

Print Wrap

The accompanying text file will take the string from a text box and send it to the printer so that it will all print, wrapping at the word breaks as delimited by spaces. The code as written is for the click event of a menu control called FilePrint, which is the Print command from the File menu option of an application of mine. The text box name is the name of my application's text box control. Your application might use different names. Just open the text file in Notepad, and paste the code into your event procedure.

If you find problems with the code or come up with a way to improve it, please let me know. Public domain.
