

Q: Why don't the services from my MAB [Multiple Architecture Binary] applications show up on my Release 3.0 machine?

A: When the service description file is located in an app wrapper of a MAB application and placed in ~/Apps, the services do not get properly registered on a Release 3.0 machine. However, the services are correctly registered on a post-Release 3.0 machine. This is a MAB bug in Release 3.0.

The workaround is to place a file or directory with a ".service" extension in either ~/Library/Services or /LocalLibrary/Services. A file with a ".service" extension must be a valid service description file. A ".service" directory must contain a valid service description file named "services" (e.g., the service description file would be named something like ~/Library/Services/myOwn.service or /LocalLibrary/Services/ALocalOne.service/services). Note that the extension **".service"** does not end in an "s", but the file named **services** does. Also, the Workspace Manager only registers the services in these directories when the user logs in, it doesn't automatically update the service cache during a working session.

For more information on installing services, refer to ../AppKit/installing\_new\_services.
