_firewall entry)
1 Host is outside the firewall
```

This is done by using hostname lookup and the `local_netmask` entry in the configuration data.

**NetConfig VALUES**

```
nntp_hosts
snpp_hosts
pop3_hosts
smtp_hosts
ph_hosts
daytime_hosts
time_hosts
```

Each is a reference to an array of hostnames (in order of preference), which should be used for the given protocol

**inet\_domain**

Your internet domain name

**ftp\_firewall**

If you have an FTP proxy firewall (**NOT** an HTTP or SOCKS firewall) then this value should be set to the firewall hostname. If your firewall does not listen to port 21, then this value should be set to "hostname:port" (eg "hostname:99")

**ftp\_firewall\_type**

There are many different ftp firewall products available. But unfortunately there is no standard for how to traverse a firewall. The list below shows the sequence of commands that Net::FTP will use

```

user Username for remote host
pass Password for remote host
fwuser Username for firewall
fwpass Password for firewall
remote.host The hostname of the remote ftp server

```

0    There is no firewall

```

1
 USER user@remote.host
 PASS pass

```

```

2
 USER fwuser
 PASS fwpass
 USER user@remote.host
 PASS pass

```

```

3
 USER fwuser
 PASS fwpass
 SITE remote.site
 USER user
 PASS pass

```

```

4
 USER fwuser
 PASS fwpass
 OPEN remote.site
 USER user
 PASS pass

```

```

5
 USER user@fwuser@remote.site
 PASS pass@fwpass

```

```

6
 USER fwuser@remote.site
 PASS fwpass
 USER user
 PASS pass

```

```

7
 USER user@remote.host
 PASS pass
 AUTH fwuser
 RESP fwpass

```

ftp\_ext\_passive

ftp\_int\_passive

FTP servers normally work on a non-passive mode. That is when you want to transfer data you have to tell the server the address and port to connect to.

With some firewalls this does not work as the server cannot connect to your machine (because you are behind a firewall) and the firewall does not re-write the command. In this case you should set `ftp_ext_passive` to a *true* value.

Some servers are configured to only work in passive mode. If you have one of these you can force

Net::FTP to always transfer in passive mode; when not going via a firewall, by setting `ftp_int_passive` to a *true* value.

#### `local_netmask`

A reference to a list of netmask strings in the form "134.99.4.0/24". These are used by the `requires_firewall` function to determine if a given host is inside or outside your firewall.

The following entries are used during installation & testing on the libnet package

#### `test_hosts`

If true then make `test` may attempt to connect to hosts given in the configuration.

#### `test_exists`

If true then Configure will check each hostname given that it exists

=for html <hr

*\$Id: //depot/libnet/Net/Config.pm#17 \$*

**NAME**

Net::Domain – Attempt to evaluate the current host's internet name and domain

**SYNOPSIS**

```
use Net::Domain qw(hostname hostfqdn hostdomain);
```

**DESCRIPTION**

Using various methods **attempt** to find the Fully Qualified Domain Name (FQDN) of the current host. From this determine the host-name and the host-domain.

Each of the functions will return *undef* if the FQDN cannot be determined.

`hostfqdn ()`

Identify and return the FQDN of the current host.

`hostname ()`

Returns the smallest part of the FQDN which can be used to identify the host.

`hostdomain ()`

Returns the remainder of the FQDN after the *hostname* has been removed.

## NAME

Net::FTP – FTP Client class

## SYNOPSIS

```
use Net::FTP;

$ftp = Net::FTP->new("some.host.name", Debug => 0);
$ftp->login("anonymous", '-anonymous@');
$ftp->cwd("/pub");
$ftp->get("that.file");
$ftp->quit;
```

## DESCRIPTION

Net::FTP is a class implementing a simple FTP client in Perl as described in RFC959. It provides wrappers for a subset of the RFC959 commands.

## OVERVIEW

FTP stands for File Transfer Protocol. It is a way of transferring files between networked machines. The protocol defines a client (whose commands are provided by this module) and a server (not implemented in this module). Communication is always initiated by the client, and the server responds with a message and a status code (and sometimes with data).

The FTP protocol allows files to be sent to or fetched from the server. Each transfer involves a **local file** (on the client) and a **remote file** (on the server). In this module, the same file name will be used for both local and remote if only one is specified. This means that transferring remote file `/path/to/file` will try to put that file in `/path/to/file` locally, unless you specify a local file name.

The protocol also defines several standard **translations** which the file can undergo during transfer. These are ASCII, EBCDIC, binary, and byte. ASCII is the default type, and indicates that the sender of files will translate the ends of lines to a standard representation which the receiver will then translate back into their local representation. EBCDIC indicates the file being transferred is in EBCDIC format. Binary (also known as image) format sends the data as a contiguous bit stream. Byte format transfers the data as bytes, the values of which remain the same regardless of differences in byte size between the two machines (in theory – in practice you should only use this if you really know what you're doing).

## CONSTRUCTOR

`new (HOST [,OPTIONS])`

This is the constructor for a new Net::FTP object. HOST is the name of the remote host to which an FTP connection is required.

OPTIONS are passed in a hash like fashion, using key and value pairs. Possible options are:

**Firewall** – The name of a machine which acts as an FTP firewall. This can be overridden by an environment variable `FTP_FIREWALL`. If specified, and the given host cannot be directly connected to, then the connection is made to the firewall machine and the string `@hostname` is appended to the login identifier. This kind of setup is also referred to as an ftp proxy.

**FirewallType** – The type of firewall running on the machine indicated by **Firewall**. This can be overridden by an environment variable `FTP_FIREWALL_TYPE`. For a list of permissible types, see the description of `ftp_firewall_type` in [Net::Config](#).

**BlockSize** – This is the block size that Net::FTP will use when doing transfers. (defaults to 10240)

**Port** – The port number to connect to on the remote machine for the FTP connection

**Timeout** – Set a timeout value (defaults to 120)

**Debug** – debug level (see the debug method in [Net::Cmd](#))

**Passive** – If set to a non-zero value then all data transfers will be done using passive mode. This is not

usually required except for some *dumb* servers, and some firewall configurations. This can also be set by the environment variable `FTP_PASSIVE`.

**Hash** – If given a reference to a file handle (e.g., `\*STDERR`), print hash marks (#) on that filehandle every 1024 bytes. This simply invokes the `hash()` method for you, so that hash marks are displayed for all transfers. You can, of course, call `hash()` explicitly whenever you'd like.

If the constructor fails `undef` will be returned and an error message will be in `$@`

## METHODS

Unless otherwise stated all methods return either a *true* or *false* value, with *true* meaning that the operation was a success. When a method states that it returns a value, failure will be returned as *undef* or an empty list.

**login** ([LOGIN [,PASSWORD [, ACCOUNT] ] ])

Log into the remote FTP server with the given login information. If no arguments are given then the `Net::FTP` uses the `Net::Netrc` package to lookup the login information for the connected host. If no information is found then a login of *anonymous* is used. If no password is given and the login is *anonymous* then *anonymous@* will be used for password.

If the connection is via a firewall then the `authorize` method will be called with no arguments.

**authorize** ( [AUTH [, RESP]] )

This is a protocol used by some firewall ftp proxies. It is used to authorise the user to send data out. If both arguments are not specified then `authorize` uses `Net::Netrc` to do a lookup.

**site** (ARGS)

Send a SITE command to the remote server and wait for a response.

Returns most significant digit of the response code.

**type** (TYPE [, ARGS])

This method will send the TYPE command to the remote FTP server to change the type of data transfer. The return value is the previous value.

**ascii** ([ARGS]) **binary** ([ARGS]) **ebcdic** ([ARGS]) **byte** ([ARGS])

Synonyms for `type` with the first arguments set correctly

**NOTE** `ebcdic` and `byte` are not fully supported.

**rename** ( OLDNAME, NEWNAME )

Rename a file on the remote FTP server from OLDNAME to NEWNAME. This is done by sending the `RNFR` and `RNTO` commands.

**delete** ( FILENAME )

Send a request to the server to delete FILENAME.

**cwd** ( [ DIR ] )

Attempt to change directory to the directory given in `$dir`. If `$dir` is `".."`, the FTP `CDUP` command is used to attempt to move up one directory. If no directory is given then an attempt is made to change the directory to the root directory.

**cdup** ( )

Change directory to the parent of the current directory.

**pwd** ( )

Returns the full pathname of the current directory.

**restart** ( WHERE )

Set the byte offset at which to begin the next data transfer. `Net::FTP` simply records this value and uses it when during the next data transfer. For this reason this method will not return an error, but setting it may cause a subsequent data transfer to fail.

`rmdir ( DIR )`

Remove the directory with the name `DIR`.

`mkdir ( DIR [, RECURSE ] )`

Create a new directory with the name `DIR`. If `RECURSE` is *true* then `mkdir` will attempt to create all the directories in the given path.

Returns the full pathname to the new directory.

`ls ( [ DIR ] )`

Get a directory listing of `DIR`, or the current directory.

In an array context, returns a list of lines returned from the server. In a scalar context, returns a reference to a list.

`dir ( [ DIR ] )`

Get a directory listing of `DIR`, or the current directory in long format.

In an array context, returns a list of lines returned from the server. In a scalar context, returns a reference to a list.

`get ( REMOTE_FILE [, LOCAL_FILE [, WHERE]] )`

Get `REMOTE_FILE` from the server and store locally. `LOCAL_FILE` may be a filename or a filehandle. If not specified, the file will be stored in the current directory with the same leafname as the remote file.

If `WHERE` is given then the first `WHERE` bytes of the file will not be transferred, and the remaining bytes will be appended to the local file if it already exists.

Returns `LOCAL_FILE`, or the generated local file name if `LOCAL_FILE` is not given. If an error was encountered `undef` is returned.

`put ( LOCAL_FILE [, REMOTE_FILE ] )`

Put a file on the remote server. `LOCAL_FILE` may be a name or a filehandle. If `LOCAL_FILE` is a filehandle then `REMOTE_FILE` must be specified. If `REMOTE_FILE` is not specified then the file will be stored in the current directory with the same leafname as `LOCAL_FILE`.

Returns `REMOTE_FILE`, or the generated remote filename if `REMOTE_FILE` is not given.

**NOTE:** If for some reason the transfer does not complete and an error is returned then the contents that had been transferred will not be removed automatically.

`put_unique ( LOCAL_FILE [, REMOTE_FILE ] )`

Same as `put` but uses the `STOU` command.

Returns the name of the file on the server.

`append ( LOCAL_FILE [, REMOTE_FILE ] )`

Same as `put` but appends to the file on the remote server.

Returns `REMOTE_FILE`, or the generated remote filename if `REMOTE_FILE` is not given.

`unique_name ( )`

Returns the name of the last file stored on the server using the `STOU` command.

`mdtm ( FILE )`

Returns the *modification time* of the given file

`size ( FILE )`

Returns the size in bytes for the given file as stored on the remote server.

**NOTE:** The size reported is the size of the stored file on the remote server. If the file is subsequently transferred from the server in ASCII mode and the remote server and local machine have different ideas about "End Of Line" then the size of file on the local machine after transfer may be different.

`supported ( CMD )`

Returns TRUE if the remote server supports the given command.

`hash ( [FILEHANDLE_GLOB_REF],[BYTES_PER_HASH_MARK] )`

Called without parameters, or with the first argument false, hash marks are suppressed. If the first argument is true but not a reference to a file handle glob, then `\*STDERR` is used. The second argument is the number of bytes per hash mark printed, and defaults to 1024. In all cases the return value is a reference to an array of two: the filehandle glob reference and the bytes per hash mark.

The following methods can return different results depending on how they are called. If the user explicitly calls either of the `pasv` or `port` methods then these methods will return a *true* or *false* value. If the user does not call either of these methods then the result will be a reference to a `Net::FTP::dataconn` based object.

`nlst ( [ DIR ] )`

Send an NLST command to the server, with an optional parameter.

`list ( [ DIR ] )`

Same as `nlst` but using the LIST command

`retr ( FILE )`

Begin the retrieval of a file called FILE from the remote server.

`stor ( FILE )`

Tell the server that you wish to store a file. FILE is the name of the new file that should be created.

`stou ( FILE )`

Same as `stor` but using the STOU command. The name of the unique file which was created on the server will be available via the `unique_name` method after the data connection has been closed.

`appe ( FILE )`

Tell the server that we want to append some data to the end of a file called FILE. If this file does not exist then create it.

If for some reason you want to have complete control over the data connection, this includes generating it and calling the `response` method when required, then the user can use these methods to do so.

However calling these methods only affects the use of the methods above that can return a data connection. They have no effect on methods `get`, `put`, `put_unique` and those that do not require data connections.

`port ( [ PORT ] )`

Send a PORT command to the server. If PORT is specified then it is sent to the server. If not, then a listen socket is created and the correct information sent to the server.

`pasv ( )`

Tell the server to go into passive mode. Returns the text that represents the port on which the server is listening, this text is in a suitable form to sent to another ftp server using the `port` method.

The following methods can be used to transfer files between two remote servers, providing that these two servers can connect directly to each other.

`pasv_xfer ( SRC_FILE, DEST_SERVER [, DEST_FILE ] )`

This method will do a file transfer between two remote ftp servers. If DEST\_FILE is omitted then the leaf name of SRC\_FILE will be used.

`pasv_xfer_unique ( SRC_FILE, DEST_SERVER [, DEST_FILE ] )`

Like `pasv_xfer` but the file is stored on the remote server using the STOU command.

`pasv_wait ( NON_PASV_SERVER )`

This method can be used to wait for a transfer to complete between a passive server and a non-passive server. The method should be called on the passive server with the `Net::FTP` object for the non-passive server passed as an argument.

`abort ( )`

Abort the current data transfer.

`quit ( )`

Send the QUIT command to the remote FTP server and close the socket connection.

### Methods for the adventurous

`Net::FTP` inherits from `Net::Cmd` so methods defined in `Net::Cmd` may be used to send commands to the remote FTP server.

`quot (CMD [,ARGS])`

Send a command, that `Net::FTP` does not directly support, to the remote server and wait for a response.

Returns most significant digit of the response code.

**WARNING** This call should only be used on commands that do not require data connections. Misuse of this method can hang the connection.

### THE dataconn CLASS

Some of the methods defined in `Net::FTP` return an object which will be derived from this class. The `dataconn` class itself is derived from the `IO::Socket::INET` class, so any normal IO operations can be performed. However the following methods are defined in the `dataconn` class and IO should be performed using these.

`read ( BUFFER, SIZE [, TIMEOUT ] )`

Read `SIZE` bytes of data from the server and place it into `BUFFER`, also performing any <CRLF translation necessary. `TIMEOUT` is optional, if not given, the timeout value from the command connection will be used.

Returns the number of bytes read before any <CRLF translation.

`write ( BUFFER, SIZE [, TIMEOUT ] )`

Write `SIZE` bytes of data from `BUFFER` to the server, also performing any <CRLF translation necessary. `TIMEOUT` is optional, if not given, the timeout value from the command connection will be used.

Returns the number of bytes written before any <CRLF translation.

`bytes_read ( )`

Returns the number of bytes read so far.

`abort ( )`

Abort the current data transfer.

`close ( )`

Close the data connection and get a response from the FTP server. Returns *true* if the connection was closed successfully and the first digit of the response from the server was a '2'.

## UNIMPLEMENTED

The following RFC959 commands have not been implemented:

### ALLO

Allocates storage for the file to be transferred.

### SMNT

Mount a different file system structure without changing login or accounting information.

### HELP

Ask the server for "helpful information" (that's what the RFC says) on the commands it accepts.

### MODE

Specifies transfer mode (stream, block or compressed) for file to be transferred.

### SYST

Request remote server system identification.

### STAT

Request remote server status.

### STRU

Specifies file structure for file to be transferred.

### REIN

Reinitialize the connection, flushing all I/O and account information.

## REPORTING BUGS

When reporting bugs/problems please include as much information as possible. It may be difficult for me to reproduce the problem as almost every setup is different.

A small script which yields the problem will probably be of help. It would also be useful if this script was run with the extra options `Debug = 1` passed to the constructor, and the output sent with the bug report. If you cannot include a small script then please include a Debug trace from a run of your program which does yield the problem.

*\$Id: //depot/libnet/Net/FTP.pm#68 \$*

**NAME**

Net::hostent – by-name interface to Perl's built-in `gethost*` () functions

**SYNOPSIS**

```
use Net::hostnet;
```

**DESCRIPTION**

This module's default exports override the core `gethostbyname()` and `gethostbyaddr()` functions, replacing them with versions that return "Net::hostent" objects. This object has methods that return the similarly named structure field name from the C's `hostent` structure from *netdb.h*; namely `name`, `aliases`, `addrtype`, `length`, and `addr_list`. The `aliases` and `addr_list` methods return array reference, the rest scalars. The `addr` method is equivalent to the zeroth element in the `addr_list` array reference.

You may also import all the structure fields directly into your namespace as regular variables using the `:FIELDS` import tag. (Note that this still overrides your core functions.) Access these fields as variables named with a preceding `h_`. Thus, `$host_obj->name()` corresponds to `$h_name` if you import the fields. Array references are available as regular array variables, so for example `@{$host_obj->aliases() }` would be simply `@h_aliases`.

The `gethost()` function is a simple front-end that forwards a numeric argument to `gethostbyaddr()` by way of `Socket::inet_aton`, and the rest to `gethostbyname()`.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. On the other hand, the built-ins are still available via the `CORE::pseudo-package`.

**EXAMPLES**

```
use Net::hostent;
use Socket;

@ARGV = ('netscape.com') unless @ARGV;

for $host (@ARGV) {
 unless ($h = gethost($host)) {
 warn "$0: no such host: $host\n";
 next;
 }

 printf "\n%s is %s\n",
 $host,
 lc($h->name) eq lc($host) ? "" : "*really* ",
 $h->name;

 print "\taliases are ", join(", ", @{$h->aliases}), "\n"
 if @{$h->aliases};

 if (@{$h->addr_list} > 1) {
 my $i;
 for $addr (@{$h->addr_list}) {
 printf "\taddr %d is [%s]\n", $i++, inet_ntoa($addr);
 }
 } else {
 printf "\taddress is [%s]\n", inet_ntoa($h->addr);
 }

 if ($h = gethostbyaddr($h->addr)) {
 if (lc($h->name) ne lc($host)) {
 printf "\tThat addr reverses to host %s!\n", $h->name;
 $host = $h->name;
 }
 }
}
```

```
 redo;
 }
}
}
```

**NOTE**

While this class is currently implemented using the `Class::Struct` module to build a struct-like class, you shouldn't rely upon this.

libnetFAQ – libnet Frequently Asked Questions

**DESCRIPTION****Where to get this document**

This document is distributed with the libnet distribution, and is also available on the libnet web page at

<http://www.pobox.com/~gbarr/libnet/>

**How to contribute to this document**

You may mail corrections, additions, and suggestions to me [gbarr@pobox.com](mailto:gbarr@pobox.com).

**Author and Copyright Information**

Copyright (c) 1997–1998 Graham Barr. All rights reserved. This document is free; you can redistribute it and/or modify it under the terms of the Artistic License.

This information is offered in good faith and in the hope that it may be of use, but is not guaranteed to be correct, up to date, or suitable for any particular purpose whatsoever. The authors accept no liability in respect of this information or its use.

**Obtaining and installing libnet****What is libnet ?**

libnet is a collection of perl5 modules which all related to network programming. The majority of the modules available provided the client side of popular server–client protocols that are used in the internet community.

**Which version of perl do I need ?**

libnet has been know to work with versions of perl from 5.002 onwards. However if your release of perl is prior to perl5.004 then you will need to obtain and install the IO distribution from CPAN. If you have perl5.004 or later then you will have the IO modules in your installation already, but CPAN may contain updates.

**What other modules do I need ?**

The only modules you will need installed are the modules from the IO distribution. If you have perl5.004 or later you will already have these modules.

**What machines support libnet ?**

libnet itself is an entirely perl–code distribution so it should work on any machine that perl runs on. However IO may not work with some machines and earlier releases of perl. But this should not be the case with perl version 5.004 or later.

**Where can I get the latest libnet release**

The latest libnet release is always on CPAN, you will find it in

<http://www.cpan.org/modules/by-module/Net/>

The latest release and information is also available on the libnet web page at

<http://www.pobox.com/~gbarr/libnet/>

**Using Net::FTP****How do I download files from an FTP server ?**

An example taken from an article posted to comp.lang.perl.misc

```
#!/your/path/to/perl
a module making life easier
```

```

use Net::FTP;

for debugging: $ftp = Net::FTP->new('site','Debug',10);
open a connection and log in!

$ftp = Net::FTP->new('target_site.somewhere.xxx');
$ftp->login('username','password');

set transfer mode to binary

$ftp->binary();

change the directory on the ftp site

$ftp->cwd('/some/path/to/somewhere/');

foreach $name ('file1', 'file2', 'file3') {

get's arguments are in the following order:
ftp server's filename
filename to save the transfer to on the local machine
can be simply used as get($name) if you want the same name

 $ftp->get($name,$name);
}

ftp done!

$ftp->quit;

```

### How do I transfer files in binary mode ?

To transfer files without <LF><CR translation Net::FTP provides the binary method

```
$ftp->binary;
```

### How can I get the size of a file on a remote FTP server ?

### How can I get the modification time of a file on a remote FTP server ?

### How can I change the permissions of a file on a remote server ?

The FTP protocol does not have a command for changing the permissions of a file on the remote server. But some ftp servers may allow a chmod command to be issued via a SITE command, eg

```
$ftp->quot('site chmod 0777',$filename);
```

But this is not guaranteed to work.

### Can I do a reget operation like the ftp command ?

### How do I get a directory listing from an FTP server ?

### Changing directory to "" does not fail ?

Passing an argument of "" to -cwd() has the same affect of calling -cwd() without any arguments. Turn on Debug (*See below*) and you will see what is happening

```

$ftp = Net::FTP->new($host, Debug => 1);
$ftp->login;
$ftp->cwd("");

```

gives

```

Net::FTP=GLOB(0x82196d8)>>> CWD /
Net::FTP=GLOB(0x82196d8)<<< 250 CWD command successful.

```

**I am behind a SOCKS firewall, but the Firewall option does not work ?**

The Firewall option is only for support of one type of firewall. The type supported is an ftp proxy.

To use Net::FTP, or any other module in the libnet distribution, through a SOCKS firewall you must create a socks-ified perl executable by compiling perl with the socks library.

**I am behind an FTP proxy firewall, but cannot access machines outside ?**

Net::FTP implements the most popular ftp proxy firewall approach. The scheme implemented is that where you log in to the firewall with `user@hostname`

I have heard of one other type of firewall which requires a login to the firewall with an account, then a second login with `user@hostname`. You can still use Net::FTP to traverse these firewalls, but a more manual approach must be taken, eg

```
$ftp = Net::FTP->new($firewall) or die $@;
$ftp->login($firewall_user, $firewall_passwd) or die $ftp->message;
$ftp->login($ext_user . '@' . $ext_host, $ext_passwd) or die $ftp->message.
```

**My ftp proxy firewall does not listen on port 21**

FTP servers usually listen on the same port number, port 21, as any other FTP server. But there is no reason why this has to be the case.

If you pass a port number to Net::FTP then it assumes this is the port number of the final destination. By default Net::FTP will always try to connect to the firewall on port 21.

Net::FTP uses IO::Socket to open the connection and IO::Socket allows the port number to be specified as part of the hostname. So this problem can be resolved by either passing a Firewall option like "hostname:1234" or by setting the `ftp_firewall` option in Net::Config to be a string in the same form.

**Is it possible to change the file permissions of a file on an FTP server ?**

The answer to this is "maybe". The FTP protocol does not specify a command to change file permissions on a remote host. However many servers do allow you to run the `chmod` command via the `SITE` command. This can be done with

```
$ftp->site('chmod', '0775', $file);
```

**I have seen scripts call a method message, but cannot find it documented ?**

Net::FTP, like several other packages in libnet, inherits from Net::Cmd, so all the methods described in Net::Cmd are also available on Net::FTP objects.

**Why does Net::FTP not implement mput and mget methods**

The quick answer is because they are easy to implement yourself. The long answer is that to write these in such a way that multiple platforms are supported correctly would just require too much code. Below are some examples how you can implement these yourself.

```
sub mput {
 my($ftp, $pattern) = @_;
 foreach my $file (glob($pattern)) {
 $ftp->put($file) or warn $ftp->message;
 }
}

sub mget {
 my($ftp, $pattern) = @_;
 foreach my $file ($ftp->ls($pattern)) {
 $ftp->get($file) or warn $ftp->message;
 }
}
```

## Using Net::SMTP

### Why can't the part of an Email address after the @ be used as the hostname ?

The part of an Email address which follows the @ is not necessarily a hostname, it is a mail domain. To find the name of a host to connect for a mail domain you need to do a DNS MX lookup

### Why does Net::SMTP not do DNS MX lookups ?

Net::SMTP implements the SMTP protocol. The DNS MX lookup is not part of this protocol.

### The verify method always returns true ?

Well it may seem that way, but it does not. The verify method returns true if the command succeeded. If you pass verify an address which the server would normally have to forward to another machine, the command will succeed with something like

```
252 Couldn't verify <someone@there> but will attempt delivery anyway
```

This command will fail only if you pass it an address in a domain the server directly delivers for, and that address does not exist.

## Debugging scripts

### How can I debug my scripts that use Net::\* modules ?

Most of the libnet client classes allow options to be passed to the constructor, in most cases one option is called Debug. Passing this option with a non-zero value will turn on a protocol trace, which will be sent to STDERR. This trace can be useful to see what commands are being sent to the remote server and what responses are being received back.

```
#!/your/path/to/perl

use Net::FTP;

my $ftp = new Net::FTP($host, Debug => 1);
$ftp->login('gbarr', 'password');
$ftp->quit;
```

this script would output something like

```
Net::FTP: Net::FTP(2.22)
Net::FTP: Exporter
Net::FTP: Net::Cmd(2.0801)
Net::FTP: IO::Socket::INET
Net::FTP: IO::Socket(1.1603)
Net::FTP: IO::Handle(1.1504)

Net::FTP=GLOB(0x8152974)<<< 220 imagine FTP server (Version wu-2.4(5) Tue Jul 29 11:
Net::FTP=GLOB(0x8152974)>>> user gbarr
Net::FTP=GLOB(0x8152974)<<< 331 Password required for gbarr.
Net::FTP=GLOB(0x8152974)>>> PASS
Net::FTP=GLOB(0x8152974)<<< 230 User gbarr logged in. Access restrictions apply.
Net::FTP=GLOB(0x8152974)>>> QUIT
Net::FTP=GLOB(0x8152974)<<< 221 Goodbye.
```

The first few lines tell you the modules that Net::FTP uses and their versions, this is useful data to me when a user reports a bug. The last seven lines show the communication with the server. Each line has three parts. The first part is the object itself, this is useful for separating the output if you are using multiple objects. The second part is either <<<< to show data coming from the server or >>>> to show data going to the server. The remainder of the line is the command being sent or response being received.

*\$Id: //depot/libnet/Net/libnetFAQ.pod#5 \$*

**NAME**

Net::netent – by-name interface to Perl's built-in `getnet*` () functions

**SYNOPSIS**

```
use Net::netent qw(:FIELDS);
getnetbyname("loopback") or die "bad net";
printf "%s is %08X\n", $n_name, $n_net;

use Net::netent;

$n = getnetbyname("loopback") or die "bad net";
{ # there's gotta be a better way, eh?
 @bytes = unpack("C4", pack("N", $n->net));
 shift @bytes while @bytes && $bytes[0] == 0;
}
printf "%s is %08X [%d.%d.%d.%d]\n", $n->name, $n->net, @bytes;
```

**DESCRIPTION**

This module's default exports override the core `getnetbyname()` and `getnetbyaddr()` functions, replacing them with versions that return "Net::netent" objects. This object has methods that return the similarly named structure field name from the C's netent structure from *netdb.h*; namely `name`, `aliases`, `addrtype`, and `net`. The `aliases` method returns an array reference, the rest scalars.

You may also import all the structure fields directly into your namespace as regular variables using the `:FIELDS` import tag. (Note that this still overrides your core functions.) Access these fields as variables named with a preceding `n_`. Thus, `$net_obj->name()` corresponds to `$n_name` if you import the fields. Array references are available as regular array variables, so for example `@{ $net_obj->aliases() }` would be simply `@n_aliases`.

The `getnet()` function is a simple front-end that forwards a numeric argument to `getnetbyaddr()`, and the rest to `getnetbyname()`.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. On the other hand, the built-ins are still available via the `CORE::pseudo-package`.

**EXAMPLES**

The `getnet()` functions do this in the Perl core:

```
sv_setiv(sv, (I32)nent->n_net);
```

The `gethost()` functions do this in the Perl core:

```
sv_setpv(sv, hent->h_addr, len);
```

That means that the address comes back in binary for the host functions, and as a regular perl integer for the net ones. This seems a bug, but here's how to deal with it:

```
use strict;
use Socket;
use Net::netent;

@ARGV = ('loopback') unless @ARGV;
my($n, $net);
for $net (@ARGV) {
 unless ($n = getnetbyname($net)) {
 warn "$0: no such net: $net\n";
 next;
 }
}
```

```

 printf "\n%s is %s%s\n",
 $net,
 lc($n->name) eq lc($net) ? "" : "*really* ",
 $n->name;

 print "\taliases are ", join(", ", @{$n->aliases}), "\n"
 if @{$n->aliases};

 # this is stupid; first, why is this not in binary?
 # second, why am i going through these convolutions
 # to make it looks right
 {
 my @a = unpack("C4", pack("N", $n->net));
 shift @a while @a && $a[0] == 0;
 printf "\taddr is %s [%d.%d.%d.%d]\n", $n->net, @a;
 }

 if ($n = getnetbyaddr($n->net)) {
 if (lc($n->name) ne lc($net)) {
 printf "\tThat addr reverses to net %s!\n", $n->name;
 $net = $n->name;
 redo;
 }
 }
}

```

**NOTE**

While this class is currently implemented using the `Class::Struct` module to build a struct-like class, you shouldn't rely upon this.

**AUTHOR**

Tom Christiansen

**NAME**

Net::Netrc – OO interface to users netrc file

**SYNOPSIS**

```
use Net::Netrc;

$mach = Net::Netrc->lookup('some.machine');
$login = $mach->login;
($login, $password, $account) = $mach->lpa;
```

**DESCRIPTION**

Net::Netrc is a class implementing a simple interface to the .netrc file used as by the ftp program.

Net::Netrc also implements security checks just like the ftp program, these checks are, first that the .netrc file must be owned by the user and second the ownership permissions should be such that only the owner has read and write access. If these conditions are not met then a warning is output and the .netrc file is not read.

**THE .netrc FILE**

The .netrc file contains login and initialization information used by the auto-login process. It resides in the user's home directory. The following tokens are recognized; they may be separated by spaces, tabs, or new-lines:

**machine name**

Identify a remote machine name. The auto-login process searches the .netrc file for a machine token that matches the remote machine specified. Once a match is made, the subsequent .netrc tokens are processed, stopping when the end of file is reached or another machine or a default token is encountered.

**default**

This is the same as machine name except that default matches any name. There can be only one default token, and it must be after all machine tokens. This is normally used as:

```
default login anonymous password user@site
```

thereby giving the user automatic anonymous login to machines not specified in .netrc.

**login name**

Identify a user on the remote machine. If this token is present, the auto-login process will initiate a login using the specified name.

**password string**

Supply a password. If this token is present, the auto-login process will supply the specified string if the remote server requires a password as part of the login process.

**account string**

Supply an additional account password. If this token is present, the auto-login process will supply the specified string if the remote server requires an additional account password.

**macdef name**

Define a macro. Net::Netrc only parses this field to be compatible with *ftp*.

**CONSTRUCTOR**

The constructor for a Net::Netrc object is not called new as it does not really create a new object. But instead is called lookup as this is essentially what it does.

**lookup ( MACHINE [, LOGIN ])**

Lookup and return a reference to the entry for MACHINE. If LOGIN is given then the entry returned will have the given login. If LOGIN is not given then the first entry in the .netrc file for MACHINE will

be returned.

If a matching entry cannot be found, and a default entry exists, then a reference to the default entry is returned.

If there is no matching entry found and there is no default defined, or no .netrc file is found, then undef is returned.

## METHODS

login ( )

Return the login id for the netrc entry

password ( )

Return the password for the netrc entry

account ( )

Return the account information for the netrc entry

lpa ( )

Return a list of login, password and account information for the netrc entry

\$Id: //depot/libnet/Net/Netrc.pm#13 \$

**NAME**

Net::NNTP – NNTP Client class

**SYNOPSIS**

```
use Net::NNTP;

$nnntp = Net::NNTP->new("some.host.name");
$nnntp->quit;
```

**DESCRIPTION**

Net::NNTP is a class implementing a simple NNTP client in Perl as described in RFC977. Net::NNTP inherits its communication methods from Net::Cmd

**CONSTRUCTOR**

`new ( [ HOST ] [, OPTIONS ] )`

This is the constructor for a new Net::NNTP object. HOST is the name of the remote host to which a NNTP connection is required. If not given two environment variables are checked, first NNTPSERVER then NEWSHOST, then Net::Config is checked, and if a host is not found then news is used.

OPTIONS are passed in a hash like fashion, using key and value pairs. Possible options are:

**Timeout** – Maximum time, in seconds, to wait for a response from the NNTP server, a value of zero will cause all IO operations to block. (default: 120)

**Debug** – Enable the printing of debugging information to STDERR

**Reader** – If the remote server is INN then initially the connection will be to nnrpd, by default Net::NNTP will issue a MODE READER command so that the remote server becomes innd. If the Reader option is given with a value of zero, then this command will not be sent and the connection will be left talking to nnrpd.

**METHODS**

Unless otherwise stated all methods return either a *true* or *false* value, with *true* meaning that the operation was a success. When a method states that it returns a value, failure will be returned as *undef* or an empty list.

`article ( [ MSGID|MSGNUM ], [FH] )`

Retrieve the header, a blank line, then the body (text) of the specified article.

If FH is specified then it is expected to be a valid filehandle and the result will be printed to it, on success a true value will be returned. If FH is not specified then the return value, on success, will be a reference to an array containing the article requested, each entry in the array will contain one line of the article.

If no arguments are passed then the current article in the currently selected newsgroup is fetched.

MSGNUM is a numeric id of an article in the current newsgroup, and will change the current article pointer. MSGID is the message id of an article as shown in that article's header. It is anticipated that the client will obtain the MSGID from a list provided by the newnews command, from references contained within another article, or from the message-id provided in the response to some other commands.

If there is an error then *undef* will be returned.

`body ( [ MSGID|MSGNUM ], [FH] )`

Like `article` but only fetches the body of the article.

`head ( [ MSGID|MSGNUM ], [FH] )`

Like `article` but only fetches the headers for the article.

`articlefh ( [ MSGID|MSGNUM ] )`  
`bodyfh ( [ MSGID|MSGNUM ] )`  
`headfh ( [ MSGID|MSGNUM ] )`

These are similar to `article()`, `body()` and `head()`, but rather than returning the requested data directly, they return a tied filehandle from which to read the article.

`nntpstat ( [ MSGID|MSGNUM ] )`

The `nntpstat` command is similar to the `article` command except that no text is returned. When selecting by message number within a group, the `nntpstat` command serves to set the "current article pointer" without sending text.

Using the `nntpstat` command to select by message-id is valid but of questionable value, since a selection by message-id does **not** alter the "current article pointer".

Returns the message-id of the "current article".

`group ( [ GROUP ] )`

Set and/or get the current group. If `GROUP` is not given then information is returned on the current group.

In a scalar context it returns the group name.

In an array context the return value is a list containing, the number of articles in the group, the number of the first article, the number of the last article and the group name.

`ihave ( MSGID [, MESSAGE ] )`

The `ihave` command informs the server that the client has an article whose id is `MSGID`. If the server desires a copy of that article, and `MESSAGE` has been given the it will be sent.

Returns *true* if the server desires the article and `MESSAGE` was successfully sent, if specified.

If `MESSAGE` is not specified then the message must be sent using the `datasend` and `dataend` methods from *Net::Cmd*

`MESSAGE` can be either an array of lines or a reference to an array.

`last ( )`

Set the "current article pointer" to the previous article in the current newsgroup.

Returns the message-id of the article.

`date ( )`

Returns the date on the remote server. This date will be in a UNIX time format (seconds since 1970)

`postok ( )`

`postok` will return *true* if the servers initial response indicated that it will allow posting.

`authinfo ( USER, PASS )`

`list ( )`

Obtain information about all the active newsgroups. The results is a reference to a hash where the key is a group name and each value is a reference to an array. The elements in this array are:– the last article number in the group, the first article number in the group and any information flags about the group.

`newgroups ( SINCE [, DISTRIBUTIONS ] )`

`SINCE` is a time value and `DISTRIBUTIONS` is either a distribution pattern or a reference to a list of distribution patterns. The result is the same as `list`, but the groups return will be limited to those created after `SINCE` and, if specified, in one of the distribution areas in `DISTRIBUTIONS`.

`newnews ( SINCE [, GROUPS [, DISTRIBUTIONS ]])`

`SINCE` is a time value. `GROUPS` is either a group pattern or a reference to a list of group patterns. `DISTRIBUTIONS` is either a distribution pattern or a reference to a list of distribution patterns.

Returns a reference to a list which contains the message-ids of all news posted after `SINCE`, that are in a groups which matched `GROUPS` and a distribution which matches `DISTRIBUTIONS`.

`next ( )`

Set the "current article pointer" to the next article in the current newsgroup.

Returns the message-id of the article.

`post ( [ MESSAGE ] )`

Post a new article to the news server. If `MESSAGE` is specified and posting is allowed then the message will be sent.

If `MESSAGE` is not specified then the message must be sent using the `datasend` and `dataend` methods from [Net::Cmd](#)

`MESSAGE` can be either an array of lines or a reference to an array.

`postfh ( )`

Post a new article to the news server using a tied filehandle. If posting is allowed, this method will return a tied filehandle that you can `print ( )` the contents of the article to be posted. You must explicitly `close ( )` the filehandle when you are finished posting the article, and the return value from the `close ( )` call will indicate whether the message was successfully posted.

`slave ( )`

Tell the remote server that I am not a user client, but probably another news server.

`quit ( )`

Quit the remote server and close the socket connection.

### Extension methods

These methods use commands that are not part of the RFC977 documentation. Some servers may not support all of them.

`newsgroups ( [ PATTERN ] )`

Returns a reference to a hash where the keys are all the group names which match `PATTERN`, or all of the groups if no pattern is specified, and each value contains the description text for the group.

`distributions ( )`

Returns a reference to a hash where the keys are all the possible distribution names and the values are the distribution descriptions.

`subscriptions ( )`

Returns a reference to a list which contains a list of groups which are recommended for a new user to subscribe to.

`overview_fmt ( )`

Returns a reference to an array which contain the names of the fields returned by `xover`.

`active_times ( )`

Returns a reference to a hash where the keys are the group names and each value is a reference to an array containing the time the groups was created and an identifier, possibly an Email address, of the creator.

**active ( [ PATTERN ] )**

Similar to `list` but only active groups that match the pattern are returned. `PATTERN` can be a group pattern.

**xgtitle ( PATTERN )**

Returns a reference to a hash where the keys are all the group names which match `PATTERN` and each value is the description text for the group.

**xhdr ( HEADER, MESSAGE-SPEC )**

Obtain the header field `HEADER` for all the messages specified.

The return value will be a reference to a hash where the keys are the message numbers and each value contains the text of the requested header for that message.

**xover ( MESSAGE-SPEC )**

The return value will be a reference to a hash where the keys are the message numbers and each value contains a reference to an array which contains the overview fields for that message.

The names of the fields can be obtained by calling `overview_fmt`.

**xpath ( MESSAGE-ID )**

Returns the path name to the file on the server which contains the specified message.

**xpat ( HEADER, PATTERN, MESSAGE-SPEC )**

The result is the same as `xhdr` except the is will be restricted to headers where the text of the header matches `PATTERN`

**xrover**

The `XROVER` command returns reference information for the article(s) specified.

Returns a reference to a `HASH` where the keys are the message numbers and the values are the References: lines from the articles

**listgroup ( [ GROUP ] )**

Returns a reference to a list of all the active messages in `GROUP`, or the current group if `GROUP` is not specified.

**reader**

Tell the server that you are a reader and not another server.

This is required by some servers. For example if you are connecting to an INN server and you have transfer permission your connection will be connected to the transfer daemon, not the NNTP daemon. Issuing this command will cause the transfer daemon to hand over control to the NNTP daemon.

Some servers do not understand this command, but issuing it and ignoring the response is harmless.

**UNSUPPORTED**

The following NNTP command are unsupported by the package, and there are no plans to do so.

AUTHINFO GENERIC  
XTHREAD  
XSEARCH  
XINDEX

**DEFINITIONS****MESSAGE-SPEC**

`MESSAGE-SPEC` is either a single message-id, a single message number, or a reference to a list of two message numbers.

If MESSAGE-SPEC is a reference to a list of two message numbers and the second number in a range is less than or equal to the first then the range represents all messages in the group after the first message number.

**NOTE** For compatibility reasons only with earlier versions of Net::NNTP a message spec can be passed as a list of two numbers, this is deprecated and a reference to the list should now be passed

## PATTERN

The NNTP protocol uses the WILDMAT format for patterns. The WILDMAT format was first developed by Rich Salz based on the format used in the UNIX "find" command to articulate file names. It was developed to provide a uniform mechanism for matching patterns in the same manner that the UNIX shell matches filenames.

Patterns are implicitly anchored at the beginning and end of each string when testing for a match.

There are five pattern matching operations other than a strict one-to-one match between the pattern and the source to be checked for a match.

The first is an asterisk \* to match any sequence of zero or more characters.

The second is a question mark ? to match any single character. The third specifies a specific set of characters.

The set is specified as a list of characters, or as a range of characters where the beginning and end of the range are separated by a minus (or dash) character, or as any combination of lists and ranges. The dash can also be included in the set as a character if it is the beginning or end of the set. This set is enclosed in square brackets. The close square bracket ] may be used in a set if it is the first character in the set.

The fourth operation is the same as the logical not of the third operation and is specified the same way as the third with the addition of a caret character ^ at the beginning of the test string just inside the open square bracket.

The final operation uses the backslash character to invalidate the special meaning of an open square bracket [, the asterisk, backslash or the question mark. Two backslashes in sequence will result in the evaluation of the backslash as a character with no special meaning.

### Examples

[^] -]

matches any single character other than a close square bracket or a minus sign/dash.

\*bdc

matches any string that ends with the string "bdc" including the string "bdc" (without quotes).

[0-9a-zA-Z]

matches any single printable alphanumeric ASCII character.

a???d

matches any four character string which begins with a and ends with d.

**NAME**

Net::Ping – check a remote host for reachability

\$Id: Ping.pm,v 1.6 2002/06/19 15:23:48 rob Exp \$

**SYNOPSIS**

```
use Net::Ping;

$p = Net::Ping->new();
print "$host is alive.\n" if $p->ping($host);
$p->close();

$p = Net::Ping->new("icmp");
$p->bind($my_addr); # Specify source interface of pings
foreach $host (@host_array)
{
 print "$host is ";
 print "NOT " unless $p->ping($host, 2);
 print "reachable.\n";
 sleep(1);
}
$p->close();

$p = Net::Ping->new("tcp", 2);
Try connecting to the www port instead of the echo port
$p->{port_num} = getservbyname("http", "tcp");
while ($stop_time > time())
{
 print "$host not reachable ", scalar(localtime()), "\n"
 unless $p->ping($host);
 sleep(300);
}
undef($p);

High precision syntax (requires Time::HiRes)
$p = Net::Ping->new();
$p->hires();
($ret, $duration, $ip) = $p->ping($host, 5.5);
printf("$host [ip: $ip] is alive (packet return time: %.2f ms)\n", 1000 * $duration)
 if $ret;
$p->close();

For backward compatibility
print "$host is alive.\n" if pingecho($host);
```

**DESCRIPTION**

This module contains methods to test the reachability of remote hosts on a network. A ping object is first created with optional parameters, a variable number of hosts may be pinged multiple times and then the connection is closed.

You may choose one of four different protocols to use for the ping. The "udp" protocol is the default. Note that a live remote host may still fail to be pingable by one or more of these protocols. For example, [www.microsoft.com](http://www.microsoft.com) is generally alive but not pingable.

With the "tcp" protocol the `ping()` method attempts to establish a connection to the remote host's echo port. If the connection is successfully established, the remote host is considered reachable. No data is actually echoed. This protocol does not require any special privileges but has higher overhead than the other two protocols.

Specifying the "udp" protocol causes the `ping()` method to send a udp packet to the remote host's echo port. If the echoed packet is received from the remote host and the received packet contains the same data as the packet that was sent, the remote host is considered reachable. This protocol does not require any special privileges. It should be borne in mind that, for a udp ping, a host will be reported as unreachable if it is not running the appropriate echo service. For Unix-like systems see [inetd\(8\)](#) for more information.

If the "icmp" protocol is specified, the `ping()` method sends an icmp echo message to the remote host, which is what the UNIX ping program does. If the echoed message is received from the remote host and the echoed information is correct, the remote host is considered reachable. Specifying the "icmp" protocol requires that the program be run as root or that the program be setuid to root.

If the "external" protocol is specified, the `ping()` method attempts to use the `Net::Ping::External` module to ping the remote host. `Net::Ping::External` interfaces with your system's default ping utility to perform the ping, and generally produces relatively accurate results. If `Net::Ping::External` is not installed on your system, specifying the "external" protocol will result in an error.

## Functions

`Net::Ping->new([ $proto [, $def_timeout [, $bytes]] ] );`

Create a new ping object. All of the parameters are optional. `$proto` specifies the protocol to use when doing a ping. The current choices are "tcp", "udp" or "icmp". The default is "udp".

If a default timeout (`$def_timeout`) in seconds is provided, it is used when a timeout is not given to the `ping()` method (below). The timeout must be greater than 0 and the default, if not specified, is 5 seconds.

If the number of data bytes (`$bytes`) is given, that many data bytes are included in the ping packet sent to the remote host. The number of data bytes is ignored if the protocol is "tcp". The minimum (and default) number of data bytes is 1 if the protocol is "udp" and 0 otherwise. The maximum number of data bytes that can be specified is 1024.

`$p->ping($host [, $timeout] );`

Ping the remote host and wait for a response. `$host` can be either the hostname or the IP number of the remote host. The optional timeout must be greater than 0 seconds and defaults to whatever was specified when the ping object was created. Returns a success flag. If the hostname cannot be found or there is a problem with the IP number, the success flag returned will be undef. Otherwise, the success flag will be 1 if the host is reachable and 0 if it is not. For most practical purposes, undef and 0 and can be treated as the same case. In array context, the elapsed time is also returned. The elapsed time value will be a float, as returned by the `Time::HiRes::time()` function, if `hires()` has been previously called, otherwise it is returned as an integer.

`$p->source_verify( { 0 | 1 } );`

Allows source endpoint verification to be enabled or disabled. This is useful for those remote destinations with multiples interfaces where the response may not originate from the same endpoint that the original destination endpoint was sent to. This only affects udp and icmp protocol pings.

This is enabled by default.

`$p->hires( { 0 | 1 } );`

Causes this module to use `Time::HiRes` module, allowing milliseconds to be returned by subsequent calls to `ping()`.

This is disabled by default.

`$p->bind($local_addr);`

Sets the source address from which pings will be sent. This must be the address of one of the interfaces on the local host. `$local_addr` may be specified as a hostname or as a text IP address such as "192.168.1.1".

If the protocol is set to "tcp", this method may be called any number of times, and each call to the

`ping()` method (below) will use the most recent `$local_addr`. If the protocol is "icmp" or "udp", then `bind()` must be called at most once per object, and (if it is called at all) must be called before the first call to `ping()` for that object.

`$p-open($host);`

When you are using the stream protocol, this call pre-opens the tcp socket. It's only necessary to do this if you want to provide a different timeout when creating the connection, or remove the overhead of establishing the connection from the first ping. If you don't call `open()`, the connection is automatically opened the first time `ping()` is called. This call simply does nothing if you are using any protocol other than stream.

`$p-close();`

Close the network connection for this ping object. The network connection is also closed by "undef `$p`". The network connection is automatically closed if the ping object goes out of scope (e.g. `$p` is local to a subroutine and you leave the subroutine).

`pingecho($host [, $timeout]);`

To provide backward compatibility with the previous version of Net::Ping, a `pingecho()` subroutine is available with the same functionality as before. `pingecho()` uses the tcp protocol. The return values and parameters are the same as described for the `ping()` method. This subroutine is obsolete and may be removed in a future version of Net::Ping.

## WARNING

`pingecho()` or a ping object with the tcp protocol use `alarm()` to implement the timeout. So, don't use `alarm()` in your program while you are using `pingecho()` or a ping object with the tcp protocol. The udp and icmp protocols do not use `alarm()` to implement the timeout.

## NOTES

There will be less network overhead (and some efficiency in your program) if you specify either the udp or the icmp protocol. The tcp protocol will generate 2.5 times or more traffic for each ping than either udp or icmp. If many hosts are pinged frequently, you may wish to implement a small wait (e.g. 25ms or more) between each ping to avoid flooding your network with packets.

The icmp protocol requires that the program be run as root or that it be setuid to root. The other protocols do not require special privileges, but not all network devices implement tcp or udp echo.

Local hosts should normally respond to pings within milliseconds. However, on a very congested network it may take up to 3 seconds or longer to receive an echo packet from the remote host. If the timeout is set too low under these conditions, it will appear that the remote host is not reachable (which is almost the truth).

Reachability doesn't necessarily mean that the remote host is actually functioning beyond its ability to echo packets. tcp is slightly better at indicating the health of a system than icmp because it uses more of the networking stack to respond.

Because of a lack of anything better, this module uses its own routines to pack and unpack ICMP packets. It would be better for a separate module to be written which understands all of the different kinds of ICMP packets.

## INSTALL

The latest source tree is available via cvs:

```
cvs -z3 -q -d :pserver:anonymous@cvs.roobik.com.: /usr/local/cvsroot/freeware co Net
cd Net-Ping
```

The tarball can be created as follows:

```
perl Makefile.PL ; make ; make dist
```

The latest Net::Ping release can be found at CPAN:

```
$CPAN/modules/by-module/Net/
```

1) Extract the tarball

```
gtar -zxvf Net-Ping-xxxx.tar.gz
cd Net-Ping-xxxx
```

2) Build:

```
make realclean
perl Makefile.PL
make
make test
```

3) Install

```
make install
```

Or install it RPM Style:

```
rpm -ta SOURCES/Net-Ping-xxxx.tar.gz
rpm -ih RPMS/noarch/perl-Net-Ping-xxxx.rpm
```

## NAME

Net::POP3 – Post Office Protocol 3 Client class (RFC1939)

## SYNOPSIS

```
use Net::POP3;

Constructors
$pop = Net::POP3->new('pop3host');
$pop = Net::POP3->new('pop3host', Timeout => 60);
```

## DESCRIPTION

This module implements a client interface to the POP3 protocol, enabling a perl5 application to talk to POP3 servers. This documentation assumes that you are familiar with the POP3 protocol described in RFC1939.

A new Net::POP3 object must be created with the *new* method. Once this has been done, all POP3 commands are accessed via method calls on the object.

## EXAMPLES

Need some small examples in here :-)

## CONSTRUCTOR

`new ( [ HOST, ] [ OPTIONS ] )`

This is the constructor for a new Net::POP3 object. HOST is the name of the remote host to which a POP3 connection is required.

If HOST is not given, then the POP3\_Host specified in Net::Config will be used.

OPTIONS are passed in a hash like fashion, using key and value pairs. Possible options are:

**ResvPort** – If given then the socket for the Net::POP3 object will be bound to the local port given using *bind* when the socket is created.

**Timeout** – Maximum time, in seconds, to wait for a response from the POP3 server (default: 120)

**Debug** – Enable debugging information

## METHODS

Unless otherwise stated all methods return either a *true* or *false* value, with *true* meaning that the operation was a success. When a method states that it returns a value, failure will be returned as *undef* or an empty list.

`user ( USER )`

Send the USER command.

`pass ( PASS )`

Send the PASS command. Returns the number of messages in the mailbox.

`login ( [ USER [, PASS ] ] )`

Send both the USER and PASS commands. If PASS is not given the Net::POP3 uses Net::Netrc to lookup the password using the host and username. If the username is not specified then the current user name will be used.

Returns the number of messages in the mailbox. However if there are no messages on the server the string "0E0" will be returned. This will give a true value in a boolean context, but zero in a numeric context.

If there was an error authenticating the user then *undef* will be returned.

`apop ( [ USER [, PASS ] ] )`

Authenticate with the server identifying as USER with password PASS. Similar to *login*, but the password is not sent in clear text.

To use this method you must have the `Digest::MD5` or the `MD5` module installed, otherwise this method will return *undef*.

`top ( MSGNUM [, NUMLINES ] )`

Get the header and the first `NUMLINES` of the body for the message `MSGNUM`. Returns a reference to an array which contains the lines of text read from the server.

`list ( [ MSGNUM ] )`

If called with an argument the `list` returns the size of the message in octets.

If called without arguments a reference to a hash is returned. The keys will be the `MSGNUM`'s of all undeleted messages and the values will be their size in octets.

`get ( MSGNUM [, FH ] )`

Get the message `MSGNUM` from the remote mailbox. If `FH` is not given then `get` returns a reference to an array which contains the lines of text read from the server. If `FH` is given then the lines returned from the server are printed to the filehandle `FH`.

`getfh ( MSGNUM )`

As per `get ( )`, but returns a tied filehandle. Reading from this filehandle returns the requested message. The filehandle will return EOF at the end of the message and should not be reused.

`last ( )`

Returns the highest `MSGNUM` of all the messages accessed.

`popstat ( )`

Returns a list of two elements. These are the number of undeleted elements and the size of the mbox in octets.

`ping ( USER )`

Returns a list of two elements. These are the number of new messages and the total number of messages for `USER`.

`uidl ( [ MSGNUM ] )`

Returns a unique identifier for `MSGNUM` if given. If `MSGNUM` is not given `uidl` returns a reference to a hash where the keys are the message numbers and the values are the unique identifiers.

`delete ( MSGNUM )`

Mark message `MSGNUM` to be deleted from the remote mailbox. All messages that are marked to be deleted will be removed from the remote mailbox when the server connection closed.

`reset ( )`

Reset the status of the remote POP3 server. This includes resetting the status of all messages to not be deleted.

`quit ( )`

Quit and close the connection to the remote POP3 server. Any messages marked as deleted will be deleted from the remote mailbox.

## NOTES

If a `Net::POP3` object goes out of scope before `quit` method is called then the `reset` method will be called before the connection is closed. This means that any messages marked to be deleted will not be.

*\$Id: //depot/libnet/Net/POP3.pm#22 \$*

## NAME

Net::protoent – by-name interface to Perl's built-in `getproto*` () functions

## SYNOPSIS

```
use Net::protoent;
$p = getprotobyname(shift || 'tcp') || die "no proto";
printf "proto for %s is %d, aliases are %s\n",
 $p->name, $p->proto, "@{$p->aliases}";

use Net::protoent qw(:FIELDS);
getprotobyname(shift || 'tcp') || die "no proto";
print "proto for $p_name is $p_proto, aliases are @p_aliases\n";
```

## DESCRIPTION

This module's default exports override the core `getprotoent()`, `getprotobyname()`, and `getnetbyport()` functions, replacing them with versions that return "Net::protoent" objects. They take default second arguments of "tcp". This object has methods that return the similarly named structure field name from the C's protoent structure from *netdb.h*; namely `name`, `aliases`, and `proto`. The `aliases` method returns an array reference, the rest scalars.

You may also import all the structure fields directly into your namespace as regular variables using the `:FIELDS` import tag. (Note that this still overrides your core functions.) Access these fields as variables named with a preceding `p_`. Thus, `$proto_obj->name()` corresponds to `$p_name` if you import the fields. Array references are available as regular array variables, so for example `@{$proto_obj->aliases() }` would be simply `@p_aliases`.

The `getproto()` function is a simple front-end that forwards a numeric argument to `getprotobyport()`, and the rest to `getprotobyname()`.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. On the other hand, the built-ins are still available via the `CORE::` pseudo-package.

## NOTE

While this class is currently implemented using the `Class::Struct` module to build a struct-like class, you shouldn't rely upon this.

## AUTHOR

Tom Christiansen

**NAME**

Net::servent – by-name interface to Perl's built-in `getserv*()` functions

**SYNOPSIS**

```
use Net::servent;
$s = getservbyname(shift || 'ftp') || die "no service";
printf "port for %s is %s, aliases are %s\n",
 $s->name, $s->port, "@{$s->aliases}";

use Net::servent qw(:FIELDS);
getservbyname(shift || 'ftp') || die "no service";
print "port for $s_name is $s_port, aliases are @s_aliases\n";
```

**DESCRIPTION**

This module's default exports override the core `getservent()`, `getservbyname()`, and `getnetbyport()` functions, replacing them with versions that return "Net::servent" objects. They take default second arguments of "tcp". This object has methods that return the similarly named structure field name from the C's servent structure from *netdb.h*; namely name, aliases, port, and proto. The aliases method returns an array reference, the rest scalars.

You may also import all the structure fields directly into your namespace as regular variables using the `:FIELDS` import tag. (Note that this still overrides your core functions.) Access these fields as variables named with a preceding `n_`. Thus, `$serv_obj->name()` corresponds to `$s_name` if you import the fields. Array references are available as regular array variables, so for example `@{$serv_obj->aliases() }` would be simply `@s_aliases`.

The `getserv()` function is a simple front-end that forwards a numeric argument to `getnetbyport()`, and the rest to `getservbyname()`.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. On the other hand, the built-ins are still available via the `CORE::` pseudo-package.

**EXAMPLES**

```
use Net::servent qw(:FIELDS);

while (@ARGV) {
 my ($service, $proto) = ((split m!/!, shift), 'tcp');
 my $valet = getserv($service, $proto);
 unless ($valet) {
 warn "$0: No service: $service/$proto\n";
 next;
 }
 printf "service $service/$proto is port %d\n", $valet->port;
 print "alias are @s_aliases\n" if @s_aliases;
}
```

**NOTE**

While this class is currently implemented using the `Class::Struct` module to build a struct-like class, you shouldn't rely upon this.

## NAME

Net::SMTP – Simple Mail Transfer Protocol Client

## SYNOPSIS

```
use Net::SMTP;

Constructors
$smtp = Net::SMTP->new('mailhost');
$smtp = Net::SMTP->new('mailhost', Timeout => 60);
```

## DESCRIPTION

This module implements a client interface to the SMTP and ESMTP protocol, enabling a perl5 application to talk to SMTP servers. This documentation assumes that you are familiar with the concepts of the SMTP protocol described in RFC821.

A new Net::SMTP object must be created with the *new* method. Once this has been done, all SMTP commands are accessed through this object.

The Net::SMTP class is a subclass of Net::Cmd and IO::Socket::INET.

## EXAMPLES

This example prints the mail domain name of the SMTP server known as mailhost:

```
#!/usr/local/bin/perl -w

use Net::SMTP;

$smtp = Net::SMTP->new('mailhost');
print $smtp->domain, "\n";
$smtp->quit;
```

This example sends a small message to the postmaster at the SMTP server known as mailhost:

```
#!/usr/local/bin/perl -w

use Net::SMTP;

$smtp = Net::SMTP->new('mailhost');

$smtp->mail($ENV{USER});
$smtp->to('postmaster');

$smtp->data();
$smtp->datasend("To: postmaster\n");
$smtp->datasend("\n");
$smtp->datasend("A simple test message\n");
$smtp->dataend();

$smtp->quit;
```

## CONSTRUCTOR

**new** Net::SMTP [ HOST, ] [ OPTIONS ]

This is the constructor for a new Net::SMTP object. HOST is the name of the remote host to which an SMTP connection is required.

If HOST is not given, then the SMTP\_Host specified in Net::Config will be used.

OPTIONS are passed in a hash like fashion, using key and value pairs. Possible options are:

**Hello** – SMTP requires that you identify yourself. This option specifies a string to pass as your mail domain. If not given a guess will be taken.

**LocalAddr** and **LocalPort** – These parameters are passed directly to IO::Socket to allow binding the

socket to a local port.

**Timeout** – Maximum time, in seconds, to wait for a response from the SMTP server (default: 120)

**Debug** – Enable debugging information

Example:

```
$smtp = Net::SMTP->new('mailhost',
 Hello => 'my.mail.domain',
 Timeout => 30,
 Debug => 1,
);
```

## METHODS

Unless otherwise stated all methods return either a *true* or *false* value, with *true* meaning that the operation was a success. When a method states that it returns a value, failure will be returned as *undef* or an empty list.

**banner ( )**

Returns the banner message which the server replied with when the initial connection was made.

**domain ( )**

Returns the domain that the remote SMTP server identified itself as during connection.

**hello ( DOMAIN )**

Tell the remote server the mail domain which you are in using the EHLO command (or HELO if EHLO fails). Since this method is invoked automatically when the Net::SMTP object is constructed the user should normally not have to call it manually.

**etrn ( DOMAIN )**

Request a queue run for the DOMAIN given.

**auth ( USERNAME, PASSWORD )**

Attempt SASL authentication.

**mail ( ADDRESS [, OPTIONS] )**

**send ( ADDRESS )**

**send\_or\_mail ( ADDRESS )**

**send\_and\_mail ( ADDRESS )**

Send the appropriate command to the server MAIL, SEND, SOML or SAML. ADDRESS is the address of the sender. This initiates the sending of a message. The method *recipient* should be called for each address that the message is to be sent to.

The mail method can some additional ESMTP OPTIONS which is passed in hash like fashion, using key and value pairs. Possible options are:

```
Size => <bytes>
Return => <??>
Bits => "7" | "8"
Transaction => <ADDRESS>
Envelope => <ENVID>
```

**reset ( )**

Reset the status of the server. This may be called after a message has been initiated, but before any data has been sent, to cancel the sending of the message.

**recipient ( ADDRESS [, ADDRESS [ ...]] [, OPTIONS] )**

Notify the server that the current message should be sent to all of the addresses given. Each address is sent as a separate command to the server. Should the sending of any address result in a failure then the process is aborted and a *false* value is returned. It is up to the user to call *reset* if they so desire.

The `recipient` method can some additional `OPTIONS` which is passed in hash like fashion, using key and value pairs. Possible options are:

```
Notify =>
SkipBad => ignore bad addresses
```

If `SkipBad` is true the `recipient` will not return an error when a bad address is encountered and it will return an array of addresses that did succeed.

```
$smtp->recipient($recipient1,$recipient2); # Good
$smtp->recipient($recipient1,$recipient2, { SkipBad => 1 }); # Good
$smtp->recipient("$recipient,$recipient2"); # BAD
```

```
to (ADDRESS [, ADDRESS [...]])
cc (ADDRESS [, ADDRESS [...]])
bcc (ADDRESS [, ADDRESS [...]])
```

Synonyms for `recipient`.

```
data ([DATA])
```

Initiate the sending of the data from the current message.

`DATA` may be a reference to a list or a list. If specified the contents of `DATA` and a termination string `".\r\n"` is sent to the server. And the result will be true if the data was accepted.

If `DATA` is not specified then the result will indicate that the server wishes the data to be sent. The data must then be sent using the `datasend` and `dataend` methods described in [Net::Cmd](#).

```
expand (ADDRESS)
```

Request the server to expand the given address Returns an array which contains the text read from the server.

```
verify (ADDRESS)
```

Verify that `ADDRESS` is a legitimate mailing address.

```
help ([$subject])
```

Request help text from the server. Returns the text or undef upon failure

```
quit ()
```

Send the `QUIT` command to the remote SMTP server and close the socket connection.

## ADDRESSES

All methods that accept addresses expect the address to be a valid rfc2821-quoted address, although `Net::SMTP` will accept accept the address surrounded by angle brackets.

```
funny user@domain WRONG
"funny user"@domain RIGHT, recommended
<"funny user"@domain> OK
```

`$Id: //depot/libnet/Net/SMTP.pm#25 $`

**NAME**

Net::Time – time and daytime network client interface

**SYNOPSIS**

```
use Net::Time qw(inet_time inet_daytime);

print inet_time(); # use default host from Net::Config
print inet_time('localhost');
print inet_time('localhost', 'tcp');

print inet_daytime(); # use default host from Net::Config
print inet_daytime('localhost');
print inet_daytime('localhost', 'tcp');
```

**DESCRIPTION**

Net::Time provides subroutines that obtain the time on a remote machine.

`inet_time ( [HOST [, PROTOCOL [, TIMEOUT]]])`

Obtain the time on `HOST`, or some default host if `HOST` is not given or not defined, using the protocol as defined in RFC868. The optional argument `PROTOCOL` should define the protocol to use, either `tcp` or `udp`. The result will be a time value in the same units as returned by `time()` or *undef* upon failure.

`inet_daytime ( [HOST [, PROTOCOL [, TIMEOUT]]])`

Obtain the time on `HOST`, or some default host if `HOST` is not given or not defined, using the protocol as defined in RFC867. The optional argument `PROTOCOL` should define the protocol to use, either `tcp` or `udp`. The result will be an ASCII string or *undef* upon failure.

*\$Id: //depot/libnet/Net/Time.pm#9 \$*

**NAME**

NEXT.pm – Provide a pseudo-class NEXT that allows method redispatch

**SYNOPSIS**

```
use NEXT;

package A;
sub A::method { print "$_[0]: A method\n"; $_[0]->NEXT::method() }
sub A::DESTROY { print "$_[0]: A dtor\n"; $_[0]->NEXT::DESTROY() }

package B;
use base qw(A);
sub B::AUTOLOAD { print "$_[0]: B AUTOLOAD\n"; $_[0]->NEXT::AUTOLOAD() }
sub B::DESTROY { print "$_[0]: B dtor\n"; $_[0]->NEXT::DESTROY() }

package C;
sub C::method { print "$_[0]: C method\n"; $_[0]->NEXT::method() }
sub C::AUTOLOAD { print "$_[0]: C AUTOLOAD\n"; $_[0]->NEXT::AUTOLOAD() }
sub C::DESTROY { print "$_[0]: C dtor\n"; $_[0]->NEXT::DESTROY() }

package D;
use base qw(B C);
sub D::method { print "$_[0]: D method\n"; $_[0]->NEXT::method() }
sub D::AUTOLOAD { print "$_[0]: D AUTOLOAD\n"; $_[0]->NEXT::AUTOLOAD() }
sub D::DESTROY { print "$_[0]: D dtor\n"; $_[0]->NEXT::DESTROY() }

package main;

my $obj = bless {}, "D";

$obj->method(); # Calls D::method, A::method, C::method
$obj->missing_method(); # Calls D::AUTOLOAD, B::AUTOLOAD, C::AUTOLOAD

Clean-up calls D::DESTROY, B::DESTROY, A::DESTROY, C::DESTROY
```

**DESCRIPTION**

NEXT.pm adds a pseudoclass named NEXT to any program that uses it. If a method `m` calls `$self-NEXT::m()`, the call to `m` is redispatched as if the calling method had not originally been found.

In other words, a call to `$self-NEXT::m()` resumes the depth-first, left-to-right search of `$self`'s class hierarchy that resulted in the original call to `m`.

Note that this is not the same thing as `$self-SUPER::m()`, which begins a new dispatch that is restricted to searching the ancestors of the current class. `$self-NEXT::m()` can backtrack past the current class — to look for a suitable method in other ancestors of `$self` — whereas `$self-SUPER::m()` cannot.

A typical use would be in the destructors of a class hierarchy, as illustrated in the synopsis above. Each class in the hierarchy has a DESTROY method that performs some class-specific action and then redispatches the call up the hierarchy. As a result, when an object of class D is destroyed, the destructors of *all* its parent classes are called (in depth-first, left-to-right order).

Another typical use of redispatch would be in AUTOLOAD'ed methods. If such a method determined that it was not able to handle a particular call, it might choose to redispatch that call, in the hope that some other AUTOLOAD (above it, or to its left) might do better.

By default, if a redispatch attempt fails to find another method elsewhere in the objects class hierarchy, it quietly gives up and does nothing (but see *"Enforcing redispatch"*). This gracious acquiescence is also unlike the (generally annoying) behaviour of SUPER, which throws an exception if it cannot redispatch.

Note that it is a fatal error for any method (including AUTOLOAD) to attempt to redispatch any method that does not have the same name. For example:

```
sub D::oops { print "oops!\n"; $_[0]->NEXT::other_method() }
```

### Enforcing redispach

It is possible to make NEXT redispach more demandingly (i.e. like SUPER does), so that the redispach throws an exception if it cannot find a "next" method to call.

To do this, simply invoke the redispach as:

```
$self->NEXT::ACTUAL::method();
```

rather than:

```
$self->NEXT::method();
```

The ACTUAL tells NEXT that there must actually be a next method to call, or it should throw an exception.

NEXT::ACTUAL is most commonly used in AUTOLOAD methods, as a means to decline an AUTOLOAD request, but preserve the normal exception-on-failure semantics:

```
sub AUTOLOAD {
 if ($AUTOLOAD =~ /foo|bar/) {
 # handle here
 }
 else { # try elsewhere
 shift->NEXT::ACTUAL::AUTOLOAD(@_);
 }
}
```

By using NEXT::ACTUAL, if there is no other AUTOLOAD to handle the method call, an exception will be thrown (as usually happens in the absence of a suitable AUTOLOAD).

### Avoiding repetitions

If NEXT redispaching is used in the methods of a "diamond" class hierarchy:

```
A B
/ \ /
C D
\ /
E

use NEXT;

package A;
sub foo { print "called A::foo\n"; shift->NEXT::foo() }

package B;
sub foo { print "called B::foo\n"; shift->NEXT::foo() }

package C; @ISA = qw(A);
sub foo { print "called C::foo\n"; shift->NEXT::foo() }

package D; @ISA = qw(A B);
sub foo { print "called D::foo\n"; shift->NEXT::foo() }

package E; @ISA = qw(C D);
sub foo { print "called E::foo\n"; shift->NEXT::foo() }

E->foo();
```

then derived classes may (re-)inherit base-class methods through two or more distinct paths (e.g. in the way E inherits A::foo twice — through C and D). In such cases, a sequence of NEXT redispaches will invoke the multiply inherited method as many times as it is inherited. For example, the above code prints:

```
called E::foo
```

```
called C::foo
called A::foo
called D::foo
called A::foo
called B::foo
```

(i.e. `A::foo` is called twice).

In some cases this *may* be the desired effect within a diamond hierarchy, but in others (e.g. for destructors) it may be more appropriate to call each method only once during a sequence of redispaches.

To cover such cases, you can redispach methods via:

```
$self->NEXT::UNSEEN::method();
```

rather than:

```
$self->NEXT::method();
```

This causes the dispatcher to skip any classes in the hierarchy that it has already visited in an earlier redispach. So, for example, if the previous example were rewritten:

```
package A;
sub foo { print "called A::foo\n"; shift->NEXT::UNSEEN::foo() }

package B;
sub foo { print "called B::foo\n"; shift->NEXT::UNSEEN::foo() }

package C; @ISA = qw(A);
sub foo { print "called C::foo\n"; shift->NEXT::UNSEEN::foo() }

package D; @ISA = qw(A B);
sub foo { print "called D::foo\n"; shift->NEXT::UNSEEN::foo() }

package E; @ISA = qw(C D);
sub foo { print "called E::foo\n"; shift->NEXT::UNSEEN::foo() }

E->foo();
```

then it would print:

```
called E::foo
called C::foo
called A::foo
called D::foo
called B::foo
```

and omit the second call to `A::foo`.

Note that you can also use:

```
$self->NEXT::UNSEEN::ACTUAL::method();
```

or:

```
$self->NEXT::ACTUAL::UNSEEN::method();
```

to get both unique invocation *and* exception-on-failure.

## AUTHOR

Damian Conway (damian@conway.org)

## BUGS AND IRRITATIONS

Because it's a module, not an integral part of the interpreter, NEXT.pm has to guess where the surrounding call was found in the method look-up sequence. In the presence of diamond inheritance patterns it occasionally guesses wrong.

It's also too slow (despite caching).

Comment, suggestions, and patches welcome.

and/or modified under the same terms as Perl itself.

**NAME**

Opcode – Disable named opcodes when compiling perl code

**SYNOPSIS**

```
use Opcode;
```

**DESCRIPTION**

Perl code is always compiled into an internal format before execution.

Evaluating perl code (e.g. via "eval" or "do 'file'") causes the code to be compiled into an internal format and then, provided there was no error in the compilation, executed. The internal format is based on many distinct *opcodes*.

By default no opmask is in effect and any code can be compiled.

The Opcode module allow you to define an *operator mask* to be in effect when perl *next* compiles any code. Attempting to compile code which contains a masked opcode will cause the compilation to fail with an error. The code will not be executed.

**NOTE**

The Opcode module is not usually used directly. See the ops pragma and Safe modules for more typical uses.

**WARNING**

The authors make **no warranty**, implied or otherwise, about the suitability of this software for safety or security purposes.

The authors shall not in any case be liable for special, incidental, consequential, indirect or other similar damages arising from the use of this software.

Your mileage will vary. If in any doubt **do not use it**.

**Operator Names and Operator Lists**

The canonical list of operator names is the contents of the array `PL_op_name` defined and initialised in file *opcode.h* of the Perl source distribution (and installed into the perl library).

Each operator has both a terse name (its *opname*) and a more verbose or recognisable descriptive name. The *opdesc* function can be used to return a list of descriptions for a list of operators.

Many of the functions and methods listed below take a list of operators as parameters. Most operator lists can be made up of several types of element. Each element can be one of

an operator name (*opname*)

Operator names are typically small lowercase words like *enterloop*, *leaveloop*, *last*, *next*, *redo* etc. Sometimes they are rather cryptic like *gv2cv*, *i\_ncmp* and *ftsctx*.

an operator tag name (*optag*)

Operator tags can be used to refer to groups (or sets) of operators. Tag names always begin with a colon. The Opcode module defines several *optags* and the user can define others using the *define\_optag* function.

a negated *opname* or *optag*

An *opname* or *optag* can be prefixed with an exclamation mark, e.g., *!mkdir*. Negating an *opname* or *optag* means remove the corresponding ops from the accumulated set of ops at that point.

an operator set (*opset*)

An *opset* as a binary string of approximately 44 bytes which holds a set or zero or more operators.

The `opset` and `opset_to_ops` functions can be used to convert from a list of operators to an opset and *vice versa*.

Wherever a list of operators can be given you can use one or more opsets. See also Manipulating Opsets below.

## Opcode Functions

The Opcode package contains functions for manipulating operator names tags and sets. All are available for export by the package.

**opcodes** In a scalar context `opcodes` returns the number of opcodes in this version of perl (around 350 for perl-5.7.0).

In a list context it returns a list of all the operator names. (Not yet implemented, use `@names = opset_to_ops(full_opset)`.)

**opset (OP, ...)**

Returns an opset containing the listed operators.

**opset\_to\_ops (OPSET)**

Returns a list of operator names corresponding to those operators in the set.

**opset\_to\_hex (OPSET)**

Returns a string representation of an opset. Can be handy for debugging.

**full\_opset** Returns an opset which includes all operators.

**empty\_opset**

Returns an opset which contains no operators.

**invert\_opset (OPSET)**

Returns an opset which is the inverse set of the one supplied.

**verify\_opset (OPSET, ...)**

Returns true if the supplied opset looks like a valid opset (is the right length etc) otherwise it returns false. If an optional second parameter is true then `verify_opset` will croak on an invalid opset instead of returning false.

Most of the other Opcode functions call `verify_opset` automatically and will croak if given an invalid opset.

**define\_optag (OPTAG, OPSET)**

Define OPTAG as a symbolic name for OPSET. Optag names always start with a colon :.

The optag name used must not be defined already (`define_optag` will croak if it is already defined). Optag names are global to the perl process and optag definitions cannot be altered or deleted once defined.

It is strongly recommended that applications using Opcode should use a leading capital letter on their tag names since lowercase names are reserved for use by the Opcode module. If using Opcode within a module you should prefix your tags names with the name of your module to ensure uniqueness and thus avoid clashes with other modules.

**opmask\_add (OPSET)**

Adds the supplied opset to the current opmask. Note that there is currently *no* mechanism for unmasking ops once they have been masked. This is intentional.

**opmask** Returns an opset corresponding to the current opmask.

**opdesc (OP, ...)**

This takes a list of operator names and returns the corresponding list of operator descriptions.

**opdump (PAT)**

Dumps to STDOUT a two column list of op names and op descriptions. If an optional pattern is given then only lines which match the (case insensitive) pattern will be output.

It's designed to be used as a handy command line utility:

```
perl -MOpc=opdump -e opdump
perl -MOpc=opdump -e 'opdump Eval'
```

**Manipulating Opsets**

Opsets may be manipulated using the perl bit vector operators & (and), | (or), ^ (xor) and ~ (negate/invert).

However you should never rely on the numerical position of any opcode within the opset. In other words both sides of a bit vector operator should be opsets returned from Opcode functions.

Also, since the number of opcodes in your current version of perl might not be an exact multiple of eight, there may be unused bits in the last byte of an opset. This should not cause any problems (Opcode functions ignore those extra bits) but it does mean that using the ~ operator will typically not produce the same 'physical' opset 'string' as the invert\_opset function.

**TO DO (maybe)**

```
$bool = opset_eq($opset1, $opset2) true if opsets are logically equiv
$yes = opset_can($opset, @ops) true if $opset has all @ops set
@diff = opset_diff($opset1, $opset2) => ('foo', '!bar', ...)
```

**Predefined Opcode Tags**

:base\_core

```
null stub scalar pushmark wantarray const defined undef
rv2sv sassign
rv2av aassign aelem aelemfast aslice av2arylen
rv2hv helem hslice each values keys exists delete
preinc i_preinc predec i_predec postinc i_postinc postdec i_postdec
int hex oct abs pow multiply i_multiply divide i_divide
modulo i_modulo add i_add subtract i_subtract
left_shift right_shift bit_and bit_xor bit_or negate i_negate
not complement
lt i_lt gt i_gt le i_le ge i_ge eq i_eq ne i_nencmp i_ncmp
slt sgt sle sge seq sne scmp
substr vec stringify study pos length index rindex ord chr
ucfirst lcfirst uc lc quotemeta trans chop schop chomp schomp
match split qr
list lslice splice push pop shift unshift reverse
cond_expr flip flop andassign orassign and or xor
warn die lineseq nextstate scope enter leave setstate
rv2cv anoncode prototype
entersub leavesub leavesublv return method method_named -- XXX loops via rec
leaveeval -- needed for Safe to operate, is safe without entereval
```

**:base\_mem**

These memory related ops are not included in :base\_core because they can easily be used to implement a resource attack (e.g., consume all available memory).

concat repeat join range

anonlist anonhash

Note that despite the existence of this optag a memory resource attack may still be possible using only :base\_core ops.

Disabling these ops is a *very* heavy handed way to attempt to prevent a memory resource attack. It's probable that a specific memory limit mechanism will be added to perl in the near future.

**:base\_loop**

These loop ops are not included in :base\_core because they can easily be used to implement a resource attack (e.g., consume all available CPU time).

grepstart grepwhile  
mapstart mapwhile  
enteriter iter  
enterloop leaveloop unstack  
last next redo  
goto

**:base\_io**

These ops enable *filehandle* (rather than filename) based input and output. These are safe on the assumption that only pre-existing filehandles are available for use. To create new filehandles other ops such as open would need to be enabled.

readline rcatline getc read  
formline enterwrite leavewrite  
print sysread syswrite send recv  
eof tell seek sysseek  
readdir telldir seekdir rewinddir

**:base\_orig**

These are a hotchpotch of opcodes still waiting to be considered

gvsv gv gelem  
padsv padav padhv padany  
rv2gv refgen srefgen ref  
bless -- could be used to change ownership of objects (reblessing)  
pushre regcmaybe regcreset regcomp subst substcont  
sprintf prtf -- can core dump  
crypt  
tie untie  
dbmopen dbmclose  
sselect select  
pipe\_op sockpair  
getppid getpgrp setpgrp getpriority setpriority localtime gmtime

entertry leavetry -- can be used to 'hide' fatal errors

custom -- where should this go

#### :base\_math

These ops are not included in :base\_core because of the risk of them being used to generate floating point exceptions (which would have to be caught using a \$SIG{FPE} handler).

atan2 sin cos exp log sqrt

These ops are not included in :base\_core because they have an effect beyond the scope of the compartment.

rand srand

#### :base\_thread

These ops are related to multi-threading.

lock threadsv

#### :default

A handy tag name for a *reasonable* default set of ops. (The current ops allowed are unstable while development continues. It will change.)

:base\_core :base\_mem :base\_loop :base\_io :base\_orig :base\_thread

If safety matters to you (and why else would you be using the Opcode module?) then you should not rely on the definition of this, or indeed any other, optag!

#### :filesystem\_read

stat lstat readlink

ftatime ftblk ftchr ftctime ftdir fteexec fteowned fteread  
ftewrite ftfile ftis ftlink ftmtime ftpipe ftrexec ftrowned

fttext ftbinary

fileno

#### :sys\_db

|                                                   |              |
|---------------------------------------------------|--------------|
| ghbyname ghbyaddr ghostent shostent ehostent      | -- hosts     |
| gnbyname gnbyaddr gnetent snetent enetent         | -- networks  |
| gpbyname gpbynumber gprotoent sprotoent eprotoent | -- protocols |
| gsbyname gsbyport gservent sservent eservent      | -- services  |
| gpwnam gpwuid gpwent spwent epwent getlogin       | -- users     |
| ggrnam ggrgid ggrent sgrent egrent                | -- groups    |

#### :browse

A handy tag name for a *reasonable* default set of ops beyond the :default optag. Like :default (and indeed all the other optags) its current definition is unstable while development continues. It will change.

The :browse tag represents the next step beyond :default. It is a superset of the :default ops and adds :filesystem\_read the :sys\_db. The intent being that scripts can access more (possibly sensitive) information about your system but not be able to change it.

:default :filesystem\_read :sys\_db

#### :filesystem\_open

sysopen open close  
umask binmode

```

 open_dir closedir -- other dir ops are in :base_io
:fileys_write
 link unlink rename symlink truncate
 mkdir rmdir
 utime chmod chown
 fcntl -- not strictly fileys related, but possibly as dangerous?
:subprocess
 backtick system
 fork
 wait waitpid
 glob -- access to Cshell via <'rm *'>
:ownprocess
 exec exit kill
 time tms -- could be used for timing attacks (paranoid?)
:others
 This tag holds groups of assorted specialist opcodes that don't warrant having optags defined for
 them.
 SystemV Interprocess Communications:
 msgctl msgget msgrcv msgsnd
 semctl semget semop
 shmctl shmget shmread shmwrite
:still_to_be_decided
 chdir
 flock ioctl
 socket getpeername sockopt
 bind connect listen accept shutdown gsockopt getsockname
 sleep alarm -- changes global timer state and signal handling
 sort -- assorted problems including core dumps
 tied -- can be used to access object implementing a tie
 pack unpack -- can be used to create/use memory pointers
 entereval -- can be used to hide code from initial compile
 require dofile
 caller -- get info about calling environment and args
 reset
 dbstate -- perl -d version of nextstate(ment) opcode
:dangerous
 This tag is simply a bucket for opcodes that are unlikely to be used via a tag name but need to be
 tagged for completeness and documentation.
 syscall dump chroot

```

**SEE ALSO**

ops(3) — perl pragma interface to Opcode module.

Safe(3) — Opcode and namespace limited execution compartments

**AUTHORS**

Originally designed and implemented by Malcolm Beattie, mbeattie@sable.ox.ac.uk as part of Safe version 1.

Split out from Safe module version 1, named opcode tags and other changes added by Tim Bunce.

**NAME**

ops – Perl pragma to restrict unsafe operations when compiling

**SYNOPSIS**

```
perl -Mops=:default ... # only allow reasonably safe operations
perl -M-ops=system ... # disable the 'system' opcode
```

**DESCRIPTION**

Since the ops pragma currently has an irreversible global effect, it is only of significant practical use with the `-M` option on the command line.

See the [Opcode](#) module for information about opcodes, optags, opmasks and important information about safety.

**SEE ALSO**

Opcode(3), Safe(3), perlrun(3)

## NAME

Safe – Compile and execute code in restricted compartments

## SYNOPSIS

```
use Safe;

$compartment = new Safe;

$compartment->permit(qw(time sort :browse));

$result = $compartment->reval($unsafe_code);
```

## DESCRIPTION

The Safe extension module allows the creation of compartments in which perl code can be evaluated. Each compartment has

### a new namespace

The "root" of the namespace (i.e. "main::") is changed to a different package and code evaluated in the compartment cannot refer to variables outside this namespace, even with run-time glob lookups and other tricks.

Code which is compiled outside the compartment can choose to place variables into (or *share* variables with) the compartment's namespace and only that data will be visible to code evaluated in the compartment.

By default, the only variables shared with compartments are the "underscore" variables `$_` and `@_` (and, technically, the less frequently used `%_`, the `_` filehandle and so on). This is because otherwise perl operators which default to `$_` will not work and neither will the assignment of arguments to `@_` on subroutine entry.

### an operator mask

Each compartment has an associated "operator mask". Recall that perl code is compiled into an internal format before execution. Evaluating perl code (e.g. via "eval" or "do 'file'") causes the code to be compiled into an internal format and then, provided there was no error in the compilation, executed. Code evaluated in a compartment compiles subject to the compartment's operator mask. Attempting to evaluate code in a compartment which contains a masked operator will cause the compilation to fail with an error. The code will not be executed.

The default operator mask for a newly created compartment is the `':default'` optag.

It is important that you read the Opcode(3) module documentation for more information, especially for detailed definitions of opnames, optags and opsets.

Since it is only at the compilation stage that the operator mask applies, controlled access to potentially unsafe operations can be achieved by having a handle to a wrapper subroutine (written outside the compartment) placed into the compartment. For example,

```
$cpt = new Safe;
sub wrapper {
 # vet arguments and perform potentially unsafe operations
}
$cpt->share('&wrapper');
```

## WARNING

The authors make **no warranty**, implied or otherwise, about the suitability of this software for safety or security purposes.

The authors shall not in any case be liable for special, incidental, consequential, indirect or other similar damages arising from the use of this software.

Your mileage will vary. If in any doubt **do not use it**.

## RECENT CHANGES

The interface to the Safe module has changed quite dramatically since version 1 (as supplied with Perl5.002). Study these pages carefully if you have code written to use Safe version 1 because you will need to make changes.

## Methods in class Safe

To create a new compartment, use

```
$cpt = new Safe;
```

Optional argument is (NAMESPACE), where NAMESPACE is the root namespace to use for the compartment (defaults to "Safe::Root0", incremented for each new compartment).

Note that version 1.00 of the Safe module supported a second optional parameter, MASK. That functionality has been withdrawn pending deeper consideration. Use the permit and deny methods described below.

The following methods can then be used on the compartment object returned by the above constructor. The object argument is implicit in each case.

permit (OP, ...)

Permit the listed operators to be used when compiling code in the compartment (in *addition* to any operators already permitted).

permit\_only (OP, ...)

Permit *only* the listed operators to be used when compiling code in the compartment (*no* other operators are permitted).

deny (OP, ...)

Deny the listed operators from being used when compiling code in the compartment (other operators may still be permitted).

deny\_only (OP, ...)

Deny *only* the listed operators from being used when compiling code in the compartment (*all* other operators will be permitted).

trap (OP, ...)

untrap (OP, ...)

The trap and untrap methods are synonyms for deny and permit respectively.

share (NAME, ...)

This shares the variable(s) in the argument list with the compartment. This is almost identical to exporting variables using the [Exporter](#) module.

Each NAME must be the **name** of a variable, typically with the leading type identifier included. A bareword is treated as a function name.

Examples of legal names are '\$foo' for a scalar, '@foo' for an array, '%foo' for a hash, '&foo' or 'foo' for a subroutine and '\*foo' for a glob (i.e. all symbol table entries associated with "foo", including scalar, array, hash, sub and filehandle).

Each NAME is assumed to be in the calling package. See share\_from for an alternative method (which share uses).

share\_from (PACKAGE, ARRAYREF)

This method is similar to share () but allows you to explicitly name the package that symbols should be shared from. The symbol names (including type characters) are supplied as an array reference.

```
$safe->share_from('main', ['$foo', '%bar', 'func']);
```

**varglob (VARNAME)**

This returns a glob reference for the symbol table entry of VARNAME in the package of the compartment. VARNAME must be the **name** of a variable without any leading type marker. For example,

```
$cpt = new Safe 'Root';
$Root::foo = "Hello world";
Equivalent version which doesn't need to know $cpt's package name:
${$cpt->varglob('foo')} = "Hello world";
```

**reval (STRING)**

This evaluates STRING as perl code inside the compartment.

The code can only see the compartment's namespace (as returned by the **root** method). The compartment's root package appears to be the `main::` package to the code inside the compartment.

Any attempt by the code in STRING to use an operator which is not permitted by the compartment will cause an error (at run-time of the main program but at compile-time for the code in STRING). The error is of the form "%s trapped by operation mask operation...".

If an operation is trapped in this way, then the code in STRING will not be executed. If such a trapped operation occurs or any other compile-time or return error, then `$@` is set to the error message, just as with an `eval()`.

If there is no error, then the method returns the value of the last expression evaluated, or a return statement may be used, just as with subroutines and **eval()**. The context (list or scalar) is determined by the caller as usual.

This behaviour differs from the beta distribution of the Safe extension where earlier versions of perl made it hard to mimic the return behaviour of the `eval()` command and the context was always scalar.

Some points to note:

If the `entereval` op is permitted then the code can use `eval "..."` to 'hide' code which might use denied ops. This is not a major problem since when the code tries to execute the `eval` it will fail because the `opmask` is still in effect. However this technique would allow clever, and possibly harmful, code to 'probe' the boundaries of what is possible.

Any string eval which is executed by code executing in a compartment, or by code called from code executing in a compartment, will be eval'd in the namespace of the compartment. This is potentially a serious problem.

Consider a function `foo()` in package `pkg` compiled outside a compartment but shared with it. Assume the compartment has a root package called 'Root'. If `foo()` contains an `eval` statement like `eval '$foo = 1'` then, normally, `$pkg::foo` will be set to 1. If `foo()` is called from the compartment (by whatever means) then instead of setting `$pkg::foo`, the eval will actually set `$Root::pkg::foo`.

This can easily be demonstrated by using a module, such as the `Socket` module, which uses `eval "..."` as part of an `AUTOLOAD` function. You can 'use' the module outside the compartment and share an (autoloaded) function with the compartment. If an autoload is triggered by code in the compartment, or by any code anywhere that is called by any means from the compartment, then the `eval` in the `Socket` module's `AUTOLOAD` function happens in the namespace of the compartment. Any variables created or used by the eval'd code are now under the control of the code in the compartment.

A similar effect applies to *all* runtime symbol lookups in code called from a compartment but not compiled within it.

**rdo (FILENAME)**

This evaluates the contents of file FILENAME inside the compartment. See above documentation on the **reval** method for further details.

**root (NAMESPACE)**

This method returns the name of the package that is the root of the compartment's namespace.

Note that this behaviour differs from version 1.00 of the Safe module where the root module could be used to change the namespace. That functionality has been withdrawn pending deeper consideration.

**mask (MASK)**

This is a get-or-set method for the compartment's operator mask.

With no MASK argument present, it returns the current operator mask of the compartment.

With the MASK argument present, it sets the operator mask for the compartment (equivalent to calling the deny\_only method).

**Some Safety Issues**

This section is currently just an outline of some of the things code in a compartment might do (intentionally or unintentionally) which can have an effect outside the compartment.

**Memory** Consuming all (or nearly all) available memory.

**CPU** Causing infinite loops etc.

**Snooping** Copying private information out of your system. Even something as simple as your user name is of value to others. Much useful information could be gleaned from your environment variables for example.

**Signals** Causing signals (especially SIGFPE and SIGALARM) to affect your process.

Setting up a signal handler will need to be carefully considered and controlled. What mask is in effect when a signal handler gets called? If a user can get an imported function to get an exception and call the user's signal handler, does that user's restricted mask get re-instated before the handler is called? Does an imported handler get called with its original mask or the user's one?

**State Changes**

Ops such as chdir obviously effect the process as a whole and not just the code in the compartment. Ops such as rand and srand have a similar but more subtle effect.

**AUTHOR**

Originally designed and implemented by Malcolm Beattie, mbeattie@sable.ox.ac.uk.

Reworked to use the Opcode module and other changes added by Tim Bunce <Tim.Bunce@ig.co.uk>.

**NAME**

open – perl pragma to set default PerlIO layers for input and output

**SYNOPSIS**

```
use open IN => ":crlf", OUT => ":bytes";
use open OUT => ':utf8';
use open IO => ":encoding(iso-8859-7)";

use open IO => ':locale';

use open ':utf8';
use open ':locale';
use open ':encoding(iso-8859-7)';

use open ':std';
```

**DESCRIPTION**

Full-fledged support for I/O layers is now implemented provided Perl is configured to use PerlIO as its IO system (which is now the default).

The open pragma serves as one of the interfaces to declare default "layers" (also known as "disciplines") for all I/O. Any open(), readpipe() (aka qx//) and similar operators found within the lexical scope of this pragma will use the declared defaults.

With the IN subpragma you can declare the default layers of input streams, and with the OUT subpragma you can declare the default layers of output streams. With the IO subpragma you can control both input and output streams simultaneously.

If you have a legacy encoding, you can use the :encoding(...) tag.

if you want to set your encoding layers based on your locale environment variables, you can use the :locale tag. For example:

```
$ENV{LANG} = 'ru_RU.KOI8-R';
the :locale will probe the locale environment variables like LANG
use open OUT => ':locale';
open(O, ">koi8");
print O chr(0x430); # Unicode CYRILLIC SMALL LETTER A = KOI8-R 0xc1
close O;
open(I, "<koi8");
printf "%#x\n", ord(<I>), "\n"; # this should print 0xc1
close I;
```

These are equivalent

```
use open ':utf8';
use open IO => ':utf8';
```

as are these

```
use open ':locale';
use open IO => ':locale';
```

and these

```
use open ':encoding(iso-8859-7)';
use open IO => ':encoding(iso-8859-7)';
```

The matching of encoding names is loose: case does not matter, and many encodings have several aliases. See [Encode::Supported](#) for details and the list of supported locales.

Note that :utf8 PerlIO layer must always be specified exactly like that, it is not subject to the loose

matching of encoding names.

When `open()` is given an explicit list of layers they are appended to the list declared using this pragma.

The `:std` subpragma on its own has no effect, but if combined with the `:utf8` or `:encoding` subpragmas, it converts the standard filehandles (STDIN, STDOUT, STDERR) to comply with encoding selected for input/output handles. For example, if both input and out are chosen to be `:utf8`, a `:std` will mean that STDIN, STDOUT, and STDERR are also in `:utf8`. On the other hand, if only output is chosen to be in `< :encoding(koi8r)`, a `:std` will cause only the STDOUT and STDERR to be in `koi8r`. The `:locale` subpragma implicitly turns on `:std`.

The logic of `:locale` is as follows:

1. If the platform supports the `langinfo(CODESET)` interface, the codeset returned is used as the default encoding for the open pragma.
2. If 1. didn't work but we are under the locale pragma, the environment variables `LC_ALL` and `LANG` (in that order) are matched for encodings (the part after `.`, if any), and if any found, that is used as the default encoding for the open pragma.
3. If 1. and 2. didn't work, the environment variables `LC_ALL` and `LANG` (in that order) are matched for anything looking like UTF-8, and if any found, `:utf8` is used as the default encoding for the open pragma.

If your locale environment variables (`LANGUAGE`, `LC_ALL`, `LC_CTYPE`, `LANG`) contain the strings 'UTF-8' or 'UTF8' (case-insensitive matching), the default encoding of your STDIN, STDOUT, and STDERR, and of **any subsequent file open**, is UTF-8.

Directory handles may also support PerlIO layers in the future.

## NONPERLIO FUNCTIONALITY

If Perl is not built to use PerlIO as its IO system then only the two pseudo-layers `:bytes` and `:crlf` are available.

The `:bytes` layer corresponds to "binary mode" and the `:crlf` layer corresponds to "text mode" on platforms that distinguish between the two modes when opening files (which is many DOS-like platforms, including Windows). These two layers are no-ops on platforms where `binmode()` is a no-op, but perform their functions everywhere if PerlIO is enabled.

## IMPLEMENTATION DETAILS

There is a class method in `PerlIO::Layer` `find` which is implemented as XS code. It is called by `import` to validate the layers:

```
PerlIO::Layer::->find("perlio")
```

The return value (if defined) is a Perl object, of class `PerlIO::Layer` which is created by the C code in *perlio.c*. As yet there is nothing useful you can do with the object at the perl level.

**NAME**

overload – Package for overloading perl operations

**SYNOPSIS**

```
package Something;

use overload
 '+' => \&myadd,
 '-' => \&mysub;
 # etc
...

package main;
$a = new Something 57;
$b=5+$a;
...
if (overload::Overloaded $b) {...}
...
$strval = overload::StrVal $b;
```

**DESCRIPTION****Declaration of overloaded functions**

The compilation directive

```
package Number;
use overload
 "+" => \&add,
 "*" => "muas";
```

declares function `Number::add()` for addition, and method `muas()` in the "class" `Number` (or one of its base classes) for the assignment form `*=` of multiplication.

Arguments of this directive come in (key, value) pairs. Legal values are values legal inside a `&{ ... }` call, so the name of a subroutine, a reference to a subroutine, or an anonymous subroutine will all work. Note that values specified as strings are interpreted as methods, not subroutines. Legal keys are listed below.

The subroutine `add` will be called to execute `$a+$b` if `$a` is a reference to an object blessed into the package `Number`, or if `$a` is not an object from a package with defined mathematic addition, but `$b` is a reference to a `Number`. It can also be called in other situations, like `$a+=7`, or `$a++`. See [MAGIC AUTOGENERATION](#). (Mathematical methods refer to methods triggered by an overloaded mathematical operator.)

Since overloading respects inheritance via the `@ISA` hierarchy, the above declaration would also trigger overloading of `+` and `*=` in all the packages which inherit from `Number`.

**Calling Conventions for Binary Operations**

The functions specified in the `use overload ...` directive are called with three (in one particular case with four, see [Last Resort](#)) arguments. If the corresponding operation is binary, then the first two arguments are the two arguments of the operation. However, due to general object calling conventions, the first argument should always be an object in the package, so in the situation of `7+$a`, the order of the arguments is interchanged. It probably does not matter when implementing the addition method, but whether the arguments are reversed is vital to the subtraction method. The method can query this information by examining the third argument, which can take three different values:

**FALSE** the order of arguments is as in the current operation.

**TRUE** the arguments are reversed.

**undef** the current operation is an assignment variant (as in `$a+=7`), but the usual function is called instead. This additional information can be used to generate some optimizations. Compare [Calling Conventions for Mutators](#).

### Calling Conventions for Unary Operations

Unary operation are considered binary operations with the second argument being `undef`. Thus the functions that overloads `{ "++" }` is called with arguments `( $a, undef, ' ' )` when `$a++` is executed.

### Calling Conventions for Mutators

Two types of mutators have different calling conventions:

**++ and --**

The routines which implement these operators are expected to actually *mutate* their arguments. So, assuming that `$obj` is a reference to a number,

```
sub incr { my $n = $ {$_[0]}; ++$n; $_[0] = bless \$n }
```

is an appropriate implementation of overloaded `++`. Note that

```
sub incr { ++$ {$_[0]} ; shift }
```

is OK if used with preincrement and with postincrement. (In the case of postincrement a copying will be performed, see [Copy Constructor](#).)

**x= and other assignment versions**

There is nothing special about these methods. They may change the value of their arguments, and may leave it as is. The result is going to be assigned to the value in the left-hand-side if different from this value.

This allows for the same method to be used as overloaded `+=` and `+`. Note that this is *allowed*, but not recommended, since by the semantic of *"Fallback"* Perl will call the method for `+` anyway, if `+=` is not overloaded.

**Warning.** Due to the presence of assignment versions of operations, routines which may be called in assignment context may create self-referential structures. Currently Perl will not free self-referential structures until cycles are explicitly broken. You may get problems when traversing your structures too.

Say,

```
use overload '+' => sub { bless [$_[0], $_[1]] };
```

is asking for trouble, since for code `$obj += $foo` the subroutine is called as `$obj = add($obj, $foo, undef)`, or `$obj = [ $_[0], $_[1] ]`. If using such a subroutine is an important optimization, one can overload `+=` explicitly by a non-"optimized" version, or switch to non-optimized version if not defined `$_[2]` (see [Calling Conventions for Binary Operations](#)).

Even if no *explicit* assignment-variants of operators are present in the script, they may be generated by the optimizer. Say, `"$, $obj, "` or `' , ' . $obj . ' , ' .` may be both optimized to

```
my $tmp = ' , ' . $obj; $tmp .= ' , ' ;
```

### Overloadable Operations

The following symbols can be specified in use `overload` directive:

- *Arithmetic operations*

```
"+", "+=", "-", "-=", "*", "*=", "/", "/=", "%", "%=",
"**", "**=", "<<", "<<=", ">>", ">>=", "x", "x=", ".", ".=",
```

For these operations a substituted non-assignment variant can be called if the assignment variant is

not available. Methods for operations `+`, `-`, `+=`, and `-=` can be called to automatically generate increment and decrement methods. The operation `-` can be used to autogenerate missing methods for unary minus or `abs`.

See "[MAGIC AUTOGENERATION](#)", "[Calling Conventions for Mutators](#)" and "[Calling Conventions for Binary Operations](#)") for details of these substitutions.

- *Comparison operations*

```
"<", "<=", ">", ">=", "==", "!=", "<=>",
"lt", "le", "gt", "ge", "eq", "ne", "cmp",
```

If the corresponding "spaceship" variant is available, it can be used to substitute for the missing operation. During sorting arrays, `cmp` is used to compare values subject to use `overload`.

- *Bit operations*

```
"&", "^", "|", "neg", "!", "~",
```

`neg` stands for unary minus. If the method for `neg` is not specified, it can be autogenerated using the method for subtraction. If the method for `!` is not specified, it can be autogenerated using the methods for `bool`, or `"`, or `0+`.

- *Increment and decrement*

```
"++", "--",
```

If undefined, addition and subtraction methods can be used instead. These operations are called both in prefix and postfix form.

- *Transcendental functions*

```
"atan2", "cos", "sin", "exp", "abs", "log", "sqrt", "int"
```

If `abs` is unavailable, it can be autogenerated using methods for `"<"` or `"<="` combined with either unary minus or subtraction.

Note that traditionally the Perl function `int` rounds to 0, thus for floating-point-like types one should follow the same semantic. If `int` is unavailable, it can be autogenerated using the overloading of `0+`.

- *Boolean, string and numeric conversion*

```
'bool', '""', '0+',
```

If one or two of these operations are not overloaded, the remaining ones can be used instead. `bool` is used in the flow control operators (like `while`) and for the ternary `?:` operation. These functions can return any arbitrary Perl value. If the corresponding operation for this value is overloaded too, that operation will be called again with this value.

As a special case if the overload returns the object itself then it will be used directly. An overloaded conversion returning the object is probably a bug, because you're likely to get something that looks like `YourPackage=HASH(0x8172b34)`.

- *Iteration*

```
"<>"
```

If not overloaded, the argument will be converted to a filehandle or glob (which may require a stringification). The same overloading happens both for the *read-filehandle* syntax `<$var>` and *globbing* syntax `<${var}>`.

**BUGS** Even in list context, the iterator is currently called only once and with scalar context.

- *Dereferencing*

```
'${}', '@{%', '%{%', '&{%', '*{%'.
```

If not overloaded, the argument will be dereferenced *as is*, thus should be of correct type. These

functions should return a reference of correct type, or another object with overloaded dereferencing.

As a special case if the overload returns the object itself then it will be used directly (provided it is the correct type).

The dereference operators must be specified explicitly they will not be passed to "nomethod".

- *Special*

"nomethod", "fallback", "=",

see [SPECIAL SYMBOLS FOR use overload](#).

See ["Fallback"](#) for an explanation of when a missing method can be autogenerated.

A computer-readable form of the above table is available in the hash %overload::ops, with values being space-separated lists of names:

```
with_assign => '+ - * / % ** << >> x .',
assign => '+= -= *= /= %= **= <=> >>= x= .=',
num_comparison => '< <= > >= == !=',
'3way_comparison'=> '<=> cmp',
str_comparison => 'lt le gt ge eq ne',
binary => '& | ^',
unary => 'neg ! ~',
mutators => '++ --',
func => 'atan2 cos sin exp abs log sqrt',
conversion => 'bool "" 0+',
iterators => '<>',
dereferencing => '${} @{} %{} &{} *{}',
special => 'nomethod fallback ='
```

## Inheritance and overloading

Inheritance interacts with overloading in two ways.

### Strings as values of use overload directive

If value in

```
use overload key => value;
```

is a string, it is interpreted as a method name.

### Overloading of an operation is inherited by derived classes

Any class derived from an overloaded class is also overloaded. The set of overloaded methods is the union of overloaded methods of all the ancestors. If some method is overloaded in several ancestor, then which description will be used is decided by the usual inheritance rules:

If A inherits from B and C (in this order), B overloads + with \&D::plus\_sub, and C overloads + by "plus\_meth", then the subroutine D::plus\_sub will be called to implement operation + for an object in package A.

Note that since the value of the fallback key is not a subroutine, its inheritance is not governed by the above rules. In the current implementation, the value of fallback in the first overloaded ancestor is used, but this is accidental and subject to change.

## SPECIAL SYMBOLS FOR use overload

Three keys are recognized by Perl that are not covered by the above description.

### Last Resort

"nomethod" should be followed by a reference to a function of four parameters. If defined, it is called when the overloading mechanism cannot find a method for some operation. The first three arguments of this function coincide with the arguments for the corresponding method if it were found, the fourth argument is

the symbol corresponding to the missing method. If several methods are tried, the last one is used. Say, `1-$a` can be equivalent to

```
&nomethodMethod($a, 1, 1, "-")
```

if the pair `"nomethod" => "nomethodMethod"` was specified in the `use overload` directive.

The `"nomethod"` mechanism is *not* used for the dereference operators (`{}`, `@{}`, `%{}` & `{}` `*{}`).

If some operation cannot be resolved, and there is no function assigned to `"nomethod"`, then an exception will be raised via `die()` — unless `"fallback"` was specified as a key in `use overload` directive.

### Fallback

The key `"fallback"` governs what to do if a method for a particular operation is not found. Three different cases are possible depending on the value of `"fallback"`:

- `undef` Perl tries to use a substituted method (see [MAGIC AUTOGENERATION](#)). If this fails, it then tries to call `"nomethod"` value; if missing, an exception will be raised.
- `TRUE` The same as for the `undef` value, but no exception is raised. Instead, it silently reverts to what it would have done were there no `use overload` present.
- `defined, but FALSE` No autogeneration is tried. Perl tries to call `"nomethod"` value, and if this is missing, raises an exception.

**Note.** `"fallback"` inheritance via `@ISA` is not carved in stone yet, see ["Inheritance and overloading"](#).

### Copy Constructor

The value for `"="` is a reference to a function with three arguments, i.e., it looks like the other values in `use overload`. However, it does not overload the Perl assignment operator. This would go against Camel hair.

This operation is called in the situations when a mutator is applied to a reference that shares its object with some other reference, such as

```
$a=$b;
++$a;
```

To make this change `$a` and not change `$b`, a copy of `$$a` is made, and `$a` is assigned a reference to this new object. This operation is done during execution of the `++$a`, and not during the assignment, (so before the increment `$$a` coincides with `$$b`). This is only done if `++` is expressed via a method for `'++'` or `'+='` (or `nomethod`). Note that if this operation is expressed via `'+'` a nonmutator, i.e., as in

```
$a=$b;
$a=$a+1;
```

then `$a` does not reference a new copy of `$$a`, since `$$a` does not appear as lvalue when the above code is executed.

If the copy constructor is required during the execution of some mutator, but a method for `'='` was not specified, it can be autogenerated as a string copy if the object is a plain scalar.

### Example

The actually executed code for

```
$a=$b;
Something else which does not modify $a or $b....
++$a;
```

may be

```
$a=$b;
Something else which does not modify $a or $b....
$a = $a->clone(undef,"");
```

```
$a->incr(undef, "");
```

if \$b was mathematical, and '++' was overloaded with \&incr, '=' was overloaded with \&clone.

Same behaviour is triggered by \$b = \$a++, which is consider a synonym for \$b = \$a; ++\$a.

## MAGIC AUTOGENERATION

If a method for an operation is not found, and the value for "fallback" is TRUE or undefined, Perl tries to autogenerate a substitute method for the missing operation based on the defined operations. Autogenerated method substitutions are possible for the following operations:

### *Assignment forms of arithmetic operations*

\$a+=\$b can use the method for "+" if the method for "+=" is not defined.

### *Conversion operations*

String, numeric, and boolean conversion are calculated in terms of one another if not all of them are defined.

### *Increment and decrement*

The ++\$a operation can be expressed in terms of \$a+=1 or \$a+1, and \$a- in terms of \$a-=1 and \$a-1.

abs(\$a) can be expressed in terms of \$a<0 and -\$a (or 0-\$a).

*Unary minus* can be expressed in terms of subtraction.

*Negation* ! and not can be expressed in terms of boolean conversion, or string or numerical conversion.

*Concatenation* can be expressed in terms of string conversion.

### *Comparison operations*

can be expressed in terms of its "spaceship" counterpart: either <=> or cmp:

|                        |                 |
|------------------------|-----------------|
| <, >, <=, >=, ==, !=   | in terms of <=> |
| lt, gt, le, ge, eq, ne | in terms of cmp |

### *Iterator*

<> in terms of builtin operations

### *Dereferencing*

\${} @{} %{} &{} \*{} in terms of builtin operations

*Copy operator* can be expressed in terms of an assignment to the dereferenced value, if this value is a scalar and not a reference.

## Losing overloading

The restriction for the comparison operation is that even if, for example, 'cmp' should return a blessed reference, the autogenerated 'lt' function will produce only a standard logical value based on the numerical value of the result of 'cmp'. In particular, a working numeric conversion is needed in this case (possibly expressed in terms of other conversions).

Similarly, .= and x= operators lose their mathematical properties if the string conversion substitution is applied.

When you chop() a mathematical object it is promoted to a string and its mathematical properties are lost. The same can happen with other operations as well.

## Run-time Overloading

Since all use directives are executed at compile-time, the only way to change overloading during run-time is to

```
eval 'use overload "+" => \&addmethod';
```

You can also use

```
eval 'no overload "+", "--", "<="';
```

though the use of these constructs during run-time is questionable.

## Public functions

Package `overload.pm` provides the following public functions:

`overload::StrVal(arg)`

Gives string value of `arg` as in absence of stringify overloading.

`overload::Overloaded(arg)`

Returns true if `arg` is subject to overloading of some operations.

`overload::Method(obj,op)`

Returns `undef` or a reference to the method that implements `op`.

## Overloading constants

For some application Perl parser mangles constants too much. It is possible to hook into this process via `overload::constant()` and `overload::remove_constant()` functions.

These functions take a hash as an argument. The recognized keys of this hash are

|                      |                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>integer</code> | to overload integer constants,                                                                                                           |
| <code>float</code>   | to overload floating point constants,                                                                                                    |
| <code>binary</code>  | to overload octal and hexadecimal constants,                                                                                             |
| <code>q</code>       | to overload <code>q</code> -quoted strings, constant pieces of <code>qq</code> - and <code>qx</code> -quoted strings and here-documents, |
| <code>qr</code>      | to overload constant pieces of regular expressions.                                                                                      |

The corresponding values are references to functions which take three arguments: the first one is the *initial* string form of the constant, the second one is how Perl interprets this constant, the third one is how the constant is used. Note that the initial string form does not contain string delimiters, and has backslashes in backslash-delimiter combinations stripped (thus the value of delimiter is not relevant for processing of this string). The return value of this function is how this constant is going to be interpreted by Perl. The third argument is undefined unless for overloaded `q`- and `qr`- constants, it is `q` in single-quote context (comes from strings, regular expressions, and single-quote HERE documents), it is `tr` for arguments of `tr/y` operators, it is `s` for right-hand side of `s`-operator, and it is `qq` otherwise.

Since an expression `"ab$cd,,"` is just a shortcut for `'ab' . $cd . ',,''`, it is expected that overloaded constant strings are equipped with reasonable overloaded catenation operator, otherwise absurd results will result. Similarly, negative numbers are considered as negations of positive constants.

Note that it is probably meaningless to call the functions `overload::constant()` and `overload::remove_constant()` from anywhere but `import()` and `unimport()` methods. From these methods they may be called as

```
sub import {
 shift;
 return unless @_;
 die "unknown import: @_ " unless @_ == 1 and $_[0] eq ':constant';
```

```

 overload::constant integer => sub {Math::BigInt->new(shift)};
 }

```

**BUGS** Currently overloaded-ness of constants does not propagate into `eval '...'`.

## IMPLEMENTATION

What follows is subject to change RSN.

The table of methods for all operations is cached in magic for the symbol table hash for the package. The cache is invalidated during processing of `use overload`, `no overload`, new function definitions, and changes in `@ISA`. However, this invalidation remains unprocessed until the next `blessing` into the package. Hence if you want to change overloading structure dynamically, you'll need an additional (fake) `blessing` to update the table.

(Every SVish thing has a magic queue, and magic is an entry in that queue. This is how a single variable may participate in multiple forms of magic simultaneously. For instance, environment variables regularly have two forms at once: their `%ENV` magic and their taint magic. However, the magic which implements overloading is applied to the stashes, which are rarely used directly, thus should not slow down Perl.)

If an object belongs to a package using `overload`, it carries a special flag. Thus the only speed penalty during arithmetic operations without overloading is the checking of this flag.

In fact, if `use overload` is not present, there is almost no overhead for overloadable operations, so most programs should not suffer measurable performance penalties. A considerable effort was made to minimize the overhead when `overload` is used in some package, but the arguments in question do not belong to packages using `overload`. When in doubt, test your speed with `use overload` and without it. So far there have been no reports of substantial speed degradation if Perl is compiled with optimization turned on.

There is no size penalty for data if `overload` is not used. The only size penalty if `overload` is used in some package is that *all* the packages acquire a magic during the next `blessing` into the package. This magic is three-words-long for packages without overloading, and carries the cache table if the package is overloaded.

Copying (`$a=$b`) is shallow; however, a one-level-deep copying is carried out before any operation that can imply an assignment to the object `$a` (or `$b`) refers to, like `$a++`. You can override this behavior by defining your own copy constructor (see "[Copy Constructor](#)").

It is expected that arguments to methods that are not explicitly supposed to be changed are constant (but this is not enforced).

## Metaphor clash

One may wonder why the semantic of overloaded `=` is so counter intuitive. If it *looks* counter intuitive to you, you are subject to a metaphor clash.

Here is a Perl object metaphor:

*object is a reference to blessed data*

and an arithmetic metaphor:

*object is a thing by itself.*

The *main* problem of overloading `=` is the fact that these metaphors imply different actions on the assignment `$a = $b` if `$a` and `$b` are objects. Perl-think implies that `$a` becomes a reference to whatever `$b` was referencing. Arithmetic-think implies that the value of "object" `$a` is changed to become the value of the object `$b`, preserving the fact that `$a` and `$b` are separate entities.

The difference is not relevant in the absence of mutators. After a Perl-way assignment an operation which mutates the data referenced by `$a` would change the data referenced by `$b` too. Effectively, after `$a = $b` values of `$a` and `$b` become *indistinguishable*.

On the other hand, anyone who has used algebraic notation knows the expressive power of the arithmetic metaphor. Overloading works hard to enable this metaphor while preserving the Perlian way as far as

possible. Since it is not possible to freely mix two contradicting metaphors, overloading allows the arithmetic way to write things *as far as all the mutators are called via overloaded access only*. The way it is done is described in [Copy Constructor](#).

If some mutator methods are directly applied to the overloaded values, one may need to *explicitly unlink* other values which references the same value:

```
$a = new Data 23;
...
$b = $a; # $b is "linked" to $a
...
$a = $a->clone; # Unlink $b from $a
$a->increment_by(4);
```

Note that overloaded access makes this transparent:

```
$a = new Data 23;
$b = $a; # $b is "linked" to $a
$a += 4; # would unlink $b automatically
```

However, it would not make

```
$a = new Data 23;
$a = 4; # Now $a is a plain 4, not 'Data'
```

preserve "objectness" of `$a`. But Perl *has* a way to make assignments to an object do whatever you want. It is just not the overload, but `tie()`ing interface (see [tie](#)). Adding a `FETCH()` method which returns the object itself, and `STORE()` method which changes the value of the object, one can reproduce the arithmetic metaphor in its completeness, at least for variables which were `tie()`d from the start.

(Note that a workaround for a bug may be needed, see ["BUGS"](#).)

## Cookbook

Please add examples to what follows!

### Two-face scalars

Put this in *two\_face.pm* in your Perl library directory:

```
package two_face; # Scalars with separate string and
 # numeric values.
sub new { my $p = shift; bless [@_], $p }
use overload '""' => \&str, '0+' => \&num, fallback => 1;
sub num {shift->[1]}
sub str {shift->[0]}
```

Use it as follows:

```
require two_face;
my $seven = new two_face ("vii", 7);
printf "seven=$seven, seven=%d, eight=%d\n", $seven, $seven+1;
print "seven contains 'i'\n" if $seven =~ /i/;
```

(The second line creates a scalar which has both a string value, and a numeric value.) This prints:

```
seven=vii, seven=7, eight=8
seven contains 'i'
```

### Two-face references

Suppose you want to create an object which is accessible as both an array reference and a hash reference, similar to the [Pseudo-hashes: Using an array as a hash in pseudo-hash/perlref](#) builtin Perl type. Let's make it better than a pseudo-hash by allowing index 0 to be treated as a normal element.

```

package two_refs;
use overload '%{}' => \&gethash, '@{}' => sub { $ {shift()} };
sub new {
 my $p = shift;
 bless \ [@_], $p;
}
sub gethash {
 my %h;
 my $self = shift;
 tie %h, ref $self, $self;
 \%h;
}

sub TIEHASH { my $p = shift; bless \ shift, $p }
my %fields;
my $i = 0;
$fields{$_} = $i++ foreach qw{zero one two three};
sub STORE {
 my $self = ${shift()};
 my $key = $fields{shift()};
 defined $key or die "Out of band access";
 $$self->[$key] = shift;
}
sub FETCH {
 my $self = ${shift()};
 my $key = $fields{shift()};
 defined $key or die "Out of band access";
 $$self->[$key];
}

```

Now one can access an object using both the array and hash syntax:

```

my $bar = new two_refs 3,4,5,6;
$bar->[2] = 11;
$bar->{two} == 11 or die 'bad hash fetch';

```

Note several important features of this example. First of all, the *actual* type of `$bar` is a scalar reference, and we do not overload the scalar dereference. Thus we can get the *actual* non-overloaded contents of `$bar` by just using `$$bar` (what we do in functions which overload dereference). Similarly, the object returned by the `TIEHASH()` method is a scalar reference.

Second, we create a new tied hash each time the hash syntax is used. This allows us not to worry about a possibility of a reference loop, which would lead to a memory leak.

Both these problems can be cured. Say, if we want to overload hash dereference on a reference to an object which is *implemented* as a hash itself, the only problem one has to circumvent is how to access this *actual* hash (as opposed to the *virtual* hash exhibited by the overloaded dereference operator). Here is one possible fetching routine:

```

sub access_hash {
 my ($self, $key) = (shift, shift);
 my $class = ref $self;
 bless $self, 'overload::dummy'; # Disable overloading of %{}
 my $out = $self->{$key};
 bless $self, $class; # Restore overloading
 $out;
}

```

To remove creation of the tied hash on each access, one may add an extra level of indirection which allows a non-circular structure of references:

```
package two_refs1;
use overload '%{}' => sub { ${shift()}->[1] },
 '@{}' => sub { ${shift()}->[0] };

sub new {
 my $p = shift;
 my $a = [@_];
 my %h;
 tie %h, $p, $a;
 bless \ [$a, \%h], $p;
}

sub gethash {
 my %h;
 my $self = shift;
 tie %h, ref $self, $self;
 \%h;
}

sub TIEHASH { my $p = shift; bless \ shift, $p }
my %fields;
my $i = 0;
$fields{$_} = $i++ foreach qw{zero one two three};
sub STORE {
 my $a = ${shift()};
 my $key = $fields{shift()};
 defined $key or die "Out of band access";
 $a->[$key] = shift;
}
sub FETCH {
 my $a = ${shift()};
 my $key = $fields{shift()};
 defined $key or die "Out of band access";
 $a->[$key];
}
```

Now if \$baz is overloaded like this, then \$baz is a reference to a reference to the intermediate array, which keeps a reference to an actual array, and the access hash. The tie()ing object for the access hash is a reference to a reference to the actual array, so

- There are no loops of references.
- Both "objects" which are blessed into the class two\_refs1 are references to a reference to an array, thus references to a *scalar*. Thus the accessor expression `$$foo->[$ind]` involves no overloaded operations.

### Symbolic calculator

Put this in *symbolic.pm* in your Perl library directory:

```
package symbolic; # Primitive symbolic calculator
use overload nomethod => \&wrap;

sub new { shift; bless ['n', @_] }
sub wrap {
 my ($obj, $other, $inv, $meth) = @_;
 ($obj, $other) = ($other, $obj) if $inv;
 bless [$meth, $obj, $other];
}
```

```
}
```

This module is very unusual as overloaded modules go: it does not provide any usual overloaded operators, instead it provides the *Last Resort* operator `nomethod`. In this example the corresponding subroutine returns an object which encapsulates operations done over the objects: `new symbolic 3` contains `['n', 3]`, `2 + new symbolic 3` contains `['+', 2, ['n', 3]]`.

Here is an example of the script which "calculates" the side of circumscribed octagon using the above package:

```
require symbolic;
my $iter = 1; # 2**($iter+2) = 8
my $side = new symbolic 1;
my $cnt = $iter;

while ($cnt-- > 0) {
 $side = (sqrt(1 + $side**2) - 1)/$side;
}
print "OK\n";
```

The value of `$side` is

```
['/', ['-', ['sqrt', ['+', 1, ['**', ['n', 1], 2]],
 undef], 1], ['n', 1]]
```

Note that while we obtained this value using a nice little script, there is no simple way to *use* this value. In fact this value may be inspected in debugger (see [perldebug](#)), but only if `bareStringify` Option is set, and not via `p` command.

If one attempts to print this value, then the overloaded operator `"` will be called, which will call `nomethod` operator. The result of this operator will be stringified again, but this result is again of type `symbolic`, which will lead to an infinite loop.

Add a pretty-printer method to the module *symbolic.pm*:

```
sub pretty {
 my ($meth, $a, $b) = @{+shift};
 $a = 'u' unless defined $a;
 $b = 'u' unless defined $b;
 $a = $a->pretty if ref $a;
 $b = $b->pretty if ref $b;
 "[$meth $a $b]";
}
```

Now one can finish the script by

```
print "side = ", $side->pretty, "\n";
```

The method `pretty` is doing object-to-string conversion, so it is natural to overload the operator `"` using this method. However, inside such a method it is not necessary to pretty-print the *components* `$a` and `$b` of an object. In the above subroutine `"[$meth $a $b]"` is a catenation of some strings and components `$a` and `$b`. If these components use overloading, the catenation operator will look for an overloaded operator `.`; if not present, it will look for an overloaded operator `"`. Thus it is enough to use

```
use overload nomethod => \&wrap, '""' => \&str;
sub str {
 my ($meth, $a, $b) = @{+shift};
 $a = 'u' unless defined $a;
 $b = 'u' unless defined $b;
 "[$meth $a $b]";
}
```

Now one can change the last line of the script to

```
print "side = $side\n";
```

which outputs

```
side = [/ [- [sqrt [+ 1 [** [n 1 u] 2]] u] 1] [n 1 u]]
```

and one can inspect the value in debugger using all the possible methods.

Something is still amiss: consider the loop variable `$cnt` of the script. It was a number, not an object. We cannot make this value of type `symbolic`, since then the loop will not terminate.

Indeed, to terminate the cycle, the `$cnt` should become false. However, the operator `bool` for checking falsity is overloaded (this time via overloaded `"`), and returns a long string, thus any object of type `symbolic` is true. To overcome this, we need a way to compare an object to 0. In fact, it is easier to write a numeric conversion routine.

Here is the text of *symbolic.pm* with such a routine added (and slightly modified `str()`):

```
package symbolic; # Primitive symbolic calculator
use overload
 nomethod => \&wrap, '""' => \&str, '0+' => \#

sub new { shift; bless ['n', @_] }
sub wrap {
 my ($obj, $other, $inv, $meth) = @_;
 ($obj, $other) = ($other, $obj) if $inv;
 bless [$meth, $obj, $other];
}
sub str {
 my ($meth, $a, $b) = @{+shift};
 $a = 'u' unless defined $a;
 if (defined $b) {
 "$meth $a $b";
 } else {
 "$meth $a";
 }
}
my %subr = (n => sub {$_[0]},
 sqrt => sub {sqrt $_[0]},
 '-' => sub {shift() - shift()},
 '+' => sub {shift() + shift()},
 '/' => sub {shift() / shift()},
 '*' => sub {shift() * shift()},
 '**' => sub {shift() ** shift()},
);
sub num {
 my ($meth, $a, $b) = @{+shift};
 my $subr = $subr{$meth}
 or die "Do not know how to ($meth) in symbolic";
 $a = $a->num if ref $a eq __PACKAGE__;
 $b = $b->num if ref $b eq __PACKAGE__;
 $subr->($a,$b);
}
```

All the work of numeric conversion is done in `%subr` and `num()`. Of course, `%subr` is not complete, it contains only operators used in the example below. Here is the extra-credit question: why do we need an explicit recursion in `num()`? (Answer is at the end of this section.)

Use this module like this:

```
require symbolic;
my $iter = new symbolic 2; # 16-gon
my $side = new symbolic 1;
my $cnt = $iter;

while ($cnt) {
 $cnt = $cnt - 1; # Mutator '--' not implemented
 $side = (sqrt(1 + $side**2) - 1)/$side;
}
printf "%s=%f\n", $side, $side;
printf "pi=%f\n", $side*(2**($iter+2));
```

It prints (without so many line breaks)

```
[/ [- [sqrt [+ 1 [** [/ [- [sqrt [+ 1 [** [n 1] 2]]] 1]
 [n 1]] 2]]] 1]
 [/ [- [sqrt [+ 1 [** [n 1] 2]]] 1] [n 1]]]=0.198912
pi=3.182598
```

The above module is very primitive. It does not implement mutator methods (++ , -= and so on), does not do deep copying (not required without mutators!), and implements only those arithmetic operations which are used in the example.

To implement most arithmetic operations is easy; one should just use the tables of operations, and change the code which fills %subr to

```
my %subr = ('n' => sub {$_[0]});
foreach my $op (split " ", $overload::ops{with_assign}) {
 $subr{$op} = $subr{"$op="} = eval "sub {shift() $op shift()}";
}
my @bins = qw(binary 3way_comparison num_comparison str_comparison);
foreach my $op (split " ", "@overload::ops{ @bins }") {
 $subr{$op} = eval "sub {shift() $op shift()}";
}
foreach my $op (split " ", "@overload::ops{qw(unary func)}") {
 print "defining '$op'\n";
 $subr{$op} = eval "sub {$op shift()}";
}
```

Due to [Calling Conventions for Mutators](#), we do not need anything special to make += and friends work, except filling += entry of %subr, and defining a copy constructor (needed since Perl has no way to know that the implementation of '+=' does not mutate the argument, compare [Copy Constructor](#)).

To implement a copy constructor, add < '=' = \&cpy to use overload line, and code (this code assumes that mutators change things one level deep only, so recursive copying is not needed):

```
sub cpy {
 my $self = shift;
 bless [@$self], ref $self;
}
```

To make ++ and -- work, we need to implement actual mutators, either directly, or in nomethod. We continue to do things inside nomethod, thus add

```
if ($meth eq '++' or $meth eq '--') {
 @$obj = ($meth, (bless [@$obj]), 1); # Avoid circular reference
 return $obj;
}
```

after the first line of `wrap()`. This is not a most effective implementation, one may consider

```
sub inc { $_[0] = bless ['++', shift, 1]; }
```

instead.

As a final remark, note that one can fill `%subr` by

```
my %subr = ('n' => sub { $_[0] });
foreach my $op (split " ", $overload::ops{with_assign}) {
 $subr{$op} = $subr{"$op="} = eval "sub {shift() $op shift()}";
}
my @bins = qw(binary 3way_comparison num_comparison str_comparison);
foreach my $op (split " ", "@overload::ops{ @bins }") {
 $subr{$op} = eval "sub {shift() $op shift()}";
}
foreach my $op (split " ", "@overload::ops{qw(unary func)}") {
 $subr{$op} = eval "sub { $op shift()}";
}
$subr{'++'} = $subr{'+'};
$subr{'--'} = $subr{'-'};
```

This finishes implementation of a primitive symbolic calculator in 50 lines of Perl code. Since the numeric values of subexpressions are not cached, the calculator is very slow.

Here is the answer for the exercise: In the case of `str()`, we need no explicit recursion since the overloaded `.-` operator will fall back to an existing overloaded operator `"."`. Overloaded arithmetic operators *do not* fall back to numeric conversion if `fallback` is not explicitly requested. Thus without an explicit recursion `num()` would convert `['+', $a, $b]` to `$a + $b`, which would just rebuild the argument of `num()`.

If you wonder why defaults for conversion are different for `str()` and `num()`, note how easy it was to write the symbolic calculator. This simplicity is due to an appropriate choice of defaults. One extra note: due to the explicit recursion `num()` is more fragile than `sym()`: we need to explicitly check for the type of `$a` and `$b`. If components `$a` and `$b` happen to be of some related type, this may lead to problems.

### Really symbolic calculator

One may wonder why we call the above calculator symbolic. The reason is that the actual calculation of the value of expression is postponed until the value is *used*.

To see it in action, add a method

```
sub STORE {
 my $obj = shift;
 $$obj = 1;
 @$obj->[0,1] = ('=', shift);
}
```

to the package `symbolic`. After this change one can do

```
my $a = new symbolic 3;
my $b = new symbolic 4;
my $c = sqrt($a**2 + $b**2);
```

and the numeric value of `$c` becomes 5. However, after calling

```
$a->STORE(12); $b->STORE(5);
```

the numeric value of `$c` becomes 13. There is no doubt now that the module `symbolic` provides a *symbolic* calculator indeed.

To hide the rough edges under the hood, provide a `tie()`d interface to the package `symbolic` (compare with [Metaphor clash](#)). Add methods

```
sub TIESCALAR { my $pack = shift; $pack->new(@_) }
sub FETCH { shift }
sub nop { } # Around a bug
```

(the bug is described in *"BUGS"*). One can use this new interface as

```
tie $a, 'symbolic', 3;
tie $b, 'symbolic', 4;
$a->nop; $b->nop; # Around a bug

my $c = sqrt($a**2 + $b**2);
```

Now numeric value of `$c` is 5. After `$a = 12; $b = 5` the numeric value of `$c` becomes 13. To insulate the user of the module add a method

```
sub vars { my $p = shift; tie($_, $p), $_->nop foreach @_; }
```

Now

```
my ($a, $b);
symbolic->vars($a, $b);
my $c = sqrt($a**2 + $b**2);

$a = 3; $b = 4;
printf "c5 %s=%f\n", $c, $c;

$a = 12; $b = 5;
printf "c13 %s=%f\n", $c, $c;
```

shows that the numeric value of `$c` follows changes to the values of `$a` and `$b`.

## DIAGNOSTICS

When Perl is run with the **-Do** switch or its equivalent, overloading induces diagnostic messages.

Using the `m` command of Perl debugger (see [perldebug](#)) one can deduce which operations are overloaded (and which ancestor triggers this overloading). Say, if `eq` is overloaded, then the method `(eq)` is shown by debugger. The method `()` corresponds to the `fallback` key (in fact a presence of this method shows that this package has overloading enabled, and it is what is used by the `Overloaded` function of module `overload`).

The module might issue the following warnings:

### Odd number of arguments for overload::constant

(W) The call to `overload::constant` contained an odd number of arguments. The arguments should come in pairs.

### '%s' is not an overloadable type

(W) You tried to overload a constant type the `overload` package is unaware of.

### '%s' is not a code reference

(W) The second (fourth, sixth, ...) argument of `overload::constant` needs to be a code reference. Either an anonymous subroutine, or a reference to a subroutine.

## BUGS

Because it is used for overloading, the per-package hash `%OVERLOAD` now has a special meaning in Perl. The symbol table is filled with names looking like line-noise.

For the purpose of inheritance every overloaded package behaves as if `fallback` is present (possibly undefined). This may create interesting effects if some package is not overloaded, but inherits from two overloaded packages.

Relation between overloading and `tie()`ing is broken. Overloading is triggered or not basing on the *previous* class of `tie()`d value.

This happens because the presence of overloading is checked too early, before any `tie()`d access is attempted. If the `FETCH()`ed class of the `tie()`d value does not change, a simple workaround is to access the value immediately after `tie()`ing, so that after this call the *previous* class coincides with the current one.

**Needed:** a way to fix this without a speed penalty.

Barewords are not covered by overloaded string constants.

This document is confusing. There are grammos and misleading language used in places. It would seem a total rewrite is needed.

**NAME**

PerlIO – On demand loader for PerlIO layers and root of PerlIO::\* name space

**SYNOPSIS**

```
open($fh,"<:crlf", "my.txt"); # portably open a text file for reading
open($fh,"<", "his.jpg"); # portably open a binary file for reading
binmode($fh);

Shell:
 PERLIO=perlio perl
```

**DESCRIPTION**

When an undefined layer 'foo' is encountered in an open or binmode layer specification then C code performs the equivalent of:

```
use PerlIO 'foo';
```

The perl code in PerlIO.pm then attempts to locate a layer by doing

```
require PerlIO::foo;
```

Otherwise the PerlIO package is a place holder for additional PerlIO related functions.

The following layers are currently defined:

**unix** Low level layer which calls read, write and lseek etc.

**stdio**

Layer which calls fread, fwrite and fseek/ftell etc. Note that as this is "real" stdio it will ignore any layers beneath it and got straight to the operating system via the C library as usual.

**perlio**

This is a re-implementation of "stdio-like" buffering written as a PerlIO "layer". As such it will call whatever layer is below it for its operations.

**crlf** A layer which does CRLF to "\n" translation distinguishing "text" and "binary" files in the manner of MS-DOS and similar operating systems. (It currently does *not* mimic MS-DOS as far as treating of Control-Z as being an end-of-file marker.)

**utf8** Declares that the stream accepts perl's internal encoding of characters. (Which really is UTF-8 on ASCII machines, but is UTF-EBCDIC on EBCDIC machines.) This allows any character perl can represent to be read from or written to the stream. The UTF-X encoding is chosen to render simple text parts (i.e. non-accented letters, digits and common punctuation) human readable in the encoded file.

Here is how to write your native data out using UTF-8 (or UTF-EBCDIC) and then read it back in.

```
open(F, ">:utf8", "data.utf");
print F $out;
close(F);

open(F, "<:utf8", "data.utf");
$in = <F>;
close(F);
```

**bytes**

This is the inverse of :utf8 layer. It turns off the flag on the layer below so that data read from it is considered to be "octets" i.e. characters in range 0..255 only. Likewise on output perl will warn if a "wide" character is written to a such a stream.

**raw** The `:raw` layer is *defined* as being identical to calling `binmode($fh)` – the stream is made suitable for passing binary data i.e. each byte is passed as-is. The stream will still be buffered. Unlike earlier versions of perl `:raw` is *not* just the inverse of `:crlf` – other layers which would affect the binary nature of the stream are also removed or disabled.

The implementation of `:raw` is as a pseudo-layer which when "pushed" pops itself and then any layers which do not declare themselves as suitable for binary data. (Undoing `:utf8` and `:crlf` are implemented by clearing flags rather than popping layers but that is an implementation detail.)

As a consequence of the fact that `:raw` normally pops layers it usually only makes sense to have it as the only or first element in a layer specification. When used as the first element it provides a known base on which to build e.g.

```
open($fh, ":raw:utf8", ...)
```

will construct a "binary" stream, but then enable UTF-8 translation.

**pop** A pseudo layer that removes the top-most layer. Gives perl code a way to manipulate the layer stack. Should be considered as experimental. Note that `:pop` only works on real layers and will not undo the effects of pseudo layers like `:utf8`. An example of a possible use might be:

```
open($fh, ...)
...
binmode($fh, ":encoding(...)"); # next chunk is encoded
...
binmode($fh, ":pop"); # back to un-encoded
```

A more elegant (and safer) interface is needed.

### Alternatives to raw

To get a binary stream an alternate method is to use:

```
open($fh, "whatever")
binmode($fh);
```

this has advantage of being backward compatible with how such things have had to be coded on some platforms for years.

To get an un-buffered stream specify an unbuffered layer (e.g. `:unix`) in the open call:

```
open($fh, "<:unix", $path)
```

### Defaults and how to override them

If the platform is MS-DOS like and normally does CRLF to "\n" translation for text files then the default layers are :

```
unix crlf
```

(The low level "unix" layer may be replaced by a platform specific low level layer.)

Otherwise if Configure found out how to do "fast" IO using system's stdio, then the default layers are :

```
unix stdio
```

Otherwise the default layers are

```
unix perlIO
```

These defaults may change once perlIO has been better tested and tuned.

The default can be overridden by setting the environment variable `PERLIO` to a space separated list of layers (unix or platform low level layer is always pushed first).

This can be used to see the effect of/bugs in the various layers e.g.

```
cd .../perl/t
PERLIO=stdio ./perl harness
PERLIO=perlio ./perl harness
```

**NAME**

PerlIO::encoding – encoding layer

**SYNOPSIS**

```
open($f, "<:encoding(foo)", "infoo");
open($f, ">:encoding(bar)", "outbar");

use Encode qw(:fallbacks);
$PerlIO::encoding::check = FB_PERLQQ;
```

**DESCRIPTION**

Open a filehandle with a transparent encoding filter.

On input, convert the bytes expected to be in the specified character set and encoding to Perl string data (Unicode and Perl's internal Unicode encoding, UTF-8). On output, convert Perl string data into the specified character set and encoding.

When the layer is pushed the current value of `$PerlIO::encoding::check` is saved and used as the check argument when calling the Encodings encode and decode.

**SEE ALSO**

[open](#), [Encode](#), [binmode](#), [perluniintro](#)

**NAME**

PerlIO::scalar – support module for in-memory IO.

**SYNOPSIS**

```
open($fh, "<", \ $scalar);
open($fh, ">", \ $scalar);

or

open($fh, "<:scalar", \ $scalar);
open($fh, ">:scalar", \ $scalar);
```

**DESCRIPTION**

PerlIO::scalar only exists to use XSLoader to load C code that provides support for treating a scalar as an "in memory" file.

All normal file operations can be performed on the handle. The scalar is considered a stream of bytes. Currently `fileno($fh)` returns `undef`.

**NAME**

PerlIO::via – Helper class for PerlIO layers implemented in perl

**SYNOPSIS**

```
use PerlIO::via::Layer;
open($fh, "<:via(Layer)", ...);

use Some::Other::Package;
open($fh, ">:via(Some::Other::Package)", ...);
```

**DESCRIPTION**

The PerlIO::via module allows you to develop PerlIO layers in Perl, without having to go into the nitty gritty of programming C with XS as the interface to Perl.

One example module, [PerlIO::via::QuotedPrint](#), is included with Perl 5.8.0, and more example modules are available from CPAN, such as [PerlIO::via::StripHTML](#) and [PerlIO::via::Base64](#). The PerlIO::via::StripHTML module for instance, allows you to say:

```
use PerlIO::via::StripHTML;
open(my $fh, "<:via(StripHTML)", "index.html");
my @line = <$fh>;
```

to obtain the text of an HTML-file in an array with all the HTML-tags automagically removed.

Please note that if the layer is created in the PerlIO::via:: namespace, it does **not** have to be fully qualified. The PerlIO::via module will prefix the PerlIO::via:: namespace if the specified modulename does not exist as a fully qualified module name.

**EXPECTED METHODS**

To create a Perl module that implements a PerlIO layer in Perl (as opposed to in C using XS as the interface to Perl), you need to supply some of the following subroutines. It is recommended to create these Perl modules in the PerlIO::via:: namespace, so that they can easily be located on CPAN and use the default namespace feature of the PerlIO::via module itself.

Please note that this is an area of recent development in Perl and that the interface described here is therefore still subject to change (and hopefully will have better documentation and more examples).

In the method descriptions below *\$fh* will be a reference to a glob which can be treated as a perl file handle. It refers to the layer below. *\$fh* is not passed if the layer is at the bottom of the stack, for this reason and to maintain some level of "compatibility" with TIEHANDLE classes it is passed last.

**\$class-PUSHED([\$mode,\$fh])**

Should return an object or the class, or -1 on failure. (Compare TIEHANDLE.) The arguments are an optional mode string ("r", "w", "w+", ...) and a filehandle for the PerlIO layer below. Mandatory.

When layer is pushed as part of an open call, PUSHED will be called *before* the actual open occurs whether than be via OPEN, SYSOPEN, FDOPEM or by letting lower layer do the open.

**\$obj-POPPED([\$fh])**

Optional – layer is about to be removed.

**\$obj-OPEN(\$path,\$mode,\$fh)**

Optional – if not present lower layer does open. If present called for normal opens after layer is pushed. This function is subject to change as there is no easy way to get lower layer to do open and then regain control.

**\$obj-BINMODE([,\$fh])**

Optional – if not available layer is popped on binmode(\$fh) or when :raw is pushed. If present it should return 0 on success -1 on error and undef to pop the layer.

**\$obj-FDOPEN(\$fd[, \$fh])**

Optional – if not present lower layer does open. If present called for opens which pass a numeric file descriptor after layer is pushed. This function is subject to change as there is no easy way to get lower layer to do open and then regain control.

**\$obj-SYSOPEN(\$path, \$imode, \$perm[, \$fh])**

Optional – if not present lower layer does open. If present called for sysopen style opens which pass a numeric mode and permissions after layer is pushed. This function is subject to change as there is no easy way to get lower layer to do open and then regain control.

**\$obj-FILENO(\$fh)**

Returns a numeric value for Unix-like file descriptor. Return -1 if there isn't one. Optional. Default is `fileno($fh)`.

**\$obj-READ(\$buffer, \$len, \$fh)**

Returns the number of octets placed in `$buffer` (must be less than or equal to `$len`). Optional. Default is to use FILL instead.

**\$obj-WRITE(\$buffer, \$fh)**

Returns the number of octets from buffer that have been successfully written.

**\$obj-FILL(\$fh)**

Should return a string to be placed in the buffer. Optional. If not provided must provide READ or reject handles open for reading in PUSHED.

**\$obj-CLOSE(\$fh)**

Should return 0 on success, -1 on error. Optional.

**\$obj-SEEK(\$posn, \$whence, \$fh)**

Should return 0 on success, -1 on error. Optional. Default is to fail, but that is likely to be changed in future.

**\$obj-TELL(\$fh)**

Returns file position. Optional. Default to be determined.

**\$obj-UNREAD(\$buffer, \$fh)**

Returns the number of octets from buffer that have been successfully saved to be returned on future FILL/READ calls. Optional. Default is to push data into a temporary layer above this one.

**\$obj-FLUSH(\$fh)**

Flush any buffered write data. May possibly be called on readable handles too. Should return 0 on success, -1 on error.

**\$obj-SETLINEBUF(\$fh)**

Optional. No return.

**\$obj-CLEARERR(\$fh)**

Optional. No return.

**\$obj-ERROR(\$fh)**

Optional. Returns error state. Default is no error until a mechanism to signal error (die?) is worked out.

**\$obj-EOF(\$fh)**

Optional. Returns end-of-file state. Default is function of return value of FILL or READ.

## EXAMPLES

Check the `PerlIO::via::` namespace on CPAN for examples of PerlIO layers implemented in Perl. To give you an idea how simple the implementation of a PerlIO layer can look, as simple example is included here.

### Example – a Hexadecimal Handle

Given the following module, `PerlIO::via::Hex` :

```
package PerlIO::via::Hex;

sub PUSHED
{
 my ($class,$mode,$fh) = @_;
 # When writing we buffer the data
 my $buf = '';
 return bless \$buf,$class;
}

sub FILL
{
 my ($obj,$fh) = @_;
 my $line = <$fh>;
 return (defined $line) ? pack("H*", $line) : undef;
}

sub WRITE
{
 my ($obj,$buf,$fh) = @_;
 $$obj .= unpack("H*", $buf);
 return length($buf);
}

sub FLUSH
{
 my ($obj,$fh) = @_;
 print $fh $$obj or return -1;
 $$obj = '';
 return 0;
}

1;
```

the following code opens up an output handle that will convert any output to hexadecimal dump of the output bytes: for example "A" will be converted to "41" (on ASCII-based machines, on EBCDIC platforms the "A" will become "c1")

```
use PerlIO::via::Hex;
open(my $fh, ">:via(Hex)", "foo.hex");
```

and the following code will read the hexdump in and convert it on the fly back into bytes:

```
open(my $fh, "<:via(Hex)", "foo.hex");
```

**NAME**

Pod::Checker, podchecker() – check pod documents for syntax errors

**SYNOPSIS**

```
use Pod::Checker;

$syntax_okay = podchecker($filepath, $outputpath, %options);

my $checker = new Pod::Checker %options;
$checker->parse_from_file($filepath, *STDERR);
```

**OPTIONS/ARGUMENTS**

`$filepath` is the input POD to read and `$outputpath` is where to write POD syntax error messages. Either argument may be a scalar indicating a file-path, or else a reference to an open filehandle. If unspecified, the input-file it defaults to `\*STDIN`, and the output-file defaults to `\*STDERR`.

**podchecker()**

This function can take a hash of options:

**-warnings => *val***

Turn warnings on/off. *val* is usually 1 for on, but higher values trigger additional warnings. See ["Warnings"](#).

**DESCRIPTION**

**podchecker** will perform syntax checking of Perl5 POD format documentation.

*NOTE THAT THIS MODULE IS CURRENTLY IN THE BETA STAGE!*

It is hoped that curious/ambitious user will help flesh out and add the additional features they wish to see in **Pod::Checker** and **podchecker** and verify that the checks are consistent with [perlpod](#).

The following checks are currently preformed:

- Unknown ‘=xxxx’ commands, unknown ‘X<...>’ interior-sequences, and unterminated interior sequences.
- Check for proper balancing of =begin and =end. The contents of such a block are generally ignored, i.e. no syntax checks are performed.
- Check for proper nesting and balancing of =over, =item and =back.
- Check for same nested interior-sequences (e.g. L<...L<...>...>).
- Check for malformed or nonexistent entities E<...>.
- Check for correct syntax of hyperlinks L<...>. See [perlpod](#) for details.
- Check for unresolved document-internal links. This check may also reveal misspelled links that seem to be internal links but should be links to something else.

**DIAGNOSTICS****Errors**

- empty =headn

A heading (=head1 or =head2) without any text? That ain’t no heading!

- =over on line *N* without closing =back

The =over command does not have a corresponding =back before the next heading (=head1 or =head2) or the end of the file.

- `=item` without previous `=over`
- `=back` without previous `=over`
  - An `=item` or `=back` command has been found outside a `=over/=back` block.
- No argument for `=begin`
  - A `=begin` command was found that is not followed by the formatter specification.
- `=end` without `=begin`
  - A standalone `=end` command was found.
- Nested `=begin`'s
  - There were at least two consecutive `=begin` commands without the corresponding `=end`. Only one `=begin` may be active at a time.
- `=for` without formatter specification
  - There is no specification of the formatter after the `=for` command.
- unresolved internal link *NAME*
  - The given link to *NAME* does not have a matching node in the current POD. This also happend when a single word node name is not enclosed in " ".
- Unknown command "*CMD*"
  - An invalid POD command has been found. Valid are `=head1`, `=head2`, `=head3`, `=head4`, `=over`, `=item`, `=back`, `=begin`, `=end`, `=for`, `=pod`, `=cut`
- Unknown interior-sequence "*SEQ*"
  - An invalid markup command has been encountered. Valid are: `B<>`, `C<>`, `E<>`, `F<>`, `I<>`, `L<>`, `S<>`, `X<>`, `Z<>`
- nested commands *CMD*<...*CMD*<...>...>
  - Two nested identical markup commands have been found. Generally this does not make sense.
- garbled entity *STRING*
  - The *STRING* found cannot be interpreted as a character entity.
- Entity number out of range
  - An entity specified by number (dec, hex, oct) is out of range (1–255).
- malformed link `L<>`
  - The link found cannot be parsed because it does not conform to the syntax described in [perlpod](#).
- nonempty `Z<>`
  - The `Z<>` sequence is supposed to be empty.
- empty `X<>`
  - The index entry specified contains nothing but whitespace.
- Spurious text after `=pod` / `=cut`
  - The commands `=pod` and `=cut` do not take any arguments.
- Spurious character(s) after `=back`
  - The `=back` command does not take any arguments.

## Warnings

These may not necessarily cause trouble, but indicate mediocre style.

- multiple occurrence of link target *name*
  - The POD file has some `=item` and/or `=head` commands that have the same text. Potential hyperlinks to such a text cannot be unique then.

- line containing nothing but whitespace in paragraph
 

There is some whitespace on a seemingly empty line. POD is very sensitive to such things, so this is flagged. **vi** users switch on the **list** option to avoid this problem.

```
=begin _disabled_
```
- file does not start with =head
 

The file starts with a different POD directive than head. This is most probably something you do not want.

```
=end _disabled_
```
- previous =item has no contents
 

There is a list =item right above the flagged line that has no text contents. You probably want to delete empty items.
- preceding non-item paragraph(s)
 

A list introduced by =over starts with a text or verbatim paragraph, but continues with =items. Move the non-item paragraph out of the =over/=back block.
- =item type mismatch (*one* vs. *two*)
 

A list started with e.g. a bulleted =item and continued with a numbered one. This is obviously inconsistent. For most translators the type of the *first* =item determines the type of the list.
- *N* unescaped <> in paragraph
 

Angle brackets not written as <lt> and <gt> can potentially cause errors as they could be misinterpreted as markup commands. This is only printed when the -warnings level is greater than 1.
- Unknown entity
 

A character entity was found that does not belong to the standard ISO set or the POD specials verbar and sol.
- No items in =over
 

The list opened with =over does not contain any items.
- No argument for =item
 

=item without any parameters is deprecated. It should either be followed by \* to indicate an unordered list, by a number (optionally followed by a dot) to indicate an ordered (numbered) list or simple text for a definition list.
- empty section in previous paragraph
 

The previous section (introduced by a =head command) does not contain any text. This usually indicates that something is missing. Note: A =head1 followed immediately by =head2 does not trigger this warning.
- Verbatim paragraph in NAME section
 

The NAME section (=head1 NAME) should consist of a single paragraph with the script/module name, followed by a dash '-' and a very short description of what the thing is good for.

## Hyperlinks

There are some warnings wrt. malformed hyperlinks.

- ignoring leading/trailing whitespace in link
 

There is whitespace at the beginning or the end of the contents of L<...>.
- (section) in '\$page' deprecated
 

There is a section detected in the page name of L<...>, e.g. L<passwd(2)>. POD hyperlinks may point to POD documents only. Please write C<passwd(2)> instead. Some formatters are able to expand this to appropriate code. For links to (builtin) functions, please say L<perlfunc/mkdir>.

without ( ).

- alternative text/node '%s' contains non-escaped | or /

The characters | and / are special in the L<...> context. Although the hyperlink parser does its best to determine which "/" is text and which is a delimiter in case of doubt, one ought to escape these literal characters like this:

```
/ E<sol>
| E<verbar>
```

## RETURN VALUE

**podchecker** returns the number of POD syntax errors found or -1 if there were no POD commands at all found in the file.

## EXAMPLES

*[T.B.D.]*

## INTERFACE

While checking, this module collects document properties, e.g. the nodes for hyperlinks (=headX, =item) and index entries (X<>). POD translators can use this feature to syntax-check and get the nodes in a first pass before actually starting to convert. This is expensive in terms of execution time, but allows for very robust conversions.

`Pod::Checker->new( %options )`

Return a reference to a new Pod::Checker object that inherits from Pod::Parser and is used for calling the required methods later. The following options are recognized:

`-warnings => num`

Print warnings if num is true. The higher the value of num, the more warnings are printed. Currently there are only levels 1 and 2.

`-quiet => num`

If num is true, do not print any errors/warnings. This is useful when Pod::Checker is used to munge POD code into plain text from within POD formatters.

`$checker->poderror( @args )`

`$checker->poderror( {%opts}, @args )`

Internal method for printing errors and warnings. If no options are given, simply prints "@\_". The following options are recognized and used to form the output:

`-msg`

A message to print prior to @args.

`-line`

The line number the error occurred in.

`-file`

The file (name) the error occurred in.

`-severity`

The error level, should be 'WARNING' or 'ERROR'.

`$checker->num_errors()`

Set (if argument specified) and retrieve the number of errors found.

`$checker->name()`

Set (if argument specified) and retrieve the canonical name of POD as found in the =head1 NAME section.

**`$checker->node()`**

Add (if argument specified) and retrieve the nodes (as defined by `=headX` and `=item`) of the current POD. The nodes are returned in the order of their occurrence. They consist of plain text, each piece of whitespace is collapsed to a single blank.

**`$checker->idx()`**

Add (if argument specified) and retrieve the index entries (as defined by `X<>`) of the current POD. They consist of plain text, each piece of whitespace is collapsed to a single blank.

**`$checker->hyperlink()`**

Add (if argument specified) and retrieve the hyperlinks (as defined by `L<>`) of the current POD. They consist of a 2-item array: line number and `Pod::Hyperlink` object.

**AUTHOR**

Brad Appleton <bradapp@enteract.com> (initial version), Marek Rouchal  
<marek@saftsack.fs.uni-bayreuth.de>

Based on code for **`Pod::Text::pod2text()`** written by Tom Christiansen <tchrist@mox.perl.com>

**NAME**

Pod::Find – find POD documents in directory trees

**SYNOPSIS**

```
use Pod::Find qw(pod_find simplify_name);
my %pods = pod_find({ -verbose => 1, -inc => 1 });
foreach(keys %pods) {
 print "found library POD '$pods{$_}' in $_\n";
}

print "podname=",simplify_name('a/b/c/mymodule.pod'),"\n";

$location = pod_where({ -inc => 1 }, "Pod::Find");
```

**DESCRIPTION**

**Pod::Find** provides a set of functions to locate POD files. Note that no function is exported by default to avoid pollution of your namespace, so be sure to specify them in the **use** statement if you need them:

```
use Pod::Find qw(pod_find);
```

**pod\_find( { %opts } , @directories )**

The function **pod\_find** searches for POD documents in a given set of files and/or directories. It returns a hash with the file names as keys and the POD name as value. The POD name is derived from the file name and its position in the directory tree.

E.g. when searching in *\$HOME/perl5lib*, the file *\$HOME/perl5lib/MyModule.pm* would get the POD name *MyModule*, whereas *\$HOME/perl5lib/Myclass/Subclass.pm* would be *Myclass::Subclass*. The name information can be used for POD translators.

Only text files containing at least one valid POD command are found.

A warning is printed if more than one POD file with the same POD name is found, e.g. *CPAN.pm* in different directories. This usually indicates duplicate occurrences of modules in the *@INC* search path.

**OPTIONS** The first argument for **pod\_find** may be a hash reference with options. The rest are either directories that are searched recursively or files. The POD names of files are the plain basenames with any Perl-like extension (.pm, .pl, .pod) stripped.

**-verbose => 1**

Print progress information while scanning.

**-perl => 1**

Apply Perl-specific heuristics to find the correct PODs. This includes stripping Perl-like extensions, omitting subdirectories that are numeric but do *not* match the current Perl interpreter's version id, suppressing *site\_perl* as a module hierarchy name etc.

**-script => 1**

Search for PODs in the current Perl interpreter's installation **scriptdir**. This is taken from the local *Config/Config* module.

**-inc => 1**

Search for PODs in the current Perl interpreter's *@INC* paths. This automatically considers paths specified in the PERL5LIB environment as this is prepended to *@INC* by the Perl interpreter itself.

**simplify\_name( \$str )**

The function **simplify\_name** is equivalent to **basename**, but also strips Perl-like extensions (.pm, .pl, .pod) and extensions like *.bat*, *.cmd* on Win32 and OS/2, or *.com* on VMS, respectively.

**pod\_where( { %opts }, \$pod )**

Returns the location of a pod document given a search directory and a module (e.g. `File::Find`) or script (e.g. `perldoc`) name.

Options:

`-inc => 1`

Search `@INC` for the pod and also the `scriptdir` defined in the [Config/Config](#) module.

`-dirs => [ $dir1, $dir2, ... ]`

Reference to an array of search directories. These are searched in order before looking in `@INC` (if `-inc`). Current directory is used if none are specified.

`-verbose => 1`

List directories as they are searched

Returns the full path of the first occurrence to the file. Package names (eg `'A::B'`) are automatically converted to directory names in the selected directory. (eg on unix `'A::B'` is converted to `'A/B'`). Additionally, `'.pm'`, `'.pl'` and `'.pod'` are appended to the search automatically if required.

A subdirectory ***pod/*** is also checked if it exists in any of the given search directories. This ensures that e.g. [perlfunc/perlfunc](#) is found.

It is assumed that if a module name is supplied, that that name matches the file name. Pods are not opened to check for the `'NAME'` entry.

A check is made to make sure that the file that is found does contain some pod documentation.

**contains\_pod( \$file , \$verbose )**

Returns true if the supplied filename (not POD module) contains some pod information.

**AUTHOR**

Marek Rouchal <marek@saftsack.fs.uni-bayreuth.de>, heavily borrowing code from Nick Ing-Simmons' PodToHtml.

Tim Jenness <t.jenness@jach.hawaii.edu> provided `pod_where` and `contains_pod`.

**NAME**

Pod::Functions – Group Perl’s functions a la perlfunc.pod

**SYNOPSIS**

```
use Pod::Functions;

my @misc_ops = @{ $Kinds{ 'Misc' } };
my $misc_dsc = $Type_Description{ 'Misc' };

or

perl /path/to/lib/Pod/Functions.pm
```

This will print a grouped list of Perl’s functions, like the *[Perl Functions by Category in perlfunc](#)* section.

**DESCRIPTION**

It exports the following variables:

**%Kinds**

This holds a hash-of-lists. Each list contains the functions in the catagory the key denotes.

**%Type**

In this hash each key represents a function and the value is the catagory. The catagory can be a comma separated list.

**%Flavor**

In this hash each key represents a function and the value is a short description of that function.

**%Type\_Description**

In this hash each key represents a catagory of functions and the value is a short description of that catagory.

**@Type\_Order**

This list of catagories is used to produce the same order as the *[Perl Functions by Category in perlfunc](#)* section.

**CHANGES**

**NAME**

Pod::Html – module to convert pod files to HTML

**SYNOPSIS**

```
use Pod::Html;
pod2html([options]);
```

**DESCRIPTION**

Converts files from pod format (see [perlpod](#)) to HTML format. It can automatically generate indexes and cross-references, and it keeps a cache of things it knows how to cross-reference.

**ARGUMENTS**

Pod::Html takes the following arguments:

**backlink**

```
--backlink="Back to Top"
```

Adds "Back to Top" links in front of every `head1` heading (except for the first). By default, no backlinks are generated.

**cachedir**

```
--cachedir=name
```

Creates the item and directory caches in the given directory.

**css**

```
--css=stylesheet
```

Specify the URL of a cascading style sheet. Also disables all HTML/CSS `style` attributes that are output by default (to avoid conflicts).

**flush**

```
--flush
```

Flushes the item and directory caches.

**header**

```
--header
--noheader
```

Creates header and footer blocks containing the text of the NAME section. By default, no headers are generated.

**help**

```
--help
```

Displays the usage message.

**htmldir**

```
--htmldir=name
```

Sets the directory in which the resulting HTML file is placed. This is used to generate relative links to other files. Not passing this causes all links to be absolute, since this is the value that tells Pod::Html the root of the documentation tree.

**htmlroot**

```
--htmlroot=name
```

Sets the base URL for the HTML files. When cross-references are made, the HTML root is prepended to the URL.

**index**

`--index`  
`--noindex`

Generate an index at the top of the HTML file. This is the default behaviour.

**infile**

`--infile=name`

Specify the pod file to convert. Input is taken from STDIN if no infile is specified.

**libpods**

`--libpods=name:...:name`

List of page names (eg, "perlfunc") which contain linkable `=items`.

**netscape**

`--netscape`  
`--nonetscape`

**Deprecated**, has no effect. For backwards compatibility only.

**outfile**

`--outfile=name`

Specify the HTML file to create. Output goes to STDOUT if no outfile is specified.

**podpath**

`--podpath=name:...:name`

Specify which subdirectories of the podroot contain pod files whose HTML converted forms can be linked to in cross references.

**podroot**

`--podroot=name`

Specify the base directory for finding library pods.

**quiet**

`--quiet`  
`--noquiet`

Don't display *mostly harmless* warning messages. These messages will be displayed by default. But this is not the same as verbose mode.

**recurse**

`--recurse`  
`--norecurse`

Recurse into subdirectories specified in podpath (default behaviour).

**title**

`--title=title`

Specify the title of the resulting HTML file.

**verbose**

`--verbose`  
`--noverbose`

Display progress messages. By default, they won't be displayed.

**EXAMPLE**

```
pod2html ("pod2html",
 "--podpath=lib:ext:pod:vms",
 "--podroot=/usr/src/perl",
 "--htmlroot=/perl/nmanual",
 "--libpods=perlfunc:perlguts:perlvar:perlrun:perlop",
 "--recurse",
 "--infile=foo.pod",
 "--outfile=/perl/nmanual/foo.html");
```

**ENVIRONMENT**

Uses `$Config{pod2html}` to setup default options.

**NAME**

Pod::InputObjects – objects representing POD input paragraphs, commands, etc.

**SYNOPSIS**

```
use Pod::InputObjects;
```

**REQUIRES**

perl5.004, Carp

**EXPORTS**

Nothing.

**DESCRIPTION**

This module defines some basic input objects used by **Pod::Parser** when reading and parsing POD text from an input source. The following objects are defined:

```
=begin __PRIVATE__
```

**package Pod::InputSource**

An object corresponding to a source of POD input text. It is mostly a wrapper around a filehandle or `IO::Handle`-type object (or anything that implements the `getline()` method) which keeps track of some additional information relevant to the parsing of PODs.

```
=end __PRIVATE__
```

**package Pod::Paragraph**

An object corresponding to a paragraph of POD input text. It may be a plain paragraph, a verbatim paragraph, or a command paragraph (see [perlpod](#)).

**package Pod::InteriorSequence**

An object corresponding to an interior sequence command from the POD input text (see [perlpod](#)).

**package Pod::ParseTree**

An object corresponding to a tree of parsed POD text. Each "node" in a parse-tree (or *ptree*) is either a text-string or a reference to a **Pod::InteriorSequence** object. The nodes appear in the parse-tree in the order in which they were parsed from left-to-right.

Each of these input objects are described in further detail in the sections which follow.

**Pod::InputSource**

This object corresponds to an input source or stream of POD documentation. When parsing PODs, it is necessary to associate and store certain context information with each input source. All of this information is kept together with the stream itself in one of these `Pod::InputSource` objects. Each such object is merely a wrapper around an `IO::Handle` object of some kind (or at least something that implements the `getline()` method). They have the following methods/attributes:

```
=end __PRIVATE__
```

**new()**

```
my $pod_input1 = Pod::InputSource->new(-handle => $filehandle);
my $pod_input2 = new Pod::InputSource(-handle => $filehandle,
 -name => $name);
my $pod_input3 = new Pod::InputSource(-handle => *STDIN);
my $pod_input4 = Pod::InputSource->new(-handle => *STDIN,
 -name => "(STDIN)");
```

This is a class method that constructs a `Pod::InputSource` object and returns a reference to the new input source object. It takes one or more keyword arguments in the form of a hash. The keyword `-handle` is required and designates the corresponding input handle. The keyword `-name` is optional and specifies the

name associated with the input handle (typically a file name).

```
=end __PRIVATE__
```

#### **name()**

```
my $filename = $pod_input->name();
$pod_input->name($new_filename_to_use);
```

This method gets/sets the name of the input source (usually a filename). If no argument is given, it returns a string containing the name of the input source; otherwise it sets the name of the input source to the contents of the given argument.

```
=end __PRIVATE__
```

#### **handle()**

```
my $handle = $pod_input->handle();
```

Returns a reference to the handle object from which input is read (the one used to construct this input source object).

```
=end __PRIVATE__
```

#### **was\_cutting()**

```
print "Yes.\n" if ($pod_input->was_cutting());
```

The value of the cutting state (that the **cutting()** method would have returned) immediately before any input was read from this input stream. After all input from this stream has been read, the cutting state is restored to this value.

```
=end __PRIVATE__
```

### **Pod::Paragraph**

An object representing a paragraph of POD input text. It has the following methods/attributes:

#### **Pod::Paragraph->new()**

```
my $pod_para1 = Pod::Paragraph->new(-text => $text);
my $pod_para2 = Pod::Paragraph->new(-name => $cmd,
 -text => $text);
my $pod_para3 = new Pod::Paragraph(-text => $text);
my $pod_para4 = new Pod::Paragraph(-name => $cmd,
 -text => $text);
my $pod_para5 = Pod::Paragraph->new(-name => $cmd,
 -text => $text,
 -file => $filename,
 -line => $line_number);
```

This is a class method that constructs a **Pod::Paragraph** object and returns a reference to the new paragraph object. It may be given one or two keyword arguments. The **-text** keyword indicates the corresponding text of the POD paragraph. The **-name** keyword indicates the name of the corresponding POD command, such as **head1** or **item** (it should *not* contain the **=** prefix); this is needed only if the POD paragraph corresponds to a command paragraph. The **-file** and **-line** keywords indicate the filename and line number corresponding to the beginning of the paragraph

#### **\$pod\_para->cmd\_name()**

```
my $para_cmd = $pod_para->cmd_name();
```

If this paragraph is a command paragraph, then this method will return the name of the command (*without* any leading **=** prefix).

**\$pod\_para->text()**

```
my $para_text = $pod_para->text();
```

This method will return the corresponding text of the paragraph.

**\$pod\_para->raw\_text()**

```
my $raw_pod_para = $pod_para->raw_text();
```

This method will return the *raw* text of the POD paragraph, exactly as it appeared in the input.

**\$pod\_para->cmd\_prefix()**

```
my $prefix = $pod_para->cmd_prefix();
```

If this paragraph is a command paragraph, then this method will return the prefix used to denote the command (which should be the string "=" or "==").

**\$pod\_para->cmd\_separator()**

```
my $separator = $pod_para->cmd_separator();
```

If this paragraph is a command paragraph, then this method will return the text used to separate the command name from the rest of the paragraph (if any).

**\$pod\_para->parse\_tree()**

```
my $ptree = $pod_parser->parse_text($pod_para->text());
$pod_para->parse_tree($ptree);
$ptree = $pod_para->parse_tree();
```

This method will get/set the corresponding parse-tree of the paragraph's text.

**\$pod\_para->file\_line()**

```
my ($filename, $line_number) = $pod_para->file_line();
my $position = $pod_para->file_line();
```

Returns the current filename and line number for the paragraph object. If called in a list context, it returns a list of two elements: first the filename, then the line number. If called in a scalar context, it returns a string containing the filename, followed by a colon (:), followed by the line number.

**Pod::InteriorSequence**

An object representing a POD interior sequence command. It has the following methods/attributes:

**Pod::InteriorSequence->new()**

```
my $pod_seq1 = Pod::InteriorSequence->new(-name => $cmd
 -ldelim => $delimiter);
my $pod_seq2 = new Pod::InteriorSequence(-name => $cmd,
 -ldelim => $delimiter);
my $pod_seq3 = new Pod::InteriorSequence(-name => $cmd,
 -ldelim => $delimiter,
 -file => $filename,
 -line => $line_number);

my $pod_seq4 = new Pod::InteriorSequence(-name => $cmd, $ptree);
my $pod_seq5 = new Pod::InteriorSequence($cmd, $ptree);
```

This is a class method that constructs a `Pod::InteriorSequence` object and returns a reference to the new interior sequence object. It should be given two keyword arguments. The `-ldelim` keyword indicates the corresponding left-delimiter of the interior sequence (e.g. '<'). The `-name` keyword indicates the name of the corresponding interior sequence command, such as I or B or C. The `-file` and `-line` keywords indicate the filename and line number corresponding to the beginning of the interior sequence. If the `$ptree` argument is given, it must be the last argument, and it must be either string, or else an array-ref suitable for passing to **Pod::ParseTree::new** (or it may be a reference to a `Pod::ParseTree` object).

```
$pod_seq->cmd_name()
```

```
my $seq_cmd = $pod_seq->cmd_name();
```

The name of the interior sequence command.

```
$pod_seq->prepend()
```

```
$pod_seq->prepend($text);
$pod_seq1->prepend($pod_seq2);
```

Prepends the given string or parse-tree or sequence object to the parse-tree of this interior sequence.

```
$pod_seq->append()
```

```
$pod_seq->append($text);
$pod_seq1->append($pod_seq2);
```

Appends the given string or parse-tree or sequence object to the parse-tree of this interior sequence.

```
$pod_seq->nested()
```

```
$outer_seq = $pod_seq->nested || print "not nested";
```

If this interior sequence is nested inside of another interior sequence, then the outer/parent sequence that contains it is returned. Otherwise undef is returned.

```
$pod_seq->raw_text()
```

```
my $seq_raw_text = $pod_seq->raw_text();
```

This method will return the *raw* text of the POD interior sequence, exactly as it appeared in the input.

```
$pod_seq->left_delimiter()
```

```
my $ldelim = $pod_seq->left_delimiter();
```

The leftmost delimiter beginning the argument text to the interior sequence (should be "<").

```
$pod_seq->right_delimiter()
```

The rightmost delimiter beginning the argument text to the interior sequence (should be "").

```
$pod_seq->parse_tree()
```

```
my $ptree = $pod_parser->parse_text($paragraph_text);
$pod_seq->parse_tree($ptree);
$ptree = $pod_seq->parse_tree();
```

This method will get/set the corresponding parse-tree of the interior sequence's text.

```
$pod_seq->file_line()
```

```
my ($filename, $line_number) = $pod_seq->file_line();
my $position = $pod_seq->file_line();
```

Returns the current filename and line number for the interior sequence object. If called in a list context, it returns a list of two elements: first the filename, then the line number. If called in a scalar context, it returns a string containing the filename, followed by a colon (':'), followed by the line number.

```
Pod::InteriorSequence::DESTROY()
```

This method performs any necessary cleanup for the interior-sequence. If you override this method then it is **imperative** that you invoke the parent method from within your own method, otherwise *interior-sequence storage will not be reclaimed upon destruction!*

```
Pod::ParseTree
```

This object corresponds to a tree of parsed POD text. As POD text is scanned from left to right, it is parsed into an ordered list of text-strings and **Pod::InteriorSequence** objects (in order of appearance). A **Pod::ParseTree** object corresponds to this list of strings and sequences. Each interior sequence in the parse-tree may itself contain a parse-tree (since interior sequences may be nested).

**Pod::ParseTree->new()**

```
my $ptree1 = Pod::ParseTree->new;
my $ptree2 = new Pod::ParseTree;
my $ptree4 = Pod::ParseTree->new($array_ref);
my $ptree3 = new Pod::ParseTree($array_ref);
```

This is a class method that constructs a `Pod::Parse_tree` object and returns a reference to the new parse-tree. If a single-argument is given, it must be a reference to an array, and is used to initialize the root (top) of the parse tree.

**\$ptree->top()**

```
my $top_node = $ptree->top();
$ptree->top($top_node);
$ptree->top(@children);
```

This method gets/sets the top node of the parse-tree. If no arguments are given, it returns the topmost node in the tree (the root), which is also a **Pod::ParseTree**. If it is given a single argument that is a reference, then the reference is assumed to a parse-tree and becomes the new top node. Otherwise, if arguments are given, they are treated as the new list of children for the top node.

**\$ptree->children()**

This method gets/sets the children of the top node in the parse-tree. If no arguments are given, it returns the list (array) of children (each of which should be either a string or a **Pod::InteriorSequence**. Otherwise, if arguments are given, they are treated as the new list of children for the top node.

**\$ptree->prepend()**

This method prepends the given text or parse-tree to the current parse-tree. If the first item on the parse-tree is text and the argument is also text, then the text is prepended to the first item (not added as a separate string). Otherwise the argument is added as a new string or parse-tree *before* the current one.

**\$ptree->append()**

This method appends the given text or parse-tree to the current parse-tree. If the last item on the parse-tree is text and the argument is also text, then the text is appended to the last item (not added as a separate string). Otherwise the argument is added as a new string or parse-tree *after* the current one.

**\$ptree->raw\_text()**

```
my $ptree_raw_text = $ptree->raw_text();
```

This method will return the *raw* text of the POD parse-tree exactly as it appeared in the input.

**Pod::ParseTree::DESTROY()**

This method performs any necessary cleanup for the parse-tree. If you override this method then it is **imperative** that you invoke the parent method from within your own method, otherwise *parse-tree storage will not be reclaimed upon destruction!*

**AUTHOR**

Brad Appleton <bradapp@enteract.com>

**NAME**

Pod::LaTeX – Convert Pod data to formatted Latex

**SYNOPSIS**

```
use Pod::LaTeX;
my $parser = Pod::LaTeX->new ();

$parser->parse_from_filehandle;

$parser->parse_from_file ('file.pod', 'file.tex');
```

**DESCRIPTION**

Pod::LaTeX is a module to convert documentation in the Pod format into Latex. The [pod2latex/pod2latex](#) X<pod2latex command uses this module for translation.

Pod::LaTeX is a derived class from [Pod::Select/Pod::Select](#).

**OBJECT METHODS**

The following methods are provided in this module. Methods inherited from Pod::Select are not described in the public interface.

```
=begin __PRIVATE__

initialize

 Initialise the object. This method is subclassed from Pod::Parser. The base class method is
 invoked. This method defines the default behaviour of the object unless overridden by supplying
 arguments to the constructor.

 Internal settings are defaulted as well as the public instance data. Internal hash values are accessed
 directly (rather than through a method) and start with an underscore.

 This method should not be invoked by the user directly.

=end __PRIVATE__
```

**Data Accessors**

The following methods are provided for accessing instance data. These methods should be used for accessing configuration parameters rather than assuming the object is a hash.

Default values can be supplied by using these names as keys to a hash of arguments when using the new() constructor.

**AddPreamble**

Logical to control whether a latex preamble is to be written. If true, a valid latex preamble is written before the pod data is written. This is similar to:

```
\documentclass{article}
\begin{document}
```

but will be more complicated if table of contents and indexing are required. Can be used to set or retrieve the current value.

```
$add = $parser->AddPreamble();
$parser->AddPreamble(1);
```

If used in conjunction with AddPostamble a full latex document will be written that could be immediately processed by latex.

**AddPostamble**

Logical to control whether a standard latex ending is written to the output file after the document has been processed. In its simplest form this is simply:

```
\end{document}
```

but can be more complicated if an index is required. Can be used to set or retrieve the current value.

```
$add = $parser->AddPostamble();
$parser->AddPostamble(1);
```

If used in conjunction with `AddPreamble` a full latex document will be written that could be immediately processed by latex.

### Head1Level

The latex sectioning level that should be used to correspond to a pod `=head1` directive. This can be used, for example, to turn a `=head1` into a latex subsection. This should hold a number corresponding to the required position in an array containing the following elements:

```
[0] chapter
[1] section
[2] subsection
[3] subsubsection
[4] paragraph
[5] subparagraph
```

Can be used to set or retrieve the current value:

```
$parser->Head1Level(2);
$sect = $parser->Head1Level;
```

Setting this number too high can result in sections that may not be reproducible in the expected way. For example, setting this to 4 would imply that `=head3` do not have a corresponding latex section (`=head1` would correspond to a paragraph).

A check is made to ensure that the supplied value is an integer in the range 0 to 5.

Default is for a value of 1 (i.e. a section).

### Label

This is the label that is prefixed to all latex label and index entries to make them unique. In general, pods have similarly titled sections (NAME, DESCRIPTION etc) and a latex label will be multiply defined if more than one pod document is to be included in a single latex file. To overcome this, this label is prefixed to a label whenever a label is required (joined with an underscore) or to an index entry (joined by an exclamation mark which is the normal index separator). For example, `\label{text}` becomes `\label{Label_text}`.

Can be used to set or retrieve the current value:

```
$label = $parser->Label;
$parser->Label($label);
```

This label is only used if `UniqueLabels` is true. Its value is set automatically from the `NAME` field if `ReplaceNAMEwithSection` is true. If this is not the case it must be set manually before starting the parse.

Default value is `undef`.

### LevelNoNum

Control the point at which latex section numbering is turned off. For example, this can be used to make sure that latex sections are numbered but subsections are not.

Can be used to set or retrieve the current value:

```
$lev = $parser->LevelNoNum;
$parser->LevelNoNum(2);
```

The argument must be an integer between 0 and 5 and is the same as the number described in `Head1Level` method description. The number has nothing to do with the pod heading number, only the latex sectioning.

Default is 2. (i.e. latex subsections are written as `subsection*` but sections are numbered).

### MakeIndex

Controls whether latex commands for creating an index are to be inserted into the preamble and postamble

```
$makeindex = $parser->MakeIndex;
$parser->MakeIndex(0);
```

Irrelevant if both `AddPreamble` and `AddPostamble` are false (or equivalently, `UserPreamble` and `UserPostamble` are set).

Default is for an index to be created.

### ReplaceNAMEwithSection

This controls whether the NAME section in the pod is to be translated literally or converted to a slightly modified output where the section name is the pod name rather than "NAME".

If true, the pod segment

```
=head1 NAME
pod::name - purpose
=head1 SYNOPSIS
```

is converted to the latex

```
\section{pod::name\label{pod_name}\index{pod::name}}
Purpose
\subsection*{SYNOPSIS\label{pod_name_SYNOPSIS}%
\index{pod::name!SYNOPSIS}}
```

(dependent on the value of `Head1Level` and `LevelNoNum`). Note that subsequent `head1` directives translate to subsections rather than sections and that the labels and index now include the pod name (dependent on the value of `UniqueLabels`).

The Label is set from the pod name regardless of any current value of `Label`.

```
$mod = $parser->ReplaceNAMEwithSection;
$parser->ReplaceNAMEwithSection(0);
```

Default is to translate the pod literally.

### StartWithNewPage

If true, each pod translation will begin with a latex `\clearpage`.

```
$parser->StartWithNewPage(1);
$newpage = $parser->StartWithNewPage;
```

Default is false.

### TableOfContents

If true, a table of contents will be created. Irrelevant if `AddPreamble` is false or `UserPreamble` is set.

```
$toc = $parser->TableOfContents;
$parser->TableOfContents(1);
```

Default is false.

### UniqueLabels

If true, the translator will attempt to make sure that each `latex` label or index entry will be uniquely identified by prefixing the contents of `Label`. This allows multiple documents to be combined without clashing common labels such as `DESCRIPTION` and `SYNOPSIS`

```
$parser->UniqueLabels(1);
$unq = $parser->UniqueLabels;
```

Default is true.

### UserPreamble

User supplied `latex` preamble. Added before the pod translation data.

If set, the contents will be prepended to the output file before the translated data regardless of the value of `AddPreamble`. `MakeIndex` and `TableOfContents` will also be ignored.

### UserPostamble

User supplied `latex` postamble. Added after the pod translation data.

If set, the contents will be prepended to the output file after the translated data regardless of the value of `AddPostamble`. `MakeIndex` will also be ignored.

### Lists

Contains details of the currently active lists.

The array contains `Pod::List` objects. A new `Pod::List` object is created each time a list is encountered and it is pushed onto this stack. When the list context ends, it is popped from the stack. The array will be empty if no lists are active.

Returns array of list information in list context Returns array ref in scalar context

`=begin __PRIVATE__`

### Subclassed methods

The following methods override methods provided in the `Pod::Select` base class. See `Pod::Parser` and `Pod::Select` for more information on what these methods require.

#### **begin\_pod**

Writes the `latex` preamble if requested.

#### **end\_pod**

Write the closing `latex` code.

#### **command**

Process basic pod commands.

#### **verbatim**

Verbatim text

#### **textblock**

Plain text paragraph.

#### **interior\_sequence**

Interior sequence expansion

### List Methods

Methods used to handle lists.

**begin\_list**

Called when a new list is found (via the `over` directive). Creates a new `Pod::List` object and stores it on the `list` stack.

```
$parser->begin_list($indent, $line_num);
```

**end\_list**

Called when the end of a list is found (the `back` directive). Pops the `Pod::List` object off the stack of lists and writes the `latex` code required to close a list.

```
$parser->end_list($line_num);
```

**add\_item**

Add items to the list. The first time an item is encountered (determined from the state of the current `Pod::List` object) the type of list is determined (ordered, unnumbered or description) and the relevant `latex` code issued.

```
$parser->add_item($paragraph, $line_num);
```

**Methods for headings****head**

Print a heading of the required level.

```
$parser->head($level, $paragraph, $parobj);
```

The first argument is the pod heading level. The second argument is the contents of the heading. The 3rd argument is a `Pod::Paragraph` object so that the line number can be extracted.

```
=end __PRIVATE__
```

```
=begin __PRIVATE__
```

**Internal methods**

Internal routines are described in this section. They do not form part of the public interface. All private methods start with an underscore.

**\_output**

Output text to the output filehandle. This method must be always be called to output parsed text.

```
$parser->_output($text);
```

Does not write anything if a `=begin` is active that should be ignored.

**\_replace\_special\_chars**

Subroutine to replace characters that are special in `latex` with the escaped forms

```
$escaped = $parser->_replace_special_chars($paragraph);
```

Need to call this routine before `interior_sequences` are munged but not if `verbatim`. It must be called before interpolation of interior sequences so that curly brackets and special `latex` characters inserted during interpolation are not themselves escaped. This means that `<` and `&` can not be modified here since the text still contains interior sequences.

Special characters and the `latex` equivalents are:

|    |                |
|----|----------------|
| }  | \}             |
| {  | \{             |
| _  | \_             |
| \$ | \\$            |
| %  | \%             |
| &  | \&             |
| \  | \$\backslash\$ |

```

^ \^{}
~ \~{}

```

### **`_replace_special_chars_late`**

Replace special characters that can not be replaced before interior sequence interpolation. See `_replace_special_chars` for a routine to replace special characters prior to interpolation of interior sequences.

Does the following transformation:

```

< $<$
> $>$
| $|$

```

### **`_create_label`**

Return a string that can be used as an internal reference in a latex document (i.e. accepted by the `\label` command)

```
$label = $parser->_create_label($string)
```

If `UniqueLabels` is true returns a label prefixed by `Label()` This can be suppressed with an optional second argument.

```
$label = $parser->_create_label($string, $suppress);
```

If a second argument is supplied (of any value including undef) the `Label()` is never prefixed. This means that this routine can be called to create a `Label()` without prefixing a previous setting.

### **`_create_index`**

Similar to `_create_label` except an index entry is created. If `UniqueLabels` is true, the index entry is prefixed by the current `Label` and an exclamation mark.

```
$ind = $parser->_create_index($paragraph);
```

An exclamation mark is used by `makeindex` to generate sub-entries in an index.

### **`_clean_latex_commands`**

Removes latex commands from text. The latex command is assumed to be of the form `\command{ text }`. "text" is retained

```
$clean = $parser->_clean_latex_commands($text);
```

### **`_split_delimited`**

Split the supplied string into two parts at approximately the specified word boundary. Special care is made to make sure that it does not split in the middle of some curly brackets.

e.g. "this text is `\textbf{very bold}`" would not be split into "this text is `\textbf{very}`" and " bold".

```
($hunk1, $hunk2) = $self->_split_delimited($para, $length);
```

The length indicates the maximum length of `hunk1`.

```
=end __PRIVATE__
```

## **NOTES**

Compatible with latex2e only. Can not be used with latex v2.09 or earlier.

A subclass of `Pod::Select` so that specific pod sections can be converted to latex by using the `select` method.

Some HTML escapes are missing and many have not been tested.

**NAME**

Pod::Man – Convert POD data to formatted \*roff input

**SYNOPSIS**

```
use Pod::Man;
my $parser = Pod::Man->new (release => $VERSION, section => 8);

Read POD from STDIN and write to STDOUT.
$parser->parse_from_filehandle;

Read POD from file.pod and write to file.1.
$parser->parse_from_file ('file.pod', 'file.1');
```

**DESCRIPTION**

Pod::Man is a module to convert documentation in the POD format (the preferred language for documenting Perl) into \*roff input using the man macro set. The resulting \*roff code is suitable for display on a terminal using *nroff(1)*, normally via *man(1)*, or printing using *troff(1)*. It is conventionally invoked using the driver script **pod2man**, but it can also be used directly.

As a derived class from Pod::Parser, Pod::Man supports the same methods and interfaces. See *Pod::Parser* for all the details; briefly, one creates a new parser with `< Pod::Man-new()` and then calls either `parse_from_filehandle()` or `parse_from_file()`.

`new()` can take options, in the form of key/value pairs that control the behavior of the parser. See below for details.

If no options are given, Pod::Man uses the name of the input file with any trailing .pod, .pm, or .pl stripped as the man page title, to section 1 unless the file ended in .pm in which case it defaults to section 3, to a centered title of "User Contributed Perl Documentation", to a centered footer of the Perl version it is run with, and to a left-hand footer of the modification date of its input (or the current date if given STDIN for input).

Pod::Man assumes that your \*roff formatters have a fixed-width font named CW. If yours is called something else (like CR), use the `fixed` option to specify it. This generally only matters for troff output for printing. Similarly, you can set the fonts used for bold, italic, and bold italic fixed-width output.

Besides the obvious pod conversions, Pod::Man also takes care of formatting `func()`, `func(3)`, and simple variable references like `$foo` or `@bar` so you don't have to use code escapes for them; complex expressions like `$fred{'stuff'}` will still need to be escaped, though. It also translates dashes that aren't used as hyphens into en dashes, makes long dashes—like this—into proper em dashes, fixes "paired quotes," makes C++ look right, puts a little space between double underbars, makes ALLCAPS a teeny bit smaller in **troff**, and escapes stuff that \*roff treats as special so that you don't have to.

The recognized options to `new()` are as follows. All options take a single argument.

**center**

Sets the centered page header to use instead of "User Contributed Perl Documentation".

**date**

Sets the left-hand footer. By default, the modification date of the input file will be used, or the current date if `stat()` can't find that file (the case if the input is from STDIN), and the date will be formatted as YYYY-MM-DD.

**fixed**

The fixed-width font to use for verbatim text and code. Defaults to CW. Some systems may want CR instead. Only matters for **troff** output.

**fixedbold**

Bold version of the fixed-width font. Defaults to CB. Only matters for **troff** output.

**fixeditalic**

Italic version of the fixed-width font (actually, something of a misnomer, since most fixed-width fonts only have an oblique version, not an italic version). Defaults to CI. Only matters for **troff** output.

**fixedbolditalic**

Bold italic (probably actually oblique) version of the fixed-width font. Pod::Man doesn't assume you have this, and defaults to CB. Some systems (such as Solaris) have this font available as CX. Only matters for **troff** output.

**name**

Set the name of the manual page. Without this option, the manual name is set to the uppercased base name of the file being converted unless the manual section is 3, in which case the path is parsed to see if it is a Perl module path. If it is, a path like `.../lib/Pod/Man.pm` is converted into a name like `Pod::Man`. This option, if given, overrides any automatic determination of the name.

**quotes**

Sets the quote marks used to surround `C< text`. If the value is a single character, it is used as both the left and right quote; if it is two characters, the first character is used as the left quote and the second as the right quoted; and if it is four characters, the first two are used as the left quote and the second two as the right quote.

This may also be set to the special value `none`, in which case no quote marks are added around `C< text` (but the font is still changed for troff output).

**release**

Set the centered footer. By default, this is the version of Perl you run Pod::Man under. Note that some system an macro sets assume that the centered footer will be a modification date and will prepend something like "Last modified: "; if this is the case, you may want to set `release` to the last modified date and `date` to the version number.

**section**

Set the section for the `.TH` macro. The standard section numbering convention is to use 1 for user commands, 2 for system calls, 3 for functions, 4 for devices, 5 for file formats, 6 for games, 7 for miscellaneous information, and 8 for administrator commands. There is a lot of variation here, however; some systems (like Solaris) use 4 for file formats, 5 for miscellaneous information, and 7 for devices. Still others use 1m instead of 8, or some mix of both. About the only section numbers that are reliably consistent are 1, 2, and 3.

By default, section 1 will be used unless the file ends in `.pm` in which case section 3 will be selected.

The standard Pod::Parser method `parse_from_filehandle()` takes up to two arguments, the first being the file handle to read POD from and the second being the file handle to write the formatted output to. The first defaults to `STDIN` if not given, and the second defaults to `STDOUT`. The method `parse_from_file()` is almost identical, except that its two arguments are the input and output disk files instead. See [Pod::Parser](#) for the specific details.

**DIAGNOSTICS**

roff font should be 1 or 2 chars, not "%s"

(F) You specified a \*roff font (using `fixed`, `fixedbold`, etc.) that wasn't either one or two characters. Pod::Man doesn't support \*roff fonts longer than two characters, although some \*roff extensions do (the canonical versions of **nroff** and **troff** don't either).

Invalid link %s

(W) The POD source contained a `L<>` formatting code that Pod::Man was unable to parse. You should never see this error message; it probably indicates a bug in Pod::Man.

**Invalid quote specification "%s"**

(F) The quote specification given (the quotes option to the constructor) was invalid. A quote specification must be one, two, or four characters long.

**%s:%d: Unknown command paragraph "%s".**

(W) The POD source contained a non-standard command paragraph (something of the form `=command args`) that Pod::Man didn't know about. It was ignored.

**%s:%d: Unknown escape E<%s>**

(W) The POD source contained an E<> escape that Pod::Man didn't know about. E<%s> was printed verbatim in the output.

**%s:%d: Unknown formatting code %s**

(W) The POD source contained a non-standard formatting code (something of the form X<>) that Pod::Man didn't know about. It was ignored.

**%s:%d: Unmatched =back**

(W) Pod::Man encountered a `=back` command that didn't correspond to an `=over` command.

**BUGS**

Eight-bit input data isn't handled at all well at present. The correct approach would be to map E<> escapes to the appropriate UTF-8 characters and then do a translation pass on the output according to the user-specified output character set. Unfortunately, we can't send eight-bit data directly to the output unless the user says this is okay, since some vendor \*roff implementations can't handle eight-bit data. If the \*roff implementation can, however, that's far superior to the current hacked characters that only work under troff.

There is currently no way to turn off the guesswork that tries to format unmarked text appropriately, and sometimes it isn't wanted (particularly when using POD to document something other than Perl).

The NAME section should be recognized specially and index entries emitted for everything in that section. This would have to be deferred until the next section, since extraneous things in NAME tends to confuse various man page processors.

Pod::Man doesn't handle font names longer than two characters. Neither do most **troff** implementations, but GNU troff does as an extension. It would be nice to support as an option for those who want to use it.

The preamble added to each output file is rather verbose, and most of it is only necessary in the presence of E<> escapes for non-ASCII characters. It would ideally be nice if all of those definitions were only output if needed, perhaps on the fly as the characters are used.

Pod::Man is excessively slow.

**CAVEATS**

The handling of hyphens and em dashes is somewhat fragile, and one may get the wrong one under some circumstances. This should only matter for **troff** output.

When and whether to use small caps is somewhat tricky, and Pod::Man doesn't necessarily get it right.

**NAME**

Pod::ParseLink – Parse an L<> formatting code in POD text

**SYNOPSIS**

```
use Pod::ParseLink;
my ($text, $inferred, $name, $section, $type) = parselink ($link);
```

**DESCRIPTION**

This module only provides a single function, `parselink()`, which takes the text of an L<> formatting code and parses it. It returns the anchor text for the link (if any was given), the anchor text possibly inferred from the name and section, the name or URL, the section if any, and the type of link. The type will be one of 'url', 'pod', or 'man', indicating a URL, a link to a POD page, or a link to a Unix manual page.

Parsing is implemented per [perlpodspec](#). For backward compatibility, links where there is no section and name contains spaces, or links where the entirety of the link (except for the anchor text if given) is enclosed in double-quotes are interpreted as links to a section (L</section>).

The inferred anchor text is implemented per [perlpodspec](#):

```
L<name> => L<name|name>
L</section> => L<"section"|/section>
L<name/section> => L<"section" in name|name/section>
```

The name may contain embedded E<> and Z<> formatting codes, and the section, anchor text, and inferred anchor text may contain any formatting codes. Any double quotes around the section are removed as part of the parsing, as is any leading or trailing whitespace.

If the text of the L<> escape is entirely enclosed in double quotes, it's interpreted as a link to a section for backwards compatibility.

No attempt is made to resolve formatting codes. This must be done after calling `parselink` (since E<> formatting codes can be used to escape characters that would otherwise be significant to the parser and resolving them before parsing would result in an incorrect parse of a formatting code like:

```
L<verticalE<verbar>barE<sol>slash>
```

which should be interpreted as a link to the `vertical|bar/slash` POD page and not as a link to the `slash` section of the `bar` POD page with an anchor text of `vertical`. Note that not only the anchor text will need to have formatting codes expanded, but so will the target of the link (to deal with E<> and Z<> formatting codes), and special handling of the section may be necessary depending on whether the translator wants to consider markup in sections to be significant when resolving links. See [perlpodspec](#) for more information.

**NAME**

Pod::Parser – base class for creating POD filters and translators

**SYNOPSIS**

```
use Pod::Parser;

package MyParser;
@ISA = qw(Pod::Parser);

sub command {
 my ($parser, $command, $paragraph, $line_num) = @_;
 ## Interpret the command and its text; sample actions might be:
 if ($command eq 'head1') { ... }
 elsif ($command eq 'head2') { ... }
 ## ... other commands and their actions
 my $out_fh = $parser->output_handle();
 my $expansion = $parser->interpolate($paragraph, $line_num);
 print $out_fh $expansion;
}

sub verbatim {
 my ($parser, $paragraph, $line_num) = @_;
 ## Format verbatim paragraph; sample actions might be:
 my $out_fh = $parser->output_handle();
 print $out_fh $paragraph;
}

sub textblock {
 my ($parser, $paragraph, $line_num) = @_;
 ## Translate/Format this block of text; sample actions might be:
 my $out_fh = $parser->output_handle();
 my $expansion = $parser->interpolate($paragraph, $line_num);
 print $out_fh $expansion;
}

sub interior_sequence {
 my ($parser, $seq_command, $seq_argument) = @_;
 ## Expand an interior sequence; sample actions might be:
 return "$seq_argument" if ($seq_command eq 'B');
 return "`$seq_argument'" if ($seq_command eq 'C');
 return "_${seq_argument}_" if ($seq_command eq 'I');
 ## ... other sequence commands and their resulting text
}

package main;

Create a parser object and have it parse file whose name was
given on the command-line (use STDIN if no files were given).
$parser = new MyParser();
$parser->parse_from_filehandle(*STDIN) if (@ARGV == 0);
for (@ARGV) { $parser->parse_from_file($_); }
```

**REQUIRES**

perl5.005, Pod::InputObjects, Exporter, Symbol, Carp

## EXPORTS

Nothing.

## DESCRIPTION

**Pod::Parser** is a base class for creating POD filters and translators. It handles most of the effort involved with parsing the POD sections from an input stream, leaving subclasses free to be concerned only with performing the actual translation of text.

**Pod::Parser** parses PODs, and makes method calls to handle the various components of the POD. Subclasses of **Pod::Parser** override these methods to translate the POD into whatever output format they desire.

## QUICK OVERVIEW

To create a POD filter for translating POD documentation into some other format, you create a subclass of **Pod::Parser** which typically overrides just the base class implementation for the following methods:

- **command()**
- **verbatim()**
- **textblock()**
- **interior\_sequence()**

You may also want to override the **begin\_input()** and **end\_input()** methods for your subclass (to perform any needed per-file and/or per-document initialization or cleanup).

If you need to perform any preprocessing of input before it is parsed you may want to override one or more of **preprocess\_line()** and/or **preprocess\_paragraph()**.

Sometimes it may be necessary to make more than one pass over the input files. If this is the case you have several options. You can make the first pass using **Pod::Parser** and override your methods to store the intermediate results in memory somewhere for the **end\_pod()** method to process. You could use **Pod::Parser** for several passes with an appropriate state variable to control the operation for each pass. If your input source can't be reset to start at the beginning, you can store it in some other structure as a string or an array and have that structure implement a **getline()** method (which is all that **parse\_from\_filehandle()** uses to read input).

Feel free to add any member data fields you need to keep track of things like current font, indentation, horizontal or vertical position, or whatever else you like. Be sure to read *"PRIVATE METHODS AND DATA"* to avoid name collisions.

For the most part, the **Pod::Parser** base class should be able to do most of the input parsing for you and leave you free to worry about how to interpret the commands and translate the result.

Note that all we have described here in this quick overview is the simplest most straightforward use of **Pod::Parser** to do stream-based parsing. It is also possible to use the **Pod::Parser::parse\_text** function to do more sophisticated tree-based parsing. See *"TREE-BASED PARSING"*.

## PARSING OPTIONS

A *parse-option* is simply a named option of **Pod::Parser** with a value that corresponds to a certain specified behavior. These various behaviors of **Pod::Parser** may be enabled/disabled by setting or unsetting one or more *parse-options* using the **parseopts()** method. The set of currently accepted parse-options is as follows:

### **-want\_nonPODs** (default: unset)

Normally (by default) **Pod::Parser** will only provide access to the POD sections of the input. Input paragraphs that are not part of the POD-format documentation are not made available to the caller (not even using **preprocess\_paragraph()**). Setting this option to a non-empty, non-zero value will allow **preprocess\_paragraph()** to see non-POD sections of the input as well as POD sections. The **cutting()** method can be used to determine if the corresponding paragraph is a POD paragraph,

or some other input paragraph.

#### **-process\_cut\_cmd** (default: unset)

Normally (by default) **Pod::Parser** handles the `=cut` POD directive by itself and does not pass it on to the caller for processing. Setting this option to a non-empty, non-zero value will cause **Pod::Parser** to pass the `=cut` directive to the caller just like any other POD command (and hence it may be processed by the `command()` method).

**Pod::Parser** will still interpret the `=cut` directive to mean that "cutting mode" has been (re)entered, but the caller will get a chance to capture the actual `=cut` paragraph itself for whatever purpose it desires.

#### **-warnings** (default: unset)

Normally (by default) **Pod::Parser** recognizes a bare minimum of pod syntax errors and warnings and issues diagnostic messages for errors, but not for warnings. (Use **Pod::Checker** to do more thorough checking of POD syntax.) Setting this option to a non-empty, non-zero value will cause **Pod::Parser** to issue diagnostics for the few warnings it recognizes as well as the errors.

Please see `"parseopts()"` for a complete description of the interface for the setting and unsetting of parse-options.

### RECOMMENDED SUBROUTINE/METHOD OVERRIDES

**Pod::Parser** provides several methods which most subclasses will probably want to override. These methods are as follows:

#### **command()**

```
$parser->command($cmd,$text,$line_num,$pod_para);
```

This method should be overridden by subclasses to take the appropriate action when a POD command paragraph (denoted by a line beginning with "=") is encountered. When such a POD directive is seen in the input, this method is called and is passed:

`$cmd`

the name of the command for this POD paragraph

`$text`

the paragraph text for the given POD paragraph command.

`$line_num`

the line-number of the beginning of the paragraph

`$pod_para`

a reference to a `Pod::Paragraph` object which contains further information about the paragraph command (see *Pod::InputObjects* for details).

**Note** that this method is called for `=pod` paragraphs.

The base class implementation of this method simply treats the raw POD command as normal block of paragraph text (invoking the `textblock()` method with the command paragraph).

#### **verbatim()**

```
$parser->verbatim($text,$line_num,$pod_para);
```

This method may be overridden by subclasses to take the appropriate action when a block of verbatim text is encountered. It is passed the following parameters:

`$text`

the block of text for the verbatim paragraph

`$line_num`

the line-number of the beginning of the paragraph

**\$pod\_para**

a reference to a `Pod::Paragraph` object which contains further information about the paragraph (see [Pod::InputObjects](#) for details).

The base class implementation of this method simply prints the textblock (unmodified) to the output filehandle.

**textblock()**

```
$parser->textblock($text,$line_num,$pod_para);
```

This method may be overridden by subclasses to take the appropriate action when a normal block of POD text is encountered (although the base class method will usually do what you want). It is passed the following parameters:

**\$text**

the block of text for the a POD paragraph

**\$line\_num**

the line-number of the beginning of the paragraph

**\$pod\_para**

a reference to a `Pod::Paragraph` object which contains further information about the paragraph (see [Pod::InputObjects](#) for details).

In order to process interior sequences, subclasses implementations of this method will probably want to invoke either **interpolate()** or **parse\_text()**, passing it the text block `$text`, and the corresponding line number in `$line_num`, and then perform any desired processing upon the returned result.

The base class implementation of this method simply prints the text block as it occurred in the input stream).

**interior\_sequence()**

```
$parser->interior_sequence($seq_cmd,$seq_arg,$pod_seq);
```

This method should be overridden by subclasses to take the appropriate action when an interior sequence is encountered. An interior sequence is an embedded command within a block of text which appears as a command name (usually a single uppercase character) followed immediately by a string of text which is enclosed in angle brackets. This method is passed the sequence command `$seq_cmd` and the corresponding text `$seq_arg`. It is invoked by the **interpolate()** method for each interior sequence that occurs in the string that it is passed. It should return the desired text string to be used in place of the interior sequence. The `$pod_seq` argument is a reference to a `Pod::InteriorSequence` object which contains further information about the interior sequence. Please see [Pod::InputObjects](#) for details if you need to access this additional information.

Subclass implementations of this method may wish to invoke the **nested()** method of `$pod_seq` to see if it is nested inside some other interior-sequence (and if so, which kind).

The base class implementation of the **interior\_sequence()** method simply returns the raw text of the interior sequence (as it occurred in the input) to the caller.

**OPTIONAL SUBROUTINE/METHOD OVERRIDES**

**Pod::Parser** provides several methods which subclasses may want to override to perform any special pre/post-processing. These methods do *not* have to be overridden, but it may be useful for subclasses to take advantage of them.

**new()**

```
my $parser = Pod::Parser->new();
```

This is the constructor for **Pod::Parser** and its subclasses. You *do not* need to override this method! It is capable of constructing subclass objects as well as base class objects, provided you use any of the following

constructor invocation styles:

```
my $parser1 = MyParser->new();
my $parser2 = new MyParser();
my $parser3 = $parser2->new();
```

where `MyParser` is some subclass of **Pod::Parser**.

Using the syntax `MyParser::new()` to invoke the constructor is *not* recommended, but if you insist on being able to do this, then the subclass *will* need to override the **new()** constructor method. If you do override the constructor, you *must* be sure to invoke the **initialize()** method of the newly blessed object.

Using any of the above invocations, the first argument to the constructor is always the corresponding package name (or object reference). No other arguments are required, but if desired, an associative array (or hash-table) may be passed to the **new()** constructor, as in:

```
my $parser1 = MyParser->new(MYDATA => $value1, MOREDATA => $value2);
my $parser2 = new MyParser(-myflag => 1);
```

All arguments passed to the **new()** constructor will be treated as key/value pairs in a hash-table. The newly constructed object will be initialized by copying the contents of the given hash-table (which may have been empty). The **new()** constructor for this class and all of its subclasses returns a blessed reference to the initialized object (hash-table).

#### **initialize()**

```
$parser->initialize();
```

This method performs any necessary object initialization. It takes no arguments (other than the object instance of course, which is typically copied to a local variable named `$self`). If subclasses override this method then they *must* be sure to invoke `$self->SUPER::initialize()`.

#### **begin\_pod()**

```
$parser->begin_pod();
```

This method is invoked at the beginning of processing for each POD document that is encountered in the input. Subclasses should override this method to perform any per-document initialization.

#### **begin\_input()**

```
$parser->begin_input();
```

This method is invoked by **parse\_from\_filehandle()** immediately *before* processing input from a filehandle. The base class implementation does nothing, however, subclasses may override it to perform any per-file initializations.

Note that if multiple files are parsed for a single POD document (perhaps the result of some future `=include` directive) this method is invoked for every file that is parsed. If you wish to perform certain initializations once per document, then you should use **begin\_pod()**.

#### **end\_input()**

```
$parser->end_input();
```

This method is invoked by **parse\_from\_filehandle()** immediately *after* processing input from a filehandle. The base class implementation does nothing, however, subclasses may override it to perform any per-file cleanup actions.

Please note that if multiple files are parsed for a single POD document (perhaps the result of some kind of `=include` directive) this method is invoked for every file that is parsed. If you wish to perform certain cleanup actions once per document, then you should use **end\_pod()**.

**end\_pod()**

```
$parser->end_pod();
```

This method is invoked at the end of processing for each POD document that is encountered in the input. Subclasses should override this method to perform any per-document finalization.

**preprocess\_line()**

```
$textline = $parser->preprocess_line($text, $line_num);
```

This method should be overridden by subclasses that wish to perform any kind of preprocessing for each *line* of input (*before* it has been determined whether or not it is part of a POD paragraph). The parameter `$text` is the input line; and the parameter `$line_num` is the line number of the corresponding text line.

The value returned should correspond to the new text to use in its place. If the empty string or an undefined value is returned then no further processing will be performed for this line.

Please note that the **preprocess\_line()** method is invoked *before* the **preprocess\_paragraph()** method. After all (possibly preprocessed) lines in a paragraph have been assembled together and it has been determined that the paragraph is part of the POD documentation from one of the selected sections, then **preprocess\_paragraph()** is invoked.

The base class implementation of this method returns the given text.

**preprocess\_paragraph()**

```
$textblock = $parser->preprocess_paragraph($text, $line_num);
```

This method should be overridden by subclasses that wish to perform any kind of preprocessing for each block (paragraph) of POD documentation that appears in the input stream. The parameter `$text` is the POD paragraph from the input file; and the parameter `$line_num` is the line number for the beginning of the corresponding paragraph.

The value returned should correspond to the new text to use in its place. If the empty string is returned or an undefined value is returned, then the given `$text` is ignored (not processed).

This method is invoked after gathering up all the lines in a paragraph and after determining the cutting state of the paragraph, but before trying to further parse or interpret them. After **preprocess\_paragraph()** returns, the current cutting state (which is returned by `$self->cutting()`) is examined. If it evaluates to true then input text (including the given `$text`) is cut (not processed) until the next POD directive is encountered.

Please note that the **preprocess\_line()** method is invoked *before* the **preprocess\_paragraph()** method. After all (possibly preprocessed) lines in a paragraph have been assembled together and either it has been determined that the paragraph is part of the POD documentation from one of the selected sections or the `-want_nonPODs` option is true, then **preprocess\_paragraph()** is invoked.

The base class implementation of this method returns the given text.

**METHODS FOR PARSING AND PROCESSING**

**Pod::Parser** provides several methods to process input text. These methods typically won't need to be overridden (and in some cases they can't be overridden), but subclasses may want to invoke them to exploit their functionality.

**parse\_text()**

```
$ptree1 = $parser->parse_text($text, $line_num);
$ptree2 = $parser->parse_text({%opts}, $text, $line_num);
$ptree3 = $parser->parse_text(\%opts, $text, $line_num);
```

This method is useful if you need to perform your own interpolation of interior sequences and can't rely upon **interpolate** to expand them in simple bottom-up order.

The parameter `$text` is a string or block of text to be parsed for interior sequences; and the parameter

`$line_num` is the line number corresponding to the beginning of `$text`.

**parse\_text()** will parse the given text into a parse-tree of "nodes." and interior-sequences. Each "node" in the parse tree is either a text-string, or a **Pod::InteriorSequence**. The result returned is a parse-tree of type **Pod::ParseTree**. Please see [Pod::InputObjects](#) for more information about **Pod::InteriorSequence** and **Pod::ParseTree**.

If desired, an optional hash-ref may be specified as the first argument to customize certain aspects of the parse-tree that is created and returned. The set of recognized option keywords are:

**-expand\_seq => code-ref|method-name**

Normally, the parse-tree returned by **parse\_text()** will contain an unexpanded **Pod::InteriorSequence** object for each interior-sequence encountered. Specifying **-expand\_seq** tells **parse\_text()** to "expand" every interior-sequence it sees by invoking the referenced function (or named method of the parser object) and using the return value as the expanded result.

If a subroutine reference was given, it is invoked as:

```
&$code_ref($parser, $sequence)
```

and if a method-name was given, it is invoked as:

```
$parser->method_name($sequence)
```

where `$parser` is a reference to the parser object, and `$sequence` is a reference to the interior-sequence object. [NOTE: If the **interior\_sequence()** method is specified, then it is invoked according to the interface specified in "[interior\\_sequence\(\)](#)".].

**-expand\_text => code-ref|method-name**

Normally, the parse-tree returned by **parse\_text()** will contain a text-string for each contiguous sequence of characters outside of an interior-sequence. Specifying **-expand\_text** tells **parse\_text()** to "preprocess" every such text-string it sees by invoking the referenced function (or named method of the parser object) and using the return value as the preprocessed (or "expanded") result. [Note that if the result is an interior-sequence, then it will *not* be expanded as specified by the **-expand\_seq** option; Any such recursive expansion needs to be handled by the specified callback routine.]

If a subroutine reference was given, it is invoked as:

```
&$code_ref($parser, $text, $ptree_node)
```

and if a method-name was given, it is invoked as:

```
$parser->method_name($text, $ptree_node)
```

where `$parser` is a reference to the parser object, `$text` is the text-string encountered, and `$ptree_node` is a reference to the current node in the parse-tree (usually an interior-sequence object or else the top-level node of the parse-tree).

**-expand\_ptree => code-ref|method-name**

Rather than returning a **Pod::ParseTree**, pass the parse-tree as an argument to the referenced subroutine (or named method of the parser object) and return the result instead of the parse-tree object.

If a subroutine reference was given, it is invoked as:

```
&$code_ref($parser, $ptree)
```

and if a method-name was given, it is invoked as:

```
$parser->method_name($ptree)
```

where `$parser` is a reference to the parser object, and `$ptree` is a reference to the parse-tree object.

**interpolate()**

```
$textblock = $parser->interpolate($text, $line_num);
```

This method translates all text (including any embedded interior sequences) in the given text string `$text` and returns the interpolated result. The parameter `$line_num` is the line number corresponding to the beginning of `$text`.

**interpolate()** merely invokes a private method to recursively expand nested interior sequences in bottom-up order (innermost sequences are expanded first). If there is a need to expand nested sequences in some alternate order, use **parse\_text** instead.

**parse\_paragraph()**

```
$parser->parse_paragraph($text, $line_num);
```

This method takes the text of a POD paragraph to be processed, along with its corresponding line number, and invokes the appropriate method (one of **command()**, **verbatim()**, or **textblock()**).

For performance reasons, this method is invoked directly without any dynamic lookup; Hence subclasses may *not* override it!

```
=end __PRIVATE__
```

**parse\_from\_filehandle()**

```
$parser->parse_from_filehandle($in_fh,$out_fh);
```

This method takes an input filehandle (which is assumed to already be opened for reading) and reads the entire input stream looking for blocks (paragraphs) of POD documentation to be processed. If no first argument is given the default input filehandle STDIN is used.

The `$in_fh` parameter may be any object that provides a **getline()** method to retrieve a single line of input text (hence, an appropriate wrapper object could be used to parse PODs from a single string or an array of strings).

Using `$in_fh->getline()`, input is read line-by-line and assembled into paragraphs or "blocks" (which are separated by lines containing nothing but whitespace). For each block of POD documentation encountered it will invoke a method to parse the given paragraph.

If a second argument is given then it should correspond to a filehandle where output should be sent (otherwise the default output filehandle is STDOUT if no output filehandle is currently in use).

**NOTE:** For performance reasons, this method caches the input stream at the top of the stack in a local variable. Any attempts by clients to change the stack contents during processing when in the midst executing of this method *will not affect* the input stream used by the current invocation of this method.

This method does *not* usually need to be overridden by subclasses.

**parse\_from\_file()**

```
$parser->parse_from_file($filename,$outfile);
```

This method takes a filename and does the following:

- opens the input and output files for reading (creating the appropriate filehandles)
- invokes the **parse\_from\_filehandle()** method passing it the corresponding input and output filehandles.
- closes the input and output files.

If the special input filename `"-"` or `"<&STDIN"` is given then the STDIN filehandle is used for input (and no open or close is performed). If no input filename is specified then `"-"` is implied.

If a second argument is given then it should be the name of the desired output file. If the special output filename `"-"` or `"&STDOUT"` is given then the STDOUT filehandle is used for output (and no open or close

is performed). If the special output filename "&STDERR" is given then the STDERR filehandle is used for output (and no open or close is performed). If no output filehandle is currently in use and no output filename is specified, then "-" is implied.

This method does *not* usually need to be overridden by subclasses.

## ACCESSOR METHODS

Clients of **Pod::Parser** should use the following methods to access instance data fields:

### errorsub()

```
$parser->errorsub("method_name");
$parser->errorsub(\&warn_user);
$parser->errorsub(sub { print STDERR, @_ });
```

Specifies the method or subroutine to use when printing error messages about POD syntax. The supplied method/subroutine *must* return TRUE upon successful printing of the message. If undef is given, then the **warn** builtin is used to issue error messages (this is the default behavior).

```
my $errorsub = $parser->errorsub();
my $errmsg = "This is an error message!\n"
(ref $errorsub) and &{$errorsub}($errmsg)
 or (defined $errorsub) and $parser->$errorsub($errmsg)
 or warn($errmsg);
```

Returns a method name, or else a reference to the user-supplied subroutine used to print error messages. Returns undef if the **warn** builtin is used to issue error messages (this is the default behavior).

### cutting()

```
$boolean = $parser->cutting();
```

Returns the current cutting state: a boolean-valued scalar which evaluates to true if text from the input file is currently being "cut" (meaning it is *not* considered part of the POD document).

```
$parser->cutting($boolean);
```

Sets the current cutting state to the given value and returns the result.

### parseopts()

When invoked with no additional arguments, **parseopts** returns a hashtable of all the current parsing options.

```
See if we are parsing non-POD sections as well as POD ones
my %opts = $parser->parseopts();
$opts{'-want_nonPODs'} and print "-want_nonPODs\n";
```

When invoked using a single string, **parseopts** treats the string as the name of a parse-option and returns its corresponding value if it exists (returns undef if it doesn't).

```
Did we ask to see '=cut' paragraphs?
my $want_cut = $parser->parseopts('-process_cut_cmd');
$want_cut and print "-process_cut_cmd\n";
```

When invoked with multiple arguments, **parseopts** treats them as key/value pairs and the specified parse-option names are set to the given values. Any unspecified parse-options are unaffected.

```
Set them back to the default
$parser->parseopts(-warnings => 0);
```

When passed a single hash-ref, **parseopts** uses that hash to completely reset the existing parse-options, all previous parse-option values are lost.

```
Reset all options to default
$parser->parseopts({ });
```

See *"PARSING OPTIONS"* for more information on the name and meaning of each parse-option currently recognized.

#### **output\_file()**

```
$fname = $parser->output_file();
```

Returns the name of the output file being written.

#### **output\_handle()**

```
$fhandle = $parser->output_handle();
```

Returns the output filehandle object.

#### **input\_file()**

```
$fname = $parser->input_file();
```

Returns the name of the input file being read.

#### **input\_handle()**

```
$fhandle = $parser->input_handle();
```

Returns the current input filehandle object.

#### **input\_streams()**

```
$listref = $parser->input_streams();
```

Returns a reference to an array which corresponds to the stack of all the input streams that are currently in the middle of being parsed.

While parsing an input stream, it is possible to invoke **parse\_from\_file()** or **parse\_from\_filehandle()** to parse a new input stream and then return to parsing the previous input stream. Each input stream to be parsed is pushed onto the end of this input stack before any of its input is read. The input stream that is currently being parsed is always at the end (or top) of the input stack. When an input stream has been exhausted, it is popped off the end of the input stack.

Each element on this input stack is a reference to `Pod::InputSource` object. Please see [Pod::InputObjects](#) for more details.

This method might be invoked when printing diagnostic messages, for example, to obtain the name and line number of the all input files that are currently being processed.

```
=end __PRIVATE__
```

#### **top\_stream()**

```
$hashref = $parser->top_stream();
```

Returns a reference to the hash-table that represents the element that is currently at the top (end) of the input stream stack (see *"input\_streams()"*). The return value will be the `undef` if the input stack is empty.

This method might be used when printing diagnostic messages, for example, to obtain the name and line number of the current input file.

```
=end __PRIVATE__
```

### **PRIVATE METHODS AND DATA**

**Pod::Parser** makes use of several internal methods and data fields which clients should not need to see or use. For the sake of avoiding name collisions for client data and methods, these methods and fields are briefly discussed here. Determined hackers may obtain further information about them by reading the **Pod::Parser** source code.

Private data fields are stored in the hash-object whose reference is returned by the **new()** constructor for this class. The names of all private methods and data-fields used by **Pod::Parser** begin with a prefix of `"_"` and match the regular expression `/^_\w+$/`.

**`_push_input_stream()`**

```
$hashref = $parser->_push_input_stream($in_fh,$out_fh);
```

This method will push the given input stream on the input stack and perform any necessary beginning-of-document or beginning-of-file processing. The argument `$in_fh` is the input stream filehandle to push, and `$out_fh` is the corresponding output filehandle to use (if it is not given or is undefined, then the current output stream is used, which defaults to standard output if it doesn't exist yet).

The value returned will be reference to the hash-table that represents the new top of the input stream stack. *Please Note* that it is possible for this method to use default values for the input and output file handles. If this happens, you will need to look at the `INPUT` and `OUTPUT` instance data members to determine their new values.

```
=end_PRIVATE_
```

**`_pop_input_stream()`**

```
$hashref = $parser->_pop_input_stream();
```

This takes no arguments. It will perform any necessary end-of-file or end-of-document processing and then pop the current input stream from the top of the input stack.

The value returned will be reference to the hash-table that represents the new top of the input stream stack.

```
=end_PRIVATE_
```

**TREE-BASED PARSING**

If straightforward stream-based parsing won't meet your needs (as is likely the case for tasks such as translating PODs into structured markup languages like HTML and XML) then you may need to take the tree-based approach. Rather than doing everything in one pass and calling the `interpolate()` method to expand sequences into text, it may be desirable to instead create a parse-tree using the `parse_text()` method to return a tree-like structure which may contain an ordered list of children (each of which may be a text-string, or a similar tree-like structure).

Pay special attention to *"METHODS FOR PARSING AND PROCESSING"* and to the objects described in *Pod::InputObjects*. The former describes the gory details and parameters for how to customize and extend the parsing behavior of **Pod::Parser**. **Pod::InputObjects** provides several objects that may all be used interchangeably as parse-trees. The most obvious one is the **Pod::ParseTree** object. It defines the basic interface and functionality that all things trying to be a POD parse-tree should do. A **Pod::ParseTree** is defined such that each "node" may be a text-string, or a reference to another parse-tree. Each **Pod::Paragraph** object and each **Pod::InteriorSequence** object also supports the basic parse-tree interface.

The `parse_text()` method takes a given paragraph of text, and returns a parse-tree that contains one or more children, each of which may be a text-string, or an `InteriorSequence` object. There are also callback-options that may be passed to `parse_text()` to customize the way it expands or transforms interior-sequences, as well as the returned result. These callbacks can be used to create a parse-tree with custom-made objects (which may or may not support the parse-tree interface, depending on how you choose to do it).

If you wish to turn an entire POD document into a parse-tree, that process is fairly straightforward. The `parse_text()` method is the key to doing this successfully. Every paragraph-callback (i.e. the polymorphic methods for `command()`, `verbatim()`, and `textblock()` paragraphs) takes a **Pod::Paragraph** object as an argument. Each paragraph object has a `parse_tree()` method that can be used to get or set a corresponding parse-tree. So for each of those paragraph-callback methods, simply call `parse_text()` with the options you desire, and then use the returned parse-tree to assign to the given paragraph object.

That gives you a parse-tree for each paragraph – so now all you need is an ordered list of paragraphs. You can maintain that yourself as a data element in the object/hash. The most straightforward way would be

simply to use an array-ref, with the desired set of custom "options" for each invocation of **parse\_text**. Let's assume the desired option-set is given by the hash %options. Then we might do something like the following:

```
package MyPodParserTree;

@ISA = qw(Pod::Parser);

...

sub begin_pod {
 my $self = shift;
 $self->{'-paragraphs'} = []; ## initialize paragraph list
}

sub command {
 my ($parser, $command, $paragraph, $line_num, $pod_para) = @_;
 my $ptree = $parser->parse_text(%options, $paragraph, ...);
 $pod_para->parse_tree($ptree);
 push @{ $self->{'-paragraphs'} }, $pod_para;
}

sub verbatim {
 my ($parser, $paragraph, $line_num, $pod_para) = @_;
 push @{ $self->{'-paragraphs'} }, $pod_para;
}

sub textblock {
 my ($parser, $paragraph, $line_num, $pod_para) = @_;
 my $ptree = $parser->parse_text(%options, $paragraph, ...);
 $pod_para->parse_tree($ptree);
 push @{ $self->{'-paragraphs'} }, $pod_para;
}

...

package main;

...
my $parser = new MyPodParserTree(...);
$parser->parse_from_file(...);
my $paragraphs_ref = $parser->{'-paragraphs'};
```

Of course, in this module-author's humble opinion, I'd be more inclined to use the existing **Pod::ParseTree** object than a simple array. That way everything in it, paragraphs and sequences, all respond to the same core interface for all parse-tree nodes. The result would look something like:

```
package MyPodParserTree2;

...

sub begin_pod {
 my $self = shift;
 $self->{'-ptree'} = new Pod::ParseTree; ## initialize parse-tree
}

sub parse_tree {
 ## convenience method to get/set the parse-tree for the entire POD
 (@_ > 1) and $_[0]->{'-ptree'} = $_[1];
 return $_[0]->{'-ptree'};
}
```

```

sub command {
 my ($parser, $command, $paragraph, $line_num, $pod_para) = @_;
 my $ptree = $parser->parse_text({<<options>>}, $paragraph, ...);
 $pod_para->parse_tree($ptree);
 $parser->parse_tree()->append($pod_para);
}

sub verbatim {
 my ($parser, $paragraph, $line_num, $pod_para) = @_;
 $parser->parse_tree()->append($pod_para);
}

sub textblock {
 my ($parser, $paragraph, $line_num, $pod_para) = @_;
 my $ptree = $parser->parse_text({<<options>>}, $paragraph, ...);
 $pod_para->parse_tree($ptree);
 $parser->parse_tree()->append($pod_para);
}

...

package main;
...
my $parser = new MyPodParserTree2(...);
$parser->parse_from_file(...);
my $ptree = $parser->parse_tree;
...

```

Now you have the entire POD document as one great big parse-tree. You can even use the `--expand_seq` option to `parse_text` to insert whole different kinds of objects. Just don't expect `Pod::Parser` to know what to do with them after that. That will need to be in your code. Or, alternatively, you can insert any object you like so long as it conforms to the `Pod::ParseTree` interface.

One could use this to create subclasses of `Pod::Paragraphs` and `Pod::InteriorSequences` for specific commands (or to create your own custom node-types in the parse-tree) and add some kind of `emit()` method to each custom node/subclass object in the tree. Then all you'd need to do is recursively walk the tree in the desired order, processing the children (most likely from left to right) by formatting them if they are text-strings, or by calling their `emit()` method if they are objects/references.

## SEE ALSO

[Pod::InputObjects](#), [Pod::Select](#)

**Pod::InputObjects** defines POD input objects corresponding to command paragraphs, parse-trees, and interior-sequences.

**Pod::Select** is a subclass of **Pod::Parser** which provides the ability to selectively include and/or exclude sections of a POD document from being translated based upon the current heading, subheading, subsubheading, etc.

=for \_\_PRIVATE\_\_ **Pod::Callbacks** is a subclass of **Pod::Parser** which gives its users the ability the employ *callback functions* instead of, or in addition to, overriding methods of the base class.

=for \_\_PRIVATE\_\_ **Pod::Select** and **Pod::Callbacks** do not override any methods nor do they define any new methods with the same name. Because of this, they may *both* be used (in combination) as a base class of the same subclass in order to combine their functionality without causing any namespace clashes due to multiple inheritance.

Based on code for **Pod::Text** written by Tom Christiansen <tchrist@mox.perl.com>

## NAME

Pod::ParseUtils – helpers for POD parsing and conversion

## SYNOPSIS

```
use Pod::ParseUtils;

my $list = new Pod::List;
my $link = Pod::Hyperlink->new('Pod::Parser');
```

## DESCRIPTION

**Pod::ParseUtils** contains a few object-oriented helper packages for POD parsing and processing (i.e. in POD formatters and translators).

### Pod::List

**Pod::List** can be used to hold information about POD lists (written as `=over ... =item ... =back`) for further processing. The following methods are available:

`Pod::List->new()`

Create a new list object. Properties may be specified through a hash reference like this:

```
my $list = Pod::List->new({ -start => $., -indent => 4 });
```

See the individual methods/properties for details.

`$list->file()`

Without argument, retrieves the file name the list is in. This must have been set before by either specifying **-file** in the **new()** method or by calling the **file()** method with a scalar argument.

`$list->start()`

Without argument, retrieves the line number where the list started. This must have been set before by either specifying **-start** in the **new()** method or by calling the **start()** method with a scalar argument.

`$list->indent()`

Without argument, retrieves the indent level of the list as specified in `=over n`. This must have been set before by either specifying **-indent** in the **new()** method or by calling the **indent()** method with a scalar argument.

`$list->type()`

Without argument, retrieves the list type, which can be an arbitrary value, e.g. OL, UL, ... when thinking the HTML way. This must have been set before by either specifying **-type** in the **new()** method or by calling the **type()** method with a scalar argument.

`$list->rx()`

Without argument, retrieves a regular expression for simplifying the individual item strings once the list type has been determined. Usage: E.g. when converting to HTML, one might strip the leading number in an ordered list as `<OL>` already prints numbers itself. This must have been set before by either specifying **-rx** in the **new()** method or by calling the **rx()** method with a scalar argument.

`$list->item()`

Without argument, retrieves the array of the items in this list. The items may be represented by any scalar. If an argument has been given, it is pushed on the list of items.

`$list->parent()`

Without argument, retrieves information about the parent holding this list, which is represented as an arbitrary scalar. This must have been set before by either specifying **-parent** in the **new()** method or by calling the **parent()** method with a scalar argument.

**\$list->tag()**

Without argument, retrieves information about the list tag, which can be any scalar. This must have been set before by either specifying **-tag** in the **new()** method or by calling the **tag()** method with a scalar argument.

**Pod::Hyperlink**

**Pod::Hyperlink** is a class for manipulation of POD hyperlinks. Usage:

```
my $link = Pod::Hyperlink->new('alternative text|page/"section in page"');
```

The **Pod::Hyperlink** class is mainly designed to parse the contents of the `L<...>` sequence, providing a simple interface for accessing the different parts of a POD hyperlink for further processing. It can also be used to construct hyperlinks.

**Pod::Hyperlink->new()**

The **new()** method can either be passed a set of key/value pairs or a single scalar value, namely the contents of a `L<...>` sequence. An object of the class **Pod::Hyperlink** is returned. The value `undef` indicates a failure, the error message is stored in `$@`.

**\$link->parse(\$string)**

This method can be used to (re)parse a (new) hyperlink, i.e. the contents of a `L<...>` sequence. The result is stored in the current object. Warnings are stored in the **warnings** property. E.g. sections like `L<open(2)>` are deprecated, as they do not point to Perl documents. `L<DBI::foo(3p)>` is wrong as well, the manpage section can simply be dropped.

**\$link->markup(\$string)**

Set/retrieve the textual value of the link. This string contains special markers `P<>` and `Q<>` that should be expanded by the translator's interior sequence expansion engine to the formatter-specific code to highlight/activate the hyperlink. The details have to be implemented in the translator.

**\$link->text()**

This method returns the textual representation of the hyperlink as above, but without markers (read only). Depending on the link type this is one of the following alternatives (the `+` and `*` denote the portions of the text that are marked up):

```
the +perl+ manpage
the *$|* entry in the +perlvar+ manpage
the section on *OPTIONS* in the +perldoc+ manpage
the section on *DESCRIPTION* elsewhere in this document
```

**\$link->warning()**

After parsing, this method returns any warnings encountered during the parsing process.

**\$link->file()****\$link->line()**

Just simple slots for storing information about the line and the file the link was encountered in. Has to be filled in manually.

**\$link->page()**

This method sets or returns the POD page this link points to.

**\$link->node()**

As above, but the destination node text of the link.

**\$link->alttext()**

Sets or returns an alternative text specified in the link.

**\$link->type()**

The node type, either `section` or `item`. As an unofficial type, there is also `hyperlink`, derived from e.g. `L<http://perl.com>`

**\$link->link()**

Returns the link as contents of `L<>`. Reciprocal to **parse()**.

**Pod::Cache**

**Pod::Cache** holds information about a set of POD documents, especially the nodes for hyperlinks. The following methods are available:

**Pod::Cache->new()**

Create a new cache object. This object can hold an arbitrary number of POD documents of class **Pod::Cache::Item**.

**\$cache->item()**

Add a new item to the cache. Without arguments, this method returns a list of all cache elements.

**\$cache->find\_page(\$name)**

Look for a POD document named `$name` in the cache. Returns the reference to the corresponding **Pod::Cache::Item** object or `undef` if not found.

**Pod::Cache::Item**

**Pod::Cache::Item** holds information about individual POD documents, that can be grouped in a **Pod::Cache** object. It is intended to hold information about the hyperlink nodes of POD documents. The following methods are available:

**Pod::Cache::Item->new()**

Create a new object.

**\$cacheitem->page()**

Set/retrieve the POD document name (e.g. `"Pod::Parser"`).

**\$cacheitem->description()**

Set/retrieve the POD short description as found in the `=head1 NAME` section.

**\$cacheitem->path()**

Set/retrieve the POD file storage path.

**\$cacheitem->file()**

Set/retrieve the POD file name.

**\$cacheitem->nodes()**

Add a node (or a list of nodes) to the document's node list. Note that the order is kept, i.e. start with the first node and end with the last. If no argument is given, the current list of nodes is returned in the same order the nodes have been added. A node can be any scalar, but usually is a pair of node string and unique id for the `find_node` method to work correctly.

**\$cacheitem->find\_node(\$name)**

Look for a node or index entry named `$name` in the object. Returns the unique id of the node (i.e. the second element of the array stored in the node array) or `undef` if not found.

**\$cacheitem->idx()**

Add an index entry (or a list of them) to the document's index list. Note that the order is kept, i.e. start with the first node and end with the last. If no argument is given, the current list of index entries is returned in the same order the entries have been added. An index entry can be any scalar, but usually is a pair of string and unique id.

Marek Rouchal <marek@saftsack.fs.uni-bayreuth.de>, borrowing a lot of things from [pod2man](#) and [pod2roff](#) as well as other POD processing tools by Tom Christiansen, Brad Appleton and Russ Allbery.

**SEE ALSO**

[pod2man](#), [pod2roff](#), [Pod::Parser](#), [Pod::Checker](#), [pod2html](#)

**NAME**

Pod::Plainer – Perl extension for converting Pod to old style Pod.

**SYNOPSIS**

```
use Pod::Plainer;

my $parser = Pod::Plainer -> new ();
$parser -> parse_from_filehandle(*STDIN);
```

**DESCRIPTION**

Pod::Plainer uses Pod::Parser which takes Pod with the (new) ‘C<< .. >>’ constructs and returns the old(er) style with just ‘C<>’; ‘<’ and ‘>’ are replaced by ‘E<It>’ and ‘E<gt>’.

This can be used to pre-process Pod before using tools which do not recognise the new style Pods.

**EXPORT**

None by default.

**AUTHOR**

Robin Barker, rmb1@cise.npl.co.uk

**SEE ALSO**

See [Pod::Parser](#).

**NAME**

Pod::Select, podselect() – extract selected sections of POD from input

**SYNOPSIS**

```
use Pod::Select;

Select all the POD sections for each file in @filelist
and print the result on standard output.
podselect(@filelist);

Same as above, but write to tmp.out
podselect({-output => "tmp.out"}, @filelist);

Select from the given filelist, only those POD sections that are
within a 1st level section named any of: NAME, SYNOPSIS, OPTIONS.
podselect({-sections => ["NAME|SYNOPSIS", "OPTIONS"]}, @filelist);

Select the "DESCRIPTION" section of the PODs from STDIN and write
the result to STDERR.
podselect({-output => ">&STDERR", -sections => ["DESCRIPTION"]}, *STDIN);

or

use Pod::Select;

Create a parser object for selecting POD sections from the input
$parser = new Pod::Select();

Select all the POD sections for each file in @filelist
and print the result to tmp.out.
$parser->parse_from_file("<&STDIN", "tmp.out");

Select from the given filelist, only those POD sections that are
within a 1st level section named any of: NAME, SYNOPSIS, OPTIONS.
$parser->select("NAME|SYNOPSIS", "OPTIONS");
for (@filelist) { $parser->parse_from_file($_); }

Select the "DESCRIPTION" and "SEE ALSO" sections of the PODs from
STDIN and write the result to STDERR.
$parser->select("DESCRIPTION");
$parser->add_selection("SEE ALSO");
$parser->parse_from_filehandle(*STDIN, *STDERR);
```

**REQUIRES**

perl5.005, Pod::Parser, Exporter, Carp

**EXPORTS**

podselect()

**DESCRIPTION**

**podselect()** is a function which will extract specified sections of pod documentation from an input stream. This ability is provided by the **Pod::Select** module which is a subclass of **Pod::Parser**. **Pod::Select** provides a method named **select()** to specify the set of POD sections to select for processing/printing. **podselect()** merely creates a **Pod::Select** object and then invokes the **podselect()** followed by **parse\_from\_file()**.

**SECTION SPECIFICATIONS**

**podselect()** and **Pod::Select::select()** may be given one or more "section specifications" to restrict the text processed to only the desired set of sections and their corresponding subsections. A section specification is a string containing one or more Perl-style regular expressions separated by forward slashes

(""). If you need to use a forward slash literally within a section title you can escape it with a backslash ("\\").

The formal syntax of a section specification is:

- *head1–title–regex/head2–title–regex/...*

Any omitted or empty regular expressions will default to ".\*". Please note that each regular expression given is implicitly anchored by adding "^" and "\$" to the beginning and end. Also, if a given regular expression starts with a "!" character, then the expression is *negated* (so `!foo` would match anything *except* `foo`).

Some example section specifications follow.

- Match the NAME and SYNOPSIS sections and all of their subsections:

NAME | SYNOPSIS

- Match only the Question and Answer subsections of the DESCRIPTION section:

DESCRIPTION/Question | Answer

- Match the Comments subsection of *all* sections:

/Comments

- Match all subsections of DESCRIPTION *except* for Comments:

DESCRIPTION/!Comments

- Match the DESCRIPTION section but do *not* match any of its subsections:

DESCRIPTION/!.+

- Match all top level sections but none of their subsections:

/!.+

=begin \_NOT\_IMPLEMENTED\_

## RANGE SPECIFICATIONS

`podselect()` and `Pod::Select::select()` may be given one or more "range specifications" to restrict the text processed to only the desired ranges of paragraphs in the desired set of sections. A range specification is a string containing a single Perl-style regular expression (a regex), or else two Perl-style regular expressions (regexs) separated by a ".." (Perl's "range" operator is ".."). The regexs in a range specification are delimited by forward slashes ("/"). If you need to use a forward slash literally within a regex you can escape it with a backslash ("\\").

The formal syntax of a range specification is:

- */start–range–regex[/end–range–regex/]*

Where each the item inside square brackets (the "." followed by the end-range-regex) is optional. Each "range-regex" is of the form:

=cmd–expr text–expr

Where *cmd–expr* is intended to match the name of one or more POD commands, and *text–expr* is intended to match the paragraph text for the command. If a range-regex is supposed to match a POD command, then the first character of the regex (the one after the initial '/') absolutely *must* be a single '=' character; it may not be anything else (not even a regex meta-character) if it is supposed to match against the name of a POD command.

If no *=cmd–expr* is given then the *text–expr* will be matched against plain textblocks unless it is preceded by a space, in which case it is matched against verbatim text–blocks. If no *text–expr* is given then only the command–portion of the paragraph is matched against.

Note that these two expressions are each implicitly anchored. This means that when matching against the `command-name`, there will be an implicit `^` and `$` around the given `=cmd-expr`; and when matching against the paragraph text there will be an implicit `\A` and `\Z` around the given `text-expr`.

Unlike with `section-specs`, the `!` character does *not* have any special meaning (negation or otherwise) at the beginning of a `range-spec`!

Some example range specifications follow.

Match all `=for` html paragraphs:

```
/=for html/
```

Match all paragraphs between `=begin` html and `=end` html (note that this will *not* work correctly if such sections are nested):

```
/=begin html/..=/end html/
```

Match all paragraphs between the given `=item` name until the end of the current section:

```
/=item mine/..=/head\d/
```

Match all paragraphs between the given `=item` until the next item, or until the end of the itemized list (note that this will *not* work as desired if the item contains an itemized list nested within it):

```
/=item mine/..=(item|back)/
```

```
=end _NOT_IMPLEMENTED_
```

## OBJECT METHODS

The following methods are provided in this module. Each one takes a reference to the object itself as an implicit first parameter.

### `curr_headings()`

```
($head1, $head2, $head3, ...) = $parser->curr_headings();
$head1 = $parser->curr_headings(1);
```

This method returns a list of the currently active section headings and subheadings in the document being parsed. The list of headings returned corresponds to the most recently parsed paragraph of the input.

If an argument is given, it must correspond to the desired section heading number, in which case only the specified section heading is returned. If there is no current section heading at the specified level, then `undef` is returned.

### `select()`

```
$parser->select($section_spec1,$section_spec2,...);
```

This method is used to select the particular sections and subsections of POD documentation that are to be printed and/or processed. The existing set of selected sections is *replaced* with the given set of sections. See `add_selection()` for adding to the current set of selected sections.

Each of the `$section_spec` arguments should be a section specification as described in ["SECTION SPECIFICATIONS"](#). The section specifications are parsed by this method and the resulting regular expressions are stored in the invoking object.

If no `$section_spec` arguments are given, then the existing set of selected sections is cleared out (which means all sections will be processed).

This method should *not* normally be overridden by subclasses.

### `add_selection()`

```
$parser->add_selection($section_spec1,$section_spec2,...);
```

This method is used to add to the currently selected sections and subsections of POD documentation that are to be printed and/or processed. See `<select()` for replacing the currently selected sections.

Each of the `$section_spec` arguments should be a section specification as described in *"SECTION SPECIFICATIONS"*. The section specifications are parsed by this method and the resulting regular expressions are stored in the invoking object.

This method should *not* normally be overridden by subclasses.

```
clear_selections()
 $parser->clear_selections();
```

This method takes no arguments, it has the exact same effect as invoking `<select()` with no arguments.

```
match_section()
 $boolean = $parser->match_section($heading1,$heading2,...);
```

Returns a value of true if the given section and subsection heading titles match any of the currently selected section specifications in effect from prior calls to **select()** and **add\_selection()** (or if there are no explicitly selected/deselected sections).

The arguments `$heading1`, `$heading2`, etc. are the heading titles of the corresponding sections, subsections, etc. to try and match. If `$headingN` is omitted then it defaults to the current corresponding section heading title in the input.

This method should *not* normally be overridden by subclasses.

```
is_selected()
 $boolean = $parser->is_selected($paragraph);
```

This method is used to determine if the block of text given in `$paragraph` falls within the currently selected set of POD sections and subsections to be printed or processed. This method is also responsible for keeping track of the current input section and subsections. It is assumed that `$paragraph` is the most recently read (but not yet processed) input paragraph.

The value returned will be true if the `$paragraph` and the rest of the text in the same section as `$paragraph` should be selected (included) for processing; otherwise a false value is returned.

## EXPORTED FUNCTIONS

The following functions are exported by this module. Please note that these are functions (not methods) and therefore do *not* take an implicit first argument.

```
podselect()
 podselect(\%options,@filelist);
```

**podselect** will print the raw (untranslated) POD paragraphs of all POD sections in the given input files specified by `@filelist` according to the given options.

If any argument to **podselect** is a reference to a hash (associative array) then the values with the following keys are processed as follows:

### -output

A string corresponding to the desired output file (or `"&STDOUT"` or `"&STDERR"`) . The default is to use standard output.

### -sections

A reference to an array of sections specifications (as described in *"SECTION SPECIFICATIONS"*) which indicate the desired set of POD sections and subsections to be selected from input. If no section specifications are given, then all sections of the PODs are used.

=begin `_NOT_IMPLEMENTED_`

### -ranges

A reference to an array of range specifications (as described in *"RANGE SPECIFICATIONS"*) which indicate the desired range of POD paragraphs to be selected from the desired input sections. If no range

specifications are given, then all paragraphs of the desired sections are used.

```
=end _NOT_IMPLEMENTED_
```

All other arguments should correspond to the names of input files containing POD sections. A file name of "-" or "<STDIN" will be interpreted to mean standard input (which is the default if no filenames are given).

## PRIVATE METHODS AND DATA

**Pod::Select** makes use of a number of internal methods and data fields which clients should not need to see or use. For the sake of avoiding name collisions with client data and methods, these methods and fields are briefly discussed here. Determined hackers may obtain further information about them by reading the **Pod::Select** source code.

Private data fields are stored in the hash-object whose reference is returned by the **new()** constructor for this class. The names of all private methods and data-fields used by **Pod::Select** begin with a prefix of "\_" and match the regular expression `/^\_w+$/`.

```
_compile_section_spec()
```

```
$listref = $parser->_compile_section_spec($section_spec);
```

This function (note it is a function and *not* a method) takes a section specification (as described in *"SECTION SPECIFICATIONS"*) given in `$section_spec`, and compiles it into a list of regular expressions. If `$section_spec` has no syntax errors, then a reference to the list (array) of corresponding regular expressions is returned; otherwise `undef` is returned and an error message is printed (using **carp**) for each invalid regex.

```
=end _PRIVATE_
```

```
$self->{_SECTION_HEADINGS}
```

A reference to an array of the current section heading titles for each heading level (note that the first heading level title is at index 0).

```
=end _PRIVATE_
```

```
$self->{_SELECTED_SECTIONS}
```

A reference to an array of references to arrays. Each subarray is a list of anchored regular expressions (preceded by a "!" if the expression is to be negated). The index of the expression in the subarray should correspond to the index of the heading title in `$self->{_SECTION_HEADINGS}` that it is to be matched against.

```
=end _PRIVATE_
```

## SEE ALSO

*Pod::Parser*

## AUTHOR

Brad Appleton <bradapp@enteract.com>

Based on code for **pod2text** written by Tom Christiansen <tchrist@mox.perl.com>

**NAME**

Pod::Text – Convert POD data to formatted ASCII text

**SYNOPSIS**

```
use Pod::Text;
my $parser = Pod::Text->new (sentence => 0, width => 78);

Read POD from STDIN and write to STDOUT.
$parser->parse_from_filehandle;

Read POD from file.pod and write to file.txt.
$parser->parse_from_file ('file.pod', 'file.txt');
```

**DESCRIPTION**

Pod::Text is a module that can convert documentation in the POD format (the preferred language for documenting Perl) into formatted ASCII. It uses no special formatting controls or codes whatsoever, and its output is therefore suitable for nearly any device.

As a derived class from Pod::Parser, Pod::Text supports the same methods and interfaces. See [Pod::Parser](#) for all the details; briefly, one creates a new parser with `< Pod::Text->new()` and then calls either `parse_from_filehandle()` or `parse_from_file()`.

`new()` can take options, in the form of key/value pairs, that control the behavior of the parser. The currently recognized options are:

**alt** If set to a true value, selects an alternate output format that, among other things, uses a different heading style and marks `=item` entries with a colon in the left margin. Defaults to false.

**code**

If set to a true value, the non-POD parts of the input file will be included in the output. Useful for viewing code documented with POD blocks with the POD rendered and the code left intact.

**indent**

The number of spaces to indent regular text, and the default indentation for `=over` blocks. Defaults to 4.

**loose**

If set to a true value, a blank line is printed after a `=head1` heading. If set to false (the default), no blank line is printed after `=head1`, although one is still printed after `=head2`. This is the default because it's the expected formatting for manual pages; if you're formatting arbitrary text documents, setting this to true may result in more pleasing output.

**quotes**

Sets the quote marks used to surround `C< text`. If the value is a single character, it is used as both the left and right quote; if it is two characters, the first character is used as the left quote and the second as the right quote; and if it is four characters, the first two are used as the left quote and the second two as the right quote.

This may also be set to the special value `none`, in which case no quote marks are added around `C< text`.

**sentence**

If set to a true value, Pod::Text will assume that each sentence ends in two spaces, and will try to preserve that spacing. If set to false, all consecutive whitespace in non-verbatim paragraphs is compressed into a single space. Defaults to true.

**width**

The column at which to wrap text on the right-hand side. Defaults to 76.

The standard `Pod::Parser` method `parse_from_filehandle()` takes up to two arguments, the first being the file handle to read POD from and the second being the file handle to write the formatted output to. The first defaults to `STDIN` if not given, and the second defaults to `STDOUT`. The method `parse_from_file()` is almost identical, except that its two arguments are the input and output disk files instead. See [Pod::Parser](#) for the specific details.

## DIAGNOSTICS

Bizarre space in item

Item called without tag

(W) Something has gone wrong in internal `=item` processing. These messages indicate a bug in `Pod::Text`; you should never see them.

Can't open %s for reading: %s

(F) `Pod::Text` was invoked via the compatibility mode `pod2text()` interface and the input file it was given could not be opened.

Invalid quote specification "%s"

(F) The quote specification given (the `quotes` option to the constructor) was invalid. A quote specification must be one, two, or four characters long.

%s:%d: Unknown command paragraph: %s

(W) The POD source contained a non-standard command paragraph (something of the form `=command args`) that `Pod::Man` didn't know about. It was ignored.

%s:%d: Unknown escape: %s

(W) The POD source contained an `E<>` escape that `Pod::Text` didn't know about.

%s:%d: Unknown formatting code: %s

(W) The POD source contained a non-standard formatting code (something of the form `X<>`) that `Pod::Text` didn't know about.

%s:%d: Unmatched `=back`

(W) `Pod::Text` encountered a `=back` command that didn't correspond to an `=over` command.

## RESTRICTIONS

Embedded `Ctrl-As` (octal 001) in the input will be mapped to spaces on output, due to an internal implementation detail.

## NOTES

This is a replacement for an earlier `Pod::Text` module written by Tom Christiansen. It has a revamped interface, since it now uses `Pod::Parser`, but an interface roughly compatible with the old `Pod::Text::pod2text()` function is still available. Please change to the new calling convention, though.

The original `Pod::Text` contained code to do formatting via `termcap` sequences, although it wasn't turned on by default and it was problematic to get it to work at all. This rewrite doesn't even try to do that, but a subclass of it does. Look for [Pod::Text::Termcap](#).

## SEE ALSO

**NAME**

Pod::Text::Color – Convert POD data to formatted color ASCII text

**SYNOPSIS**

```
use Pod::Text::Color;
my $parser = Pod::Text::Color->new (sentence => 0, width => 78);

Read POD from STDIN and write to STDOUT.
$parser->parse_from_filehandle;

Read POD from file.pod and write to file.txt.
$parser->parse_from_file ('file.pod', 'file.txt');
```

**DESCRIPTION**

Pod::Text::Color is a simple subclass of Pod::Text that highlights output text using ANSI color escape sequences. Apart from the color, it in all ways functions like Pod::Text. See [Pod::Text](#) for details and available options.

Term::ANSIColor is used to get colors and therefore must be installed to use this module.

**BUGS**

This is just a basic proof of concept. It should be seriously expanded to support configurable coloration via options passed to the constructor, and **pod2text** should be taught about those.

**NAME**

Pod::Text::Overstrike – Convert POD data to formatted overstrike text

**SYNOPSIS**

```
use Pod::Text::Overstrike;
my $parser = Pod::Text::Overstrike->new (sentence => 0, width => 78);

Read POD from STDIN and write to STDOUT.
$parser->parse_from_filehandle;

Read POD from file.pod and write to file.txt.
$parser->parse_from_file ('file.pod', 'file.txt');
```

**DESCRIPTION**

Pod::Text::Overstrike is a simple subclass of Pod::Text that highlights output text using overstrike sequences, in a manner similar to nroff. Characters in bold text are overstruck (character, backspace, character) and characters in underlined text are converted to overstruck underscores (underscore, backspace, character). This format was originally designed for hardcopy terminals and/or lineprinters, yet is readable on softcopy (CRT) terminals.

Overstruck text is best viewed by page-at-a-time programs that take advantage of the terminal's **stand-out** and *underline* capabilities, such as the less program on Unix.

Apart from the overstrike, it in all ways functions like Pod::Text. See [Pod::Text](#) for details and available options.

**BUGS**

Currently, the outermost formatting instruction wins, so for example underlined text inside a region of bold text is displayed as simply bold. There may be some better approach possible.

**NAME**

Pod::Text::Termcap – Convert POD data to ASCII text with format escapes

**SYNOPSIS**

```
use Pod::Text::Termcap;
my $parser = Pod::Text::Termcap->new (sentence => 0, width => 78);

Read POD from STDIN and write to STDOUT.
$parser->parse_from_filehandle;

Read POD from file.pod and write to file.txt.
$parser->parse_from_file ('file.pod', 'file.txt');
```

**DESCRIPTION**

Pod::Text::Termcap is a simple subclass of Pod::Text that highlights output text using the correct termcap escape sequences for the current terminal. Apart from the format codes, it in all ways functions like Pod::Text. See *Pod::Text* for details and available options.

**NOTES**

This module uses Term::Cap to retrieve the formatting escape sequences for the current terminal, and falls back on the ECMA-48 (the same in this regard as ANSI X3.64 and ISO 6429, the escape codes also used by DEC VT100 terminals) if the bold, underline, and reset codes aren't set in the termcap information.

**NAME**

Pod::Usage, pod2usage() – print a usage message from embedded pod documentation

**SYNOPSIS**

```
use Pod::Usage

my $message_text = "This text precedes the usage message.";
my $exit_status = 2; ## The exit status to use
my $verbose_level = 0; ## The verbose level to use
my $filehandle = *STDERR; ## The filehandle to write to

pod2usage($message_text);

pod2usage($exit_status);

pod2usage({ -message => $message_text ,
 -exitval => $exit_status ,
 -verbose => $verbose_level,
 -output => $filehandle });

pod2usage(-msg => $message_text ,
 -exitval => $exit_status ,
 -verbose => $verbose_level,
 -output => $filehandle);
```

**ARGUMENTS**

**pod2usage** should be given either a single argument, or a list of arguments corresponding to an associative array (a "hash"). When a single argument is given, it should correspond to exactly one of the following:

- A string containing the text of a message to print *before* printing the usage message
- A numeric value corresponding to the desired exit status
- A reference to a hash

If more than one argument is given then the entire argument list is assumed to be a hash. If a hash is supplied (either as a reference or as a list) it should contain one or more elements with the following keys:

**-message**

**-msg**

The text of a message to print immediately prior to printing the program's usage message.

**-exitval**

The desired exit status to pass to the **exit()** function. This should be an integer, or else the string "NOEXIT" to indicate that control should simply be returned without terminating the invoking process.

**-verbose**

The desired level of "verboseness" to use when printing the usage message. If the corresponding value is 0, then only the "SYNOPSIS" section of the pod documentation is printed. If the corresponding value is 1, then the "SYNOPSIS" section, along with any section entitled "OPTIONS", "ARGUMENTS", or "OPTIONS AND ARGUMENTS" is printed. If the corresponding value is 2 or more then the entire manpage is printed.

**-output**

A reference to a filehandle, or the pathname of a file to which the usage message should be written. The default is `\*STDERR` unless the exit value is less than 2 (in which case the default is `\*STDOUT`).

**-input**

A reference to a filehandle, or the pathname of a file from which the invoking script's pod documentation should be read. It defaults to the file indicated by \$0 (\$PROGRAM\_NAME for users of *English.pm*).

**-pathlist**

A list of directory paths. If the input file does not exist, then it will be searched for in the given directory list (in the order the directories appear in the list). It defaults to the list of directories implied by \$ENV{PATH}. The list may be specified either by a reference to an array, or by a string of directory paths which use the same path separator as \$ENV{PATH} on your system (e.g., : for Unix, ; for MSWin32 and DOS).

**DESCRIPTION**

**pod2usage** will print a usage message for the invoking script (using its embedded pod documentation) and then exit the script with the desired exit status. The usage message printed may have any one of three levels of "verboseness": If the verbose level is 0, then only a synopsis is printed. If the verbose level is 1, then the synopsis is printed along with a description (if present) of the command line options and arguments. If the verbose level is 2, then the entire manual page is printed.

Unless they are explicitly specified, the default values for the exit status, verbose level, and output stream to use are determined as follows:

- If neither the exit status nor the verbose level is specified, then the default is to use an exit status of 2 with a verbose level of 0.
- If an exit status *is* specified but the verbose level is *not*, then the verbose level will default to 1 if the exit status is less than 2 and will default to 0 otherwise.
- If an exit status is *not* specified but verbose level *is* given, then the exit status will default to 2 if the verbose level is 0 and will default to 1 otherwise.
- If the exit status used is less than 2, then output is printed on STDOUT. Otherwise output is printed on STDERR.

Although the above may seem a bit confusing at first, it generally does "the right thing" in most situations. This determination of the default values to use is based upon the following typical Unix conventions:

- An exit status of 0 implies "success". For example, **diff(1)** exits with a status of 0 if the two files have the same contents.
- An exit status of 1 implies possibly abnormal, but non-defective, program termination. For example, **grep(1)** exits with a status of 1 if it did *not* find a matching line for the given regular expression.
- An exit status of 2 or more implies a fatal error. For example, **ls(1)** exits with a status of 2 if you specify an illegal (unknown) option on the command line.
- Usage messages issued as a result of bad command-line syntax should go to STDERR. However, usage messages issued due to an explicit request to print usage (like specifying **-help** on the command line) should go to STDOUT, just in case the user wants to pipe the output to a pager (such as **more(1)**).
- If program usage has been explicitly requested by the user, it is often desirable to exit with a status of 1 (as opposed to 0) after issuing the user-requested usage message. It is also desirable to give a more verbose description of program usage in this case.

**pod2usage** doesn't force the above conventions upon you, but it will use them by default if you don't expressly tell it to do otherwise. The ability of **pod2usage()** to accept a single number or a string makes it convenient to use as an innocent looking error message handling function:

```
use Pod::Usage;
use Getopt::Long;
```

```
Parse options
GetOptions("help", "man", "flag1") || pod2usage(2);
pod2usage(1) if ($opt_help);
pod2usage(-verbose => 2) if ($opt_man);

Check for too many filenames
pod2usage("$0: Too many files given.\n") if (@ARGV > 1);
```

Some user's however may feel that the above "economy of expression" is not particularly readable nor consistent and may instead choose to do something more like the following:

```
use Pod::Usage;
use Getopt::Long;

Parse options
GetOptions("help", "man", "flag1") || pod2usage(-verbose => 0);
pod2usage(-verbose => 1) if ($opt_help);
pod2usage(-verbose => 2) if ($opt_man);

Check for too many filenames
pod2usage(-verbose => 2, -message => "$0: Too many files given.\n")
 if (@ARGV > 1);
```

As with all things in Perl, *there's more than one way to do it*, and **pod2usage()** adheres to this philosophy. If you are interested in seeing a number of different ways to invoke **pod2usage** (although by no means exhaustive), please refer to *"EXAMPLES"*.

## EXAMPLES

Each of the following invocations of **pod2usage()** will print just the "SYNOPSIS" section to STDERR and will exit with a status of 2:

```
pod2usage();
pod2usage(2);
pod2usage(-verbose => 0);
pod2usage(-exitval => 2);
pod2usage({-exitval => 2, -output => *STDERR});
pod2usage({-verbose => 0, -output => *STDERR});
pod2usage(-exitval => 2, -verbose => 0);
pod2usage(-exitval => 2, -verbose => 0, -output => *STDERR);
```

Each of the following invocations of **pod2usage()** will print a message of "Syntax error." (followed by a newline) to STDERR, immediately followed by just the "SYNOPSIS" section (also printed to STDERR) and will exit with a status of 2:

```
pod2usage("Syntax error.");
pod2usage(-message => "Syntax error.", -verbose => 0);
pod2usage(-msg => "Syntax error.", -exitval => 2);
pod2usage({-msg => "Syntax error.", -exitval => 2, -output => *STDERR});
pod2usage({-msg => "Syntax error.", -verbose => 0, -output => *STDERR});
pod2usage(-msg => "Syntax error.", -exitval => 2, -verbose => 0);
pod2usage(-message => "Syntax error.",
 -exitval => 2,
 -verbose => 0,
```

```
-output => *STDERR);
```

Each of the following invocations of `pod2usage()` will print the "SYNOPSIS" section and any "OPTIONS" and/or "ARGUMENTS" sections to `STDOUT` and will exit with a status of 1:

```
pod2usage(1);
pod2usage(-verbose => 1);
pod2usage(-exitval => 1);
pod2usage({-exitval => 1, -output => *STDOUT});
pod2usage({-verbose => 1, -output => *STDOUT});
pod2usage(-exitval => 1, -verbose => 1);
pod2usage(-exitval => 1, -verbose => 1, -output => *STDOUT);
```

Each of the following invocations of `pod2usage()` will print the entire manual page to `STDOUT` and will exit with a status of 1:

```
pod2usage(-verbose => 2);
pod2usage({-verbose => 2, -output => *STDOUT});
pod2usage(-exitval => 1, -verbose => 2);
pod2usage({-exitval => 1, -verbose => 2, -output => *STDOUT});
```

### Recommended Use

Most scripts should print some type of usage message to `STDERR` when a command line syntax error is detected. They should also provide an option (usually `-H` or `-help`) to print a (possibly more verbose) usage message to `STDOUT`. Some scripts may even wish to go so far as to provide a means of printing their complete documentation to `STDOUT` (perhaps by allowing a `-man` option). The following complete example uses **Pod::Usage** in combination with **Getopt::Long** to do all of these things:

```
use Getopt::Long;
use Pod::Usage;

my $man = 0;
my $help = 0;
Parse options and print usage if there is a syntax error,
or if usage was explicitly requested.
GetOptions('help|?' => \$help, man => \$man) or pod2usage(2);
pod2usage(1) if $help;
pod2usage(-verbose => 2) if $man;

If no arguments were given, then allow STDIN to be used only
if it's not connected to a terminal (otherwise print usage)
pod2usage("$0: No files given.") if ((@ARGV == 0) && (-t STDIN));
__END__

useful with the contents thereof.

=cut
```

## CAVEATS

By default, **pod2usage()** will use `$0` as the path to the pod input file. Unfortunately, not all systems on which Perl runs will set `$0` properly (although if `$0` isn't found, **pod2usage()** will search `$ENV{PATH}` or else the list specified by the `-pathlist` option). If this is the case for your system, you may need to explicitly specify the path to the pod docs for the invoking script using something similar to the following:

```
pod2usage(-exitval => 2, -input => "/path/to/your/pod/docs");
```

## AUTHOR

Brad Appleton <bradapp@enteract.com>

Steven McDougall <swmcd@world.std.com> for his help and patience with re-writing this manpage.

**NAME**

POSIX – Perl interface to IEEE Std 1003.1

**SYNOPSIS**

```
use POSIX;
use POSIX qw(setsid);
use POSIX qw(:errno_h :fcntl_h);

printf "EINTR is %d\n", EINTR;

$sess_id = POSIX::setsid();

$fd = POSIX::open($path, O_CREAT|O_EXCL|O_WRONLY, 0644);
note: that's a filedescriptor, *NOT* a filehandle
```

**DESCRIPTION**

The POSIX module permits you to access all (or nearly all) the standard POSIX 1003.1 identifiers. Many of these identifiers have been given Perl-ish interfaces. Things which are `#defines` in C, like `EINTR` or `O_NDELAY`, are automatically exported into your namespace. All functions are only exported if you ask for them explicitly. Most likely people will prefer to use the fully-qualified function names.

This document gives a condensed list of the features available in the POSIX module. Consult your operating system's manpages for general information on most features. Consult *perlfunc* for functions which are noted as being identical to Perl's builtin functions.

The first section describes POSIX functions from the 1003.1 specification. The second section describes some classes for signal objects, TTY objects, and other miscellaneous objects. The remaining sections list various constants and macros in an organization which roughly follows IEEE Std 1003.1b–1993.

**NOTE**

The POSIX module is probably the most complex Perl module supplied with the standard distribution. It incorporates autoloading, namespace games, and dynamic loading of code that's in Perl, C, or both. It's a great source of wisdom.

**CAVEATS**

A few functions are not implemented because they are C specific. If you attempt to call these, they will print a message telling you that they aren't implemented, and suggest using the Perl equivalent should one exist. For example, trying to access the `setjmp()` call will elicit the message "`setjmp()` is C-specific: use `eval {}` instead".

Furthermore, some evil vendors will claim 1003.1 compliance, but in fact are not so: they will not pass the PCTS (POSIX Compliance Test Suites). For example, one vendor may not define `EDEADLK`, or the semantics of the `errno` values set by `open(2)` might not be quite right. Perl does not attempt to verify POSIX compliance. That means you can currently successfully say "use POSIX", and then later in your program you find that your vendor has been lax and there's no usable `ICANON` macro after all. This could be construed to be a bug.

**FUNCTIONS**

|                    |                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_exit</code> | This is identical to the C function <code>_exit()</code> . It exits the program immediately which means among other things buffered I/O is <b>not</b> flushed.                                                                               |
| <code>abort</code> | This is identical to the C function <code>abort()</code> . It terminates the process with a <code>SIGABRT</code> signal unless caught by a signal handler or if the handler does not return normally (it e.g. does a <code>longjmp</code> ). |
| <code>abs</code>   | This is identical to Perl's builtin <code>abs()</code> function, returning the absolute value of its numerical argument.                                                                                                                     |

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| access  | <p>Determines the accessibility of a file.</p> <pre> if( POSIX::access( "/", &amp;POSIX::R_OK ) ){     print "have read permission\n"; } </pre> <p>Returns undef on failure. Note: do not use <code>access()</code> for security purposes. Between the <code>access()</code> call and the operation you are preparing for the permissions might change: a classic <i>race condition</i>.</p>                                                                                                                                                                          |
| acos    | <p>This is identical to the C function <code>acos()</code>, returning the arcus cosine of its numerical argument. See also <a href="#">Math::Trig</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                            |
| alarm   | <p>This is identical to Perl's builtin <code>alarm()</code> function, either for arming or disarming the SIGALRM timer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| asctime | <p>This is identical to the C function <code>asctime()</code>. It returns a string of the form</p> <pre> "Fri Jun  2 18:22:13 2000\n\0" </pre> <p>and it is called thusly</p> <pre> \$asctime = asctime(\$sec, \$min, \$hour, \$mday, \$mon, \$year,                   \$yday, \$yday, \$isdst); </pre> <p>The <code>\$mon</code> is zero-based: January equals 0. The <code>\$year</code> is 1900-based: 2001 equals 101. The <code>\$yday</code>, <code>\$yday</code>, and <code>\$isdst</code> default to zero (and the first two are usually ignored anyway).</p> |
| asin    | <p>This is identical to the C function <code>asin()</code>, returning the arcus sine of its numerical argument. See also <a href="#">Math::Trig</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| assert  | <p>Unimplemented, but you can use <a href="#">die</a> and the <a href="#">Carp</a> module to achieve similar things.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| atan    | <p>This is identical to the C function <code>atan()</code>, returning the arcus tangent of its numerical argument. See also <a href="#">Math::Trig</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |
| atan2   | <p>This is identical to Perl's builtin <code>atan2()</code> function, returning the arcus tangent defined by its two numerical arguments, the <i>y</i> coordinate and the <i>x</i> coordinate. See also <a href="#">Math::Trig</a>.</p>                                                                                                                                                                                                                                                                                                                               |
| atexit  | <p><code>atexit()</code> is C-specific: use <code>END {}</code> instead, see <a href="#">perlsub</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| atof    | <p><code>atof()</code> is C-specific. Perl converts strings to numbers transparently. If you need to force a scalar to a number, add a zero to it.</p>                                                                                                                                                                                                                                                                                                                                                                                                                |
| atoi    | <p><code>atoi()</code> is C-specific. Perl converts strings to numbers transparently. If you need to force a scalar to a number, add a zero to it. If you need to have just the integer part, see <a href="#">int</a>.</p>                                                                                                                                                                                                                                                                                                                                            |
| atol    | <p><code>atol()</code> is C-specific. Perl converts strings to numbers transparently. If you need to force a scalar to a number, add a zero to it. If you need to have just the integer part, see <a href="#">int</a>.</p>                                                                                                                                                                                                                                                                                                                                            |
| bsearch | <p><code>bsearch()</code> not supplied. For doing binary search on wordlists, see <a href="#">Search::Dict</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| calloc  | <p><code>calloc()</code> is C-specific. Perl does memory management transparently.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ceil    | <p>This is identical to the C function <code>ceil()</code>, returning the smallest integer value greater than or equal to the given numerical argument.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |
| chdir   | <p>This is identical to Perl's builtin <code>chdir()</code> function, allowing one to change the working (default) directory, see <a href="#">chdir</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |
| chmod   | <p>This is identical to Perl's builtin <code>chmod()</code> function, allowing one to change file and directory permissions, see <a href="#">chmod</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |

- chown** This is identical to Perl's builtin `chown()` function, allowing one to change file and directory owners and groups, see [chown](#).
- clearerr** Use the method `IO::Handle::clearerr()` instead, to reset the error state (if any) and EOF state (if any) of the given stream.
- clock** This is identical to the C function `clock()`, returning the amount of spent processor time in microseconds.
- close** Close the file. This uses file descriptors such as those obtained by calling `POSIX::open`.
- ```
$fd = POSIX::open( "foo", &POSIX::O_RDONLY );
POSIX::close( $fd );
```
- Returns `undef` on failure.
- See also [close](#).
- closedir** This is identical to Perl's builtin `closedir()` function for closing a directory handle, see [closedir](#).
- cos** This is identical to Perl's builtin `cos()` function, for returning the cosine of its numerical argument, see [cos](#). See also [Math::Trig](#).
- cosh** This is identical to the C function `cosh()`, for returning the hyperbolic cosine of its numeric argument. See also [Math::Trig](#).
- creat** Create a new file. This returns a file descriptor like the ones returned by `POSIX::open`. Use `POSIX::close` to close the file.
- ```
$fd = POSIX::creat("foo", 0611);
POSIX::close($fd);
```
- See also [sysopen](#) and its `O_CREAT` flag.
- ctermid** Generates the path name for the controlling terminal.
- ```
$path = POSIX::ctermid();
```
- ctime** This is identical to the C function `ctime()` and equivalent to `asctime(localtime(...))`, see [asctime](#) and [localtime](#).
- cuserid** Get the login name of the owner of the current process.
- ```
$name = POSIX::cuserid();
```
- difftime** This is identical to the C function `difftime()`, for returning the time difference (in seconds) between two times (as returned by `time()`), see [time](#).
- div** `div()` is C-specific, use [int](#) on the usual `/` division and the modulus `%`.
- dup** This is similar to the C function `dup()`, for duplicating a file descriptor.
- This uses file descriptors such as those obtained by calling `POSIX::open`.
- Returns `undef` on failure.
- dup2** This is similar to the C function `dup2()`, for duplicating a file descriptor to an another known file descriptor.
- This uses file descriptors such as those obtained by calling `POSIX::open`.
- Returns `undef` on failure.
- errno** Returns the value of `errno`.
- ```
$errno = POSIX::errno();
```

	This identical to the numerical values of the <code>\$!</code> , see \$ERRNO .
<code>execl</code>	<code>execl()</code> is C-specific, see exec .
<code>execle</code>	<code>execle()</code> is C-specific, see exec .
<code>execlp</code>	<code>execlp()</code> is C-specific, see exec .
<code>execv</code>	<code>execv()</code> is C-specific, see exec .
<code>execve</code>	<code>execve()</code> is C-specific, see exec .
<code>execvp</code>	<code>execvp()</code> is C-specific, see exec .
<code>exit</code>	This is identical to Perl's builtin <code>exit()</code> function for exiting the program, see exit .
<code>exp</code>	This is identical to Perl's builtin <code>exp()</code> function for returning the exponent (<i>e</i> -based) of the numerical argument, see exp .
<code>fabs</code>	This is identical to Perl's builtin <code>abs()</code> function for returning the absolute value of the numerical argument, see abs .
<code>fclose</code>	Use method <code>IO::Handle::close()</code> instead, or see close .
<code>fcntl</code>	This is identical to Perl's builtin <code>fcntl()</code> function, see fcntl .
<code>fdopen</code>	Use method <code>IO::Handle::new_from_fd()</code> instead, or see open .
<code>feof</code>	Use method <code>IO::Handle::eof()</code> instead, or see eof .
<code>ferror</code>	Use method <code>IO::Handle::error()</code> instead.
<code>fflush</code>	Use method <code>IO::Handle::flush()</code> instead. See also \$OUTPUT_AUTOFLUSH .
<code>fgetc</code>	Use method <code>IO::Handle::getc()</code> instead, or see read .
<code>fgetpos</code>	Use method <code>IO::Seekable::getpos()</code> instead, or see seek .
<code>fgets</code>	Use method <code>IO::Handle::gets()</code> instead. Similar to <code><></code> , also known as readline .
<code>fileno</code>	Use method <code>IO::Handle::fileno()</code> instead, or see fileno .
<code>floor</code>	This is identical to the C function <code>floor()</code> , returning the largest integer value less than or equal to the numerical argument.
<code>fmod</code>	This is identical to the C function <code>fmod()</code> . <pre>\$r = fmod(\$x, \$y);</pre> <p>It returns the remainder $\\$r = \\$x - \\$n * \\y, where $\\$n = \text{trunc}(\\$x / \\$y)$. The $\\$r$ has the same sign as $\\$x$ and magnitude (absolute value) less than the magnitude of $\\$y$.</p>
<code>fdopen</code>	Use method <code>IO::File::open()</code> instead, or see open .
<code>fork</code>	This is identical to Perl's builtin <code>fork()</code> function for duplicating the current process, see fork and perlfork if you are in Windows.
<code>fpathconf</code>	Retrieves the value of a configurable limit on a file or directory. This uses file descriptors such as those obtained by calling <code>POSIX::open</code> . <p>The following will determine the maximum length of the longest allowable pathname on the filesystem which holds <code>/tmp/foo</code>.</p> <pre>\$fd = POSIX::open("/tmp/foo", &POSIX::O_RDONLY); \$path_max = POSIX::fpathconf(\$fd, &POSIX::_PC_PATH_MAX);</pre> <p>Returns <code>undef</code> on failure.</p>

<code>fprintf</code>	<code>fprintf()</code> is C-specific, see printf instead.
<code>fputc</code>	<code>fputc()</code> is C-specific, see print instead.
<code>fputs</code>	<code>fputs()</code> is C-specific, see print instead.
<code>fread</code>	<code>fread()</code> is C-specific, see read instead.
<code>free</code>	<code>free()</code> is C-specific. Perl does memory management transparently.
<code>freopen</code>	<code>freopen()</code> is C-specific, see open instead.
<code>frexp</code>	Return the mantissa and exponent of a floating-point number. <pre>(\$mantissa, \$exponent) = POSIX::frexp(1.234e56);</pre>
<code>fscanf</code>	<code>fscanf()</code> is C-specific, use <code><></code> and regular expressions instead.
<code>fseek</code>	Use method <code>IO::Seekable::seek()</code> instead, or see seek .
<code>fsetpos</code>	Use method <code>IO::Seekable::setpos()</code> instead, or see seek .
<code>fstat</code>	Get file status. This uses file descriptors such as those obtained by calling <code>POSIX::open</code> . The data returned is identical to the data from Perl's builtin <code>stat</code> function. <pre>\$fd = POSIX::open("foo", &POSIX::O_RDONLY); @stats = POSIX::fstat(\$fd);</pre>
<code>ftell</code>	Use method <code>IO::Seekable::tell()</code> instead, or see tell .
<code>fwrite</code>	<code>fwrite()</code> is C-specific, see print instead.
<code>getc</code>	This is identical to Perl's builtin <code>getc()</code> function, see getc .
<code>getchar</code>	Returns one character from STDIN. Identical to Perl's <code>getc()</code> , see getc .
<code>getcwd</code>	Returns the name of the current working directory. See also Cwd .
<code>getegid</code>	Returns the effective group identifier. Similar to Perl's builtin variable <code>\$<</code> , see \$EGID .
<code>getenv</code>	Returns the value of the specified environment variable. The same information is available through the <code>%ENV</code> array.
<code>geteuid</code>	Returns the effective user identifier. Identical to Perl's builtin <code>\$></code> variable, see \$EUID .
<code>getgid</code>	Returns the user's real group identifier. Similar to Perl's builtin variable <code>\$)</code> , see \$GID .
<code>getgrgid</code>	This is identical to Perl's builtin <code>getgrgid()</code> function for returning group entries by group identifiers, see getgrgid .
<code>getgrnam</code>	This is identical to Perl's builtin <code>getgrnam()</code> function for returning group entries by group names, see getgrnam .
<code>getgroups</code>	Returns the ids of the user's supplementary groups. Similar to Perl's builtin variable <code>\$)</code> , see \$GID .
<code>getlogin</code>	This is identical to Perl's builtin <code>getlogin()</code> function for returning the user name associated with the current session, see getlogin .
<code>getpgrp</code>	This is identical to Perl's builtin <code>getpgrp()</code> function for returning the process group identifier of the current process, see getpgrp .
<code>getpid</code>	Returns the process identifier. Identical to Perl's builtin variable <code>\$\$</code> , see \$PID .
<code>getppid</code>	This is identical to Perl's builtin <code>getppid()</code> function for returning the process identifier of the parent process of the current process, see getppid .

getpwnam

This is identical to Perl's builtin `getpwnam()` function for returning user entries by user names, see [getpwnam](#).

getpwuid

This is identical to Perl's builtin `getpwuid()` function for returning user entries by user identifiers, see [getpwuid](#).

gets

Returns one line from STDIN, similar to `<>`, also known as the `readline()` function, see [readline](#).

NOTE: if you have C programs that still use `gets()`, be very afraid. The `gets()` function is a source of endless grief because it has no buffer overrun checks. It should **never** be used. The `fgets()` function should be preferred instead.

getuid

Returns the user's identifier. Identical to Perl's builtin `$<` variable, see [\\$UID](#).

gmtime

This is identical to Perl's builtin `gmtime()` function for converting seconds since the epoch to a date in Greenwich Mean Time, see [gmtime](#).

isalnum

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:alnum:]]/` construct instead, or possibly the `/\w/` construct.

isalpha

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:alpha:]]/` construct instead.

isatty

Returns a boolean indicating whether the specified filehandle is connected to a tty. Similar to the `-t` operator, see [-X](#).

isctrl

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:cntrl:]]/` construct instead.

isdigit

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:digit:]]/` construct instead, or the `/\d/` construct.

isgraph

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:graph:]]/` construct instead.

islower

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:lower:]]/` construct instead. Do **not** use `/[a-z]/`.

isprint

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:print:]]/` construct instead.

ispunct

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:punct:]]/` construct instead.

isspace

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:space:]]/` construct instead, or the `/\s/` construct. (Note that `/\s/` and `/[[:space:]]/` are slightly different in that `/[[:space:]]/` can normally match a vertical tab, while `/\s/` does not.)

isupper

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:upper:]]/` construct instead. Do **not** use `/[A-Z]/`.

isxdigit

This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using regular expressions and the `/[[:xdigit:]]/` construct instead, or simply `/[0-9a-f]/i`.

kill This is identical to Perl's builtin `kill()` function for sending signals to processes (often to terminate them), see [kill](#).

labs (For returning absolute values of long integers.) `labs()` is C-specific, see [abs](#) instead.

ldexp This is identical to the C function `ldexp()` for multiplying floating point numbers with powers of two.

```
$x_quadrupled = POSIX::ldexp($x, 2);
```

ldiv (For computing dividends of long integers.) `ldiv()` is C-specific, use `/` and `int()` instead.

link This is identical to Perl's builtin `link()` function for creating hard links into files, see [link](#).

localeconv

Get numeric formatting information. Returns a reference to a hash containing the current locale formatting values.

Here is how to query the database for the **de** (Deutsch or German) locale.

```
$loc = POSIX::setlocale( &POSIX::LC_ALL, "de" );
print "Locale = $loc\n";
$lconv = POSIX::localeconv();
print "decimal_point    = ", $lconv->{decimal_point},    "\n";
print "thousands_sep    = ", $lconv->{thousands_sep},    "\n";
print "grouping          = ", $lconv->{grouping},          "\n";
print "int_curr_symbol    = ", $lconv->{int_curr_symbol},  "\n";
print "currency_symbol    = ", $lconv->{currency_symbol},  "\n";
print "mon_decimal_point = ", $lconv->{mon_decimal_point}, "\n";
print "mon_thousands_sep = ", $lconv->{mon_thousands_sep}, "\n";
print "mon_grouping       = ", $lconv->{mon_grouping},     "\n";
print "positive_sign     = ", $lconv->{positive_sign},    "\n";
print "negative_sign     = ", $lconv->{negative_sign},    "\n";
print "int_frac_digits    = ", $lconv->{int_frac_digits},  "\n";
print "frac_digits       = ", $lconv->{frac_digits},      "\n";
print "p_cs_precedes      = ", $lconv->{p_cs_precedes},   "\n";
print "p_sep_by_space     = ", $lconv->{p_sep_by_space},   "\n";
print "n_cs_precedes      = ", $lconv->{n_cs_precedes},   "\n";
print "n_sep_by_space     = ", $lconv->{n_sep_by_space},   "\n";
print "p_sign_posn        = ", $lconv->{p_sign_posn},     "\n";
print "n_sign_posn        = ", $lconv->{n_sign_posn},     "\n";
```

localtime This is identical to Perl's builtin `localtime()` function for converting seconds since the epoch to a date see [localtime](#).

log This is identical to Perl's builtin `log()` function, returning the natural (*e*-based) logarithm of the numerical argument, see [log](#).

log10 This is identical to the C function `log10()`, returning the 10-base logarithm of the numerical argument. You can also use

```
sub log10 { log($_[0]) / log(10) }
```

or

```
sub log10 { log($_[0]) / 2.30258509299405 }
```

or

```
sub log10 { log($_[0]) * 0.434294481903252 }
```

- longjmp** `longjmp()` is C-specific: use [die](#) instead.
- lseek** Move the file's read/write position. This uses file descriptors such as those obtained by calling `POSIX::open`.
- ```
$fd = POSIX::open("foo", &POSIX::O_RDONLY);
$off_t = POSIX::lseek($fd, 0, &POSIX::SEEK_SET);
```
- Returns `undef` on failure.
- malloc** `malloc()` is C-specific. Perl does memory management transparently.
- mblen** This is identical to the C function `mblen()`. Perl does not have any support for the wide and multibyte characters of the C standards, so this might be a rather useless function.
- mbstowcs** This is identical to the C function `mbstowcs()`. Perl does not have any support for the wide and multibyte characters of the C standards, so this might be a rather useless function.
- mbtowc** This is identical to the C function `mbtowc()`. Perl does not have any support for the wide and multibyte characters of the C standards, so this might be a rather useless function.
- memchr** `memchr()` is C-specific, see [index](#) instead.
- memcmp** `memcmp()` is C-specific, use `eq` instead, see [perlop](#).
- memcpy** `memcpy()` is C-specific, use `=`, see [perlop](#), or see [substr](#).
- memmove** `memmove()` is C-specific, use `=`, see [perlop](#), or see [substr](#).
- memset** `memset()` is C-specific, use `x` instead, see [perlop](#).
- mkdir** This is identical to Perl's builtin `mkdir()` function for creating directories, see [mkdir](#).
- mkfifo** This is similar to the C function `mkfifo()` for creating FIFO special files.
- ```
if (mkfifo($path, $mode)) { ....
```
- Returns `undef` on failure. The `$mode` is similar to the mode of `mkdir()`, see [mkdir](#).
- mktime** Convert date/time info to a calendar time.
- Synopsis:
- ```
mktime(sec, min, hour, mday, mon, year, wday = 0, yday = 0, isdst = 0)
```
- The month (`mon`), weekday (`wday`), and yearday (`yday`) begin at zero. I.e. January is 0, not 1; Sunday is 0, not 1; January 1st is 0, not 1. The year (`year`) is given in years since 1900. I.e. The year 1995 is 95; the year 2001 is 101. Consult your system's `mktime()` manpage for details about these and the other arguments.
- Calendar time for December 12, 1995, at 10:30 am.
- ```
$time_t = POSIX::mktime( 0, 30, 10, 12, 11, 95 );
print "Date = ", POSIX::ctime($time_t);
```
- Returns `undef` on failure.
- modf** Return the integral and fractional parts of a floating-point number.
- ```
($fractional, $integral) = POSIX::modf(3.14);
```
- nice** This is similar to the C function `nice()`, for changing the scheduling preference of the current process. Positive arguments mean more polite process, negative values more needy process. Normal user processes can only be more polite.

- Returns `undef` on failure.
- offsetof** `offsetof()` is C-specific, you probably want to see [pack](#) instead.
- open** Open a file for reading or writing. This returns file descriptors, not Perl filehandles. Use `POSIX::close` to close the file.
- Open a file read-only with mode 0666.
- ```
$fd = POSIX::open( "foo" );
```
- Open a file for read and write.
- ```
$fd = POSIX::open("foo", &POSIX::O_RDWR);
```
- Open a file for write, with truncation.
- ```
$fd = POSIX::open( "foo", &POSIX::O_WRONLY | &POSIX::O_TRUNC );
```
- Create a new file with mode 0640. Set up the file for writing.
- ```
$fd = POSIX::open("foo", &POSIX::O_CREAT | &POSIX::O_WRONLY, 0640);
```
- Returns `undef` on failure.
- See also [sysopen](#).
- opendir** Open a directory for reading.
- ```
$dir = POSIX::opendir( "/tmp" );
@files = POSIX::readdir( $dir );
POSIX::closedir( $dir );
```
- Returns `undef` on failure.
- pathconf** Retrieves the value of a configurable limit on a file or directory.
- The following will determine the maximum length of the longest allowable pathname on the filesystem which holds `/tmp`.
- ```
$path_max = POSIX::pathconf("/tmp", &POSIX::_PC_PATH_MAX);
```
- Returns `undef` on failure.
- pause** This is similar to the C function `pause()`, which suspends the execution of the current process until a signal is received.
- Returns `undef` on failure.
- perror** This is identical to the C function `perror()`, which outputs to the standard error stream the specified message followed by `": "` and the current error string. Use the `warn()` function and the `$!` variable instead, see [warn](#) and [\\$ERRNO](#).
- pipe** Create an interprocess channel. This returns file descriptors like those returned by `POSIX::open`.
- ```
($fd0, $fd1) = POSIX::pipe();
POSIX::write( $fd0, "hello", 5 );
POSIX::read( $fd1, $buf, 5 );
```
- See also [pipe](#).
- pow** Computes `$x` raised to the power `$exponent`.
- ```
$ret = POSIX::pow($x, $exponent);
```
- You can also use the `**` operator, see [perlop](#).

- printf**      Formats and prints the specified arguments to STDOUT. See also [printf](#).
- putc**        `putc()` is C-specific, see [print](#) instead.
- putchar**    `putchar()` is C-specific, see [print](#) instead.
- puts**        `puts()` is C-specific, see [print](#) instead.
- qsort**        `qsort()` is C-specific, see [sort](#) instead.
- raise**        Sends the specified signal to the current process. See also [kill](#) and the `$$` in [\\$PID](#).
- rand**        `rand()` is non-portable, see [rand](#) instead.
- read**        Read from a file. This uses file descriptors such as those obtained by calling `POSIX::open`. If the buffer `$buf` is not large enough for the read then Perl will extend it to make room for the request.
- ```

        $fd = POSIX::open( "foo", &POSIX::O_RDONLY );
        $bytes = POSIX::read( $fd, $buf, 3 );

```
- Returns `undef` on failure.
- See also [sysread](#).
- readdir** This is identical to Perl's builtin `readdir()` function for reading directory entries, see [readdir](#).
- realloc** `realloc()` is C-specific. Perl does memory management transparently.
- remove** This is identical to Perl's builtin `unlink()` function for removing files, see [unlink](#).
- rename** This is identical to Perl's builtin `rename()` function for renaming files, see [rename](#).
- rewind** Seeks to the beginning of the file.
- rewinddir** This is identical to Perl's builtin `rewinddir()` function for rewinding directory entry streams, see [rewinddir](#).
- rmdir** This is identical to Perl's builtin `rmdir()` function for removing (empty) directories, see [rmdir](#).
- scanf** `scanf()` is C-specific, use `<>` and regular expressions instead, see [perlre](#).
- setgid** Sets the real group identifier and the effective group identifier for this process. Similar to assigning a value to the Perl's builtin `$)` variable, see [\\$GID](#), except that the latter will change only the real user identifier, and that the `setgid()` uses only a single numeric argument, as opposed to a space-separated list of numbers.
- setjmp** `setjmp()` is C-specific: use `eval {}` instead, see [eval](#).
- setlocale** Modifies and queries program's locale. The following examples assume
- ```

 use POSIX qw(setlocale LC_ALL LC_CTYPE);

```
- has been issued.
- The following will set the traditional UNIX system locale behavior (the second argument "C").
- ```

        $loc = setlocale( LC_ALL, "C" );

```
- The following will query the current `LC_CTYPE` category. (No second argument means 'query'.)
- ```

 $loc = setlocale(LC_CTYPE);

```
- The following will set the `LC_CTYPE` behaviour according to the locale environment variables (the second argument ""). Please see your systems `setlocale(3)` documentation for the

locale environment variables' meaning or consult [perllocale](#).

```
$loc = setlocale(LC_CTYPE, "");
```

The following will set the LC\_COLLATE behaviour to Argentinian Spanish. **NOTE:** The naming and availability of locales depends on your operating system. Please consult [perllocale](#) for how to find out which locales are available in your system.

```
$loc = setlocale(LC_ALL, "es_AR.ISO8859-1");
```

**setpgid** This is similar to the C function `setpgid()` for setting the process group identifier of the current process.

Returns undef on failure.

**setsid** This is identical to the C function `setsid()` for setting the session identifier of the current process.

**setuid** Sets the real user identifier and the effective user identifier for this process. Similar to assigning a value to the Perl's builtin `$<` variable, see [\\$UID](#), except that the latter will change only the real user identifier.

**sigaction** Detailed signal management. This uses `POSIX::SigAction` objects for the `action` and `oldaction` arguments. Consult your system's `sigaction` manpage for details.

Synopsis:

```
sigaction(sig, action, oldaction = 0)
```

Returns undef on failure.

**siglongjmp**

`siglongjmp()` is C-specific: use [die](#) instead.

**sigpending**

Examine signals that are blocked and pending. This uses `POSIX::SigSet` objects for the `sigset` argument. Consult your system's `sigpending` manpage for details.

Synopsis:

```
sigpending(sigset)
```

Returns undef on failure.

**sigprocmask**

Change and/or examine calling process's signal mask. This uses `POSIX::SigSet` objects for the `sigset` and `oldsigset` arguments. Consult your system's `sigprocmask` manpage for details.

Synopsis:

```
sigprocmask(how, sigset, oldsigset = 0)
```

Returns undef on failure.

**sigsetjmp** `sigsetjmp()` is C-specific: use `eval {}` instead, see [eval](#).

**sigsuspend**

Install a signal mask and suspend process until signal arrives. This uses `POSIX::SigSet` objects for the `signal_mask` argument. Consult your system's `sigsuspend` manpage for details.

Synopsis:

```
sigsuspend(signal_mask)
```

|                       |                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | Returns undef on failure.                                                                                                                                                                                                                                                                                                                                                                       |
| <code>sin</code>      | This is identical to Perl's builtin <code>sin()</code> function for returning the sine of the numerical argument, see <a href="#">sin</a> . See also <a href="#">Math::Trig</a> .                                                                                                                                                                                                               |
| <code>sinh</code>     | This is identical to the C function <code>sinh()</code> for returning the hyperbolic sine of the numerical argument. See also <a href="#">Math::Trig</a> .                                                                                                                                                                                                                                      |
| <code>sleep</code>    | This is functionally identical to Perl's builtin <code>sleep()</code> function for suspending the execution of the current process for certain number of seconds, see <a href="#">sleep</a> . There is one significant difference, however: <code>POSIX::sleep()</code> returns the number of <b>unslept</b> seconds, while the <code>CORE::sleep()</code> returns the number of slept seconds. |
| <code>sprintf</code>  | This is similar to Perl's builtin <code>sprintf()</code> function for returning a string that has the arguments formatted as requested, see <a href="#">sprintf</a> .                                                                                                                                                                                                                           |
| <code>sqrt</code>     | This is identical to Perl's builtin <code>sqrt()</code> function. for returning the square root of the numerical argument, see <a href="#">sqrt</a> .                                                                                                                                                                                                                                           |
| <code>srand</code>    | Give a seed the pseudorandom number generator, see <a href="#">srand</a> .                                                                                                                                                                                                                                                                                                                      |
| <code>sscanf</code>   | <code>sscanf()</code> is C-specific, use regular expressions instead, see <a href="#">perlre</a> .                                                                                                                                                                                                                                                                                              |
| <code>stat</code>     | This is identical to Perl's builtin <code>stat()</code> function for returning information about files and directories.                                                                                                                                                                                                                                                                         |
| <code>strcat</code>   | <code>strcat()</code> is C-specific, use <code>.</code> instead, see <a href="#">perlop</a> .                                                                                                                                                                                                                                                                                                   |
| <code>strchr</code>   | <code>strchr()</code> is C-specific, see <a href="#">index</a> instead.                                                                                                                                                                                                                                                                                                                         |
| <code>strcmp</code>   | <code>strcmp()</code> is C-specific, use <code>eq</code> or <code>cmp</code> instead, see <a href="#">perlop</a> .                                                                                                                                                                                                                                                                              |
| <code>strcoll</code>  | This is identical to the C function <code>strcoll()</code> for collating (comparing) strings transformed using the <code>strxfrm()</code> function. Not really needed since Perl can do this transparently, see <a href="#">perllocale</a> .                                                                                                                                                    |
| <code>strcpy</code>   | <code>strcpy()</code> is C-specific, use <code>=</code> instead, see <a href="#">perlop</a> .                                                                                                                                                                                                                                                                                                   |
| <code>strcspn</code>  | <code>strcspn()</code> is C-specific, use regular expressions instead, see <a href="#">perlre</a> .                                                                                                                                                                                                                                                                                             |
| <code>strerror</code> | Returns the error string for the specified <code>errno</code> . Identical to the string form of the <code>\$!</code> , see <a href="#">\$ERRNO</a> .                                                                                                                                                                                                                                            |
| <code>strftime</code> | Convert date and time information to string. Returns the string.                                                                                                                                                                                                                                                                                                                                |

Synopsis:

```
strftime(fmt, sec, min, hour, mday, mon, year, wday = -1, yday = -1,
```

The month (`mon`), weekday (`wday`), and yearday (`yday`) begin at zero. I.e. January is 0, not 1; Sunday is 0, not 1; January 1st is 0, not 1. The year (`year`) is given in years since 1900. I.e., the year 1995 is 95; the year 2001 is 101. Consult your system's `strftime()` manpage for details about these and the other arguments. If you want your code to be portable, your format (`fmt`) argument should use only the conversion specifiers defined by the ANSI C standard. These are `aAbBcdHIjmMpSUWxXyYZ%`. The given arguments are made consistent as though by calling `mktime()` before calling your system's `strftime()` function, except that the `isdst` value is not affected.

The string for Tuesday, December 12, 1995.

```
$str = POSIX::strftime("%A, %B %d, %Y", 0, 0, 0, 12, 11, 95, 2);
print "$str\n";
```

- strlen**     `strlen()` is C-specific, use `length()` instead, see [length](#).
- strncat**     `strncat()` is C-specific, use `.` instead, see [perlop](#).
- strncmp**     `strncmp()` is C-specific, use `eq` instead, see [perlop](#).
- strncpy**     `strncpy()` is C-specific, use `=` instead, see [perlop](#).
- strpbrk**     `strpbrk()` is C-specific, use regular expressions instead, see [perlre](#).
- strrchr**     `strrchr()` is C-specific, see [rindex](#) instead.
- strspn**     `strspn()` is C-specific, use regular expressions instead, see [perlre](#).
- strstr**     This is identical to Perl's builtin `index()` function, see [index](#).
- strtod**     String to double translation. Returns the parsed number and the number of characters in the unparsed portion of the string. Truly POSIX-compliant systems set `$!` (`$ERRNO`) to indicate a translation error, so clear `$!` before calling `strtod`. However, non-POSIX systems may not check for overflow, and therefore will never set `$!`.
- `strtod` should respect any POSIX `setlocale()` settings.
- To parse a string `$str` as a floating point number use
- ```
$! = 0;
($num, $n_unparsed) = POSIX::strtod($str);
```
- The second returned item and `$!` can be used to check for valid input:
- ```
if (($str eq '') || ($n_unparsed != 0) || !$!) {
 die "Non-numeric input $str" . $! ? ": $!\n" : "\n";
}
```
- When called in a scalar context `strtod` returns the parsed number.
- strtok**     `strtok()` is C-specific, use regular expressions instead, see [perlre](#), or [split](#).
- strtol**     String to (long) integer translation. Returns the parsed number and the number of characters in the unparsed portion of the string. Truly POSIX-compliant systems set `$!` (`$ERRNO`) to indicate a translation error, so clear `$!` before calling `strtol`. However, non-POSIX systems may not check for overflow, and therefore will never set `$!`.
- `strtol` should respect any POSIX `setlocale()` settings.
- To parse a string `$str` as a number in some base `$base` use
- ```
$! = 0;
($num, $n_unparsed) = POSIX::strtol($str, $base);
```
- The base should be zero or between 2 and 36, inclusive. When the base is zero or omitted `strtol` will use the string itself to determine the base: a leading "0x" or "0X" means hexadecimal; a leading "0" means octal; any other leading characters mean decimal. Thus, "1234" is parsed as a decimal number, "01234" as an octal number, and "0x1234" as a hexadecimal number.
- The second returned item and `$!` can be used to check for valid input:
- ```
if (($str eq '') || ($n_unparsed != 0) || !$!) {
 die "Non-numeric input $str" . $! ? ": $!\n" : "\n";
}
```
- When called in a scalar context `strtol` returns the parsed number.
- strtoul**     String to unsigned (long) integer translation. `strtoul()` is identical to `strtol()` except that `strtoul()` only parses unsigned integers. See [strtol](#) for details.

Note: Some vendors supply `strtod()` and `strtol()` but not `strtoul()`. Other vendors that do supply `strtoul()` parse "-1" as a valid value.

**strxfrm** String transformation. Returns the transformed string.

```
$dst = POSIX::strxfrm($src);
```

Used in conjunction with the `strcoll()` function, see [/strcoll](#).

Not really needed since Perl can do this transparently, see [perllocale](#).

**sysconf** Retrieves values of system configurable variables.

The following will get the machine's clock speed.

```
$clock_ticks = POSIX::sysconf(&POSIX::_SC_CLK_TCK);
```

Returns `undef` on failure.

**system** This is identical to Perl's builtin `system()` function, see [system](#).

**tan** This is identical to the C function `tan()`, returning the tangent of the numerical argument. See also [Math::Trig](#).

**tanh** This is identical to the C function `tanh()`, returning the hyperbolic tangent of the numerical argument. See also [Math::Trig](#).

**tcdrain** This is similar to the C function `tcdrain()` for draining the output queue of its argument stream.

Returns `undef` on failure.

**tcflow** This is similar to the C function `tcflow()` for controlling the flow of its argument stream.

Returns `undef` on failure.

**tcflush** This is similar to the C function `tcflush()` for flushing the I/O buffers of its argument stream.

Returns `undef` on failure.

**tcgetpgrp** This is identical to the C function `tcgetpgrp()` for returning the process group identifier of the foreground process group of the controlling terminal.

**tcsendbreak**

This is similar to the C function `tcsendbreak()` for sending a break on its argument stream.

Returns `undef` on failure.

**tcsetpgrp** This is similar to the C function `tcsetpgrp()` for setting the process group identifier of the foreground process group of the controlling terminal.

Returns `undef` on failure.

**time** This is identical to Perl's builtin `time()` function for returning the number of seconds since the epoch (whatever it is for the system), see [time](#).

**times** The `times()` function returns elapsed realtime since some point in the past (such as system startup), user and system times for this process, and user and system times used by child processes. All times are returned in clock ticks.

```
($realtime, $user, $system, $cuser, $csystem) = POSIX::times();
```

Note: Perl's builtin `times()` function returns four values, measured in seconds.

**tmpfile** Use method `IO::File::new_tmpfile()` instead, or see [File::Temp](#).

**tmpnam** Returns a name for a temporary file.

```
$tmpfile = POSIX::tmpnam();
```

For security reasons, which are probably detailed in your system's documentation for the C library `tmpnam()` function, this interface should not be used; instead see [File::Temp](#).

**tolower** This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using the `lc()` function, see [lc](#), or the equivalent `\L` operator inside doublequotish strings.

**toupper** This is identical to the C function, except that it can apply to a single character or to a whole string. Consider using the `uc()` function, see [uc](#), or the equivalent `\U` operator inside doublequotish strings.

**ttyname** This is identical to the C function `ttyname()` for returning the name of the current terminal.

**tzname** Retrieves the time conversion information from the `tzname` variable.

```
POSIX::tzset();
($std, $dst) = POSIX::tzname();
```

**tzset** This is identical to the C function `tzset()` for setting the current timezone based on the environment variable `TZ`, to be used by `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions.

**umask** This is identical to Perl's builtin `umask()` function for setting (and querying) the file creation permission mask, see [umask](#).

**uname** Get name of current operating system.

```
($sysname, $nodename, $release, $version, $machine) = POSIX::uname();
```

Note that the actual meanings of the various fields are not that well standardized, do not expect any great portability. The `$sysname` might be the name of the operating system, the `$nodename` might be the name of the host, the `$release` might be the (major) release number of the operating system, the `$version` might be the (minor) release number of the operating system, and the `$machine` might be a hardware identifier. Maybe.

**ungetc** Use method `IO::Handle::ungetc()` instead.

**unlink** This is identical to Perl's builtin `unlink()` function for removing files, see [unlink](#).

**utime** This is identical to Perl's builtin `utime()` function for changing the time stamps of files and directories, see [utime](#).

**vfprintf** `vfprintf()` is C-specific, see [printf](#) instead.

**vprintf** `vprintf()` is C-specific, see [printf](#) instead.

**vsprintf** `vsprintf()` is C-specific, see [sprintf](#) instead.

**wait** This is identical to Perl's builtin `wait()` function, see [wait](#).

**waitpid** Wait for a child process to change state. This is identical to Perl's builtin `waitpid()` function, see [waitpid](#).

```
$pid = POSIX::waitpid(-1, POSIX::WNOHANG);
print "status = ", ($? / 256), "\n";
```

**wcstombs**

This is identical to the C function `wcstombs()`. Perl does not have any support for the wide and multibyte characters of the C standards, so this might be a rather useless function.

**wctomb** This is identical to the C function `wctomb()`. Perl does not have any support for the wide and multibyte characters of the C standards, so this might be a rather useless function.

**write** Write to a file. This uses file descriptors such as those obtained by calling `POSIX::open`.

```
$fd = POSIX::open("foo", &POSIX::O_WRONLY);
$buf = "hello";
$bytes = POSIX::write($b, $buf, 5);
```

Returns `undef` on failure.

See also [syswrite](#).

## CLASSES

### POSIX::SigAction

**new** Creates a new `POSIX::SigAction` object which corresponds to the C struct `sigaction`. This object will be destroyed automatically when it is no longer needed. The first parameter is the fully-qualified name of a sub which is a signal-handler. The second parameter is a `POSIX::SigSet` object, it defaults to the empty set. The third parameter contains the `sa_flags`, it defaults to 0.

```
$sigset = POSIX::SigSet->new(SIGINT, SIGQUIT);
$sigaction = POSIX::SigAction->new('main::handler', $sigset, &POSIX::
```

This `POSIX::SigAction` object should be used with the `POSIX::sigaction()` function.

### POSIX::SigSet

**new** Create a new `SigSet` object. This object will be destroyed automatically when it is no longer needed. Arguments may be supplied to initialize the set.

Create an empty set.

```
$sigset = POSIX::SigSet->new;
```

Create a set with `SIGUSR1`.

```
$sigset = POSIX::SigSet->new(&POSIX::SIGUSR1);
```

**addset** Add a signal to a `SigSet` object.

```
$sigset->addset(&POSIX::SIGUSR2);
```

Returns `undef` on failure.

**delset** Remove a signal from the `SigSet` object.

```
$sigset->delset(&POSIX::SIGUSR2);
```

Returns `undef` on failure.

**emptyset** Initialize the `SigSet` object to be empty.

```
$sigset->emptyset();
```

Returns `undef` on failure.

**fillset** Initialize the `SigSet` object to include all signals.

```
$sigset->fillset();
```

Returns `undef` on failure.

**ismember**

Tests the SigSet object to see if it contains a specific signal.

```
if($sigset->ismember(&POSIX::SIGUSR1)){
 print "contains SIGUSR1\n";
}
```

**POSIX::Termios****new**

Create a new Termios object. This object will be destroyed automatically when it is no longer needed. A Termios object corresponds to the termios C struct. `new()` mallocs a new one, `getattr()` fills it from a file descriptor, and `setattr()` sets a file descriptor's parameters to match Termios' contents.

```
$termios = POSIX::Termios->new;
```

**getattr**

Get terminal control attributes.

Obtain the attributes for stdin.

```
$termios->getattr()
```

Obtain the attributes for stdout.

```
$termios->getattr(1)
```

Returns undef on failure.

**getcc**

Retrieve a value from the `c_cc` field of a termios object. The `c_cc` field is an array so an index must be specified.

```
$c_cc[1] = $termios->getcc(1);
```

**getcflag**

Retrieve the `c_cflag` field of a termios object.

```
$c_cflag = $termios->getcflag;
```

**getiflag**

Retrieve the `c_iflag` field of a termios object.

```
$c_iflag = $termios->getiflag;
```

**getispeed**

Retrieve the input baud rate.

```
$ispeed = $termios->getispeed;
```

**getlflag**

Retrieve the `c_lflag` field of a termios object.

```
$c_lflag = $termios->getlflag;
```

**getoflag**

Retrieve the `c_oflag` field of a termios object.

```
$c_oflag = $termios->getoflag;
```

**getospeed**

Retrieve the output baud rate.

```
$ospeed = $termios->getospeed;
```

**setattr**

Set terminal control attributes.

Set attributes immediately for stdout.

```
$termios->setattr(1, &POSIX::TCSANOW);
```

Returns undef on failure.

**setcc** Set a value in the `c_cc` field of a `termios` object. The `c_cc` field is an array so an index must be specified.

```
$termios->setcc(&POSIX::VEOF, 1);
```

**setcflag** Set the `c_cflag` field of a `termios` object.

```
$termios->setcflag($c_cflag | &POSIX::CLOCAL);
```

**setiflag** Set the `c_iflag` field of a `termios` object.

```
$termios->setiflag($c_iflag | &POSIX::BRKINT);
```

**setispeed** Set the input baud rate.

```
$termios->setispeed(&POSIX::B9600);
```

Returns `undef` on failure.

**setlflag** Set the `c_lflag` field of a `termios` object.

```
$termios->setlflag($c_lflag | &POSIX::ECHO);
```

**setoflag** Set the `c_oflag` field of a `termios` object.

```
$termios->setoflag($c_oflag | &POSIX::OPOST);
```

**setospeed**

Set the output baud rate.

```
$termios->setospeed(&POSIX::B9600);
```

Returns `undef` on failure.

**Baud rate values**

B38400 B75 B200 B134 B300 B1800 B150 B0 B19200 B1200 B9600 B600 B4800 B50 B2400

| WIFSIGNALED | WIFSIGNALED(\$?) returns true if the child process terminated because of a signal                                                                       |
| WTERMSIG    | WTERMSIG(\$?) returns the signal the child process terminated for (only meaningful if WIFSIGNALED(\$?) is true)                                         |
| WIFSTOPPED  | WIFSTOPPED(\$?) returns true if the child process is currently stopped (can happen only if you specified the WUNTRACED flag to <code>waitpid()</code> ) |
| WSTOPSIG    | WSTOPSIG(\$?) returns the signal the child process was stopped for (only meaningful if WIFSTOPPED(\$?) is true)                                         |

**NAME**

re – Perl pragma to alter regular expression behaviour

**SYNOPSIS**

```
use re 'taint';
($x) = ($^X =~ /^(.*)$/s); # $x is tainted here

$pat = '(?{ $foo = 1 })';
use re 'eval';
/foo${pat}bar/; # won't fail (when not under -T switch)

{
 no re 'taint'; # the default
 ($x) = ($^X =~ /^(.*)$/s); # $x is not tainted here

 no re 'eval'; # the default
 /foo${pat}bar/; # disallowed (with or without -T switch)
}

use re 'debug'; # NOT lexically scoped (as others are)
/^(.*)$/s; # output debugging info during
 # compile and run time

use re 'debugcolor'; # same as 'debug', but with colored output
...
```

(We use `$_X` in these examples because it's tainted by default.)

**DESCRIPTION**

When `use re 'taint'` is in effect, and a tainted string is the target of a regex, the regex memories (or values returned by the `m//` operator in list context) are tainted. This feature is useful when regex operations on tainted data aren't meant to extract safe substrings, but to perform other transformations.

When `use re 'eval'` is in effect, a regex is allowed to contain `(?{ ... })` zero-width assertions even if regular expression contains variable interpolation. That is normally disallowed, since it is a potential security risk. Note that this pragma is ignored when the regular expression is obtained from tainted data, i.e. evaluation is always disallowed with tainted regular expressions. See [\(?{ code }\)](#).

For the purpose of this pragma, interpolation of precompiled regular expressions (i.e., the result of `qr//`) is *not* considered variable interpolation. Thus:

```
/foo${pat}bar/
```

is allowed if `$pat` is a precompiled regular expression, even if `$pat` contains `(?{ ... })` assertions.

When `use re 'debug'` is in effect, perl emits debugging messages when compiling and using regular expressions. The output is the same as that obtained by running a `-DDEBUGGING`-enabled perl interpreter with the `-Dr` switch. It may be quite voluminous depending on the complexity of the match. Using `debugcolor` instead of `debug` enables a form of output that can be used to get a colorful display on terminals that understand termcap color sequences. Set `$ENV{PERL_RE_TC}` to a comma-separated list of termcap properties to use for highlighting strings on/off, pre-point part on/off. See [Debugging regular expressions in perldebug](#) for additional info.

The directive `use re 'debug'` is *not lexically scoped*, as the other directives are. It has both compile-time and run-time effects.

See [Pragmatic Modules](#).

**NAME**

Search::Dict, look – search for key in dictionary file

**SYNOPSIS**

```
use Search::Dict;
look *FILEHANDLE, $key, $dict, $fold;

use Search::Dict;
look *FILEHANDLE, $params;
```

**DESCRIPTION**

Sets file position in FILEHANDLE to be first line greater than or equal (stringwise) to *\$key*. Returns the new file position, or *-1* if an error occurs.

The flags specify dictionary order and case folding:

If *\$dict* is true, search by dictionary order (ignore anything but word characters and whitespace). The default is honour all characters.

If *\$fold* is true, ignore case. The default is to honour case.

If there are only three arguments and the third argument is a hash reference, the keys of that hash can have values *dict*, *fold*, and *comp* or *xfrm* (see below), and their corresponding values will be used as the parameters.

If a comparison subroutine (*comp*) is defined, it must return less than zero, zero, or greater than zero, if the first comparand is less than, equal, or greater than the second comparand.

If a transformation subroutine (*xfrm*) is defined, its value is used to transform the lines read from the filehandle before their comparison.

**NAME**

SelectSaver – save and restore selected file handle

**SYNOPSIS**

```
use SelectSaver;

{
 my $saver = new SelectSaver(FILEHANDLE);
 # FILEHANDLE is selected
}
previous handle is selected

{
 my $saver = new SelectSaver;
 # new handle may be selected, or not
}
previous handle is selected
```

**DESCRIPTION**

A `SelectSaver` object contains a reference to the file handle that was selected when it was created. If its `new` method gets an extra parameter, then that parameter is selected; otherwise, the selected file handle remains unchanged.

When a `SelectSaver` is destroyed, it re-selects the file handle that was selected when it was created.

## NAME

SelfLoader – load functions only on demand

## SYNOPSIS

```
package FOOBAR;
use SelfLoader;

... (initializing code)

__DATA__
sub {....
```

## DESCRIPTION

This module tells its users that functions in the FOOBAR package are to be autoloaded from after the `__DATA__` token. See also [Autoloading in perlsub](#).

### The `__DATA__` token

The `__DATA__` token tells the perl compiler that the perl code for compilation is finished. Everything after the `__DATA__` token is available for reading via the filehandle `FOOBAR::DATA`, where FOOBAR is the name of the current package when the `__DATA__` token is reached. This works just the same as `__END__` does in package 'main', but for other modules data after `__END__` is not automatically retrievable, whereas data after `__DATA__` is. The `__DATA__` token is not recognized in versions of perl prior to 5.001m.

Note that it is possible to have `__DATA__` tokens in the same package in multiple files, and that the last `__DATA__` token in a given package that is encountered by the compiler is the one accessible by the filehandle. This also applies to `__END__` and main, i.e. if the 'main' program has an `__END__`, but a module 'require'd (not 'use'd) by that program has a 'package main;' declaration followed by an `__DATA__`, then the `DATA` filehandle is set to access the data after the `__DATA__` in the module, not the data after the `__END__` token in the 'main' program, since the compiler encounters the 'require'd file later.

### SelfLoader autoloading

The **SelfLoader** works by the user placing the `__DATA__` token *after* perl code which needs to be compiled and run at 'require' time, but *before* subroutine declarations that can be loaded in later – usually because they may never be called.

The **SelfLoader** will read from the `FOOBAR::DATA` filehandle to load in the data after `__DATA__`, and load in any subroutine when it is called. The costs are the one-time parsing of the data after `__DATA__`, and a load delay for the `_first_` call of any autoloaded function. The benefits (hopefully) are a speeded up compilation phase, with no need to load functions which are never used.

The **SelfLoader** will stop reading from `__DATA__` if it encounters the `__END__` token – just as you would expect. If the `__END__` token is present, and is followed by the token `DATA`, then the **SelfLoader** leaves the `FOOBAR::DATA` filehandle open on the line after that token.

The **SelfLoader** exports the `AUTOLOAD` subroutine to the package using the **SelfLoader**, and this loads the called subroutine when it is first called.

There is no advantage to putting subroutines which will `_always_` be called after the `__DATA__` token.

### Autoloading and package lexicals

A 'my `$pack_lexical`' statement makes the variable `$pack_lexical` local `_only_` to the file up to the `__DATA__` token. Subroutines declared elsewhere `_cannot_` see these types of variables, just as if you declared subroutines in the package but in another file, they cannot see these variables.

So specifically, autoloaded functions cannot see package lexicals (this applies to both the **SelfLoader** and the Autoloader). The `vars` pragma provides an alternative to defining package-level globals that will be visible to autoloaded routines. See the documentation on **vars** in the pragma section of [perlmod](#).

## SelfLoader and AutoLoader

The **SelfLoader** can replace the AutoLoader – just change ‘use AutoLoader’ to ‘use SelfLoader’ (though note that the **SelfLoader** exports the AUTOLOAD function – but if you have your own AUTOLOAD and are using the AutoLoader too, you probably know what you’re doing), and the `__END__` token to `__DATA__`. You will need perl version 5.001m or later to use this (version 5.001 with all patches up to patch m).

There is no need to inherit from the **SelfLoader**.

The **SelfLoader** works similarly to the AutoLoader, but picks up the subs from after the `__DATA__` instead of in the ‘lib/auto’ directory. There is a maintenance gain in not needing to run AutoSplit on the module at installation, and a runtime gain in not needing to keep opening and closing files to load subs. There is a runtime loss in needing to parse the code after the `__DATA__`. Details of the **AutoLoader** and another view of these distinctions can be found in that module’s documentation.

### `__DATA__`, `__END__`, and the `FOOBAR::DATA` filehandle.

This section is only relevant if you want to use the `FOOBAR::DATA` together with the **SelfLoader**.

Data after the `__DATA__` token in a module is read using the `FOOBAR::DATA` filehandle. `__END__` can still be used to denote the end of the `__DATA__` section if followed by the token `DATA` – this is supported by the **SelfLoader**. The `FOOBAR::DATA` filehandle is left open if an `__END__` followed by a `DATA` is found, with the filehandle positioned at the start of the line after the `__END__` token. If no `__END__` token is present, or an `__END__` token with no `DATA` token on the same line, then the filehandle is closed.

The **SelfLoader** reads from wherever the current position of the `FOOBAR::DATA` filehandle is, until the EOF or `__END__`. This means that if you want to use that filehandle (and ONLY if you want to), you should either

1. Put all your subroutine declarations immediately after the `__DATA__` token and put your own data after those declarations, using the `__END__` token to mark the end of subroutine declarations. You must also ensure that the **SelfLoader** reads first by calling `'SelfLoader->load_stubs()'`, or by using a function which is selfloaded;

or

2. You should read the `FOOBAR::DATA` filehandle first, leaving the handle open and positioned at the first line of subroutine declarations.

You could conceivably do both.

## Classes and inherited methods.

For modules which are not classes, this section is not relevant. This section is only relevant if you have methods which could be inherited.

A subroutine stub (or forward declaration) looks like

```
sub stub;
```

i.e. it is a subroutine declaration without the body of the subroutine. For modules which are not classes, there is no real need for stubs as far as autoloading is concerned.

For modules which ARE classes, and need to handle inherited methods, stubs are needed to ensure that the method inheritance mechanism works properly. You can load the stubs into the module at ‘require’ time, by adding the statement `'SelfLoader->load_stubs()'` to the module to do this.

The alternative is to put the stubs in before the `__DATA__` token BEFORE releasing the module, and for this purpose the `Devel::SelfStubber` module is available. However this does require the extra step of ensuring that the stubs are in the module. If this is done I strongly recommend that this is done BEFORE releasing the module – it should NOT be done at install time in general.

**Multiple packages and fully qualified subroutine names**

Subroutines in multiple packages within the same file are supported – but you should note that this requires exporting the `SelfLoader::AUTOLOAD` to every package which requires it. This is done automatically by the **SelfLoader** when it first loads the subs into the cache, but you should really specify it in the initialization before the `__DATA__` by putting a ‘use SelfLoader’ statement in each package.

Fully qualified subroutine names are also supported. For example,

```
__DATA__
sub foo::bar {23}
package baz;
sub dob {32}
```

will all be loaded correctly by the **SelfLoader**, and the **SelfLoader** will ensure that the packages ‘foo’ and ‘baz’ correctly have the **SelfLoader** `AUTOLOAD` method when the data after `__DATA__` is first parsed.

**NAME**

Shell – run shell commands transparently within perl

**SYNOPSIS**

See below.

**DESCRIPTION**

```
Date: Thu, 22 Sep 94 16:18:16 -0700
Message-Id: <9409222318.AA17072@scalpel.netlabs.com>
To: perl5-porters@isu.edu
From: Larry Wall <lwall@scalpel.netlabs.com>
Subject: a new module I just wrote
```

Here's one that'll whack your mind a little out.

```
#!/usr/bin/perl

use Shell;

$foo = echo("howdy", "<funny>", "world");
print $foo;

$passwd = cat("</etc/passwd");
print $passwd;

sub ps;
print ps -ww;

cp("/etc/passwd", "/tmp/passwd");
```

That's maybe too gonzo. It actually exports an AUTOLOAD to the current package (and uncovered a bug in Beta 3, by the way). Maybe the usual usage should be

```
use Shell qw(echo cat ps cp);
```

Larry

If you set `$Shell::capture_stderr` to 1, the module will attempt to capture the STDERR of the process as well.

The module now should work on Win32.

Jenda

There seemed to be a problem where all arguments to a shell command were quoted before being executed. As in the following example:

```
cat('</etc/passwd');
ls('*.*pl');
```

really turned into:

```
cat '</etc/passwd'
ls '*.*pl'
```

instead of:

```
cat </etc/passwd
ls *.*pl
```

and of course, this is wrong.

I have fixed this bug, it was brought up by Wolfgang Laun [ID 20000326.008]

Casey

**OBJECT ORIENTED SYNTAX**

Shell now has an OO interface. Good for namespace conservation and shell representation.

```
use Shell;
my $sh = Shell->new;
print $sh->ls;
```

## NAME

sigtrap – Perl pragma to enable simple signal handling

## SYNOPSIS

```
use sigtrap;
use sigtrap qw(stack-trace old-interface-signals); # equivalent
use sigtrap qw(BUS SEGV PIPE ABRT);
use sigtrap qw(die INT QUIT);
use sigtrap qw(die normal-signals);
use sigtrap qw(die untrapped normal-signals);
use sigtrap qw(die untrapped normal-signals
 stack-trace any error-signals);
use sigtrap 'handler' => \&my_handler, 'normal-signals';
use sigtrap qw(handler my_handler normal-signals
 stack-trace error-signals);
```

## DESCRIPTION

The **sigtrap** pragma is a simple interface to installing signal handlers. You can have it install one of two handlers supplied by **sigtrap** itself (one which provides a Perl stack trace and one which simply `die()`s), or alternately you can supply your own handler for it to install. It can be told only to install a handler for signals which are either untrapped or ignored. It has a couple of lists of signals to trap, plus you can supply your own list of signals.

The arguments passed to the `use` statement which invokes **sigtrap** are processed in order. When a signal name or the name of one of **sigtrap**'s signal lists is encountered a handler is immediately installed, when an option is encountered it affects subsequently installed handlers.

## OPTIONS

### SIGNAL HANDLERS

These options affect which handler will be used for subsequently installed signals.

#### **stack-trace**

The handler used for subsequently installed signals outputs a Perl stack trace to `STDERR` and then tries to dump core. This is the default signal handler.

**die** The handler used for subsequently installed signals calls `die` (actually `croak`) with a message indicating which signal was caught.

#### **handler *your-handler***

*your-handler* will be used as the handler for subsequently installed signals. *your-handler* can be any value which is valid as an assignment to an element of `%SIG`.

### SIGNAL LISTS

**sigtrap** has a few built-in lists of signals to trap. They are:

#### **normal-signals**

These are the signals which a program might normally expect to encounter and which by default cause it to terminate. They are `HUP`, `INT`, `PIPE` and `TERM`.

#### **error-signals**

These signals usually indicate a serious problem with the Perl interpreter or with your script. They are `ABRT`, `BUS`, `EMT`, `FPE`, `ILL`, `QUIT`, `SEGV`, `SYS` and `TRAP`.

#### **old-interface-signals**

These are the signals which were trapped by default by the old **sigtrap** interface, they are `ABRT`, `BUS`, `EMT`, `FPE`, `ILL`, `PIPE`, `QUIT`, `SEGV`, `SYS`, `TERM`, and `TRAP`. If no signals or signals lists are passed to **sigtrap**, this list is used.

For each of these three lists, the collection of signals set to be trapped is checked before trapping; if your architecture does not implement a particular signal, it will not be trapped but rather silently ignored.

## OTHER

### untrapped

This token tells **sigtrap** to install handlers only for subsequently listed signals which aren't already trapped or ignored.

**any** This token tells **sigtrap** to install handlers for all subsequently listed signals. This is the default behavior.

### signal

Any argument which looks like a signal name (that is, `/^[A-Z] [A-Z0-9] *$/`) indicates that **sigtrap** should install a handler for that name.

### number

Require that at least version *number* of **sigtrap** is being used.

## EXAMPLES

Provide a stack trace for the old-interface-signals:

```
use sigtrap;
```

Ditto:

```
use sigtrap qw(stack-trace old-interface-signals);
```

Provide a stack trace on the 4 listed signals only:

```
use sigtrap qw(BUS SEGV PIPE ABRT);
```

Die on INT or QUIT:

```
use sigtrap qw(die INT QUIT);
```

Die on HUP, INT, PIPE or TERM:

```
use sigtrap qw(die normal-signals);
```

Die on HUP, INT, PIPE or TERM, except don't change the behavior for signals which are already trapped or ignored:

```
use sigtrap qw(die untrapped normal-signals);
```

Die on receipt one of an of the **normal-signals** which is currently **untrapped**, provide a stack trace on receipt of **any** of the **error-signals**:

```
use sigtrap qw(die untrapped normal-signals
 stack-trace any error-signals);
```

Install `my_handler()` as the handler for the **normal-signals**:

```
use sigtrap 'handler', \&my_handler, 'normal-signals';
```

Install `my_handler()` as the handler for the normal-signals, provide a Perl stack trace on receipt of one of the error-signals:

```
use sigtrap qw(handler my_handler normal-signals
 stack-trace error-signals);
```

**NAME**

Socket, sockaddr\_in, sockaddr\_un, inet\_aton, inet\_ntoa – load the C socket.h defines and structure manipulators

**SYNOPSIS**

```
use Socket;

$proto = getprotobyname('udp');
socket(Socket_Handle, PF_INET, SOCK_DGRAM, $proto);
$iaddr = gethostbyname('hishost.com');
$port = getservbyname('time', 'udp');
$sin = sockaddr_in($port, $iaddr);
send(Socket_Handle, 0, 0, $sin);

$proto = getprotobyname('tcp');
socket(Socket_Handle, PF_INET, SOCK_STREAM, $proto);
$port = getservbyname('smtp', 'tcp');
$sin = sockaddr_in($port, inet_aton("127.1"));
$sin = sockaddr_in(7, inet_aton("localhost"));
$sin = sockaddr_in(7, INADDR_LOOPBACK);
connect(Socket_Handle, $sin);

($port, $iaddr) = sockaddr_in(getpeername(Socket_Handle));
$peer_host = gethostbyaddr($iaddr, AF_INET);
$peer_addr = inet_ntoa($iaddr);

$proto = getprotobyname('tcp');
socket(Socket_Handle, PF_UNIX, SOCK_STREAM, $proto);
unlink('/tmp/usock');
$sun = sockaddr_un('/tmp/usock');
connect(Socket_Handle, $sun);
```

**DESCRIPTION**

This module is just a translation of the C *socket.h* file. Unlike the old mechanism of requiring a translated *socket.ph* file, this uses the **h2xs** program (see the Perl source distribution) and your native C compiler. This means that it has a far more likely chance of getting the numbers right. This includes all of the commonly used pound–defines like AF\_INET, SOCK\_STREAM, etc.

Also, some common socket "newline" constants are provided: the constants CR, LF, and CRLF, as well as \$CR, \$LF, and \$CRLF, which map to \015, \012, and \015\012. If you do not want to use the literal characters in your programs, then use the constants provided here. They are not exported by default, but can be imported individually, and with the :crlf export tag:

```
use Socket qw(:DEFAULT :crlf);
```

In addition, some structure manipulation functions are available:

**inet\_aton HOSTNAME**

Takes a string giving the name of a host, and translates that to an opaque string (if programming in C, struct in\_addr). Takes arguments of both the 'rtfm.mit.edu' type and '18.181.0.24'. If the host name cannot be resolved, returns undef. For multi–homed hosts (hosts with more than one address), the first address found is returned.

For portability do not assume that the result of `inet_aton()` is 32 bits wide, in other words, that it would contain only the IPv4 address in network order.

**inet\_ntoa IP\_ADDRESS**

Takes a string (an opaque string as returned by `inet_aton()`, or a v–string representing the four octets of the IPv4 address in network order) and translates it into a string of the form 'd.d.d.d' where

the 'd's are numbers less than 256 (the normal human-readable four dotted number notation for Internet addresses).

#### INADDR\_ANY

Note: does not return a number, but a packed string.

Returns the 4-byte wildcard ip address which specifies any of the hosts ip addresses. (A particular machine can have more than one ip address, each address corresponding to a particular network interface. This wildcard address allows you to bind to all of them simultaneously.) Normally equivalent to `inet_aton('0.0.0.0')`.

#### INADDR\_BROADCAST

Note: does not return a number, but a packed string.

Returns the 4-byte 'this-lan' ip broadcast address. This can be useful for some protocols to solicit information from all servers on the same LAN cable. Normally equivalent to `inet_aton('255.255.255.255')`.

#### INADDR\_LOOPBACK

Note – does not return a number.

Returns the 4-byte loopback address. Normally equivalent to `inet_aton('localhost')`.

#### INADDR\_NONE

Note – does not return a number.

Returns the 4-byte 'invalid' ip address. Normally equivalent to `inet_aton('255.255.255.255')`.

#### sockaddr\_family SOCKADDR

Takes a sockaddr structure (as returned by `pack_sockaddr_in()`, `pack_sockaddr_un()` or the perl builtin functions `getsockname()` and `getpeername()`) and returns the address family tag. It will match the constant `AF_INET` for a `sockaddr_in` and `AF_UNIX` for a `sockaddr_un`. It can be used to figure out what unpacker to use for a sockaddr of unknown type.

#### sockaddr\_in PORT, ADDRESS

##### sockaddr\_in SOCKADDR\_IN

In a list context, unpacks its `SOCKADDR_IN` argument and returns an array consisting of (PORT, ADDRESS). In a scalar context, packs its (PORT, ADDRESS) arguments as a `SOCKADDR_IN` and returns it. If this is confusing, use `pack_sockaddr_in()` and `unpack_sockaddr_in()` explicitly.

#### pack\_sockaddr\_in PORT, IP\_ADDRESS

Takes two arguments, a port number and an opaque string, `IP_ADDRESS` (as returned by `inet_aton()`, or a v-string). Returns the `sockaddr_in` structure with those arguments packed in with `AF_INET` filled in. For Internet domain sockets, this structure is normally what you need for the arguments in `bind()`, `connect()`, and `send()`, and is also returned by `getpeername()`, `getsockname()` and `recv()`.

#### unpack\_sockaddr\_in SOCKADDR\_IN

Takes a `sockaddr_in` structure (as returned by `pack_sockaddr_in()`) and returns an array of two elements: the port and an opaque string representing the IP address (you can use `inet_ntoa()` to convert the address to the four-dotted numeric format). Will croak if the structure does not have `AF_INET` in the right place.

#### sockaddr\_un PATHNAME

##### sockaddr\_un SOCKADDR\_UN

In a list context, unpacks its `SOCKADDR_UN` argument and returns an array consisting of (PATHNAME). In a scalar context, packs its `PATHNAME` arguments as a `SOCKADDR_UN` and returns it. If this is confusing, use `pack_sockaddr_un()` and `unpack_sockaddr_un()`

explicitly. These are only supported if your system has `<sys/un.h>`.

`pack_sockaddr_un` PATH

Takes one argument, a pathname. Returns the `sockaddr_un` structure with that path packed in with `AF_UNIX` filled in. For unix domain sockets, this structure is normally what you need for the arguments in `bind()`, `connect()`, and `send()`, and is also returned by `getpeername()`, `getsockname()` and `recv()`.

`unpack_sockaddr_un` SOCKADDR\_UN

Takes a `sockaddr_un` structure (as returned by `pack_sockaddr_un()`) and returns the pathname. Will croak if the structure does not have `AF_UNIX` in the right place.

**NAME**

sort – perl pragma to control sort () behaviour

**SYNOPSIS**

```
use sort 'stable'; # guarantee stability
use sort '_quicksort'; # use a quicksort algorithm
use sort '_mergesort'; # use a mergesort algorithm

use sort '_qsort'; # alias for quicksort

my $current = sort::current(); # identify prevailing algorithm
```

**DESCRIPTION**

With the sort pragma you can control the behaviour of the builtin sort () function.

In Perl versions 5.6 and earlier the quicksort algorithm was used to implement sort (), but in Perl 5.8 a mergesort algorithm was also made available, mainly to guarantee worst case  $O(N \log N)$  behaviour: the worst case of quicksort is  $O(N^2)$ . In Perl 5.8 and later, quicksort defends against quadratic behaviour by shuffling large arrays before sorting.

A stable sort means that for records that compare equal, the original input ordering is preserved. Mergesort is stable, quicksort is not. Stability will matter only if elements that compare equal can be distinguished in some other way. That means that simple numerical and lexical sorts do not profit from stability, since equal elements are indistinguishable. However, with a comparison such as

```
{ substr($a, 0, 3) cmp substr($b, 0, 3) }
```

stability might matter because elements that compare equal on the first 3 characters may be distinguished based on subsequent characters. In Perl 5.8 and later, quicksort can be stabilized, but doing so will add overhead, so it should only be done if it matters.

The best algorithm depends on many things. On average, mergesort does fewer comparisons than quicksort, so it may be better when complicated comparison routines are used. Mergesort also takes advantage of pre-existing order, so it would be favored for using sort to merge several sorted arrays. On the other hand, quicksort is often faster for small arrays, and on platforms with small memory caches that are much faster than main memory. You can force the choice of algorithm with this pragma, but this feels heavy-handed, so the subpragmas beginning with a \_ may not persist beyond Perl 5.8.

**CAVEATS**

This pragma is not lexically scoped : its effect is global to the program it appears in. This may change in future versions.

**NAME**

Storable – persistence for Perl data structures

**SYNOPSIS**

```
use Storable;
store \%table, 'file';
$hashref = retrieve('file');

use Storable qw(nstore store_fd nstore_fd freeze thaw dclone);

Network order
nstore \%table, 'file';
$hashref = retrieve('file'); # There is NO nretrieve()

Storing to and retrieving from an already opened file
store_fd \@array, *STDOUT;
nstore_fd \%table, *STDOUT;
$arrayref = fd_retrieve(*SOCKET);
$hashref = fd_retrieve(*SOCKET);

Serializing to memory
$serialized = freeze \%table;
%table_clone = %{ thaw($serialized) };

Deep (recursive) cloning
$cloneref = dclone($ref);

Advisory locking
use Storable qw(lock_store lock_nstore lock_retrieve)
lock_store \%table, 'file';
lock_nstore \%table, 'file';
$hashref = lock_retrieve('file');
```

**DESCRIPTION**

The Storable package brings persistence to your Perl data structures containing SCALAR, ARRAY, HASH or REF objects, i.e. anything that can be conveniently stored to disk and retrieved at a later time.

It can be used in the regular procedural way by calling `store` with a reference to the object to be stored, along with the file name where the image should be written.

The routine returns `undef` for I/O problems or other internal error, a true value otherwise. Serious errors are propagated as a die exception.

To retrieve data stored to disk, use `retrieve` with a file name. The objects stored into that file are recreated into memory for you, and a *reference* to the root object is returned. In case an I/O error occurs while reading, `undef` is returned instead. Other serious errors are propagated via `die`.

Since storage is performed recursively, you might want to stuff references to objects that share a lot of common data into a single array or hash table, and then store that object. That way, when you retrieve back the whole thing, the objects will continue to share what they originally shared.

At the cost of a slight header overhead, you may store to an already opened file descriptor using the `store_fd` routine, and retrieve from a file via `fd_retrieve`. Those names aren't imported by default, so you will have to do that explicitly if you need those routines. The file descriptor you supply must be already opened, for read if you're going to retrieve and for write if you wish to store.

```
store_fd(\%table, *STDOUT) || die "can't store to stdout\n";
$hashref = fd_retrieve(*STDIN);
```

You can also store data in network order to allow easy sharing across multiple platforms, or when storing on a socket known to be remotely connected. The routines to call have an initial `n` prefix for *network*, as in

`nstore` and `nstore_fd`. At retrieval time, your data will be correctly restored so you don't have to know whether you're restoring from native or network ordered data. Double values are stored stringified to ensure portability as well, at the slight risk of loosing some precision in the last decimals.

When using `fd_retrieve`, objects are retrieved in sequence, one object (i.e. one recursive tree) per associated `store_fd`.

If you're more from the object-oriented camp, you can inherit from `Storable` and directly store your objects by invoking `store` as a method. The fact that the root of the to-be-stored tree is a blessed reference (i.e. an object) is special-cased so that the retrieve does not provide a reference to that object but rather the blessed object reference itself. (Otherwise, you'd get a reference to that blessed object).

## MEMORY STORE

The `Storable` engine can also store data into a Perl scalar instead, to later retrieve them. This is mainly used to freeze a complex structure in some safe compact memory place (where it can possibly be sent to another process via some IPC, since freezing the structure also serializes it in effect). Later on, and maybe somewhere else, you can thaw the Perl scalar out and recreate the original complex structure in memory.

Surprisingly, the routines to be called are named `freeze` and `thaw`. If you wish to send out the frozen scalar to another machine, use `nfreeze` instead to get a portable image.

Note that freezing an object structure and immediately thawing it actually achieves a deep cloning of that structure:

```
dclone(.) = thaw(freeze(.))
```

`Storable` provides you with a `dclone` interface which does not create that intermediary scalar but instead freezes the structure in some internal memory space and then immediately thaws it out.

## ADVISORY LOCKING

The `lock_store` and `lock_nstore` routine are equivalent to `store` and `nstore`, except that they get an exclusive lock on the file before writing. Likewise, `lock_retrieve` does the same as `retrieve`, but also gets a shared lock on the file before reading.

As with any advisory locking scheme, the protection only works if you systematically use `lock_store` and `lock_retrieve`. If one side of your application uses `store` whilst the other uses `lock_retrieve`, you will get no protection at all.

The internal advisory locking is implemented using Perl's `flock()` routine. If your system does not support any form of `flock()`, or if you share your files across NFS, you might wish to use other forms of locking by using modules such as `LockFile::Simple` which lock a file using a filesystem entry, instead of locking the file descriptor.

## SPEED

The heart of `Storable` is written in C for decent speed. Extra low-level optimizations have been made when manipulating perl internals, to sacrifice encapsulation for the benefit of greater speed.

## CANONICAL REPRESENTATION

Normally, `Storable` stores elements of hashes in the order they are stored internally by Perl, i.e. pseudo-randomly. If you set `$Storable::canonical` to some TRUE value, `Storable` will store hashes with the elements sorted by their key. This allows you to compare data structures by comparing their frozen representations (or even the compressed frozen representations), which can be useful for creating lookup tables for complicated queries.

Canonical order does not imply network order; those are two orthogonal settings.

## FORWARD COMPATIBILITY

This release of `Storable` can be used on a newer version of Perl to serialize data which is not supported by earlier Perls. By default, `Storable` will attempt to do the right thing, by `croak()`ing if it encounters data that it cannot deserialize. However, the defaults can be changed as follows:

### utf8 data

Perl 5.6 added support for Unicode characters with code points `> 255`, and Perl 5.8 has full support for Unicode characters in hash keys. Perl internally encodes strings with these characters using utf8, and Storable serializes them as utf8. By default, if an older version of Perl encounters a utf8 value it cannot represent, it will `croak()`. To change this behaviour so that Storable deserializes utf8 encoded values as the string of bytes (effectively dropping the `is_utf8` flag) set `$Storable::drop_utf8` to some TRUE value. This is a form of data loss, because with `$drop_utf8` true, it becomes impossible to tell whether the original data was the Unicode string, or a series of bytes that happen to be valid utf8.

### restricted hashes

Perl 5.8 adds support for restricted hashes, which have keys restricted to a given set, and can have values locked to be read only. By default, when Storable encounters a restricted hash on a perl that doesn't support them, it will deserialize it as a normal hash, silently discarding any placeholder keys and leaving the keys and all values unlocked. To make Storable `croak()` instead, set `$Storable::downgrade_restricted` to a FALSE value. To restore the default set it back to some TRUE value.

### files from future versions of Storable

Earlier versions of Storable would immediately croak if they encountered a file with a higher internal version number than the reading Storable knew about. Internal version numbers are increased each time new data types (such as restricted hashes) are added to the vocabulary of the file format. This meant that a newer Storable module had no way of writing a file readable by an older Storable, even if the writer didn't store newer data types.

This version of Storable will defer croaking until it encounters a data type in the file that it does not recognize. This means that it will continue to read files generated by newer Storable modules which are careful in what they write out, making it easier to upgrade Storable modules in a mixed environment.

The old behaviour of immediate croaking can be re-instated by setting `$Storable::accept_future_minor` to some FALSE value.

All these variables have no effect on a newer Perl which supports the relevant feature.

## ERROR REPORTING

Storable uses the "exception" paradigm, in that it does not try to workaround failures: if something bad happens, an exception is generated from the caller's perspective (see [Carp](#) and `croak()`). Use `eval {}` to trap those exceptions.

When Storable croaks, it tries to report the error via the `logcroak()` routine from the `Log::Agent` package, if it is available.

Normal errors are reported by having `store()` or `retrieve()` return `undef`. Such errors are usually I/O errors (or truncated stream errors at retrieval).

## WIZARDS ONLY

### Hooks

Any class may define hooks that will be called during the serialization and deserialization process on objects that are instances of that class. Those hooks can redefine the way serialization is performed (and therefore, how the symmetrical deserialization should be conducted).

Since we said earlier:

```
dclone(.) = thaw(freeze(.))
```

everything we say about hooks should also hold for deep cloning. However, hooks get to know whether the operation is a mere serialization, or a cloning.

Therefore, when serializing hooks are involved,

```
dclone(.) <> thaw(freeze(.))
```

Well, you could keep them in sync, but there's no guarantee it will always hold on classes somebody else wrote. Besides, there is little to gain in doing so: a serializing hook could keep only one attribute of an object, which is probably not what should happen during a deep cloning of that same object.

Here is the hooking interface:

`STORABLE_freeze` *obj, cloning*

The serializing hook, called on the object during serialization. It can be inherited, or defined in the class itself, like any other method.

Arguments: *obj* is the object to serialize, *cloning* is a flag indicating whether we're in a `dclone()` or a regular serialization via `store()` or `freeze()`.

Returned value: A LIST (`$serialized`, `$ref1`, `$ref2`, ...) where `$serialized` is the serialized form to be used, and the optional `$ref1`, `$ref2`, etc... are extra references that you wish to let the Storable engine serialize.

At deserialization time, you will be given back the same LIST, but all the extra references will be pointing into the deserialized structure.

The **first time** the hook is hit in a serialization flow, you may have it return an empty list. That will signal the Storable engine to further discard that hook for this class and to therefore revert to the default serialization of the underlying Perl data. The hook will again be normally processed in the next serialization.

Unless you know better, serializing hook should always say:

```
sub STORABLE_freeze {
 my ($self, $cloning) = @_;
 return if $cloning; # Regular default serialization

}
```

in order to keep reasonable `dclone()` semantics.

`STORABLE_thaw` *obj, cloning, serialized, ...*

The deserializing hook called on the object during deserialization. But wait: if we're deserializing, there's no object yet... right?

Wrong: the Storable engine creates an empty one for you. If you know Eiffel, you can view `STORABLE_thaw` as an alternate creation routine.

This means the hook can be inherited like any other method, and that *obj* is your blessed reference for this particular instance.

The other arguments should look familiar if you know `STORABLE_freeze`: *cloning* is true when we're part of a deep clone operation, *serialized* is the serialized string you returned to the engine in `STORABLE_freeze`, and there may be an optional list of references, in the same order you gave them at serialization time, pointing to the deserialized objects (which have been processed courtesy of the Storable engine).

When the Storable engine does not find any `STORABLE_thaw` hook routine, it tries to load the class by requiring the package dynamically (using the blessed package name), and then re-attempts the lookup. If at that time the hook cannot be located, the engine croaks. Note that this mechanism will fail if you define several classes in the same file, but *perlmod* warned you.

It is up to you to use this information to populate *obj* the way you want.

Returned value: none.

## Predicates

Predicates are not exportable. They must be called by explicitly prefixing them with the Storable package name.

`Storable::last_op_in_netorder`

The `Storable::last_op_in_netorder()` predicate will tell you whether network order was used in the last store or retrieve operation. If you don't know how to use this, just forget about it.

`Storable::is_storing`

Returns true if within a store operation (via `STORABLE_freeze` hook).

`Storable::is_retrieving`

Returns true if within a retrieve operation (via `STORABLE_thaw` hook).

## Recursion

With hooks comes the ability to recurse back to the Storable engine. Indeed, hooks are regular Perl code, and Storable is convenient when it comes to serializing and deserializing things, so why not use it to handle the serialization string?

There are a few things you need to know, however:

- You can create endless loops if the things you serialize via `freeze()` (for instance) point back to the object we're trying to serialize in the hook.
- Shared references among objects will not stay shared: if we're serializing the list of object [A, C] where both object A and C refer to the SAME object B, and if there is a serializing hook in A that says `freeze(B)`, then when deserializing, we'll get [A', C'] where A' refers to B', but C' refers to D, a deep clone of B'. The topology was not preserved.

That's why `STORABLE_freeze` lets you provide a list of references to serialize. The engine guarantees that those will be serialized in the same context as the other objects, and therefore that shared objects will stay shared.

In the above [A, C] example, the `STORABLE_freeze` hook could return:

```
("something", $self->{B})
```

and the B part would be serialized by the engine. In `STORABLE_thaw`, you would get back the reference to the B' object, deserialized for you.

Therefore, recursion should normally be avoided, but is nonetheless supported.

## Deep Cloning

There is a Clone module available on CPAN which implements deep cloning natively, i.e. without freezing to memory and thawing the result. It is aimed to replace Storable's `dclone()` some day. However, it does not currently support Storable hooks to redefine the way deep cloning is performed.

## Storable magic

Yes, there's a lot of that :-). But more precisely, in UNIX systems there's a utility called `file`, which recognizes data files based on their contents (usually their first few bytes). For this to work, a certain file called *magic* needs to be taught about the *signature* of the data. Where that configuration file lives depends on the UNIX flavour; often it's something like `/usr/share/misc/magic` or `/etc/magic`. Your system administrator needs to do the updating of the *magic* file. The necessary signature information is output to STDOUT by invoking `Storable::show_file_magic()`. Note that the GNU implementation of the `file` utility, version 3.38 or later, is expected to contain support for recognising Storable files out-of-the-box, in addition to other kinds of Perl files.

## EXAMPLES

Here are some code samples showing a possible usage of Storable:

```

use Storable qw(store retrieve freeze thaw dclone);

%color = ('Blue' => 0.1, 'Red' => 0.8, 'Black' => 0, 'White' => 1);
store(\%color, '/tmp/colors') or die "Can't store %a in /tmp/colors!\n";
$colref = retrieve('/tmp/colors');
die "Unable to retrieve from /tmp/colors!\n" unless defined $colref;
printf "Blue is still %lf\n", $colref->{'Blue'};

$colref2 = dclone(\%color);

$str = freeze(\%color);
printf "Serialization of %color is %d bytes long.\n", length($str);
$colref3 = thaw($str);

```

which prints (on my machine):

```

Blue is still 0.100000
Serialization of %color is 102 bytes long.

```

## WARNING

If you're using references as keys within your hash tables, you're bound to be disappointed when retrieving your data. Indeed, Perl stringifies references used as hash table keys. If you later wish to access the items via another reference stringification (i.e. using the same reference that was used for the key originally to record the value into the hash table), it will work because both references stringify to the same string.

It won't work across a sequence of `store` and `retrieve` operations, however, because the addresses in the retrieved objects, which are part of the stringified references, will probably differ from the original addresses. The topology of your structure is preserved, but not hidden semantics like those.

On platforms where it matters, be sure to call `binmode()` on the descriptors that you pass to Storable functions.

Storing data canonically that contains large hashes can be significantly slower than storing the same data normally, as temporary arrays to hold the keys for each hash have to be allocated, populated, sorted and freed. Some tests have shown a halving of the speed of storing — the exact penalty will depend on the complexity of your data. There is no slowdown on retrieval.

## BUGS

You can't store `GLOB`, `CODE`, `FORMLINE`, etc.... If you can define semantics for those operations, feel free to enhance Storable so that it can deal with them.

The store functions will croak if they run into such references unless you set `$Storable::forgive_me` to some TRUE value. In that case, the fatal message is turned in a warning and some meaningless string is stored instead.

Setting `$Storable::canonical` may not yield frozen strings that compare equal due to possible stringification of numbers. When the string version of a scalar exists, it is the form stored; therefore, if you happen to use your numbers as strings between two freezing operations on the same data structures, you will get different results.

When storing doubles in network order, their value is stored as text. However, you should also not expect non-numeric floating-point values such as infinity and "not a number" to pass successfully through a `nstore()/retrieve()` pair.

As Storable neither knows nor cares about character sets (although it does know that characters may be more than eight bits wide), any difference in the interpretation of character codes between a host and a target system is your problem. In particular, if host and target use different code points to represent the characters

used in the text representation of floating-point numbers, you will not be able to exchange floating-point data, even with `nstore()`.

`Storable::drop_utf8` is a blunt tool. There is no facility either to return **all** strings as utf8 sequences, or to attempt to convert utf8 data back to 8 bit and `croak()` if the conversion fails.

Prior to Storable 2.01, no distinction was made between signed and unsigned integers on storing. By default Storable prefers to store a scalar's string representation (if it has one) so this would only cause problems when storing large unsigned integers that had never been converted to string or floating point. In other words values that had been generated by integer operations such as logic ops and then not used in any string or arithmetic context before storing.

### 64 bit data in perl 5.6.0 and 5.6.1

This section only applies to you if you have existing data written out by Storable 2.02 or earlier on perl 5.6.0 or 5.6.1 on Unix or Linux which has been configured with 64 bit integer support (not the default). If you got a precompiled perl, rather than running Configure to build your own perl from source, then it almost certainly does not affect you, and you can stop reading now (unless you're curious). If you're using perl on Windows it does not affect you.

Storable writes a file header which contains the sizes of various C language types for the C compiler that built Storable (when not writing in network order), and will refuse to load files written by a Storable not on the same (or compatible) architecture. This check and a check on machine byteorder is needed because the size of various fields in the file are given by the sizes of the C language types, and so files written on different architectures are incompatible. This is done for increased speed. (When writing in network order, all fields are written out as standard lengths, which allows full interworking, but takes longer to read and write)

Perl 5.6.x introduced the ability to optionally configure the perl interpreter to use C's `long long` type to allow scalars to store 64 bit integers on 32 bit systems. However, due to the way the Perl configuration system generated the C configuration files on non-Windows platforms, and the way Storable generates its header, nothing in the Storable file header reflected whether the perl writing was using 32 or 64 bit integers, despite the fact that Storable was storing some data differently in the file. Hence Storable running on perl with 64 bit integers will read the header from a file written by a 32 bit perl, not realise that the data is actually in a subtly incompatible format, and then go horribly wrong (possibly crashing) if it encountered a stored integer. This is a design failure.

Storable has now been changed to write out and read in a file header with information about the size of integers. It's impossible to detect whether an old file being read in was written with 32 or 64 bit integers (they have the same header) so it's impossible to automatically switch to a correct backwards compatibility mode. Hence this Storable defaults to the new, correct behaviour.

What this means is that if you have data written by Storable 1.x running on perl 5.6.0 or 5.6.1 configured with 64 bit integers on Unix or Linux then by default this Storable will refuse to read it, giving the error *Byte order is not compatible*. If you have such data then you should set `$Storable::interwork_56_64bit` to a true value to make this Storable read and write files with the old header. You should also migrate your data, or any older perl you are communicating with, to this current version of Storable.

If you don't have data written with specific configuration of perl described above, then you do not and should not do anything. Don't set the flag – not only will Storable on an identically configured perl refuse to load them, but Storable a differently configured perl will load them believing them to be correct for it, and then may well fail or crash part way through reading them.

## SEE ALSO

[\*Clone\*](#).

**NAME**

strict – Perl pragma to restrict unsafe constructs

**SYNOPSIS**

```
use strict;

use strict "vars";
use strict "refs";
use strict "subs";

use strict;
no strict "vars";
```

**DESCRIPTION**

If no import list is supplied, all possible restrictions are assumed. (This is the safest mode to operate in, but is sometimes too strict for casual programming.) Currently, there are three possible things to be strict about: "subs", "vars", and "refs".

strict refs

This generates a runtime error if you use symbolic references (see [perlref](#)).

```
use strict 'refs';
$ref = \ $foo;
print $$ref; # ok
$ref = "foo";
print $$ref; # runtime error; normally ok
$file = "STDOUT";
print $file "Hi!"; # error; note: no comma after $file
```

There is one exception to this rule:

```
$bar = \&{'foo'};
&$bar;
```

is allowed so that `goto &$AUTOLOAD` would not break under stricture.

strict vars

This generates a compile-time error if you access a variable that wasn't declared via `"our"` or `use vars`, localized via `my()`, or wasn't fully qualified. Because this is to avoid variable suicide problems and subtle dynamic scoping issues, a merely `local()` variable isn't good enough. See [my](#) and [local](#).

```
use strict 'vars';
$X::foo = 1; # ok, fully qualified
my $foo = 10; # ok, my() var
local $foo = 9; # blows up

package Cinna;
our $bar; # Declares $bar in current package
$bar = 'HgS'; # ok, global declared via pragma
```

The `local()` generated a compile-time error because you just touched a global name without fully qualifying it.

Because of their special use by `sort()`, the variables `$a` and `$b` are exempted from this check.

strict subs

This disables the poetry optimization, generating a compile-time error if you try to use a bareword identifier that's not a subroutine, unless it appears in curly braces or on the left hand side of the `"=>"` symbol.

```
use strict 'subs';
$SIG{PIPE} = Plumber# blows up
$SIG{PIPE} = "Plumbe#" just fine: bareword in curlies always ok
$SIG{PIPE} = \&Plumber# preferred form
```

See [Pragmatic Modules](#).

**NAME**

subs – Perl pragma to predeclare sub names

**SYNOPSIS**

```
use subs qw(frob);
frob 3..10;
```

**DESCRIPTION**

This will predeclare all the subroutine whose names are in the list, allowing you to use them without parentheses even before they're declared.

Unlike pragmas that affect the `%^H` hints variable, the `use vars` and `use subs` declarations are not BLOCK-scoped. They are thus effective for the entire file in which they appear. You may not rescind such declarations with `no vars` or `no subs`.

See [Pragmatic Modules](#) and [strict subs](#).

**NAME**

Switch – A switch statement for Perl

**VERSION**

This document describes version 2.09 of Switch, released June 12, 2002.

**SYNOPSIS**

```
use Switch;

switch ($val) {

 case 1 { print "number 1" }
 case "a" { print "string a" }
 case [1..10,42] { print "number in list" }
 case (@array) { print "number in list" }
 case /\w+/ { print "pattern" }
 case qr/\w+/ { print "pattern" }
 case (%hash) { print "entry in hash" }
 case (\%hash) { print "entry in hash" }
 case (\&sub) { print "arg to subroutine" }
 else { print "previous case not true" }

}
```

**BACKGROUND**

[Skip ahead to "[DESCRIPTION](#)" if you don't care about the whys and wherefores of this control structure]

In seeking to devise a "Swiss Army" case mechanism suitable for Perl, it is useful to generalize this notion of distributed conditional testing as far as possible. Specifically, the concept of "matching" between the switch value and the various case values need not be restricted to numeric (or string or referential) equality, as it is in other languages. Indeed, as Table 1 illustrates, Perl offers at least eighteen different ways in which two values could generate a match.

Table 1: Matching a switch value (\$s) with a case value (\$c)

| Switch Value         | Case Value           | Type of Match Implied                                                                       | Matching Code                                                                        |
|----------------------|----------------------|---------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| =====                | =====                | =====                                                                                       | =====                                                                                |
| number or ref        | same                 | numeric or referential equality                                                             | match if \$s == \$c;                                                                 |
| object ref           | method name or ref   | result of method call                                                                       | match if \$s->\$c();<br>match if defined \$s->\$c();                                 |
| other non-ref scalar | other non-ref scalar | string equality                                                                             | match if \$s eq \$c;                                                                 |
| string               | regex                | pattern match                                                                               | match if \$s =~ /\$c/;                                                               |
| array ref            | scalar               | array entry existence<br>array entry definition<br>array entry truth                        | match if 0<=\$c && \$c<@\$s;<br>match if defined \$s->[\$c];<br>match if \$s->[\$c]; |
| array ref            | array ref            | array intersection<br>(apply this table to all pairs of elements \$s->[\$i] and \$c->[\$j]) | match if intersects(@\$s, @\$c);                                                     |

|              |        |                                                                   |                                                                                     |
|--------------|--------|-------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| array<br>ref | regex  | array grep                                                        | match if grep /\$c/, @\$s;                                                          |
| hash<br>ref  | scalar | hash entry existence<br>hash entry definition<br>hash entry truth | match if exists \$s->{\$c};<br>match if defined \$s->{\$c};<br>match if \$s->{\$c}; |
| hash<br>ref  | regex  | hash grep                                                         | match if grep /\$c/, keys %\$s;                                                     |
| sub<br>ref   | scalar | return value defn<br>return value truth                           | match if defined \$s->(\$c);<br>match if \$s->(\$c);                                |
| sub<br>ref   | array  | return value defn<br>return value truth                           | match if defined \$s->(@\$c);<br>match if \$s->(@\$c);                              |

In reality, Table 1 covers 31 alternatives, because only the equality and intersection tests are commutative; in all other cases, the roles of the `$s` and `$c` variables could be reversed to produce a different test. For example, instead of testing a single hash for the existence of a series of keys (`match if exists $s->{$c}`), one could test for the existence of a single key in a series of hashes (`match if exists $c->{$s}`).

As *perlto* observes, a Perl case mechanism must support all these "ways to do it".

## DESCRIPTION

The `Switch.pm` module implements a generalized case mechanism that covers the numerous possible combinations of switch and case values described above.

The module augments the standard Perl syntax with two new control statements: `switch` and `case`. The `switch` statement takes a single scalar argument of any type, specified in parentheses. `switch` stores this value as the current switch value in a (localized) control variable. The value is followed by a block which may contain one or more Perl statements (including the `case` statement described below). The block is unconditionally executed once the switch value has been cached.

A `case` statement takes a single scalar argument (in mandatory parentheses if it's a variable; otherwise the parens are optional) and selects the appropriate type of matching between that argument and the current switch value. The type of matching used is determined by the respective types of the switch value and the case argument, as specified in Table 1. If the match is successful, the mandatory block associated with the case statement is executed.

In most other respects, the `case` statement is semantically identical to an `if` statement. For example, it can be followed by an `else` clause, and can be used as a postfix statement qualifier.

However, when a `case` block has been executed control is automatically transferred to the statement after the immediately enclosing `switch` block, rather than to the next statement within the block. In other words, the success of any `case` statement prevents other cases in the same scope from executing. But see *"Allowing fall-through"* below.

Together these two new statements provide a fully generalized case mechanism:

```
use Switch;

AND LATER...

%special = (woohoo => 1, d'oh => 1);

while (<>) {
 switch ($_) {
 case (%special) { print "homer\n"; } # if $special{$_}
 case /a-z/i { print "alpha\n"; } # if $_ =~ /a-z/i
 case [1..9] { print "small num\n"; } # if $_ in [1..9]
```

```

 case { $_[0] >= 10 } { # if $_ >= 10
 my $age = <>;
 switch (sub{ $_[0] < $age }) {
 case 20 { print "teens\n"; } # if 20 < $age
 case 30 { print "twenties\n"; } # if 30 < $age
 else { print "history\n"; }
 }
 }
 print "must be punctuation\n" case /\W/; # if $_ =~ /\W/
}

```

Note that switches can be nested within case (or any other) blocks, and a series of case statements can try different types of matches — hash membership, pattern match, array intersection, simple equality, etc. — against the same switch value.

The use of intersection tests against an array reference is particularly useful for aggregating integral cases:

```

sub classify_digit
{
 switch ($_[0]) { case 0 { return 'zero' }
 case [2,4,6,8] { return 'even' }
 case [1,3,4,7,9] { return 'odd' }
 case /[A-F]/i { return 'hex' }
 }
}

```

### Allowing fall-through

Fall-through (trying another case after one has already succeeded) is usually a Bad Idea in a switch statement. However, this is Perl, not a police state, so there *is* a way to do it, if you must.

If a case block executes an untargetted `next`, control is immediately transferred to the statement *after* the case statement (i.e. usually another case), rather than out of the surrounding switch block.

For example:

```

switch ($val) {
 case 1 { handle_num_1(); next } # and try next case...
 case "1" { handle_str_1(); next } # and try next case...
 case [0..9] { handle_num_any(); } # and we're done
 case /\d/ { handle_dig_any(); next } # and try next case...
 case /.*/ { handle_str_any(); next } # and try next case...
}

```

If `$val` held the number 1, the above switch block would call the first three `handle_...` subroutines, jumping to the next case test each time it encountered a `next`. After the third case block was executed, control would jump to the end of the enclosing switch block.

On the other hand, if `$val` held 10, then only the last two `handle_...` subroutines would be called.

Note that this mechanism allows the notion of *conditional fall-through*. For example:

```

switch ($val) {
 case [0..9] { handle_num_any(); next if $val < 7; }
 case /\d/ { handle_dig_any(); }
}

```

If an untargetted last statement is executed in a case block, this immediately transfers control out of the enclosing switch block (in other words, there is an implicit `last` at the end of each normal case block). Thus the previous example could also have been written:

```

switch ($val) {
 case [0..9] { handle_num_any(); last if $val >= 7; next; }
 case /\d/ { handle_dig_any(); }
}

```

### Automating fall-through

In situations where case fall-through should be the norm, rather than an exception, an endless succession of terminal `next`s is tedious and ugly. Hence, it is possible to reverse the default behaviour by specifying the string "fallthrough" when importing the module. For example, the following code is equivalent to the first example in *"Allowing fall-through"*:

```

use Switch 'fallthrough';

switch ($val) {
 case 1 { handle_num_1(); }
 case "1" { handle_str_1(); }
 case [0..9] { handle_num_any(); last }
 case /\d/ { handle_dig_any(); }
 case /.*/ { handle_str_any(); }
}

```

Note the explicit use of a `last` to preserve the non-fall-through behaviour of the third case.

### Alternative syntax

Perl 6 will provide a built-in switch statement with essentially the same semantics as those offered by `Switch.pm`, but with a different pair of keywords. In Perl 6 `switch` will be spelled `given`, and `case` will be pronounced `when`. In addition, the `when` statement will not require switch or case values to be parenthesized.

This future syntax is also (largely) available via the `Switch.pm` module, by importing it with the argument "Perl6". For example:

```

use Switch 'Perl6';

given ($val) {
 when 1 { handle_num_1(); }
 when ($str1) { handle_str_1(); }
 when [0..9] { handle_num_any(); last }
 when /\d/ { handle_dig_any(); }
 when /.*/ { handle_str_any(); }
}

```

Note that scalars still need to be parenthesized, since they would be ambiguous in Perl 5.

Note too that you can mix and match both syntaxes by importing the module with:

```

use Switch 'Perl5', 'Perl6';

```

### Higher-order Operations

One situation in which `switch` and `case` do not provide a good substitute for a cascaded `if`, is where a switch value needs to be tested against a series of conditions. For example:

```

sub beverage {
 switch (shift) {
 case sub { $_[0] < 10 } { return 'milk' }
 case sub { $_[0] < 20 } { return 'coke' }
 case sub { $_[0] < 30 } { return 'beer' }
 case sub { $_[0] < 40 } { return 'wine' }
 case sub { $_[0] < 50 } { return 'malt' }
 case sub { $_[0] < 60 } { return 'Moet' }
 }
}

```

```

 else { return 'milk' }
 }
}

```

The need to specify each condition as a subroutine block is tiresome. To overcome this, when importing Switch.pm, a special "placeholder" subroutine named `__` [sic] may also be imported. This subroutine converts (almost) any expression in which it appears to a reference to a higher-order function. That is, the expression:

```

use Switch '__';

__ < 2 + __

```

is equivalent to:

```

sub { $_[0] < 2 + $_[1] }

```

With `__`, the previous ugly case statements can be rewritten:

```

case __ < 10 { return 'milk' }
case __ < 20 { return 'coke' }
case __ < 30 { return 'beer' }
case __ < 40 { return 'wine' }
case __ < 50 { return 'malt' }
case __ < 60 { return 'Moet' }
else { return 'milk' }

```

The `__` subroutine makes extensive use of operator overloading to perform its magic. All operations involving `__` are overloaded to produce an anonymous subroutine that implements a lazy version of the original operation.

The only problem is that operator overloading does not allow the boolean operators `&&` and `||` to be overloaded. So a case statement like this:

```

case 0 <= __ && __ < 10 { return 'digit' }

```

doesn't act as expected, because when it is executed, it constructs two higher order subroutines and then treats the two resulting references as arguments to `&&`:

```

sub { 0 <= $_[0] } && sub { $_[0] < 10 }

```

This boolean expression is inevitably true, since both references are non-`false`. Fortunately, the overloaded `'bool'` operator catches this situation and flags it as a error.

## DEPENDENCIES

The module is implemented using `Filter::Util::Call` and `Text::Balanced` and requires both these modules to be installed.

## AUTHOR

Damian Conway (damian@conway.org)

## BUGS

There are undoubtedly serious bugs lurking somewhere in code this funky :-). Bug reports and other feedback are most welcome.

## LIMITATION

Due to the heuristic nature of Switch.pm's source parsing, the presence of regexes specified with raw `?...?` delimiters may cause mysterious errors. The workaround is to use `m?...?` instead.

and/or modified under the same terms as Perl itself.

**NAME**

Symbol – manipulate Perl symbols and their names

**SYNOPSIS**

```
use Symbol;

$sym = gensym;
open($sym, "filename");
$_ = <$sym>;
etc.

ungensym $sym; # no effect

replace *FOO{IO} handle but not $FOO, %FOO, etc.
*FOO = geniosym;

print qualify("x"), "\n"; # "Test::x"
print qualify("x", "FOO"), "\n"; # "FOO::x"
print qualify("BAR::x"), "\n"; # "BAR::x"
print qualify("BAR::x", "FOO"), "\n"; # "BAR::x"
print qualify("STDOUT", "FOO"), "\n"; # "main::STDOUT" (global)
print qualify(*x), "\n"; # returns *x
print qualify(*x, "FOO"), "\n"; # returns *x

use strict refs;
print { qualify_to_ref $fh } "foo!\n";
$ref = qualify_to_ref $name, $pkg;

use Symbol qw(delete_package);
delete_package('Foo::Bar');
print "deleted\n" unless exists $Foo::{'Bar::'};
```

**DESCRIPTION**

`Symbol::gensym` creates an anonymous glob and returns a reference to it. Such a glob reference can be used as a file or directory handle.

For backward compatibility with older implementations that didn't support anonymous globs, `Symbol::ungensym` is also provided. But it doesn't do anything.

`Symbol::geniosym` creates an anonymous IO handle. This can be assigned into an existing glob without affecting the non-IO portions of the glob.

`Symbol::qualify` turns unqualified symbol names into qualified variable names (e.g. "myvar" → "MyPackage::myvar"). If it is given a second parameter, `qualify` uses it as the default package; otherwise, it uses the package of its caller. Regardless, global variable names (e.g. "STDOUT", "ENV", "SIG") are always qualified with "main::".

Qualification applies only to symbol names (strings). References are left unchanged under the assumption that they are glob references, which are qualified by their nature.

`Symbol::qualify_to_ref` is just like `Symbol::qualify` except that it returns a glob ref rather than a symbol name, so you can use the result even if `use strict 'refs'` is in effect.

`Symbol::delete_package` wipes out a whole package namespace. Note this routine is not exported by default—you may want to import it explicitly.

**NAME**

Sys::Hostname – Try every conceivable way to get hostname

**SYNOPSIS**

```
use Sys::Hostname;
$host = hostname;
```

**DESCRIPTION**

Attempts several methods of getting the system hostname and then caches the result. It tries the first available of the C library's `gethostname()`, ``$Config{aphostname}'`, `uname(2)`, `syscall(SYS_gethostname)`, `'hostname'`, `'uname -n'`, and the file */com/host*. If all that fails it croaks.

All NULs, returns, and newlines are removed from the result.

David Sundstrom <*sunds@asictest.sc.ti.com*>

Texas Instruments

XS code added by Greg Bacon <*gbacon@cs.uah.edu*>

**NAME**

Sys::Syslog, openlog, closelog, setlogmask, syslog – Perl interface to the UNIX syslog(3) calls

**SYNOPSIS**

```
use Sys::Syslog; # all except setlogsock, or:
use Sys::Syslog qw(:DEFAULT setlogsock); # default set, plus setlogsock

setlogsock $sock_type;
openlog $ident, $logopt, $facility;
syslog $priority, $format, @args;
$oldmask = setlogmask $mask_priority;
closelog;
```

**DESCRIPTION**

Sys::Syslog is an interface to the UNIX syslog(3) program. Call syslog() with a string priority and a list of printf() args just like syslog(3).

Syslog provides the functions:

**openlog** \$ident, \$logopt, \$facility

*\$ident* is prepended to every message. *\$logopt* contains zero or more of the words *pid*, *ndelay*, *nowait*. The *cons* option is ignored, since the failover mechanism will drop down to the console automatically if all other media fail. *\$facility* specifies the part of the system

**syslog** \$priority, \$format, @args

If *\$priority* permits, logs (*\$format*, @args) printed as by printf(3V), with the addition that *%m* is replaced with "\$!" (the latest error message).

**setlogmask** \$mask\_priority

Sets log mask *\$mask\_priority* and returns the old mask.

**setlogsock** \$sock\_type [\$stream\_location] (added in 5.004\_02)

Sets the socket type to be used for the next call to openlog() or syslog() and returns TRUE on success, undef on failure.

A value of 'unix' will connect to the UNIX domain socket returned by the `_PATH_LOG` macro (if your system defines it) in *syslog.ph*. A value of 'stream' will connect to the stream indicated by the pathname provided as the optional second parameter. A value of 'inet' will connect to an INET socket (either tcp or udp, tried in that order) returned by `getservbyname()`. 'tcp' and 'udp' can also be given as values. The value 'console' will send messages directly to the console, as for the 'cons' option in the logopts in openlog().

A reference to an array can also be passed as the first parameter. When this calling method is used, the array should contain a list of sock\_types which are attempted in order.

The default is to try tcp, udp, unix, stream, console.

Giving an invalid value for sock\_type will croak.

**closelog**

Closes the log file.

Note that openlog now takes three arguments, just like openlog(3).

**EXAMPLES**

```
openlog($program, 'cons,pid', 'user');
syslog('info', 'this is another test');
syslog('mail|warning', 'this is a better test: %d', time);
closelog();
```

```
syslog('debug', 'this is the last test');
setlogsock('unix');
openlog("$program $$", 'ndelay', 'user');
syslog('notice', 'fooprogram: this is really done');

setlogsock('inet');
$! = 55;
syslog('info', 'problem was %m'); # %m == $! in syslog(3)
```

## NAME

Term::ANSIColor – Color screen output using ANSI escape sequences

## SYNOPSIS

```
use Term::ANSIColor;
print color 'bold blue';
print "This text is bold blue.\n";
print color 'reset';
print "This text is normal.\n";
print colored ("Yellow on magenta.\n", 'yellow on_magenta');
print "This text is normal.\n";
print colored ['yellow on_magenta'], "Yellow on magenta.\n";

use Term::ANSIColor qw(uncolor);
print uncolor '01;31', "\n";

use Term::ANSIColor qw(:constants);
print BOLD, BLUE, "This text is in bold blue.\n", RESET;

use Term::ANSIColor qw(:constants);
$Term::ANSIColor::AUTORESET = 1;
print BOLD BLUE "This text is in bold blue.\n";
print "This text is normal.\n";
```

## DESCRIPTION

This module has two interfaces, one through `color()` and `colored()` and the other through `constants`. It also offers the utility function `uncolor()`, which has to be explicitly imported to be used (see [SYNOPSIS](#)).

`color()` takes any number of strings as arguments and considers them to be space-separated lists of attributes. It then forms and returns the escape sequence to set those attributes. It doesn't print it out, just returns it, so you'll have to print it yourself if you want to (this is so that you can save it as a string, pass it to something else, send it to a file handle, or do anything else with it that you might care to).

`uncolor()` performs the opposite translation, turning escape sequences into a list of strings.

The recognized attributes (all of which should be fairly intuitive) are clear, reset, dark, bold, underline, underscore, blink, reverse, concealed, black, red, green, yellow, blue, magenta, on\_black, on\_red, on\_green, on\_yellow, on\_blue, on\_magenta, on\_cyan, and on\_white. Case is not significant. Underline and underscore are equivalent, as are clear and reset, so use whichever is the most intuitive to you. The color alone sets the foreground color, and on\_color sets the background color.

Note that not all attributes are supported by all terminal types, and some terminals may not support any of these sequences. Dark, blink, and concealed in particular are frequently not implemented.

Attributes, once set, last until they are unset (by sending the attribute "reset"). Be careful to do this, or otherwise your attribute will last after your script is done running, and people get very annoyed at having their prompt and typing changed to weird colors.

As an aid to help with this, `colored()` takes a scalar as the first argument and any number of attribute strings as the second argument and returns the scalar wrapped in escape codes so that the attributes will be set as requested before the string and reset to normal after the string. Alternately, you can pass a reference to an array as the first argument, and then the contents of that array will be taken as attributes and color codes and the remainder of the arguments as text to colorize.

Normally, `colored()` just puts attribute codes at the beginning and end of the string, but if you set `$Term::ANSIColor::EACHLINE` to some string, that string will be considered the line delimiter and the attribute will be set at the beginning of each line of the passed string and reset at the end of each line. This is often desirable if the output is being sent to a program like a pager that can be confused by attributes

that span lines. Normally you'll want to set `$Term::ANSIColor::EACHLINE` to `"\n"` to use this feature.

Alternately, if you import `:constants`, you can use the constants `CLEAR`, `RESET`, `BOLD`, `DARK`, `UNDERLINE`, `UNDERSCORE`, `BLINK`, `REVERSE`, `CONCEALED`, `BLACK`, `RED`, `GREEN`, `YELLOW`, `BLUE`, `MAGENTA`, `ON_BLACK`, `ON_RED`, `ON_GREEN`, `ON_YELLOW`, `ON_BLUE`, `ON_MAGENTA`, `ON_CYAN`, and `ON_WHITE` directly. These are the same as `color('attribute')` and can be used if you prefer typing:

```
print BOLD BLUE ON_WHITE "Text\n", RESET;

to

print colored ("Text\n", 'bold blue on_white');
```

When using the constants, if you don't want to have to remember to add the `, RESET` at the end of each print line, you can set `$Term::ANSIColor::AUTORESET` to a true value. Then, the display mode will automatically be reset if there is no comma after the constant. In other words, with that variable set:

```
print BOLD BLUE "Text\n";

will reset the display mode afterwards, whereas:

print BOLD, BLUE, "Text\n";
```

will not.

The subroutine interface has the advantage over the constants interface in that only two subroutines are exported into your namespace, versus twenty-two in the constants interface. On the flip side, the constants interface has the advantage of better compile time error checking, since misspelled names of colors or attributes in calls to `color()` and `colored()` won't be caught until runtime whereas misspelled names of constants will be caught at compile time. So, pollute your namespace with almost two dozen subroutines that you may not even use that often, or risk a silly bug by mistyping an attribute. Your choice, TMTOWTDI after all.

## DIAGNOSTICS

### Bad escape sequence %s

(F) You passed an invalid ANSI escape sequence to `uncolor()`.

### Bareword "%s" not allowed while "strict subs" in use

(F) You probably mistyped a constant color name such as:

```
$Foobar = FOOBAR . "This line should be blue\n";

or:
```

```
@Foobar = FOOBAR, "This line should be blue\n";
```

This will only show up under `use strict` (another good reason to run under `use strict`).

### Invalid attribute name %s

(F) You passed an invalid attribute name to either `color()` or `colored()`.

### Name "%s" used only once: possible typo

(W) You probably mistyped a constant color name such as:

```
print FOOBAR "This text is color FOOBAR\n";
```

It's probably better to always use commas after constant names in order to force the next error.

### No comma allowed after filehandle

(F) You probably mistyped a constant color name such as:

```
print FOOBAR, "This text is color FOOBAR\n";
```

Generating this fatal compile error is one of the main advantages of using the constants interface, since you'll immediately know if you mistype a color name.

#### No name for escape sequence %s

(F) The ANSI escape sequence passed to `uncolor()` contains escapes which aren't recognized and can't be translated to names.

## ENVIRONMENT

### ANSI\_COLORS\_DISABLED

If this environment variable is set, all of the functions defined by this module (`color()`, `colored()`, and all of the constants not previously used in the program) will not output any escape sequences and instead will just return the empty string or pass through the original text as appropriate. This is intended to support easy use of scripts using this module on platforms that don't support ANSI escape sequences.

For it to have its proper effect, this environment variable must be set before any color constants are used in the program.

## RESTRICTIONS

It would be nice if one could leave off the commas around the constants entirely and just say:

```
print BOLD BLUE ON_WHITE "Text\n" RESET;
```

but the syntax of Perl doesn't allow this. You need a comma after the string. (Of course, you may consider it a bug that commas between all the constants aren't required, in which case you may feel free to insert commas unless you're using `$Term::ANSIColor::AUTORESET`.)

For easier debugging, you may prefer to always use the commas when not setting `$Term::ANSIColor::AUTORESET` so that you'll get a fatal compile error rather than a warning.

## NOTES

The codes generated by this module are standard terminal control codes, complying with ECMA-48 and ISO 6429 (generally referred to as "ANSI color" for the color codes). The non-color control codes (bold, dark, italic, underline, and reverse) are part of the earlier ANSI X3.64 standard for control sequences for video terminals and peripherals.

Note that not all displays are ISO 6429-compliant, or even X3.64-compliant (or are even attempting to be so). This module will not work as expected on displays that do not honor these escape sequences, such as `cmd.exe`, `4nt.exe`, and `command.com` under either Windows NT or Windows 2000. They may just be ignored, or they may display as an ESC character followed by some apparent garbage.

Jean Delvare provided the following table of different common terminal emulators and their support for the various attributes:

|          | clear | bold    | dark | under | blink      | reverse | conceal |
|----------|-------|---------|------|-------|------------|---------|---------|
| xterm    | yes   | yes     | no   | yes   | bold       | yes     | yes     |
| linux    | yes   | yes     | yes  | bold  | yes        | yes     | no      |
| rxvt     | yes   | yes     | no   | yes   | bold/black | yes     | no      |
| dtterm   | yes   | yes     | yes  | yes   | reverse    | yes     | yes     |
| teraterm | yes   | reverse | no   | yes   | rev/red    | yes     | no      |
| aixterm  | kinda | normal  | no   | yes   | no         | yes     | yes     |

Where the entry is other than yes or no, that emulator interpret the given attribute as something else instead. Note that on an `aixterm`, `clear` doesn't reset colors; you have to explicitly set the colors back to what you want. More entries in this table are welcome.

Note that codes 3 (italic), 6 (rapid blink), and 9 (strikethrough) are specified in ANSI X3.64 and ECMA-048 but are not commonly supported by most displays and emulators and therefore aren't supported by this module at the present time. ECMA-048 also specifies a large number of other attributes, including a

sequence of attributes for font changes, Fraktur characters, double-underlining, framing, circling, and overlining. As none of these attributes are widely supported or useful, they also aren't currently supported by this module.

**SEE ALSO**

ECMA-048 is available on-line (at least at the time of this writing) at  
<http://www.ecma.ch/ecma1/STAND/ECMA-048.HTM>.

ISO 6429 is available from ISO for a charge; the author of this module does not own a copy of it. Since the source material for ISO 6429 was ECMA-048 and the latter is available for free, there seems little reason to obtain the ISO standard.

The current version of this module is always available from its web site at  
<http://www.eyrie.org/~eagle/software/ansicolor/>. It is also part of the Perl core distribution as of 5.6.0.

**AUTHORS**

Original idea (using constants) by Zenin, reimplemented using subs by Russ Allbery <rra@stanford.edu>, and then combined with the original idea by Russ with input from Zenin. Russ Allbery now maintains this module.

**NAME**

Term::Cap – Perl termcap interface

**SYNOPSIS**

```
require Term::Cap;
$terminal = Tgetent Term::Cap { TERM => undef, OSPEED => $ospeed };
$terminal->Trequire(qw/ce ku kd/);
$terminal->Tgoto('cm', $col, $row, $FH);
$terminal->Tputs('dl', $count, $FH);
$terminal->Tpad($string, $count, $FH);
```

**DESCRIPTION**

These are low-level functions to extract and use capabilities from a terminal capability (termcap) database.

More information on the terminal capabilities will be found in the termcap manpage on most Unix-like systems.

**METHODS**

The output strings for **Tputs** are cached for counts of 1 for performance. **Tgoto** and **Tpad** do not cache. `$self->{_xx}` is the raw termcap data and `$self->{xx}` is the cached version.

```
print $terminal->Tpad($self->{_xx}, 1);
```

**Tgoto**, **Tputs**, and **Tpad** return the string and will also output the string to `$FH` if specified.

**Tgetent**

Returns a blessed object reference which the user can then use to send the control strings to the terminal using **Tputs** and **Tgoto**.

The function extracts the entry of the specified terminal type *TERM* (defaults to the environment variable *TERM*) from the database.

It will look in the environment for a *TERMCAP* variable. If found, and the value does not begin with a slash, and the terminal type name is the same as the environment string *TERM*, the *TERMCAP* string is used instead of reading a termcap file. If it does begin with a slash, the string is used as a path name of the termcap file to search. If *TERMCAP* does not begin with a slash and name is different from *TERM*, **Tgetent** searches the files *\$HOME/.termcap*, */etc/termcap*, and */usr/share/misc/termcap*, in that order, unless the environment variable *TERMPATH* exists, in which case it specifies a list of file pathnames (separated by spaces or colons) to be searched **instead**. Whenever multiple files are searched and a tc field occurs in the requested entry, the entry it names must be found in the same file or one of the succeeding files. If there is a `:tc=...` in the *TERMCAP* environment variable string it will continue the search in the files as above.

The extracted termcap entry is available in the object as `$self->{TERMCAP}`.

It takes a hash reference as an argument with two optional keys:

**OSPEED**

The terminal output bit rate (often mistakenly called the baud rate) for this terminal – if not set a warning will be generated and it will be defaulted to 9600. *OSPEED* can be specified as either a POSIX termios/SYSV termio speeds (where 9600 equals 9600) or an old DSD-style speed (where 13 equals 9600).

**TERM**

The terminal type whose termcap entry will be used – if not supplied it will default to `$ENV{TERM}`: if that is not set then **Tgetent** will croak.

It calls `croak` on failure.

**Tpad**

Outputs a literal string with appropriate padding for the current terminal.

It takes three arguments:

**\$string**

The literal string to be output. If it starts with a number and an optional '\*' then the padding will be increased by an amount relative to this number, if the '\*' is present then this amount will be multiplied by \$cnt. This part of \$string is removed before output/

**\$cnt**

Will be used to modify the padding applied to string as described above.

**\$FH**

An optional filehandle (or IO::Handle ) that output will be printed to.

The padded \$string is returned.

**Tputs**

Output the string for the given capability padded as appropriate without any parameter substitution.

It takes three arguments:

**\$cap**

The capability whose string is to be output.

**\$cnt**

A count passed to Tpad to modify the padding applied to the output string. If \$cnt is zero or one then the resulting string will be cached.

**\$FH**

An optional filehandle (or IO::Handle ) that output will be printed to.

The appropriate string for the capability will be returned.

**Tgoto**

**Tgoto** decodes a cursor addressing string with the given parameters.

There are four arguments:

**\$cap**

The name of the capability to be output.

**\$col**

The first value to be substituted in the output string ( usually the column in a cursor addressing capability )

**\$row**

The second value to be substituted in the output string (usually the row in cursor addressing capabilities)

**\$FH**

An optional filehandle (or IO::Handle ) to which the output string will be printed.

Substitutions are made with \$col and \$row in the output string with the following sprintf() line formats:

```
%% output '%'
%d output value as in printf %d
%2 output value as in printf %2d
%3 output value as in printf %3d
```

```

%. output value as in printf %c
%+x add x to value, then do %.

%>xy if value > x then add y, no output
%r reverse order of two parameters, no output
%i increment by one, no output
%B BCD (16*(value/10)) + (value%10), no output

%n exclusive-or all parameters with 0140 (Datamedia 2500)
%D Reverse coding (value - 2*(value%16)), no output (Delta Data)

```

The output string will be returned.

### Trequire

Takes a list of capabilities as an argument and will croak if one is not found.

### EXAMPLES

```

use Term::Cap;

Get terminal output speed
require POSIX;
my $termios = new POSIX::Termios;
$termios->getattr;
my $ospeed = $termios->getospeed;

Old-style ioctl code to get ospeed:
require 'ioctl.pl';
ioctl(TTY,$TIOCGGETP,$sgtty);
($ispeed,$ospeed) = unpack('cc',$sgtty);

allocate and initialize a terminal structure
$terminal = Tgetent Term::Cap { TERM => undef, OSPEED => $ospeed };

require certain capabilities to be available
$terminal->Trequire(qw/ce ku kd/);

Output Routines, if $FH is undefined these just return the string

Tgoto does the % expansion stuff with the given args
$terminal->Tgoto('cm', $col, $row, $FH);

Tputs doesn't do any % expansion.
$terminal->Tputs('dl', $count = 1, $FH);

```

**NAME**

Term::Complete – Perl word completion module

**SYNOPSIS**

```
$input = Complete('prompt_string', \@completion_list);
$input = Complete('prompt_string', @completion_list);
```

**DESCRIPTION**

This routine provides word completion on the list of words in the array (or array ref).

The tty driver is put into raw mode and restored using an operating system specific command, in UNIX-like environments `stty`.

The following command characters are defined:

<tab>

Attempts word completion. Cannot be changed.

**^D** Prints completion list. Defined by `$Term::Complete::complete`.

**^U** Erases the current input. Defined by `$Term::Complete::kill`.

<del>, <bs>

Erases one character. Defined by `$Term::Complete::erase1` and `$Term::Complete::erase2`.

**DIAGNOSTICS**

Bell sounds when word completion fails.

**BUGS**

The completion character <tab> cannot be changed.

**AUTHOR**

Wayne Thompson

**NAME**

Term::ReadLine – Perl interface to various readline packages. If no real package is found, substitutes stubs instead of basic functions.

**SYNOPSIS**

```
use Term::ReadLine;
my $term = new Term::ReadLine 'Simple Perl calc';
my $prompt = "Enter your arithmetic expression: ";
my $OUT = $term->OUT || *STDOUT;
while (defined ($_ = $term->readline($prompt))) {
 my $res = eval($_, "\n");
 warn $@ if $@;
 print $OUT $res, "\n" unless $@;
 $term->addhistory($_) if /\S/;
}
```

**DESCRIPTION**

This package is just a front end to some other packages. At the moment this description is written, the only such package is Term-ReadLine, available on CPAN near you. The real target of this stub package is to set up a common interface to whatever Readline emerges with time.

**Minimal set of supported functions**

All the supported functions should be called as methods, i.e., either as

```
$term = new Term::ReadLine 'name';
```

or as

```
$term->addhistory('row');
```

where \$term is a return value of Term::ReadLine->Init.

|             |                                                                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ReadLine    | returns the actual package that executes the commands. Among possible values are Term::ReadLine::Gnu, Term::ReadLine::Perl, Term::ReadLine::Stub.                                                                                                                     |
| new         | returns the handle for subsequent calls to following functions. Argument is the name of the application. Optionally can be followed by two arguments for IN and OUT filehandles. These arguments should be globs.                                                     |
| readline    | gets an input line, <i>possibly</i> with actual readline support. Trailing newline is removed. Returns undef on EOF.                                                                                                                                                  |
| addhistory  | adds the line to the history of input, from where it can be used if the actual readline is present.                                                                                                                                                                   |
| IN, \$OUT   | return the filehandles for input and output or undef if readline input and output cannot be used for Perl.                                                                                                                                                            |
| MinLine     | If argument is specified, it is an advice on minimal size of line to be included into history. undef means do not include anything into history. Returns the old value.                                                                                               |
| findConsole | returns an array with two strings that give most appropriate names for files for input and output using conventions "<\$in", ">out".                                                                                                                                  |
| Attribs     | returns a reference to a hash which describes internal configuration of the package. Names of keys in this hash conform to standard conventions with the leading rl_ stripped.                                                                                        |
| Features    | Returns a reference to a hash with keys being features present in current implementation. Several optional features are used in the minimal interface: appname should be present if the first argument to new is recognized, and minline should be present if MinLine |

method is not dummy. `autohistory` should be present if lines are put into history automatically (maybe subject to `MinLine`), and `addhistory` if `addhistory` method is not dummy.

If `Features` method reports a feature `attrs` as present, the method `Attrs` is not dummy.

### Additional supported functions

Actually `Term::ReadLine` can use some other package, that will support richer set of commands.

All these commands are callable via method interface and have names which conform to standard conventions with the leading `rl_` stripped.

The stub package included with the perl distribution allows some additional methods:

|                        |                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tkRunning</code> | makes Tk event loop run when waiting for user input (i.e., during <code>readline</code> method).                                                                                                                                                                                                                                                 |
| <code>ornaments</code> | makes the command line stand out by using termcap data. The argument to <code>ornaments</code> should be 0, 1, or a string of a form <code>"aa,bb,cc,dd"</code> . Four components of this string should be names of <i>terminal capacities</i> , first two will be issued to make the prompt standout, last two to make the input line standout. |
| <code>newTTY</code>    | takes two arguments which are input filehandle and output filehandle. Switches to use these filehandles.                                                                                                                                                                                                                                         |

One can check whether the currently loaded `ReadLine` package supports these methods by checking for corresponding `Features`.

### EXPORTS

None

### ENVIRONMENT

The environment variable `PERL_RL` governs which `ReadLine` clone is loaded. If the value is false, a dummy interface is used. If the value is true, it should be tail of the name of the package to use, such as `Perl` or `Gnu`.

As a special case, if the value of this variable is space-separated, the tail might be used to disable the ornaments by setting the tail to be `o=0` or `ornaments=0`. The head should be as described above, say

If the variable is not set, or if the head of space-separated list is empty, the best available package is loaded.

```
export "PERL_RL=Perl o=0" # Use Perl ReadLine without ornaments
export "PERL_RL= o=0" # Use best available ReadLine without ornaments
```

(Note that processing of `PERL_RL` for ornaments is in the discretion of the particular used `Term::ReadLine::*` package).

### CAVEATS

It seems that using `Term::ReadLine` from Emacs minibuffer doesn't work quite right and one will get an error message like

```
Cannot open /dev/tty for read at ...
```

One possible workaround for this is to explicitly open `/dev/tty` like this

```
open (FH, "/dev/tty")
or eval 'sub Term::ReadLine::findConsole { ("&STDIN", "&STDERR") }';
die $@ if $@;
close (FH);
```

or you can try using the 4-argument form of `Term::ReadLine-new()`.

**NAME**

Test – provides a simple framework for writing test scripts

**SYNOPSIS**

```
use strict;
use Test;

use a BEGIN block so we print our plan before MyModule is loaded
BEGIN { plan tests => 14, todo => [3,4] }

load your module...
use MyModule;

ok(0); # failure
ok(1); # success

ok(0); # ok, expected failure (see todo list, above)
ok(1); # surprise success!

ok(0,1); # failure: '0' ne '1'
ok('broke','fixed'); # failure: 'broke' ne 'fixed'
ok('fixed','fixed'); # success: 'fixed' eq 'fixed'
ok('fixed',qr/x/); # success: 'fixed' =~ qr/x/

ok(sub { 1+1 }, 2); # success: '2' eq '2'
ok(sub { 1+1 }, 3); # failure: '2' ne '3'
ok(0, int(rand(2))); # (just kidding :-)

my @list = (0,0);
ok @list, 3, "@list=".join(', ', @list); #extra diagnostics
ok 'segmentation fault', '/(?i)success/'; #regex match

skip($feature_is_missing, ...); #do platform specific test
```

**DESCRIPTION**

**STOP!** If you are writing a new test, we *highly suggest* you use the new `Test::Simple` and `Test::More` modules instead.

[\*Test::Harness\*](#)/[\*Test::Harness\*](#) expects to see particular output when it executes tests. This module aims to make writing proper test scripts just a little bit easier (and less error prone :-).

**Functions**

All the following are exported by Test by default.

**plan**

```
BEGIN { plan %theplan; }
```

This should be the first thing you call in your test script. It declares your testing plan, how many there will be, if any of them should be allowed to fail, etc...

Typical usage is just:

```
use Test;
BEGIN { plan tests => 23 }
```

Things you can put in the plan:

|        |                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------|
| tests  | The number of tests in your script.<br>This means all <code>ok()</code> and <code>skip()</code> calls. |
| todo   | A reference to a list of tests which are allowed to fail. See <code>L&lt;TODO TESTS&gt;</code> .       |
| onfail | A subroutine reference to be run at the end of                                                         |

the test script should any of the tests fail.  
See `L</ONFAIL>`.

You must call `plan()` once and only once.

### `_to_value`

```
my $value = _to_value($input);
```

Converts an `ok` parameter to its value. Typically this just means running it if its a code reference. You should run all inputted values through this.

### `ok`

```
ok(1 + 1 == 2);
ok($have, $expect);
ok($have, $expect, $diagnostics);
```

This is the reason for `Test`'s existence. Its the basic function that handles printing "ok" or "not ok" along with the current test number.

In its most basic usage, it simply takes an expression. If its true, the test passes, if false, the test fails. Simp.

```
ok(1 + 1 == 2); # ok if 1 + 1 == 2
ok($foo =~ /bar/); # ok if $foo contains 'bar'
ok(baz($x + $y) eq 'Armondo'); # ok if baz($x + $y) returns
 # 'Armondo'
ok(@a == @b); # ok if @a and @b are the same length
```

The expression is evaluated in scalar context. So the following will work:

```
ok(@stuff); # ok if @stuff has any elements
ok(!grep !defined $_, @stuff); # ok if everything in @stuff is
 # defined.
```

A special case is if the expression is a subroutine reference. In that case, it is executed and its value (true or false) determines if the test passes or fails.

In its two argument form it compares the two values to see if they equal (with `eq`).

```
ok("this", "that"); # not ok, 'this' ne 'that'
```

If either is a subroutine reference, that is run and used as a comparison.

Should `$expect` either be a regex reference (ie. `qr/`) or a string that looks like a regex (ie. `'/foo/'`) `ok()` will perform a pattern match against it rather than using `eq`.

```
ok('JaffO', '/Jaff/'); # ok, 'JaffO' =~ /Jaff/
ok('JaffO', qr/Jaff/); # ok, 'JaffO' =~ qr/Jaff/;
ok('JaffO', '/(?i)jaff/'); # ok, 'JaffO' =~ /jaff/i;
```

Finally, an optional set of `$diagnostics` will be printed should the test fail. This should usually be some useful information about the test pertaining to why it failed or perhaps a description of the test. Or both.

```
ok(grep($_ eq 'something unique', @stuff), 1,
 "Something that should be unique isn't!\n".
 '@stuff = ' . join ' ', @stuff
);
```

Unfortunately, a diagnostic cannot be used with the single argument style of `ok()`.

All these special cases can cause some problems. See [/BUGS and CAVEATS](#).

## TEST TYPES

### • NORMAL TESTS

These tests are expected to succeed. If they don't something's screwed up!

### • SKIPPED TESTS

Skip is for tests that might or might not be possible to run depending on the availability of platform specific features. The first argument should evaluate to true (think "yes, please skip") if the required feature is not available. After the first argument, skip works exactly the same way as do normal tests.

### • TODO TESTS

TODO tests are designed for maintaining an **executable TODO list**. These tests are expected NOT to succeed. If a TODO test does succeed, the feature in question should not be on the TODO list, now should it?

Packages should NOT be released with succeeding TODO tests. As soon as a TODO test starts working, it should be promoted to a normal test and the newly working feature should be documented in the release notes or change log.

## ONFAIL

```
BEGIN { plan test => 4, onfail => sub { warn "CALL 911!" } }
```

While test failures should be enough, extra diagnostics can be triggered at the end of a test run. `onfail` is passed an array ref of hash refs that describe each test failure. Each hash will contain at least the following fields: `package`, `repetition`, and `result`. (The file, line, and test number are not included because their correspondence to a particular test is tenuous.) If the test had an expected value or a diagnostic string, these will also be included.

The **optional** `onfail` hook might be used simply to print out the version of your package and/or how to report problems. It might also be used to generate extremely sophisticated diagnostics for a particularly bizarre test failure. However it's not a panacea. Core dumps or other unrecoverable errors prevent the `onfail` hook from running. (It is run inside an `END` block.) Besides, `onfail` is probably over-kill in most cases. (Your test code should be simpler than the code it is testing, yes?)

## BUGS and CAVEATS

`ok()`'s special handling of subroutine references is an unfortunate "feature" that can't be removed due to compatibility.

`ok()`'s use of string eq can sometimes cause odd problems when comparing numbers, especially if you're casting a string to a number:

```
$foo = "1.0";
ok($foo, 1); # not ok, "1.0" ne 1
```

Your best bet is to use the single argument form:

```
ok($foo == 1); # ok "1.0" == 1
```

`ok()`'s special handling of strings which look like they might be regexes can also cause unexpected behavior. An innocent:

```
ok($fileglob, '/path/to/some/*stuff/');
```

will fail since `Test.pm` considers the second argument to a regex. Again, best bet is to use the single argument form:

```
ok($fileglob eq '/path/to/some/*stuff/');
```

## NOTE

This module is no longer actively being developed, only bug fixes and small tweaks (I'll still accept patches). If you desire additional functionality, consider [Test::More](#) or [Test::Unit](#).

## NAME

Test::Builder – Backend for building test libraries

## SYNOPSIS

```
package My::Test::Module;
use Test::Builder;
require Exporter;
@ISA = qw(Exporter);
@EXPORT = qw(ok);

my $Test = Test::Builder->new;
$Test->output('my_logfile');

sub import {
 my($self) = shift;
 my $pack = caller;

 $Test->exported_to($pack);
 $Test->plan(@_);

 $self->export_to_level(1, $self, 'ok');
}

sub ok {
 my($test, $name) = @_;
 $Test->ok($test, $name);
}
```

## DESCRIPTION

Test::Simple and Test::More have proven to be popular testing modules, but they're not always flexible enough. Test::Builder provides the a building block upon which to write your own test libraries *which can work together*.

## Construction

### new

```
my $Test = Test::Builder->new;
```

Returns a Test::Builder object representing the current state of the test.

Since you only run one test per program, there is **one and only one** Test::Builder object. No matter how many times you call `new()`, you're getting the same object. (This is called a singleton).

## Setting up tests

These methods are for setting up tests and declaring how many there are. You usually only want to call one of these methods.

### exported\_to

```
my $pack = $Test->exported_to;
$Test->exported_to($pack);
```

Tells Test::Builder what package you exported your functions to. This is important for getting TODO tests right.

### plan

```
$Test->plan('no_plan');
$Test->plan(skip_all => $reason);
$Test->plan(tests => $num_tests);
```

A convenient way to set up your tests. Call this and Test::Builder will print the appropriate headers

and take the appropriate actions.

If you call `plan()`, don't call any of the other methods below.

### **expected\_tests**

```
my $max = $Test->expected_tests;
$Test->expected_tests($max);
```

Gets/sets the # of tests we expect this test to run and prints out the appropriate headers.

### **no\_plan**

```
$Test->no_plan;
```

Declares that this test will run an indeterminate # of tests.

### **skip\_all**

```
$Test->skip_all;
$Test->skip_all($reason);
```

Skips all the tests, using the given `$reason`. Exits immediately with 0.

## **Running tests**

These actually run the tests, analogous to the functions in `Test::More`.

`$name` is always optional.

### **ok**

```
$Test->ok($test, $name);
```

Your basic test. Pass if `$test` is true, fail if `$test` is false. Just like `Test::Simple`'s `ok()`.

### **is\_eq**

```
$Test->is_eq($got, $expected, $name);
```

Like `Test::More`'s `is()`. Checks if `$got` eq `$expected`. This is the string version.

### **is\_num**

```
$Test->is_num($got, $expected, $name);
```

Like `Test::More`'s `is()`. Checks if `$got` == `$expected`. This is the numeric version.

### **isnt\_eq**

```
$Test->isnt_eq($got, $dont_expect, $name);
```

Like `Test::More`'s `isnt()`. Checks if `$got` ne `$dont_expect`. This is the string version.

### **isnt\_num**

```
$Test->isnt_num($got, $dont_expect, $name);
```

Like `Test::More`'s `isnt()`. Checks if `$got` ne `$dont_expect`. This is the numeric version.

### **like**

```
$Test->like($this, qr/$regex/, $name);
$Test->like($this, '/$regex/', $name);
```

Like `Test::More`'s `like()`. Checks if `$this` matches the given `$regex`.

You'll want to avoid `qr//` if you want your tests to work before 5.005.

### **unlike**

```
$Test->unlike($this, qr/$regex/, $name);
$Test->unlike($this, '/$regex/', $name);
```

Like `Test::More`'s `unlike()`. Checks if `$this` **does not match** the given `$regex`.

**maybe\_regex**

```
$Test->maybe_regex(qr/$regex/);
$Test->maybe_regex('/$regex/');
```

Convenience method for building testing functions that take regular expressions as arguments, but need to work before perl 5.005.

Takes a quoted regular expression produced by qr//, or a string representing a regular expression.

Returns a Perl value which may be used instead of the corresponding regular expression, or undef if it's argument is not recognised.

For example, a version of like(), sans the useful diagnostic messages, could be written as:

```
sub laconic_like {
 my ($self, $this, $regex, $name) = @_;
 my $usable_regex = $self->maybe_regex($regex);
 die "expecting regex, found '$regex'\n"
 unless $usable_regex;
 $self->ok($this =~ m/$usable_regex/, $name);
}
```

**cmp\_ok**

```
$Test->cmp_ok($this, $type, $that, $name);
```

Works just like Test::More's cmp\_ok().

```
$Test->cmp_ok($big_num, '!=', $other_big_num);
```

**BAILOUT**

```
$Test->BAILOUT($reason);
```

Indicates to the Test::Harness that things are going so badly all testing should terminate. This includes running any additional test scripts.

It will exit with 255.

**skip**

```
$Test->skip;
$Test->skip($why);
```

Skips the current test, reporting \$why.

**todo\_skip**

```
$Test->todo_skip;
$Test->todo_skip($why);
```

Like skip(), only it will declare the test as failing and TODO. Similar to

```
print "not ok $tnum # TODO $why\n";
```

**skip\_rest**

```
$Test->skip_rest;
$Test->skip_rest($reason);
```

Like skip(), only it skips all the rest of the tests you plan to run and terminates the test.

If you're running under no\_plan, it skips once and terminates the test.

=end\_unimplemented

## Test style

### level

```
$Test->level($show_high);
```

How far up the call stack should \$Test look when reporting where the test failed.

Defaults to 1.

Setting \$Test::Builder::Level overrides. This is typically useful localized:

```
{
 local $Test::Builder::Level = 2;
 $Test->ok($test);
}
```

### use\_numbers

```
$Test->use_numbers($on_or_off);
```

Whether or not the test should output numbers. That is, this if true:

```
ok 1
ok 2
ok 3
```

or this if false

```
ok
ok
ok
```

Most useful when you can't depend on the test output order, such as when threads or forking is involved.

Test::Harness will accept either, but avoid mixing the two styles.

Defaults to on.

### no\_header

```
$Test->no_header($no_header);
```

If set to true, no "1..N" header will be printed.

### no\_ending

```
$Test->no_ending($no_ending);
```

Normally, Test::Builder does some extra diagnostics when the test ends. It also changes the exit code as described in Test::Simple.

If this is true, none of that will be done.

## Output

Controlling where the test output goes.

It's ok for your test to change where STDOUT and STDERR point to, Test::Builder's default output settings will not be affected.

### diag

```
$Test->diag(@msgs);
```

Prints out the given \$message. Normally, it uses the failure\_output() handle, but if this is for a TODO test, the todo\_output() handle is used.

Output will be indented and marked with a # so as not to interfere with test output. A newline will be

put on the end if there isn't one already.

We encourage using this rather than calling `print` directly.

Returns false. Why? Because `diag()` is often used in conjunction with a failing test (`ok()` || `diag()`) it "passes through" the failure.

```
return ok(...) || diag(...);
```

=for blame transfer Mark Fowler <mark@twoshortplanks.com>

### **\_print**

```
$Test->_print(@msgs);
```

Prints to the `output()` filehandle.

=end\_private

### **output**

```
$Test->output($fh);
$Test->output($file);
```

Where normal "ok/not ok" test output should go.

Defaults to `STDOUT`.

### **failure\_output**

```
$Test->failure_output($fh);
$Test->failure_output($file);
```

Where diagnostic output on test failures and `diag()` should go.

Defaults to `STDERR`.

### **todo\_output**

```
$Test->todo_output($fh);
$Test->todo_output($file);
```

Where diagnostics about todo test failures and `diag()` should go.

Defaults to `STDOUT`.

## **Test Status and Info**

### **current\_test**

```
my $curr_test = $Test->current_test;
$Test->current_test($num);
```

Gets/sets the current test # we're on.

You usually shouldn't have to set this.

### **summary**

```
my @tests = $Test->summary;
```

A simple summary of the tests so far. True for pass, false for fail. This is a logical pass/fail, so todos are passes.

Of course, test #1 is `$tests[0]`, etc...

### **details** *UNIMPLEMENTED*

```
my @tests = $Test->details;
```

Like `summary()`, but with a lot more detail.

```
$tests[$test_num - 1] =
```

```

{ ok => is the test considered ok?
 actual_ok => did it literally say 'ok'?
 name => name of the test (if any)
 type => 'skip' or 'todo' (if any)
 reason => reason for the above (if any)
};

```

**todo**

```

my $todo_reason = $Test->todo;
my $todo_reason = $Test->todo($pack);

```

`todo()` looks for a `$TODO` variable in your tests. If set, all tests will be considered 'todo' (see `Test::More` and `Test::Harness` for details). Returns the reason (ie. the value of `$TODO`) if running as todo tests, false otherwise.

`todo()` is pretty part about finding the right package to look for `$TODO` in. It uses the `exported_to()` package to find it. If that's not set, it's pretty good at guessing the right package to look at.

Sometimes there is some confusion about where `todo()` should be looking for the `$TODO` variable. If you want to be sure, tell it explicitly what `$pack` to use.

**caller**

```

my $package = $Test->caller;
my($pack, $file, $line) = $Test->caller;
my($pack, $file, $line) = $Test->caller($height);

```

Like the normal `caller()`, except it reports according to your `level()`.

**\_sanity\_check**

```
_sanity_check();
```

Runs a bunch of end of test sanity checks to make sure reality came through ok. If anything is wrong it will die with a fairly friendly error message.

**\_whoa**

```
_whoa($check, $description);
```

A sanity check, similar to `assert()`. If the `$check` is true, something has gone horribly wrong. It will die with the given `$description` and a note to contact the author.

**\_my\_exit**

```
_my_exit($exit_num);
```

Perl seems to have some trouble with exiting inside an `END` block. 5.005\_03 and 5.6.1 both seem to do odd things. Instead, this function edits `$?` directly. It should ONLY be called from inside an `END` block. It doesn't actually exit, that's your job.

```
=end_private
```

**THREADS**

In perl 5.8.0 and later, `Test::Builder` is thread-safe. The test number is shared amongst all threads. This means if one thread sets the test number using `current_test()` they will all be effected.

**EXAMPLES**

CPAN can provide the best examples. `Test::Simple`, `Test::More`, `Test::Exception` and `Test::Differences` all use `Test::Builder`.

**NAME**

Test::Harness – run perl standard test scripts with statistics

**SYNOPSIS**

```
use Test::Harness;

runtests(@test_files);
```

**DESCRIPTION**

**STOP!** If all you want to do is write a test script, consider using Test::Simple. Otherwise, read on.

(By using the Test module, you can write test scripts without knowing the exact output this module expects. However, if you need to know the specifics, read on!)

Perl test scripts print to standard output "ok N" for each single test, where N is an increasing sequence of integers. The first line output by a standard test script is "1..M" with M being the number of tests that should be run within the test script. Test::Harness::runtests(@tests) runs all the testscripts named as arguments and checks standard output for the expected "ok N" strings.

After all tests have been performed, runtests() prints some performance statistics that are computed by the Benchmark module.

**The test script output**

The following explains how Test::Harness interprets the output of your test program.

**‘1..M’**

This header tells how many tests there will be. For example, 1..10 means you plan on running 10 tests. This is a safeguard in case your test dies quietly in the middle of its run.

It should be the first non-comment line output by your test program.

In certain instances, you may not know how many tests you will ultimately be running. In this case, it is permitted for the 1..M header to appear as the **last** line output by your test (again, it can be followed by further comments).

Under **no** circumstances should 1..M appear in the middle of your output or more than once.

**‘ok’, ‘not ok’. Ok?**

Any output from the testscript to standard error is ignored and bypassed, thus will be seen by the user. Lines written to standard output containing `/^(not\s+)?ok\b/` are interpreted as feedback for runtests(). All other lines are discarded.

`/^not ok/` indicates a failed test. `/^ok/` is a successful test.

**test numbers**

Perl normally expects the ‘ok’ or ‘not ok’ to be followed by a test number. It is tolerated if the test numbers after ‘ok’ are omitted. In this case Test::Harness maintains temporarily its own counter until the script supplies test numbers again. So the following test script

```
print <<END;
1..6
not ok
ok
not ok
ok
ok
END
```

will generate

```
FAILED tests 1, 3, 6
```

Failed 3/6 tests, 50.00% okay

### test names

Anything after the test number but before the # is considered to be the name of the test.

```
ok 42 this is the name of the test
```

Currently, Test::Harness does nothing with this information.

### Skipping tests

If the standard output line contains the substring `# Skip` (with variations in spacing and case) after `ok` or `ok NUMBER`, it is counted as a skipped test. If the whole testscript succeeds, the count of skipped tests is included in the generated output. Test::Harness reports the text after `# Skip\S*\s+` as a reason for skipping.

```
ok 23 # skip Insufficient flogiston pressure.
```

Similarly, one can include a similar explanation in a `1..0` line emitted if the test script is skipped completely:

```
1..0 # Skipped: no leverage found
```

### Todo tests

If the standard output line contains the substring `# TODO` after `not ok` or `not ok NUMBER`, it is counted as a todo test. The text afterwards is the thing that has to be done before this test will succeed.

```
not ok 13 # TODO harness the power of the atom
=end _deprecated
```

Alternatively, you can specify a list of what tests are todo as part of the test header.

```
1..23 todo 5 12 23
```

This only works if the header appears at the beginning of the test.

This style is **deprecated**.

```
=end _deprecated
```

These tests represent a feature to be implemented or a bug to be fixed and act as something of an executable "thing to do" list. They are **not** expected to succeed. Should a todo test begin succeeding, Test::Harness will report it as a bonus. This indicates that whatever you were supposed to do has been done and you should promote this to a normal test.

### Bail out!

As an emergency measure, a test script can decide that further tests are useless (e.g. missing dependencies) and testing should stop immediately. In that case the test script prints the magic words

```
Bail out!
```

to standard output. Any message after these words will be displayed by Test::Harness as the reason why testing is stopped.

### Comments

Additional comments may be put into the testing output on their own lines. Comment lines should begin with a '#', Test::Harness will ignore them.

```
ok 1
Life is good, the sun is shining, RAM is cheap.
not ok 2
got 'Bush' expected 'Gore'
```

**Anything else**

Any other output Test::Harness sees it will silently ignore **BUT WE PLAN TO CHANGE THIS!** If you wish to place additional output in your test script, please use a comment.

**Taint mode**

Test::Harness will honor the `-T` in the `#!` line on your test files. So if you begin a test with:

```
#!/perl -T
```

the test will be run with taint mode on.

**Configuration variables.**

These variables can be used to configure the behavior of Test::Harness. They are exported on request.

**\$Test::Harness::verbose**

The global variable `$Test::Harness::verbose` is exportable and can be used to let `runtests()` display the standard output of the script without altering the behavior otherwise.

**\$Test::Harness::switches**

The global variable `$Test::Harness::switches` is exportable and can be used to set perl command line options used for running the test script(s). The default value is `-w`.

**Failure**

It will happen, your tests will fail. After you mop up your ego, you can begin examining the summary report:

```
t/base.....ok
t/nonumbers.....ok
t/ok.....ok
t/test-harness.....ok
t/waterloo.....dubious
 Test returned status 3 (wstat 768, 0x300)
DIED. FAILED tests 1, 3, 5, 7, 9, 11, 13, 15, 17, 19
 Failed 10/20 tests, 50.00% okay
Failed Test Stat Wstat Total Fail Failed List of Failed

t/waterloo.t 3 768 20 10 50.00% 1 3 5 7 9 11 13 15 17 19
Failed 1/5 test scripts, 80.00% okay. 10/44 subtests failed, 77.27% okay.
```

Everything passed but `t/waterloo.t`. It failed 10 of 20 tests and exited with non-zero status indicating something dubious happened.

The columns in the summary report mean:

**Failed Test**

The test file which failed.

**Stat** If the test exited with non-zero, this is its exit status.

**Wstat**

The wait status of the test *umm, I need a better explanation here.*

**Total**

Total number of tests expected to run.

**Fail** Number which failed, either from "not ok" or because they never ran.

**Failed**

Percentage of the total tests which failed.

## List of Failed

A list of the tests which failed. Successive failures may be abbreviated (ie. 15–20 to indicate that tests 15, 16, 17, 18, 19 and 20 failed).

## Functions

Test::Harness currently only has one function, here it is.

### runtests

```
my $all_ok = runtests(@test_files);
```

This runs all the given @test\_files and divines whether they passed or failed based on their output to STDOUT (details above). It prints out each individual test which failed along with a summary report and a how long it all took.

It returns true if everything was ok. Otherwise it will die() with one of the messages in the DIAGNOSTICS section.

```
=for_private This is just _run_all_tests() plus _show_results()
```

### \_all\_ok

```
my $ok = _all_ok(\%tot);
```

Tells you if this test run is overall successful or not.

### \_globdir

```
my @files = _globdir $dir;
```

Returns all the files in a directory. This is shorthand for backwards compatibility on systems where glob() doesn't work right.

### \_run\_all\_tests

```
my($total, $failed) = _run_all_tests(@test_files);
```

Runs all the given @test\_files (as runtests()) but does it quietly (no report). \$total is a hash ref summary of all the tests run. Its keys and values are this:

|             |                                                     |
|-------------|-----------------------------------------------------|
| bonus       | Number of individual todo tests unexpectedly passed |
| max         | Number of individual tests ran                      |
| ok          | Number of individual tests passed                   |
| sub_skipped | Number of individual tests skipped                  |
| todo        | Number of individual todo tests                     |
| files       | Number of test files ran                            |
| good        | Number of test files passed                         |
| bad         | Number of test files failed                         |
| tests       | Number of test files originally given               |
| skipped     | Number of test files skipped                        |

If \$total->{bad} == 0 and \$total->{max} 0, you've got a successful test.

\$failed is a hash ref of all the test scripts which failed. Each key is the name of a test script, each value is another hash representing how that script failed. Its keys are these:

|         |                                         |
|---------|-----------------------------------------|
| name    | Name of the test which failed           |
| estat   | Script's exit value                     |
| wstat   | Script's wait status                    |
| max     | Number of individual tests              |
| failed  | Number which failed                     |
| percent | Percentage of tests which failed        |
| canon   | List of tests which failed (as string). |

Needless to say, `$failed` should be empty if everything passed.

**NOTE** Currently this function is still noisy. I'm working on it.

### **`_mk_leader`**

```
my($leader, $ml) = _mk_leader($test_file, $width);
```

Generates the `'t/foo.....'` `$leader` for the given `$test_file` as well as a similar version which will overwrite the current line (by use of `\r` and `such`). `$ml` may be empty if `Test::Harness` doesn't think you're on TTY.

The `$width` is the width of the "yada/blah.." string.

### **`_leader_width`**

```
my($width) = _leader_width(@test_files);
```

Calculates how wide the leader should be based on the length of the longest test name.

## **EXPORT**

`&runtests` is exported by `Test::Harness` per default.

`$verbose` and `$switches` are exported upon request.

## **DIAGNOSTICS**

```
All tests successful.\nFiles=%d, Tests=%d, %s
```

If all tests are successful some statistics about the performance are printed.

```
FAILED tests %s\n\tFailed %d/%d tests, %.2f%% okay.
```

For any single script that has failing subtests statistics like the above are printed.

```
Test returned status %d (wstat %d)
```

Scripts that return a non-zero exit status, both `$? > 8` and `$?` are printed in a message similar to the above.

```
Failed 1 test, %.2f%% okay. %s
```

```
Failed %d/%d tests, %.2f%% okay. %s
```

If not all tests were successful, the script dies with one of the above messages.

```
FAILED-Further testing stopped: %s
```

If a single subtest decides that further testing will not make sense, the script dies with this message.

## **ENVIRONMENT**

### **`HARNESS_ACTIVE`**

Harness sets this before executing the individual tests. This allows the tests to determine if they are being executed through the harness or by any other means.

### **`HARNESS_COLUMNS`**

This value will be used for the width of the terminal. If it is not set then it will default to `COLUMNS`. If this is not set, it will default to 80. Note that users of Bourne-sh based shells will need to `export COLUMNS` for this module to use that variable.

### **`HARNESS_COMPILE_TEST`**

When true it will make harness attempt to compile the test using `perlcc` before running it.

**NOTE** This currently only works when sitting in the perl source directory!

### **`HARNESS_FILELEAK_IN_DIR`**

When set to the name of a directory, harness will check after each test whether new files appeared in that directory, and report them as

```
LEAKED FILES: scr.tmp 0 my.db
```

If relative, directory name is with respect to the current directory at the moment `runtests()` was called. Putting absolute path into `HARNESS_FILELEAK_IN_DIR` may give more predictable results.

`HARNESS_IGNORE_EXITCODE`

Makes harness ignore the exit status of child processes when defined.

`HARNESS_NOTTY`

When set to a true value, forces it to behave as though `STDOUT` were not a console. You may need to set this if you don't want harness to output more frequent progress messages using carriage returns. Some consoles may not handle carriage returns properly (which results in a somewhat messy output).

`HARNESS_PERL_SWITCHES`

Its value will be prepended to the switches used to invoke perl on each test. For example, setting `HARNESS_PERL_SWITCHES` to `-W` will run all tests with all warnings enabled.

`HARNESS_VERBOSE`

If true, `Test::Harness` will output the verbose results of running its tests. Setting `$Test::Harness::verbose` will override this.

## EXAMPLE

Here's how `Test::Harness` tests itself

```
$ cd ~/src/devel/Test-Harness
$ perl -Mblib -e 'use Test::Harness qw(&runtests $verbose);
 $verbose=0; runtests @ARGV;' t/*.t
Using /home/schwern/src/devel/Test-Harness/blib
t/base.....ok
t/nonumbers.....ok
t/ok.....ok
t/test-harness.....ok
All tests successful.
Files=4, Tests=24, 2 wallclock secs (0.61 cusr + 0.41 csys = 1.02 CPU)
```

## SEE ALSO

[Test](#) and [Test::Simple](#) for writing test scripts, [Benchmark](#) for the underlying timing routines, [Devel::CoreStack](#) to generate core dumps from failed tests and [Devel::Cover](#) for test coverage analysis.

## AUTHORS

Either Tim Bunce or Andreas Koenig, we don't know. What we know for sure is, that it was inspired by Larry Wall's `TEST` script that came with perl distributions for ages. Numerous anonymous contributors exist. Andreas Koenig held the torch for many years.

Current maintainer is Michael G Schwern <schwern@pobox.com>

## TODO

Provide a way of running tests quietly (ie. no printing) for automated validation of tests. This will probably take the form of a version of `runtests()` which rather than printing its output returns raw data on the state of the tests. (Partially done in `Test::Harness::Straps`)

Fix `HARNESS_COMPILE_TEST` without breaking its core usage.

Figure a way to report test names in the failure summary.

Rework the test summary so long test names are not truncated as badly. (Partially done with new skip test styles)

Deal with VMS's "not \nok 4\n" mistake.

Add option for coverage analysis.

=for \_private Keeping whittling away at `_run_all_tests()`

=for \_private Clean up how the summary is printed. Get rid of those damned formats.

## BUGS

HARNESS\_COMPILE\_TEST currently assumes it's run from the Perl source directory.

**NAME**

Test::Harness::Assert – simple assert

**SYNOPSIS**

```
FOR INTERNAL USE ONLY ###

use Test::Harness::Assert;

assert(EXPR, $name);
```

**DESCRIPTION**

A simple assert routine since we don't have Carp::Assert handy.

**For internal use by Test::Harness ONLY!**

**Functions****assert**

```
assert(EXPR, $name);
```

If the expression is false the program aborts.

**AUTHOR**

Michael G Schwern <schwern@pobox.com>

**SEE ALSO**

*[Carp::Assert](#)*

**NAME**

Test::Harness::Iterator – Internal Test::Harness Iterator

**SYNOPSIS**

```
use Test::Harness::Iterator;
use Test::Harness::Iterator;
my $it = Test::Harness::Iterator->new(*TEST);
my $it = Test::Harness::Iterator->new(\@array);

my $line = $it->next;
```

**DESCRIPTION****FOR INTERNAL USE ONLY!**

This is a simple iterator wrapper for arrays and filehandles.

**NAME**

Test::Harness::Straps – detailed analysis of test results

**SYNOPSIS**

```
use Test::Harness::Straps;

my $strap = Test::Harness::Straps->new;

Various ways to interpret a test
my %results = $strap->analyze($name, \@test_output);
my %results = $strap->analyze_fh($name, $test_filehandle);
my %results = $strap->analyze_file($test_file);

UNIMPLEMENTED
my %total = $strap->total_results;

Altering the behavior of the strap UNIMPLEMENTED
my $verbose_output = $strap->dump_verbose();
$strap->dump_verbose_fh($output_filehandle);
```

**DESCRIPTION**

**THIS IS ALPHA SOFTWARE** in that the interface is subject to change in incompatible ways. It is otherwise stable.

Test::Harness is limited to printing out its results. This makes analysis of the test results difficult for anything but a human. To make it easier for programs to work with test results, we provide Test::Harness::Straps. Instead of printing the results, straps provide them as raw data. You can also configure how the tests are to be run.

The interface is currently incomplete. *Please* contact the author if you'd like a feature added or something change or just have comments.

**Construction****new**

```
my $strap = Test::Harness::Straps->new;
```

Initialize a new strap.

**\_init**

```
$strap->_init;
```

Initialize the internal state of a strap to make it ready for parsing.

**Analysis****analyze**

```
my %results = $strap->analyze($name, \@test_output);
```

Analyzes the output of a single test, assigning it the given \$name for use in the total report. Returns the %results of the test. See [Results](#).

@test\_output should be the raw output from the test, including newlines.

**analyze\_fh**

```
my %results = $strap->analyze_fh($name, $test_filehandle);
```

Like analyze, but it reads from the given filehandle.

**analyze\_file**

```
my %results = $strap->analyze_file($test_file);
```

Like `analyze`, but it runs the given `$test_file` and parses it's results. It will also use that name for the total report.

#### **`_switches`**

```
my $switches = $self->_switches($file);
```

Formats and returns the switches necessary to run the test.

#### **`_INC2PERL5LIB`**

```
local $ENV{PERL5LIB} = $self->_INC2PERL5LIB;
```

Takes the current value of `@INC` and turns it into something suitable for putting onto `PERL5LIB`.

#### **`_filtered_INC`**

```
my @filtered_inc = $self->_filtered_INC;
```

Shortens `@INC` by removing redundant and unnecessary entries. Necessary for OS's with limited command line lengths, like VMS.

#### **`_restore_PERL5LIB`**

```
$self->_restore_PERL5LIB;
```

This restores the original value of the `PERL5LIB` environment variable. Necessary on VMS, otherwise a no-op.

`=begin _private`

### **Parsing**

Methods for identifying what sort of line you're looking at.

#### **`_is_comment`**

```
my $is_comment = $strap->_is_comment($line, \$comment);
```

Checks if the given line is a comment. If so, it will place it into `$comment` (sans #).

#### **`_is_header`**

```
my $is_header = $strap->_is_header($line);
```

Checks if the given line is a header (1..M) line. If so, it places how many tests there will be in `$strap-{max}`, a list of which tests are todo in `$strap-{todo}` and if the whole test was skipped `$strap-{skip_all}` contains the reason.

#### **`_is_test`**

```
my $is_test = $strap->_is_test($line, \%test);
```

Checks if the `$line` is a test report (ie. 'ok/not ok'). Reports the result back in `%test` which will contain:

|                     |                                                       |
|---------------------|-------------------------------------------------------|
| <code>ok</code>     | did it succeed? This is the literal 'ok' or 'not ok'. |
| <code>name</code>   | name of the test (if any)                             |
| <code>number</code> | test number (if any)                                  |
| <code>type</code>   | 'todo' or 'skip' (if any)                             |
| <code>reason</code> | why is it todo or skip? (if any)                      |

If will also catch lone 'not' lines, note it saw them `$strap-{saw_lone_not}` and the line in `$strap-{lone_not_line}`.

#### **`_is_bail_out`**

```
my $is_bail_out = $strap->_is_bail_out($line, \$reason);
```

Checks if the line is a "Bail out!". Places the reason for bailing (if any) in `$reason`.

**\_reset\_file\_state**

```
$strap->_reset_file_state;
```

Resets things like \$strap-{max}, \$strap-{skip\_all}, etc... so its ready to parse the next file.

```
=end_private
```

**Results**

The %results returned from analyze() contain the following information:

|          |                                                                                     |
|----------|-------------------------------------------------------------------------------------|
| passing  | true if the whole test is considered a pass<br>(or skipped), false if its a failure |
| exit     | the exit code of the test run, if from a file                                       |
| wait     | the wait code of the test run, if from a file                                       |
| max      | total tests which should have been run                                              |
| seen     | total tests actually seen                                                           |
| skip_all | if the whole test was skipped, this will<br>contain the reason.                     |
| ok       | number of tests which passed<br>(including todo and skips)                          |
| todo     | number of todo tests seen                                                           |
| bonus    | number of todo tests which<br>unexpectedly passed                                   |
| skip     | number of tests skipped                                                             |

So a successful test should have max == seen == ok.

There is one final item, the details.

|         |                                                                    |
|---------|--------------------------------------------------------------------|
| details | an array ref reporting the result of<br>each test looks like this: |
|---------|--------------------------------------------------------------------|

```
$results{details}[$test_num - 1] =
 { ok => is the test considered ok?
 actual_ok => did it literally say 'ok'?
 name => name of the test (if any)
 type => 'skip' or 'todo' (if any)
 reason => reason for the above (if any)
 };
```

Element 0 of the details is test #1. I tried it with element 1 being #1 and 0 being empty, this is less awkward.

```
=begin_private
```

**\_detailize**

```
my %details = $strap->_detailize($pass, \%test);
```

Generates the details based on the last test line seen. \$pass is true if it was considered to be a passed test. %test is the results of the test you're summarizing.

```
=end_private
```

**EXAMPLES**

See *examples/mini\_harness.plx* for an example of use.

```

**DESCRIPTION**

**STOP!** If you're just getting started writing tests, have a look at `Test::Simple` first. This is a drop in replacement for `Test::Simple` which you can switch to once you get the hang of basic testing.

The purpose of this module is to provide a wide range of testing utilities. Various ways to say "ok" with better diagnostics, facilities to skip tests, test future features and compare complicated data structures. While you can do almost anything with a simple `ok()` function, it doesn't provide good diagnostic output.

**I love it when a plan comes together**

Before anything else, you need a testing plan. This basically declares how many tests your script is going to run to protect against premature failure.

The preferred way to do this is to declare a plan when you use `Test::More`.

```
use Test::More tests => $Num_Tests;
```

There are rare cases when you will not know beforehand how many tests your script is going to run. In this case, you can declare that you have no plan. (Try to avoid using this as it weakens your test.)

```
use Test::More qw(no_plan);
```

In some cases, you'll want to completely skip an entire testing script.

```
use Test::More skip_all => $skip_reason;
```

Your script will declare a skip with the reason why you skipped and exit immediately with a zero (success). See [Test::Harness](#) for details.

If you want to control what functions `Test::More` will export, you have to use the 'import' option. For example, to import everything but 'fail', you'd do:

```
use Test::More tests => 23, import => ['!fail'];
```

Alternatively, you can use the `plan()` function. Useful for when you have to calculate the number of tests.

```
use Test::More;
plan tests => keys %Stuff * 3;
```

or for deciding between running the tests at all:

```
use Test::More;
if($^O eq 'MacOS') {
 plan skip_all => 'Test irrelevant on MacOS';
}
else {
 plan tests => 42;
}
```

**Test names**

By convention, each test is assigned a number in order. This is largely done automatically for you. However, it's often very useful to assign a name to each test. Which would you rather see:

```
ok 4
not ok 5
ok 6
```

or

```
ok 4 - basic multi-variable
not ok 5 - simple exponential
ok 6 - force == mass * acceleration
```

The later gives you some idea of what failed. It also makes it easier to find the test in your script, simply

search for "simple exponential".

All test functions take a name argument. It's optional, but highly suggested that you use it.

### I'm ok, you're not ok.

The basic purpose of this module is to print out either "ok #" or "not ok #" depending on if a given test succeeded or failed. Everything else is just gravy.

All of the following print "ok" or "not ok" depending on if the test succeeded or failed. They all also return true or false, respectively.

#### ok

```
ok($this eq $that, $test_name);
```

This simply evaluates any expression (`$this eq $that` is just a simple example) and uses that to determine if the test succeeded or failed. A true expression passes, a false one fails. Very simple.

For example:

```
ok($exp{9} == 81, 'simple exponential');
ok(Film->can('db_Main'), 'set_db()');
ok($p->tests == 4, 'saw tests');
ok(!grep !defined $_, @items, 'items populated');
```

(Mnemonic: "This is ok.")

`$test_name` is a very short description of the test that will be printed out. It makes it very easy to find a test in your script when it fails and gives others an idea of your intentions. `$test_name` is optional, but we **very** strongly encourage its use.

Should an `ok()` fail, it will produce some diagnostics:

```
not ok 18 - sufficient mucus
Failed test 18 (foo.t at line 42)
```

This is actually `Test::Simple`'s `ok()` routine.

#### is

#### isnt

```
is ($this, $that, $test_name);
isnt($this, $that, $test_name);
```

Similar to `ok()`, `is()` and `isnt()` compare their two arguments with `eq` and `ne` respectively and use the result of that to determine if the test succeeded or failed. So these:

```
Is the ultimate answer 42?
is(ultimate_answer(), 42, "Meaning of Life");

$foo isn't empty
isnt($foo, '', "Got some foo");
```

are similar to these:

```
ok(ultimate_answer() eq 42, "Meaning of Life");
ok($foo ne '', "Got some foo");
```

(Mnemonic: "This is that." "This isn't that.")

So why use these? They produce better diagnostics on failure. `ok()` cannot know what you are testing for (beyond the name), but `is()` and `isnt()` know what the test was and why it failed. For example this test:

```
my $foo = 'waffle'; my $bar = 'yarblokos';
is($foo, $bar, 'Is foo the same as bar?');
```

Will produce something like this:

```
not ok 17 - Is foo the same as bar?
Failed test 1 (foo.t at line 139)
got: 'waffle'
expected: 'yarblokos'
```

So you can figure out what went wrong without rerunning the test.

You are encouraged to use `is()` and `isnt()` over `ok()` where possible, however do not be tempted to use them to find out if something is true or false!

```
XXX BAD! $pope->isa('Catholic') eq 1
is($pope->isa('Catholic'), 1, 'Is the Pope Catholic?');
```

This does not check if `$pope->isa('Catholic')` is true, it checks if it returns 1. Very different. Similar caveats exist for false and 0. In these cases, use `ok()`.

```
ok($pope->isa('Catholic')), 'Is the Pope Catholic?');
```

For those grammatical pedants out there, there's an `isn't()` function which is an alias of `isnt()`.

### like

```
like($this, qr/that/, $test_name);
```

Similar to `ok()`, `like()` matches `$this` against the regex `qr/that/`.

So this:

```
like($this, qr/that/, 'this is like that');
```

is similar to:

```
ok($this =~ /that/, 'this is like that');
```

(Mnemonic "This is like that".)

The second argument is a regular expression. It may be given as a regex reference (i.e. `qr//`) or (for better compatibility with older perls) as a string that looks like a regex (alternative delimiters are currently not supported):

```
like($this, '/that/', 'this is like that');
```

Regex options may be placed on the end (`'/that/i'`).

Its advantages over `ok()` are similar to that of `is()` and `isnt()`. Better diagnostics on failure.

### unlike

```
unlike($this, qr/that/, $test_name);
```

Works exactly as `like()`, only it checks if `$this` **does not** match the given pattern.

### cmp\_ok

```
cmp_ok($this, $op, $that, $test_name);
```

Halfway between `ok()` and `is()` lies `cmp_ok()`. This allows you to compare two arguments using any binary perl operator.

```
ok($this eq $that);
cmp_ok($this, 'eq', $that, 'this eq that');

ok($this == $that);
cmp_ok($this, '==', $that, 'this == that');

ok($this && $that);
cmp_ok($this, '&&', $that, 'this || that');
```

...etc...

Its advantage over `ok()` is when the test fails you'll know what `$this` and `$that` were:

```
not ok 1
Failed test (foo.t at line 12)
'23'
&&
undef
```

It's also useful in those cases where you are comparing numbers and `is()`'s use of `eq` will interfere:

```
cmp_ok($big_hairy_number, '==', $another_big_hairy_number);
```

### **can\_ok**

```
can_ok($module, @methods);
can_ok($object, @methods);
```

Checks to make sure the `$module` or `$object` can do these `@methods` (works with functions, too).

```
can_ok('Foo', qw(this that whatever));
```

is almost exactly like saying:

```
ok(Foo->can('this') &&
 Foo->can('that') &&
 Foo->can('whatever')
);
```

only without all the typing and with a better interface. Handy for quickly testing an interface.

No matter how many `@methods` you check, a single `can_ok()` call counts as one test. If you desire otherwise, use:

```
foreach my $meth (@methods) {
 can_ok('Foo', $meth);
}
```

### **isa\_ok**

```
isa_ok($object, $class, $object_name);
isa_ok($ref, $type, $ref_name);
```

Checks to see if the given `$object` `isa($class)`. Also checks to make sure the object was defined in the first place. Handy for this sort of thing:

```
my $obj = Some::Module->new;
isa_ok($obj, 'Some::Module');
```

where you'd otherwise have to write

```
my $obj = Some::Module->new;
ok(defined $obj && $obj->isa('Some::Module'));
```

to safeguard against your test script blowing up.

It works on references, too:

```
isa_ok($array_ref, 'ARRAY');
```

The diagnostics of this test normally just refer to 'the object'. If you'd like them to be more specific, you can supply an `$object_name` (for example 'Test customer').

### **pass**

**fail**

```
pass($test_name);
fail($test_name);
```

Sometimes you just want to say that the tests have passed. Usually the case is you've got some complicated condition that is difficult to wedge into an `ok()`. In this case, you can simply use `pass()` (to declare the test ok) or `fail()` (for not ok). They are synonyms for `ok(1)` and `ok(0)`.

Use these very, very, very sparingly.

**Diagnostics**

If you pick the right test function, you'll usually get a good idea of what went wrong when it failed. But sometimes it doesn't work out that way. So here we have ways for you to write your own diagnostic messages which are safer than just `print STDERR`.

**diag**

```
diag(@diagnostic_message);
```

Prints a diagnostic message which is guaranteed not to interfere with test output. Handy for this sort of thing:

```
ok(grep(/foo/, @users), "There's a foo user") or
 diag("Since there's no foo, check that /etc/bar is set up right");
```

which would produce:

```
not ok 42 - There's a foo user
Failed test (foo.t at line 52)
Since there's no foo, check that /etc/bar is set up right.
```

You might remember `ok()` or `diag()` with the mnemonic `open()` or `die()`.

**NOTE** The exact formatting of the diagnostic output is still changing, but it is guaranteed that whatever you throw at it it won't interfere with the test.

**Module tests**

You usually want to test if the module you're testing loads ok, rather than just vomiting if its load fails. For such purposes we have `use_ok` and `require_ok`.

**use\_ok**

```
BEGIN { use_ok($module); }
BEGIN { use_ok($module, @imports); }
```

These simply use the given `$module` and test to make sure the load happened ok. It's recommended that you run `use_ok()` inside a `BEGIN` block so its functions are exported at compile-time and prototypes are properly honored.

If `@imports` are given, they are passed through to the `use`. So this:

```
BEGIN { use_ok('Some::Module', qw(foo bar)) }
```

is like doing this:

```
use Some::Module qw(foo bar);
```

don't try to do this:

```
BEGIN {
 use_ok('Some::Module');
 ...some code that depends on the use...
 ...happening at compile time...
}
```

instead, you want:

```
BEGIN { use_ok('Some::Module') }
BEGIN { ...some code that depends on the use... }
```

### **require\_ok**

```
require_ok($module);
```

Like `use_ok()`, except it requires the `$module`.

### **Conditional tests**

Sometimes running a test under certain conditions will cause the test script to die. A certain function or method isn't implemented (such as `fork()` on MacOS), some resource isn't available (like a net connection) or a module isn't available. In these cases it's necessary to skip tests, or declare that they are supposed to fail but will work in the future (a todo test).

For more details on the mechanics of skip and todo tests see [Test::Harness](#).

The way `Test::More` handles this is with a named block. Basically, a block of tests which can be skipped over or made todo. It's best if I just show you...

### **SKIP: BLOCK**

```
SKIP: {
 skip $why, $how_many if $condition;
 ...normal testing code goes here...
}
```

This declares a block of tests that might be skipped, `$how_many` tests there are, `$why` and under what `$condition` to skip them. An example is the easiest way to illustrate:

```
SKIP: {
 eval { require HTML::Lint };
 skip "HTML::Lint not installed", 2 if $@;
 my $lint = new HTML::Lint;
 ok($lint, "Created object");
 $lint->parse($html);
 is(scalar $lint->errors, 0, "No errors found in HTML");
}
```

If the user does not have `HTML::Lint` installed, the whole block of code *won't be run at all*. `Test::More` will output special ok's which `Test::Harness` interprets as skipped, but passing, tests. It's important that `$how_many` accurately reflects the number of tests in the `SKIP` block so the # of tests run will match up with your plan.

It's perfectly safe to nest `SKIP` blocks. Each `SKIP` block must have the label `SKIP`, or `Test::More` can't work its magic.

You don't skip tests which are failing because there's a bug in your program, or for which you don't yet have code written. For that you use `TODO`. Read on.

### **TODO: BLOCK**

```
TODO: {
 local $TODO = $why if $condition;
 ...normal testing code goes here...
}
```

Declares a block of tests you expect to fail and `$why`. Perhaps it's because you haven't fixed a bug or haven't finished a new feature:

```

TODO: {
 local $TODO = "URI::Geller not finished";

 my $card = "Eight of clubs";
 is(URI::Geller->your_card, $card, 'Is THIS your card?');

 my $spoon;
 URI::Geller->bend_spoon;
 is($spoon, 'bent', "Spoon bending, that's original");
}

```

With a todo block, the tests inside are expected to fail. Test::More will run the tests normally, but print out special flags indicating they are "todo". Test::Harness will interpret failures as being ok. Should anything succeed, it will report it as an unexpected success. You then know the thing you had todo is done and can remove the TODO flag.

The nice part about todo tests, as opposed to simply commenting out a block of tests, is it's like having a programmatic todo list. You know how much work is left to be done, you're aware of what bugs there are, and you'll know immediately when they're fixed.

Once a todo test starts succeeding, simply move it outside the block. When the block is empty, delete it.

### todo\_skip

```

TODO: {
 todo_skip $why, $show_many if $condition;
 ...normal testing code...
}

```

With todo tests, it's best to have the tests actually run. That way you'll know when they start passing. Sometimes this isn't possible. Often a failing test will cause the whole program to die or hang, even inside an eval BLOCK with and using alarm. In these extreme cases you have no choice but to skip over the broken tests entirely.

The syntax and behavior is similar to a SKIP: BLOCK except the tests will be marked as failing but todo. Test::Harness will interpret them as passing.

### When do I use SKIP vs. TODO?

**If it's something the user might not be able to do**, use SKIP. This includes optional modules that aren't installed, running under an OS that doesn't have some feature (like fork() or symlinks), or maybe you need an Internet connection and one isn't available.

**If it's something the programmer hasn't done yet**, use TODO. This is for any code you haven't written yet, or bugs you have yet to fix, but want to put tests in your testing script (always a good idea).

## Comparison functions

Not everything is a simple eq check or regex. There are times you need to see if two arrays are equivalent, for instance. For these instances, Test::More provides a handful of useful functions.

**NOTE** These are NOT well-tested on circular references. Nor am I quite sure what will happen with filehandles.

### is\_deeply

```
is_deeply($this, $that, $test_name);
```

Similar to is(), except that if \$this and \$that are hash or array references, it does a deep comparison walking each data structure to see if they are equivalent. If the two structures are different, it will display the place where they start differing.

Barrie Slaymaker's Test::Differences module provides more in-depth functionality along these lines, and it plays well with Test::More.

**NOTE** Display of scalar refs is not quite 100%

### eq\_array

```
eq_array(\@this, \@that);
```

Checks if two arrays are equivalent. This is a deep check, so multi-level structures are handled correctly.

### eq\_hash

```
eq_hash(\%this, \%that);
```

Determines if the two hashes contain the same keys and values. This is a deep check.

### eq\_set

```
eq_set(\@this, \@that);
```

Similar to eq\_array(), except the order of the elements is **not** important. This is a deep check, but the irrelevancy of order only applies to the top level.

## Extending and Embedding Test::More

Sometimes the Test::More interface isn't quite enough. Fortunately, Test::More is built on top of Test::Builder which provides a single, unified backend for any test library to use. This means two test libraries which both use Test::Builder **can be used together in the same program**.

If you simply want to do a little tweaking of how the tests behave, you can access the underlying Test::Builder object like so:

### builder

```
my $test_builder = Test::More->builder;
```

Returns the Test::Builder object underlying Test::More for you to play with.

## NOTES

Test::More is **explicitly** tested all the way back to perl 5.004.

Test::More is thread-safe for perl 5.8.0 and up.

## BUGS and CAVEATS

Making your own ok()

If you are trying to extend Test::More, don't. Use Test::Builder instead.

The eq\_\* family has some caveats.

Test::Harness upgrades

no\_plan and todo depend on new Test::Harness features and fixes. If you're going to distribute tests that use no\_plan or todo your end-users will have to upgrade Test::Harness to the latest one on CPAN.

If you avoid no\_plan and TODO tests, the stock Test::Harness will work fine.

If you simply depend on Test::More, it's own dependencies will cause a Test::Harness upgrade.

## HISTORY

This is a case of convergent evolution with Joshua Pritikin's Test module. I was largely unaware of its existence when I'd first written my own ok() routines. This module exists because I can't figure out how to easily wedge test names into Test's interface (along with a few other problems).

The goal here is to have a testing utility that's simple to learn, quick to use and difficult to trip yourself up with while still providing more flexibility than the existing Test.pm. As such, the names of the most common routines are kept tiny, special cases and magic side-effects are kept to a minimum. WYSIWYG.

**SEE ALSO**

*Test::Simple* if all this confuses you and you just want to write some tests. You can upgrade to *Test::More* later (it's forward compatible).

*Test::Differences* for more ways to test complex data structures. And it plays well with *Test::More*.

*Test* is the old testing module. Its main benefit is that it has been distributed with Perl since 5.004\_05.

*Test::Harness* for details on how your test results are interpreted by Perl.

*Test::Unit* describes a very featureful unit testing interface.

*Test::Inline* shows the idea of embedded testing.

*SelfTest* is another approach to embedded testing.

**NAME**

Test::Simple – Basic utilities for writing tests.

**SYNOPSIS**

```
use Test::Simple tests => 1;

ok($foo eq $bar, 'foo is bar');
```

**DESCRIPTION**

**\*\* If you are unfamiliar with testing read `Test::Tutorial` first! \*\***

This is an extremely simple, extremely basic module for writing tests suitable for CPAN modules and other pursuits. If you wish to do more complicated testing, use the `Test::More` module (a drop-in replacement for this one).

The basic unit of Perl testing is the `ok`. For each thing you want to test your program will print out an "ok" or "not ok" to indicate pass or fail. You do this with the `ok()` function (see below).

The only other constraint is you must pre-declare how many tests you plan to run. This is in case something goes horribly wrong during the test and your test program aborts, or skips a test or whatever. You do this like so:

```
use Test::Simple tests => 23;
```

You must have a plan.

**ok**

```
ok($foo eq $bar, $name);
ok($foo eq $bar);
```

`ok()` is given an expression (in this case `$foo eq $bar`). If it's true, the test passed. If it's false, it didn't. That's about it.

`ok()` prints out either "ok" or "not ok" along with a test number (it keeps track of that for you).

```
This produces "ok 1 - Hell not yet frozen over" (or not ok)
ok(get_temperature($hell) > 0, 'Hell not yet frozen over');
```

If you provide a `$name`, that will be printed along with the "ok/not ok" to make it easier to find your test when it fails (just search for the name). It also makes it easier for the next guy to understand what your test is for. It's highly recommended you use test names.

All tests are run in scalar context. So this:

```
ok(@stuff, 'I have some stuff');
```

will do what you mean (fail if `stuff` is empty)

`Test::Simple` will start by printing number of tests run in the form "1..M" (so "1..5" means you're going to run 5 tests). This strange format lets `Test::Harness` know how many tests you plan on running in case something goes horribly wrong.

If all your tests passed, `Test::Simple` will exit with zero (which is normal). If anything failed it will exit with how many failed. If you run less (or more) tests than you planned, the missing (or extras) will be considered failures. If no tests were ever run `Test::Simple` will throw a warning and exit with 255. If the test died, even after having successfully completed all its tests, it will still be considered a failure and will exit with 255.

So the exit codes are...

|                  |                                               |
|------------------|-----------------------------------------------|
| 0                | all tests successful                          |
| 255              | test died                                     |
| any other number | how many failed (including missing or extras) |

If you fail more than 254 tests, it will be reported as 254.

This module is by no means trying to be a complete testing system. It's just to get you started. Once you're off the ground its recommended you look at [Test::More](#).

## EXAMPLE

Here's an example of a simple .t file for the fictional Film module.

```
use Test::Simple tests => 5;

use Film; # What you're testing.

my $btaste = Film->new({ Title => 'Bad Taste',
 Director => 'Peter Jackson',
 Rating => 'R',
 NumExplodingSheep => 1
 });

ok(defined($btaste) and ref $btaste eq 'Film', 'new() works');

ok($btaste->Title eq 'Bad Taste', 'Title() get');
ok($btaste->Director eq 'Peter Jackson', 'Director() get');
ok($btaste->Rating eq 'R', 'Rating() get');
ok($btaste->NumExplodingSheep == 1, 'NumExplodingSheep() get');
```

It will produce output like this:

```
1..5
ok 1 - new() works
ok 2 - Title() get
ok 3 - Director() get
not ok 4 - Rating() get
Failed test (t/film.t at line 14)
ok 5 - NumExplodingSheep() get
Looks like you failed 1 tests of 5
```

Indicating the `Film::Rating()` method is broken.

## CAVEATS

`Test::Simple` will only report a maximum of 254 failures in its exit code. If this is a problem, you probably have a huge test script. Split it into multiple files. (Otherwise blame the Unix folks for using an unsigned short integer as the exit status).

Because VMS's exit codes are much, much different than the rest of the universe, and perl does horrible mangling to them that gets in my way, it works like this on VMS.

|   |             |                      |
|---|-------------|----------------------|
| 0 | SS\$_NORMAL | all tests successful |
| 4 | SS\$_ABORT  | something went wrong |

Unfortunately, I can't differentiate any further.

## NOTES

`Test::Simple` is **explicitly** tested all the way back to perl 5.004.

`Test::Simple` is thread-safe in perl 5.8.0 and up.

## HISTORY

This module was conceived while talking with Tony Bowden in his kitchen one night about the problems I was having writing some really complicated feature into the new Testing module. He observed that the main problem is not dealing with these edge cases but that people hate to write tests **at all**. What was needed was a dead simple module that took all the hard work out of testing and was really, really easy to learn. Paul Johnson simultaneously had this idea (unfortunately, he wasn't in Tony's kitchen). This is it.

**SEE ALSO***Test::More*

More testing functions! Once you outgrow `Test::Simple`, look at `Test::More`. `Test::Simple` is 100% forward compatible with `Test::More` (i.e. you can just use `Test::More` instead of `Test::Simple` in your programs and things will still work).

*Test*

The original Perl testing module.

*Test::Unit*

Elaborate unit testing.

*Test::Inline*, *SelfTest*

Embed tests in your code!

*Test::Harness*

Interprets the output of your test program.

**AUTHORS**

Idea by Tony Bowden and Paul Johnson, code by Michael G Schwern <schwern@pobox.com>, wardrobe by Calvin Klein.

**NAME**

Test::Tutorial – A tutorial about writing really basic tests

**DESCRIPTION**

*AHHHHHHH!!!! NOT TESTING! Anything but testing! Beat me, whip me, send me to Detroit, but don't make me write tests!*

*\*sob\**

*Besides, I don't know how to write the damned things.*

Is this you? Is writing tests right up there with writing documentation and having your fingernails pulled out? Did you open up a test and read

```
We start with some black magic
and decide that's quite enough for you?
```

It's ok. That's all gone now. We've done all the black magic for you. And here are the tricks...

**Nuts and bolts of testing.**

Here's the most basic test program.

```
#!/usr/bin/perl -w
print "1..1\n";
print 1 + 1 == 2 ? "ok 1\n" : "not ok 1\n";
```

since 1 + 1 is 2, it prints:

```
1..1
ok 1
```

What this says is: 1..1 "I'm going to run one test." [1] ok 1 "The first test passed". And that's about all magic there is to testing. Your basic unit of testing is the *ok*. For each thing you test, an *ok* is printed. Simple. **Test::Harness** interprets your test results to determine if you succeeded or failed (more on that later).

Writing all these print statements rapidly gets tedious. Fortunately, there's **Test::Simple**. It has one function, `ok()`.

```
#!/usr/bin/perl -w
use Test::Simple tests => 1;
ok(1 + 1 == 2);
```

and that does the same thing as the code above. `ok()` is the backbone of Perl testing, and we'll be using it instead of roll-your-own from here on. If `ok()` gets a true value, the test passes. False, it fails.

```
#!/usr/bin/perl -w
use Test::Simple tests => 2;
ok(1 + 1 == 2);
ok(2 + 2 == 5);
```

from that comes

```
1..2
ok 1
not ok 2
Failed test (test.pl at line 5)
Looks like you failed 1 tests of 2.
```

1..2 "I'm going to run two tests." This number is used to ensure your test program ran all the way through and didn't die or skip some tests. `ok 1 "The first test passed."` `not ok 2 "The second test failed"`. `Test::Simple` helpfully prints out some extra commentary about your tests.

It's not scary. Come, hold my hand. We're going to give an example of testing a module. For our example, we'll be testing a date library, **Date::ICal**. It's on CPAN, so download a copy and follow along. [2]

### Where to start?

This is the hardest part of testing, where do you start? People often get overwhelmed at the apparent enormity of the task of testing a whole module. Best place to start is at the beginning. `Date::ICal` is an object-oriented module, and that means you start by making an object. So we test `new()`.

```
#!/usr/bin/perl -w

use Test::Simple tests => 2;

use Date::ICal;

my $ical = Date::ICal->new; # create an object
ok(defined $ical); # check that we got something
ok($ical->isa('Date::ICal')); # and it's the right class
```

run that and you should get:

```
1..2
ok 1
ok 2
```

congratulations, you've written your first useful test.

### Names

That output isn't terribly descriptive, is it? When you have two tests you can figure out which one is #2, but what if you have 102?

Each test can be given a little descriptive name as the second argument to `ok()`.

```
use Test::Simple tests => 2;

ok(defined $ical, 'new() returned something');
ok($ical->isa('Date::ICal'), " and it's the right class");
```

So now you'd see...

```
1..2
ok 1 - new() returned something
ok 2 - and it's the right class
```

### Test the manual

Simplest way to build up a decent testing suite is to just test what the manual says it does. [3] Let's pull something out of the [Date::ICal/SYNOPSIS](#) and test that all its bits work.

```
#!/usr/bin/perl -w

use Test::Simple tests => 8;

use Date::ICal;

$ical = Date::ICal->new(year => 1964, month => 10, day => 16,
 hour => 16, min => 12, sec => 47,
 tz => '0530');

ok(defined $ical, 'new() returned something');
ok($ical->isa('Date::ICal'), " and it's the right class");
ok($ical->sec == 47, ' sec()');
```

```

ok($ical->min == 12, ' min()');
ok($ical->hour == 16, ' hour()');
ok($ical->day == 17, ' day()');
ok($ical->month == 10, ' month()');
ok($ical->year == 1964, ' year()');

```

run that and you get:

```

1..8
ok 1 - new() returned something
ok 2 - and it's the right class
ok 3 - sec()
ok 4 - min()
ok 5 - hour()
not ok 6 - day()
Failed test (- at line 16)
ok 7 - month()
ok 8 - year()
Looks like you failed 1 tests of 8.

```

Whoops, a failure! [4] `Test::Simple` helpfully lets us know on what line the failure occurred, but not much else. We were supposed to get 17, but we didn't. What did we get?? Dunno. We'll have to re-run the test in the debugger or throw in some print statements to find out.

Instead, we'll switch from **Test::Simple** to **Test::More**. **Test::More** does everything **Test::Simple** does, and more! In fact, `Test::More` does things *exactly* the way `Test::Simple` does. You can literally swap `Test::Simple` out and put `Test::More` in its place. That's just what we're going to do.

`Test::More` does more than `Test::Simple`. The most important difference at this point is it provides more informative ways to say "ok". Although you can write almost any test with a generic `ok()`, it can't tell you what went wrong. Instead, we'll use the `is()` function, which lets us declare that something is supposed to be the same as something else:

```

#!/usr/bin/perl -w

use Test::More tests => 8;

use Date::ICal;

$ical = Date::ICal->new(year => 1964, month => 10, day => 16,
 hour => 16, min => 12, sec => 47,
 tz => '0530');

ok(defined $ical, 'new() returned something');
ok($ical->isa('Date::ICal'), " and it's the right class");
is($ical->sec, 47, ' sec()');
is($ical->min, 12, ' min()');
is($ical->hour, 16, ' hour()');
is($ical->day, 17, ' day()');
is($ical->month, 10, ' month()');
is($ical->year, 1964, ' year()');

```

"Is `$ical->sec 47`?" "Is `$ical->min 12`?" With `is()` in place, you get some more information

```

1..8
ok 1 - new() returned something
ok 2 - and it's the right class
ok 3 - sec()
ok 4 - min()
ok 5 - hour()

```

```

not ok 6 - day()
Failed test (- at line 16)
got: '16'
expected: '17'
ok 7 - month()
ok 8 - year()
Looks like you failed 1 tests of 8.

```

letting us know that `$ical->day` returned 16, but we expected 17. A quick check shows that the code is working fine, we made a mistake when writing up the tests. Just change it to:

```
is($ical->day, 16, ' day()');
```

and everything works.

So any time you're doing a "this equals that" sort of test, use `is()`. It even works on arrays. The test is always in scalar context, so you can test how many elements are in a list this way. [5]

```
is(@foo, 5, 'foo has 5 elements');
```

### Sometimes the tests are wrong

Which brings us to a very important lesson. Code has bugs. Tests are code. Ergo, tests have bugs. A failing test could mean a bug in the code, but don't discount the possibility that the test is wrong.

On the flip side, don't be tempted to prematurely declare a test incorrect just because you're having trouble finding the bug. Invalidating a test isn't something to be taken lightly, and don't use it as a cop out to avoid work.

### Testing lots of values

We're going to be wanting to test a lot of dates here, trying to trick the code with lots of different edge cases. Does it work before 1970? After 2038? Before 1904? Do years after 10,000 give it trouble? Does it get leap years right? We could keep repeating the code above, or we could set up a little try/expect loop.

```

use Test::More tests => 32;
use Date::ICal;

my %ICal_Dates = (
 # An ICal string And the year, month, date
 # hour, minute and second we expect.
 '19971024T120000' => # from the docs.
 [1997, 10, 24, 12, 0, 0],
 '20390123T232832' => # after the Unix epoch
 [2039, 1, 23, 23, 28, 32],
 '19671225T000000' => # before the Unix epoch
 [1967, 12, 25, 0, 0, 0],
 '18990505T232323' => # before the MacOS epoch
 [1899, 5, 5, 23, 23, 23],
);

while(my($ical_str, $expect) = each %ICal_Dates) {
 my $ical = Date::ICal->new(ical => $ical_str);

 ok(defined $ical, "new(ical => '$ical_str')");
 ok($ical->isa('Date::ICal'), " and it's the right class");

 is($ical->year, $expect->[0], ' year()');
 is($ical->month, $expect->[1], ' month()');
 is($ical->day, $expect->[2], ' day()');
 is($ical->hour, $expect->[3], ' hour()');
 is($ical->min, $expect->[4], ' min()');
 is($ical->sec, $expect->[5], ' sec()');
}

```

```
}
```

So now we can test bunches of dates by just adding them to %ICal\_Dates. Now that it's less work to test with more dates, you'll be inclined to just throw more in as you think of them. Only problem is, every time we add to that we have to keep adjusting the use `Test::More tests => ##` line. That can rapidly get annoying. Instead we use `no_plan`. This means we're just running some tests, don't know how many. [6]

```
use Test::More 'no_plan'; # instead of tests => 32
```

now we can just add tests and not have to do all sorts of math to figure out how many we're running.

### Informative names

Take a look at this line here

```
ok(defined $ical, "new(ical => '$ical_str')");
```

we've added more detail about what we're testing and the ICal string itself we're trying out to the name. So you get results like:

```
ok 25 - new(ical => '19971024T120000')
ok 26 - and it's the right class
ok 27 - year()
ok 28 - month()
ok 29 - day()
ok 30 - hour()
ok 31 - min()
ok 32 - sec()
```

if something in there fails, you'll know which one it was and that will make tracking down the problem easier. So try to put a bit of debugging information into the test names.

Describe what the tests test, to make debugging a failed test easier for you or for the next person who runs your test.

### Skipping tests

Poking around in the existing Date::ICal tests, I found this in *t/01sanity.t* [7]

```
#!/usr/bin/perl -w

use Test::More tests => 7;
use Date::ICal;

Make sure epoch time is being handled sanely.
my $t1 = Date::ICal->new(epoch => 0);
is($t1->epoch, 0, "Epoch time of 0");

XXX This will only work on unix systems.
is($t1->ical, '19700101Z', "epoch to ical");

is($t1->year, 1970, "year()");
is($t1->month, 1, "month()");
is($t1->day, 1, "day()");

like the tests above, but starting with ical instead of epoch
my $t2 = Date::ICal->new(ical => '19700101Z');
is($t2->ical, '19700101Z', "Start of epoch in ICal notation");

is($t2->epoch, 0, "and back to ICal");
```

The beginning of the epoch is different on most non-Unix operating systems [8]. Even though Perl smooths out the differences for the most part, certain ports do it differently. MacPerl is one off the top of my head. [9] We *know* this will never work on MacOS. So rather than just putting a comment in the test, we can

explicitly say it's never going to work and skip the test.

```
use Test::More tests => 7;
use Date::ICal;

Make sure epoch time is being handled sanely.
my $t1 = Date::ICal->new(epoch => 0);
is($t1->epoch, 0, "Epoch time of 0");

SKIP: {
 skip('epoch to ICal not working on MacOS', 6)
 if $^O eq 'MacOS';

 is($t1->ical, '19700101Z', " epoch to ical");

 is($t1->year, 1970, " year()");
 is($t1->month, 1, " month()");
 is($t1->day, 1, " day()");

 # like the tests above, but starting with ical instead of epoch
 my $t2 = Date::ICal->new(ical => '19700101Z');
 is($t2->ical, '19700101Z', "Start of epoch in ICal notation");
 is($t2->epoch, 0, " and back to ICal");
}
```

A little bit of magic happens here. When running on anything but MacOS, all the tests run normally. But when on MacOS, `skip()` causes the entire contents of the SKIP block to be jumped over. It's never run. Instead, it prints special output that tells Test::Harness that the tests have been skipped.

```
1..7
ok 1 - Epoch time of 0
ok 2 # skip epoch to ICal not working on MacOS
ok 3 # skip epoch to ICal not working on MacOS
ok 4 # skip epoch to ICal not working on MacOS
ok 5 # skip epoch to ICal not working on MacOS
ok 6 # skip epoch to ICal not working on MacOS
ok 7 # skip epoch to ICal not working on MacOS
```

This means your tests won't fail on MacOS. This means less emails from MacPerl users telling you about failing tests that you know will never work. You've got to be careful with skip tests. These are for tests which don't work and *never will*. It is not for skipping genuine bugs (we'll get to that in a moment).

The tests are wholly and completely skipped. [10] This will work.

```
SKIP: {
 skip("I don't wanna die!");
 die, die, die, die, die;
}
```

## Todo tests

Thumbing through the Date::ICal man page, I came across this:

```
ical

 $ical_string = $ical->ical;

Retrieves, or sets, the date on the object, using any
valid ICal date/time string.
```

"Retrieves or sets". Hmmm, didn't see a test for using `ical()` to set the date in the Date::ICal test suite. So I'll write one.

```

use Test::More tests => 1;

my $ical = Date::ICal->new;
$ical->ical('20201231Z');
is($ical->ical, '20201231Z', 'Setting via ical()');

```

run that and I get

```

1..1
not ok 1 - Setting via ical()
Failed test (- at line 6)
got: '20010814T233649Z'
expected: '20201231Z'
Looks like you failed 1 tests of 1.

```

Whoops! Looks like it's unimplemented. Let's assume we don't have the time to fix this. [11] Normally, you'd just comment out the test and put a note in a todo list somewhere. Instead, we're going to explicitly state "this test will fail" by wrapping it in a TODO block.

```

use Test::More tests => 1;

TODO: {
 local $TODO = 'ical($ical) not yet implemented';

 my $ical = Date::ICal->new;
 $ical->ical('20201231Z');

 is($ical->ical, '20201231Z', 'Setting via ical()');
}

```

Now when you run, it's a little different:

```

1..1
not ok 1 - Setting via ical() # TODO ical($ical) not yet implemented
got: '20010822T201551Z'
expected: '20201231Z'

```

Test::More doesn't say "Looks like you failed 1 tests of 1". That '# TODO' tells Test::Harness "this is supposed to fail" and it treats a failure as a successful test. So you can write tests even before you've fixed the underlying code.

If a TODO test passes, Test::Harness will report it "UNEXPECTEDLY SUCCEEDED". When that happens, you simply remove the TODO block with `local $TODO` and turn it into a real test.

### Testing with taint mode.

Taint mode is a funny thing. It's the globeleest of all global features. Once you turn it on it effects *all* code in your program and *all* modules used (and all the modules they use). If a single piece of code isn't taint clean, the whole thing explodes. With that in mind, it's very important to ensure your module works under taint mode.

It's very simple to have your tests run under taint mode. Just throw a `-T` into the `#!` line. Test::Harness will read the switches in `#!` and use them to run your tests.

```

#!/usr/bin/perl -Tw

use Test::More 'no_plan';

...test normally here...

```

So when you say `make test` it will be run with taint mode and warnings on.

## FOOTNOTES

- 1 The first number doesn't really mean anything, but it has to be 1. It's the second number that's important.
- 2 For those following along at home, I'm using version 1.31. It has some bugs, which is good — we'll uncover them with our tests.
- 3 You can actually take this one step further and test the manual itself. Have a look at **Test::Inline** (formerly **Pod::Tests**).
- 4 Yes, there's a mistake in the test suite. What! Me, contrived?
- 5 We'll get to testing the contents of lists later.
- 6 But what happens if your test program dies halfway through?! Since we didn't say how many tests we're going to run, how can we know it failed? No problem, **Test::More** employs some magic to catch that death and turn the test into a failure, even if every test passed up to that point.
- 7 I cleaned it up a little.
- 8 Most Operating Systems record time as the number of seconds since a certain date. This date is the beginning of the epoch. Unix's starts at midnight January 1st, 1970 GMT.
- 9 MacOS's epoch is midnight January 1st, 1904. VMS's is midnight, November 17th, 1858, but **vmperl** emulates the Unix epoch so it's not a problem.
- 10 As long as the code inside the **SKIP** block at least compiles. Please don't ask how. No, it's not a filter.
- 11 Do NOT be tempted to use **TODO** tests as a way to avoid fixing simple bugs!

**NAME**

abbrev – create an abbreviation table from a list

**SYNOPSIS**

```
use Text::Abbrev;
abbrev $hashref, LIST
```

**DESCRIPTION**

Stores all unambiguous truncations of each element of `LIST` as keys in the associative array referenced by `$hashref`. The values are the original list elements.

**EXAMPLE**

```
$hashref = abbrev qw(list edit send abort gripe);
%hash = abbrev qw(list edit send abort gripe);
abbrev $hashref, qw(list edit send abort gripe);
abbrev(*hash, qw(list edit send abort gripe));
```

**NAME**

Text::Balanced – Extract delimited text sequences from strings.

**SYNOPSIS**

```
use Text::Balanced qw (
 extract_delimited
 extract_bracketed
 extract_quotelike
 extract_codeblock
 extract_variable
 extract_tagged
 extract_multiple

 gen_delimited_pat
 gen_extract_tagged
);

Extract the initial substring of $text that is delimited by
two (unescaped) instances of the first character in $delim.

($extracted, $remainder) = extract_delimited($text,$delim);

Extract the initial substring of $text that is bracketed
with a delimiter(s) specified by $delim (where the string
in $delim contains one or more of '(){}[]<>').

($extracted, $remainder) = extract_bracketed($text,$delim);

Extract the initial substring of $text that is bounded by
an HTML/XML tag.

($extracted, $remainder) = extract_tagged($text);

Extract the initial substring of $text that is bounded by
a C<BEGIN>...C<END> pair. Don't allow nested C<BEGIN> tags

($extracted, $remainder) =
 extract_tagged($text,"BEGIN","END",undef,{bad=>["BEGIN"]});

Extract the initial substring of $text that represents a
Perl "quote or quote-like operation"

($extracted, $remainder) = extract_quotelike($text);

Extract the initial substring of $text that represents a block
of Perl code, bracketed by any of character(s) specified by $delim
(where the string $delim contains one or more of '(){}[]<>').

($extracted, $remainder) = extract_codeblock($text,$delim);

Extract the initial substrings of $text that would be extracted by
one or more sequential applications of the specified functions
or regular expressions

@extracted = extract_multiple($text,
 [\&extract_bracketed,
 \&extract_quotelike,
 \&some_other_extractor_sub,
 qr/[xyz]*/,
 'literal',
]);
```

# Create a string representing an optimized pattern (a la Friedl) # that matches a substring delimited by any of the specified characters # (in this case: any type of quote or a slash)

```
$patstring = gen_delimited_pat(q{'"\'/});
```

# Generate a reference to an anonymous sub that is just like `extract_tagged` # but pre-compiled and optimized for a specific pair of tags, and consequently # much faster (i.e. 3 times faster). It uses `qr//` for better performance on # repeated calls, so it only works under Perl 5.005 or later.

```
$extract_head = gen_extract_tagged('<HEAD>', '</HEAD>');
```

```
($extracted, $remainder) = $extract_head->($text);
```

## DESCRIPTION

The various `extract_...` subroutines may be used to extract a delimited string (possibly after skipping a specified prefix string). The search for the string always begins at the current `pos` location of the string's variable (or at index zero, if no `pos` position is defined).

### General behaviour in list contexts

In a list context, all the subroutines return a list, the first three elements of which are always:

- [0] The extracted string, including the specified delimiters. If the extraction fails an empty string is returned.
- [1] The remainder of the input string (i.e. the characters after the extracted string). On failure, the entire string is returned.
- [2] The skipped prefix (i.e. the characters before the extracted string). On failure, the empty string is returned.

Note that in a list context, the contents of the original input text (the first argument) are not modified in any way.

However, if the input text was passed in a variable, that variable's `pos` value is updated to point at the first character after the extracted text. That means that in a list context the various subroutines can be used much like regular expressions. For example:

```
while ($next = (extract_quotelike($text))[0])
{
 # process next quote-like (in $next)
}
```

### General behaviour in scalar and void contexts

In a scalar context, the extracted string is returned, having first been removed from the input text. Thus, the following code also processes each quote-like operation, but actually removes them from `$text`:

```
while ($next = extract_quotelike($text))
{
 # process next quote-like (in $next)
}
```

Note that if the input text is a read-only string (i.e. a literal), no attempt is made to remove the extracted text.

In a void context the behaviour of the extraction subroutines is exactly the same as in a scalar context, except (of course) that the extracted substring is not returned.

### A note about prefixes

Prefix patterns are matched without any trailing modifiers (`/gimsx` etc.) This can bite you if you're expecting a prefix specification like `'.*(?=<H1)'` to skip everything up to the first `<H1` tag. Such a prefix pattern will only succeed if the `<H1` tag is on the current line, since `.` normally doesn't match newlines.

To overcome this limitation, you need to turn on /s matching within the prefix pattern, using the (?s) directive: '(?s).\*(?=<H1)'

```
extract delimited
```

The `extract_delimited` function formalizes the common idiom of extracting a single-character-delimited substring from the start of a string. For example, to extract a single-quote delimited string, the following code is typically used:

```
($remainder = $text) =~ s/\A('(\.|\[^\])*')//s;
$extracted = $1;
```

but with `extract delimited` it can be simplified to:

```
($extracted,$remainder) = extract delimited($text, "'");
```

`extract_delimited` takes up to four scalars (the input text, the delimiters, a prefix pattern to be skipped, and any escape characters) and extracts the initial substring of the text that is appropriately delimited. If the delimiter string has multiple characters, the first one encountered in the text is taken to delimit the substring. The third argument specifies a prefix pattern that is to be skipped (but must be present!) before the substring is extracted. The final argument specifies the escape character to be used for each delimiter.

All arguments are optional. If the escape characters are not specified, every delimiter is escaped with a backslash (\). If the prefix is not specified, the pattern `\s*` – optional whitespace – is used. If the delimiter set is also not specified, the set `/[\"'`]/` is used. If the text to be processed is not specified either, `$` is used.

In list context, `extract_delimited` returns an array of three elements, the extracted substring (*including the surrounding delimiters*), the remainder of the text, and the skipped prefix (if any). If a suitable delimited substring is not found, the first element of the array is the empty string, the second is the complete original text, and the prefix returned in the third element is an empty string.

In a scalar context, just the extracted substring is returned. In a void context, the extracted substring (and any prefix) are simply removed from the beginning of the first argument.

Examples:

```
Remove a single-quoted substring from the very beginning of $text:
 $substring = extract_delimited($text, "'", '');

Remove a single-quoted Pascalish substring (i.e. one in which
doubling the quote character escapes it) from the very
beginning of $text:
 $substring = extract_delimited($text, "'", '"');

Extract a single- or double- quoted substring from the
beginning of $text, optionally after some whitespace
(note the list context to protect $text from modification):
 ($substring) = extract_delimited $text, q{"'"};

Delete the substring delimited by the first '/' in $text:
 $text = join '', (extract_delimited($text, '/', '['^/]*')[2,1]);
```

Note that this last example is *not* the same as deleting the first quote-like pattern. For instance, if `$text` contained the string:

```
"if ('./cmd' =~ m/$UNIXCMD/s) { $cmd = $1; }"
```

then after the deletion it would contain:

```
"if ('. $UNIXCMD/s) { $cmd = $1; }"
```

not:

```
"if ('./cmd' =~ ms) { $cmd = $1; }"
```

See ["extract\\_quotelike"](#) for a (partial) solution to this problem.

### extract\_bracketed

Like `extract_delimited`, the `extract_bracketed` function takes up to three optional scalar arguments: a string to extract from, a delimiter specifier, and a prefix pattern. As before, a missing prefix defaults to optional whitespace and a missing text defaults to `$_`. However, a missing delimiter specifier defaults to `'{ } ( ) [ ] < >'` (see below).

`extract_bracketed` extracts a balanced-bracket-delimited substring (using any one (or more) of the user-specified delimiter brackets: `'(..)', '{..}', '[..]',` or `'<..'`). Optionally it will also respect quoted unbalanced brackets (see below).

A "delimiter bracket" is a bracket in list of delimiters passed as `extract_bracketed`'s second argument. Delimiter brackets are specified by giving either the left or right (or both!) versions of the required bracket(s). Note that the order in which two or more delimiter brackets are specified is not significant.

A "balanced-bracket-delimited substring" is a substring bounded by matched brackets, such that any other (left or right) delimiter bracket *within* the substring is also matched by an opposite (right or left) delimiter bracket *at the same level of nesting*. Any type of bracket not in the delimiter list is treated as an ordinary character.

In other words, each type of bracket specified as a delimiter must be balanced and correctly nested within the substring, and any other kind of ("non-delimiter") bracket in the substring is ignored.

For example, given the string:

```
$text = "{ an '[irregularly :-() {} parenthesized >:-)' string }";
```

then a call to `extract_bracketed` in a list context:

```
@result = extract_bracketed($text, '{ }');
```

would return:

```
("{ an '[irregularly :-() {} parenthesized >:-)' string }" , "" , "")
```

since both sets of `'{ .. }'` brackets are properly nested and evenly balanced. (In a scalar context just the first element of the array would be returned. In a void context, `$text` would be replaced by an empty string.)

Likewise the call in:

```
@result = extract_bracketed($text, '[]');
```

would return the same result, since all sets of both types of specified delimiter brackets are correctly nested and balanced.

However, the call in:

```
@result = extract_bracketed($text, '{ (<');
```

would fail, returning:

```
(undef , "{ an '[irregularly :-() {} parenthesized >:-)' string }");
```

because the embedded pairs of `'(..)'`s and `'[..]'`s are "cross-nested" and the embedded `'>'` is unbalanced. (In a scalar context, this call would return an empty string. In a void context, `$text` would be unchanged.)

Note that the embedded single-quotes in the string don't help in this case, since they have not been specified

as acceptable delimiters and are therefore treated as non-delimiter characters (and ignored).

However, if a particular species of quote character is included in the delimiter specification, then that type of quote will be correctly handled. for example, if `$text` is:

```
$text = '>>>">link';
```

then

```
@result = extract_bracketed($text, '<">');
```

returns:

```
('>>>">', 'link', "")
```

as expected. Without the specification of `"` as an embedded quoter:

```
@result = extract_bracketed($text, '<>');
```

the result would be:

```
('', '>>>>">link', "")
```

In addition to the quote delimiters `'`, `"`, and ```, full Perl quote-like quoting (i.e. `q{string}`, `qq{string}`, etc) can be specified by including the letter `'q'` as a delimiter. Hence:

```
@result = extract_bracketed($text, '<q>');
```

would correctly match something like this:

```
$text = '<leftop: conj /and/ conj>';
```

See also: `"extract_quotelike"` and `"extract_codeblock"`.

### **extract\_tagged**

`extract_tagged` extracts and segments text between (balanced) specified tags.

The subroutine takes up to five optional arguments:

1. A string to be processed (`$_` if the string is omitted or `undef`)
2. A string specifying a pattern to be matched as the opening tag. If the pattern string is omitted (or `undef`) then a pattern that matches any standard HTML/XML tag is used.
3. A string specifying a pattern to be matched at the closing tag. If the pattern string is omitted (or `undef`) then the closing tag is constructed by inserting a `/` after any leading bracket characters in the actual opening tag that was matched (*not* the pattern that matched the tag). For example, if the opening tag pattern is specified as `'{\w+}'` and actually matched the opening tag `"{DATA}"`, then the constructed closing tag would be `"{/DATA}"`.
4. A string specifying a pattern to be matched as a prefix (which is to be skipped). If omitted, optional whitespace is skipped.
5. A hash reference containing various parsing options (see below)

The various options that can be specified are:

```
reject => $listref
```

The list reference contains one or more strings specifying patterns that must *not* appear within the tagged text.

For example, to extract an HTML link (which should not contain nested links) use:

```
extract_tagged($text, '<A>', '', undef, {reject => ['<A>']});
```

**ignore => \$listref**

The list reference contains one or more strings specifying patterns that are *not* to be treated as nested tags within the tagged text (even if they would match the start tag pattern).

For example, to extract an arbitrary XML tag, but ignore "empty" elements:

```
extract_tagged($text, undef, undef, undef, {ignore => ['<[^>]*>']});
```

(also see *["gen\\_delimited\\_pat"](#)* below).

**fail => \$str**

The `fail` option indicates the action to be taken if a matching end tag is not encountered (i.e. before the end of the string or some `reject` pattern matches). By default, a failure to match a closing tag causes `extract_tagged` to immediately fail.

However, if the string value associated with `<reject` is "MAX", then `extract_tagged` returns the complete text up to the point of failure. If the string is "PARA", `extract_tagged` returns only the first paragraph after the tag (up to the first line that is either empty or contains only whitespace characters). If the string is "", the default behaviour (i.e. failure) is reinstated.

For example, suppose the start tag `/para` introduces a paragraph, which then continues until the next `/endpara` tag or until another `/para` tag is encountered:

```
$text = "/para line 1\n\nline 3\n/para line 4";
extract_tagged($text, '/para', '/endpara', undef,
 {reject => '/para', fail => MAX });

EXTRACTED: "/para line 1\n\nline 3\n"
```

Suppose instead, that if no matching `/endpara` tag is found, the `/para` tag refers only to the immediately following paragraph:

```
$text = "/para line 1\n\nline 3\n/para line 4";
extract_tagged($text, '/para', '/endpara', undef,
 {reject => '/para', fail => MAX });

EXTRACTED: "/para line 1\n"
```

Note that the specified `fail` behaviour applies to nested tags as well.

On success in a list context, an array of 6 elements is returned. The elements are:

- [0] the extracted tagged substring (including the outermost tags),
- [1] the remainder of the input text,
- [2] the prefix substring (if any),
- [3] the opening tag
- [4] the text between the opening and closing tags
- [5] the closing tag (or "" if no closing tag was found)

On failure, all of these values (except the remaining text) are `undef`.

In a scalar context, `extract_tagged` returns just the complete substring that matched a tagged text (including the start and end tags). `undef` is returned on failure. In addition, the original input text has the returned substring (and any prefix) removed from it.

In a void context, the input text just has the matched substring (and any specified prefix) removed.

**gen\_extract\_tagged**

(Note: This subroutine is only available under Perl5.005)

`gen_extract_tagged` generates a new anonymous subroutine which extracts text between (balanced) specified tags. In other words, it generates a function identical in function to `extract_tagged`.

The difference between `extract_tagged` and the anonymous subroutines generated by `gen_extract_tagged`, is that those generated subroutines:

- do not have to reparse tag specification or parsing options every time they are called (whereas `extract_tagged` has to effectively rebuild its tag parser on every call);
- make use of the new `qr//` construct to pre-compile the regexes they use (whereas `extract_tagged` uses standard string variable interpolation to create tag-matching patterns).

The subroutine takes up to four optional arguments (the same set as `extract_tagged` except for the string to be processed). It returns a reference to a subroutine which in turn takes a single argument (the text to be extracted from).

In other words, the implementation of `extract_tagged` is exactly equivalent to:

```
sub extract_tagged
{
 my $text = shift;
 $extractor = gen_extract_tagged(@_);
 return $extractor->($text);
}
```

(although `extract_tagged` is not currently implemented that way, in order to preserve pre-5.005 compatibility).

Using `gen_extract_tagged` to create extraction functions for specific tags is a good idea if those functions are going to be called more than once, since their performance is typically twice as good as the more general-purpose `extract_tagged`.

**extract\_quotelike**

`extract_quotelike` attempts to recognize, extract, and segment any one of the various Perl quotes and quotelike operators (see [perlop\(3\)](#)) Nested backslashed delimiters, embedded balanced bracket delimiters (for the quotelike operators), and trailing modifiers are all caught. For example, in:

```
extract_quotelike 'q # an octothorpe: \# (not the end of the q!) #'
extract_quotelike ' "You said, \"Use sed\".\" '
extract_quotelike ' s{ ([A-Z]{1,8}\\. [A-Z]{3}) } /\L$1\E/; '
extract_quotelike ' tr/\\\\/\\\\\\\\\\\\/ds; '
```

the full Perl quotelike operations are all extracted correctly.

Note too that, when using the `/x` modifier on a regex, any comment containing the current pattern delimiter will cause the regex to be immediately terminated. In other words:

```
'm /
 (?i) # CASE INSENSITIVE
 [a-z_] # LEADING ALPHABETIC/UNDERSCORE
 [a-z0-9]* # FOLLOWED BY ANY NUMBER OF ALPHANUMERICS
/x'
```

will be extracted as if it were:

```
'm /
 (?i) # CASE INSENSITIVE
```

```
[a-z_] # LEADING ALPHABETIC/'
```

This behaviour is identical to that of the actual compiler.

`extract_quotelike` takes two arguments: the text to be processed and a prefix to be matched at the very beginning of the text. If no prefix is specified, optional whitespace is the default. If no text is given, `$_` is used.

In a list context, an array of 11 elements is returned. The elements are:

- [0] the extracted quotelike substring (including trailing modifiers),
- [1] the remainder of the input text,
- [2] the prefix substring (if any),
- [3] the name of the quotelike operator (if any),
- [4] the left delimiter of the first block of the operation,
- [5] the text of the first block of the operation (that is, the contents of a quote, the regex of a match or substitution or the target list of a translation),
- [6] the right delimiter of the first block of the operation,
- [7] the left delimiter of the second block of the operation (that is, if it is an `s`, `tr`, or `y`),
- [8] the text of the second block of the operation (that is, the replacement of a substitution or the translation list of a translation),
- [9] the right delimiter of the second block of the operation (if any),
- [10] the trailing modifiers on the operation (if any).

For each of the fields marked "(if any)" the default value on success is an empty string. On failure, all of these values (except the remaining text) are `undef`.

In a scalar context, `extract_quotelike` returns just the complete substring that matched a quotelike operation (or `undef` on failure). In a scalar or void context, the input text has the same substring (and any specified prefix) removed.

Examples:

```
Remove the first quotelike literal that appears in text
 $quotelike = extract_quotelike($text, '.*?');

Replace one or more leading whitespace-separated quotelike
literals in $_ with "<QLL>"
 do { $_ = join '<QLL>', (extract_quotelike)[2,1] } until $@;

Isolate the search pattern in a quotelike operation from $text
 ($op,$pat) = (extract_quotelike $text)[3,5];
 if ($op =~ /[ms]/)
 {
 print "search pattern: $pat\n";
 }
 else
 {
 print "$op is not a pattern matching operation\n";
 }
}
```

**extract\_quotelike and "here documents"**

`extract_quotelike` can successfully extract "here documents" from an input string, but with an important caveat in list contexts.

Unlike other types of quote-like literals, a here document is rarely a contiguous substring. For example, a typical piece of code using here document might look like this:

```
<<'EOMSG' || die;
This is the message.
EOMSG
exit;
```

Given this as an input string in a scalar context, `extract_quotelike` would correctly return the string "<<'EOMSG'\nThis is the message.\nEOMSG", leaving the string " || die;\nexit;" in the original variable. In other words, the two separate pieces of the here document are successfully extracted and concatenated.

In a list context, `extract_quotelike` would return the list

- [0] "<<'EOMSG'\nThis is the message.\nEOMSG\n" (i.e. the full extracted here document, including fore and aft delimiters),
- [1] " || die;\nexit;" (i.e. the remainder of the input text, concatenated),
- [2] "" (i.e. the prefix substring — trivial in this case),
- [3] "<<" (i.e. the "name" of the quotelike operator)
- [4] "'EOMSG'" (i.e. the left delimiter of the here document, including any quotes),
- [5] "This is the message.\n" (i.e. the text of the here document),
- [6] "EOMSG" (i.e. the right delimiter of the here document),
- [7..10] "" (a here document has no second left delimiter, second text, second right delimiter, or trailing modifiers).

However, the matching position of the input variable would be set to "exit;" (i.e. *after* the closing delimiter of the here document), which would cause the earlier " || die;\nexit;" to be skipped in any sequence of code fragment extractions.

To avoid this problem, when it encounters a here document while extracting from a modifiable string, `extract_quotelike` silently rearranges the string to an equivalent piece of Perl:

```
<<'EOMSG'
This is the message.
EOMSG
|| die;
exit;
```

in which the here document *is* contiguous. It still leaves the matching position after the here document, but now the rest of the line on which the here document starts is not skipped.

To prevent `<extract_quotelike` from mucking about with the input in this way (this is the only case where a list-context `extract_quotelike` does so), you can pass the input variable as an interpolated literal:

```
$quotelike = extract_quotelike("$var");
```

**extract\_codeblock**

`extract_codeblock` attempts to recognize and extract a balanced bracket delimited substring that may contain unbalanced brackets inside Perl quotes or quotelike operations. That is, `extract_codeblock` is like a combination of "`extract_bracketed`" and "`extract_quotelike`".

`extract_codeblock` takes the same initial three parameters as `extract_bracketed`: a text to process, a set of delimiter brackets to look for, and a prefix to match first. It also takes an optional fourth parameter, which allows the outermost delimiter brackets to be specified separately (see below).

Omitting the first argument (input text) means process `$_` instead. Omitting the second argument (delimiter brackets) indicates that only `{ }` is to be used. Omitting the third argument (prefix argument) implies optional whitespace at the start. Omitting the fourth argument (outermost delimiter brackets) indicates that the value of the second argument is to be used for the outermost delimiters.

Once the prefix and the outermost opening delimiter bracket have been recognized, code blocks are extracted by stepping through the input text and trying the following alternatives in sequence:

1. Try and match a closing delimiter bracket. If the bracket was the same species as the last opening bracket, return the substring to that point. If the bracket was mismatched, return an error.
2. Try to match a quote or quotelike operator. If found, call `extract_quotelike` to eat it. If `extract_quotelike` fails, return the error it returned. Otherwise go back to step 1.
3. Try to match an opening delimiter bracket. If found, call `extract_codeblock` recursively to eat the embedded block. If the recursive call fails, return an error. Otherwise, go back to step 1.
4. Unconditionally match a bareword or any other single character, and then go back to step 1.

Examples:

```
Find a while loop in the text
 if ($text =~ s/. *?while\s*\{ /\{ /)
 {
 $loop = "while " . extract_codeblock($text);
 }

Remove the first round-bracketed list (which may include
round- or curly-bracketed code blocks or quotelike operators)
 extract_codeblock $text, "(){}", '[^()*]*';
```

The ability to specify a different outermost delimiter bracket is useful in some circumstances. For example, in the `Parse::RecDescent` module, parser actions which are to be performed only on a successful parse are specified using a `<defer: ...>` directive. For example:

```
sentence: subject verb object
 <defer: { $::theVerb = $item{verb} } >
```

`Parse::RecDescent` uses `extract_codeblock($text, '{ }<>')` to extract the code within the `<defer: ...>` directive, but there's a problem.

A deferred action like this:

```
<defer: { if ($count > 10) { $count -- } } >
```

will be incorrectly parsed as:

```
<defer: { if ($count >
```

because the "less than" operator is interpreted as a closing delimiter.

But, by extracting the directive using `extract_codeblock($text, '{ }', undef, '<>')` the `>` character is only treated as a delimited at the outermost level of the code block, so the directive is parsed correctly.

### **extract\_multiple**

The `extract_multiple` subroutine takes a string to be processed and a list of extractors (subroutines or regular expressions) to apply to that string.

In an array context `extract_multiple` returns an array of substrings of the original string, as extracted by the specified extractors. In a scalar context, `extract_multiple` returns the first substring successfully extracted from the original string. In both scalar and void contexts the original string has the first successfully extracted substring removed from it. In all contexts `extract_multiple` starts at the current `pos` of the string, and sets that `pos` appropriately after it matches.

Hence, the aim of a call to `extract_multiple` in a list context is to split the processed string into as many non-overlapping fields as possible, by repeatedly applying each of the specified extractors to the remainder of the string. Thus `extract_multiple` is a generalized form of Perl's `split` subroutine.

The subroutine takes up to four optional arguments:

1. A string to be processed (`$_` if the string is omitted or `undef`)
2. A reference to a list of subroutine references and/or `qr//` objects and/or literal strings and/or hash references, specifying the extractors to be used to split the string. If this argument is omitted (or `undef`) the list:

```
[
 sub { extract_variable($_[0], '') },
 sub { extract_quotelike($_[0], '') },
 sub { extract_codeblock($_[0], '{', '}', '') },
]
```

is used.

3. A number specifying the maximum number of fields to return. If this argument is omitted (or `undef`), `split` continues as long as possible.

If the third argument is *N*, then extraction continues until *N* fields have been successfully extracted, or until the string has been completely processed.

Note that in scalar and void contexts the value of this argument is automatically reset to 1 (under `-w`, a warning is issued if the argument has to be reset).

4. A value indicating whether unmatched substrings (see below) within the text should be skipped or returned as fields. If the value is true, such substrings are skipped. Otherwise, they are returned.

The extraction process works by applying each extractor in sequence to the text string.

If the extractor is a subroutine it is called in a list context and is expected to return a list of a single element, namely the extracted text. It may optionally also return two further arguments: a string representing the text left after extraction (like `$'` for a pattern match), and a string representing any prefix skipped before the extraction (like `$`` in a pattern match). Note that this is designed to facilitate the use of other `Text::Balanced` subroutines with `extract_multiple`. Note too that the value returned by an extractor subroutine need not bear any relationship to the corresponding substring of the original text (see examples below).

If the extractor is a precompiled regular expression or a string, it is matched against the text in a scalar context with a leading `'G'` and the `gc` modifiers enabled. The extracted value is either `$1` if that variable is defined after the match, or else the complete match (i.e. `$&`).

If the extractor is a hash reference, it must contain exactly one element. The value of that element is one of the above extractor types (subroutine reference, regular expression, or string). The key of that element is the name of a class into which the successful return value of the extractor will be blessed.

If an extractor returns a defined value, that value is immediately treated as the next extracted field and pushed onto the list of fields. If the extractor was specified in a hash reference, the field is also blessed into the appropriate class,

If the extractor fails to match (in the case of a regex extractor), or returns an empty list or an undefined value (in the case of a subroutine extractor), it is assumed to have failed to extract. If none of the extractor subroutines succeeds, then one character is extracted from the start of the text and the extraction subroutines

reapplied. Characters which are thus removed are accumulated and eventually become the next field (unless the fourth argument is true, in which case they are discarded).

For example, the following extracts substrings that are valid Perl variables:

```
@fields = extract_multiple($text,
 [sub { extract_variable($_[0]) }],
 undef, 1);
```

This example separates a text into fields which are quote delimited, curly bracketed, and anything else. The delimited and bracketed parts are also blessed to identify them (the "anything else" is unblessed):

```
@fields = extract_multiple($text,
 [
 { Delim => sub { extract_delimited($_[0], q{'"'}) } },
 { Brack => sub { extract_bracketed($_[0], '{ }') } },
]);
```

This call extracts the next single substring that is a valid Perl quotelike operator (and removes it from \$text):

```
$quotelike = extract_multiple($text,
 [
 sub { extract_quotelike($_[0]) },
], undef, 1);
```

Finally, here is yet another way to do comma-separated value parsing:

```
@fields = extract_multiple($csv_text,
 [
 sub { extract_delimited($_[0], q{'"'}) },
 qr/([^\,]+)(.*)/,
],
 undef, 1);
```

The list in the second argument means: *"Try and extract a ' or " delimited string, otherwise extract anything up to a comma..."*. The undef third argument means: *"...as many times as possible..."*, and the true value in the fourth argument means *"...discarding anything else that appears (i.e. the commas)"*.

If you wanted the commas preserved as separate fields (i.e. like split does if your split pattern has capturing parentheses), you would just make the last parameter undefined (or remove it).

### gen\_delimited\_pat

The `gen_delimited_pat` subroutine takes a single (string) argument and builds a Friedl-style optimized regex that matches a string delimited by any one of the characters in the single argument. For example:

```
gen_delimited_pat(q{'"'})
```

returns the regex:

```
(?:\"(?:\\\"|(?!\")\S)*\"|\'(?:\\\'|(?!\\')\S)*\')
```

Note that the specified delimiters are automatically quotemeta'd.

A typical use of `gen_delimited_pat` would be to build special purpose tags for `extract_tagged`. For example, to properly ignore "empty" XML elements (which might contain quoted strings):

```
my $empty_tag = '<(' . gen_delimited_pat(q{'"'}) . ' |.)+>';
extract_tagged($text, undef, undef, undef, {ignore => [$empty_tag]});
```

`gen_delimited_pat` may also be called with an optional second argument, which specifies the "escape" character(s) to be used for each delimiter. For example to match a Pascal-style string (where ' is the

delimiter and `` is a literal ` within the string):

```
gen_delimited_pat(q{''},q{''}) ;
```

Different escape characters can be specified for different delimiters. For example, to specify that `/` is the escape for single quotes and `%` is the escape for double quotes:

```
gen_delimited_pat(q{' "%'},q{'/%'}) ;
```

If more delimiters than escape chars are specified, the last escape char is used for the remaining delimiters. If no escape char is specified for a given specified delimiter, `` is used.

Note that `gen_delimited_pat` was previously called `delimited_pat`. That name may still be used, but is now deprecated.

## DIAGNOSTICS

In a list context, all the functions return `(undef,$original_text)` on failure. In a scalar context, failure is indicated by returning `undef` (in this case the input text is not modified in any way).

In addition, on failure in *any* context, the `$@` variable is set. Accessing `$@->{error}` returns one of the error diagnostics listed below. Accessing `$@->{pos}` returns the offset into the original string at which the error was detected (although not necessarily where it occurred!) Printing `$@` directly produces the error message, with the offset appended. On success, the `$@` variable is guaranteed to be `undef`.

The available diagnostics are:

Did not find a suitable bracket: "%s"

The delimiter provided to `extract_bracketed` was not one of `() [] <> {}`.

Did not find prefix: /%s/

A non-optional prefix was specified but wasn't found at the start of the text.

Did not find opening bracket after prefix: "%s"

`extract_bracketed` or `extract_codeblock` was expecting a particular kind of bracket at the start of the text, and didn't find it.

No quotelike operator found after prefix: "%s"

`extract_quotelike` didn't find one of the quotelike operators `q`, `qq`, `qw`, `qx`, `s`, `tr` or `y` at the start of the substring it was extracting.

Unmatched closing bracket: "%c"

`extract_bracketed`, `extract_quotelike` or `extract_codeblock` encountered a closing bracket where none was expected.

Unmatched opening bracket(s): "%s"

`extract_bracketed`, `extract_quotelike` or `extract_codeblock` ran out of characters in the text before closing one or more levels of nested brackets.

Unmatched embedded quote (%s)

`extract_bracketed` attempted to match an embedded quoted substring, but failed to find a closing quote to match it.

Did not find closing delimiter to match '%s'

`extract_quotelike` was unable to find a closing delimiter to match the one that opened the quote-like operation.

Mismatched closing bracket: expected "%c" but found "%s"

`extract_bracketed`, `extract_quotelike` or `extract_codeblock` found a valid bracket delimiter, but it was the wrong species. This usually indicates a nesting error, but may indicate incorrect quoting or escaping.

**No block delimiter found after quotelike "%s"**

`extract_quotelike` or `extract_codeblock` found one of the quotelike operators `q`, `qq`, `qw`, `qx`, `s`, `tr` or `y` without a suitable block after it.

**Did not find leading dereferencer**

`extract_variable` was expecting one of `'$'`, `'@'`, or `'%'` at the start of a variable, but didn't find any of them.

**Bad identifier after dereferencer**

`extract_variable` found a `'$'`, `'@'`, or `'%'` indicating a variable, but that character was not followed by a legal Perl identifier.

**Did not find expected opening bracket at %s**

`extract_codeblock` failed to find any of the outermost opening brackets that were specified.

**Improperly nested codeblock at %s**

A nested code block was found that started with a delimiter that was specified as being only to be used as an outermost bracket.

**Missing second block for quotelike "%s"**

`extract_codeblock` or `extract_quotelike` found one of the quotelike operators `s`, `tr` or `y` followed by only one block.

**No match found for opening bracket**

`extract_codeblock` failed to find a closing bracket to match the outermost opening bracket.

**Did not find opening tag: %s/**

`extract_tagged` did not find a suitable opening tag (after any specified prefix was removed).

**Unable to construct closing tag to match: %s/**

`extract_tagged` matched the specified opening tag and tried to modify the matched text to produce a matching closing tag (because none was specified). It failed to generate the closing tag, almost certainly because the opening tag did not start with a bracket of some kind.

**Found invalid nested tag: %s**

`extract_tagged` found a nested tag that appeared in the "reject" list (and the failure mode was not "MAX" or "PARA").

**Found unbalanced nested tag: %s**

`extract_tagged` found a nested opening tag that was not matched by a corresponding nested closing tag (and the failure mode was not "MAX" or "PARA").

**Did not find closing tag**

`extract_tagged` reached the end of the text without finding a closing tag to match the original opening tag (and the failure mode was not "MAX" or "PARA").

**BUGS AND IRRITATIONS**

There are undoubtedly serious bugs lurking somewhere in this code, if only because parts of it give the impression of understanding a great deal more about Perl than they really do.

Bug reports and other feedback are most welcome.

**NAME**

Text::ParseWords – parse text into an array of tokens or array of arrays

**SYNOPSIS**

```
use Text::ParseWords;
@lists = &nested_quotewords($delim, $keep, @lines);
@words = "ewords($delim, $keep, @lines);
@words = &shellwords(@lines);
@words = &parse_line($delim, $keep, $line);
@words = &old_shellwords(@lines); # DEPRECATED!
```

**DESCRIPTION**

The `&nested_quotewords()` and `&quotewords()` functions accept a delimiter (which can be a regular expression) and a list of lines and then breaks those lines up into a list of words ignoring delimiters that appear inside quotes. `&quotewords()` returns all of the tokens in a single long list, while `&nested_quotewords()` returns a list of token lists corresponding to the elements of `@lines`. `&parse_line()` does tokenizing on a single string. The `&*quotewords()` functions simply call `&parse_lines()`, so if you're only splitting one line you can call `&parse_lines()` directly and save a function call.

The `$keep` argument is a boolean flag. If true, then the tokens are split on the specified delimiter, but all other characters (quotes, backslashes, etc.) are kept in the tokens. If `$keep` is false then the `&*quotewords()` functions remove all quotes and backslashes that are not themselves backslash-escaped or inside of single quotes (i.e., `&quotewords()` tries to interpret these characters just like the Bourne shell). NB: these semantics are significantly different from the original version of this module shipped with Perl 5.000 through 5.004. As an additional feature, `$keep` may be the keyword "delimiters" which causes the functions to preserve the delimiters in each string as tokens in the token lists, in addition to preserving quote and backslash characters.

`&shellwords()` is written as a special case of `&quotewords()`, and it does token parsing with whitespace as a delimiter— similar to most Unix shells.

**EXAMPLES**

The sample program:

```
use Text::ParseWords;
@words = "ewords('\s+', 0, q{this is "a test" of\ quotewords \"for you});
$i = 0;
foreach (@words) {
 print "$i: <$_>\n";
 $i++;
}
```

produces:

```
0: <this>
1: <is>
2: <a test>
3: <of quotewords>
4: <"for>
5: <you>
```

demonstrating:

- 0 a simple word
- 1 multiple spaces are skipped because of our `$delim`

- 2 use of quotes to include a space in a word
- 3 use of a backslash to include a space in a word
- 4 use of a backslash to remove the special meaning of a double-quote
- 5 another simple word (note the lack of effect of the backslashed double-quote)

Replacing `&quotewords('\s+', 0, q{this is...})` with `&shellwords(q{this is...})` is a simpler way to accomplish the same thing.

## AUTHORS

Maintainer is Hal Pomeranz <pomeranz@netcom.com, 1994–1997 (Original author unknown). Much of the code for `&parse_line()` (including the primary regexp) from Joerk Behrends <jbehrends@multimediaproduzenten.de.

Examples section another documentation provided by John Heidemann <johnh@ISI.EDU

Bug reports, patches, and nagging provided by lots of folks— thanks everybody! Special thanks to Michael Schwern <schwern@envirolink.org for assuring me that a `&nested_quotewords()` would be useful, and to Jeff Friedl <jfriedl@yahoo-inc.com for telling me not to worry about error-checking (sort of— you had to be there).

## NAME

Text::Soundex – Implementation of the Soundex Algorithm as Described by Knuth

## SYNOPSIS

```
use Text::Soundex;

$code = soundex $string; # get soundex code for a string
@codes = soundex @list; # get list of codes for list of strings

set value to be returned for strings without soundex code

$soundex_nocode = 'Z000';
```

## DESCRIPTION

This module implements the soundex algorithm as described by Donald Knuth in Volume 3 of **The Art of Computer Programming**. The algorithm is intended to hash words (in particular surnames) into a small space using a simple model which approximates the sound of the word when spoken by an English speaker. Each word is reduced to a four character string, the first character being an upper case letter and the remaining three being digits.

If there is no soundex code representation for a string then the value of `$soundex_nocode` is returned. This is initially set to `undef`, but many people seem to prefer an *unlikely* value like `Z000` (how unlikely this is depends on the data set being dealt with.) Any value can be assigned to `$soundex_nocode`.

In scalar context `soundex` returns the soundex code of its first argument, and in list context a list is returned in which each element is the soundex code for the corresponding argument passed to `soundex` e.g.

```
@codes = soundex qw(Mike Stok);
```

leaves `@codes` containing `('M200', 'S320')`.

## EXAMPLES

Knuth's examples of various names and the soundex codes they map to are listed below:

```
Euler, Ellery -> E460
Gauss, Ghosh -> G200
Hilbert, Heilbronn -> H416
Knuth, Kant -> K530
Lloyd, Ladd -> L300
Lukasiewicz, Lissajous -> L222
```

so:

```
$code = soundex 'Knuth'; # $code contains 'K530'
@list = soundex qw(Lloyd Gauss); # @list contains 'L300', 'G200'
```

## LIMITATIONS

As the soundex algorithm was originally used a **long** time ago in the US it considers only the English alphabet and pronunciation.

As it is mapping a large space (arbitrary length strings) onto a small space (single letter plus 3 digits) no inference can be made about the similarity of two strings which end up with the same soundex code. For example, both Hilbert and Heilbronn end up with a soundex code of H416.

## AUTHOR

This code was implemented by Mike Stok ([stok@cybercom.net](mailto:stok@cybercom.net)) from the description given by Knuth. Ian Phillipps ([ian@pipex.net](mailto:ian@pipex.net)) and Rich Pinder ([rpinder@hsc.usc.edu](mailto:rpinder@hsc.usc.edu)) supplied ideas and spotted mistakes.

**NAME**

Text::Tabs — expand and unexpand tabs per the unix `expand(1)` and `unexpand(1)`

**SYNOPSIS**

```
use Text::Tabs;

$tabstop = 4;
@lines_without_tabs = expand(@lines_with_tabs);
@lines_with_tabs = unexpand(@lines_without_tabs);
```

**DESCRIPTION**

Text::Tabs does about what the unix utilities `expand(1)` and `unexpand(1)` do. Given a line with tabs in it, `expand` will replace the tabs with the appropriate number of spaces. Given a line with or without tabs in it, `unexpand` will add tabs when it can save bytes by doing so. Invisible compression with plain ascii!

**BUGS**

`expand` doesn't handle newlines very quickly — do not feed it an entire document in one string. Instead feed it an array of lines.

**AUTHOR**

David Muir Sharnoff <muir@idiom.com>

**NAME**

Text::Wrap – line wrapping to form simple paragraphs

**SYNOPSIS****Example 1**

```
use Text::Wrap

$initial_tab = "\t"; # Tab before first line
$subsequent_tab = ""; # All other lines flush left

print wrap($initial_tab, $subsequent_tab, @text);
print fill($initial_tab, $subsequent_tab, @text);

@lines = wrap($initial_tab, $subsequent_tab, @text);

@paragraphs = fill($initial_tab, $subsequent_tab, @text);
```

**Example 2**

```
use Text::Wrap qw(wrap $columns $huge);

$columns = 132; # Wrap at 132 characters
$huge = 'die';
$huge = 'wrap';
$huge = 'overflow';
```

**Example 3**

```
use Text::Wrap

$Text::Wrap::columns = 72;
print wrap(' ', ' ', @text);
```

**DESCRIPTION**

`Text::Wrap::wrap()` is a very simple paragraph formatter. It formats a single paragraph at a time by breaking lines at word boundaries. Indentation is controlled for the first line (`$initial_tab`) and all subsequent lines (`$subsequent_tab`) independently. Please note: `$initial_tab` and `$subsequent_tab` are the literal strings that will be used: it is unlikely you would want to pass in a number.

`Text::Wrap::fill()` is a simple multi-paragraph formatter. It formats each paragraph separately and then joins them together when it's done. It will destroy any whitespace in the original text. It breaks text into paragraphs by looking for whitespace after a newline. In other respects it acts like `wrap()`.

**OVERRIDES**

`Text::Wrap::wrap()` has a number of variables that control its behavior. Because other modules might be using `Text::Wrap::wrap()` it is suggested that you leave these variables alone! If you can't do that, then use `local($Text::Wrap::VARIABLE) = YOURVALUE` when you change the values so that the original value is restored. This `local()` trick will not work if you import the variable into your own namespace.

Lines are wrapped at `$Text::Wrap::columns` columns. `$Text::Wrap::columns` should be set to the full width of your output device. In fact, every resulting line will have length of no more than `$columns - 1`.

It is possible to control which characters terminate words by modifying `$Text::Wrap::break`. Set this to a string such as `'[\s:]'` (to break before spaces or colons) or a pre-compiled regexp such as `qr/[\s']/` (to break before spaces or apostrophes). The default is simply `'\s'`; that is, words are terminated by spaces. (This means, among other things, that trailing punctuation such as full stops or commas stay with the word they are "attached" to.)

Beginner note: In example 2, above `$columns` is imported into the local namespace, and set locally. In example 3, `$Text::Wrap::columns` is set in its own namespace without importing it.

`Text::Wrap::wrap()` starts its work by expanding all the tabs in its input into spaces. The last thing it does is to turn spaces back into tabs. If you do not want tabs in your results, set

`$Text::Wrap::unexpand` to a false value. Likewise if you do not want to use 8-character tabstops, set `$Text::Wrap::tabstop` to the number of characters you do want for your tabstops.

If you want to separate your lines with something other than `\n` then set `$Text::Wrap::separator` to your preference.

When words that are longer than `$columns` are encountered, they are broken up. `wrap()` adds a `"\n"` at column `$columns`. This behavior can be overridden by setting `$huge` to `'die'` or to `'overflow'`. When set to `'die'`, large words will cause `die()` to be called. When set to `'overflow'`, large words will be left intact.

Historical notes: `'die'` used to be the default value of `$huge`. Now, `'wrap'` is the default value.

## EXAMPLE

```
print wrap("\t","", "This is a bit of text that forms
a normal book-style paragraph");
```

**NAME**

Thread – manipulate threads in Perl (for old code only)

**CAVEAT**

Perl has two thread models.

In Perl 5.005 the thread model was that all data is implicitly shared and shared access to data has to be explicitly synchronized. This model is called "5005threads".

In Perl 5.6 a new model was introduced in which all is was thread local and shared access to data has to be explicitly declared. This model is called "ithreads", for "interpreter threads".

In Perl 5.6 the ithreads model was not available as a public API, only as an internal API that was available for extension writers, and to implement `fork()` emulation on Win32 platforms.

In Perl 5.8 the ithreads model became available through the `threads` module.

Neither model is configured by default into Perl (except, as mentioned above, in Win32 ithreads are always available.) You can see your Perl's threading configuration by running `perl -V` and looking for the *use...threads* variables, or inside script by `use Config;` and testing for `$Config{use5005threads}` and `$Config{useithreads}`.

For old code and interim backwards compatibility, the Thread module has been reworked to function as a frontend for both 5005threads and ithreads.

Note that the compatibility is not complete: because the data sharing models are directly opposed, anything to do with data sharing has to be thought differently. With the ithreads you must explicitly `share()` variables between the threads.

For new code the use of the Thread module is discouraged and the direct use of the `threads` and `threads::shared` modules is encouraged instead.

Finally, note that there are many known serious problems with the 5005threads, one of the least of which is that regular expression match variables like `$1` are not threadsafe, that is, they easily get corrupted by competing threads. Other problems include more insidious data corruption and mysterious crashes. You are seriously urged to use ithreads instead.

**SYNOPSIS**

```
use Thread;

my $t = Thread->new(&start_sub, @start_args);

$result = $t->join;
$result = $t->eval;
$t->detach;

if ($t->done) {
 $t->join;
}

if ($t->equal($another_thread)) {
 # ...
}

yield();

my $tid = Thread->self->tid;

lock($scalar);
lock(@array);
lock(%hash);
```

```
lock(\&sub); # not available with ithreads

$flags = $t->flags; # not available with ithreads

my @list = Thread->list; # not available with ithreads

use Thread 'async';
```

## DESCRIPTION

The Thread module provides multithreading support for perl.

## FUNCTIONS

```
$thread = Thread->new(\&start_sub)
$thread = Thread->new(\&start_sub, LIST)
```

`new` starts a new thread of execution in the referenced subroutine. The optional list is passed as parameters to the subroutine. Execution continues in both the subroutine and the code after the new call.

`Thread->new` returns a thread object representing the newly created thread.

### lock VARIABLE

`lock` places a lock on a variable until the lock goes out of scope.

If the variable is locked by another thread, the `lock` call will block until it's available. `lock` is recursive, so multiple calls to `lock` are safe—the variable will remain locked until the outermost lock on the variable goes out of scope.

Locks on variables only affect `lock` calls—they do *not* affect normal access to a variable. (Locks on subs are different, and covered in a bit.) If you really, *really* want locks to block access, then go ahead and tie them to something and manage this yourself. This is done on purpose. While managing access to variables is a good thing, Perl doesn't force you out of its living room...

If a container object, such as a hash or array, is locked, all the elements of that container are not locked. For example, if a thread does a `lock @a`, any other thread doing a `lock ($a[12])` won't block.

With 5005threads you may also lock a sub, using `lock &sub`. Any calls to that sub from another thread will block until the lock is released. This behaviour is not equivalent to declaring the sub with the `locked` attribute. The `locked` attribute serializes access to a subroutine, but allows different threads non-simultaneous access. `lock &sub`, on the other hand, will not allow *any* other thread access for the duration of the lock.

Finally, `lock` will traverse up references exactly *one* level. `lock(\$a)` is equivalent to `lock($a)`, while `lock(\(\$a)` is not.

### async BLOCK;

`async` creates a thread to execute the block immediately following it. This block is treated as an anonymous sub, and so must have a semi-colon after the closing brace. Like `Thread->new`, `async` returns a thread object.

### Thread->self

The `Thread->self` function returns a thread object that represents the thread making the `Thread->self` call.

### cond\_wait VARIABLE

The `cond_wait` function takes a **locked** variable as a parameter, unlocks the variable, and blocks until another thread does a `cond_signal` or `cond_broadcast` for that same locked variable. The variable that `cond_wait` blocked on is relocked after the `cond_wait` is satisfied. If there are multiple threads `cond_waiting` on the same variable, all but one will

reblock waiting to reacquire the lock on the variable. (So if you're only using `cond_wait` for synchronization, give up the lock as soon as possible.)

#### `cond_signal` VARIABLE

The `cond_signal` function takes a locked variable as a parameter and unblocks one thread that's `cond_waiting` on that variable. If more than one thread is blocked in a `cond_wait` on that variable, only one (and which one is indeterminate) will be unblocked.

If there are no threads blocked in a `cond_wait` on the variable, the signal is discarded.

#### `cond_broadcast` VARIABLE

The `cond_broadcast` function works similarly to `cond_signal`. `cond_broadcast`, though, will unblock **all** the threads that are blocked in a `cond_wait` on the locked variable, rather than only one.

`yield` The `yield` function allows another thread to take control of the CPU. The exact results are implementation-dependent.

### METHODS

`join` `join` waits for a thread to end and returns any values the thread exited with. `join` will block until the thread has ended, though it won't block if the thread has already terminated.

If the thread being joined died, the error it died with will be returned at this time. If you don't want the thread performing the `join` to die as well, you should either wrap the `join` in an `eval` or use the `eval` thread method instead of `join`.

`eval` The `eval` method wraps an `eval` around a `join`, and so waits for a thread to exit, passing along any values the thread might have returned. Errors, of course, get placed into `$@`. (Not available with `ithreads`.)

`detach` `detach` tells a thread that it is never going to be joined i.e. that all traces of its existence can be removed once it stops running. Errors in detached threads will not be visible anywhere – if you want to catch them, you should use `$SIG{__DIE__}` or something like that.

`equal` `equal` tests whether two thread objects represent the same thread and returns true if they do.

`tid` The `tid` method returns the `tid` of a thread. The `tid` is a monotonically increasing integer assigned when a thread is created. The main thread of a program will have a `tid` of zero, while subsequent threads will have `tids` assigned starting with one.

`flags` The `flags` method returns the flags for the thread. This is the integer value corresponding to the internal flags for the thread, and the value may not be all that meaningful to you. (Not available with `ithreads`.)

`done` The `done` method returns true if the thread you're checking has finished, and false otherwise. (Not available with `ithreads`.)

### LIMITATIONS

The sequence number used to assign `tids` is a simple integer, and no checking is done to make sure the `tid` isn't currently in use. If a program creates more than  $2^{32} - 1$  threads in a single run, threads may be assigned duplicate `tids`. This limitation may be lifted in a future version of Perl.

### SEE ALSO

[\*threads::shared\*](#) (not available with `5005threads`)

[\*attributes\*](#), [\*Thread::Queue\*](#), [\*Thread::Semaphore\*](#), [\*Thread::Specific\*](#) (not available with `ithreads`)

**NAME**

Thread::Queue – thread-safe queues

**SYNOPSIS**

```
use Thread::Queue;
my $q = new Thread::Queue;
$q->enqueue("foo", "bar");
my $foo = $q->dequeue; # The "bar" is still in the queue.
my $foo = $q->dequeue_nb; # returns "bar", or undef if the queue was empty
my $left = $q->pending; # returns the number of items still in the queue
```

**DESCRIPTION**

A queue, as implemented by Thread::Queue is a thread-safe data structure much like a list. Any number of threads can safely add elements to the end of the list, or remove elements from the head of the list. (Queues don't permit adding or removing elements from the middle of the list).

**FUNCTIONS AND METHODS**

**new**        The new function creates a new empty queue.

**enqueue LIST**

The enqueue method adds a list of scalars on to the end of the queue. The queue will grow as needed to accommodate the list.

**dequeue**    The dequeue method removes a scalar from the head of the queue and returns it. If the queue is currently empty, dequeue will block the thread until another thread enqueues a scalar.

**dequeue\_nb**

The dequeue\_nb method, like the dequeue method, removes a scalar from the head of the queue and returns it. Unlike dequeue, though, dequeue\_nb won't block if the queue is empty, instead returning undef.

**pending**    The pending method returns the number of items still in the queue.

**SEE ALSO**

*threads, threads::shared*

**NAME**

Thread::Semaphore – thread-safe semaphores

**SYNOPSIS**

```
use Thread::Semaphore;
my $s = new Thread::Semaphore;
$s->up; # Also known as the semaphore V -operation.
The guarded section is here
$s->down; # Also known as the semaphore P -operation.

The default semaphore value is 1.
my $s = new Thread::Semaphore($initial_value);
$s->up($up_value);
$s->down($down_value);
```

**DESCRIPTION**

Semaphores provide a mechanism to regulate access to resources. Semaphores, unlike locks, aren't tied to particular scalars, and so may be used to control access to anything you care to use them for.

Semaphores don't limit their values to zero or one, so they can be used to control access to some resource that there may be more than one of. (For example, filehandles). Increment and decrement amounts aren't fixed at one either, so threads can reserve or return multiple resources at once.

**FUNCTIONS AND METHODS**

**new**  
**new NUMBER**

**new** creates a new semaphore, and initializes its count to the passed number. If no number is passed, the semaphore's count is set to one.

**down**  
**down NUMBER**

The **down** method decreases the semaphore's count by the specified number, or by one if no number has been specified. If the semaphore's count would drop below zero, this method will block until such time that the semaphore's count is equal to or larger than the amount you're downing the semaphore's count by.

**up**  
**up NUMBER**

The **up** method increases the semaphore's count by the number specified, or by one if no number has been specified. This will unblock any thread blocked trying to down the semaphore if the up raises the semaphore count above the amount that the downs are trying to decrement it by.

**NAME**

Thread::Signal – Start a thread which runs signal handlers reliably (for old code)

**CAVEAT**

For new code the use of the `Thread::Signal` module is discouraged and the direct use of the `threads` and associated modules is encouraged instead.

However, there is no direct equivalent of the `Thread::Signal` module in the new implementation of threads. On the bright side: signals are now delivered reliably to Perl programs that do not use threads. The handling of signals with the new threading features is up to the underlying thread implementation that is being used and may therefore be less reliable.

If you want to specify a thread-specific signal, you can alter the `%SIG` hash in the thread where you want to handle a signal differently from other threads. This at least seems to work under Linux. But there are no guarantees and your mileage may vary.

For the whole story about the development of threads in Perl, and why you should **not** be using this module unless you know what you're doing, see the CAVEAT of the `Thread` module.

**SYNOPSIS**

```
use Thread::Signal;

$SIG{HUP} = \&some_handler;
```

**DESCRIPTION**

The `Thread::Signal` module starts up a special signal handler thread. All signals to the process are delivered to it and it runs the associated `$SIG{FOO}` handlers for them. Without this module, signals arriving at inopportune moments (such as when perl's internals are in the middle of updating critical structures) cause the perl code of the handler to be run unsafely which can cause memory corruption or worse.

**BUGS**

This module changes the semantics of signal handling slightly in that the signal handler is run separately from the main thread (and in parallel with it). This means that tricks such as calling `die` from a signal handler behave differently (and, in particular, can't be used to exit directly from a system call).

**NAME**

Thread::Specific – thread-specific keys

**SYNOPSIS**

```
use Thread::Specific;
my $k = key_create Thread::Specific;
```

**DESCRIPTION**

`key_create` returns a unique thread-specific key.

**NAME**

threads::shared – Perl extension for sharing data structures between threads

**SYNOPSIS**

```
use threads;
use threads::shared;

my $var : shared;

my($scalar, @array, %hash);
share($scalar);
share(@array);
share(%hash);
my $bar = &share([]);
$hash{bar} = &share({});

{ lock(%hash); ... }

cond_wait($scalar);
cond_broadcast(@array);
cond_signal(%hash);
```

**DESCRIPTION**

By default, variables are private to each thread, and each newly created thread gets a private copy of each existing variable. This module allows you to share variables across different threads (and pseudoforks on Win32). It is used together with the threads module.

**EXPORT**

share, lock, cond\_wait, cond\_signal, cond\_broadcast

Note that if this module is imported when threads has not yet been loaded, then these functions all become no-ops. This makes it possible to write modules that will work in both threaded and non-threaded environments.

**FUNCTIONS****share VARIABLE**

share takes a value and marks it as shared. You can share a scalar, array, hash, scalar ref, array ref or hash ref. share will return the shared rvalue.

share will traverse up references exactly *one* level. share(\\$a) is equivalent to share(\$a), while share(\\\$a) is not.

A variable can also be marked as shared at compile time by using the shared attribute: my \$var : shared.

If you want to share a newly created reference unfortunately you need to use &share([]) and &share({}) syntax due to problems with Perl's prototyping.

**lock VARIABLE**

lock places a lock on a variable until the lock goes out of scope. If the variable is locked by another thread, the lock call will block until it's available. lock is recursive, so multiple calls to lock are safe — the variable will remain locked until the outermost lock on the variable goes out of scope.

If a container object, such as a hash or array, is locked, all the elements of that container are not locked. For example, if a thread does a lock @a, any other thread doing a lock(\$a[12]) won't block.

lock will traverse up references exactly *one* level. lock(\\$a) is equivalent to lock(\$a), while lock(\\\$a) is not.

Note that you cannot explicitly unlock a variable; you can only wait for the lock to go out of scope. If you need more fine-grained control, see [Thread::Semaphore](#).

#### cond\_wait VARIABLE

The `cond_wait` function takes a **locked** variable as a parameter, unlocks the variable, and blocks until another thread does a `cond_signal` or `cond_broadcast` for that same locked variable. The variable that `cond_wait` blocked on is relocked after the `cond_wait` is satisfied. If there are multiple threads `cond_waiting` on the same variable, all but one will reblock waiting to reacquire the lock on the variable. (So if you're only using `cond_wait` for synchronisation, give up the lock as soon as possible). The two actions of unlocking the variable and entering the blocked wait state are atomic. The two actions of exiting from the blocked wait state and relocking the variable are not.

It is important to note that the variable can be notified even if no thread `cond_signal` or `cond_broadcast` on the variable. It is therefore important to check the value of the variable and go back to waiting if the requirement is not fulfilled.

#### cond\_signal VARIABLE

The `cond_signal` function takes a **locked** variable as a parameter and unblocks one thread that's `cond_waiting` on that variable. If more than one thread is blocked in a `cond_wait` on that variable, only one (and which one is indeterminate) will be unblocked.

If there are no threads blocked in a `cond_wait` on the variable, the signal is discarded. By always locking before signaling, you can (with care), avoid signaling before another thread has entered `cond_wait()`.

`cond_signal` will normally generate a warning if you attempt to use it on an unlocked variable. On the rare occasions where doing this may be sensible, you can skip the warning with

```
{ no warnings 'threads'; cond_signal($foo) }
```

#### cond\_broadcast VARIABLE

The `cond_broadcast` function works similarly to `cond_signal`. `cond_broadcast`, though, will unblock **all** the threads that are blocked in a `cond_wait` on the locked variable, rather than only one.

## NOTES

`threads::shared` is designed to disable itself silently if threads are not available. If you want access to threads, you must use `threads` before you use `threads::shared`. `threads` will emit a warning if you use it after `threads::shared`.

## BUGS

`bless` is not supported on shared references. In the current version, `bless` will only bless the thread local reference and the blessing will not propagate to the other threads. This is expected to be implemented in a future version of Perl.

Does not support splice on arrays!

Taking references to the elements of shared arrays and hashes does not autovivify the elements, and neither does slicing a shared array/hash over non-existent indices/keys autovivify the elements.

`share()` allows you to share `$hashref->{key}` without giving any error message. But the `$hashref->{key}` is **not** shared, causing the error "locking can only be used on shared values" to occur when you attempt to lock `$hashref->{key}`.

## AUTHOR

`threads::shared` is released under the same license as Perl

Documentation borrowed from the old Thread.pm

**SEE ALSO**

*threads*, *perlthrtut*, <http://www.perl.com/pub/a/2002/06/11/threads.html>

**NAME**

threads – Perl extension allowing use of interpreter based threads from perl

**SYNOPSIS**

```
use threads;

sub start_thread {
 print "Thread started\n";
}

my $thread = threads->create("start_thread", "argument");
my $thread2 = $thread->create(sub { print "I am a thread" }, "argument");
my $thread3 = async { foreach (@files) { ... } };

$thread->join();
$thread->detach();

$thread = threads->self();
$thread = threads->object($tid);

$thread->tid();
threads->tid();
threads->self->tid();

threads->yield();

threads->list();
```

**DESCRIPTION**

Perl 5.6 introduced something called interpreter threads. Interpreter threads are different from "5005threads" (the thread model of Perl 5.005) by creating a new perl interpreter per thread and not sharing any data or state between threads by default.

Prior to perl 5.8 this has only been available to people embedding perl and for emulating `fork()` on windows.

The threads API is loosely based on the old Thread.pm API. It is very important to note that variables are not shared between threads, all variables are per default thread local. To use shared variables one must use `threads::shared`.

It is also important to note that you must enable threads by doing `use threads` as early as possible in the script itself and that it is not possible to enable threading inside an `eval` "", `do`, `require`, or `use`. In particular, if you are intending to share variables with `threads::shared`, you must use `threads` before you use `threads::shared` and `threads` will emit a warning if you do it the other way around.

`$thread = threads->create(function, LIST)`

This will create a new thread with the entry point function and give it LIST as parameters. It will return the corresponding threads object. The `new()` method is an alias for `create()`.

`$thread->join`

This will wait for the corresponding thread to join. When the thread finishes, `join()` will return the return values of the entry point function. If the thread has been detached, an error will be thrown. If the program exits without all other threads having been either joined or detached, then a warning will be issued. (A program exits either because one of its threads explicitly calls `exit()`, or in the case of the main thread, reaches the end of the main program file.)

`$thread->detach`

Will make the thread unjoinable, and cause any eventual return value to be discarded.

**threads-self**

This will return the thread object for the current thread.

**\$thread-tid**

This will return the id of the thread. Thread IDs are integers, with the main thread in a program being 0. Currently Perl assigns a unique tid to every thread ever created in your program, assigning the first thread to be created a tid of 1, and increasing the tid by 1 for each new thread that's created.

NB the class method `< threads-tid()` is a quick way to get the current thread id if you don't have your thread object handy.

**threads-object( tid )**

This will return the thread object for the thread associated with the specified tid. Returns undef if there is no thread associated with the tid or no tid is specified or the specified tid is undef.

**threads-yield();**

This is a suggestion to the OS to let this thread yield CPU time to other threads. What actually happens is highly dependent upon the underlying thread implementation.

You may do `use threads qw(yield)` then use just a bare `yield` in your code.

**threads-list();**

This will return a list of all non joined, non detached threads.

**async BLOCK;**

`async` creates a thread to execute the block immediately following it. This block is treated as an anonymous sub, and so must have a semi-colon after the closing brace. Like `< threads-new`, `async` returns a thread object.

**WARNINGS****A thread exited while %d other threads were still running**

A thread (not necessarily the main thread) exited while there were still other threads running. Usually it's a good idea to first collect the return values of the created threads by joining them, and only then exit from the main thread.

**TODO**

The current implementation of threads has been an attempt to get a correct threading system working that could be built on, and optimized, in newer versions of perl.

Currently the overhead of creating a thread is rather large, also the cost of returning values can be large. These are areas where there most likely will be work done to optimize what data that needs to be cloned.

**BUGS****Parent-Child threads.**

On some platforms it might not be possible to destroy "parent" threads while there are still existing child "threads".

This will possibly be fixed in later versions of perl.

**tid is l32**

The thread id is a 32 bit integer, it can potentially overflow. This might be fixed in a later version of perl.

**Returning objects**

When you return an object the entire stash that the object is blessed as well. This will lead to a large memory usage. The ideal situation would be to detect the original stash if it existed.

### Creating threads inside BEGIN blocks

Creating threads inside BEGIN blocks (or during the compilation phase in general) does not work. (In Windows, trying to use `fork()` inside BEGIN blocks is an equally losing proposition, since it has been implemented in very much the same way as threads.)

PERL\_OLD\_SIGNALS are not threadsafe, will not be.

If your Perl has been built with PERL\_OLD\_SIGNALS (one has to explicitly add that symbol to `cflags`, see `perl -V`), signal handling is not threadsafe.

**NAME**

Tie::Array – base class for tied arrays

**SYNOPSIS**

```
package Tie::NewArray;
use Tie::Array;
@ISA = ('Tie::Array');

mandatory methods
sub TIEARRAY { ... }
sub FETCH { ... }
sub FETCHSIZE { ... }

sub STORE { ... } # mandatory if elements writeable
sub STORESIZE { ... } # mandatory if elements can be added/deleted
sub EXISTS { ... } # mandatory if exists() expected to work
sub DELETE { ... } # mandatory if delete() expected to work

optional methods - for efficiency
sub CLEAR { ... }
sub PUSH { ... }
sub POP { ... }
sub SHIFT { ... }
sub UNSHIFT { ... }
sub SPLICE { ... }
sub EXTEND { ... }
sub DESTROY { ... }

package Tie::NewStdArray;
use Tie::Array;

@ISA = ('Tie::StdArray');

all methods provided by default

package main;

$object = tie @somearray, Tie::NewArray;
$object = tie @somearray, Tie::StdArray;
$object = tie @somearray, Tie::NewStdArray;
```

**DESCRIPTION**

This module provides methods for array-tying classes. See [perltie](#) for a list of the functions required in order to tie an array to a package. The basic **Tie::Array** package provides stub DESTROY, and EXTEND methods that do nothing, stub DELETE and EXISTS methods that croak() if the delete() or exists() builtins are ever called on the tied array, and implementations of PUSH, POP, SHIFT, UNSHIFT, SPLICE and CLEAR in terms of basic FETCH, STORE, FETCHSIZE, STORESIZE.

The **Tie::StdArray** package provides efficient methods required for tied arrays which are implemented as blessed references to an "inner" perl array. It inherits from **Tie::Array**, and should cause tied arrays to behave exactly like standard arrays, allowing for selective overloading of methods.

For developers wishing to write their own tied arrays, the required methods are briefly defined below. See the [perltie](#) section for more detailed descriptive, as well as example code:

**TIEARRAY classname, LIST**

The class method is invoked by the command `tie @array, classname`. Associates an array instance with the specified class. LIST would represent additional arguments (along the lines of [AnyDBM\\_File](#) and compatriots) needed to complete the association. The method should return an object of a class which provides the methods below.

**STORE** *this*, *index*, *value*

Store datum *value* into *index* for the tied array associated with object *this*. If this makes the array larger then class's mapping of `undef` should be returned for new positions.

**FETCH** *this*, *index*

Retrieve the datum in *index* for the tied array associated with object *this*.

**FETCHSIZE** *this*

Returns the total number of items in the tied array associated with object *this*. (Equivalent to `scalar(@array)`).

**STORESIZE** *this*, *count*

Sets the total number of items in the tied array associated with object *this* to be *count*. If this makes the array larger then class's mapping of `undef` should be returned for new positions. If the array becomes smaller then entries beyond *count* should be deleted.

**EXTEND** *this*, *count*

Informative call that array is likely to grow to have *count* entries. Can be used to optimize allocation. This method need do nothing.

**EXISTS** *this*, *key*

Verify that the element at index *key* exists in the tied array *this*.

The **Tie::Array** implementation is a stub that simply croaks.

**DELETE** *this*, *key*

Delete the element at index *key* from the tied array *this*.

The **Tie::Array** implementation is a stub that simply croaks.

**CLEAR** *this*

Clear (remove, delete, ...) all values from the tied array associated with object *this*.

**DESTROY** *this*

Normal object destructor method.

**PUSH** *this*, *LIST*

Append elements of *LIST* to the array.

**POP** *this*

Remove last element of the array and return it.

**SHIFT** *this*

Remove the first element of the array (shifting other elements down) and return it.

**UNSHIFT** *this*, *LIST*

Insert *LIST* elements at the beginning of the array, moving existing elements up to make room.

**SPLICE** *this*, *offset*, *length*, *LIST*

Perform the equivalent of `splice` on the array.

*offset* is optional and defaults to zero, negative values count back from the end of the array.

*length* is optional and defaults to rest of the array.

*LIST* may be empty.

Returns a list of the original *length* elements at *offset*.

**CAVEATS**

There is no support at present for tied @ISA. There is a potential conflict between magic entries needed to notice setting of @ISA, and those needed to implement 'tie'.

Very little consideration has been given to the behaviour of tied arrays when \$[ is not default value of zero.

**AUTHOR**

Nick Ing-Simmons <nik@tiuk.ti.com>

**NAME**

Tie::File – Access the lines of a disk file via a Perl array

**SYNOPSIS**

```
This file documents Tie::File version 0.93

tie @array, 'Tie::File', filename or die ...;

$array[13] = 'blah'; # line 13 of the file is now 'blah'
print $array[42]; # display line 42 of the file

$n_recs = @array; # how many records are in the file?
$#array -= 2; # chop two records off the end

for (@array) {
 s/PERL/Perl/g; # Replace PERL with Perl everywhere in the file
}

These are just like regular push, pop, unshift, shift, and splice
Except that they modify the file in the way you would expect

push @array, new_recs...;
my $r1 = pop @array;
unshift @array, new_recs...;
my $r1 = shift @array;
@old_recs = splice @array, 3, 7, new_recs...;

untie @array; # all finished
```

**DESCRIPTION**

Tie::File represents a regular text file as a Perl array. Each element in the array corresponds to a record in the file. The first line of the file is element 0 of the array; the second line is element 1, and so on.

The file is *not* loaded into memory, so this will work even for gigantic files.

Changes to the array are reflected in the file immediately.

Lazy people and beginners may now stop reading the manual.

**recsep**

What is a 'record'? By default, the meaning is the same as for the `<...>` operator: It's a string terminated by `$/`, which is probably `"\n"`. (Minor exception: on dos and Win32 systems, a 'record' is a string terminated by `"\r\n"`.) You may change the definition of "record" by supplying the `recsep` option in the `tie` call:

```
tie @array, 'Tie::File', $file, recsep => 'es';
```

This says that records are delimited by the string `es`. If the file contained the following data:

```
Curse these pesky flies!\n
```

then the `@array` would appear to have four elements:

```
"Curse th"
"e p"
"ky fli"
"!\n"
```

An undefined value is not permitted as a record separator. Perl's special "paragraph mode" semantics (à la `$/ = ""`) are not emulated.

Records read from the tied array do not have the record separator string on the end; this is to allow

```
$array[17] .= "extra";
```

to work as expected.

(See *"autochomp"*, below.) Records stored into the array will have the record separator string appended before they are written to the file, if they don't have one already. For example, if the record separator string is `"\n"`, then the following two lines do exactly the same thing:

```
$array[17] = "Cherry pie";
$array[17] = "Cherry pie\n";
```

The result is that the contents of line 17 of the file will be replaced with "Cherry pie"; a newline character will separate line 17 from line 18. This means that this code will do nothing:

```
chomp $array[17];
```

Because the chomped value will have the separator reattached when it is written back to the file. There is no way to create a file whose trailing record separator string is missing.

Inserting records that *contain* the record separator string is not supported by this module. It will probably produce a reasonable result, but what this result will be may change in a future version. Use `'splice'` to insert records or to replace one record with several.

### autochomp

Normally, array elements have the record separator removed, so that if the file contains the text

```
Gold
Frankincense
Myrrh
```

the tied array will appear to contain `("Gold", "Frankincense", "Myrrh")`. If you set `autochomp` to a false value, the record separator will not be removed. If the file above was tied with

```
tie @gifts, "Tie::File", $gifts, autochomp => 0;
```

then the array `@gifts` would appear to contain `("Gold\n", "Frankincense\n", "Myrrh\n")`, or (on Win32 systems) `("Gold\r\n", "Frankincense\r\n", "Myrrh\r\n")`.

### mode

Normally, the specified file will be opened for read and write access, and will be created if it does not exist. (That is, the flags `O_RDWR` | `O_CREAT` are supplied in the open call.) If you want to change this, you may supply alternative flags in the mode option. See *Fcntl* for a listing of available flags. For example:

```
open the file if it exists, but fail if it does not exist
use Fcntl 'O_RDWR';
tie @array, 'Tie::File', $file, mode => O_RDWR;

create the file if it does not exist
use Fcntl 'O_RDWR', 'O_CREAT';
tie @array, 'Tie::File', $file, mode => O_RDWR | O_CREAT;

open an existing file in read-only mode
use Fcntl 'O_RDONLY';
tie @array, 'Tie::File', $file, mode => O_RDONLY;
```

Opening the data file in write-only or append mode is not supported.

### memory

This is an upper limit on the amount of memory that `Tie::File` will consume at any time while managing the file. This is used for two things: managing the *read cache* and managing the *deferred write buffer*.

Records read in from the file are cached, to avoid having to re-read them repeatedly. If you read the same record twice, the first time it will be stored in memory, and the second time it will be fetched from the *read*

*cache*. The amount of data in the read cache will not exceed the value you specified for memory. If `Tie::File` wants to cache a new record, but the read cache is full, it will make room by expiring the least-recently visited records from the read cache.

The default memory limit is 2Mib. You can adjust the maximum read cache size by supplying the `memory` option. The argument is the desired cache size, in bytes.

```
I have a lot of memory, so use a large cache to speed up access
tie @array, 'Tie::File', $file, memory => 20_000_000;
```

Setting the memory limit to 0 will inhibit caching; records will be fetched from disk every time you examine them.

The memory value is not an absolute or exact limit on the memory used. `Tie::File` objects contains some structures besides the read cache and the deferred write buffer, whose sizes are not charged against memory.

### dw\_size

(This is an advanced feature. Skip this section on first reading.)

If you use deferred writing (See ["Deferred Writing"](#), below) then data you write into the array will not be written directly to the file; instead, it will be saved in the *deferred write buffer* to be written out later. Data in the deferred write buffer is also charged against the memory limit you set with the `memory` option.

You may set the `dw_size` option to limit the amount of data that can be saved in the deferred write buffer. This limit may not exceed the total memory limit. For example, if you set `dw_size` to 1000 and `memory` to 2500, that means that no more than 1000 bytes of deferred writes will be saved up. The space available for the read cache will vary, but it will always be at least 1500 bytes (if the deferred write buffer is full) and it could grow as large as 2500 bytes (if the deferred write buffer is empty.)

If you don't specify a `dw_size`, it defaults to the entire memory limit.

### Option Format

`-mode` is a synonym for `mode`. `-recsep` is a synonym for `recsep`. `-memory` is a synonym for `memory`. You get the idea.

### Public Methods

The `tie` call returns an object, say `$o`. You may call

```
$rec = $o->FETCH($n);
$o->STORE($n, $rec);
```

to fetch or store the record at line `$n`, respectively; similarly the other tied array methods. (See [perl tie](#) for details.) You may also call the following methods on this object:

### flock

```
$o->flock(MODE)
```

will lock the tied file. `MODE` has the same meaning as the second argument to the Perl built-in `flock` function; for example `LOCK_SH` or `LOCK_EX` | `LOCK_NB`. (These constants are provided by the use `Fcntl` `':flock'` declaration.)

`MODE` is optional; the default is `LOCK_EX`.

`Tie::File` promises that the following sequence of operations will be safe:

```
my $o = tie @array, "Tie::File", $filename;
$o->flock;
```

In particular, `Tie::File` will *not* read or write the file during the `tie` call. (Exception: Using `mode => O_TRUNC` will, of course, erase the file during the `tie` call. If you want to do this safely, then open the file without `O_TRUNC`, lock the file, and use `@array = ()`.)

The best way to unlock a file is to discard the object and untie the array. It is probably unsafe to unlock the file without also untying it, because if you do, changes may remain unwritten inside the object. That is why there is no shortcut for unlocking. If you really want to unlock the file prematurely, you know what to do; if you don't know what to do, then don't do it.

All the usual warnings about file locking apply here. In particular, note that file locking in Perl is **advisory**, which means that holding a lock will not prevent anyone else from reading, writing, or erasing the file; it only prevents them from getting another lock at the same time. Locks are analogous to green traffic lights: If you have a green light, that does not prevent the idiot coming the other way from plowing into you sideways; it merely guarantees to you that the idiot does not also have a green light at the same time.

#### **autochomp**

```
my $old_value = $o->autochomp(0); # disable autochomp option
my $old_value = $o->autochomp(1); # enable autochomp option

my $ac = $o->autochomp(); # recover current value
```

See *"autochomp"*, above.

#### **defer, flush, discard, and autodefer**

See *"Deferred Writing"*, below.

#### **Tying to an already-opened filehandle**

If `$fh` is a filehandle, such as is returned by `IO::File` or one of the other IO modules, you may use:

```
tie @array, 'Tie::File', $fh, ...;
```

Similarly if you opened that handle `FH` with regular `open` or `sysopen`, you may use:

```
tie @array, 'Tie::File', *FH, ...;
```

Handles that were opened write-only won't work. Handles that were opened read-only will work as long as you don't try to modify the array. Handles must be attached to seekable sources of data—that means no pipes or sockets. If `Tie::File` can detect that you supplied a non-seekable handle, the `tie` call will throw an exception. (On Unix systems, it can detect this.)

#### **Deferred Writing**

(This is an advanced feature. Skip this section on first reading.)

Normally, modifying a `Tie::File` array writes to the underlying file immediately. Every assignment like `$a[3] = ...` rewrites as much of the file as is necessary; typically, everything from line 3 through the end will need to be rewritten. This is the simplest and most transparent behavior. Performance even for large files is reasonably good.

However, under some circumstances, this behavior may be excessively slow. For example, suppose you have a million-record file, and you want to do:

```
for (@FILE) {
 $_ = "> $_";
}
```

The first time through the loop, you will rewrite the entire file, from line 0 through the end. The second time through the loop, you will rewrite the entire file from line 1 through the end. The third time through the loop, you will rewrite the entire file from line 2 to the end. And so on.

If the performance in such cases is unacceptable, you may defer the actual writing, and then have it done all at once. The following loop will perform much better for large files:

```
(tied @a)->defer;
for (@a) {
 $_ = "> $_";
}
```

```
(tied @a)->flush;
```

If `Tie::File`'s memory limit is large enough, all the writing will be done in memory. Then, when you call `->flush`, the entire file will be rewritten in a single pass.

(Actually, the preceding discussion is something of a fib. You don't need to enable deferred writing to get good performance for this common case, because `Tie::File` will do it for you automatically unless you specifically tell it not to. See ["autodefering"](#), below.)

Calling `->flush` returns the array to immediate-write mode. If you wish to discard the deferred writes, you may call `->discard` instead of `->flush`. Note that in some cases, some of the data will have been written already, and it will be too late for `->discard` to discard all the changes. Support for `->discard` may be withdrawn in a future version of `Tie::File`.

Deferred writes are cached in memory up to the limit specified by the `dw_size` option (see above). If the deferred-write buffer is full and you try to write still more deferred data, the buffer will be flushed. All buffered data will be written immediately, the buffer will be emptied, and the now-empty space will be used for future deferred writes.

If the deferred-write buffer isn't yet full, but the total size of the buffer and the read cache would exceed the memory limit, the oldest records will be expired from the read cache until the total size is under the limit.

`push`, `pop`, `shift`, `unshift`, and `splice` cannot be deferred. When you perform one of these operations, any deferred data is written to the file and the operation is performed immediately. This may change in a future version.

If you resize the array with deferred writing enabled, the file will be resized immediately, but deferred records will not be written. This has a surprising consequence: `@a = ( ... )` erases the file immediately, but the writing of the actual data is deferred. This might be a bug. If it is a bug, it will be fixed in a future version.

## Autodefering

`Tie::File` tries to guess when deferred writing might be helpful, and to turn it on and off automatically.

```
for (@a) {
 $_ = "> $_";
}
```

In this example, only the first two assignments will be done immediately; after this, all the changes to the file will be deferred up to the user-specified memory limit.

You should usually be able to ignore this and just use the module without thinking about deferring. However, special applications may require fine control over which writes are deferred, or may require that all writes be immediate. To disable the autodeferment feature, use

```
(tied @o)->autodefer(0);
```

or

```
tie @array, 'Tie::File', $file, autodefer => 0;
```

Similarly, `->autodefer(1)` re-enables autodeferment, and `->autodefer()` recovers the current value of the autodefer setting.

## CAVEATS

(That's Latin for 'warnings'.)

- This is BETA RELEASE SOFTWARE. It may have bugs. See the discussion below about the (lack of any) warranty.

In particular, this means that the interface may change in incompatible ways from one version to the next, without warning. That has happened at least once already. The interface will freeze before Perl 5.8 is released, probably sometime in April 2002.

- Reasonable effort was made to make this module efficient. Nevertheless, changing the size of a record in the middle of a large file will always be fairly slow, because everything after the new record must be moved.
- The behavior of tied arrays is not precisely the same as for regular arrays. For example:

```
This DOES print "How unusual!"
undef $a[10]; print "How unusual!\n" if defined $a[10];
```

undef-ing a Tie::File array element just blanks out the corresponding record in the file. When you read it back again, you'll get the empty string, so the supposedly-undef'ed value will be defined. Similarly, if you have `autochomp` disabled, then

```
This DOES print "How unusual!" if 'autochomp' is disabled
undef $a[10];
print "How unusual!\n" if $a[10];
```

Because when `autochomp` is disabled, `$a[10]` will read back as `"\n"` (or whatever the record separator string is.)

There are other minor differences, particularly regarding `exists` and `delete`, but in general, the correspondence is extremely close.

- Not quite every effort was made to make this module as efficient as possible. `FETCHSIZE` should use binary search instead of linear search.

The performance of the `flush` method could be improved. At present, it still rewrites the tail of the file once for each block of contiguous lines to be changed. In the typical case, this will result in only one rewrite, but in peculiar cases it might be bad. It should be possible to perform *all* deferred writing with a single rewrite.

Profiling suggests that these defects are probably minor; in any event, they will be fixed in a future version of the module.

- I have supposed that since this module is concerned with file I/O, almost all normal use of it will be heavily I/O bound. This means that the time to maintain complicated data structures inside the module will be dominated by the time to actually perform the I/O. When there was an opportunity to spend CPU time to avoid doing I/O, I tried to take it.
- You might be tempted to think that deferred writing is like transactions, with `flush` as `commit` and `discard` as `rollback`, but it isn't, so don't.

## SUBCLASSING

This version promises absolutely nothing about the internals, which may change without notice. A future version of the module will have a well-defined and stable subclassing API.

## WHAT ABOUT DB\_File?

People sometimes point out that *DB\_File* will do something similar, and ask why Tie::File module is necessary.

There are a number of reasons that you might prefer Tie::File. A list is available at [http://perl.plover.com/TieFile/why-not-DB\\_File](http://perl.plover.com/TieFile/why-not-DB_File).

## THANKS

Gigantic thanks to Jarkko Hietaniemi, for agreeing to put this in the core when I hadn't written it yet, and for generally being helpful, supportive, and competent. (Usually the rule is "choose any one.") Also big thanks to Abhijit Menon-Sen for all of the same things.

Special thanks to Craig Berry and Peter Prymmer (for VMS portability help), Randy Kobes (for Win32 portability help), Clinton Pierce and Autrijus Tang (for heroic eleventh-hour Win32 testing above and beyond the call of duty), Michael G Schwern (for testing advice), and the rest of the CPAN testers (for testing generally).

Additional thanks to: Edward Avis / Gerrit Haase / Nikola Knezevic / Nick Ing-Simmons / Tassilo von Parseval / H. Dieter Pearcey / Slaven Rezić / Peter Scott / Peter Somu / Autrijus Tang (again) / Tels / Juero Wallboer

## TODO

More tests. (The cache and heap modules need more unit tests.)

Improve SPLICE algorithm to use deferred writing machinery.

Cleverer strategy for flushing deferred writes.

More tests. (Stuff I didn't think of yet.)

Paragraph mode?

Fixed-length mode. Leave-blanks mode.

Maybe an autolocking mode?

Record locking with `fcntl()`? Then the module might support an undo log and get real transactions. What a tour de force that would be.

More tests.

**NAME**

Tie::Handle, Tie::StdHandle – base class definitions for tied handles

**SYNOPSIS**

```
package NewHandle;
require Tie::Handle;

@ISA = qw(Tie::Handle);

sub READ { ... } # Provide a needed method
sub TIEHANDLE { ... } # Overrides inherited method

package main;

tie *FH, 'NewHandle';
```

**DESCRIPTION**

This module provides some skeletal methods for handle-tying classes. See [perltie](#) for a list of the functions required in tying a handle to a package. The basic **Tie::Handle** package provides a new method, as well as methods TIEHANDLE, PRINT, PRINTF and GETC.

For developers wishing to write their own tied-handle classes, the methods are summarized below. The [perltie](#) section not only documents these, but has sample code as well:

**TIEHANDLE classname, LIST**

The method invoked by the command `tie *glob, classname`. Associates a new glob instance with the specified class. *LIST* would represent additional arguments (along the lines of [AnyDBM\\_File](#) and compatriots) needed to complete the association.

**WRITE this, scalar, length, offset**

Write *length* bytes of data from *scalar* starting at *offset*.

**PRINT this, LIST**

Print the values in *LIST*

**PRINTF this, format, LIST**

Print the values in *LIST* using *format*

**READ this, scalar, length, offset**

Read *length* bytes of data into *scalar* starting at *offset*.

**READLINE this**

Read a single line

**GETC this**

Get a single character

**CLOSE this**

Close the handle

**OPEN this, filename**

(Re-)open the handle

**BINMODE this**

Specify content is binary

**EOF this**

Test for end of file.

TELL this

Return position in the file.

SEEK this, offset, whence

Position the file.

Test for end of file.

DESTROY this

Free the storage associated with the tied handle referenced by *this*. This is rarely needed, as Perl manages its memory quite well. But the option exists, should a class wish to perform specific actions upon the destruction of an instance.

## MORE INFORMATION

The [perltie](#) section contains an example of tying handles.

## COMPATIBILITY

This version of Tie::Handle is neither related to nor compatible with the Tie::Handle (3.0) module available on CPAN. It was due to an accident that two modules with the same name appeared. The namespace clash has been cleared in favor of this module that comes with the perl core in September 2000 and accordingly the version number has been bumped up to 4.0.

**NAME**

Tie::Hash, Tie::StdHash, Tie::ExtraHash – base class definitions for tied hashes

**SYNOPSIS**

```
package NewHash;
require Tie::Hash;

@ISA = (Tie::Hash);

sub DELETE { ... } # Provides needed method
sub CLEAR { ... } # Overrides inherited method

package NewStdHash;
require Tie::Hash;

@ISA = (Tie::StdHash);

All methods provided by default, define only those needing overrides
Accessors access the storage in %{$_[0]};
TIEHANDLE should return a reference to the actual storage
sub DELETE { ... }

package NewExtraHash;
require Tie::Hash;

@ISA = (Tie::ExtraHash);

All methods provided by default, define only those needing overrides
Accessors access the storage in %{$_[0][0]};
TIEHANDLE should return an array reference with the first element being
the reference to the actual storage
sub DELETE {
 $_[0][1]->('del', $_[0][0], $_[1]); # Call the report writer
 delete $_[0][0]->{$_[1]}; # $_[0]->SUPER::DELETE($_[1]) }

package main;

tie %new_hash, 'NewHash';
tie %new_std_hash, 'NewStdHash';
tie %new_extra_hash, 'NewExtraHash',
 sub {warn "Doing \U$_[1]\E of $_[2].\n"};
```

**DESCRIPTION**

This module provides some skeletal methods for hash-tying classes. See [perltie](#) for a list of the functions required in order to tie a hash to a package. The basic **Tie::Hash** package provides a new method, as well as methods TIEHASH, EXISTS and CLEAR. The **Tie::StdHash** and **Tie::ExtraHash** packages provide most methods for hashes described in [perltie](#) (the exceptions are UNTIE and DESTROY). They cause tied hashes to behave exactly like standard hashes, and allow for selective overwriting of methods. **Tie::Hash** grandfathers the new method: it is used if TIEHASH is not defined in the case a class forgets to include a TIEHASH method.

For developers wishing to write their own tied hashes, the required methods are briefly defined below. See the [perltie](#) section for more detailed descriptive, as well as example code:

**TIEHASH classname, LIST**

The method invoked by the command `tie %hash, classname`. Associates a new hash instance with the specified class. LIST would represent additional arguments (along the lines of [AnyDBM\\_File](#) and compatriots) needed to complete the association.

STORE this, key, value

Store datum *value* into *key* for the tied hash *this*.

FETCH this, key

Retrieve the datum in *key* for the tied hash *this*.

FIRSTKEY this

Return the first key in the hash.

NEXTKEY this, lastkey

Return the next key in the hash.

EXISTS this, key

Verify that *key* exists with the tied hash *this*.

The **Tie::Hash** implementation is a stub that simply croaks.

DELETE this, key

Delete the key *key* from the tied hash *this*.

CLEAR this

Clear all values from the tied hash *this*.

### Inheriting from Tie::StdHash

The accessor methods assume that the actual storage for the data in the tied hash is in the hash referenced by `tied(%tiedhash)`. Thus overwritten `TIEHANDLE` method should return a hash reference, and the remaining methods should operate on the hash referenced by the first argument:

```
package ReportHash;
our @ISA = 'Tie::StdHash';

sub TIEHASH {
 my $storage = bless {}, shift;
 warn "New ReportHash created, stored in $storage.\n";
 $storage
}
sub STORE {
 warn "Storing data with key $_[1] at $_[0].\n";
 $_[0]{$_[1]} = $_[2]
}
```

### Inheriting from Tie::ExtraHash

The accessor methods assume that the actual storage for the data in the tied hash is in the hash referenced by `(tied(%tiedhash))[0]`. Thus overwritten `TIEHANDLE` method should return an array reference with the first element being a hash reference, and the remaining methods should operate on the hash `< %{$_[0]-[0]}`:

```
package ReportHash;
our @ISA = 'Tie::StdHash';

sub TIEHASH {
 my $storage = bless {}, shift;
 warn "New ReportHash created, stored in $storage.\n";
 [$storage, @_]
}
sub STORE {
 warn "Storing data with key $_[1] at $_[0].\n";
 $_[0][0]{$_[1]} = $_[2]
}
```

The default `TIEHANDLE` method stores "extra" arguments to `tie()` starting from offset 1 in the array referenced by `tied(%tiedhash)`; this is the same storage algorithm as in `TIEHASH` subroutine above. Hence, a typical package inheriting from **Tie::ExtraHash** does not need to overwrite this method.

#### UNTIE and DESTROY

The methods `UNTIE` and `DESTROY` are not defined in **Tie::Hash**, **Tie::StdHash**, or **Tie::ExtraHash**. Tied hashes do not require presense of these methods, but if defined, the methods will be called in proper time, see [perltie](#).

If needed, these methods should be defined by the package inheriting from **Tie::Hash**, **Tie::StdHash**, or **Tie::ExtraHash**.

#### MORE INFORMATION

The packages relating to various DBM-related implementations (*DB\_File*, *NDBM\_File*, etc.) show examples of general tied hashes, as does the [Config](#) module. While these do not utilize **Tie::Hash**, they serve as good working examples.

**NAME**

Tie::Memoize – add data to hash when needed

**SYNOPSIS**

```
require Tie::Memoize;
tie %hash, 'Tie::Memoize',
 \&fetch, # The rest is optional
 $DATA, \&exists,
 {%ini_value}, {%ini_existence};
```

**DESCRIPTION**

This package allows a tied hash to autoloading its values on the first access, and to use the cached value on the following accesses.

Only read-accesses (via fetching the value or `exists`) result in calls to the functions; the modify-accesses are performed as on a normal hash.

The required arguments during `tie` are the hash, the package, and the reference to the `FETCHing` function. The optional arguments are an arbitrary scalar `$data`, the reference to the `EXISTS` function, and initial values of the hash and of the existence cache.

Both the `FETCHing` function and the `EXISTS` functions have the same signature: the arguments are `$key`, `$data`; `$data` is the same value as given as argument during `tie()`ing. Both functions should return an empty list if the value does not exist. If `EXISTS` function is different from the `FETCHing` function, it should return a `TRUE` value on success. The `FETCHing` function should return the intended value if the key is valid.

**Inheriting from Tie::Memoize**

The structure of the `tied()` data is an array reference with elements

```
0: cache of known values
1: cache of known existence of keys
2: FETCH function
3: EXISTS function
4: $data
```

The rest is for internal usage of this package. In particular, if `TIEHASH` is overwritten, it should call `SUPER::TIEHASH`.

**EXAMPLE**

```
sub slurp {
 my ($key, $dir) = shift;
 open my $h, '<', "$dir/$key" or return;
 local $/; <$h> # slurp it all
}
sub exists { my ($key, $dir) = shift; return -f "$dir/$key" }

tie %hash, 'Tie::Memoize', \&slurp, $directory, \&exists,
 { fake_file1 => $content1, fake_file2 => $content2 },
 { pretend_does_not_exists => 0, known_to_exist => 1 };
```

This example treats the slightly modified contents of `$directory` as a hash. The modifications are that the keys *fake\_file1* and *fake\_file2* fetch values `$content1` and `$content2`, and *pretend\_does\_not\_exists* will never be accessed. Additionally, the existence of *known\_to\_exist* is never checked (so if it does not exist when its content is needed, the user of `%hash` may be confused).

**BUGS**

FIRSTKEY and NEXTKEY methods go through the keys which were already read, not all the possible keys of the hash.

**AUTHOR**

Ilya Zakharevich <mailto:perl-module-hash-memoize@ilyaz.org>.

**NAME**

Tie::RefHash – use references as hash keys

**SYNOPSIS**

```
require 5.004;
use Tie::RefHash;
tie HASHVARIABLE, 'Tie::RefHash', LIST;
tie HASHVARIABLE, 'Tie::RefHash::Nestable', LIST;

untie HASHVARIABLE;
```

**DESCRIPTION**

This module provides the ability to use references as hash keys if you first tie the hash variable to this module. Normally, only the keys of the tied hash itself are preserved as references; to use references as keys in hashes-of-hashes, use Tie::RefHash::Nestable, included as part of Tie::RefHash.

It is implemented using the standard perl TIEHASH interface. Please see the tie entry in perlfunc(1) and perltie(1) for more information.

The Nestable version works by looking for hash references being stored and converting them to tied hashes so that they too can have references as keys. This will happen without warning whenever you store a reference to one of your own hashes in the tied hash.

**EXAMPLE**

```
use Tie::RefHash;
tie %h, 'Tie::RefHash';
$a = [];
$b = {};
$c = *main;
$d = \"gunk";
$e = sub { 'foo' };
%h = ($a => 1, $b => 2, $c => 3, $d => 4, $e => 5);
$a->[0] = 'foo';
$b->{foo} = 'bar';
for (keys %h) {
 print ref($_), "\n";
}

tie %h, 'Tie::RefHash::Nestable';
$h{$a}->{$b} = 1;
for (keys %h, keys %{$h{$a}}) {
 print ref($_), "\n";
}
```

**NAME**

Tie::Scalar, Tie::StdScalar – base class definitions for tied scalars

**SYNOPSIS**

```
package NewScalar;
require Tie::Scalar;

@ISA = (Tie::Scalar);

sub FETCH { ... } # Provide a needed method
sub TIESCALAR { ... } # Overrides inherited method

package NewStdScalar;
require Tie::Scalar;

@ISA = (Tie::StdScalar);

All methods provided by default, so define only what needs be overridden
sub FETCH { ... }

package main;

tie $new_scalar, 'NewScalar';
tie $new_std_scalar, 'NewStdScalar';
```

**DESCRIPTION**

This module provides some skeletal methods for scalar-tying classes. See [perlty](#) for a list of the functions required in tying a scalar to a package. The basic **Tie::Scalar** package provides a new method, as well as methods TIESCALAR, FETCH and STORE. The **Tie::StdScalar** package provides all the methods specified in [perlty](#). It inherits from **Tie::Scalar** and causes scalars tied to it to behave exactly like the built-in scalars, allowing for selective overloading of methods. The new method is provided as a means of grandfathering, for classes that forget to provide their own TIESCALAR method.

For developers wishing to write their own tied-scalar classes, the methods are summarized below. The [perlty](#) section not only documents these, but has sample code as well:

**TIESCALAR** classname, LIST

The method invoked by the command `tie $scalar, classname`. Associates a new scalar instance with the specified class. LIST would represent additional arguments (along the lines of [AnyDBM\\_File](#) and `compatriots`) needed to complete the association.

**FETCH** this

Retrieve the value of the tied scalar referenced by *this*.

**STORE** this, value

Store data *value* in the tied scalar referenced by *this*.

**DESTROY** this

Free the storage associated with the tied scalar referenced by *this*. This is rarely needed, as Perl manages its memory quite well. But the option exists, should a class wish to perform specific actions upon the destruction of an instance.

**MORE INFORMATION**

The [perlty](#) section uses a good example of tying scalars by associating process IDs with priority.

**NAME**

Tie::SubstrHash – Fixed-table-size, fixed-key-length hashing

**SYNOPSIS**

```
require Tie::SubstrHash;

tie %myhash, 'Tie::SubstrHash', $key_len, $value_len, $table_size;
```

**DESCRIPTION**

The **Tie::SubstrHash** package provides a hash-table-like interface to an array of determinate size, with constant key size and record size.

Upon tying a new hash to this package, the developer must specify the size of the keys that will be used, the size of the value fields that the keys will index, and the size of the overall table (in terms of key-value pairs, not size in hard memory). *These values will not change for the duration of the tied hash.* The newly-allocated hash table may now have data stored and retrieved. Efforts to store more than `$table_size` elements will result in a fatal error, as will efforts to store a value not exactly `$value_len` characters in length, or reference through a key not exactly `$key_len` characters in length. While these constraints may seem excessive, the result is a hash table using much less internal memory than an equivalent freely-allocated hash table.

**CAVEATS**

Because the current implementation uses the table and key sizes for the hashing algorithm, there is no means by which to dynamically change the value of any of the initialization parameters.

The hash does not support `exists()`.

## NAME

Time::gmtime – by-name interface to Perl's built-in `gmtime()` function

## SYNOPSIS

```
use Time::gmtime;
$gm = gmtime();
printf "The day in Greenwich is %s\n",
 (qw(Sun Mon Tue Wed Thu Fri Sat Sun))[gm->wday()];

use Time::gmtime w(:FIELDS);
printf "The day in Greenwich is %s\n",
 (qw(Sun Mon Tue Wed Thu Fri Sat Sun))[gm_wday()];

$now = gmctime();

use Time::gmtime;
use File::stat;
$date_string = gmctime(stat($file)->mtime);
```

## DESCRIPTION

This module's default exports override the core `gmtime()` function, replacing it with a version that returns "Time::tm" objects. This object has methods that return the similarly named structure field name from the C's tm structure from *time.h*; namely `sec`, `min`, `hour`, `mday`, `mon`, `year`, `wday`, `yday`, and `isdst`.

You may also import all the structure fields directly into your namespace as regular variables using the `:FIELDS` import tag. (Note that this still overrides your core functions.) Access these fields as variables named with a preceding `tm_` in front their method names. Thus, `$tm_obj->mday()` corresponds to `$tm_mday` if you import the fields.

The `gmctime()` function provides a way of getting at the scalar sense of the original `CORE::gmtime()` function.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. On the other hand, the built-ins are still available via the `CORE::` pseudo-package.

## NOTE

While this class is currently implemented using the `Class::Struct` module to build a struct-like class, you shouldn't rely upon this.

**NAME**

Time::HiRes – High resolution alarm, sleep, gettimeofday, interval timers

**SYNOPSIS**

```
use Time::HiRes qw(usleep ualarm gettimeofday tv_interval);

usleep ($microseconds);

ualarm ($microseconds);
ualarm ($microseconds, $interval_microseconds);

$t0 = [gettimeofday];
($seconds, $microseconds) = gettimeofday;

$elapsed = tv_interval ($t0, [$seconds, $microseconds]);
$elapsed = tv_interval ($t0, [gettimeofday]);
$elapsed = tv_interval ($t0);

use Time::HiRes qw (time alarm sleep);

$now_fractions = time;
sleep ($floating_seconds);
alarm ($floating_seconds);
alarm ($floating_seconds, $floating_interval);

use Time::HiRes qw(setitimer getitimer
 ITIMER_REAL ITIMER_VIRTUAL ITIMER_PROF);

setitimer ($which, $floating_seconds, $floating_interval);
getitimer ($which);
```

**DESCRIPTION**

The Time::HiRes module implements a Perl interface to the usleep, ualarm, gettimeofday, and setitimer/getitimer system calls. See the EXAMPLES section below and the test scripts for usage; see your system documentation for the description of the underlying usleep, ualarm, gettimeofday, and setitimer/getitimer calls.

If your system lacks gettimeofday(2) or an emulation of it you don't get gettimeofday() or the one-arg form of tv\_interval(). If you don't have usleep(3) or select(2) you don't get usleep() or sleep().

If your system don't have ualarm(3) or setitimer(2) you don't get ualarm() or alarm(). If you try to import an unimplemented function in the use statement it will fail at compile time.

The following functions can be imported from this module. No functions are exported by default.

**gettimeofday ( )**

In array context returns a 2 element array with the seconds and microseconds since the epoch. In scalar context returns floating seconds like Time::HiRes::time() (see below).

**usleep ( \$useconds )**

Sleeps for the number of microseconds specified. Returns the number of microseconds actually slept. Can sleep for more than one second unlike the usleep system call. See also Time::HiRes::sleep() below.

**ualarm ( \$useconds [, \$interval\_useconds ] )**

Issues a ualarm call; interval\_useconds is optional and will be 0 if unspecified, resulting in alarm-like behaviour.

**tv\_interval**

tv\_interval ( \$ref\_to\_gettimeofday [, \$ref\_to\_later\_gettimeofday] )

Returns the floating seconds between the two times, which should have been returned by

`gettimeofday()`. If the second argument is omitted, then the current time is used.

#### `time()`

Returns a floating seconds since the epoch. This function can be imported, resulting in a nice drop-in replacement for the `time` provided with core Perl, see the EXAMPLES below.

**NOTE 1:** this higher resolution timer can return values either less or more than the core `time()`, depending on whether your platform rounds the higher resolution timer values up, down, or to the nearest to get the core `time()`, but naturally the difference should be never more than half a second.

**NOTE 2:** Since Sunday, September 9th, 2001 at 01:46:40 AM GMT (when the `time()` seconds since epoch rolled over to 1\_000\_000\_000), the default floating point format of Perl and the seconds since epoch have conspired to produce an apparent bug: if you print the value of

`Time::HiRes::time()` you seem to be getting only five decimals, not six as promised (microseconds). Not to worry, the microseconds are there (assuming your platform supports such granularity). What is going on is that the default floating point format of Perl only outputs 15 digits. In this case that means ten digits before the decimal separator and five after. To see the microseconds you can use either `printf/sprintf` with `%.6f`, or the `gettimeofday()` function in list context, which will give you the seconds and microseconds as two separate values.

#### `sleep($floating_seconds)`

Sleeps for the specified amount of seconds. Returns the number of seconds actually slept (a floating point value). This function can be imported, resulting in a nice drop-in replacement for the `sleep` provided with perl, see the EXAMPLES below.

#### `alarm($floating_seconds[, $interval_floating_seconds])`

The SIGALRM signal is sent after the specified number of seconds. Implemented using `ualarm()`. The `$interval_floating_seconds` argument is optional and will be 0 if unspecified, resulting in `alarm()`-like behaviour. This function can be imported, resulting in a nice drop-in replacement for the `alarm` provided with perl, see the EXAMPLES below.

#### `setitimer`

`setitimer($which, $floating_seconds[, $interval_floating_seconds])`

Start up an interval timer: after a certain time, a signal arrives, and more signals may keep arriving at certain intervals. To disable a timer, use time of zero. If interval is set to zero (or unspecified), the timer is disabled **after** the next delivered signal.

Use of interval timers may interfere with `alarm()`, `sleep()`, and `usleep()`. In standard-speak the "interaction is unspecified", which means that *anything* may happen: it may work, it may not.

In scalar context, the remaining time in the timer is returned.

In list context, both the remaining time and the interval are returned.

There are three interval timers: the `$which` can be `ITIMER_REAL`, `ITIMER_VIRTUAL`, or `ITIMER_PROF`.

`ITIMER_REAL` results in `alarm()`-like behavior. Time is counted in *real time*, that is, wallclock time. SIGALRM is delivered when the timer expires.

`ITIMER_VIRTUAL` counts time in (process) *virtual time*, that is, only when the process is running. In multiprocessor/user/CPU systems this may be more or less than real or wallclock time. (This time is also known as the *user time*.) SIGVTALRM is delivered when the timer expires.

`ITIMER_PROF` counts time when either the process virtual time or when the operating system is running on behalf of the process (such as I/O). (This time is also known as the *system time*.) (Collectively these times are also known as the *CPU time*.) SIGPROF is delivered when the timer expires. SIGPROF can interrupt system calls.

The semantics of interval timers for multithreaded programs are system-specific, and some systems may support additional interval timers. See your `setitimer()` documentation.

#### `getitimer ( $which )`

Return the remaining time in the interval timer specified by `$which`.

In scalar context, the remaining time is returned.

In list context, both the remaining time and the interval are returned. The interval is always what you put in using `setitimer()`.

### EXAMPLES

```
use Time::HiRes qw(usleep ualarm gettimeofday tv_interval);

$microseconds = 750_000;
usleep $microseconds;

signal alarm in 2.5s & every .1s thereafter
ualarm 2_500_000, 100_000;

get seconds and microseconds since the epoch
($s, $usec) = gettimeofday;

measure elapsed time
(could also do by subtracting 2 gettimeofday return values)
$t0 = [gettimeofday];
do bunch of stuff here
$t1 = [gettimeofday];
do more stuff here
$t0_t1 = tv_interval $t0, $t1;

$elapsed = tv_interval ($t0, [gettimeofday]);
$elapsed = tv_interval ($t0); # equivalent code

#
replacements for time, alarm and sleep that know about
floating seconds
#
use Time::HiRes;
$now_fractions = Time::HiRes::time;
Time::HiRes::sleep (2.5);
Time::HiRes::alarm (10.6666666);

use Time::HiRes qw (time alarm sleep);
$now_fractions = time;
sleep (2.5);
alarm (10.6666666);

Arm an interval timer to go off first at 10 seconds and
after that every 2.5 seconds, in process virtual time

use Time::HiRes qw (setitimer ITIMER_VIRTUAL time);

$SIG{VTALARM} = sub { print time, "\n" };
setitimer(ITIMER_VIRTUAL, 10, 2.5);
```

### C API

In addition to the perl API described above, a C API is available for extension writers. The following C functions are available in the `modglobal` hash:

| name  | C prototype |
|-------|-------------|
| ----- | -----       |

```
Time::NVtime double (*)()
Time::U2time void (*) (UV ret[2])
```

Both functions return equivalent information (like `gettimeofday`) but with different representations. The names `NVtime` and `U2time` were selected mainly because they are operating system independent. (`gettimeofday` is Un\*x-centric.)

Here is an example of using `NVtime` from C:

```
double (*myNVtime)();
SV **svp = hv_fetch(PL_modglobal, "Time::NVtime", 12, 0);
if (!svp) croak("Time::HiRes is required");
if (!SvIOK(*svp)) croak("Time::NVtime isn't a function pointer");
myNVtime = INT2PTR(double(*)(), SvIV(*svp));
printf("The current time is: %f\n", (*myNVtime)());
```

## CAVEATS

Notice that the core `time()` maybe rounding rather than truncating. What this means that the core `time()` may be giving time one second later than `gettimeofday()`, also known as `Time::HiRes::time()`.

**NAME**

Time::Local – efficiently compute time from local and GMT time

**SYNOPSIS**

```
$time = timelocal($sec,$min,$hour,$mday,$mon,$year);
$time = timegm($sec,$min,$hour,$mday,$mon,$year);
```

**DESCRIPTION**

These routines are the inverse of built-in perl functions `localtime()` and `gmtime()`. They accept a date as a six-element array, and return the corresponding `time(2)` value in seconds since the Epoch (Midnight, January 1, 1970). This value can be positive or negative.

It is worth drawing particular attention to the expected ranges for the values provided. The value for the day of the month is the actual day (ie 1..31), while the month is the number of months since January (0..11). This is consistent with the values returned from `localtime()` and `gmtime()`.

The `timelocal()` and `timegm()` functions perform range checking on the input `$sec`, `$min`, `$hour`, `$mday`, and `$mon` values by default. If you'd rather they didn't, you can explicitly import the `timelocal_nocheck()` and `timegm_nocheck()` functions.

```
use Time::Local 'timelocal_nocheck';

{
 # The 365th day of 1999
 print scalar localtime timelocal_nocheck 0,0,0,365,0,99;

 # The twenty thousandth day since 1970
 print scalar localtime timelocal_nocheck 0,0,0,20000,0,70;

 # And even the 10,000,000th second since 1999!
 print scalar localtime timelocal_nocheck 10000000,0,0,1,0,99;
}
```

Your mileage may vary when trying these with minutes and hours, and it doesn't work at all for months.

Strictly speaking, the year should also be specified in a form consistent with `localtime()`, i.e. the offset from 1900. In order to make the interpretation of the year easier for humans, however, who are more accustomed to seeing years as two-digit or four-digit values, the following conventions are followed:

- Years greater than 999 are interpreted as being the actual year, rather than the offset from 1900. Thus, 1963 would indicate the year Martin Luther King won the Nobel prize, not the year 2863.
- Years in the range 100..999 are interpreted as offset from 1900, so that 112 indicates 2012. This rule also applies to years less than zero (but see note below regarding date range).
- Years in the range 0..99 are interpreted as shorthand for years in the rolling "current century," defined as 50 years on either side of the current year. Thus, today, in 1999, 0 would refer to 2000, and 45 to 2045, but 55 would refer to 1955. Twenty years from now, 55 would instead refer to 2055. This is messy, but matches the way people currently think about two digit dates. Whenever possible, use an absolute four digit year instead.

The scheme above allows interpretation of a wide range of dates, particularly if 4-digit years are used.

Please note, however, that the range of dates that can be actually be handled depends on the size of an integer (`time_t`) on a given platform. Currently, this is 32 bits for most systems, yielding an approximate range from Dec 1901 to Jan 2038.

Both `timelocal()` and `timegm()` croak if given dates outside the supported range.

## IMPLEMENTATION

These routines are quite efficient and yet are always guaranteed to agree with `localtime()` and `gmtime()`. We manage this by caching the start times of any months we've seen before. If we know the start time of the month, we can always calculate any time within the month. The start times are calculated using a mathematical formula. Unlike other algorithms that do multiple calls to `gmtime()`.

`timelocal()` is implemented using the same cache. We just assume that we're translating a GMT time, and then fudge it when we're done for the timezone and daylight savings arguments. Note that the timezone is evaluated for each date because countries occasionally change their official timezones. Assuming that `localtime()` corrects for these changes, this routine will also be correct.

## BUGS

The whole scheme for interpreting two-digit years can be considered a bug.

The proclivity to `croak()` is probably a bug.

**NAME**

Time::localtime – by-name interface to Perl's built-in localtime() function

**SYNOPSIS**

```
use Time::localtime;
printf "Year is %d\n", localtime->year() + 1900;

$now = ctime();

use Time::localtime;
use File::stat;
$date_string = ctime(stat($file)->mtime);
```

**DESCRIPTION**

This module's default exports override the core localtime() function, replacing it with a version that returns "Time::tm" objects. This object has methods that return the similarly named structure field name from the C's tm structure from *time.h*; namely sec, min, hour, mday, mon, year, wday, yday, and isdst.

You may also import all the structure fields directly into your namespace as regular variables using the :FIELDS import tag. (Note that this still overrides your core functions.) Access these fields as variables named with a preceding tm\_ in front their method names. Thus, \$tm\_obj->mday() corresponds to \$tm\_mday if you import the fields.

The ctime() function provides a way of getting at the scalar sense of the original CORE::localtime() function.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. On the other hand, the built-ins are still available via the CORE::pseudo-package.

**NOTE**

While this class is currently implemented using the Class::Struct module to build a struct-like class, you shouldn't rely upon this.

**AUTHOR**

Tom Christiansen

**NAME**

Time::tm – internal object used by Time::gmtime and Time::localtime

**SYNOPSIS**

Don't use this module directly.

**DESCRIPTION**

This module is used internally as a base class by Time::localtime And Time::gmtime functions. It creates a Time::tm struct object which is addressable just like's C's tm structure from *time.h*; namely with sec, min, hour, mday, mon, year, wday, yday, and isdst.

This class is an internal interface only.

**AUTHOR**

Tom Christiansen

**NAME**

Unicode::Collate – Unicode Collation Algorithm

**SYNOPSIS**

```
use Unicode::Collate;

#construct
$Collator = Unicode::Collate->new(%tailoring);

#sort
@sorted = $Collator->sort(@not_sorted);

#compare
$result = $Collator->cmp($a, $b); # returns 1, 0, or -1.
```

**DESCRIPTION****Constructor and Tailoring**

The new method returns a collator object.

```
$Collator = Unicode::Collate->new(
 alternate => $alternate,
 backwards => $levelNumber, # or \@levelNumbers
 entry => $element,
 normalization => $normalization_form,
 ignoreName => qr/$ignoreName/,
 ignoreChar => qr/$ignoreChar/,
 katakana_before_hiragana => $bool,
 level => $collationLevel,
 overrideCJK => \&overrideCJK,
 overrideHangul => \&overrideHangul,
 preprocess => \&preprocess,
 rearrange => \@charList,
 table => $filename,
 undefName => qr/$undefName/,
 undefChar => qr/$undefChar/,
 upper_before_lower => $bool,
);
if %tailoring is false (i.e. empty),
$Collator should do the default collation.
```

**alternate**

— see 3.2.2 Alternate Weighting, UTR #10.

This key allows to alternate weighting for variable collation elements, which are marked with an **ASTERISK** in the table (NOTE: Many punctuation marks and symbols are variable in *allkeys.txt*).

```
alternate => 'blanked', 'non-ignorable', 'shifted', or 'shift-trimmed'.
```

These names are case-insensitive. By default (if specification is omitted), 'shifted' is adopted.

|                 |                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Blanked'       | Variable elements are ignorable at levels 1 through 3; considered at the 4th level.                                                                                   |
| 'Non-ignorable' | Variable elements are not reset to ignorable.                                                                                                                         |
| 'Shifted'       | Variable elements are ignorable at levels 1 through 3 their level 4 weight is replaced by the old level 1 weight. Level 4 weight for Non-Variable elements is 0xFFFF. |

'Shift-Trimmed' Same as 'shifted', but all FFFF's at the 4th level are trimmed.

### backwards

— see 3.1.2 French Accents, UTR #10.

```
backwards => $levelNumber or \@levelNumbers
```

Weights in reverse order; ex. level 2 (diacritic ordering) in French. If omitted, forwards at all the levels.

### entry

— see 3.1 Linguistic Features; 3.2.1 File Format, UTR #10.

Overrides a default order or defines additional collation elements

```
entry => <<'ENTRIES', # use the UCA file format
00E6 ; [0861.0020.0002.00E6] [08B1.0020.0002.00E6] # ligature <ae as <a<e 0063 0068 ;
[0893.0020.0002.0063] # "ch" in traditional Spanish 0043 0068 ; [0893.0020.0008.0043] #
"Ch" in traditional Spanish ENTRIES
```

### ignoreName

#### ignoreChar

— see Completely Ignorable, 3.2.2 Alternate Weighting, UTR #10.

Makes the entry in the table ignorable. If a collation element is ignorable, it is ignored as if the element had been deleted from there.

E.g. when 'a' and 'e' are ignorable, 'element' is equal to 'lament' (or 'lmnt').

### level

— see 4.3 Form a sort key for each string, UTR #10.

Set the maximum level. Any higher levels than the specified one are ignored.

```
Level 1: alphabetic ordering
Level 2: diacritic ordering
Level 3: case ordering
Level 4: tie-breaking (e.g. in the case when alternate is 'shifted')

ex.level => 2,
```

If omitted, the maximum is the 4th.

### normalization

— see 4.1 Normalize each input string, UTR #10.

If specified, strings are normalized before preparation of sort keys (the normalization is executed after preprocess).

As a form name, one of the following names must be used.

```
'C' or 'NFC' for Normalization Form C
'D' or 'NFD' for Normalization Form D
'KC' or 'NFKC' for Normalization Form KC
'KD' or 'NFKD' for Normalization Form KD
```

If omitted, the string is put into Normalization Form D.

If undef is passed explicitly as the value for this key, any normalization is not carried out (this may make tailoring easier if any normalization is not desired).

see **CAVEAT**.

**overrideCJK**

— see 7.1 Derived Collation Elements, UTR #10.

By default, mapping of CJK Unified Ideographs uses the Unicode codepoint order. But the mapping of CJK Unified Ideographs may be overridden.

ex. CJK Unified Ideographs in the JIS code point order.

```
overrideCJK => sub {
 my $u = shift; # get a Unicode codepoint
 my $b = pack('n', $u); # to UTF-16BE
 my $s = your_unicode_to_sjis_converter($b); # convert
 my $n = unpack('n', $s); # convert sjis to short
 [$n, 0x20, 0x2, $u]; # return the collation element
},
```

ex. ignores all CJK Unified Ideographs.

```
overrideCJK => sub { () }, # CODEREF returning empty list

where ->eq("Pe\x{4E00}rl", "Perl") is true
as U+4E00 is a CJK Unified Ideograph and to be ignorable.
```

If undef is passed explicitly as the value for this key, weights for CJK Unified Ideographs are treated as undefined. But assignment of weight for CJK Unified Ideographs in table or [entry](#) is still valid.

**overrideHangul**

— see 7.1 Derived Collation Elements, UTR #10.

By default, Hangul Syllables are decomposed into Hangul Jamo. But the mapping of Hangul Syllables may be overridden.

This tag works like [overrideCJK](#), so see there for examples.

If you want to override the mapping of Hangul Syllables, the Normalization Forms D and KD are not appropriate (they will be decomposed before overriding).

If undef is passed explicitly as the value for this key, weight for Hangul Syllables is treated as undefined without decomposition into Hangul Jamo. But definition of weight for Hangul Syllables in table or [entry](#) is still valid.

**preprocess**

— see 5.1 Preprocessing, UTR #10.

If specified, the coderef is used to preprocess before the formation of sort keys.

ex. dropping English articles, such as "a" or "the". Then, "the pen" is before "a pencil".

```
preprocess => sub {
 my $str = shift;
 $str =~ s/\b(?:an?|the)\s+//gi;
 $str;
},
```

**rearrange**

— see 3.1.3 Rearrangement, UTR #10.

Characters that are not coded in logical order and to be rearranged. By default,

```
rearrange => [0x0E40..0x0E44, 0x0EC0..0x0EC4],
```

If you want to disallow any rearrangement, pass undef or [] (a reference to an empty list) as the value for this key.

**table**

— see 3.2 Default Unicode Collation Element Table, UTR #10.

You can use another element table if desired. The table file must be in your `lib/Unicode/Collate` directory.

By default, the file `lib/Unicode/Collate/allkeys.txt` is used.

If `undef` is passed explicitly as the value for this key, no file is read (but you can define collation elements via [entry](#)).

A typical way to define a collation element table without any file of table:

```
$onlyABC = Unicode::Collate->new(
 table => undef,
 entry => << 'ENTRIES',
 0061 ; [.0101.0020.0002.0061] # LATIN SMALL LETTER A 0041 ; [.0101.0020.0008.0041] #
 LATIN CAPITAL LETTER A 0062 ; [.0102.0020.0002.0062] # LATIN SMALL LETTER B 0042 ;
 [.0102.0020.0008.0042] # LATIN CAPITAL LETTER B 0063 ; [.0103.0020.0002.0063] # LATIN
 SMALL LETTER C 0043 ; [.0103.0020.0008.0043] # LATIN CAPITAL LETTER C ENTRIES
);
```

**undefName****undefChar**

— see 6.3.4 Reducing the Repertoire, UTR #10.

Undefines the collation element as if it were unassigned in the table. This reduces the size of the table. If an unassigned character appears in the string to be collated, the sort key is made from its codepoint as a single-character collation element, as it is greater than any other assigned collation elements (in the codepoint order among the unassigned characters). But, it'd be better to ignore characters unfamiliar to you and maybe never used.

**katakana\_before\_hiragana****upper\_before\_lower**

— see 6.6 Case Comparisons; 7.3.1 Tertiary Weight Table, UTR #10.

By default, lowercase is before uppercase and hiragana is before katakana.

If the tag is made true, this is reversed.

**NOTE:** These tags simply assume any lowercase/uppercase or hiragana/katakana distinctions should occur in level 3, and their weights at level 3 should be same as those mentioned in 7.3.1, UTR #10. If you define your collation elements which violates this, these tags doesn't work validly.

**Methods for Collation**

```
@sorted = $Collator->sort(@not_sorted)
```

Sorts a list of strings.

```
$result = $Collator->cmp($a, $b)
```

Returns 1 (when `$a` is greater than `$b`) or 0 (when `$a` is equal to `$b`) or -1 (when `$a` is lesser than `$b`).

```
$result = $Collator->eq($a, $b)
```

```
$result = $Collator->ne($a, $b)
```

```
$result = $Collator->lt($a, $b)
```

```
$result = $Collator->le($a, $b)
```

```
$result = $Collator->gt($a, $b)
```

```
$result = $Collator->ge($a, $b)
```

They works like the same name operators as theirs.

```

eq : whether $a is equal to $b.
ne : whether $a is not equal to $b.
lt : whether $a is lesser than $b.
le : whether $a is lesser than $b or equal to $b.
gt : whether $a is greater than $b.
ge : whether $a is greater than $b or equal to $b.

```

```
$sortKey = $Collator->getSortKey($string)
```

— see 4.3 Form a sort key for each string, UTR #10.

Returns a sort key.

You compare the sort keys using a binary comparison and get the result of the comparison of the strings using UCA.

```

$Collator->getSortKey($a) cmp $Collator->getSortKey($b)

is equivalent to

$Collator->cmp($a, $b)

```

```
$sortKeyForm = $Collator->viewSortKey($string)
```

Returns a string formalized to display a sort key. Weights are enclosed with '[' and ']' and level boundaries are denoted by '| '.

```

use Unicode::Collate;
my $c = Unicode::Collate->new();
print $c->viewSortKey("Perl"), "\n";

output:
[09B3 08B1 09CB 094F|0020 0020 0020 0020|0008 0002 0002 0002|FFFF FFFF FFFF
Level 1 Level 2 Level 3 Level 4

```

```
$position = $Collator->index($string, $substring)
```

```
($position, $length) = $Collator->index($string, $substring)
```

— see 6.8 Searching, UTR #10.

If \$substring matches a part of \$string, returns the position of the first occurrence of the matching part in scalar context; in list context, returns a two-element list of the position and the length of the matching part.

**Notice** that the length of the matching part may differ from the length of \$substring.

**Note** that the position and the length are counted on the string after the process of preprocess, normalization, and rearrangement. Therefore, in case the specified string is not binary equal to the preprocessed/normalized/rearranged string, the position and the length may differ from those on the specified string. But it is guaranteed that, if matched, it returns a non-negative value as \$position.

If \$substring does not match any part of \$string, returns -1 in scalar context and an empty list in list context.

e.g. you say

```

my $Collator = Unicode::Collate->new(normalization => undef, level => 1);
my $str = "Ich mu\x{00DF} studieren.";
my $sub = "m\x{00FC}ss";
my $match;
if (my($pos,$len) = $Collator->index($str, $sub)) {
 $match = substr($str, $pos, $len);
}

```

and get "mu\x{00DF}" in `$match` since "mu" is primary equal to "mss".

## Other Methods

### UCA\_Version

Returns the version number of Unicode Technical Standard 10 this module consults.

### Base\_Unicode\_Version

Returns the version number of the Unicode Standard this module is based on.

## EXPORT

None by default.

## TODO

Unicode::Collate has not been ported to EBCDIC. The code mostly would work just fine but a decision needs to be made: how the module should work in EBCDIC? Should the low 256 characters be understood as Unicode or as EBCDIC code points? Should one be chosen or should there be a way to do either? Or should such translation be left outside the module for the user to do, for example by using `Encode::from_to()`? (or `utf8::unicode_to_native()/utf8::native_to_unicode()`?)

## CAVEAT

Use of the `normalization` parameter requires the **Unicode::Normalize** module.

If you need not it (say, in the case when you need not handle any combining characters), assign `normalization => undef` explicitly.

— see 6.5 Avoiding Normalization, UTR #10.

## BUGS

`index()` is an experimental method and its return value may be unreliable. The correct implementation for `index()` must be based on Locale-Sensitive Support: Level 3 in UTR #18, *Unicode Regular Expression Guidelines*.

See also 4.2 Locale-Dependent Graphemes in UTR #18.

*Unicode::Normalize*

**NAME**

Unicode::Normalize – Unicode Normalization Forms

**SYNOPSIS**

```
use Unicode::Normalize;

$NFD_string = NFD($string); # Normalization Form D
$NFC_string = NFC($string); # Normalization Form C
$NFKD_string = NFKD($string); # Normalization Form KD
$NFKC_string = NFKC($string); # Normalization Form KC

or

use Unicode::Normalize 'normalize';

$NFD_string = normalize('D', $string); # Normalization Form D
$NFC_string = normalize('C', $string); # Normalization Form C
$NFKD_string = normalize('KD', $string); # Normalization Form KD
$NFKC_string = normalize('KC', $string); # Normalization Form KC
```

**DESCRIPTION****Normalization Forms**

```
$NFD_string = NFD($string)
 returns the Normalization Form D (formed by canonical decomposition).

$NFC_string = NFC($string)
 returns the Normalization Form C (formed by canonical decomposition followed by canonical
 composition).

$NFKD_string = NFKD($string)
 returns the Normalization Form KD (formed by compatibility decomposition).

$NFKC_string = NFKC($string)
 returns the Normalization Form KC (formed by compatibility decomposition followed by canonical
 composition).

$normalized_string = normalize($form_name, $string)
 As $form_name, one of the following names must be given.

 'C' or 'NFC' for Normalization Form C
 'D' or 'NFD' for Normalization Form D
 'KC' or 'NFKC' for Normalization Form KC
 'KD' or 'NFKD' for Normalization Form KD
```

**Decomposition and Composition**

```
$decomposed_string = decompose($string)
$decomposed_string = decompose($string, $useCompatMapping)
 Decompose the specified string and returns the result.
```

If the second parameter (a boolean) is omitted or false, decomposes it using the Canonical Decomposition Mapping. If true, decomposes it using the Compatibility Decomposition Mapping.

The string returned is not always in NFD/NFKD. Reordering may be required.

```
$NFD_string = reorder(decompose($string)); # eq. to NFD()
$NFKD_string = reorder(decompose($string, TRUE)); # eq. to NFKD()
```

```
$reordered_string = reorder($string)
```

Reorder the combining characters and the like in the canonical ordering and returns the result.

E.g., when you have a list of NFD/NFKD strings, you can get the concatenated NFD/NFKD string from them, saying

```
$concat_NFD = reorder(join ' ', @NFD_strings);
$concat_NFKD = reorder(join ' ', @NFKD_strings);
```

```
$composed_string = compose($string)
```

Returns the string where composable pairs are composed.

E.g., when you have a NFD/NFKD string, you can get its NFC/NFKC string, saying

```
$NFC_string = compose($NFD_string);
$NFKC_string = compose($NFKD_string);
```

### Quick Check

(see Annex 8, UAX #15; *DerivedNormalizationProps.txt*)

The following functions check whether the string is in that normalization form.

The result returned will be:

```
YES The string is in that normalization form.
NO The string is not in that normalization form.
MAYBE Dubious. Maybe yes, maybe no.
```

```
$result = checkNFD($string)
returns YES (1) or NO (empty string).
```

```
$result = checkNFC($string)
returns YES (1), NO (empty string), or MAYBE (undef).
```

```
$result = checkNFKD($string)
returns YES (1) or NO (empty string).
```

```
$result = checkNFKC($string)
returns YES (1), NO (empty string), or MAYBE (undef).
```

```
$result = check($form_name, $string)
returns YES (1), NO (empty string), or MAYBE (undef).
$form_name is alike to that for normalize().
```

### Note

In the cases of NFD and NFKD, the answer must be either YES or NO. The answer MAYBE may be returned in the cases of NFC and NFKC.

A MAYBE-NFC/NFKC string should contain at least one combining character or the like. For example, COMBINING ACUTE ACCENT has the MAYBE\_NFC/MAYBE\_NFKC property. Both `checkNFC("A\N{COMBINING ACUTE ACCENT}")` and `checkNFKC("B\N{COMBINING ACUTE ACCENT}")` will return MAYBE. "A\N{COMBINING ACUTE ACCENT}" is not in NFC (its NFC is "\N{LATIN CAPITAL LETTER A WITH ACUTE}"), while "B\N{COMBINING ACUTE ACCENT}" is in NFC.

If you want to check exactly, compare the string with its NFC/NFKC; i.e.,

```
$string eq NFC($string) # more thorough than checkNFC($string)
$string eq NFKC($string) # more thorough than checkNFKC($string)
```

## Character Data

These functions are interface of character data used internally. If you want only to get Unicode normalization forms, you don't need call them yourself.

```
$canonical_decomposed = getCanon($codepoint)
```

If the character of the specified codepoint is canonically decomposable (including Hangul Syllables), returns the **completely decomposed** string canonically equivalent to it.

If it is not decomposable, returns undef.

```
$compatibility_decomposed = getCompat($codepoint)
```

If the character of the specified codepoint is compatibility decomposable (including Hangul Syllables), returns the **completely decomposed** string compatibility equivalent to it.

If it is not decomposable, returns undef.

```
$codepoint_composite = getComposite($codepoint_here, $codepoint_next)
```

If two characters here and next (as codepoints) are composable (including Hangul Jamo/Syllables and Composition Exclusions), returns the codepoint of the composite.

If they are not composable, returns undef.

```
$combining_class = getCombinClass($codepoint)
```

Returns the combining class of the character as an integer.

```
$is_exclusion = isExclusion($codepoint)
```

Returns a boolean whether the character of the specified codepoint is a composition exclusion.

```
$is_singleton = isSingleton($codepoint)
```

Returns a boolean whether the character of the specified codepoint is a singleton.

```
$is_non_startar_decomposition = isNonStDecomp($codepoint)
```

Returns a boolean whether the canonical decomposition of the character of the specified codepoint is a Non-Starter Decomposition.

```
$may_be_composed_with_prev_char = isComp2nd($codepoint)
```

Returns a boolean whether the character of the specified codepoint may be composed with the previous one in a certain composition (including Hangul Compositions, but excluding Composition Exclusions and Non-Starter Decompositions).

## EXPORT

NFC, NFD, NFKC, NFKD: by default.

normalize and other some functions: on request.

Derived Normalization Properties

**NAME**

Unicode::UCD – Unicode character database

**SYNOPSIS**

```
use Unicode::UCD 'charinfo';
my $charinfo = charinfo($codepoint);

use Unicode::UCD 'charblock';
my $charblock = charblock($codepoint);

use Unicode::UCD 'charscript';
my $charscript = charblock($codepoint);

use Unicode::UCD 'charblocks';
my $charblocks = charblocks();

use Unicode::UCD 'charscripts';
my %charscripts = charscripts();

use Unicode::UCD qw(charscript charinrange);
my $range = charscript($script);
print "looks like $script\n" if charinrange($range, $codepoint);

use Unicode::UCD 'compexcl';
my $compexcl = compexcl($codepoint);

my $unicode_version = Unicode::UCD::UnicodeVersion();
```

**DESCRIPTION**

The Unicode::UCD module offers a simple interface to the Unicode Character Database.

**charinfo**

```
use Unicode::UCD 'charinfo';
my $charinfo = charinfo(0x41);
```

`charinfo()` returns a reference to a hash that has the following fields as defined by the Unicode standard:

| key           |                                                                  |
|---------------|------------------------------------------------------------------|
| code          | code point with at least four hexdigits                          |
| name          | name of the character IN UPPER CASE                              |
| category      | general category of the character                                |
| combining     | classes used in the Canonical Ordering Algorithm                 |
| bidirectional | bidirectional category                                           |
| decomposition | character decomposition mapping                                  |
| decimal       | if decimal digit this is the integer numeric value               |
| digit         | if digit this is the numeric value                               |
| numeric       | if numeric is the integer or rational numeric value              |
| mirrored      | if mirrored in bidirectional text                                |
| unicode10     | Unicode 1.0 name if existed and different                        |
| comment       | ISO 10646 comment field                                          |
| upper         | uppercase equivalent mapping                                     |
| lower         | lowercase equivalent mapping                                     |
| title         | titlecase equivalent mapping                                     |
| block         | block the character belongs to (used in <code>\p{In...}</code> ) |
| script        | script the character belongs to                                  |

If no match is found, a reference to an empty hash is returned.

The `block` property is the same as returned by `charinfo()`. It is not defined in the Unicode Character Database proper (Chapter 4 of the Unicode 3.0 Standard, aka TUS3) but instead in an auxiliary database (Chapter 14 of TUS3). Similarly for the `script` property.

Note that you cannot do (de)composition and casing based solely on the above decomposition and lower, upper, title, properties, you will need also the `compexcl()`, `casefold()`, and `casespec()` functions.

### charblock

```
use Unicode::UCD 'charblock';

my $charblock = charblock(0x41);
my $charblock = charblock(1234);
my $charblock = charblock("0x263a");
my $charblock = charblock("U+263a");

my $range = charblock('Armenian');
```

With a **code point argument** `charblock()` returns the *block* the character belongs to, e.g. Basic Latin. Note that not all the character positions within all blocks are defined.

See also [/Blocks versus Scripts](#).

If supplied with an argument that can't be a code point, `charblock()` tries to do the opposite and interpret the argument as a character block. The return value is a *range*: an anonymous list of lists that contain *start-of-range*, *end-of-range* code point pairs. You can test whether a code point is in a range using the [/charinrange](#) function. If the argument is not a known character block, `undef` is returned.

### charscript

```
use Unicode::UCD 'charscript';

my $charscript = charscript(0x41);
my $charscript = charscript(1234);
my $charscript = charscript("U+263a");

my $range = charscript('Thai');
```

With a **code point argument** `charscript()` returns the *script* the character belongs to, e.g. Latin, Greek, Han.

See also [/Blocks versus Scripts](#).

If supplied with an argument that can't be a code point, `charscript()` tries to do the opposite and interpret the argument as a character script. The return value is a *range*: an anonymous list of lists that contain *start-of-range*, *end-of-range* code point pairs. You can test whether a code point is in a range using the [/charinrange](#) function. If the argument is not a known character script, `undef` is returned.

### charblocks

```
use Unicode::UCD 'charblocks';

my $charblocks = charblocks();
```

`charblocks()` returns a reference to a hash with the known block names as the keys, and the code point ranges (see [/charblock](#)) as the values.

See also [/Blocks versus Scripts](#).

### charscripts

```
use Unicode::UCD 'charscripts';

my %charscripts = charscripts();
```

`charscripts()` returns a hash with the known script names as the keys, and the code point ranges (see [/charscript](#)) as the values.

See also */Blocks versus Scripts*.

## Blocks versus Scripts

The difference between a block and a script is that scripts are closer to the linguistic notion of a set of characters required to present languages, while block is more of an artifact of the Unicode character numbering and separation into blocks of (mostly) 256 characters.

For example the Latin **script** is spread over several **blocks**, such as Basic Latin, Latin 1 Supplement, Latin Extended-A, and Latin Extended-B. On the other hand, the Latin script does not contain all the characters of the Basic Latin block (also known as the ASCII): it includes only the letters, and not, for example, the digits or the punctuation.

For blocks see <http://www.unicode.org/Public/UNIDATA/Blocks.txt>

For scripts see UTR #24: <http://www.unicode.org/unicode/reports/tr24/>

## Matching Scripts and Blocks

Scripts are matched with the regular-expression construct `\p{...}` (e.g. `\p{Tibetan}` matches characters of the Tibetan script), while `\p{In...}` is used for blocks (e.g. `\p{InTibetan}` matches any of the 256 code points in the Tibetan block).

## Code Point Arguments

A *code point argument* is either a decimal or a hexadecimal scalar designating a Unicode character, or U+ followed by hexadecimals designating a Unicode character. Note that Unicode is **not** limited to 16 bits (the number of Unicode characters is open-ended, in theory unlimited): you may have more than 4 hexdigits.

## charinrange

In addition to using the `\p{In...}` and `\P{In...}` constructs, you can also test whether a code point is in the *range* as returned by */charblock* and */charscript* or as the values of the hash returned by */charblocks* and */charscripts* by using `charinrange()`:

```
use Unicode::UCD qw(charscript charinrange);

$range = charscript('Hiragana');
print "looks like hiragana\n" if charinrange($range, $codepoint);
```

## compexcl

```
use Unicode::UCD 'compexcl';

my $compexcl = compexcl("09dc");
```

The `compexcl()` returns the composition exclusion (that is, if the character should not be produced during a precomposition) of the character specified by a **code point argument**.

If there is a composition exclusion for the character, true is returned. Otherwise, false is returned.

## casefold

```
use Unicode::UCD 'casefold';

my %casefold = casefold("09dc");
```

The `casefold()` returns the locale-independent case folding of the character specified by a **code point argument**.

If there is a case folding for that character, a reference to a hash with the following fields is returned:

|         |                                         |
|---------|-----------------------------------------|
| key     |                                         |
| code    | code point with at least four hexdigits |
| status  | "C", "F", "S", or "I"                   |
| mapping | one or more codes separated by spaces   |

The meaning of the *status* is as follows:

|   |                                                                                                                                                                                                                                                                                                                                                              |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C | common case folding, common mappings shared by both simple and full mappings                                                                                                                                                                                                                                                                                 |
| F | full case folding, mappings that cause strings to grow in length. Multiple characters are separated by spaces                                                                                                                                                                                                                                                |
| S | simple case folding, mappings to single characters where different from F                                                                                                                                                                                                                                                                                    |
| I | special case for dotted uppercase I and dotless lowercase i <ul style="list-style-type: none"> <li>- If this mapping is included, the result is case-insensitive, but dotless and dotted I's are not distinguished</li> <li>- If this mapping is excluded, the result is not fully case-insensitive, but dotless and dotted I's are distinguished</li> </ul> |

If there is no case folding for that character, undef is returned.

For more information about case mappings see <http://www.unicode.org/unicode/reports/tr21/>

### casespec

```
use Unicode::UCD 'casespec';

my %casespec = casespec("09dc");
```

The `casespec()` returns the potentially locale-dependent case mapping of the character specified by a **code point argument**. The mapping may change the length of the string (which the basic Unicode case mappings as returned by `charinfo()` never do).

If there is a case folding for that character, a reference to a hash with the following fields is returned:

|           |                                         |
|-----------|-----------------------------------------|
| key       |                                         |
| code      | code point with at least four hexdigits |
| lower     | lowercase                               |
| title     | titlecase                               |
| upper     | uppercase                               |
| condition | condition list (may be undef)           |

The condition is optional. Where present, it consists of one or more *locales* or *contexts*, separated by spaces (other than as used to separate elements, spaces are to be ignored). A condition list overrides the normal behavior if all of the listed conditions are true. Case distinctions in the condition list are not significant. Conditions preceded by "NON\_" represent the negation of the condition

Note that when there are multiple case folding definitions for a single code point because of different locales, the value returned by `casespec()` is a hash reference which has the locales as the keys and hash references as described above as the values.

A *locale* is defined as a 2-letter ISO 3166 country code, possibly followed by a "\_" and a 2-letter ISO language code (possibly followed by a "\_" and a variant code). You can find the lists of those codes, see [Locale::Country](#) and [Locale::Language](#).

A *context* is one of the following choices:

|         |                                                                                           |
|---------|-------------------------------------------------------------------------------------------|
| FINAL   | The letter is not followed by a letter of general category L (e.g. Ll, Lt, Lu, Lm, or Lo) |
| MODERN  | The mapping is only used for modern text                                                  |
| AFTER_i | The last base character was "i" (U+0069)                                                  |

For more information about case mappings see <http://www.unicode.org/unicode/reports/tr21/>

**Unicode::UCD::UnicodeVersion**

`Unicode::UCD::UnicodeVersion()` returns the version of the Unicode Character Database, in other words, the version of the Unicode standard the database implements. The version is a string of numbers delimited by dots ( `' . '` ).

**Implementation Note**

The first use of `charinfo()` opens a read-only filehandle to the Unicode Character Database (the database is included in the Perl distribution). The filehandle is then kept open for further queries. In other words, if you are wondering where one of your filehandles went, that's where.

**BUGS**

Does not yet support EBCDIC platforms.

**AUTHOR**

Jarkko Hietaniemi

**NAME**

UNIVERSAL – base class for ALL classes (blessed references)

**SYNOPSIS**

```
$is_io = $fd->isa("IO::Handle");
$is_io = Class->isa("IO::Handle");

$sub = $obj->can("print");
$sub = Class->can("print");

use UNIVERSAL qw(isa can VERSION);
$yes = isa $ref, "HASH" ;
$sub = can $ref, "fandango" ;
$ver = VERSION $obj ;
```

**DESCRIPTION**

UNIVERSAL is the base class which all bless references will inherit from, see [perlobj](#).

UNIVERSAL provides the following methods and functions:

`$obj-isa( TYPE ), CLASS-isa( TYPE ), isa( VAL, TYPE )`

C<TYPE> is a package name  
 \$obj is a blessed reference or a string containing a package name  
 C<CLASS> is a package name  
 C<VAL> is any of the above or an unblessed reference

When used as an instance or class method (`$obj-isa( TYPE )`), `isa` returns *true* if `$obj` is blessed into package `TYPE` or inherits from package `TYPE`.

When used as a class method (`CLASS-isa( TYPE )`; sometimes referred to as a static method), `isa` returns *true* if `CLASS` inherits from (or is itself) the name of the package `TYPE` or inherits from package `TYPE`.

When used as a function, like

```
use UNIVERSAL qw(isa) ;
$yes = isa $h, "HASH";
$yes = isa "Foo", "Bar";
```

or

```
require UNIVERSAL ;
$yes = UNIVERSAL::isa $a, "ARRAY";
```

, `isa` returns *true* in the same cases as above and also if `VAL` is an unblessed reference to a perl variable of type `TYPE`, such as "HASH", "ARRAY", or "Regexp".

`$obj-can( METHOD ), CLASS-can( METHOD ), can( VAL, METHOD )`

`can` checks if the object or class has a method called `METHOD`. If it does then a reference to the sub is returned. If it does not then *undef* is returned. This includes methods inherited or imported by `$obj`, `CLASS`, or `VAL`.

`can` cannot know whether an object will be able to provide a method through AUTOLOAD, so a return value of *undef* does not necessarily mean the object will not be able to handle the method call. To get around this some module authors use a forward declaration (see [perlsub](#)) for methods they will handle via AUTOLOAD. For such ‘dummy’ subs, `can` will still return a code reference, which, when called, will fall through to the AUTOLOAD. If no suitable AUTOLOAD is provided, calling the coderef will cause an error.

`can` can be called as a class (static) method, an object method, or a function.

When used as a function, if VAL is a blessed reference or package name which has a method called METHOD, can returns a reference to the subroutine. If VAL is not a blessed reference, or if it does not have a method METHOD, *undef* is returned.

#### VERSION ( [ REQUIRE ] )

VERSION will return the value of the variable \$VERSION in the package the object is blessed into. If REQUIRE is given then it will do a comparison and die if the package version is not greater than or equal to REQUIRE.

VERSION can be called as either a class (static) method, an object method or or a function.

These subroutines should *not* be imported via `use UNIVERSAL qw(...)`. If you want simple local access to them you can do

```
*isa = \&UNIVERSAL::isa;
```

to import isa into your package.

**NAME**

User::grent – by-name interface to Perl's built-in `getgr*` () functions

**SYNOPSIS**

```
use User::grent;
$gr = getgrgid(0) or die "No group zero";
if ($gr->name eq 'wheel' && @{$gr->members} > 1) {
 print "gid zero name wheel, with other members";
}

use User::grent qw(:FIELDS;
getgrgid(0) or die "No group zero";
if ($gr_name eq 'wheel' && @gr_members > 1) {
 print "gid zero name wheel, with other members";
}

$gr = getgr($whoever);
```

**DESCRIPTION**

This module's default exports override the core `getgrent()`, `getgruid()`, and `getgrnam()` functions, replacing them with versions that return "User::grent" objects. This object has methods that return the similarly named structure field name from the C's `passwd` structure from *grp.h*; namely `name`, `passwd`, `gid`, and `members` (not `mem`). The first three return scalars, the last an array reference.

You may also import all the structure fields directly into your namespace as regular variables using the `:FIELDS` import tag. (Note that this still overrides your core functions.) Access these fields as variables named with a preceding `gr_`. Thus, `$group_obj->gid()` corresponds to `$gr_gid` if you import the fields. Array references are available as regular array variables, so `@{ $group_obj->members() }` would be simply `@gr_members`.

The `getpw()` function is a simple front-end that forwards a numeric argument to `getpwuid()` and the rest to `getpwnam()`.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. On the other hand, the built-ins are still available via the `CORE::pseudo-package`.

**NOTE**

While this class is currently implemented using the `Class::Struct` module to build a struct-like class, you shouldn't rely upon this.

**AUTHOR**

Tom Christiansen

**NAME**

User::pwent – by-name interface to Perl's built-in `getpw*` () functions

**SYNOPSIS**

```
use User::pwent;
$pw = getpwnam('daemon') || die "No daemon user";
if ($pw->uid == 1 && $pw->dir =~ m#^(bin|tmp)?\z#s) {
 print "gid 1 on root dir";
}

$real_shell = $pw->shell || '/bin/sh';

for (($fullname, $office, $workphone, $homephone) =
 split /\s*,\s*/, $pw->gecos)
{
 s/&/ucfirst(lc($pw->name))/ge;
}

use User::pwent qw(:FIELDS);
getpwnam('daemon') || die "No daemon user";
if ($pw_uid == 1 && $pw_dir =~ m#^(bin|tmp)?\z#s) {
 print "gid 1 on root dir";
}

$pw = getpw($whoever);

use User::pwent qw/:DEFAULT pw_has/;
if (pw_has(qw[gecos expire quota])) { }
if (pw_has("name uid gid passwd")) { }
print "Your struct pwd has: ", scalar pw_has(), "\n";
```

**DESCRIPTION**

This module's default exports override the core `getpwent()`, `getpwuid()`, and `getpwnam()` functions, replacing them with versions that return `User::pwent` objects. This object has methods that return the similarly named structure field name from the C's `passwd` structure from *pwd.h*, stripped of their leading "pw\_" parts, namely `name`, `passwd`, `uid`, `gid`, `change`, `age`, `quota`, `comment`, `class`, `gecos`, `dir`, `shell`, and `expire`. The `passwd`, `gecos`, and `shell` fields are tainted when running in taint mode.

You may also import all the structure fields directly into your namespace as regular variables using the `:FIELDS` import tag. (Note that this still overrides your core functions.) Access these fields as variables named with a preceding `pw_` in front of their method names. Thus, `< $passwd_obj-shell` corresponds to `$pw_shell` if you import the fields.

The `getpw()` function is a simple front-end that forwards a numeric argument to `getpwuid()` and the rest to `getpwnam()`.

To access this functionality without the core overrides, pass the use an empty import list, and then access function functions with their full qualified names. The built-ins are always still available via the `CORE::` pseudo-package.

**System Specifics**

Perl believes that no machine ever has more than one of `change`, `age`, or `quota` implemented, nor more than one of either `comment` or `class`. Some machines do not support `expire`, `gecos`, or allegedly, `passwd`. You may call these methods no matter what machine you're on, but they return `undef` if unimplemented.

You may ask whether one of these was implemented on the system Perl was built on by asking the importable `pw_has` function about them. This function returns true if all parameters are supported fields on

the build platform, false if one or more were not, and raises an exception if you asked about a field that Perl never knows how to provide. Parameters may be in a space-separated string, or as separate arguments. If you pass no parameters, the function returns the list of `struct pwd` fields supported by your build platform's C library, as a list in list context, or a space-separated string in scalar context. Note that just because your C library had a field doesn't necessarily mean that it's fully implemented on that system.

Interpretation of the `gecos` field varies between systems, but traditionally holds 4 comma-separated fields containing the user's full name, office location, work phone number, and home phone number. An `&` in the `gecos` field should be replaced by the user's properly capitalized login name. The `shell` field, if blank, must be assumed to be `/bin/sh`. Perl does not do this for you. The `passwd` is one-way hashed garble, not clear text, and may not be unhashed save by brute-force guessing. Secure systems use more a more secure hashing than DES. On systems supporting shadow password systems, Perl automatically returns the shadow password entry when called by a suitably empowered user, even if your underlying vendor-provided C library was too short-sighted to realize it should do this.

See `passwd(5)` and `getpwent(3)` for details.

## NOTE

While this class is currently implemented using the `Class::Struct` module to build a struct-like class, you shouldn't rely upon this.

## AUTHOR

Tom Christiansen

## HISTORY

March 18th, 2000

Reworked internals to support better interface to dodgy fields than normal Perl function provides.  
Added `pw_has()` field. Improved documentation.

## NAME

utf8 – Perl pragma to enable/disable UTF-8 (or UTF-EBCDIC) in source code

## SYNOPSIS

```
use utf8;
no utf8;
```

## DESCRIPTION

The `use utf8` pragma tells the Perl parser to allow UTF-8 in the program text in the current lexical scope (allow UTF-EBCDIC on EBCDIC based platforms). The `no utf8` pragma tells Perl to switch back to treating the source text as literal bytes in the current lexical scope.

This pragma is primarily a compatibility device. Perl versions earlier than 5.6 allowed arbitrary bytes in source code, whereas in future we would like to standardize on the UTF-8 encoding for source text. Until UTF-8 becomes the default format for source text, this pragma should be used to recognize UTF-8 in the source. When UTF-8 becomes the standard source format, this pragma will effectively become a `no-op`. For convenience in what follows the term *UTF-X* is used to refer to UTF-8 on ASCII and ISO Latin based platforms and UTF-EBCDIC on EBCDIC based platforms.

Enabling the `utf8` pragma has the following effect:

- Bytes in the source text that have their high-bit set will be treated as being part of a literal UTF-8 character. This includes most literals such as identifier names, string constants, and constant regular expression patterns.

On EBCDIC platforms characters in the Latin 1 character set are treated as being part of a literal UTF-EBCDIC character.

Note that if you have bytes with the eighth bit on in your script (for example embedded Latin-1 in your string literals), `use utf8` will be unhappy since the bytes are most probably not well-formed UTF-8. If you want to have such bytes and use `utf8`, you can disable `utf8` until the end the block (or file, if at top level) by `no utf8;`.

## Utility functions

The following functions are defined in the `utf8::` package by the perl core.

- `$num_octets = utf8::upgrade($string);`  
Converts (in-place) internal representation of string to Perl's internal *UTF-X* form. Returns the number of octets necessary to represent the string as *UTF-X*. Can be used to make sure that the UTF-8 flag is on, so that `\w` or `lc()` work as expected on strings containing characters in the range 0x80–0xFF. Note that this should not be used to convert a legacy byte encoding to Unicode: use `Encode` for that. Affected by the encoding pragma.
- `utf8::downgrade($string[, FAIL_OK])`  
Converts (in-place) internal representation of string to be un-encoded bytes. Returns true on success. On failure dies or, if the value of `FAIL_OK` is true, returns false. Can be used to make sure that the UTF-8 flag is off, e.g. when you want to make sure that the `substr()` or `length()` function works with the usually faster byte algorithm. Note that this should not be used to convert Unicode back to a legacy byte encoding: use `Encode` for that. **Not** affected by the encoding pragma.
- `utf8::encode($string)`  
Converts (in-place) *\$string* from logical characters to octet sequence representing it in Perl's *UTF-X* encoding. Same as `Encode::encode_utf8()`. Note that this should not be used to convert a legacy byte encoding to Unicode: use `Encode` for that.
- `$flag = utf8::decode($string)`  
Attempts to convert *\$string* in-place from Perl's *UTF-X* encoding into logical characters. Same as `Encode::decode_utf8()`. Note that this should not be used to convert Unicode back to a legacy

byte encoding: use Encode for that.

- `$flag = utf8::valid(String)`

[INTERNAL] Test whether `String` is in a consistent state. Will return true if string is held as bytes, or is well-formed UTF-8 and has the UTF-8 flag on. Main reason for this routine is to allow Perl's testsuite to check that operations have left strings in a consistent state.

`utf8::encode` is like `utf8::upgrade`, but the UTF8 flag is cleared. See [perlunicode](#) for more on the UTF8 flag and the C API functions `sv_utf8_upgrade`, `sv_utf8_downgrade`, `sv_utf8_encode`, and `sv_utf8_decode`, which are wrapped by the Perl functions `utf8::upgrade`, `utf8::downgrade`, `utf8::encode` and `utf8::decode`. Note that in the Perl 5.8.0 implementation the functions `utf8::valid`, `utf8::encode`, `utf8::decode`, `utf8::upgrade`, and `utf8::downgrade` are always available, without a `require utf8` statement—this may change in future releases.

## BUGS

One can have Unicode in identifier names, but not in package/class or subroutine names. While some limited functionality towards this does exist as of Perl 5.8.0, that is more accidental than designed; use of Unicode for the said purposes is unsupported.

One reason of this unfinishedness is its (currently) inherent unportability: since both package names and subroutine names may need to be mapped to file and directory names, the Unicode capability of the filesystem becomes important—and there unfortunately aren't portable answers.

## SEE ALSO

**NAME**

vars – Perl pragma to predeclare global variable names (obsolete)

**SYNOPSIS**

```
use vars qw($frob @mung %seen);
```

**DESCRIPTION**

NOTE: For variables in the current package, the functionality provided by this pragma has been superseded by `our` declarations, available in Perl v5.6.0 or later. See [our](#).

This will predeclare all the variables whose names are in the list, allowing you to use them under "use strict", and disabling any typo warnings.

Unlike pragmas that affect the `%^H` hints variable, the `use vars` and `use subs` declarations are not BLOCK-scoped. They are thus effective for the entire file in which they appear. You may not rescind such declarations with `no vars` or `no subs`.

Packages such as the **AutoLoader** and **SelfLoader** that delay loading of subroutines within packages can create problems with package lexicals defined using `my()`. While the **vars** pragma cannot duplicate the effect of package lexicals (total transparency outside of the package), it can act as an acceptable substitute by pre-declaring global symbols, ensuring their availability to the later-loaded routines.

See [Pragmatic Modules](#).

**NAME**

vmsish – Perl pragma to control VMS-specific language features

**SYNOPSIS**

```
use vmsish;

use vmsish 'status'; # or '$?'
use vmsish 'exit';
use vmsish 'time';

use vmsish 'hushed';
no vmsish 'hushed';
vmsish::hushed($hush);

use vmsish;
no vmsish 'time';
```

**DESCRIPTION**

If no import list is supplied, all possible VMS-specific features are assumed. Currently, there are four VMS-specific features available: 'status' (a.k.a '\$?'), 'exit', 'time' and 'hushed'.

If you're not running VMS, this module does nothing.

**vmsish status**

This makes \$? and system return the native VMS exit status instead of emulating the POSIX exit status.

**vmsish exit**

This makes `exit 1` produce a successful exit (with status `SS$_NORMAL`), instead of emulating `UNIX exit()`, which considers `exit 1` to indicate an error. As with the CRTL's `exit()` function, `exit 0` is also mapped to an exit status of `SS$_NORMAL`, and any other argument to `exit()` is used directly as Perl's exit status.

**vmsish time**

This makes all times relative to the local time zone, instead of the default of Universal Time (a.k.a Greenwich Mean Time, or GMT).

**vmsish hushed**

This suppresses printing of VMS status messages to `SYS$OUTPUT` and `SYS$ERROR` if Perl terminates with an error status. and allows programs that are expecting "unix-style" Perl to avoid having to parse VMS error messages. It does not suppress any messages from Perl itself, just the messages generated by DCL after Perl exits. The DCL symbol `$STATUS` will still have the termination status, but with a high-order bit set:

**EXAMPLE:**

```
$ perl -e"exit 44;" Non-hushed error exit
%SYSTEM-F-ABORT, abort DCL message
$ show sym $STATUS
$STATUS == "%X0000002C"

$ perl -e"use vmsish qw(hushed); exit 44;" Hushed error exit
$ show sym $STATUS
$STATUS == "%X1000002C"
```

The 'hushed' flag has a global scope during compilation: the `exit()` or `die()` commands that are compiled after 'vmsish hushed' will be hushed when they are executed. Doing a "no vmsish 'hushed'" turns off the hushed flag.

The status of the hushed flag also affects output of VMS error messages from compilation errors. Again, you still get the Perl error message (and the code in `$STATUS`)

## EXAMPLE:

```
use vmsish 'hushed'; # turn on hushed flag
use Carp; # Carp compiled hushed
exit 44; # will be hushed
croak('I die'); # will be hushed
no vmsish 'hushed'; # turn off hushed flag
exit 44; # will not be hushed
croak('I die2'): # WILL be hushed, croak was compiled hushed
```

You can also control the 'hushed' flag at run-time, using the built-in routine `vmsish::hushed()`. Without argument, it returns the hushed status. Since `vmsish::hushed` is built-in, you do not need to "use vmsish" to call it.

## EXAMPLE:

```
if ($quiet_exit) {
 vmsish::hushed(1);
}
print "Ssshhhh...I'm hushed...\n" if vmsish::hushed();
exit 44;
```

Note that an `exit()` or `die()` that is compiled 'hushed' because of "use vmsish" is not un-hushed by calling `vmsish::hushed(0)` at runtime.

The messages from error exits from inside the Perl core are generally more serious, and are not suppressed.

See [Pragmatic Modules](#).

**NAME**

warnings – Perl pragma to control optional warnings

**SYNOPSIS**

```
use warnings;
no warnings;

use warnings "all";
no warnings "all";

use warnings::register;
if (warnings::enabled()) {
 warnings::warn("some warning");
}

if (warnings::enabled("void")) {
 warnings::warn("void", "some warning");
}

if (warnings::enabled($object)) {
 warnings::warn($object, "some warning");
}

warnings::warnif("some warning");
warnings::warnif("void", "some warning");
warnings::warnif($object, "some warning");
```

**DESCRIPTION**

If no import list is supplied, all possible warnings are either enabled or disabled.

A number of functions are provided to assist module authors.

**use warnings::register**

Creates a new warnings category with the same name as the package where the call to the pragma is used.

**warnings::enabled()**

Use the warnings category with the same name as the current package.

Return TRUE if that warnings category is enabled in the calling module. Otherwise returns FALSE.

**warnings::enabled(\$category)**

Return TRUE if the warnings category, *\$category*, is enabled in the calling module. Otherwise returns FALSE.

**warnings::enabled(\$object)**

Use the name of the class for the object reference, *\$object*, as the warnings category.

Return TRUE if that warnings category is enabled in the first scope where the object is used. Otherwise returns FALSE.

**warnings::warn(\$message)**

Print *\$message* to STDERR.

Use the warnings category with the same name as the current package.

If that warnings category has been set to "FATAL" in the calling module then die. Otherwise return.

**warnings::warn(\$category, \$message)**

Print *\$message* to STDERR.

If the warnings category, `$category`, has been set to "FATAL" in the calling module then die. Otherwise return.

`warnings::warn($object, $message)`

Print `$message` to STDERR.

Use the name of the class for the object reference, `$object`, as the warnings category.

If that warnings category has been set to "FATAL" in the scope where `$object` is first used then die. Otherwise return.

`warnings::warnif($message)`

Equivalent to:

```
if (warnings::enabled())
{ warnings::warn($message) }
```

`warnings::warnif($category, $message)`

Equivalent to:

```
if (warnings::enabled($category))
{ warnings::warn($category, $message) }
```

`warnings::warnif($object, $message)`

Equivalent to:

```
if (warnings::enabled($object))
{ warnings::warn($object, $message) }
```

See [Pragmatic Modules](#) and [perllexwarn](#).

**NAME**

warnings::register – warnings import function

**SYNOPSIS**

```
use warnings::register ;
```

**DESCRIPTION**

Create a warnings category with the same name as the current package.

See [Pragmatic Modules](#) and [perllexwarn](#).

**NAME**

Win32 – Interfaces to some Win32 API Functions

**DESCRIPTION**

Perl on Win32 contains several functions to access Win32 APIs. Some are included in Perl itself (on Win32) and some are only available after explicitly requesting the Win32 module with:

```
use Win32;
```

The builtin functions are marked as [CORE] and the other ones as [EXT] in the following alphabetical listing. The Win32 module is not part of the Perl source distribution; it is distributed in the libwin32 bundle of Win32::\* modules on CPAN. The module is already preinstalled in binary distributions like ActivePerl.

**Alphabetical Listing of Win32 Functions**

Win32::AbortSystemShutdown(MACHINE)

[EXT] Aborts a system shutdown (started by the InitiateSystemShutdown function) on the specified MACHINE.

Win32::BuildNumber()

[CORE] Returns the ActivePerl build number. This function is only available in the ActivePerl binary distribution.

Win32::CopyFile(FROM, TO, OVERWRITE)

[CORE] The Win32::CopyFile() function copies an existing file to a new file. All file information like creation time and file attributes will be copied to the new file. However it will **not** copy the security information. If the destination file already exists it will only be overwritten when the OVERWRITE parameter is true. But even this will not overwrite a read-only file; you have to unlink() it first yourself.

Win32::DomainName()

[CORE] Returns the name of the Microsoft Network domain that the owner of the current perl process is logged into. This function does **not** work on Windows 9x.

Win32::ExpandEnvironmentStrings(STRING)

[EXT] Takes STRING and replaces all referenced environment variable names with their defined values. References to environment variables take the form %VariableName%. Case is ignored when looking up the VariableName in the environment. If the variable is not found then the original %VariableName% text is retained. Has the same effect as the following:

```
$string =~ s/%([^\%]*)%/$ENV{$1} || "%$1%"/eg
```

Win32::FormatMessage(ERRORCODE)

[CORE] Converts the supplied Win32 error number (e.g. returned by Win32::GetLastError()) to a descriptive string. Analogous to the perror() standard-C library function. Note that \$^E used in a string context has much the same effect.

```
C:\> perl -e "$^E = 26; print $^E;"
The specified disk or diskette cannot be accessed
```

Win32::FsType()

[CORE] Returns the name of the filesystem of the currently active drive (like 'FAT' or 'NTFS'). In list context it returns three values: (FSTYPE, FLAGS, MAXCOMPLEN). FSTYPE is the filesystem type as before. FLAGS is a combination of values of the following table:

|            |                                   |
|------------|-----------------------------------|
| 0x00000001 | supports case-sensitive filenames |
| 0x00000002 | preserves the case of filenames   |
| 0x00000004 | supports Unicode in filenames     |
| 0x00000008 | preserves and enforces ACLs       |

|            |                                           |
|------------|-------------------------------------------|
| 0x00000010 | supports file-based compression           |
| 0x00000020 | supports disk quotas                      |
| 0x00000040 | supports sparse files                     |
| 0x00000080 | supports reparse points                   |
| 0x00000100 | supports remote storage                   |
| 0x00008000 | is a compressed volume (e.g. DoubleSpace) |
| 0x00010000 | supports object identifiers               |
| 0x00020000 | supports the Encrypted File System (EFS)  |

MAXCOMPLEN is the maximum length of a filename component (the part between two backslashes) on this file system.

### Win32::FreeLibrary(HANDLE)

[EXT] Unloads a previously loaded dynamic-link library. The HANDLE is no longer valid after this call. See [LoadLibrary/Win32::LoadLibrary\(LIBNAME\)](#) for information on dynamically loading a library.

### Win32::GetArchName()

[EXT] Use of this function is deprecated. It is equivalent with `$ENV{PROCESSOR_ARCHITECTURE}`. This might not work on Win9X.

### Win32::GetChipName()

[EXT] Returns the processor type: 386, 486 or 586 for Intel processors, 21064 for the Alpha chip.

### Win32::GetCwd()

[CORE] Returns the current active drive and directory. This function does not return a UNC path, since the functionality required for such a feature is not available under Windows 95.

### Win32::GetFullPathName(FILENAME)

[CORE] GetFullPathName combines the FILENAME with the current drive and directory name and returns a fully qualified (aka, absolute) path name. In list context it returns two elements: (PATH, FILE) where PATH is the complete pathname component (including trailing backslash) and FILE is just the filename part. Note that no attempt is made to convert 8.3 components in the supplied FILENAME to longnames or vice-versa. Compare with Win32::GetShortPathName and Win32::GetLongPathName.

This function has been added for Perl 5.6.

### Win32::GetLastError()

[CORE] Returns the last error value generated by a call to a Win32 API function. Note that `$_E` used in a numeric context amounts to the same value.

### Win32::GetLongPathName(PATHNAME)

[CORE] Returns a representation of PATHNAME composed of longname components (if any). The result may not necessarily be longer than PATHNAME. No attempt is made to convert PATHNAME to the absolute path. Compare with Win32::GetShortPathName and Win32::GetFullPathName.

This function has been added for Perl 5.6.

### Win32::GetNextAvailDrive()

[CORE] Returns a string in the form of "<d:" where <d is the first available drive letter.

### Win32::GetOSVersion()

[CORE] Returns the array (STRING, MAJOR, MINOR, BUILD, ID), where the elements are, respectively: An arbitrary descriptive string, the major version number of the operating system, the minor version number, the build number, and a digit indicating the actual operating system. For the ID, the values are 0 for Win32s, 1 for Windows 9X and 2 for Windows NT/2000/XP. In scalar context it returns just the ID.

Currently known values for ID MAJOR and MINOR are as follows:

| OS                  | ID | MAJOR | MINOR |
|---------------------|----|-------|-------|
| Win32s              | 0  | -     | -     |
| Windows 95          | 1  | 4     | 0     |
| Windows 98          | 1  | 4     | 10    |
| Windows Me          | 1  | 4     | 90    |
| Windows NT 3.51     | 2  | 3     | 51    |
| Windows NT 4        | 2  | 4     | 0     |
| Windows 2000        | 2  | 5     | 0     |
| Windows XP          | 2  | 5     | 1     |
| Windows .NET Server | 2  | 5     | 1     |

Unfortunately as of June 2002 there is no way to distinguish between .NET servers and XP servers without using additional modules.

`Win32::GetOSName()`

[EXT] In scalar context returns the name of the Win32 operating system being used. In list context returns a two element list of the OS name and whatever edition information is known about the particular build (for Win9x boxes) and whatever service packs have been installed. The latter is roughly equivalent to the first item returned by `GetOSVersion()` in list context.

Currently the possible values for the OS name are

`Win32s Win95 Win98 WinMe Win2000 WinXP/.Net WinNT3.51 WinNT4`

This routine is just a simple interface into `GetOSVersion()`. More specific or demanding situations should use that instead. Another option would be to use `POSIX::uname()`, however the latter appears to report only the OS family name and not the specific OS. In scalar context it returns just the ID.

`Win32::GetShortPathName(PATHNAME)`

[CORE] Returns a representation of `PATHNAME` composed only of short (8.3) path components. The result may not necessarily be shorter than `PATHNAME`. Compare with `Win32::GetFullPathName` and `Win32::GetLongPathName`.

`Win32::GetProcAddress(INSTANCE, PROCNAME)`

[EXT] Returns the address of a function inside a loaded library. The information about what you can do with this address has been lost in the mist of time. Use the `Win32::API` module instead of this deprecated function.

`Win32::GetTickCount()`

[CORE] Returns the number of milliseconds elapsed since the last system boot. Resolution is limited to system timer ticks (about 10ms on WinNT and 55ms on Win9X).

`Win32::InitiateSystemShutdown`

(`MACHINE`, `MESSAGE`, `TIMEOUT`, `FORCECLOSE`, `REBOOT`)

[EXT] Shutdown the specified `MACHINE`, notifying users with the supplied `MESSAGE`, within the specified `TIMEOUT` interval. Forces closing of all documents without prompting the user if `FORCECLOSE` is true, and reboots the machine if `REBOOT` is true. This function works only on WinNT.

`Win32::IsWinNT()`

[CORE] Returns non zero if the Win32 subsystem is Windows NT.

`Win32::IsWin95()`

[CORE] Returns non zero if the Win32 subsystem is Windows 95.

**Win32::LoadLibrary(LIBNAME)**

[EXT] Loads a dynamic link library into memory and returns its module handle. This handle can be used with Win32::GetProcAddress and Win32::FreeLibrary. This function is deprecated. Use the Win32::API module instead.

**Win32::LoginName()**

[CORE] Returns the username of the owner of the current perl process.

**Win32::LookupAccountName(SYSTEM, ACCOUNT, DOMAIN, SID, SIDTYPE)**

[EXT] Looks up ACCOUNT on SYSTEM and returns the domain name the SID and the SID type.

**Win32::LookupAccountSID(SYSTEM, SID, ACCOUNT, DOMAIN, SIDTYPE)**

[EXT] Looks up SID on SYSTEM and returns the account name, domain name, and the SID type.

**Win32::MsgBox(MESSAGE [, FLAGS [, TITLE]])**

[EXT] Create a dialogbox containing MESSAGE. FLAGS specifies the required icon and buttons according to the following table:

|                    |   |                                       |
|--------------------|---|---------------------------------------|
| 0                  | = | OK                                    |
| 1                  | = | OK and Cancel                         |
| 2                  | = | Abort, Retry, and Ignore              |
| 3                  | = | Yes, No and Cancel                    |
| 4                  | = | Yes and No                            |
| 5                  | = | Retry and Cancel                      |
| MB_ICONSTOP        |   | "X" in a red circle                   |
| MB_ICONQUESTION    |   | question mark in a bubble             |
| MB_ICONEXCLAMATION |   | exclamation mark in a yellow triangle |
| MB_ICONINFORMATION |   | "i" in a bubble                       |

TITLE specifies an optional window title. The default is "Perl".

The function returns the menu id of the selected push button:

|   |        |
|---|--------|
| 0 | Error  |
| 1 | OK     |
| 2 | Cancel |
| 3 | Abort  |
| 4 | Retry  |
| 5 | Ignore |
| 6 | Yes    |
| 7 | No     |

**Win32::NodeName()**

[CORE] Returns the Microsoft Network node-name of the current machine.

**Win32::RegisterServer(LIBRARYNAME)**

[EXT] Loads the DLL LIBRARYNAME and calls the function DllRegisterServer.

**Win32::SetChildShowWindow(SHOWWINDOW)**

[CORE] Sets the *ShowMode* of child processes started by `system()`. By default `system()` will create a new console window for child processes if Perl itself is not running from a console. Calling `SetChildShowWindow(0)` will make these new console windows invisible. Calling `SetChildShowWindow()` without arguments reverts `system()` to the default behavior. The return value of `SetChildShowWindow()` is the previous setting or undef.

[EXT] The following symbolic constants for SHOWWINDOW are available (but not exported) from the Win32 module: SW\_HIDE, SW\_SHOWNORMAL, SW\_SHOWMINIMIZED,

SW\_SHOWMAXIMIZED and SW\_SHOWNOACTIVATE.

Win32::SetCwd(NEWDIRECTORY)

[CORE] Sets the current active drive and directory. This function does not work with UNC paths, since the functionality required to required for such a feature is not available under Windows 95.

Win32::SetLastError(ERROR)

[CORE] Sets the value of the last error encountered to ERROR. This is that value that will be returned by the `Win32::GetLastError()` function. This functions has been added for Perl 5.6.

Win32::Sleep(TIME)

[CORE] Pauses for TIME milliseconds. The timeslices are made available to other processes and threads.

Win32::Spawn(COMMAND, ARGS, PID)

[CORE] Spawns a new process using the supplied COMMAND, passing in arguments in the string ARGS. The pid of the new process is stored in PID. This function is deprecated. Please use the Win32::Process module instead.

Win32::UnregisterServer(LIBRARYNAME)

[EXT] Loads the DLL LIBRARYNAME and calls the function DllUnregisterServer.

**NAME**

GDBM\_File – Perl5 access to the gdbm library.

**SYNOPSIS**

```
use GDBM_File ;
tie %hash, 'GDBM_File', $filename, &GDBM_WRCREAT, 0640;
Use the %hash array.
untie %hash ;
```

**DESCRIPTION**

**GDBM\_File** is a module which allows Perl programs to make use of the facilities provided by the GNU gdbm library. If you intend to use this module you should really have a copy of the gdbm manualpage at hand.

Most of the libgdbm.a functions are available through the GDBM\_File interface.

**AVAILABILITY**

gdbm is available from any GNU archive. The master site is <ftp.gnu.org>, but you are strongly urged to use one of the many mirrors. You can obtain a list of mirror sites from <http://www.gnu.org/order/ftp.html>.

**BUGS**

The available functions and the gdbm/perl interface need to be documented.

**SEE ALSO**

*[perl\(1\)](#), [DB\\_File\(3\)](#), [perldbmsfilter](#).*

## NAME

ODBM\_File – Tied access to odbm files

## SYNOPSIS

```
use Fcntl; # For O_RDWR, O_CREAT, etc.
use ODBM_File;

Now read and change the hash
$h{newkey} = newvalue;
print $h{oldkey};
...

untie %h;
```

## DESCRIPTION

ODBM\_File establishes a connection between a Perl hash variable and a file in ODBM\_File format. You can manipulate the data in the file just as if it were in a Perl hash, but when your program exits, the data will remain in the file, to be used the next time your program runs.

Use ODBM\_File with the Perl built-in `tie` function to establish the connection between the variable and the file. The arguments to `tie` should be:

1. The hash variable you want to tie.
2. The string "ODBM\_File". (This tells Perl to use the ODBM\_File package to perform the functions of the hash.)
3. The name of the file you want to tie to the hash.
4. Flags. Use one of:

O\_RDONLY

Read-only access to the data in the file.

O\_WRONLY

Write-only access to the data in the file.

O\_RDWR

Both read and write access.

If you want to create the file if it does not exist, add O\_CREAT to any of these, as in the example. If you omit O\_CREAT and the file does not already exist, the `tie` call will fail.

5. The default permissions to use if a new file is created. The actual permissions will be modified by the user's `umask`, so you should probably use 0666 here. (See [umask](#).)

## DIAGNOSTICS

On failure, the `tie` call returns an undefined value and probably sets `$!` to contain the reason the file could not be tied.

**odbm store returned -1, errno 22, key "... at ...**

This warning is emitted when you try to store a key or a value that is too long. It means that the change was not recorded in the database. See BUGS AND WARNINGS below.

## BUGS AND WARNINGS

There are a number of limits on the size of the data that you can store in the ODBM file. The most important is that the length of a key, plus the length of its associated value, may not exceed 1008 bytes.

See [tie](#), [perlodbmfilter](#), [Fcntl](#)

## NAME

NDBM\_File – Tied access to ndbm files

## SYNOPSIS

```
use Fcntl; # For O_RDWR, O_CREAT, etc.
use NDBM_File;

Now read and change the hash
$h{newkey} = newvalue;
print $h{oldkey};
...

untie %h;
```

## DESCRIPTION

NDBM\_File establishes a connection between a Perl hash variable and a file in NDBM\_File format. You can manipulate the data in the file just as if it were in a Perl hash, but when your program exits, the data will remain in the file, to be used the next time your program runs.

Use NDBM\_File with the Perl built-in `tie` function to establish the connection between the variable and the file. The arguments to `tie` should be:

1. The hash variable you want to tie.
2. The string "NDBM\_File". (This tells Perl to use the NDBM\_File package to perform the functions of the hash.)
3. The name of the file you want to tie to the hash.
4. Flags. Use one of:

O\_RDONLY

Read-only access to the data in the file.

O\_WRONLY

Write-only access to the data in the file.

O\_RDWR

Both read and write access.

If you want to create the file if it does not exist, add O\_CREAT to any of these, as in the example. If you omit O\_CREAT and the file does not already exist, the `tie` call will fail.

5. The default permissions to use if a new file is created. The actual permissions will be modified by the user's `umask`, so you should probably use 0666 here. (See [umask](#).)

## DIAGNOSTICS

On failure, the `tie` call returns an undefined value and probably sets `$!` to contain the reason the file could not be tied.

**ndbm store returned -1, errno 22, key "... " at ...**

This warning is emitted when you try to store a key or a value that is too long. It means that the change was not recorded in the database. See **BUGS AND WARNINGS** below.

## BUGS AND WARNINGS

There are a number of limits on the size of the data that you can store in the NDBM file. The most important is that the length of a key, plus the length of its associated value, may not exceed 1008 bytes.

See [tie](#), [perlndbmfilter](#), [Fcntl](#)

## NAME

SDBM\_File – Tied access to sdbm files

## SYNOPSIS

```
use Fcntl; # For O_RDWR, O_CREAT, etc.
use SDBM_File;

tie(%h, 'SDBM_File', 'filename', O_RDWR|O_CREAT, 0666)
 or die "Couldn't tie SDBM file 'filename': $!; aborting";

Now read and change the hash
$h{newkey} = newvalue;
print $h{oldkey};
...

untie %h;
```

## DESCRIPTION

SDBM\_File establishes a connection between a Perl hash variable and a file in SDBM\_File format. You can manipulate the data in the file just as if it were in a Perl hash, but when your program exits, the data will remain in the file, to be used the next time your program runs.

Use SDBM\_File with the Perl built-in `tie` function to establish the connection between the variable and the file. The arguments to `tie` should be:

1. The hash variable you want to tie.
2. The string "SDBM\_File". (This tells Perl to use the SDBM\_File package to perform the functions of the hash.)
3. The name of the file you want to tie to the hash.
4. Flags. Use one of:

`O_RDONLY`

Read-only access to the data in the file.

`O_WRONLY`

Write-only access to the data in the file.

`O_RDWR`

Both read and write access.

If you want to create the file if it does not exist, add `O_CREAT` to any of these, as in the example. If you omit `O_CREAT` and the file does not already exist, the `tie` call will fail.

5. The default permissions to use if a new file is created. The actual permissions will be modified by the user's `umask`, so you should probably use 0666 here. (See [umask](#).)

## DIAGNOSTICS

On failure, the `tie` call returns an undefined value and probably sets `$!` to contain the reason the file could not be tied.

**sdbm store returned -1, errno 22, key "..."** at ...

This warning is emitted when you try to store a key or a value that is too long. It means that the change was not recorded in the database. See **BUGS AND WARNINGS** below.

## BUGS AND WARNINGS

There are a number of limits on the size of the data that you can store in the SDBM file. The most important is that the length of a key, plus the length of its associated value, may not exceed 1008 bytes.

See *[tie](#)*, *[perldbmfilter](#)*, *[Fcntl](#)*

**NAME**

XS::Typemap – module to test the XS typemaps distributed with perl

**SYNOPSIS**

```
use XS::Typemap;

$output = T_IV($input);
$output = T_PV($input);
@output = T_ARRAY(@input);
```

**DESCRIPTION**

This module is used to test that the XS typemaps distributed with perl are working as advertised. A function is available for each typemap definition (eventually). In general each function takes a variable, processes it through the OUTPUT typemap and then returns it using the INPUT typemap.

A test script can then compare the input and output to make sure they are the expected values. When only an input or output function is provided the function will be named after the typemap entry and have either ‘\_IN’ or ‘\_OUT’ appended.

All the functions are exported. There is no reason not to do this since the entire purpose is for testing Perl. Namespace pollution will be limited to the test script.

**NOTES**

This module is for testing only and should not normally be installed.

**NAME**

Tutorial – Perl and Java

**SYNOPSIS**

Java and Perl have different strengths and complement each other well.

You can connect them at runtime with tools such as JPL, PJC, or ActiveX. In theory, you can convert Perl to Java bytecode, and vice-versa.

**Note:**

Not actually a conversion.

At this stage, we are generating Java opcodes by walking Perl's syntax tree. This is very different from converting Perl to Java. It's a lot easier!

**1.1 Perl and Java, Compared**

Perl offers rich text processing features, high-level network APIs, excellent database integration, and a centralized repository of reusable code:

- Regular expression engine is a powerful sub language that can perform complex text manipulations and extract data.
- Packages such as libwww-perl (LWP) and libnet are powerful, high-level interfaces to network functionality.
- The Perl DBI is an interface to SQL data sources.
- CPAN provides a centralized, organized archive of reusable code.

Java has a powerful graphical API, has numerous embedded implementations, excellent database integration, but no single recognized repository of reusable code.

- The Swing (JFC) toolkit is a powerful toolkit for developing user interfaces. Java also boasts 2D and 3D graphics APIs.
- Java comes in embedded flavors, such as:
  - Kaffe <http://www.transvirtual.com/> – embedded implementations for different platforms
  - Waba <http://www.wabasoft.com/> – a subset of Java for Windows CE and PalmOS
  - It's embedded into web browsers (Netscape and MS Internet Explorer)
  - and more...
- Java's JDBC is similar to Perl's DBI
- Java has many different repositories of code. Efforts such as the Giant Java Tree <http://www.gjt.org/> attempt to create a unified repository.

**1.2 Opportunities to Combine Java and Perl**

You have a Java program with a lot of data that needs to be parsed, filed, briefed, debriefed, and numbered.

You want to build your GUI in Java, but let Perl do the heavy lifting.

You've adopted the "Java is a systems language, Perl is a scripting language" paradigm, and it works for you.

You're not sure which regex implementation to use:

```
org.teeth.green.loony.raving.monster.regex.*;
com.zeppelin.regex.*;
```

You want the **best of both worlds**.

### 1.3 Important Differences between Java and Perl

- `perl` compiles and executes programs each time you run them (unless you use the Perl compiler).
- `javac` compiles programs in advance, `java` runs them in the Java interpreter.
- The Java interpreter supports method overloading (methods can have the same name, but are differentiated on the basis of their argument types). Overloaded methods generally perform the same function, but methods with a shorter argument list often use defaults:

```
// Draw a circle in the center of the screen
int drawCircle(int radius);
```

```
// Draw a circle at specified coordinates
int drawCircle(int radius, int h, int k);
```

- The Perl interpreter doesn't support method overloading. In JPL, when we call Java from Perl, we need to use some tricks to specify the Java method we want to invoke. We'll learn about this when we see JPL's `getmeth` function.

#### Note:

At the time this presentation was prepared, JPL did not work with Perl for Win32. However, JPL is in the core Perl distribution, and there are plans to make it work with Perl for Win32.

With that in mind, I'm presenting the JPL material first, because it is of interest to both Win32 and Unix Perl people. The Win32-specific stuff (alternatives to JPL) will come last. I won't be offended if the Unix people leave when I move to this section of the tutorial, since there is no Unix material in that section. I'm perfectly happy to take questions between JPL and ActiveX sections.

A subset of JPL now works on Win32. You can embed Java in Perl, but you cannot embed Perl in Java (yet).

## 2.1 JPL Overview

Let's look at an overview of JPL.

### 2.1.1 Calling Perl from Java

Well-supported by JPL, but it is a complicated process:

- The JPL preprocessor parses the *.jpl* file and generates C code wrappers for Perl methods. It also generates Java and Perl source files.
- The C compiler compiles the wrapper and links it to the *libPerlInterpreter.so* shared library, producing a shared library for the wrapper.
- The Java compiler compiles the Java source file, which uses native methods to load the wrapper.
- The wrapper connects the Java code to the Perl code in the Perl source file.

Fortunately, a generic ***Makefile.PL*** simplifies the process. This is a Perl script that generates a *Makefile* for you.

### 2.1.2 Calling Java from Perl

This works best when Perl is embedded within a Java program.

The JNI Perl module creates and loads a JVM. There is no precompiler, nothing extra — it's just a Perl module and extension.

B<A Problem, Though>. In theory, you can call Java from standalone Perl programs, but this doesn't work because some implementations of Java use a user-level threads package (green threads) that override some functions in the C library. Perl is comfortable using these functions, but Java is not happy using the standard C

library functions.

So, with green threads, you can't reliably embed Java in a standalone Perl program.

Many Java implementations now use native threads. JPL has been tested on Solaris with JDK 1.1.x and native threads, but not on Linux.

**Note:**

Oddly enough, this is the only way it works on Win32.

On Unix, I've still had trouble, even with native threads. I might need to recompile perl with `-DREENTRANT`, but I'm not sure.

## 2.2 Working with JPL

How to set up a JPL application, compile, and install it.

### 2.2.1 Setting up a Project

- 1 The `install-jpl` script creates the `setvars` script. Source the output of `setvars` into your shell when you want to develop or run JPL applications.
- 2 Create a directory with the name of your project, such as *Frotz*. (if you want to use the generic *Makefile.PL*, you need a separate directory for each JPL class you create).
- 3 Copy the generic *Makefile.PL* into the project directory. The `jpl/Sample` directory in the Perl distribution includes the generic *Makefile.PL*.
- 4 Write a `.jpl` program with the same name as the project (such as *Frotz.jpl*)

### 2.2.2 Compiling and Installing a Project

Type `make` to compile the application, and `make install` to install it. This installs the application in the `jpl` directory you created when you installed JPL.

B<Beware>. The default `I<jpl>` directory is the same as the directory you install it `I<from>`. If you go with the default and delete your Perl source, you'll delete your JPL installation!

Type `java Frotz` (or the name you chose in step 2 of section 2.2.1) to run it

### 2.2.3 What's in the `jpl` Directory?

- **libPerlInterpreter.so**: a shared library that loads the Perl interpreter.
- Compiled *.class* files for JPL applications you have written.
- Native code shared library wrappers for JPL applications you have written.
- Perl scripts that contain the Perl code to load at runtime.

Beware. If you issue the `C<make>` command and then run the examples in your development directory, you might be in for a surprise! If the JPL directories come first in your `CLASSPATH` and `LD_LIBRARY_PATH`, you'll keep running the installed, older version, rather than the one you are developing

**Note:**

"Source" means to load it into your current shell, with something like:

```
eval-backtick-setvars-backtick
```

as opposed to just executing it, because then only the subshell gets the environment vars.

## 2.3 Calling Perl from Java

Now, we'll look at how you can invoke Perl from Java.

### 2.3.1 Perl Methods

You can put Perl methods in your *.jpl* file. Perl methods are declared `perl` and use double curly braces to make life easier on the JPL preprocessor:

```
perl int perlMultiply(int a, int b) {{
 my $result = $a * $b;
 return $result;
}}
```

In your Java code, you can invoke Perl methods like a Java method. The native code wrappers take care of running the Perl code:

```
public void invokePerlFunction() {
 int x = 3;
 int y = 6;
 int retval = perlMultiply(x, y);
 System.out.println(x + " * " + y + " = " + retval);
}

class MethodDemo

class MethodDemo {
 // A Perl method to multiply two numbers and
 // return the result.
 //
 perl int perlMultiply(int a, int b) {{
 my $result = $a * $b;
 return $result;
 }}

 // A Java method to call the Perl function.
 //
 public void invokePerlFunction() {
 int x = 3;
 int y = 6;
 int retval = perlMultiply(x, y);
 System.out.println(x + " * " + y + " = " + retval);
 }

 public static void main(String[] args) {
 MethodDemo demo = new MethodDemo();
 demo.invokePerlFunction();
 }
}
```

### Where did `$self` go?

Don't worry, `$self` is still there. JPL takes care of fetching it, as well as all the other arguments:

```
perl int perlMultiply(int a, int b) {{
 my $result = $a * $b;
 return $result;
}}

perl void calculateProduct() {{
 my $x = 3;
 my $y = 6;
```

```

 my $retval = $self->perlMultiply($x, $y);
 print "$x * $y = $retval\n";
 }}

```

B<Note>. JPL takes care of putting all the arguments, including C<\$self>, into variables. If you see a variable in the function header, you will get a variable of the same name without having to use C<shift> or C<@\_>, guaranteed.

NOTE: I've added a line that prints the output of "ref dollar sign self" You'll see this when I run the demo.

```

class SelfDemo {
 // A Perl method to multiply two values.
 //
 perl int perlMultiply(int a, int b) {{
 my $result = $a * $b;
 return $result;
 }}

 // A Perl method to invoke another Perl method.
 //
 perl void calculateProduct() {{
 my $x = 3;
 my $y = 6;
 # Ahhh. There's our old friend, $self!
 #
 my $retval = $self->perlMultiply($x, $y);
 # Display the results.
 #
 print "$x * $y = $retval\n";
 }}

 public static void main(String[] args) {
 SelfDemo demo = new SelfDemo();
 demo.calculateProduct();
 }
}

```

## Passing Arrays

If you pass an array from Java into a Perl method, it arrives in the form of a scalar reference.

Use the `GetIntArrayElements()` JNI function to convert that scalar into an array of integers.

```

perl void min_max(int[] data) {{
 # Get the array elements
 #
 my @new_array = GetIntArrayElements($data);
 # Sort the array numerically
 #
 my @sorted = sort { $a <=> $b } @new_array;

 print "Min: $sorted[0], ",
 "Max: $sorted[$#sorted]\n";
}}

void minMaxDemo() {
 int[] data = {101, 99, 42, 666, 23};
 min_max(data);
}

```

```
}
```

Some JNI Array Functions

**GetBooleanArrayElements( scalar )**

Converts scalar to an array of booleans.

**GetByteArrayElements( scalar )**

Converts scalar to an array of bytes.

**GetCharArrayElements( scalar )**

Converts scalar to an array of characters.

**GetShortArrayElements( scalar )**

Converts scalar to an array of short integers.

**GetIntArrayElements( scalar )**

Converts scalar to an array of integers.

**GetLongArrayElements( scalar )**

Converts scalar to an array of long integers.

**GetFloatArrayElements( scalar )**

Converts scalar to an array of floating point numbers.

**GetDoubleArrayElements( scalar )**

Converts scalar to an array of double precision numbers.

**GetArrayLength( scalar )**

Returns the length of the array.

**PerlTakesArray.jpl**

```
// Show how to pass an array from Java to Perl.
```

```
//
```

```
public class PerlTakesArray {
perl void min_max(int[] data) {{
 # Get the array elements
 #
 my @new_array = GetIntArrayElements($data);
 # Sort the array numerically
 #
 my @sorted = sort {$a <=> $b} @new_array;
 print "Min: $sorted[0], ",
 "Max: $sorted[$#sorted]\n";
}}

void minMaxDemo() {
 // Create an array and ask Perl to tell us
 // the min and max values.
 int[] data = {101, 99, 42, 666, 23};
 min_max(data);
}

public static void main(String[] argv) {
 PerlTakesArray demo = new PerlTakesArray();
 demo.minMaxDemo();
}
```

```
}
```

### 2.3.4 Passing Arrays of Objects

Working with arrays of objects is a little more complicated, because you need to work with them one at a time.

Fetch one element at a time with `GetObjectArrayElement()`, which returns an object of type `java.lang.Object` (the most generic type).

Explicitly cast the `Object` to its real type with `bless()`.

```
perl void sortArray(String[] names) {{
 my @new_array;
 for (my $i = 0; $i < GetArrayLength($names); $i++) {
 my $string = GetObjectArrayElement($names, $i);
 bless $string, "java::lang::String";
 push @new_array, $string;
 }
 print join(', ', sort @new_array), "\n";
}}

void arrayDemo() {
 String[] names = {"Omega", "Gamma", "Beta", "Alpha"};
 sortArray(names);
}
```

Note. `String` is not a primitive type: it is a class (`java.lang.String`). So, you need to use this technique for `Strings` as well. You can't use the technique in 2.3.3.

`PerlTakesObjectArray.jpl`

```
public class PerlTakesObjectArray {
 // Perl method to sort an array of strings.
 //
 perl void sortArray(String[] names) {{
 my @new_array; # an array to copy names[] to

 # Fetch each element from the array.
 for (my $i = 0; $i < GetArrayLength($names); $i++) {
 # Get the object (it's not a String yet!) at
 # the current index ($i).
 my $string = GetObjectArrayElement($names, $i);

 # Cast (bless) it into a String.
 bless $string, "java::lang::String";

 # Add it to the array.
 push @new_array, $string;
 }

 # Print the sorted, comma-delimited array.
 print join(', ', sort @new_array), "\n";
 }}

 // Create a String array and ask Perl to sort it for us.
 //

 void arrayDemo() {
 String[] names = {"Omega", "Gamma", "Beta", "Alpha"};
 sortArray(names);
 }
}
```

```

 }

 public static void main(String[] argv) {
 PerlTakesObjectArray demo = new PerlTakesObjectArray();
 demo.arrayDemo();
 }
}

```

### 2.3.5 Returning Arrays from Perl to Java

To write a Perl method that returns an array, declare its return value as an array type. Make sure you return a reference to the array, not a list:

```

perl int[] getTime() {{
 my ($sec, $min, $hour, @unused) = localtime(time);
 # Return an array with seconds, minutes, hours
 my @time_array = ($sec, $min, $hour);
 return \@time_array;
}}

void testArray() {
 int time[] = getTime();
 System.out.println(time[2] + ":" + time[1]);
}

```

PerlGivesArray.jpl

```

// Simple JPL demo to show how to send an array to Java
// from Perl

class PerlGivesArray {
 // Call the Perl method to get an array and print
 // the hour and minute elements.

 void testArray() {
 int time[] = getTime();
 System.out.println(time[2] + ":" + time[1]);
 }

 // Perl method that returns an array reference.
 //
 perl int[] getTime() {{
 # Get the first three arguments from localtime,
 # discard the rest.
 my ($sec, $min, $hour, @unused) = localtime(time);

 # Return an array with seconds, minutes, hours
 my @time_array = ($sec, $min, $hour);
 return \@time_array;
 }}

 public static void main(String[] argv) {
 PerlGivesArray demo = new PerlGivesArray();
 demo.testArray();
 }
}

```

### 2.3.6 Arrays from Strings

JPL will slice Perl strings up into Java arrays for you. If you declare a Perl method as an array type and return a string (instead of an array reference), JPL splits up the elements into an array.

Consider this example, where a GIF stored in a string gets turned into an array of bytes so Java can make an Image out of it:

```
void generateImage() {
 Toolkit kit = Toolkit.getDefaultToolkit();
 byte[] image_data = mkImage();
 img = kit.createImage(image_data);
}

perl byte[] mkImage() {{
 use GD;
 my $im = new GD::Image($self->width, $self->height);
 my $white = $im->colorAllocate(255, 255, 255);
 my $blue = $im->colorAllocate(0, 0, 255);
 $im->fill($white, 0, 0);
 $im->string(gdLargeFont, 10, 10, "Hello, World", $blue);
 return $im->gif;
}}
```

GifDemo.jpl

```
import java.awt.*;
import java.awt.event.*;
import java.awt.image.*;

/*
 * A JPL program that demonstrates passing byte arrays
 * between Java and Perl
 */

class GIFDemo extends Canvas {
 Image img;
 int width = 200;
 int height = 30;

 // Constructor for this class.
 public GIFDemo() {
 this.setSize(width, height);
 }

 // Java method to create an image.
 //
 void generateImage() {
 Toolkit kit = Toolkit.getDefaultToolkit();

 // Invoke the mkImage() Perl method to generate an
 // image.

 byte[] image_data = mkImage();

 // Create the image with the byte array we got
 // from the Perl method.

 img = kit.createImage(image_data);
 }

 // A Perl method to generate an image.
 perl byte[] mkImage() {{
```

```

 # Use the GD image manipulation extension.
 use GD;

 # Create a new image with the height and width specified
 # in the enclosing Java class.
 my $im = new GD::Image($self->width, $self->height);

 # Allocate two colors.
 my $white = $im->colorAllocate(255, 255, 255);
 my $blue = $im->colorAllocate(0, 0, 255);

 # Fill the image with white and draw a greeting.
 $im->fill($white, 0, 0);
 $im->string(gdLargeFont, 10, 10,
 "Hello, World", $blue);
 return $im->gif;
}}

// Java uses this to repaint the image when necessary.
public void paint(Graphics g) {
 g.drawImage(img, 0, 0, this);
}

// The entry point.
public static void main(String[] argv) {
 // Set up a frame and create an image.
 Frame f = new Frame("GD Example");
 f.setLayout(new BorderLayout());

 GIFDemo demo = new GIFDemo();
 demo.generateImage();

 f.add("Center", demo);
 f.addWindowListener(new Handler());

 f.pack();
 f.show();
}
}

// A handler to process a request to close a window.
class Handler extends WindowAdapter {
 public void windowClosing(WindowEvent e) {
 System.exit(0);
 }
}
}

```

### 2.3.7 Summary: Calling Perl from Java

- 1 Put your embedded Perl code in methods that are declared `perl`.
- 2 Use double, rather than single, curly braces (`{{` and `}}`).
- 3 Invoke the Perl methods from Java just like any other Java method.

- 4 No need to pull arguments off of @\_ with shift: JPL takes care of this for you. This includes \$self.
- 5 If you pass a Java array into a Perl method, it comes in as a scalar reference.
- 6 Convert references to arrays of primitives with Get\*ArrayElements
- 7 Use GetObjectArrayElement to get elements from arrays of strings and other objects.
- 8 To return an array from a perl method, declare the method as returning an array type, and either:
  - 9 Return an array reference.
  - 10 Return a string: JPL slices it up for you.

## 2.4 Calling Java from Perl

Next, let's look at how to invoke Java from Perl.

### 2.4.1 Java in Perl in Java

Remember the issues from 2.1.2 – this is unstable unless you are calling Java from Perl methods that are themselves embedded in a Java program.

### 2.4.2 Java in Perl: Simple Constructors

Use JPL::Class to load the class:

```
use JPL::Class "java::awt::Frame";
```

Invoke the constructor to create an instance of the class:

```
my $f = java::awt::Frame-new;
```

You've got a reference to a Java object in \$f, a Perl scalar. I think this is cool.

### 2.4.3 Constructors that Take Parameters

If the constructor has parameters, look up the method signature with getmeth:

```
my $new = getmeth("new", ['java.lang.String'], []);
```

The first argument to getmeth is the name of the method. The second argument is a reference to an array that contains a list of the argument types. The final argument to getmeth is a reference to an array containing a single element with the return type. Constructors always have a null (void) return type, even though they return an instance of an object.

Invoke the method through the variable you created:

```
my $f = java::awt::Frame-$new("Frame Demo");
```

Because Java supports method overloading, the only way Java can distinguish between different methods that have the same name is through the method signature. The getmeth function simply returns a mangled, Perl-friendly version of the signature. JPL's AutoLoader takes care of finding the right class.

For example, the method signature for \$new is (Ljava/lang/String;)V. In Perl, this is translated to new\_\_Ljava\_lang\_String\_2\_\_V. Sure, it means something to Java, but thanks to getmeth and JPL's AutoLoader, we don't have to worry about it!

### 2.4.4 More on getmeth

The getmeth function is not just for constructors. You'll use it to look up method signatures for any method that takes arguments.

To use getmeth, just supply the Java names of the types and objects in the argument or return value list. Here are a few examples:

- Two int arguments, void return type:  
`$setSize = getmeth("setSize", ['int', 'int'], []);`
- One argument (java.awt.Component), with a return type of the same:  
`$add = getmeth("add", ['java.awt.Component'],  
 ['java.awt.Component']);`
- Two arguments, a String object and a boolean value, and a void return type:  
`$new = getmeth("new",  
 ['java.lang.String', 'boolean'], []);`
- A String argument with a java.lang.Class return type:  
`$forName = getmeth("forName",  
 ['java.lang.String'],  
 ['java.lang.Class']);`
- No arguments, but a boolean return value:  
`$next = getmeth("next", [], ['boolean']);`

#### 2.4.5 Instance Variables

Java instance variables that belong to a class can be reached through `$self` and a method with the same name as the instance variables:

```
$frame->$setSize($self->width, $self->height);
```

Here is an example:

```
class VarDemo {
 int foo = 100;
 perl int perlChange() {{
 my $current_value = $self->foo;
 # Change foo to ten times itself.
 $self->foo($current_value * 10);
 }}
 void executeChange() {
 perlChange();
 System.out.println(foo);
 }
 public static void main(String[] args) {
 VarDemo demo = new VarDemo();
 demo.executeChange();
 }
}
```

Note. JPL creates these methods with the same name as the variable. You can also supply a value to set the variable's value. If you create a method with this name, it will collide with the one that JPL defines.

FrameDemo.jpl

```
/*
 * FrameDemo - create and show a Frame in Perl.
 *
 */

public class FrameDemo {
 int height = 50;
 int width = 200;
 perl void make_frame () {{
 # Import two Java classes.

 use JPL::Class "java::awt::Frame";
 use JPL::Class "java::awt::Button";

 # Create a Frame and a Button. The two calls to new()
 # have the same signature.

 my $new = getmeth("new", ['java.lang.String'], []);
 my $frame = java::awt::Frame->$new("Frame Demo");
 my $btn = java::awt::Button->$new("Do Not Press Me");

 # Add the button to the frame.

 my $add = getmeth("add", ['java.awt.Component'],
 ['java.awt.Component']);
 $frame->$add($btn);

 # Set the size of the frame and show it.

 my $setSize = getmeth("setSize", ['int', 'int'], []);
 $frame->$setSize($self->width, $self->height);
 $frame->show;
 }}

 public static void main(String[] argv) {
 FrameDemo demo = new FrameDemo();
 demo.make_frame();
 }
}
```

#### 2.4.6 Summary: Calling Java from Perl

- 1 Use JPL::Class to specify a Java class to import.
- 2 You can directly invoke constructors and methods that take no arguments.
- 3 If the constructor or method takes arguments, use getmeth to look up its signature.
- 4 Use \$self to access Java instance variables and methods.

<http://perrin.dimensional.com/perl/perlpatch.html>

**How to contribute to this document**

You may mail corrections, additions, and suggestions to me at [dgris@dimensional.com](mailto:dgris@dimensional.com) but the preferred method would be to follow the instructions set forth in this document and submit a patch 8–).

**Description****Why this document exists**

As an open source project Perl relies on patches and contributions from its users to continue functioning properly and to root out the inevitable bugs. But, some users are unsure as to the *right* way to prepare a patch and end up submitting seriously malformed patches. This makes it very difficult for the current maintainer to integrate said patches into their distribution. This document sets out usage guidelines for patches in an attempt to make everybody's life easier.

**Common problems**

The most common problems appear to be patches being mangled by certain mailers (I won't name names, but most of these seem to be originating on boxes running a certain popular commercial operating system). Other problems include patches not rooted in the appropriate place in the directory structure, and patches not produced using standard utilities (such as diff).

**Proper Patch Guidelines****What to patch**

Generally speaking you should patch the latest development release of perl. The maintainers of the individual branches will see to it that patches are picked up and applied as appropriate.

**How to prepare your patch****Creating your patch**

First, back up the original files. This can't be stressed enough, back everything up *\_first\_*.

Also, please create patches against a clean distribution of the perl source. This ensures that everyone else can apply your patch without clobbering their source tree.

**diff** While individual tastes vary (and are not the point here) patches should be created using either `-u` or `-c` arguments to diff. These produce, respectively, unified diffs (where the changed line appears immediately next to the original) and context diffs (where several lines surrounding the changes are included). See the manpage for diff for more details.

The preferred method for creating a unified diff suitable for feeding to the patch program is:

```
diff -u old-file new-file > patch-file
```

Note the order of files. See below for how to create a patch from two directory trees.

If your patch is for wider consumption, it may be better to create it as a context diff as some machines have broken patch utilities that choke on unified diffs. A context diff is made using `diff -c` rather than `diff -u`.

GNU diff has many desirable features not provided by most vendor-supplied diffs. Some examples using GNU diff:

```
generate a patch for a newly added file
% diff -u /dev/null new/file
```

```
generate a patch to remove a file (patch > v2.4 will remove it cleanly)
% diff -u old/goner /dev/null

get additions, deletions along with everything else, recursively
% diff -ruN olddir newdir

ignore whitespace
% diff -bu a/file b/file

show function name in every hunk (safer, more informative)
% diff -u -F '^[_a-zA-Z0-9]+ *(' old/file new/file
```

### Derived Files

Many files in the distribution are derivative—avoid patching them. Patch the originals instead. Most utilities (like `perldoc`) are in this category, i.e. `patch utils/perldoc.PL` rather than `utils/perldoc`. Similarly, don't create patches for files under `$src_root/ext` from their copies found in `$install_root/lib`. If you are unsure about the proper location of a file that may have gotten copied while building the source distribution, consult the MANIFEST.

### Filenames

The most usual convention when submitting patches for a single file is to make your changes to a copy of the file with the same name as the original. Rename the original file in such a way that it is obvious what is being patched (`$file.dist` or `$file.old` seem to be popular).

If you are submitting patches that affect multiple files then you should backup the entire directory tree (to `$source_root.old/` for example). This will allow `diff -ruN old-dir new-dir` to create all the patches at once.

### Directories

**IMPORTANT:** Patches should be generated from the source root directory, not from the directory that the patched file resides in. This ensures that the maintainer patches the proper file.

For larger patches that are dealing with multiple files or directories, Johan Vromans has written a powerful utility: `makepatch`. See the JV directory on CPAN for the current version. If you have this program available, it is recommended to create a duplicate of the perl directory tree against which you are intending to provide a patch and let `makepatch` figure out all the changes you made to your copy of the sources. As perl comes with a MANIFEST file, you need not delete object files and other derivative files from the two directory trees, `makepatch` is smart about them.

Say, you have created a directory `perl-5.7.1@8685/` for the perl you are taking as the base and a directory `perl-5.7.1@8685-withfoo/` where you have your changes, you would run `makepatch` as follows:

```
makepatch -oldman perl-5.7.1@8685/MANIFEST \
 -newman perl-5.7.1@8685-withfoo/MANIFEST \
 -diff "diff -u" \
 perl-5.7.1@8685 perl-5.7.1@8685-withfoo
```

### Try it yourself

Just to make sure your patch "works", be sure to apply it to the Perl distribution, rebuild everything, and make sure the testsuite runs without incident.

## What to include in your patch

### Description of problem

The first thing you should include is a description of the problem that the patch corrects. If it is a code patch (rather than a documentation patch) you should also include a small test case that illustrates the bug.

### Directions for application

You should include instructions on how to properly apply your patch. These should include the files affected, any shell scripts or commands that need to be run before or after application of the patch, and the command line necessary for application.

### If you have a code patch

If you are submitting a code patch there are several other things that you need to do.

### Comments, Comments, Comments

Be sure to adequately comment your code. While commenting every line is unnecessary, anything that takes advantage of side effects of operators, that creates changes that will be felt outside of the function being patched, or that others may find confusing should be documented. If you are going to err, it is better to err on the side of adding too many comments than too few.

### Style

In general, please follow the particular style of the code you are patching.

In particular, follow these general guidelines for patching Perl sources:

```
8-wide tabs (no exceptions!)
4-wide indents for code, 2-wide indents for nested CPP #defines
try hard not to exceed 79-columns
ANSI C prototypes
uncuddled elses and "K&R" style for indenting control constructs
no C++ style (//) comments, most C compilers will choke on them
mark places that need to be revisited with XXX (and revisit often!)
opening brace lines up with "if" when conditional spans multiple
 lines; should be at end-of-line otherwise
in function definitions, name starts in column 0 (return value is on
 previous line)
single space after keywords that are followed by parens, no space
 between function name and following paren
avoid assignments in conditionals, but if they're unavoidable, use
 extra paren, e.g. "if (a && (b = c)) ..."
"return foo;" rather than "return(foo);"
"if (!foo) ..." rather than "if (foo == FALSE) ..." etc.
```

### Testsuite

When submitting a patch you should make every effort to also include an addition to perl's regression tests to properly exercise your patch. Your testsuite additions should generally follow these guidelines (courtesy of Gurusamy Sarathy <gsar@activestate.com>):

```
Know what you're testing. Read the docs, and the source.
Tend to fail, not succeed.
Interpret results strictly.
Use unrelated features (this will flush out bizarre interactions).
Use non-standard idioms (otherwise you are not testing TIMTOWTDI).
Avoid using hardcoded test numbers whenever possible (the
 EXPECTED/GOT found in t/op/tie.t is much more maintainable,
 and gives better failure reports).
Give meaningful error messages when a test fails.
Avoid using qx// and system() unless you are testing for them. If yo
 do use them, make sure that you cover _all_ perl platforms.
Unlink any temporary files you create.
Promote unforeseen warnings to errors with $SIG{__WARN__}.
Be sure to use the libraries and modules shipped with the version
 being tested, not those that were already installed.
```

Add comments to the code explaining what you are testing for. Make updating the '1..42' string unnecessary. Or make sure that you update it.

Test `_all_` behaviors of a given operator, library, or function:

- All optional arguments
- Return values in various contexts (boolean, scalar, list, lvalue)
- Use both global and lexical variables
- Don't forget the exceptional, pathological cases.

### Test your patch

Apply your patch to a clean distribution, compile, and run the regression test suite (you did remember to add one for your patch, didn't you).

### An example patch creation

This should work for most patches:

```
cp MANIFEST MANIFEST.old
emacs MANIFEST
(make changes)
cd ..
diff -c perl5.7.42/MANIFEST.old perl5.7.42/MANIFEST > mypatch
(testing the patch:)
mv perl5.7.42/MANIFEST perl5.7.42/MANIFEST.new
cp perl5.7.42/MANIFEST.old perl5.7.42/MANIFEST
patch -p < mypatch
(should succeed)
diff perl5.7.42/MANIFEST perl5.7.42/MANIFEST.new
(should produce no output)
```

### Submitting your patch

#### Mailers

Please, please, please (get the point? 8-) don't use a mailer that word wraps your patch. This leaves the patch essentially worthless to the maintainers.

Unfortunately many mailers word wrap the main text of messages, but luckily you can usually send your patches as email attachments without them getting "helpfully" word wrapped.

If you have no choice in mailers and no way to get your hands on a better one, there is, of course, a Perl solution. Just do this:

```
perl -ne 'print pack("u*",$_)' patch > patch.uue
```

and post patch.uue with a note saying to unpack it using

```
perl -ne 'print unpack("u*",$_)' patch.uue > patch
```

#### Subject lines for patches

The subject line on your patch should read

```
[PATCH 5.x.x AREA] Description
```

where the x's are replaced by the appropriate version number. The description should be a very brief but accurate summary of the problem (don't forget this is an email header).

Examples:

```
[PATCH 5.6.4 DOC] fix minor typos
```

```
[PATCH 5.7.9 CORE] New warning for foo() when frobbing
```

```
[PATCH 5.7.16 CONFIG] Added support for fribnatz 1.5
```

The name of the file being patched makes for a poor subject line if no other descriptive text accompanies it.

### Where to send your patch

If your patch is for a specific bug in the Perl core, it should be sent using the `perlbug` utility. Don't forget to describe the problem and the fix adequately.

If it is a patch to a module that you downloaded from CPAN you should submit your patch to that module's author.

If your patch addresses one of the items described in `perltodo.pod`, please discuss your approach **before** you make the patch at `<perl5-porters@perl.org`. Be sure to browse the archives of past discussions (see `perltodo.pod` for archive locations).

## Applying a patch

### General notes on applying patches

The following are some general notes on applying a patch to your perl distribution.

#### `patch -p`

It is generally easier to apply patches with the `-p N` argument to `patch` (where `N` is the number of path components to skip in the files found in the headers). This helps reconcile differing paths between the machine the patch was created on and the machine on which it is being applied.

### Cut and paste

**Never** cut and paste a patch into your editor. This usually clobbers the tabs and confuses `patch`.

### Hand editing patches

Avoid hand editing patches as this almost always screws up the line numbers and offsets in the patch, making it useless.

## Final notes

If you follow these guidelines it will make everybody's life a little easier. You'll have the satisfaction of having contributed to perl, others will have an easy time using your work, and it should be easier for the maintainers to coordinate the occasionally large numbers of patches received.

Also, just because you're not a brilliant coder doesn't mean that you can't contribute. As valuable as code patches are there is always a need for better documentation (especially considering the general level of joy that most programmers feel when forced to sit down and write docs). If all you do is patch the documentation you have still contributed more than the person who sent in an amazing new feature that no one can use because no one understands the code (what I'm getting at is that documentation is both the hardest part to do (because everyone hates doing it) and the most valuable).

Mostly, when contributing patches, imagine that it is **you** receiving hundreds of patches and that it is **your** responsibility to integrate them into the source. Obviously you'd want the patches to be as easy to apply as possible. Keep that in mind. 8-)

## Author and Copyright Information

Copyright (c) 1998, 1999 Daniel Grisinger

Adapted from a posting to `perl5-porters` by Tim Bunce (`Tim.Bunce@ig.co.uk`).

I'd like to thank the `perl5-porters` for their suggestions.

**NAME**

Pumpkin – Notes on handling the Perl Patch Pumpkin And Porting Perl

**SYNOPSIS**

There is no simple synopsis, yet.

**DESCRIPTION**

This document attempts to begin to describe some of the considerations involved in patching, porting, and maintaining perl.

This document is still under construction, and still subject to significant changes. Still, I hope parts of it will be useful, so I'm releasing it even though it's not done.

For the most part, it's a collection of anecdotal information that already assumes some familiarity with the Perl sources. I really need an introductory section that describes the organization of the sources and all the various auxiliary files that are part of the distribution.

**Where Do I Get Perl Sources and Related Material?**

The Comprehensive Perl Archive Network (or CPAN) is the place to go. There are many mirrors, but the easiest thing to use is probably <http://www.cpan.org/README.html>, which automatically points you to a mirror site "close" to you.

**Perl5-porters mailing list**

The mailing list `perl5-porters@perl.org` is the main group working with the development of perl. If you're interested in all the latest developments, you should definitely subscribe. The list is high volume, but generally has a fairly low noise level.

Subscribe by sending the message (in the body of your letter)

```
subscribe perl5-porters
```

to `perl5-porters-request@perl.org`.

Archives of the list are held at:

```
http://www.rosat.mpe-garching.mpg.de/mailling-lists/perl-porters/
```

**How are Perl Releases Numbered?**

Beginning with v5.6.0, even versions will stand for maintenance releases and odd versions for development releases, i.e., v5.6.x for maintenance releases, and v5.7.x for development releases. Before v5.6.0, subversions \_01 through \_49 were reserved for bug-fix maintenance releases, and subversions \_50 through \_99 for unstable development versions.

For example, in v5.6.1, the revision number is 5, the version is 6, and 1 is the subversion.

For compatibility with the older numbering scheme the composite floating point version number continues to be available as the magic variable `$]`, and amounts to `$revision + $version/1000 + $subversion/100000`. This can still be used in comparisons.

```
print "You've got an old perl\n" if $] < 5.005_03;
```

In addition, the version is also available as a string in `$^V`.

```
print "You've got a new perl\n" if $^V and $^V ge v5.6.0;
```

You can also require particular version (or later) with:

```
use 5.006;
```

or using the new syntax available only from v5.6 onward:

```
use v5.6.0;
```

At some point in the future, we may need to decide what to call the next big revision. In the `.package` file used by `metaconfig` to generate `Configure`, there are two variables that might be relevant: `$baserev=5` and `$package=perl5`.

Perl releases produced by the members of `perl5-porters` are usually available on CPAN in the *src/5.0/maint* and *src/5.0/devel* directories.

## Maintenance and Development Subversions

The first rule of maintenance work is "First, do no harm."

Trial releases of bug-fix maintenance releases are announced on `perl5-porters`. Trial releases use the new subversion number (to avoid testers installing it over the previous release) and include a 'local patch' entry in `patchlevel.h`. The distribution file contains the string `MAINT_TRIAL` to make clear that the file is not meant for public consumption.

In general, the names of official distribution files for the public always match the regular expression:

```
^perl\d+\.(\d+)\. \. \d+(-MAINT_TRIAL_\d+)\.tar\.gz$
```

\$1 in the pattern is always an even number for maintenance versions, and odd for developer releases.

In the past it has been observed that pumpkings tend to invent new naming conventions on the fly. If you are a pumpking, before you invent a new name for any of the three types of perl distributions, please inform the guys from the CPAN who are doing indexing and provide the trees of symlinks and the like. They will have to know *in advance* what you decide.

## Why is it called the patch pumpkin?

Chip Salzenberg gets credit for that, with a nod to his cow orker, David Croy. We had passed around various names (baton, token, hot potato) but none caught on. Then, Chip asked:

[begin quote]

Who has the patch pumpkin?

To explain: David Croy once told me once that at a previous job, there was one tape drive and multiple systems that used it for backups. But instead of some high-tech exclusion software, they used a low-tech method to prevent multiple simultaneous backups: a stuffed pumpkin. No one was allowed to make backups unless they had the "backup pumpkin".

[end quote]

The name has stuck.

## Philosophical Issues in Patching and Porting Perl

There are no absolute rules, but there are some general guidelines I have tried to follow as I apply patches to the perl sources. (This section is still under construction.)

### Solve problems as generally as possible

Never implement a specific restricted solution to a problem when you can solve the same problem in a more general, flexible way.

For example, for dynamic loading to work on some SVR4 systems, we had to build a shared `libperl.so` library. In order to build "FAT" binaries on NeXT 4.0 systems, we had to build a special `libperl` library. Rather than continuing to build a contorted nest of special cases, I generalized the process of building `libperl` so that NeXT and SVR4 users could still get their work done, but others could build a shared `libperl` if they wanted to as well.

Contain your changes carefully. Assume nothing about other operating systems, not even closely related ones. Your changes must not affect other platforms.

Spy shamelessly on how similar patching or porting issues have been settled elsewhere.

If feasible, try to keep filenames 8.3-compliant to humor those poor souls that get joy from running Perl

under such dire limitations. There's a script, `check83.pl`, for keeping your nose 8.3-clean.

### Seek consensus on major changes

If you are making big changes, don't do it in secret. Discuss the ideas in advance on `perl5-porters`.

### Keep the documentation up-to-date

If your changes may affect how users use perl, then check to be sure that the documentation is in sync with your changes. Be sure to check all the files `pod/*.pod` and also the *INSTALL* document.

Consider writing the appropriate documentation first and then implementing your change to correspond to the documentation.

### Avoid machine-specific `#ifdef`'s

To the extent reasonable, try to avoid machine-specific `#ifdef`'s in the sources. Instead, use feature-specific `#ifdef`'s. The reason is that the machine-specific `#ifdef`'s may not be valid across major releases of the operating system. Further, the feature-specific tests may help out folks on another platform who have the same problem.

### Machine-specific files

#### source code

If you have many machine-specific `#defines` or `#includes`, consider creating an `osish.h` (`os2ish.h`, `vmsish.h`, and so on) and including that in `perl.h`. If you have several machine-specific files (function emulations, function stubs, build utility wrappers) you may create a separate subdirectory (`djgpp`, `win32`) and put the files in there. Remember to update *MANIFEST* when you add files.

If your system supports dynamic loading but none of the existing methods at `ext/DynaLoader/dl_*.xs` work for you, you must write a new one. Study the existing ones to see what kind of interface you must supply.

#### build hints

There are two kinds of hints: hints for building Perl and hints for extensions. The former live in the `hints` subdirectory, the latter in `ext/*/hints` subdirectories.

The top level hints are Bourne-shell scripts that set, modify and unset appropriate Configure variables, based on the Configure command line options and possibly existing `config.sh` and `Policy.sh` files from previous Configure runs.

The extension hints are written in Perl (by the time they are used `miniperl` has been built) and control the building of their respective extensions. They can be used to for example manipulate compilation and linking flags.

#### build and installation Makefiles, scripts, and so forth

Sometimes you will also need to tweak the Perl build and installation procedure itself, like for example *Makefile.SH* and *installperl*. Tread very carefully, even more than usual. Contain your changes with utmost care.

#### test suite

Many of the tests in `t` subdirectory assume machine-specific things like existence of certain functions, something about filesystem semantics, certain external utilities and their error messages. Use the `$^O` and the `Config` module (which contains the results of the Configure run, in effect the `config.sh` converted to Perl) to either skip (preferably not) or customize (preferable) the tests for your platform.

#### modules

Certain standard modules may need updating if your operating system sports for example a native filesystem naming. You may want to update some or all of the modules `File::Basename`, `File::Spec`, `File::Path`, and `File::Copy` to become aware of your native filesystem syntax and peculiarities.

Remember to have a `$VERSION` in the modules. You can use the `Porting/checkVERSION.pl` script for checking this.

## documentation

If your operating system comes from outside UNIX you almost certainly will have differences in the available operating system functionality (missing system calls, different semantics, whatever). Please document these at *pod/perlport.pod*. If your operating system is the first **not** to have a system call also update the list of "portability-bewares" at the beginning of *pod/perlfunc.pod*.

A file called *README.youros* at the top level that explains things like how to install perl at this platform, where to get any possibly required additional software, and for example what test suite errors to expect, is nice too. Such files are in the process of being written in pod format and will eventually be renamed *INSTALL.youros*.

You may also want to write a separate *.pod* file for your operating system to tell about existing mailing lists, os-specific modules, documentation, whatever. Please name these along the lines of *perlyouros.pod*. [unfinished: where to put this file (the pod/ subdirectory, of course: but more importantly, which/what index files should be updated?)]

## Allow for lots of testing

We should never release a main version without testing it as a subversion first.

## Test popular applications and modules.

We should never release a main version without testing whether or not it breaks various popular modules and applications. A partial list of such things would include majordomo, metaconfig, apache, Tk, CGI, libnet, and libwww, to name just a few. Of course it's quite possible that some of those things will be just plain broken and need to be fixed, but, in general, we ought to try to avoid breaking widely-installed things.

## Automated generation of derivative files

The *embed.h*, *keywords.h*, *opcode.h*, and *perltoc.pod* files are all automatically generated by perl scripts. In general, don't patch these directly; patch the data files instead.

*Configure* and *config\_h.SH* are also automatically generated by *metaconfig*. In general, you should patch the metaconfig units instead of patching these files directly. However, very minor changes to *Configure* may be made in between major sync-ups with the metaconfig units, which tends to be complicated operations. But be careful, this can quickly spiral out of control. Running metaconfig is not really hard.

Also *Makefile* is automatically produced from *Makefile.SH*. In general, look out for all *\*.SH* files.

Finally, the sample files in the *Porting/* subdirectory are generated automatically by the script *U/mksample* included with the metaconfig units. See "*run metaconfig*" below for information on obtaining the metaconfig units.

## How to Make a Distribution

There really ought to be a 'make dist' target, but there isn't. The 'dist' suite of tools also contains a number of tools that I haven't learned how to use yet. Some of them may make this all a bit easier.

Here are the steps I go through to prepare a patch & distribution.

Lots of it could doubtless be automated but isn't. The *Porting/makerel* (make release) perl script does now help automate some parts of it.

## Announce your intentions

First, you should volunteer out loud to take the patch pumpkin. It's generally counter-productive to have multiple people working in secret on the same thing.

At the same time, announce what you plan to do with the patch pumpkin, to allow folks a chance to object or suggest alternatives, or do it for you. Naturally, the patch pumpkin holder ought to incorporate various bug fixes and documentation improvements that are posted while he or she has the pumpkin, but there might also be larger issues at stake.

One of the precepts of the subversion idea is that we shouldn't give the patch pumpkin to anyone unless we have some idea what he or she is going to do with it.

### refresh pod/perltoctoc.pod

Presumably, you have done a full make in your working source directory. Before you make `spotless` (if you do), and if you have changed any documentation in any module or pod file, change to the *pod* directory and run `make toc`.

### run installhtml to check the validity of the pod files

#### update patchlevel.h

Don't be shy about using the subversion number, even for a relatively modest patch. We've never even come close to using all 99 subversions, and it's better to have a distinctive number for your patch. If you need feedback on your patch, go ahead and issue it and promise to incorporate that feedback quickly (e.g. within 1 week) and send out a second patch.

If you update the subversion number, you may need to change the version number near the top of the *Changes* file.

#### run metaconfig

If you need to make changes to `Configure` or `config_h.SH`, it may be best to change the appropriate metaconfig units instead, and regenerate `Configure`.

```
metaconfig -m
```

will regenerate `Configure` and `config_h.SH`. Much more information on obtaining and running metaconfig is in the *U/README* file that comes with Perl's metaconfig units. Perl's metaconfig units should be available on CPAN. A set of units that will work with perl5.005 is in the file *mc\_units-5.005\_00-01.tar.gz* under <http://www.cpan.org/authors/id/ANDYD/>. The *mc\_units* tar file should be unpacked in your main perl source directory. Note: those units were for use with 5.005. There may have been changes since then. Check for later versions or contact [perl5-porters@perl.org](mailto:perl5-porters@perl.org) to obtain a pointer to the current version.

Alternatively, do consider if the *\*ish.h* files might be a better place for your changes.

### MANIFEST

Make sure the MANIFEST is up-to-date. You can use dist's **manicheck** program for this. You can also use

```
perl -w -MExtUtils::Manifest=fullcheck -e fullcheck
```

Both commands will also list extra files in the directory that are not listed in MANIFEST.

The MANIFEST is normally sorted.

If you are using metaconfig to regenerate `Configure`, then you should note that metaconfig actually uses `MANIFEST.new`, so you want to be sure `MANIFEST.new` is up-to-date too. I haven't found the `MANIFEST/MANIFEST.new` distinction particularly useful, but that's probably because I still haven't learned how to use the full suite of tools in the dist distribution.

### Check permissions

All the tests in the `t/` directory ought to be executable. The main makefile used to do a `'chmod t/*/*.*'`, but that resulted in a self-modifying distribution—something some users would strongly prefer to avoid. The *t/TEST* script will check for this and do the `chmod` if needed, but the tests still ought to be executable.

In all, the following files should probably be executable:

```
Configure
configpm
configure.gnu
embed.pl
installperl
installman
keywords.pl
myconfig
```

```
opcode.pl
perly.fixer
t/TEST
t/*/*.t
*.SH
vms/ext/Stdio/test.pl
vms/ext/filespec.t
x2p/*.SH
```

Other things ought to be readable, at least :-).

Probably, the permissions for the files could be encoded in MANIFEST somehow, but I'm reluctant to change MANIFEST itself because that could break old scripts that use MANIFEST.

I seem to recall that some SVR3 systems kept some sort of file that listed permissions for system files; something like that might be appropriate.

## Run Configure

This will build a config.sh and config.h. You can skip this if you haven't changed Configure or config\_h.SH at all. I use the following command

```
sh Configure -Dprefix=/opt/perl -Doptimize=-O -Dusethreads \
-Dcf_by='yourname' \
-Dcf_email='yourname@yourhost.yourplace.com' \
-Dperladmin='yourname@yourhost.yourplace.com' \
-Dmydomain='.yourplace.com' \
-Dmyhostname='yourhost' \
-des
```

## Update Porting/config.sh and Porting/config\_H

[XXX This section needs revision. We're currently working on easing the task of keeping the vms, win32, and plan9 config.sh info up-to-date. The plan is to use keep up-to-date 'canned' config.sh files in the appropriate subdirectories and then generate 'canned' config.h files for vms, win32, etc. from the generic config.sh file. This is to ease maintenance. When Configure gets updated, the parts sometimes get scrambled around, and the changes in config\_H can sometimes be very hard to follow. config.sh, on the other hand, can safely be sorted, so it's easy to track (typically very small) changes to config.sh and then propagate them to a canned 'config.h' by any number of means, including a perl script in win32/ or carrying config.sh and config\_h.SH to a Unix system and running sh config\_h.SH.) Vms uses configure.com to generate its own config.sh and config.h. If you want to add a new variable to config.sh check with vms folk how to add it to configure.com too. XXX]

The Porting/config.sh and Porting/config\_H files are provided to help those folks who can't run Configure. It is important to keep them up-to-date. If you have changed config\_h.SH, those changes must be reflected in config\_H as well. (The name config\_H was chosen to distinguish the file from config.h even on case-insensitive file systems.) Simply edit the existing config\_H file; keep the first few explanatory lines and then copy your new config.h below.

It may also be necessary to update win32/config.?c, and plan9/config.plan9, though you should be quite careful in doing so if you are not familiar with those systems. You might want to issue your patch with a promise to quickly issue a follow-up that handles those directories.

## make run\_byacc

If you have byacc-1.8.2 (available from CPAN), and if there have been changes to *perly.y*, you can regenerate the *perly.c* file. The run\_byacc makefile target does this by running byacc and then applying some patches so that byacc dynamically allocates space, rather than having fixed limits. This patch is handled by the *perly.fixer* script. Depending on the nature of the changes to *perly.y*, you may or may not have to hand-edit the patch to apply correctly. If you do, you should include the edited patch in the new distribution. If you have byacc-1.9, the patch won't apply cleanly. Changes to the printf output statements

mean the patch won't apply cleanly. Long ago I started to fix *perly\_fixer* to detect this, but I never completed the task.

If *perly.c* or *perly.h* changes, make sure you run `perl vms/vms_yfix.pl` to update the corresponding VMS files. This could be taken care of by the `regen_all` target in the Unix Makefile. See also [VMS-specific updates](#).

Some additional notes from Larry on this:

Don't forget to regenerate *perly\_c.diff*.

```
byacc -d perly.y
mv y.tab.c perly.c
patch perly.c <perly_c.diff
manually apply any failed hunks
diff -c perly.c.orig perly.c >perly_c.diff
```

One chunk of lines that often fails begins with

```
#line 29 "perly.y"
```

and ends one line before

```
#define YYERRCODE 256
```

This only happens when you add or remove a token type. I suppose this could be automated, but it doesn't happen very often nowadays.

Larry

### make regen\_all

This target takes care of the `PERLYVMS`, `regen_headers`, and `regen_pods` targets.

### make regen\_headers

The *embed.h*, *keywords.h*, and *opcode.h* files are all automatically generated by perl scripts. Since the user isn't guaranteed to have a working perl, we can't require the user to generate them. Hence you have to, if you're making a distribution.

I used to include rules like the following in the makefile:

```
The following three header files are generated automatically
The correct versions should be already supplied with the perl kit,
in case you don't have perl or 'sh' available.
The - is to ignore error return codes in case you have the source
installed read-only or you don't have perl yet.
keywords.h: keywords.pl
 @echo "Don't worry if this fails."
 - perl keywords.pl
```

However, I got **lots** of mail consisting of people worrying because the command failed. I eventually decided that I would save myself time and effort by manually running `make regen_headers` myself rather than answering all the questions and complaints about the failing command.

### make regen\_pods

Will run 'make regen\_pods' in the pod directory for indexing.

### global.sym, interp.sym and perlio.sym

Make sure these files are up-to-date. Read the comments in these files and in *perl\_exp.SH* to see what to do.

## Binary compatibility

If you do change *global.sym* or *interp.sym*, think carefully about what you are doing. To the extent reasonable, we'd like to maintain source and binary compatibility with older releases of perl. That way, extensions built under one version of perl will continue to work with new versions of perl.

Of course, some incompatible changes may well be necessary. I'm just suggesting that we not make any such changes without thinking carefully about them first. If possible, we should provide backwards-compatibility stubs. There's a lot of XS code out there. Let's not force people to keep changing it.

## Changes

Be sure to update the *Changes* file. Try to include both an overall summary as well as detailed descriptions of the changes. Your audience will include other developers and users, so describe user-visible changes (if any) in terms they will understand, not in code like "initialize foo variable in bar function".

There are differing opinions on whether the detailed descriptions ought to go in the Changes file or whether they ought to be available separately in the patch file (or both). There is no disagreement that detailed descriptions ought to be easily available somewhere.

If you update the subversion number in *patchlevel.h*, you may need to change the version number near the top of the *Changes* file.

## Todo

The *Todo* file contains a roughly-categorized unordered list of aspects of Perl that could use enhancement, features that could be added, areas that could be cleaned up, and so on. During your term as pumpkin-holder, you will probably address some of these issues, and perhaps identify others which, while you decide not to address them this time around, may be tackled in the future. Update the file reflect the situation as it stands when you hand over the pumpkin.

You might like, early in your pumpkin-holding career, to see if you can find champions for particular issues on the to-do list: an issue owned is an issue more likely to be resolved.

There are also some more porting-specific *Todo* items later in this file.

## OS/2-specific updates

In the os2 directory is *diff.configure*, a set of OS/2-specific diffs against *Configure*. If you make changes to *Configure*, you may want to consider regenerating this diff file to save trouble for the OS/2 maintainer.

You can also consider the OS/2 diffs as reminders of portability things that need to be fixed in *Configure*.

## VMS-specific updates

If you have changed *perly.y* or *perly.c*, then you most probably want to update *vms/perly\_{h,c}.vms* by running `perl vms/vms_yfix.pl`, or by running 'make regen\_all' which will run that script for you.

The Perl revision number appears as "perl5" in *configure.com*. It is courteous to update that if necessary.

## Making the new distribution

Suppose, for example, that you want to make version 5.004\_08. Then you can do something like the following

```
mkdir ../perl5.004_08
awk '{print $1}' MANIFEST | cpio -pdm ../perl5.004_08
cd ../
tar cf perl5.004_08.tar perl5.004_08
gzip --best perl5.004_08.tar
```

These steps, with extra checks, are automated by the *Porting/makerel* script.

## Making a new patch

I find the *makepatch* utility quite handy for making patches. You can obtain it from any CPAN archive under [http://www.cpan.org/authors/Johan\\_Vromans/](http://www.cpan.org/authors/Johan_Vromans/). There are a couple of differences between my version and the standard one. I have mine do a

```
Print a reassuring "End of Patch" note so people won't
wonder if their mailer truncated patches.
print "\n\nEnd of Patch.\n";
```

at the end. That's because I used to get questions from people asking if their mail was truncated.

It also writes Index: lines which include the new directory prefix (change Index: print, approx line 294 or 310 depending on the version, to read: `print PATCH ("Index: $newdir$new\n");`). That helps patches work with more POSIX conformant patch programs.

Here's how I generate a new patch. I'll use the hypothetical 5.004\_07 to 5.004\_08 patch as an example.

```
unpack perl5.004_07/
gzip -d -c perl5.004_07.tar.gz | tar -xof -
unpack perl5.004_08/
gzip -d -c perl5.004_08.tar.gz | tar -xof -
makepatch perl5.004_07 perl5.004_08 > perl5.004_08.pat
```

Makepatch will automatically generate appropriate **rm** commands to remove deleted files. Unfortunately, it will not correctly set permissions for newly created files, so you may have to do so manually. For example, patch 5.003\_04 created a new test *t/op/gv.t* which needs to be executable, so at the top of the patch, I inserted the following lines:

```
Make a new test
touch t/op/gv.t
chmod +x t/opt/gv.t
```

Now, of course, my patch is now wrong because makepatch didn't know I was going to do that command, and it patched against /dev/null.

So, what I do is sort out all such shell commands that need to be in the patch (including possible mv-ing of files, if needed) and put that in the shell commands at the top of the patch. Next, I delete all the patch parts of perl5.004\_08.pat, leaving just the shell commands. Then, I do the following:

```
cd perl5.004_07
sh ../perl5.004_08.pat
cd ..
makepatch perl5.004_07 perl5.004_08 >> perl5.004_08.pat
```

(Note the append to preserve my shell commands.) Now, my patch will line up with what the end users are going to do.

## Testing your patch

It seems obvious, but be sure to test your patch. That is, verify that it produces exactly the same thing as your full distribution.

```
rm -rf perl5.004_07
gzip -d -c perl5.004_07.tar.gz | tar -xf -
cd perl5.004_07
sh ../perl5.004_08.pat
patch -p1 -N < ../perl5.004_08.pat
cd ..
gdiff -r perl5.004_07 perl5.004_08
```

where **gdiff** is GNU diff. Other diff's may also do recursive checking.

## More testing

Again, it's obvious, but you should test your new version as widely as you can. You can be sure you'll hear about it quickly if your version doesn't work on both ANSI and pre-ANSI compilers, and on common systems such as SunOS 4.1.[34], Solaris, and Linux.

If your changes include conditional code, try to test the different branches as thoroughly as you can. For example, if your system supports dynamic loading, you can also test static loading with

```
sh Configure -Uusedl
```

You can also hand-tweak your config.h to try out different #ifdef branches.

## Other tests

### CHECK\_FORMAT

To test the correct use of printf-style arguments, Configure with `-Dccflags='-DCHECK_FORMAT -Wformat'` and run `make`. The compiler will produce warning of incorrect use of format arguments. `CHECK_FORMAT` changes perl-defined formats to common formats, so DO NOT USE the executable produced by this process.

A more accurate approach is the following commands:

- build miniperl with `-DCHECK_FORMAT`

```
make clean
make miniperl OPTIMIZE=-DCHECK_FORMAT >& mini.log
```
- build a clean miniperl, and build everything else from that with `-DCHECK_FORMAT`

```
make clean
make miniperl
make all OPTIMIZE='-DCHECK_FORMAT -Wformat' >& make.log
```
- clean up, and print warnings from the log files

```
make clean
perl -nwe 'print if /^S+:/ and not /^make\b/' \
mini.log make.log
```

(`-Wformat` support by Robin Barker.)

## Running Purify

Purify is a commercial tool that is helpful in identifying memory overruns, wild pointers, memory leaks and other such badness. Perl must be compiled in a specific way for optimal testing with Purify.

Use the following commands to test perl with Purify:

```
sh Configure -des -Doptimize=-g -Uusemymalloc -Dusemultiplicity \
-Dccflags=-DPURIFY
setenv PURIFYOPTIONS "-chain-length=25"
make all pureperl
cd t
ln -s ../pureperl perl
setenv PERL_DESTRUCT_LEVEL 2
./perl TEST
```

Disabling Perl's malloc allows Purify to monitor allocations and leaks more closely; using Perl's malloc will make Purify report most leaks in the "potential" leaks category. Enabling the multiplicity option allows perl to clean up thoroughly when the interpreter shuts down, which reduces the number of bogus leak reports from Purify. The `-DPURIFY` enables any Purify-specific debugging code in the sources.

Purify outputs messages in "Viewer" windows by default. If you don't have a windowing environment or if you simply want the Purify output to unobtrusively go to a log file instead of to the interactive window, use the following options instead:

```
setenv PURIFYOPTIONS "-chain-length=25 -windows=no -log-file=perl.log \
-append-logfile=yes"
```

The only currently known leaks happen when there are compile-time errors within eval or require. (Fixing these is non-trivial, unfortunately, but they must be fixed eventually.)

### Common Gotcha's

**#elif** The `#elif` preprocessor directive is not understood on all systems. Specifically, I know that Pyramids don't understand it. Thus instead of the simple

```
#if defined(I_FOO)
include <foo.h>
#elif defined(I_BAR)
include <bar.h>
#else
include <fubar.h>
#endif
```

You have to do the more Byzantine

```
#if defined(I_FOO)
include <foo.h>
#else
if defined(I_BAR)
include <bar.h>
else
include <fubar.h>
endif
#endif
```

Incidentally, whitespace between the leading `#` and the preprocessor command is not guaranteed, but is very portable and you may use it freely. I think it makes things a bit more readable, especially once things get rather deeply nested. I also think that things should almost never get too deeply nested, so it ought to be a moot point :-)

### Probably Prefer POSIX

It's often the case that you'll need to choose whether to do something the BSD-ish way or the POSIX-ish way. It's usually not a big problem when the two systems use different names for similar functions, such as `memcmp()` and `bcmp()`. The `perl.h` header file handles these by appropriate `#defines`, selecting the POSIX `mem*` functions if available, but falling back on the `b*` functions, if need be.

More serious is the case where some brilliant person decided to use the same function name but give it a different meaning or calling sequence :-). `getpgrp()` and `setpgrp()` come to mind. These are a real problem on systems that aim for conformance to one standard (e.g. POSIX), but still try to support the other way of doing things (e.g. BSD). My general advice (still not really implemented in the source) is to do something like the following. Suppose there are two alternative versions, `fooPOSIX()` and `fooBSD()`.

```
#ifdef HAS_FOOPOSIX
/* use fooPOSIX(); */
#else
ifdef HAS_FOOBSD
/* try to emulate fooPOSIX() with fooBSD();
perhaps with the following: */
```

```
define fooPOSIX fooBSD
else
/* Uh, oh. We have to supply our own. */
define fooPOSIX Perl_fooPOSIX
endif
#endif
```

### Think positively

If you need to add an `#ifdef` test, it is usually easier to follow if you think positively, e.g.

```
#ifdef HAS_NEATO_FEATURE
 /* use neato feature */
#else
 /* use some fallback mechanism */
#endif
```

rather than the more impenetrable

```
#ifndef MISSING_NEATO_FEATURE
 /* Not missing it, so we must have it, so use it */
#else
 /* Are missing it, so fall back on something else. */
#endif
```

Of course for this toy example, there's not much difference. But when the `#ifdef`'s start spanning a couple of screen fulls, and the `#else`'s are marked something like

```
#else /* !MISSING_NEATO_FEATURE */
```

I find it easy to get lost.

### Providing Missing Functions — Problem

Not all systems have all the neat functions you might want or need, so you might decide to be helpful and provide an emulation. This is sound in theory and very kind of you, but please be careful about what you name the function. Let me use the `pause()` function as an illustration.

Perl5.003 has the following in *perl.h*

```
#ifndef HAS_PAUSE
#define pause() sleep((32767<<16)+32767)
#endif
```

Configure sets `HAS_PAUSE` if the system has the `pause()` function, so this `#define` only kicks in if the `pause()` function is missing. Nice idea, right?

Unfortunately, some systems apparently have a prototype for `pause()` in *unistd.h*, but don't actually have the function in the library. (Or maybe they do have it in a library we're not using.)

Thus, the compiler sees something like

```
extern int pause(void);
/* . . . */
#define pause() sleep((32767<<16)+32767)
```

and dies with an error message. (Some compilers don't mind this; others apparently do.)

To work around this, 5.003\_03 and later have the following in *perl.h*:

```
/* Some unistd.h's give a prototype for pause() even though
 HAS_PAUSE ends up undefined. This causes the #define
 below to be rejected by the compiler. Sigh.
*/
#ifdef HAS_PAUSE
```

```
define Pause
#else
define Pause() sleep((32767<<16)+32767)
#endif
```

This works.

The curious reader may wonder why I didn't do the following in *util.c* instead:

```
#ifndef HAS_PAUSE
void pause()
{
 sleep((32767<<16)+32767);
}
#endif
```

That is, since the function is missing, just provide it. Then things would probably be been alright, it would seem.

Well, almost. It could be made to work. The problem arises from the conflicting needs of dynamic loading and namespace protection.

For dynamic loading to work on AIX (and VMS) we need to provide a list of symbols to be exported. This is done by the script *perl\_exp.SH*, which reads *global.sym* and *interp.sym*. Thus, the pause symbol would have to be added to *global.sym*. So far, so good.

On the other hand, one of the goals of Perl5 is to make it easy to either extend or embed perl and link it with other libraries. This means we have to be careful to keep the visible namespace "clean". That is, we don't want perl's global variables to conflict with those in the other application library. Although this work is still in progress, the way it is currently done is via the *embed.h* file. This file is built from the *global.sym* and *interp.sym* files, since those files already list the globally visible symbols. If we had added pause to *global.sym*, then *embed.h* would contain the line

```
#define pause Perl_pause
```

and calls to pause in the perl sources would now point to Perl\_pause. Now, when *ld* is run to build the *perl* executable, it will go looking for perl\_pause, which probably won't exist in any of the standard libraries. Thus the build of perl will fail.

Those systems where HAS\_PAUSE is not defined would be ok, however, since they would get a Perl\_pause function in util.c. The rest of the world would be in trouble.

And yes, this scenario has happened. On SCO, the function chsize is available. (I think it's in *-lx*, the Xenix compatibility library.) Since the perl4 days (and possibly before), Perl has included a chsize function that gets called something akin to

```
#ifndef HAS_CHSIZE
I32 chsize(fd, length)
/* . . . */
#endif
```

When 5.003 added

```
#define chsize Perl_chsize
```

to *embed.h*, the compile started failing on SCO systems.

The "fix" is to give the function a different name. The one implemented in 5.003\_05 isn't optimal, but here's what was done:

```
#ifdef HAS_CHSIZE
ifdef my_chsize /* Probably #defined to Perl_my_chsize in embed.h */
undef my_chsize
```

```
endif
define my_chsize chsize
#endif
```

My explanatory comment in patch 5.003\_05 said:

```
Undef and then re-define my_chsize from Perl_my_chsize to
just plain chsize if this system HAS_CHSIZE. This probably only
applies to SCO. This shows the perils of having internal
functions with the same name as external library functions :-).
```

Now, we can safely put my\_chsize in *global.sym*, export it, and hide it with *embed.h*.

To be consistent with what I did for pause, I probably should have called the new function Chsize, rather than my\_chsize. However, the perl sources are quite inconsistent on this (Consider New, Mymalloc, and Myrealloc, to name just a few.)

There is a problem with this fix, however, in that Perl\_chsize was available as a *libperl.a* library function in 5.003, but it isn't available any more (as of 5.003\_07). This means that we've broken binary compatibility. This is not good.

#### Providing missing functions — some ideas

We currently don't have a standard way of handling such missing function names. Right now, I'm effectively thinking aloud about a solution. Some day, I'll try to formally propose a solution.

Part of the problem is that we want to have some functions listed as exported but not have their names mangled by embed.h or possibly conflict with names in standard system headers. We actually already have such a list at the end of *perl\_exp.SH* (though that list is out-of-date):

```
extra globals not included above.
cat <<END >> perl.exp
perl_init_ext
perl_init_fold
perl_init_i18nl14n
perl_alloc
perl_construct
perl_destruct
perl_free
perl_parse
perl_run
perl_get_sv
perl_get_av
perl_get_hv
perl_get_cv
perl_call_argv
perl_call_pv
perl_call_method
perl_call_sv
perl_requirepv
safecalloc
safemalloc
saferealloc
safefree
```

This still needs much thought, but I'm inclined to think that one possible solution is to prefix all such functions with perl\_ in the source and list them along with the other perl\_\* functions in *perl\_exp.SH*.

Thus, for chsize, we'd do something like the following:

```
/* in perl.h */
#ifdef HAS_CHSIZE
define perl_chsize chsize
#endif
```

then in some file (e.g. *util.c* or *doio.c*) do

```
#ifndef HAS_CHSIZE
I32 perl_chsize(fd, length)
/* implement the function here . . . */
#endif
```

Alternatively, we could just always use *chsize* everywhere and move *chsize* from *global.sym* to the end of *perl\_exp.SH*. That would probably be fine as long as our *chsize* function agreed with all the *chsize* function prototypes in the various systems we'll be using. As long as the prototypes in actual use don't vary that much, this is probably a good alternative. (As a counter-example, note how *Configure* and *perl* have to go through hoops to find and use *get Malloc\_t* and *Free\_t* for *malloc* and *free*.)

At the moment, this latter option is what I tend to prefer.

### All the world's a VAX

Sorry, showing my age:–). Still, all the world is not BSD 4.[34], SVR4, or POSIX. Be aware that SVR3–derived systems are still quite common (do you have any idea how many systems run SCO?) If you don't have a bunch of v7 manuals handy, the metaconfig units (by default installed in */usr/local/lib/dist/U*) are a good resource to look at for portability.

## Miscellaneous Topics

### Autoconf

Why does *perl* use a metaconfig–generated *Configure* script instead of an autoconf–generated *configure* script?

Metaconfig and autoconf are two tools with very similar purposes. Metaconfig is actually the older of the two, and was originally written by Larry Wall, while autoconf is probably now used in a wider variety of packages. The autoconf info file discusses the history of autoconf and how it came to be. The curious reader is referred there for further information.

Overall, both tools are quite good, I think, and the choice of which one to use could be argued either way. In March, 1994, when I was just starting to work on *Configure* support for Perl5, I considered both autoconf and metaconfig, and eventually decided to use metaconfig for the following reasons:

#### Compatibility with Perl4

Perl4 used metaconfig, so many of the *#ifdef*'s were already set up for metaconfig. Of course metaconfig had evolved some since Perl4's days, but not so much that it posed any serious problems.

#### Metaconfig worked for me

My system at the time was Interactive 2.2, an SVR3.2/386 derivative that also had some POSIX support. Metaconfig–generated *Configure* scripts worked fine for me on that system. On the other hand, autoconf–generated scripts usually didn't. (They did come quite close, though, in some cases.) At the time, I actually fetched a large number of GNU packages and checked. Not a single one configured and compiled correctly out–of–the–box with the system's *cc* compiler.

#### Configure can be interactive

With both autoconf and metaconfig, if the script works, everything is fine. However, one of my main problems with autoconf–generated scripts was that if it guessed wrong about something, it could be **very** hard to go back and fix it. For example, autoconf always insisted on passing the *-Xp* flag to *cc* (to turn on POSIX behavior), even when that wasn't what I wanted or needed for that package. There was no way short of editing the *configure* script to turn this off. You couldn't just edit the resulting *Makefile* at the end because the *-Xp* flag influenced a number of other *configure* tests.

Metaconfig's Configure scripts, on the other hand, can be interactive. Thus if Configure is guessing things incorrectly, you can go back and fix them. This isn't as important now as it was when we were actively developing Configure support for new features such as dynamic loading, but it's still useful occasionally.

### GPL

At the time, autoconf-generated scripts were covered under the GNU Public License, and hence weren't suitable for inclusion with Perl, which has a different licensing policy. (Autoconf's licensing has since changed.)

### Modularity

Metaconfig builds up Configure from a collection of discrete pieces called "units". You can override the standard behavior by supplying your own unit. With autoconf, you have to patch the standard files instead. I find the metaconfig "unit" method easier to work with. Others may find metaconfig's units clumsy to work with.

### Why isn't there a directory to override Perl's library?

Mainly because no one's gotten around to making one. Note that "making one" involves changing perl.c, Configure, config\_h.SH (and associated files, see above), and *documenting* it all in the INSTALL file.

Apparently, most folks who want to override one of the standard library files simply do it by overwriting the standard library files.

### APPLLIB

In the perl.c sources, you'll find an undocumented APPLLIB\_EXP variable, sort of like PRIVLIB\_EXP and ARCHLIB\_EXP (which are documented in config\_h.SH). Here's what APPLLIB\_EXP is for, from a mail message from Larry:

The main intent of APPLLIB\_EXP is for folks who want to send out a version of Perl embedded in their product. They would set the symbol to be the name of the library containing the files needed to run or to support their particular application. This works at the "override" level to make sure they get their own versions of any library code that they absolutely must have configuration control over.

As such, I don't see any conflict with a sysadmin using it for a override-ish sort of thing, when installing a generic Perl. It should probably have been named something to do with overriding though. Since it's undocumented we could still change it... :-)

Given that it's already there, you can use it to override distribution modules. If you do

```
sh Configure -Dccflags='-DAPPLLIB_EXP=/my/override'
```

then perl.c will put /my/override ahead of ARCHLIB and PRIVLIB.

### Shared libperl.so location

Why isn't the shared libperl.so installed in /usr/lib/ along with "all the other" shared libraries? Instead, it is installed in \$archlib, which is typically something like

```
/usr/local/lib/perl5/archname/5.00404
```

and is architecture- and version-specific.

The basic reason why a shared libperl.so gets put in \$archlib is so that you can have more than one version of perl on the system at the same time, and have each refer to its own libperl.so.

Three examples might help. All of these work now; none would work if you put libperl.so in /usr/lib.

1. Suppose you want to have both threaded and non-threaded perl versions around. Configure will name both perl libraries "libperl.so" (so that you can link to them with `-lperl`). The perl binaries tell them apart by having looking in the appropriate `$archlib` directories.
2. Suppose you have perl5.004\_04 installed and you want to try to compile it again, perhaps with different options or after applying a patch. If you already have libperl.so installed in `/usr/lib/`, then it may be either difficult or impossible to get `ld.so` to find the new libperl.so that you're trying to build. If, instead, libperl.so is tucked away in `$archlib`, then you can always just change `$archlib` in the current perl you're trying to build so that `ld.so` won't find your old libperl.so. (The INSTALL file suggests you do this when building a debugging perl.)
3. The shared perl library is not a "well-behaved" shared library with proper major and minor version numbers, so you can't necessarily have perl5.004\_04 and perl5.004\_05 installed simultaneously. Suppose perl5.004\_04 were to install `/usr/lib/libperl.so.4.4`, and perl5.004\_05 were to install `/usr/lib/libperl.so.4.5`. Now, when you try to run perl5.004\_04, `ld.so` might try to load libperl.so.4.5, since it has the right "major version" number. If this works at all, it almost certainly defeats the reason for keeping perl5.004\_04 around. Worse, with development subversions, you certainly can't guarantee that libperl.so.4.4 and libperl.so.4.55 will be compatible.

Anyway, all this leads to quite obscure failures that are sure to drive casual users crazy. Even experienced users will get confused :-). Upon reflection, I'd say leave libperl.so in `$archlib`.

4. Indentation style: over the years Perl has become a mishmash of various indentation styles, but the original "Larry style" can probably be restored with (GNU) indent somewhat like this:

```
indent -kr -nce -psl -sc
```

A more ambitious solution would also specify a list of Perl specific types with `-TSV -TAV -THV .. -TMAGIC -TPerIO ...` but that list would be quite ungainly. Also note that GNU indent also doesn't do aligning of consecutive assignments, which would truly wreck the layout in places like `sv.c:Perl_sv_upgrade()` or `sv.c:Perl_clone_using()`. Similarly nicely aligned `&&s`, `||s` and `==s` would not be respected.

### Upload Your Work to CPAN

You can upload your work to CPAN if you have a CPAN id. Check out <http://www.cpan.org/modules/04pause.html> for information on `_PAUSE_`, the Perl Author's Upload Server.

I typically upload both the patch file, e.g. *perl5.004\_08.pat.gz* and the full tar file, e.g. *perl5.004\_08.tar.gz*.

If you want your patch to appear in the *src/5.0/unsupported* directory on CPAN, send e-mail to the CPAN master librarian. (Check out <http://www.cpan.org/CPAN.html> ).

### Help Save the World

You should definitely announce your patch on the perl5-porters list. You should also consider announcing your patch on `comp.lang.perl.announce`, though you should make it quite clear that a subversion is not a production release, and be prepared to deal with people who will not read your disclaimer.

### Todo

Here, in no particular order, are some Configure and build-related items that merit consideration. This list isn't exhaustive, it's just what I came up with off the top of my head.

### Adding missing library functions to Perl

The perl Configure script automatically determines which headers and functions you have available on your system and arranges for them to be included in the compilation and linking process. Occasionally, when porting perl to an operating system for the first time, you may find that the operating system is missing a key function. While perl may still build without this function, no perl program will be able to reference the missing function. You may be able to write the missing function yourself, or you may be able to find the missing function in the distribution files for another software package. In this case, you need to instruct the perl configure-and-build process to use your function. Perform these steps.

- Code and test the function you wish to add. Test it carefully; you will have a much easier time debugging your code independently than when it is a part of perl.
- Here is an implementation of the POSIX truncate function for an operating system (VOS) that does not supply one, but which does supply the `ftruncate()` function.

```
/* Beginning of modification history */
/* Written 02-01-02 by Nick Ing-Simmons (nick@ing-simmons.net) */
/* End of modification history */

/* VOS doesn't supply a truncate function, so we build one up
 from the available POSIX functions. */

#include <fcntl.h>
#include <sys/types.h>
#include <unistd.h>

int
truncate(const char *path, off_t len)
{
 int fd = open(path, O_WRONLY);
 int code = -1;
 if (fd >= 0) {
 code = ftruncate(fd, len);
 close(fd);
 }
 return code;
}
```

Place this file into a subdirectory that has the same name as the operating system. This file is named `perl/vos/vos.c`

- If your operating system has a hints file (in `perl/hints/XXX.sh` for an operating system named XXX), then start with it. If your operating system has no hints file, then create one. You can use a hints file for a similar operating system, if one exists, as a template.
- Add lines like the following to your hints file. The first line (`d_truncate="define"`) instructs Configure that the `truncate()` function exists. The second line (`archobjs="vos.o"`) instructs the makefiles that the perl executable depends on the existence of a file named "vos.o". (Make will automatically look for "vos.c" and compile it with the same options as the perl source code). The final line ("`test -h...`") adds a symbolic link to the top-level directory so that make can find `vos.c`. Of course, you should use your own operating system name for the source file of extensions, not "vos.c".

```
VOS does not havetruncate() but we supply one in vos.c
d_truncate="define"
archobjs="vos.o"

Help gmake find vos.c
test -h vos.c || ln -s vos/vos.c vos.c
```

The hints file is a series of shell commands that are run in the top-level directory (the "perl" directory). Thus, these commands are simply executed by Configure at an appropriate place during its execution.

- At this point, you can run the Configure script and rebuild perl. Carefully test the newly-built perl to ensure that normal paths, and error paths, behave as you expect.

### Good ideas waiting for round tuits

Configure `-Dsrc=/blah/blah`

We should be able to emulate **configure** `—sreaddir`. Tom Tromey [tromey@creche.cygnum.com](mailto:tromey@creche.cygnum.com) has submitted some patches to the dist-users mailing list along these lines. They have been folded back

into the main distribution, but various parts of the perl Configure/build/install process still assume `src='.'`.

#### Hint file fixes

Various hint files work around Configure problems. We ought to fix Configure so that most of them aren't needed.

#### Hint file information

Some of the hint file information (particularly dynamic loading stuff) ought to be fed back into the main metaconfig distribution.

### Probably good ideas waiting for round tuits

#### GNU configure —options

I've received sensible suggestions for `--exec_prefix` and other GNU configure —options. It's not always obvious exactly what is intended, but this merits investigation.

#### make clean

Currently, **make clean** isn't all that useful, though **make realclean** and **make distclean** are. This needs a bit of thought and documentation before it gets cleaned up.

#### Try gcc if cc fails

Currently, we just give up.

#### bypassing safe\*alloc wrappers

On some systems, it may be safe to call the system malloc directly without going through the util.c safe\* layers. (Such systems would accept free(0), for example.) This might be a time-saver for systems that already have a good malloc. (Recent Linux libc's apparently have a nice malloc that is well-tuned for the system.)

### Vague possibilities

#### MacPerl

Get some of the Macintosh stuff folded back into the main distribution.

#### gconvert replacement

Maybe include a replacement function that doesn't lose data in rare cases of coercion between string and numerical values.

#### Improve makedepend

The current makedepend process is clunky and annoyingly slow, but it works for most folks. Alas, it assumes that there is a filename `$firstmakefile` that the **make** command will try to use before it uses **Makefile**. Such may not be the case for all **make** commands, particularly those on non-Unix systems.

Probably some variant of the BSD **.depend** file will be useful. We ought to check how other packages do this, if they do it at all. We could probably pre-generate the dependencies (with the exception of malloc.o, which could probably be determined at **Makefile.SH** extraction time).

#### GNU Makefile standard targets

GNU software generally has standardized Makefile targets. Unless we have good reason to do otherwise, I see no reason not to support them.

#### File locking

Somehow, straighten out, document, and implement `lockf()`, `flock()`, and/or `fcntl()` file locking. It's a mess. See `$d_fcntl_can_lock` in recent config.sh files though.

## NAME

repository – Using the Perl repository

## Synopsis

First, we assume here that you have already decided that you will need **write** access to the repository. If all you need is **read** access, there are much better ways to access the most current state of the perl repository, or explore individual files and patches therein. See [perlhack](#) for details.

This document describes what a Perl Porter needs to do to start using the Perl repository.

## Prerequisites

You'll need to get hold of the following software.

### Perforce

Download a perforce client from:

<http://www.perforce.com/perforce/loadprog.html>

You'll probably also want to look at:

<http://www.perforce.com/perforce/technical.html>

where you can look at or download its documentation.

**ssh** If you don't already have access to an ssh client, then look at its home site

<http://www.cs.hut.fi/ssh> which mentions ftp sites from which it's available. You only need to build the client parts (ssh and ssh-keygen should suffice).

## Creating an SSH Key Pair

If you already use ssh and want to use the same key pair for perl repository access then you can skip the rest of this section. Otherwise, generate an ssh key pair for use with the repository by typing the command

```
ssh-keygen
```

After generating a key pair and testing it, ssh-keygen will ask you to enter a filename in which to save the key. The default it offers will be the file `~/.ssh/identity` which is suitable unless you particularly want to keep separate ssh identities for some reason. If so, you could save the perl repository private key in the file `~/.ssh/perl`, for example, but I will use the standard filename in the remainder of the examples of this document.

After typing in the filename, it will prompt you to type in a passphrase. The private key will itself be encrypted so that it is usable only when that passphrase is typed. (When using ssh, you will be prompted when it requires a pass phrase to unlock a private key.) If you provide a blank passphrase then no passphrase will be needed to unlock the key and, as a consequence, anyone who gains access to the key file gains access to accounts protected with that key (barring additional configuration to restrict access by IP address).

When you have typed the passphrase in twice, ssh-keygen will confirm where it has saved the private key (in the filename you gave and with permissions set to be only readable by you), what your public key is (don't worry: you don't need to memorise it) and where it has saved the corresponding public key. The public key is saved in a filename corresponding to your private key's filename but with ".pub" appended, usually `~/.ssh/identity.pub`. That public key can be (but need not be) world readable. It is not used by your own system at all.

## Notifying the Repository Keeper

Mail the contents of that public key file to the keeper of the perl repository (see [/Contact Information](#) below). When the key is added to the repository host's configuration file, you will be able to connect to it with ssh by using the corresponding private key file (after unlocking it with your chosen passphrase).

## Connecting to the Repository

Connections to the repository are made by using ssh to provide a TCP "tunnel" rather than by using ssh to login to or invoke any ordinary commands on the repository. When you want to start a session using the repository, use the command

```
ssh -l perlrep -f -q -x -L 1666:127.0.0.1:1666 sickle.activestate.com foo
```

If you are not using the default filename of `~/.ssh/identity` to hold your perl repository private key then you'll need to add the option `-i filename` to tell ssh where it is. Unless you chose a blank passphrase for that private key, ssh will prompt you for the passphrase to unlock that key. Then ssh will fork and put itself in the background, returning you (silently) to your shell prompt. The tunnel for repository access is now ready for use.

For the sake of completeness (and for the case where the chosen port of 1666 is already in use on your machine), I'll briefly describe what all those ssh arguments are for.

### **-l perlrep**

Use a remote username of perlrep. (The account on the repository which provides the end-point of the ssh tunnel is named "perlrep".)

**-f** Tells ssh to fork and remain running in the background. Since ssh is only being used for its tunnelling capabilities, the command that ssh runs never does any I/O and can sit silently in the background.

**-q** Tells ssh to be quiet. Without this option, ssh will output a message each time you use a p4 command (since each p4 command tunnels over the ssh connection to reach the repository).

**-x** Tells ssh not to bother to set up a tunnel for X11 connections. The repository doesn't allow this anyway.

### **-L 1666:127.0.0.1:1666**

This is the important option. It tells ssh to listen out for connections made to port 1666 on your local machine. When such a connection is made, the ssh client tells the remote side (the corresponding ssh daemon on the repository) to make a connection to IP address 127.0.0.1, port 1666. Data flowing along that connection is tunnelled over the ssh connection (encrypted). The perforce daemon running on the repository only accepts connections from localhost and that is exactly where ssh-tunnelled connections appear to come from.

If port 1666 is already in use on your machine then you can choose any non-privileged port (a number between 1024 and 65535) which happens to be free on your machine. It's the first of the three colon separated values that you should change. Picking port 2345 would mean changing the option to **-L 2345:127.0.0.1:1666**. Whatever port number you choose should be used for the value of the P4PORT environment variable (q.v.).

sickle.activestate.com

This is the canonical name of the host on which the perl repository resides. Its IP address is 199.60.48.20.

foo This is a dummy place holder argument. Without an argument here, ssh will try to perform an interactive login to the repository which is not allowed. Ordinarily, this argument is for the one-off command which is to be executed on the remote host. However, the repository's ssh configuration file uses the "command=" option to force a particular command to run so the actual value of the argument is ignored. The command that's actually run merely pauses and waits for the ssh connection to drop, then exits.

## Problems

You should normally get a prompt that asks for the passphrase for your RSA key when you connect with the ssh command shown above. If you see a prompt that looks like:

```
perlrep@sickle.activestate.com's password:
```

Then you either don't have a `~/.ssh/identity` file corresponding to your public key, or your `~/.ssh/identity` file is not readable. Fix the problem and try again.

## Using the Perforce Client

Remember to read the documentation for Perforce. You need to make sure that three environment variable are set correctly before using the `p4` client with the perl repository.

### P4PORT

Set this to `localhost:1666` (the port for your ssh client to listen on) unless that port is already in use on your host. If it is, see the section above on the `-L 1666:127.0.0.1:1666` option to `ssh`.

### P4CLIENT

The value of this is the name by which Perforce knows your host's workspace. You need to pick a name (normally, your Perforce username, a dash, and your hostname) when you first start using the perl repository and then stick with it.

Perforce keeps track of the files you have on your machine. It does this through your client. When you first sync a version of a file, the file comes from the server to your machine. If you sync the same file again the server does nothing because it knows you already have the file.

You should NOT use the same client on different machines. If you do you probably won't get the files you expect, and may end up with nasty corruption. Perforce allows you to have as many clients as you want. For example, `sally-home`, `sally-openbsd`, `sally-laptop`.

Also, never change the client's root and view at the same time. See

[http://www.perforce.com/perforce/doc.002/manuals/p4guide/04\\_details.html#1048341](http://www.perforce.com/perforce/doc.002/manuals/p4guide/04_details.html#1048341)

If you have multiple hosts sharing the same directory structure via NFS then you may be able to get away with only one client name, but be careful.

The `p4 clients` command lists all currently known clients.

### P4USER

This is the username by which perforce knows you. Use your username if you have a well known or obvious one or else pick a new one which other `perl5-porters` will recognise. There is a licence limit on the number of these usernames, so be sure not to use more than one.

It is very important to set a password for your Perforce username, or else anyone can impersonate you. Use the `p4 passwd` command to do this. Once a password is set for your account, you'll need to tell Perforce what it is. You can do this by setting the environment variable `P4PASSWD`, or you can use the `-P` flag with the `p4` command.

There are a few techniques you can use to avoid having to either set an environment variable or type the password on every command. One is to create a shell alias, for example, in `bash`, add something like

```
alias p4='p4 -P secret'
```

to your *.bash\_profile* file. Another way is to create a small shell script, for example

```
#!/bin/bash
```

```
p4 -P secret $@
```

And use this instead of running `p4` directly.

With either of these, be sure the file containing your password (the *.bash\_profile* or shell script file) is only readable by you.

The `p4 users` command lists all currently known users.

Once these three environment variables are set, you can use the perforce `p4` client exactly as described in its documentation. After setting these variables and connecting to the repository for the first time, you should use the `p4 user` and `p4 client` commands to tell perforce the details of your new username and your new client workspace specifications.

## Ending a Repository Session

When you have finished a session using the repository, you should kill off the ssh client process to break the tunnel. Since ssh forked itself into the background, you'll need to use something like ps with the appropriate options to find the ssh process and then kill it manually. The default signal of SIGTERM is fine.

## Overview of the Repository

Please read at least the introductory sections of the Perforce User Guide (and perhaps the Quick Start Guide as well) before reading this section.

Every repository user typically "owns" a "branch" of the mainline code in the repository. They hold the "pumpkin" for things in this area, and are usually the only user who will modify files there. This is not strictly enforced in order to allow the flexibility of other users stealing the pumpkin for short periods with the owner's permission.

Here is the current structure of the repository:

```

/-----+-----perl - Mainline development (bleadperl)
 +-----perlio - PerlIO Pumpkin's Perl
 +-----vmsperl - VMS Pumpkin's Perl
 +-----maint-5.004-----perl - Maintenance branches
 +-----maint-5.005-----perl
 +-----maint-5.6-----perl
 +-----maint-5.6-----pureperl

```

Perforce uses a branching model that simply tracks relationships between files. It does not care about directories at all, so any file can be a branch of any other file—the fully qualified depot path name (of the form `//depot/foo/bar.c`) uniquely determines a file for the purpose of establishing branching relationships. Since a branch usually involves hundreds of files, such relationships are typically specified en masse using a branch map (try `'p4 help branch'`). `'p4 branches'` lists the existing branches that have been set up. `'p4 branch -o branchname'` can be used to view the map for a particular branch, if you want to determine the ancestor for a particular set of files.

The mainline (aka "trunk") code in the Perl repository is under `"//depot/perl/..."`. Most branches typically map its entire contents under a directory that goes by the same name as the branch name. Thus the contents of the perlio branch are to be found in `//depot/perlio`.

Run `'p4 client'` to specify how the repository contents should map to your local disk. Most users will typically have a client map that includes at least their entire branch and the contents of the mainline.

Run `'p4 changes -l -m10'` to check on the activity in the repository. `//depot/perl/Porting/genlog` is useful to get an annotated changelog that shows files and branches. You can use this listing to determine if there are any changes in the mainline that you need to merge into your own branch. A typical merging session looks like this:

```

% cd ~/p4view/perlio
% p4 integrate -b perlio # to bring parent changes into perlio
% p4 resolve -am ./... # auto merge the changes
% p4 resolve ./... # manual merge conflicting changes
% p4 submit ./... # check in

```

If the owner of the mainline wants to bring the changes in perlio back into the mainline, they do:

```

% p4 integrate -r -b perlio
...

```

Generating a patch for change#42 is done as follows:

```

% p4genpatch 42 > change-42.patch

```

*p4genpatch* is to be found in `//depot/perl/Porting/`.

The usual routine to apply a patch is

```
% p4 edit file.c file.h
% patch < patch.txt
```

(any necessary, re-Configure, make regen\_headers, make clean, etc, here)

```
% make all test
```

(preferably make all test in several platforms and under several different Configurations)

```
% while unhappy
do
 $EDITOR
 make all test
done
% p4 submit
```

Other useful Perforce commands

```
% p4 describe -du 12345 # show change 12345
```

Note: the output of "p4 describe" is not in proper diff format, use the *Porting/p4genpatch* to get a diff-compatible format.

```
% p4 diff -se ./... # have I modified something but forgotten
 # to "p4 edit", easy faux pas with autogenerated
 # files like proto.h, or if one forgets to
 # look carefully which files a patch modifies
% p4 sync file.h # if someone else has modified file.h
% p4 opened # which files are opened (p4 edit) by me
% p4 opened -a # which files are opened by anybody
% p4 diff -du file.c # what changes have I done
% p4 revert file.h # never mind my changes
% p4 sync -f argh.c # forcibly synchronize your file
 # from the repository
% p4 diff -sr | p4 -x - revert
 # throw away (opened but) unchanged files
 # (in Perforce it's a little bit too easy
 # to checkin unchanged files)
```

Integrate patch 12345 from the mainline to the maint-5.6 branch: (you have to in the directory that has both the mainline and the maint-5.6/perl as subdirectories)

```
% p4 integrate -d perl/...@12345,12345 maint-5.6/perl/...
```

Integrate patches 12347-12350 from the perl5 branch to the mainline:

```
% p4 integrate -d perl5/...@12347,12350 perl/...
```

## Contact Information

The mail alias <perl-repository-keepers@perl.org> can be used to reach all current users of the repository.

The repository keeper is currently Gurusamy Sarathy <gsar@activestate.com>.
