

Navigating with the keyboard

Line.tiff ↗

Keyboard control (i.e. the processing of all keyboard input) can be taken either by the main browser or by the value view. Besides the arrow keys which are processed similarly by both there is a set of special key strokes:

Within the main browser

- `<return>` unhide the value view and \pm if exactly one owner and one default are selected \pm display the corresponding value and place the insertion marker at the end
- `<enter>` unhide the value view and \pm if exactly one owner and one default are selected \pm display the corresponding value and select it
- `<delete>` hide the value view
- `<tab>` toggle the display of the value view (same as clicking the toggle button)

Within the value view

- `<enter>` saves the actual value in the database (if there were any changes), disables the **Save** and **Revert** buttons and gives key control back to the main browser
- `<esc>` discards all changes in the value view, disables the **Save** and **Revert** buttons and gives key control back to the main browser

PixelRule1.tiff ↗

- If `<enter>` or `<esc>` do real work, i.e. save or revert a changed value, the corresponding button flashes

- You can redirect keyboard control at any time with a single mouse click on the desired object
