

A common requirement in file-based applications is to accept a filename as input from the user. With the advent of case-preserved filesystems on Windows 95 and NT it is no longer trivial to determine the proper case of a pathname the user has entered.

If the user enters MYDOCS\MYFILE.TXT to open a file stored as MyDocs\MyFile.txt the program should display the stored name MyDocs\MyFile.txt, not the entered name. With the Shell Control Pack, just call **ShellGetDisplayPathname** to obtain the proper casing for the whole pathname. Easy!
