Q: How can I determine which TextField is being edited, while performing a delegate method such as textWillEnd: or textDidChange:?

A: All of TextField's delegate methods send the Text object as an argument.   You can message this Text object to get *its* delegate, which has been set to the id of the TextField being edited. If you have several TextFields in a Matrix (or a Form) then the Matrix (or the Form) is the delegate of the Text object. In which case you should use the following method calls to get the actual TextField:

```
[[sender delegate] selectedCell];
```

This code also works for individual TextFields, because single Controls return self when asked for selectedCell.   We recommend that you use the above code snippet in all cases.
