```

1.2   ARexxGuide | Functions reference (3 of 12) | WORD MANIPULATION

```
    DELWORD    (<string>,<wordnum>, [<length>])
    SPACE      (<string>,<number>,[<padchar>])
    SUBWORD    (<string>,<wordnum>, [<length>])
    WORD       (<string>,<wordnum>)
    WORDINDEX (<string>,<wordnum>)
    WORDLENGTH(<string>,<wordnum>)
    WORDS      (<string>)

Related function:
    FIND

                    Also see  String manipulation functions
                              PARSE instruction

A 'word' is any collection of characters separated by blanks from other
characters in a string. These functions allow the programmer to manipulate
such words in a quick and elegant manner.

Next: Translation func. | Prev: String functions | Contents: Function reference
```

1.3   ARexxGuide | Functions reference | Words (1 of 7) | DELWORD

```
DELWORD(<string>,<wordnum>, [<length>])
      returns a string
```

Deletes a portion of <string> beginning at the word represented by
<wordnum> for <length> number of words. If <wordnum> is greater than the
number of words in <string> then <string> is returned unchanged.

If <length> is omitted, everything to the right of (and including) the
word at <wordnum> position is deleted.

```
   Examples:
        say delword('the indestructible chaos of timeless things',3,3);
                                    >>> the indestructible things

   Also see @{ " DELSTR          " link ARx_Func.ag/DELSTR()}
            @{ " SUBWORD         " link SUBWORD()}
```

Next: SPACE() | Prev: Word functions | Contents: Word functions

1.4 ARexxGuide | Functions reference | Words (2 of 7) | SPACE

```
SPACE(<string>,<wordnum>,[<padchar>])
      returns a string
```

Formats the original string by placing <number> of <padchar> characters
between each set of blank-delimited words. Leading and trailing blanks are
always removed. If <number> is 0, then all spaces in the string are
removed.

The default for <number> is 1. The default pad character is a blank.

```
   Example:
        say space('I don''t know what it is',3);
                            >>> I   don't   know   what   it   is
        say space('In the end it was magic',1,'_');
                            >>> In_the_end_it_was_magic

   Also see @{ " CENTER          " link ARx_Func.ag/CENTER()}
            @{ " COMPRESS        " link ARx_Func.ag/COMPRESS()}
```

Next: SUBWORD() | Prev: DELWORD() | Contents: Word functions

1.5 ARexxGuide | Functions reference | Words (3 of 7) | SUBWORD

```
SUBWORD(<string>,<wordnum>, [<length>])
      returns a string
```

The result is a string of <length> blank-delimited words made up the words
in <string> beginning at word <wordnum>.

```
   Example:
```

```
        say subword('yet nothing is changed',2,2);     >>> nothing is

   Also see @{ " WORD          " link WORD()}
           @{ " SUBSTR        " link ARx_Func.ag/SUBSTR()}
           @{ " FIND          " link ARx_Func.ag/FIND()}
           @{ " DELWORD       " link DELWORD()}
```

1.6   ARexxGuide | Functions reference | Words (4 of 7) | WORD

```
WORD(<string>,<wordnum>)
      returns a string
```

The result is the blank-delimited word in <string> at position <wordnum>,
or a null string if there are fewer than <wordnum> words in <string>.

```
   Example:
        say word('the most you can hope',5);     >>> hope

   Also see @{ " SUBWORD            " link SUBWORD()}
           @{ " PARSE TOKENIZATION " link ARx_Instr2.ag/PARSETMP2} instruction
```

1.7   ARexxGuide | Functions reference | Words (5 of 7) | WORDINDEX

```
WORDINDEX(<string>,<wordnum>)
      returns a number
```

The result is the character position of the first character in the word at
postion <wordnum> in <string> or 0 if there are fewer than <wordnum> words.

```
   Example:
        say wordindex('to be a little less the creature',4);  >>> 9

   Also see @{ " FIND          " link ARx_Func.ag/FIND()}
           @{ " WORDS         " link WORDS()}
           @{ " WORDLENGTH    " link WORDLENGTH()}
```

1.8   ARexxGuide | Functions reference | Words (6 of 7) | WORDLENGTH

```
WORDLENGTH(<string>,<wordnum>)
      returns a number
```

The result is the length of the blank-delimited word at postion <wordnum>
in <string>.

```
    Example:
          say wordlength('you were in the beginning',3);         >>> 2

    Also see @{ " FIND          " link ARx_Func.ag/FIND()}
            @{ " WORDINDEX     " link WORDINDEX()}
            @{ " WORDS         " link WORDS()}
```

1.9   ARexxGuide | Functions reference | Words (7 of 7) | WORDS

```
WORDS(<string>)
      returns a number
```

The result is the number of blank-delimited words in <string>.

```
    Example:
        say words('and the middle');       >>> 3

    Also see @{ " FIND          " link ARx_Func.ag/FIND()}
            @{ " WORDINDEX     " link WORDINDEX()}
            @{ " WORDLENGTH    " link WORDLENGTH()}
```

1.10   ARexxGuide | Functions reference (4 of 12) | TRANSLATION

```
    B2C         (<binary-string>)
    C2B         (<string>)
    C2D         (<string>, [<numbytes>])
    C2X         (<string>)
    D2C         (<whole number>, [<length>])
    D2X         (<whole number>, [<length>])
    X2C         (<hex-string>)
    X2D         (<hex-string>)
```

The function in this list translate values from one form of representation
to another.

Since ARexx stores all values as strings , it is difficult to decipher
some of the values it returns -- such as the addresses returned by
 GETSPACE() or WAITPKT() . The C2D() function can translate those
values into a more readily understood format.

1.11   ARexxGuide | Functions reference | Translation (1 of 8) | B2C

```
B2C(<binary number>)
      returns a character
```

Translates a binary number into its ASCII character representation.

Spaces are allowed at the byte boundaries in the input <binary number>.

```
   Example:
        say b2c(01100001);                      >>> a
        say b2c(01000110 01000110 01010011);    >>> FFS
```

   Also see @{ " C2B   " link C2B()}

Next: C2B() | Prev: Translation func. | Contents: Translation func.

1.12   ARexxGuide | Functions reference | Translation (2 of 8) | C2B

```
C2B(<string>)
      returns a binary number
```

Converts <string> into binary digits.

```
   Examples:
        say c2b('FFS');              >>> 010001100100011001010011
        say c2b('F') c2b('F') c2b('S');>>> 01000110 01000110 01010011
        say c2b('a');                >>> 01100001
```

Each character in the argument string is converted to its binary
representation. The value returned is a concatenation of each of those
binary numbers. This is the way <string> would be represented in the
machine's memory.

   Also see @{ " B2C   " link B2C()}

Next: C2D() | Prev: B2C() | Contents: Translation func.

1.13   ARexxGuide | Functions reference | Translation (3 of 8) | C2D

```
C2D(<string>, [<chars>])
      returns a number
```

In its simplest form, when <string> is one character, the function
converts <string> to its ASCII value expressed as a decimal number.

```
   Examples:
        say c2d('b');         >>> 98
        say c2d(0)            >>> 49
```

The function will accept a <string> of up to four characters (four bytes)
in length. When multiple characters are supplied, the function treats each
character as a binary number, concatenates the result (see c2b() for an

example) and then returns the decimal equivalent of concatenated number.

```
   Example:
        say c2d('FFS')           >>> 4605523
```

The second argument, which must be a number from 1 to 4, allows a string
shorter than that supplied by the first argument to be evaluated. The
string is truncated from the right to the number of characters specified.

```
   Examples:
   /**/
        say c2d('miga')          >>> 1835624289
        say c2d('Amiga', 4)      >>> 1835624289
        say c2d('a')             >>> 97
        say c2d('Amiga', 1)      >>> 97

   Also see @{ " C2B             " link C2B()}
           @{ " D2C             " link D2C()}
```

Next: C2X() | Prev: C2B() | Contents: Translation func.

1.14   ARexxGuide | Functions reference | Translation (4 of 8) | C2X

```
C2X(<string>)
      returns a string (formatted as a hex number)
```

In its simplest form, when <string> is one character, the function
converts <string> to its ASCII value expressed as a hexadecimal number.

```
   Example:
        say c2x('b');            >>> 62
        say c2x('F') c2x('S');   >>> 46 53
        say c2x('FFS');          >>> 464653
```

When multiple characters are included in <string>, each character is
converted to its hexadecimal representation. The value returned is a
 concatenation of each of those hex numbers. This is way the programmers
usually prefer to view values of a binary file.

```
   Also see @{ " X2C             " link X2C()}
```

Next: D2C() | Prev: C2D() | Contents: Translation func.

1.15   ARexxGuide | Functions reference | Translation (5 of 8) | D2C

```
D2C(<whole number>, [<length>])
      returns a string
```

Converts a decimal <whole number> into a character string.

If <length> is supplied, the result will be truncated from the right to
that size.

```
    Example:
          say d2c(98);                >>> b

    Also see @{ " C2D        " link C2D()}
```

Next: D2X() | Prev: C2X() | Contents: Translation func.

1.16   ARexxGuide | Functions reference | Translation (6 of 8) | D2X

```
D2X(<whole number>, [<length>])
      returns a string
```

Converts a decimal <whole number> into an equivalent hexadecimal string.

If <length> is supplied, the result will be truncated from the right or
padded with '0' characters to to that size. d2x(<number>, <trunc>)
produces the same result as right(d2x(<number>), <trunc>, '0') .

```
    Example:
          say d2x(98);              >>> 62
          say d2x(464653);          >>> 7170D
          say d2x(464653,6);        >>> 07170D
          say d2x(464653,4);        >>> 170D
```

Next: X2C() | Prev: D2C() | Contents: Translation func.

1.17   ARexxGuide | Functions reference | Translation (7 of 8) | X2C

```
X2C(<string>)
      returns a string
```

Converts a string of hexadecimal digits to their ASCII character
representation.

<string> must be an expression that evaluates to a valid hex number -- a
string of digits and/or the characters {a} through {f} or {A} through {F}.
It will be padded, if necessary, with a leading 0 to produce an even
number of characters.

```
    Examples:
          say x2c(416D696761);      >>> Amiga
          say x2c(464653);          >>> FFS
```

Next: X2D() | Prev: D2X() | Contents: Translation func.

1.18   ARexxGuide | Functions reference | Translation (8 of 8) | X2D

```
X2D(<string>, [<length>])
      returns a string
```

Converts a string of hexadecimal digits to a whole decimal number. The
setting of NUMERIC DIGITS determines the size of number that can be
returned without generating an error.

<string> must be an expression that evaluates to a valid hex number -- a
string of digits and/or the characters {a} through {f} or {A} through {F}.
It will be padded, if necessary, with a leading 0 to produce an even
number of characters.

If <length> is specified, then <string> is either padded on the left with
0's or truncated to that length before the translation.

```
   Examples:
        say x2d(416D6967);        >>> 1097689447
        say x2d(464653);          >>> 4605523
```

Next: Translation func. | Prev: X2C() | Contents: Translation func.

1.19   ARexxGuide | Functions reference (5 of 12) | NUMBER MANIPULATION

```
    ABS        (<number>)
    HASH       (<string>)
    MAX        (<number>,<number> [,<number>,...])
    MIN        (<number>,<number>, [,<number>,...])
    RANDOM     ([<min>],[<max>],[<seed>})
    RANDU      ([<seed>])
    SIGN       (<number>)
    TRUNC      (<number>, [<places>])
```

                   Also see String manipulation functions

The functions take decimal digits as arguments. They perform some common
alterations of the arguments, or return information about the number. The
arguments sent to the function and the values returned are subject to
alteration based on the setting of NUMERIC DIGITS . If a number is larger
than the current DIGITS() setting, it will be converted to the current
precision.

Next: Information func. | Prev: Translation func. | Contents: Function reference

1.20   ARexxGuide | Functions reference | Number (1 of 9) | ABS

```
ABS(<number>)
      returns a number
```

Returns the absolute value of <number>. The result will not have a sign
and will be formatted according to the current settings of NUMERIC .

```
    Examples:
        say abs(-100);                   >>> 100
        say abs(10.5);                   >>> 10.5
        say abs(-30);                    >>> 30
```

```
    Also see @{ " SIGN          " link SIGN()}
             @{ " DATATYPE       " link ARx_Func3.ag/DATATYPE()}
```

Next: HASH() | Prev: Number functions | Contents: Number functions

1.21   ARexxGuide | Functions reference | Number (2 of 9) | HASH

```
HASH(<string>)
        returns a number
```

Returns the hash attribute of a string as a decimal number.

A hash attribute is a number assigned to a string and is often used in
indexing schemes to provide a quick initial value for locating the string
within a range of data.

```
    Examples:
        say hash('AMIGA')        >>> 95
        say hash('Amiga')        >>> 223
        say hash('MAGIA')        >>> 95
```

The hash value is determined by adding the decimal ASCII values of each
character in the string and then performing a remainder-division (//) on
the result. Given a variable [Word], the following program would return
the same value as HASH(word):

```
    /**/
    Wtot = 0
    do i = 1 to length(Word)
        Wtot = Wtot + c2d(substr(Word,i,1))
    end
    return Wtot // 256
```

Next: MAX() | Prev: ABS() | Contents: Number functions

1.22   ARexxGuide | Functions reference | Number (3 of 9) | MAX

```
MAX(<number>,<number> [,<number>,...])
        returns a number
```

The result is the largest of the <number>s in the supplied list. It is
returned in the format specified by the current NUMERIC
settings.

```
    Examples:
        say max(3, 24/5, 2)                      >>> 4.8
        say max(length('pale'), length('gloom'))  >>> 5
```

```
    Also see @{ " MIN           " link MIN()}
```

1.23   ARexxGuide | Functions reference | Number (4 of 9) | MIN

```
MIN(<number>,<number>, [,<number>,...])
      returns a number
```

The result is the smallest of the <number>s in the supplied list. It is
returned in the format specified by the current NUMERIC settings.

```
    Examples:
    /**/
        say min(3, 24/5, 2)                        >>> 2
        say min(length('pale'), length('gloom'))  >>> 4

    Also see @{ " MAX           " link MAX()}
```

1.24   ARexxGuide | Functions reference | Number (5 of 9) | RANDOM

```
RANDOM([<min>],[<max>],[<seed>})
      returns a number
```

The result is a quasi-random non-negative whole number in the range <min>
to <max> inclusive. The default for <min> is 0. The default for <max> is
999. If only one number is specified, it will be treated as the maximum
value.

If a <seed> value (which must be an integer) is specified, it will begin a
repeatable sequence of results.

```
    Examples:
        say random(10, 48)                          >>> 29  /* always */
        say random()                                >>> 493 /* always */
        say random(10,48,506)                       >>> 31  /* always */
        say random(,, time(s))                      >>> 25  /* maybe  */
        call random(,, time(s));say random(10, 48)  >>> 34  /* maybe  */

    Also see @{ " RANDU          " link RANDU()}
```

Unless the function is seeded once within each script in which it is used,
it will always return the same values for a specified range of numbers.
When a seed is specified, each call to random() will return a range of
numbers that can be repeated exactly when the same seed value is used
again. The TIME() function can provide a seed value that is itself
random enough to produce a more truly random set of numbers during
subsequent calls to random() without a seed.

1.25   ARexxGuide | Functions reference | Number (6 of 9) | RANDU

```
RANDU([<seed>])
      returns a number
```

The result is a quasi-random number between 0 and 1. The number of digits
of precision is determined by the current setting of NUMERIC DIGITS.

If a <seed> value is specified, it will begin a repeatable sequence of
results.

```
   Examples:
        say randu(48)                    >>> 0.423783344  /* always */
        say randu()                      >>> 0.646834773  /* always */
        say randu(506)                   >>> 0.867625551  /* always */
        say randu(time(s))               >>> 0.234561918  /* maybe  */
        call randu(time(s));say randu(48) >>> 0.739330433  /* maybe  */

   Also see @{ " RANDOM        " link RANDOM()}
```

1.26   ARexxGuide | Functions reference | Number (7 of 9) | SIGN

```
SIGN(<number>)
      returns '-1', '0', or '1'
```

A result of '-1' indicates that the supplied number is less than 0. '1'
indicates that it is greater than 0. A result of '0' is returned when
<number> is 0.

```
   Examples:
        say sign(45)      >>> 1
        say sign(-86);    >>> -1

   Also see @{ " ABS          " link ABS()}
           @{ " DATATYPE     " link ARx_Func3.ag/DATATYPE()}
```

1.27   ARexxGuide | Functions reference | Number (8 of 9) | TRUNC

```
TRUNC(<number>, [<places>])
      returns a number
```

The result is the integer part of the supplied <number> formatted to
<places> decimal places. 0's are added if <number> did not have that many
decimal places.

If <places> is less than the number of decimals supplied, the fraction is
truncated without rounding.

The function truncates the number without rounding so trunc(6.19,2)
returns 6.1 rather than 6.2. The setting of NUMERIC DIGITS may be
manipulated to create a rounded number.

```
    Example:
        say trunc(10.5, 2)                >>> 10.50
        say trunc(6.7899, 3)              >>> 6.789
        say trunc(3, 4)                   >>> 3.0000
        say '$'right(trunc(25.7, 2),8)    >>> $   25.70
        say '$'right(trunc(125.4, 2),8)   >>> $  125.40
```

    Also see @{ " SUBSTR   " link ARx_Func.ag/SUBSTR()}
            @{ " RIGHT   " link ARx_Func.ag/RIGHT()}

                              NOTE: Formatting tables

1.28 ARexxGuide | Functions reference (6 of 12) | INFORMATIONAL

```
    DATE      ([<option>], [<date>, <format>])
    SHOW      (<option>, [<name>], [<separator>])
    SHOWDIR   (<directory>, ['ALL'|'FILE'|'DIR'], <separator>)
    SHOWLIST  (<option>, [<name>], [<separator>], ['A'])
    TIME      (<option>)
```

    PRAGMA
    ADDRESS

                    Also see File management functions

Like the SOURCE and VERSION options to the PARSE instruction, these
functions give an ARexx script information about the system on which a
script is running and (since dates and times are important to most of us)
a bit of information about the world at large.

The DATE() function may also be used to translate dates from one format
into another.

1.29 ARexxGuide | Functions reference | Informative (1 of 5) | DATE

```
DATE([<option>], [<date>, <format>])
      returns a formatted string
```

Without arguments, the result is the current system date.

The <option> argument (B|C|E|I|J|M|N|O|S|U|W) determines the
format of the result. It defaults to Normal format -- for example,
'20 Apr 1993'.

The second and third arguments provide information about other dates.
<date> must be entered in either Sorted or Internal
format and specified as the third argument (S|I).
>>
    Examples:
          say date();   >>> 20 Apr 1993
          say date(w);   >>> Tuesday
          say date(i,'19930419',s);   >>> 5587
          say date(n,'5587',i);   >>> 19 Apr 1993
          say date(w,'19991231',s);   >>> Friday

    Also see @{ " TIME   " link TIME()}

                              NOTE: Persistence of DATE() value

Next: SHOW() | Prev: Information func. | Contents: Information func.

1.30   ARexxGuide | Functions reference | Informative | DATE (1 of 1) | OPTIONS

These are the <option>s recognized by the date function, they are:
All of these options can be shortened to the first character.

        Option   Information returned
        ~~~~~~~~~   ~~~~~~
        Normal   the date in the form dd MMM yy e.g. 09 Mar 1993
        Ordered   the date in the form YY/MM/DD e.g. 93/09/03
        Sorted   the date in the form YYYYMMDD e.g. 19930903
        European   the date in the form DD/MM/YY e.g. 03/09/93
        USA   the date in the form MM/DD/YY e.g. 09/03/93
        Basedate   number of days since January 1, 0001
        Julian   the date in the form YYDDD e.g. 91246
        Century   number of days since January 1 of the current
                    century
        Days   number of days since January 1 of the current
                    year
        Internal   the date in internal system days e.g. 4993
        Month   the current month in mixed case e.g. September
        Weekday   the day of the week, mixed case e.g. Tuesday

Next, Prev. & Contents: DATE()

1.31   ARexxGuide | Functions reference | Informative (2 of 5) | SHOW

```
SHOW(<option>, [<name>], [<separator>])
      returns a string
```

Returns a list of ARexx resources matching the specified <option>:

```
   Option          Displays
   ------------    -------------------------------------------------------
   Clips           The names of clips created by  SETCLIP()  or  RXSET .
   File            The logical names of files created with  OPEN() , and the
                   names of  standard I/O files .
   Libraries       The names on the ARexx  Library List , added by  ADDLIB()
   Ports           The names of all system  message ports .
```

Only the first character of the <option> keyword need be used.

An optional <separator> can be used to divide the resource names, some of
which may have embedded blanks. (Be sure to use two commas before the
<separator>.)

If <name> is specified, the function will check for the existence of that
resource and return a Boolean success flag.

```
   Example:
        say show(p);              >>> REXX AREXX ConClip.rendezvous blanker
        say show(c);              >>> Molloy
        say show(c,'Molloy');     >>> 1
        say show(p,,'0a'x);       >>> REXX
                                      AREXX
                                      ConClip.rendezvous
                                      blanker
```

If 'L' is specified as the argument, a list of currently available ARexx
function libraries is returned. The support library function SHOWLIST() ,
on the other hand, returns a list of all system libraries available when
the same argument is used.

SHOW('P') will return a list of all public message ports available on the
system. Some of those ports cannot be used as hosts for commands from
ARexx.

   Also see @{ " SHOWLIST   " link SHOWLIST()}

Next: SHOWDIR() | Prev: DATE() | Contents: Information func.

1.32   ARexxGuide | Functions reference | Informative (3 of 5) | SHOWDIR

```
                                              a rexxsupport.library function
SHOWDIR(<directory>, ['ALL'|'FILE'|'DIR'], <separator>)
      returns a string
```

The result is a list of files matching the type specified by the second
argument and located in the <directory> specified.

The <separator> can be any character (including a null). It can be used to
separate filenames with a character (such as '0a'x) that cannot be used in
a filename.

```
   Examples:
        say showdir('sys:rexxc');
                 >>> HI RX RXC RXLIB RXSET TCC TCO TE TS WaitForPort

   Also see @{ " SHOWLIST      " link SHOWLIST()}
           @{ " STATEF        " link ARx_Func3.ag/STATEF()}
           @{ " PRAGMA        " link ARx_Func3.ag/PRAGMA()}
```

The function library rexxarplib.library, which is available on many
networks and bulletin boards, includes a function, FILELIST(), that is more
versatile since it will list only those files matching a specified pattern.

Next: SHOWLIST() | Prev: SHOW() | Contents: Information func.

1.33   ARexxGuide | Functions reference | Informative (4 of 5) | SHOWLIST

```
                                              a rexxsupport.library function
SHOWLIST(<option>, [<name>], [<separator>], ['A'])
      returns a string
           or a Boolean value
```

Returns a list of system resources matching the specified <option>
and separated by the optional <separator> character.

If <name> is specified, the function will check for the existence of that
resource and return a Boolean success flag.

The <separator> can be any character, including '0a'x, which is a
convenient way to separate names in the list.

The optional fourth argument 'Address' or 'A' specifies that the function
is to return the address of the located node, and is valid only if a node
name (second argument) has been supplied. The 'Address' option is valid
for both EXEC and DOS lists.

```
   Examples:
        say showlist(L);  >>> utility.library graphics.library keymap.library ...
        say showlist(L,'rexxsupport.library');      >>> 1
        say showlist(M);              >>> expansion memory chip memory
        say showlist(M,,'+');      >>> expansion memory+chip memory
        say showlist(D);  >>> gameport.device timer.device keyboard.device ...
```

```
         say showlist(V,,'|');        >>> XFER|WK|RAM DISK|HD1|HD0
         say showlist(R);  >>> potgo.resource ciaa.resource ciab.resource ...
         say showlist(A,'FONTS');    >>> 1
         say c2d(showlist(L ,'amigaguide.library',,A))
                                  >>> 5153220        /* for example */

   Also see @{ " SHOW          " link SHOW()}
           @{ " SHOWDIR       " link SHOWDIR()}
           @{ " PRAGMA        " link ARx_Func3.ag/PRAGMA()}

Next: TIME() | Prev: SHOWDIR() | Contents: Information Func.
```

1.34 ARexxGuide | Functions reference | Informative | showlist (1 of 1) | OPTIONS

Any <option> to SHOWLIST() (some of them esoteric) may be specified by
using only the single character capitalized in the list below:

```
   Option          Information returned
   ------------    -------------------------------------------------------
   Ports           Same information as SHOW('P'): all named message ports.
   Libraries       All system libraries, not just ARexx libs.
   Volumes         The volume names of all disks currently available.
   Assign          The names of all assigned directories.
   Handlers        The AmigaDOS interfaces to hardware devices. Includes
                   names like DF0, PRT, CON.
   Devices         The lower-level interface to hardware. Might include
                   names like 'scsi.device', 'keyboard.device'.
   Resources       The lowest-level software interface to some hardware
                   elements of the machine. The resources cannot be
                   accessed from ARexx, but this option returns names like
                   'potgo.resource'.
   Memory-types    Will usually return 'expansion memory chip memory'.
   Waiting         A list of all the many tasks waiting for something to
                   happen on the system.
   Task-ready      A list of tasks ready to be called to task by the
                   scheduler.
   Semaphores      Used by some software to prevent conflicting access to
                   facilities it controls. (Since AmigaGuide uses
                   semaphores, there may be an item on the list for this
                   application.)
   Interrupts      A list of node names on the list of interrupts in the
                   Exec Library structure.
```

<option> can, reportedly, be given as the (4-byte) absolute address of a
list header; the function performs several tests to make sure that it
really is a header.

Next, Prev. & Contents: SHOWLIST()

1.35 ARexxGuide | Functions reference | Informative (5 of 5) | TIME

```
TIME(<option>)
      returns a formatted string

Without arguments, the result is the current system time in Normal 24-hour
clock format -- hh:mm:ss

The  <option>  argument (C|E|H|M|N|R|S) determines the format
of the result and controls the  elapsed time counter .

   Examples:
        say time()              >>> 20:08:52
        say time(c)             >>> 8:08PM
        say time(h)             >>> 20
        say time(m)             >>> 1208
        say time(s)             >>> 72532
        call time(r);call delay 500;say time(e)  >>> 10.06

   Also see @{ " DATE           " link DATE()}
           @{ " DELAY          " link ARx_Func3.ag/DELAY()}

                                  NOTE: Persistence of TIME() value
```

1.36 ARexxGuide | Functions reference | Informative | TIME (1 of 1) | OPTIONS

```
      The following <option> keywords are available for the TIME():

         Keyword         Description
         --------        ------------------------------------------
         Civil           Current time in civil format: hh:mm[AM|PM]
         Elapsed         Elapsed time in seconds
         Hours           Current time in hours since midnight
         Minutes         Current time in minutes since midnight
         Normal          Default 24-hour format: hh:mm:ss
         Reset           Reset the elapsed-time clock
         Seconds         Current time in seconds since midnight

      Only the first letter of the option need be used.
```
