

1 @category

@category — Specify a category to organize the documented element's package into

Synopsis

@category categoryname

Description

The @category tag is used to organize groups of packages together. This is directly applicable to the XML:DocBook/peardoc2 Converter, and can be used by other converters. Other Converters packaged with phpDocumentor ignore the category, but this may change in future versions. It is also possible to dynamically specify category using the { @tutorial phpDocumentor.howto.pkg#using.commline.defaultcategoryname} command-line switch.

Example

Here's an example:

```
/**
 * Page-Level DocBlock
 * @package MyPackage
 * @category mycategory
 */

/**
 * @global array used for stuff
 */
function mine()
{
    global $baz;
    ...
}
```
