The Dining Philosophers Problem

A Monitor-Based Solution

(coded in the KPL language)

1

The Philosophers' Threads

```
function PhilosphizeAndEat (p: int)
  var i: int
  for i = 1 to 7
    -- Now he is thinking
    mon.PickupForks (p)
    -- Now he is eating
    mon.PutDownForks (p)
  endFor
endFunction
```

Startup Code

```
var
   mon: ForkMonitor
   philosopher: array [5] of Thread =
                   new array of Thread { 5 of new Thread }
...

-- Initialize the monitor...
mon = new ForkMonitor
mon.Init ()
mon.PrintAllStatus ()

-- Start up a thread for each philosopher...
philosopher[0].Init ("Plato")
philosopher[0].Fork (PhilosophizeAndEat, 0)
     ...etc...
philosopher[4].Init ("Aristotle")
philosopher[4].Fork (PhilosophizeAndEat, 4)
```

3

The Monitor

```
class ForkMonitor
  superclass Object
  fields
    monitorLock: Mutex
    status: array [5] of int
            -- HUNGRY, EATING, or THINKING
    startEating: array [5] of Condition
            -- Signaled when eating can begin
  methods
    Init ()
    PickupForks (p: int)        -- Entry Method
    PutDownForks (p: int)       -- Entry Method
    CheckAboutEating (p: int)   -- Local Method
    PrintAllStatus ()           -- Local Method
endClass
```

4

Init

```
method Init ()
   -- Initialize so that all philosophers are
   -- THINKING.  Also create the monitor lock
   -- and the 5 condition variables.
     var i: int
     status = new array of int { 5 of THINKING }
     startEating = new array of Condition
                                { 5 of new Condition }

     for i = 0 to 4
       startEating[i].Init ()
     endFor
     monitorLock = new Mutex
     monitorLock.Init ()
   endMethod
```

PickupForks

```
method PickupForks (p: int)
  -- This method is called when philosopher 'p'
  -- wants to eat.  Change his status to HUNGRY
  -- and then see if he can begin eating.  If he
  -- was not able to begin immediately, then
  -- this thread must wait.
    monitorLock.Lock ()
    status [p] = HUNGRY
    self.PrintAllStatus ()
    self.CheckAboutEating (p)
    if status [p] != EATING
      startEating [p].Wait (& monitorLock)
    endIf
    monitorLock.Unlock ()
  endMethod
```

6

PutDownForks

```
method PutDownForks (p: int)
   -- This method is called when the philosopher 'p'
   -- is done eating.  Change his status.  Also,
   -- this might make it possible for his left and
   -- right neighbors to begin eating, so check
   -- on them.
     monitorLock.Lock ()
     status [p] = THINKING
     self.PrintAllStatus ()
     self.CheckAboutEating ((p+1) % 5)
     self.CheckAboutEating ((p-1) % 5)
     monitorLock.Unlock ()
   endMethod
```

7

CheckAboutEating

```
method CheckAboutEating (p: int)
   -- See if the p-th philosopher should begin
   -- eating.  He should begin if he is HUNGRY and
   -- if his left and right neighbors are not
   -- eating.  If so, change his status to EATING.
   -- Also, it could be that philosopher p's
   -- thread is waiting.  Signal that thread's
   -- condition so it can resume, if it is waiting.
     if status [p] == HUNGRY &&
        status [(p+1) % 5] != EATING &&
        status [(p-1) % 5] != EATING
       status [p] = EATING
       self.PrintAllStatus ()
       startEating [p].Signal (& monitorLock)
     endIf
   endMethod
```

PrintAllStatus

```
method PrintAllStatus ()
  -- This is a "local" method.
    var p: int
    for p = 0 to 4
      switch status [p]
        case HUNGRY:
          print ("     ")
          break
        case EATING:
          print ("E    ")
          break
        case THINKING:
          print (".    ")
          break
      endSwitch
    endFor
    nl ()
  endMethod
```
