Q: What method is sent to my inspector when an object is newly selected and the inspector must update the attributes for that object?

A: The **revert:** method is sent to the inspector when an object of that type is selected by the user.   The **revert:** method should restore the attributes on the inspector panel according the state of the selected object.   The selected object is named **'object'** within the scope of the **revert:** method.   Remember that this method is also called from when the user clicks the panel's revert button, so the method should work under both scenarios.
