
NSDateFormatter

Inherits From:	NSDateFormatter : NSObject
Conforms To:	NSObject (NSObject) NSCoding NSCopying
Declared In:	Foundation/NSDateFormatter.h

Class Description

Instances of NSDateFormatter format the textual representation of cells that contain NSDate objects (including NSDateCalendarDate objects), and convert textual representations of dates and times into NSDate objects. You can express the representation of dates and times very flexibly: “Thu 22 Dec 1994” is just as acceptable as “12/22/94”. With natural-language processing for dates enabled, users can also express dates colloquially, such as “today,” “day after tomorrow,” and “a month from today.”

To use an NSDateFormatter, allocate an instance of it and initialize it with **initWithDateFormat:allowNaturalLanguage:** In the first argument use **strftime**-style conversion specifiers to compose the format string for textual representation. (For more information on these specifiers, see the description of NSDateCalendarDate’s **dateWithCalendarFormat:timeZone:** method.) Then use NSDateFormatter’s **setFormatter:** method to associate the NSDateFormatter object with a cell. The value of a cell (NSDateFormatter) is represented by an object, typically an NSDate object in this case. When this value needs to be displayed or edited, the cell passes its object to the NSDateFormatter instance, which returns the formatted string. When the user enters a string, or when one is programmatically written in a cell (using **setStringValue:**), the cell obtains the equivalent NSDate object from the NSDateFormatter.

NSDateFormatter provides delegation methods that permit you to validate cell contents and to handle errors in formatting. See the specification of the NSDateFormatter class for details.

When a cell with a NSDateFormatter is copied, the new cell retains the NSDateFormatter object instead of copying it. You remove an NSDateFormatter from a cell by specifying **nil** as the argument of **setFormatter:**.

Instances of NSDateFormatter are immutable.

NSDateFormatter Methods for Date Formatting

Alternatively, you can associate an NSDateFormatter object with a cell using an NSDateFormatter method. Send **setEntryType:** with an argument of **NSDateType** to a cell to associate that cell with a NSDateFormatter. The date format string is taken from the user default NSDateFormatterString and natural-language processing

of dates is enabled. To determine if a cell can accept a date conforming to the `NSDateFormatString`, send **`isEntryAcceptable:`** to the cell.

Note: The `NSDateFormatter` approach is recommended over `NSCell`'s **`setEntryType:`** because it allows you greater freedom in specifying the representation of dates. However, `NSCell`'s **`setEntryType:`** and **`isEntryAcceptable:`** are OpenStep-compliant whereas the `NSDateFormatter` API is an extension to OpenStep.

Method Types

Initializing an `NSDateFormatter`

– `initWithDateFormat:allowNaturalLanguage:`

Determining attributes

– `allowsNaturalLanguage`

– `dateFormat`

Instance Methods

`allowsNaturalLanguage`

– (BOOL)**`allowsNaturalLanguage`**

Returns YES if the `NSDateFormatter` attempts to process dates entered as a vernacular string (“today,” “day before yesterday,” and so on). Returns NO if the `NSDateFormatter` does not do any natural-language processing of these date expressions.

`dateFormat`

– (NSString *)**`dateFormat`**

Returns the date format string used by an `NSDateFormatter` object. See the description of `NSDateFormatter`'s **`dateFormat:`** for a list of the conversion specifiers permitted in date format strings.

`initWithDateFormat:allowNaturalLanguage`

– (id)**`initWithDateFormat:(NSString *)format
allowNaturalLanguage:(BOOL)flag`**

Initializes and returns an `NSDateFormatter` instance that uses the date *format* in its conversions. See the description of `NSDateFormatter`'s **`dateFormat:`** for a list of conversion specifiers permitted in date format strings. Set *flag* to YES if you want the `NSDateFormatter` to process dates entered as expressions in the vernacular (for example, “tomorrow”); `NSDateFormatter` attempts natural-language processing only after it fails to interpret an entered string according to *format*. The following example

creates a date formatter with the format string (as example) “Mar 15 1994” and then associates the formatter with the cells of a form (**contactsForm**).

```
NSDateFormatter *dateFormat = [[NSDateFormatter alloc]
    initWithDateFormat:@"%b %d %Y" allowNaturalLanguage:NO];
[[contactsForm cells] makeObjectsPerform:@selector(setFormatter:)
    withObject:dateFormat];
```
