The Discounted Rate of Return (DRR) corrects a theoretical flaw in the IRR calculation. The IRR calculation effectively assumes that the cash inflows over the analysis period are reinvested at the discovered IRR rate. When the IRR rate goes above a realistically achievable rate, say, 15%, it may not be possible to achieve such high percentage earnings by reinvesting the cash inflows in other projects or ventures. The DRR uses the Input Rate as the Reinvestment Rate. The cash flows in column G are reinvested at the Input Rate, with the result printed in column H. The rate which makes the sum of column H equal the investment, is the Discounted Rate of Return.
