

This is the first public release of **NewFile**.

The code in this application was borrowed from, inspired by and extrapolated from several sources, mainly NeXT documentation and several of the mini-examples and service providers available on ftp sites, particularly Piper (by **Dave Griffiths** of **Primitive Software Ltd**). The main reason I wrote this is because I was annoyed that the OpenWindows 'file manager' lets you create a text file in a directory, but the Workspace Manager doesn't. Hopefully, this is one better.

**NewFile** shouldn't do anything nasty to your files, such as overwriting an existing file without requesting your confirmation. However, neither I nor Queen's University make any promise as to the suitability of otherwise of this application or its source code for any purpose: use at your own risk.

Do as you wish with **NewFile** and its source code so long as you give me due credit. As I've borrowed code from other public domain software, **NewFile** is also public domain, so you're not allowed to make a profit from it or from the source code.
