Up until now, I have been brewing with Red Star Ale Yeast (no rotten tomatoes, please!), with relatively good success. Now I want to move on to good yeast,

and maintaining pure cultures of that yeast. My questions are:

- 1) Is there a significantly better dry finishing (high or low attenuating, I can never remember the nomenclature) ale yeast than Chico Ale (Wyeast 1056). I have heard good things about it.
- 2) I plan to prepare about a year's worth of single use stock tube slants, so I don't have to worry about too much mutation. How stable is Chico Ale genetically. I have heard that some other strains are quite unstable.
- 3) (This one is unrelated to my own yeast concerns) If the yeast used for trappist ale is a mixture of several species and/or strains, how would one go about making a trappist from pure culture? Stated differently, what sort of pitching ratios of the different strains should be used.

Comments about my past use of Red Star should be made to me personally, but I think help with my other CURRENT problems should be posted to the digest.

Thanks for your help!

Wow! A 500 gallon starter. (Really - might this help cut down on  
their yeast costs?)

> How far do you folks think this process could be carried on: to a third  
> addition 48 hours later? A fourth after 72 hours? etc?

I would guess that you could continue until you ran out of space or  
patience. Of course, you would want to stop the cycle eventually so  
you could complete your brew! All that work is bound to make you  
thirsty.

> brew with? Seems like it should be pure unadulterated water....  
>

Watch out!!! Lots of nasties will be growing in this water!!!  
De-humidifiers work by passing large quantities of the room's air over a  
cooling coil, where condensation of excess moisture takes place. Any wee  
beasties suspended in the air can be trapped in the water droplets on the  
coil and will drip into the collector along with them. You say yourself  
that the cellar gets "musty"; you're smelling moulds and mildews, or at  
least their spores suspended in the air.

Sounds like an efficient way to infect your beer with everything there is  
to infect it with in your house!

Subject: Bending Tubing

Greetings All:

I feel like a stranger in these parts it's been so long since I've posted.  
School's over and brew season is slowing down so I hope to get back to posting with some degree of regularity.

Hugh Bynum mentioned tubing benders as a way to bend copper. They do the trick. But you can also bend copper fairly easily by bending it around something that's already round, like a tree limb! The key is to hold the tubing firmly to the surface as you bend. I use a nail that's bent over in a right angle so that the tail of the "L" is a little more than 3/8" above the surface of the limb.

```
|----- 7/16"
 / / |-----
 /   limb /
```

Oh, the wonders of ascii graphics!!

Cheers!

From: "Shannon 'Hydrocortisone' Posniewski" <imagesys!SHANNON@uu.psi.com>

Subject: Chocolate in beer

Chocolate and Brown Ale being important staples in my life, I decided to mix the two in a brew. It came out OK: it had a subtle chocolate smell, but no real chocolate taste.

We used 8oz of unsweetened baker's chocolate in a slightly modified 5 gallon batch of Papazian's Elbro Nerkte Brown Ale. We added it to the boil at finishing time (with the finishing hops) along with 1/3c of dark brown sugar.

My only comment is that the "real" chocolate has fats in it which (during fermentation) coagulate and make what look like enormous corn flakes on the top of the wort. I simply siphoned around them when racking.

Another note: it is habit for me to taste anything which come in contact with the brew (that way you know which ingredients create what tastes in the beer). Well, I tasted one of these flakes (which smelled like chocolate). DON'T BOTHER! They tasted awful! Like fat with a lot of hops. VERY bitter. VERY icky.

Subject: yeast and copper

Noel Damon asks:

> [...] the last batch was made in a new mash/lauter tun in which I used  
> a 1" circular copper slotted tube as the filter element. This was its  
first  
> use, and although I cleaned the copper well, when the mash was done,  
the  
> tube was a much brighter uniform color than when I started. Is it  
possible  
> that copper salts were generated which did a number on some of the  
yeasties,  
> or am I left to conclude a yeast problem?

Hi Noel, the acidic nature of a mash will remove the oxydized layer  
from the copper (kitchen hint: use ketchup to "clean" copper pans because  
its acid will brighten them). The amount of copper ions removed should  
be consumed by the yeast without a problem[\*]. Many folks use the  
slotted copper pipe system for lautering, so I suspect a yeast problem  
(assuming that all cleaning used beer-safe chemicals).

Bob Devine

[\*] While some copper is okay, too much can be damaging. Big commercial  
breweries do use copper boil kettles but don't use copper pipes or  
copper lager & holding tanks not only because of cost concerns but  
because  
the first runnings through copper do have a much higher concentration so  
that a more consistent "product" is obtained with stainless steel.

Subject: Brewferm Kreik

>Has anyone tried the Brewferm Kreik kit (from Belgium)? How close is it to  
>the wonderful Kreik Lambic I tried? It isn't cheap (Cdn\$20.59) esp. as  
it  
>makes only 12L (instead of the normal 19L). I plan on starting it this  
>weekend to generate those "gallons" my wife wants for the hot weather.

I made up a batch this spring. I used 2 of the kits, 1 lbs dry light malt extract, 1 oz hallertau, brought the wort volume up to 5 gallons for the boil, cooled with a wort chiller, aerated and pitched whitbread ale yeast.

The yeast packet that came with the kit says "product of england", so I figured that it was regular brewing yeast, and not really appropriate to make a lambic (tell me if I'm wrong), but of course, whitbread ale isn't either. So what I got is a cherry beer, but not lambic. Nevermind - It was delicious (and it's all gone). Give it at least 2 months in the bottle to age and clarify.

A cheaper route, but not as foolproof, is just to add 5 lb or so of cherries and a little acid blend to a normal pale ale. For a more authentic flavor, I've been able to culture the dregs from a bottle of Timmerman's peche (no luck with Lindemann's) but haven't yet had the guts to risk an entire batch with uncertain yeast.

I got my kits from the Grape & Grain in Springfeild, IL. (1-800-524-6469) for \$17.95 each (ouch!). Their prices are usually a little more expensive than other stores (but not too far out of line, like the local hobby shop), but the owner is friendly, and fellow homebrewer, and gives good advice.

bb

P.S. has anyone tried out any of the recipes in the back of Guinard's Lamic book?

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: A use for spent grains

I've discovered a rather innovative use for my spent grains. (Then again, everytime I think I've discovered something new, I find out that someone else in HBD- land has already tried it.) To start your day off right, try sprinkling a spoonful of dried grains over a bowl of cereal. This adds texture, flavor, nutrition, and general peace of mind. Since I'm an extract/specialty grain brewer, I don't generate more than about 1 lb per 5 gallon batch. Over a long period of time, the amount of grains I produce is pretty close to the amount I eat. Except for that batch of Rainy Day Porter, which generated too many grains for me to bother with.

Trust me, your colon will thank you.  
Chuck

P.S. I don't recommend this to anyone wearing dentures; this stuff is pretty hard!

Subject: Kzoo Brew

Howdy!

Does anyone out there live in the Kalamazoo, Michigan area, or have visited there recently?

I used to live there (grew up there) and am wondering if anyone has recently stopped by the Kalamazoo Brewery in downtown KZOO. I used to frequent the establishment quite often to partake in the fabulous brews. They had a great amber ale, porter, and lager (I think) which were usually readily available. I even managed to get my hands on a case of Cherry Stout one christmas (it was a limited edition type deal) which was very good. At the time I wasn't homebrewing myself, but now that I'm over my head in homebrew I'd like to try to reproduce that porter. I can't get any in Albany, NY.

If anyone lives there, visited there, or knows the brew of which I'm speaking please let me know. I don't know if they hand out recipes, but I'd like to get an idea of some possible ingredients so I can come close to it. If you know of it, or live there and can ask around, I'd appreciate any response.

Thanks -

Subject: Re: Kriek

Bill asks about the Brewferm Kriek kit and making Kriek from scratch.

I've tried the Brewferm Kriek kit and offered it up for review at BOSS (Brewers of South Suburbia (Chicago's)), CBS (Chicago Beer Society) and Headhunters (Sugar Grove -- near Aurora, IL) club meetings and the concensus is that it is not a Kriek by any stretch of the imagination. I used two cans of the Brewferm Kriek in a 5 gallon batch and used Wyeast #1028 in stead of the kit yeast. Barely any cherry flavor.

Not a bad beer, but not nearly enough cherry flavor. It had a sourness, but that was probably from the citric acid which is listed on the label.

On to bigger an better things: homebrewed pseudo-Lambics (I offer that we should respect the natural process of making Lambics and therefore respect the appellations "Lambic," "Kriek," "Framboise," etc.). I have a 15 gallon batch of pseudo-Lambic fermenting in my basement. You can get two of the most dominant beasties from G.W.Kent in Ann Arbor Michigan.

You'll have to go through your retailer. My retailer charged me \$8 each for Brettanomyces Lambicus and Pediococcus Cerevisiae. The third of the three dominant beasties is Saccharomyces Cerevisiae (I used Wyeast #1056 - -- Chico Ale) which is your basic Ale yeast. Pick up J-X Guinard's book,

"Lambic." It has a lot of good info and the history (much of which is still alive in Belgium) makes for interesting reading too. The amounts of cherries needed to make pseudo-Kriek are staggering. Granted, the Sharbeek cherries used by the most-traditional Belgian brewers have a very high pit-to-pulp ratio, but if my memory serves me correctly, ene brewer uses 300 lbs of cherries with 30 gallons of Lambic to make their Kriek. I plan to use 13.5 lbs of pitted cherries (I would have used unpitted, but at the time when I bought them, the only unsweetened ones I could find were pitted and frozen) with 3.5 gallons of my pseudo-Lambic.

You know where you can find me immediately after the Conference: in Michigan picking cherries -- I'll have to buy another freezer just for cherries (that will make six fridges at my house!).

Al.

Subject: The 3 Faces of Whitbread

Jack Schmidling asks:

> Someone just posted an article about Whitbred yeast being a combination  
of  
> several strains. Is this a fact or another momily? Does it apply to  
the dry  
> version?  
> I just pure cultured some from a pack of dry and will be pitiching in  
my next  
> batch. If it is true, I just wasted a lot of effort.

Yes, there are 3 strains (see the Zymurgy special Yeast issue mentioned  
by Noel Damon or a posting to HBD by George Fix). If you've cultivated  
it, you likely only have one of the 3 strains (or even a wild yeast!).  
I suggest it is not worth the bother to cultivate Whitbread because you  
need to grow all 3 strains and then combine them in the right proportion  
(which may not be 1:1:1...).

As an experiment, go ahead with a small batch based on your yeast  
culture.  
If it takes off quickly, you have strain #1. If it has a long lag time,  
it's #2 or #3.

> You do not leave grains of any sort in the boil.

My coffee : beer intake ratio is about 7 : 1, so I think I have the  
experience to strongly recommend that NOBODY EVER BOIL BREWED COFFEE.  
The flavor of coffee is very delicate, and essentially any temperature  
changes other than the conventional brew-N-cool (or ice) will  
probably damage it. You don't even want to keep it hot for very long.  
If you're going to the expense of using gourmet coffee, you should  
probably just brew in like normal, near the end of the boil, and just  
pour it in to the wort as it's cooling.

(I don't have any experience with the cold, acid-free (viz. acid-LESS)  
method of coffee brewing yet. That might work even better, as it's  
supposed to be much smoother, if you're adding coffee flavor to a beer  
as harmonious as the Platonic Pumpernickel Porter.)

Good luck and have fun,  
Jake.

> it is desirable to use a higher enzyme lager malt, and a lower  
> temp (122F) protein rest, according to TCHOHB (Miller).  
>
- >3) Replace the molasses with brown sugar. Molasses leaves a notorious  
> aftertaste, but this will fade with time (a long time - 6  
> months to a year or more - depending upon the type of molasses)

In #1 I don't agree with the need for a Lager Malt - unless you are using an English Pale Ale malt. Any domestic 2-row Malt should be active enough to convert reasonable amounts of unmalted adjunct. I have used GWM Pale Malt (Klages/Harrington mix) with as much as 20% unmalted adjunct (i.e. 7lb of malt + 2lb of unmalted barley/oats) and had no problem with conversion.

With regard to #2, I thought the conventional advice was to use a small amount of molasses rather than Brown sugar. The sugar seems to contribute an undesirable taste to beer (cidery/thin) - and besides, the brown, in brown sugar is just molasses added to regular sugar.

From: whg@tellabf.tellabs.com  
Subject: Re: Whitbred Ale

The subject of Whitbred ales three strains has been discussed here  
several ti  
times. If I'm not mistaken, gfix has described the rather impressive in  
interactions of these three strains, throughout the fermentation cycle.  
My  
apologies the Mr. Fix for my foggy memory, but I think that one strain is  
a  
fairly quick starter, one dominates through the middle of the  
fermentation cycle  
and the final strain finishes off the brew as the alcohol level forces  
the f  
the first two strains into dormancy.

As I understand, and I'm sure I'll be corrected if I'm wrong :-),  
Vermont has the largest number of micros/brewpubs per capita:

Population: circa 550,000  
Micros/Brewpubs:  
  Catamount  
  Vermont Pub & Brewery  
  Mountain Brewers (Long trail ale)  
  Otter Creek

2 others in brattleboro I believe, but only counting the 4 above,  
we get about 1 micro/brewpub per 150,000 residents.

Subject: Re: Calories in homebrew

I had just recently finally gotten around to trying to decipher the post about determining calories in homebrew which was presented a few digests ago. It seems much to complicated and in some areas does not make any sense to me. If I was given a true/false test in chemistry and the question was "Is this the formula for determining calories in homebrew" I would have guessed false.

Anyway, that formula really is no good to me since there is too much work involved to come up with a number just out of curiosity. Anyone have a formula which approximates the number of calories just based on the OG and FG. I envision something along the lines:

$$\text{calories per oz} = X * (\text{OG} - \text{FG}) + Y * \text{FG}$$

where X is the calories per specific gravity unit and Y is the calories contributed by residuals per specific gravity unit.

The program I use to record my recipes calculates the % alc. (by weight or volume obviously) from the OG and FG figures already. I would just need an approximation for the value of Y and a number for the value of X (number of calories per oz. based on the % alc. as determined from the SG scale).

It should be easy to come up with approximations shouldn't it? After all, if it's off by as much as 10% that's no big deal (to me at least).

Subject: Hops in SN Pale Ale

Steven Boege asks:

> Greetings,  
> Would someone please tell me which hop varieties are used in Sierra  
> Nevada India Pale Ale and in Dinkel Acker Dark.  
> Thanks,  
> Steven J. Boege

According to the information I got when I toured the brewery, SN Pale Ale uses two forms of Cascade Hops. The boil uses an experimental, high-alpha Cascade and regular Cascade Hops are used for aroma.

A note about the post boil hopping: they use whole leaf hops as a filter stage in addition to flavor. They load a large fitting, that sits in the pipe between the boiling vessel and the heat-exchanger cooling apparatus, with the hops and force pump the wort through it. I guess this works because SN Pale Ale sure had a strong hop aroma.

The thing looks something like this (please excuse the ASCII graphics):

```
-----  
/ /  
-----/ /-----  
from boiler ----> wort flow HOPS ---->To heat-exchanger  
-----/ /-----  
/ /  
-----
```

Al Taylor asks about yeast:

> 1) Is there a significantly better dry finishing (high or low  
> attenuating, I can never remember the nomenclature) ale yeast  
> than Chico Ale (Wyeast 1056). I have heard good things about it.

I've found that Wyeast Irish Ale (#1084) is one of their most attentive, but it does take a while to finish (i.e. the last few points take a few weeks).

Attenuation is a measure of how much of the sugars a particular yeast will eat. Highly attenuative yeasts will eat even very big sugar molecules, whereas less attenuative yeast will eat only the simplest sugars (like glucose and maltose). There is a two or three page sheet that you should be able to get from your supplier -- heck, it's no secret, maybe if I remember to bring it in, I'll post it.

> 3) (This one is unrelated to my own yeast concerns) If the yeast  
> used for trappist ale is a mixture of several species and/or  
> strains, how would one go about making a trappist from pure  
> culture? Stated differently, what sort of pitching ratios of  
> the different strains should be used.

Trappist Ales are generally made with single-strain cultures. It's Lambics that are made from a variety of strains of yeast as well as bacteria. Generally speaking, most pseudo-Lambic homebrewers use only the three primary organisms, *Saccharomyces Cerevisiae* (I use Wyeast #1056), *Brettanomyces Lambicus* and *Pediococcus Cerevisiae*. If you want to be even more close to the "real thing," then you can buy some *Brettanomyces Bruxellensis* (sp?), but it will cost you a good \$50 or so. The other two can be purchased from G.W.Kent through your retailer.

You may be speaking about the fact that Orval bottles with 5 strains. This is true, but they ferment with only one. I cultured the dregs of several Orval bottles and got starters that tasted very different from each other. I chose the one that tasted most like Orval and brewed a batch with that.

Subject: simple yeast-starter recipe, cherry mead

Greetings

Two quick question for the readership:

1) Can someone post a simple recipe for a yeast starter? I know that I can just use a liter or so of wort, but what if I don't want to brew an entire batch? I know the ingredients; it's the quantities about which I'm concerned. How much extract (prefer volume), how much hops, for, say a quart of water? Can corn sugar (dextrose) be used? (It's easy to measure small quantities, compared to malt extract, which is gooey, and is generally a mess.) I've tried bottling wort, but nasties always manage to get in the bottle, and in a few months I've got a glass grenade on my hands.

2) As a result of the unusually warm spring we've had here in Utah, the cherries are almost ripe already. I'm looking forward to making my third annual cherry beer, and have no shortage of ideas for that one, let me tell you. But, I brewed my first mead this past December, and was thinking that a cherry mead might be nice. Suggestions?

Thanks to everyone for all the great info that comes out in the HBD, and especially thanks to Rob for maintaining the digest. I'd like to mention that I'm grateful that this digest is still being distributed by email, since I have no access to all these r.c.b.-type forums (fora?).

Cheers,  
Chuck

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: Re: Bending Tubing

One thing I didn't see mentioned about bending copper tubing is that you can't just bend any old piece of tubing. You need to get tubing that is sold for bending. Then you can use a tree limb, your hands or a tubing bender to make your racking tube.

Another nifty little gadget you can make with 6" of surplus tubing: Drill several 1/16" holes around the tubing about one inch from one end. Stick that end into the outlet of your chiller/racking hose. When racking the holes will suck in air and aerate your wort. No need to shake the carboy after using one of these gizmos.

From: DAMON\_NOEL/HP0800\_01@mailhub.cs.itc.hp.com@cs.itc.hp.com  
Subject: nastyeast

Thanks for all the feedback on copper coils and yeast care. The answer to the problem I posted a couple issues back is now clear. The batch brewed in the new mash tun with copper coil finally went into the static phase at an FG of 1.006, down from OG of 1.054. VERY strong phenol smell/taste. It seems a fair conclusion that my free liquid yeast culture was contaminated since standard sanitation procedures were followed. 5 gal>>>drain. I think the lesson learned is to plate out any yeast of possibly suspect origin. I am reasonably sure that wild yeast strains somehow entered the original culture. In the plating process do wild yeasts look significantly different from the good guys? I'm sure that bacterial infections would show up but how about the odd yeasts?

a  
>starter culture of this will the S. Delbrucki also grow in regular DME  
starter  
>or do I have to have some wheat malt included in the starter for the  
Wheat  
>yeast to grow?  
>  
>Thanks for the Help, Bill

Here is a quick and a long answer from my experience of several months

1) it will grow fine on pure malt extract

2) despite being "50%" of each strain, I was not convinced that my  
original  
pack of 3056 was a 50:50 mix of anything. I took the original package  
(that was 2 weeks past the date on the cover, always refrigerated) and  
opened it sterily and streaked it for single colonies on a malt-agar  
plate.

I got numerous single-colonies, and I expected to be able to tell the two  
species apart by their appearance on the plate, at least after several  
days, since someone here had advised me so. However, nearly all of the  
colonies looked the same, large, wrinkled (after a week) and very pale  
brown. With some scrutiny I picked out a few that were smaller, and when  
re-streaked onto fresh plates this phenotype was retained.

So I got 2 colony types; large and wrinkled, and tiny.

I then grew up a dozen colonies in 200 ml cultures of wort (unhopped,  
sterile) and fermented them out. Upon tasting, all 9 of the large  
colonies  
seemed identical, estery, slightly sweet, with the characteristic  
Weissbier  
cloveyness. The three "tiny" colonies were distinctly different, very  
dry product with little ester taste.

I conclude that there were indeed two organisms, quite distinct, in my  
3056, but at least by the time I got it opened one was vastly predominant  
to the other.

What I've been doing for my weissbiers now is to make two starters, one  
with the "Large" (estery) colony and inoculate that upon cooling the  
wort.

I then inoculate the fermenting wort with the "tiny" (dry, non estery)  
starter at day 3. I want to give the wort a few days to develop the clovy  
tang before hitting it with the other culture.

Has anyone out there similar or different experience with 3056? Does  
anyone

know if wyeast really tries to make it a 50:50 mix?

thanks,  
dennis

G.W. Kent has a small retail outlet at the warehouse in Ann Arbor. They just won't sell retail by mail. Prices are generally a little lower than the same product in a retail store, but higher than wholesale. (e.g., Coopers Light extract 1.7kg was about \$9 at Kent, and \$12 at a local HB store). It's open 9-6 M-F and 12-4 Sat. Take Morgan Rd. west from Platt just south of the landfill (about a mile south of I-94). They're located at the end of the road, right by US 23.

One question, Al. How do you keep the Brettanomyces and Pediococcus from infecting your other brews?

> Rich

Oregon ---

Population: circa 3,250,000  
Micros/Brewpubs:  
Widmer Brewing/BrewPub (2) - Portland  
FullSail Brewing/BrewPub (2) - Hood River, Portland  
Bridgeport Brewery/BrewPub - Portland  
Oregon Trail Brewery/BrewPub - Corvallis  
SteelHead Brewery/BrewPub - Eugene  
Deschutes Brewery/BrewPub - Bend  
Umpqua Brewery/BrewPub - Roseburg  
Rogue Brewery/BrewPub (2) - Ashland, Newport  
Portland Ale/BrewPub - Portland  
McMenamins - (10) - Hillsdale, Salem, Eugene, Roadhouse, Oak Hills,  
Edgefield,  
Lincoln City, Fulton, Highland, Murray Road.

There maybe 2 others I believe, but only counting the 22 above,  
we get about 1 micro/brewpub per 147,000 residents...

If you just look at Portland metro area alone:  
15 Micros/BrewPubs/1.5 million people, you get 1 micro/brewpub per 100,  
000  
residents. People have said there are more McMenamins Pubs/Brewpubs in  
the Portland area than McDonalds... (better food at least - A pint of  
ale beats a BigMac anyday!!!).

Not a bad idea. Here is another way.

I have been getting excellent aeration by racking the chilled wort from my boiler into a small funnel resting atop my carboy. By directing the stream against the side of the funnel, you get a significant amount of vorticity in the fluid mass in the funnel. This creates a falling tubular wort stream below the funnel, which tends to break up into small droplets.

From: kerl@cmack.b11.ingr.com (Dan Kerl)  
Subject: dehumidifier water for brewing...

As I understand it, condensation water from refrigeration equipment (particularly air conditioning equipment) has been identified as the habitat of the pathogen responsible for causing "Legionaire's Disease". I suspect that a prolonged boil would wipe this out. Another thing that I've noticed about condensation water is the funky "plastic-like" odor it carries, probably resulting from all the airborne junk that gets sucked-in to the appliance along with the moisture-laden air. A decent activated-charcoal water filter might extract this. All in all, condensate could be a good source of soft water, if it can be cleaned-up. After all, you could always say "It's in the water.." ;-)

**Subject: small break**

There was very little break material in the batch I brewed last night, and I was wondering why. It had 9 lbs. 2-row, .75 lb cara-pils, and .5 lb. munich. Infusion mash at 155, 90 minute boil, chilled with copper wort chiller. This produced less than 1/3 of the usual trub. The difference may have been the hops; they were in grain bags, rather than loose. Would the reduced surface area make that much of a difference in the break production?

Subject: Re: Brett & Pedio

Spencer asks:

>One question, Al. How do you keep the Brettanomyces and Pediococcus  
>from infecting your other brews?

Up till now, I have simply used the same sanitation techniques that I've  
always used. I plan to use the 15 gallon HDPE fermenter I'm using for  
the pseudo-Lambic, *\*only\** for pseudo-Lambic. Martin Lodahl has  
successfully  
brewed pseudo-Lambics followed by non-Lambics and has reported no  
infections.  
Since this 15 gallon primary is HDPE, I'm hesitant to use it for non-  
Lambics.  
I will soon be using 5 gallon glass secondaries, but will not fear using  
them later for non-Lambics since I have more confidence in my sanitation  
of  
glass fermenters. By the way, I use two tablespoons of household  
chlorine  
bleach per gallon of water for sanitizing.

Date: Mon, 1 Jun 92 12:13 CDT  
From: korz@iepubj.att.com  
Subject: Read retention

Frank asks about head retention.

The primary source of good head retention is protein. Dextrins also contribute, but to a lesser extent. Try adding a little wheat malt or flaked barley or steel-cut oats to your mash to increase your protein content and enjoy the pleasure of getting longer-lasting head. For extract brews, you can steep 4 ounces of flaked barley in your boil water at 170F water for 15 minutes before removing the grain and bringing the water to a boil. This will give you a very cloudy beer, so I only do this for my extract stouts and porters in which the color hides the haze.

Another problem may be too much finings. Are you using Irish Moss or another fining agent? My head retention severely decreased when I began using 1/2 tsp of Irish Moss in the boil. I stopped using it, chilled quickly with a wort chiller to coagulate the big proteins but still probably increased the protein content of my beers as compared to those with Irish Moss used. My head retention improved as compared to the beers made with Irish Moss.

Chill haze can be reduced by either fining-out the proteins or by fining-out the tannins. I don't recall which finings work on which molecules, but I'm sure that Irish Moss fines-out proteins and Polyclar fines-out tannins. By fining-out the tannins and leaving the proteins, you could eliminate chill haze while preserving head retention. Could someone post which finings work on which molecules? -- I know it's an electrical attraction of some sort, but I cannot find my notes on it.

Date: Mon, 1 Jun 92 16:04:02 -0400  
From: bradley@adx.adelphi.edu (Dr. Robert Bradley)  
Subject: formula for calories

Dan Roman asked about a simplified version of George Fix's formula(e) for the caloric content of a 12 oz. bottle of beer in a form which is linear with respect to starting and ending gravity.

Of course, George's formula can be solved in terms of OG and FG only, or in terms of OE and AE only. The answer isn't linear, and no amount of wishing will make it so, especially as there is a term involving OE which is the denominator of a rational function.

On the other hand "every differentiable function is locally linear". This was Newton's great insight (although Archimedes, Gallileo and Pascal, among others, probably had a gut feeling to this effect). If it were not for this important principle, there would be no such thing as an economist. Or at least one who is earning a salary :-)

So....assuming that your original gravity is in the range 1.036 - 1.060, the following is a good approximation to Goerge's Law:

$$\text{calories}/12 \text{ oz.} = \text{FG}[12.876*\text{OE} + 1.324*\text{AE} - 1.42]$$

This still doesn't satisfy Dan's wish for a linear function. However, within reasonable limits (FG in the range 1.005 - 1.015), we can drop the multiplier and constant term to get

$$\begin{aligned} \text{calories}/12 \text{ oz.} &= 12.876*\text{OE} + 1.324*\text{AE} \\ &= 3219*\text{OG} + 331*\text{FG} - 3550 \quad (*) \end{aligned}$$

where OE = hydrometer reading before fermentation, degrees Plato  
AE = hydrometer reading after fermentation, degrees Plato  
OG = hydrometer reading before fermentation, specific gravity  
FG = hydrometer reading after fermentation, specific gravity

With the given example OG=1.045, OE=11.25  
FG=1.010, AE= 2.5,

We hav calories = 148.165 in either case. Of course, we have no reason in the world to trust those final digits. 148 calories is probably even more accuracy than we're entitled to (this is not to casr aspersion on the accuracy of George's coefficients, rather a reflection of the fact that we're approximating a rational function by a polynomial).

For barley wines or ultra-light brews, different fudge factors would be needed, although the numbers won't change too much.

It's interesting to note that original gravity tells almost the whole story when it comes to calories.

Starting Gravity 1.050 Final Gravity Calories in 12 oz.  
1.030 (heavy!) 171  
1.020 168  
1.010 164  
1.005 163  
1.000 (yuck!) 161

Moral, when a yeast eats a sugar, it doesn't use much of the stored energy.

Now a question:

-----  
a number of sources (incl. TCJOHB and George Fix's posting) give  
or use the formula

$$\text{degrees Plato} = (\text{fractional part of gravity} * 1000) / 4$$

(I used it too, to derive formula (\*) from the one above it.)  
Nevertheless, every hydrometer I've ever seen contradicts this.  
1.047 appears to be 12 degrees Plato or even 12 1/4 instead  
of the predicted 11.75.

SO.....are the hydrometers off, or is the formula above just a  
rough and ready approximation? Just curious.

Rob  
(bradley@adx.adelphi.edu)

P.S. I'm embarassed by the fact that the sysop changed the identifier  
that follows my e-mail address to "Dr. Rob..." while I was in Colorado.  
Now he's on vacation and I want to change the thing so as to look a  
little less like the pompous techno-dweeb that I am. Is there any  
Unix guru out there that can tell me how to change that thang?

Subject: Wyeat datum

Well, I finally got around to trying Wyeast. (You gasp! He's never used Wyeast until now???????) In my defence: I used MeV liquid yeast on a number of occasions when I lived in Canada. As well, for all that Wyeast is the standard for homebrewing today, when I joined this list a scant 25 months ago it was still quite new. Lil' Ole Winemaking Shoppe, for instance, only started carrying it sometime last season (Sept-May). For a shiftless academic sch as myself, it's sometimes hard to keep up with the latest trends.

My analysis Character: 10, Purity:2

I used Belgian Ale yeast (number has been forgotten). With the exception of finishing and dry hopping with a different variety (Fuggles instead of Hallertau or Cascade), the recipe was essentially the same as my usual pale ale. Yet the sample I had at racking (day 5) tasted, well, a bit like Chimay ordinaire or Duvel. It had that slightly thin, slightly hot estery taste that I associate with Belgian beers. And the only thing that was different from IPA was the yeast!

The yeast is more attenuative than the Edme, Munton & Fison and Whitbread. It went from 1.052 to 1.013 in 5 days. With the same mash technique, a similar OG and one of the above dry yeasts, I would normally ferment out at 1.018-1.020 (consequently, my Belgian beer was a little over-hopped, but that kind of suits the style).

The bad news: either I got a bad batch, or this stuff keeps fermenting for a long, long time, even at 70 degrees. By day 25, the yeast was still working away, the gravity was down to 1.010 and the aroma of bananas was unmistakable.

Only one data point, I'll admit, but brewed using a certain degree of control in that the ingredients, techniques, times and temperatures are the same ones that used on many an occasion in my 205 batch career.

I'll just wait and see what happens. Not worrying,

Rob

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Wyeat datum  
Subject: Calories in Beer (George Fix)

I hope it was clear from my original post on calories that the formula quoted was not due to me. It is something that has been floating around for a few years. I found out about it at a local MBAA meeting from some folks at AB-Houston. An older and somewhat less accurate version can be found in Vol. 2 of Malting and Brewing Science by Hough, et al.

One of the legacies passed on to homebrewing from home winemaking has been the use of specific gravity as a unit for expressing extract. For wines this makes a good deal of sense as all of the technical research on wine has used these units. Unfortunately, all the work on beer uses different units, namely % extract on a weight to weight basis, or degrees Plato if you like. The only time specific gravity is used is to convert numbers involving weight to ones involving volume. For example, in the formula for calories the specific gravity of beer multiplies the entire term. Without it the formula will give the number of calories per 1/3 kg. of beer. With it we get the number of calories per 1/3 liter, or approximately calories per 12 oz.

What is truly unfortunate is that there no simple way of going back and forth from specific gravity to degrees Plato without directly looking them up in the extract tables. Sometimes the factor of 4 is cited, and it does work for some values. Thus a wort which is 12 deg. Plato has a specific gravity of 1.048, and  $48 = 12 * 4$ . A quick glance at the extract tables shows the number 4 does not give very good results for other values. What this means is that the classic beer formulas like Balling's and others can not be accurately expressed in terms of gravities. In fact, most of the formulas I have seen which use gravities have come from winemaking. They work well there, but they are highly suspect when applied to beer.

>the wonderful Kriek Lambic I tried? It isn't cheap (Cdn\$20.59) esp. as it  
>makes only 12L (instead of the normal 19L). I plan on starting it this  
>weekend to generate those "gallons" my wife wants for the hot weather.  
>  
>It calls for some sugar (500g I think), but I was thinking of substituting  
>alfalfa honey. I think it will give me the light body called for (which  
>DME wouldn't) without the off flavours of corn sugar. Comments?

It ain't cheap, and you won't get a typical 'commercial' Kriek. I used two  
cans (3 kg) of the Brewferm Kriek, \*no\* sugar, a touch of Tettnanger hops at  
the very end of the boil for aroma (the extract is already is hopped), and  
DME at bottling (again, no sugar -- I'm still bottling and priming the hard  
way, so I use dried malt extract instead. Cornelius kegs and CO2 are still  
down the road for me :-). This was for a standard 5-gallon batch.

>Which reminds me, what about the yeast in the Kriek kit?

It's the usual dried yeast - the packet that came with mine even says "made in England" on it. I used Wyeast Belgian Ale yeast, and the results  
were quite good - probably the best beer from extract I've made yet (take that with a grain of salt - I've only made half-a-dozen batches so far!)

I did a single-stage primary fermentation, and bottled at 1008 FG. I tasted  
the bit that was left over after bottling, and was pleasantly surprised at  
the dryness and finish of the still-immature beer. I tried one after three  
weeks in the bottle - again, pleasantly surprised. It isn't a Kriek-Lambic  
by any stretch of the imagination, nor a Kriek-brown-ale (like, say, Liefmans). It's more like a cherry-flavoured pale ale - imagine something  
like De Koninck, the pale ale of Antwerp, with a noticeable cherry component  
to it. Also surprising was that it clarified very easily - in fact, I didn't add any clarifying agents to the boil. In another three weeks, I will have two cases (minus one bottle!) of wonderful cherry ale for summer  
imbibing. The Brewferm extracts are pricey, but then, Belgian ales in the  
USA are pretty expensive anyway. Still worth it, IMHO.

> The difficulty is obtaining the proper yeast(s) (can it/they be  
obtained  
>commercially at all?). If I know which Wyeast to order my brew store  
will  
>special order it for me. They normally only carry 5 strains.

Arrgh - I can't remember the catalog number of Wyeast's Belgian Ale  
yeast.  
I think it was #1056. I hope I'm not confusing that with Wyeast's  
Bavarian  
Weiss, #3056 I think.

More on yeastie beasties:

the dry  
>version?

>  
>I just pure cultured some from a pack of dry and will be pitiching in my  
next  
>batch. If it is true, I just wasted a lot of effort.

Yes, the Whitbread ale yeast is a combination of several strains, not a  
pure  
single culture. I'll gladly pay extra for Wyeast's liquid cultures for  
this  
very reason; you don't get that funky 'homebrew' nose that you get with  
the  
dry yeast. See above re: Belgian ale yeast - which played no small part  
in  
the quality of the finished product.

From: John Fitzgerald <johnf@ccgate.SanDiegoCA.NCR.COM>  
Subject: mineral content of my water

I've got a quick question for all of you Chem-types that might be reading, or anybody else that knows, of course! I've received a water analysis from my local district office, but all of the concentrations are in g/l. Can anybody tell me how to convert this to ppm? ppm seems to be the standard way that Zymurgy, and TNCJoHB describe water contents, but I couldn't find any conversion formulas.

On a side note, (I realize it is getting kinda late in the year for this, but I've been dying to try one of these), I'd like to try making a holiday spiced ale. If I hurry, will 6 months be enough time? I just got a copy of the Cat's Meow II, and I could use some recommendations for a good recipe.

Any and all input is appreciated.

John Fitzgerald

Subject: beer warmer

Some people use the "wet t-shirt and pan of water" method to keep their carboy cool in the summer heat. I have just the opposite problem; my brewroom stays at 60 degF in the summer (in the winter it's heated).  
Wyeast  
1056 (Chico Ale) just doesn't seem to like it that cold; it was \*very\* slow to start, and not making any krausen at all. Not wanting to move 6.5 gallons of beer to a warmer spot, I instead filled 6 gallon-jars with hot tap water, and surrounded the carboy with them. This morning the little carboy closet is 68 degF, and there's a nice krausen. I suppose it might also work the opposite way with ice-water in the jars.

>couldn't find any conversion formulas.

To convert from g/l to ppm multiply by 1000. For example: 0.100 g/l of  
CaCO<sub>3</sub>  
would be equivalent to 100 ppm carbonate hardness. Are you sure the  
numbers  
are in g/l and not mg/l? My water analysis list the mineral content in  
the  
latter ( mg/l ). In this case the conversion is really simple ( you  
multiply  
by 1 :-).

>for a long, long time, even at 70 degrees. By day 25, the yeast was  
>still working away, the gravity was down to 1.010 and the aroma of  
>bananas was unmistakable.

Aside:

First of all, I'd like to point out that I'm not at all affiliated  
with Wyeast, other than being a satisfied customer.

It appears that too many Wyeast users blame the yeast for infections  
rather than their sanitation techniques. I've been using Wyeast for  
three years and have yet to have an infected batch since starting to  
use Wyeast (except for one made with Munton & Fison Dry Yeast). The  
four years of dry yeast brewing prior to that, had many infected  
batches, but then again, I was less-skilled back then also.

I don't recall how long it took a recent Chimay-clone to ferment out  
using Wyeast Belgian Ale yeast, but I think it may have been a bit longer  
than most. The problem with the banana aroma is because you are  
fermenting at too high a temperature. I forget who it was that posted  
this phenomenon a few months ago (Martin maybe?) but I, foolishly,  
confirmed  
it. My ferment was at a consistent 65F and \*that\* was too warm. The  
beer  
turned out quite authentic except for the banana aroma. "Darn!" I said  
to myself, and plan to soon try it again at 57F. The moral of the story  
is:

Ferment Wyeast Belgian Ale yeast well below 65F,  
unless you really like bananas.

I'd bet you get as much inaccuracy from a typical \$5-10 hydrometer as  
from  
the mathematical approximation; I would assume any report of specific  
gravity to have a possible error of +/- .002 (effectively, ~5% for  
typical  
changes in gravity), given the coarseness of the markings and the  
difficulty of finding the meniscus precisely. But 5% is still likely to  
be  
about as precise as a dieter can measure (absent a scale that is  
inconveniently large to carry to meals).

mecca!? Hey, that's in Franconia (Germany), with the cities of Bamberg and Forchheim as the main axis! Or maybe the Rheinland, with Duesseldorf and Koeln as the axis ... ;-)

Well, I live in Seattle - Maritime Pacific is a bit over a mile and a half from my house, and Red Hook is two and a half miles down the road. Really, Jackson's Pocket Guide to Beer is a reasonably reliable guide, but for maximum pubbing in a small area, check out the Fremont district, home of the Red Door, the Dubliner, the Triangle Pub, and Red Hook's Trolleyman Pub.

The Red Door has the best selection, but is also filled to the rafters with what we used to call yuppies. The food is quite good, and the place is impossible to get into or be heard in (I've nicknamed it the Loud Door) on Thursday, Friday, and Saturday nights. All local breweries are well-represented, and there are also a couple of imports on draught; Fullers ESB is usually among them. The Dubliner - formerly Poor Richard's - is right next to the Red Door, not quite as upscale, but it serves as a sort of spillover pub for those seeking a less-crowded room. Live music has been a part of this venue in the past. Red Hook and Full Sail are available, among others. The Triangle - so named for the shape of the room - is a recent remodel of a dive, and the improvement is substantial. Eight beers on tap, including Full Sail, Red Hook ESB, Maritime Pacific Dark, Pyramid Wheaten, Widmer Hefeweizen, and Guinness Stout. And then there's the Trolleyman, the pub located in the Red Hook Brewery complex, in a building that used to house streetcars (when Seattle had 'em). Strictly Red Hook products on tap, no-smoking room, and quite popular at weekends. In short, Fremont, starting at North 34th Street and Fremont Avenue North, can be the site of a worthwhile pub crawl, with four pubs in walking distance of each other.

There are other pubs scattered around town, including my favourite brewpub, the Big Time, located on University Way N.E. Wonderful, full-flavoured ales are brewed here. Farther afield, there's the Maple Leaf Grill - pub

atmosphere, restaurant-quality food, and Thomas Kemper's Hefeweizen among the dozen taps, the best hefeweizen made in the N.W. (IMHO). Find this one up on Roosevelt Ave. N.E. at 89th. Also good is the 74th Street Ale House, at Greenwood Ave. N. and N. 74th. Or the Latona, at Latona Ave. N. and N. 65th Street, although I don't usually care for the music in the evenings. And then there are two old standbys - Murphy's on 45th, in new, larger premises, and Cooper's, on Lake City Way. All of these pubs will satisfy your desire for N.W. ales and ambiance.

This is a sampling of what's available - I've mentioned mostly neighbourhood pubs, rather than more upscale places downtown.

E-mail me if you need more info, or if you need help finding one of the pubs - or if you need help in emptying a pitcher :-).

Date: Tue, 02 Jun 92 10:23:55 -0700  
From: Nick Cuccia <cuccia@remarque.berkeley.edu>  
Subject: g/l (re: mineral content of my water)

One of the things that I love about the metric system is how all of the units are tied together. An example of this is the relationship between mass, volume, and length. One liter is (or was originally) defined as the volume of a cube ten centimeters per side. A kilogram was defined as the mass of one liter of water at four degrees celsius (the temperature at which water is at its most dense at one atmosphere pressure). Note that because of a change in the definition of the length of a meter (from a fraction of the distance from the equator to the North Pole to the distance some number of waves travels, these definitions are probably no longer exact, unless the defs of liter and gram were altered, as well. The above is probably close enough for our purposes, however.

Given this, a number with units g/l roughly gives you how many parts per thousand of a compound or ion there are. Dividing this by 1000 gives you parts per million or mg/l.

- --Nick

-----

Date: Tue, 2 Jun 92 13:15:15 -0700  
From: dreger@sfsuvox1.sfsu.edu (Kurt Dreger)  
Subject: ppm conversion

In response to John Fitzgerald's <johnf@ccgate.SanDiegoCA.NCR.COM>  
question  
on June 2:

1 ppm (parts per million) is equal to 1 mg/l. Therefore,  
1 g/l = 1000 mg/l = 1000 ppm. So just multiply g/l by 1000  
to get ppm.

Good luck,  
Kurt

Are you sure it was in g/L and not mg/L? mg/L is equivalent to ppm.

Anyway, if it was in g/L that's equivalent to parts per thousand.  
Multiply by 1000 to get parts per million:

$X \text{ g/L} * 1000 \text{ mg/g} = 1000X \text{ mg/L} = 1000X \text{ ppm}$

From: mcnally@wsl.dec.com

Subject: Chimay yeast and bananas

Keep in mind that there are two things that can cause the iso-amyl acetate (banana) (and I could be wrong about the chemical) problem. One is high temperature, but I've fermented batches with Chimay at high temperatures without any problems. The other is insufficient aeration at pitching time. Insufficient oxygen causes some yeast to develop with very thin cell walls, and for some reason completely unknown to me this results in excessive production of the ester.

On the bright side, I've found that the banana taste fades with age.

Date: Wed, 3 Jun 92 11:11:10 MDT  
From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)  
Subject: Re: Calories in homebrew

I know that there have already been answers to this question, including disclaimers by George Fix and a nice linearized version with analysis by Robert Bradley, but I thought someone might like to see yet another version of the formulas. These are the same formulas that George Fix gave, except that they have been converted to FG and OG (using the Plato to SG (divide by four) conversion that is not exact according to George). This is probably what Robert did, before he linearized them. Anyway, here they are:

Note that OG and FG are used in the full form (e.g. 1.045). C stands for the calorie content per 12 ozs., and the [alc] and [ext] subscripts signify the fractions from alcohol and extract respectively.

Other definitions:

A = alcohol content of finished beer in % by weight.  
RE = real extract of finished beer in degrees Plato.  
OG = original gravity of the beer.  
FG = final gravity of finished beer.

$76.8 (OG - FG)$

$A = \frac{\quad}{(1.775 - OG)}$

$RE = 250 (0.1808 OG + 0.8192 FG - 1)$

$C_{[alc]} = \frac{1881.22 FG (OG - FG)}{(1.775 - OG)}$

$C_{[ext]} = 3550 FG (0.1808 OG + 0.8192 FG - 1.0004)$

$C = C_{[alc]} + C_{[ext]}$

$C = \frac{0.53 (OG - FG)}{1.775 - OG} + 3550 FG (0.1808 OG + 0.8192 FG - 1.0004)$

Subject: Wyeast Belgian revisited

In hbd 894, Al korz@iepubj.att.com writes:

> It appears that too many Wyeast users blame the yeast for infections  
> rather than their sanitation techniques.

It also appears that too many Wyeast defenders blame the sanitation techniques of users rather than the yeast :-)

I'm (slightly) miffed that Tom would blame my procedures, sight unseen, for my problems. Nobody can be assured of perfect sanitation every time but, as I made abundantly clear in my posting, I used a tried-and-true combination of recipe and technique which, I believe, gave me a pretty good basis for comparison. Meanwhile, Tom actually put his finger on the real problems (slowness of the yeast, high temperature) later in his own post, making this ad hominem all the more unfair.

For the record:

- 1 - Last night (day 29), the fermentation appeared to be finished, the gravity still read 1.010 (no perceptible change in 4 days) and the estery quality seemed to have significantly subsided. I plan to bottle tonight (if I can get it done before the game).
- 2 - I've heard from other users of Wyeast Belgian who agree that the stuff takes a long time to ferment out (you're one of them, Al!) and that it sometimes takes bottle aging to get over an initial roughness.
- 3 - 70 degrees was a ballpark, and for most of the period, it was probably in the mid-high 60s. As Al points out, that's too hot for this strain of yeast.

My patience (and lack of worry), seems to be paying off. I've revised my opinion of Wyeast Belgian upwards and had intended to tell the HBD as much. I think HBD readers who might someday want to try this yeast deserve to know that

- (1) the yeast is slow and
- (2) the yeast might not be happy if you don't have a cellar.

Cheers,

Rob

From: MILBRANDT\_J@WUMS.wustl.edu  
Subject: Saccharomyces delbrueckii

In response to a message I read in the HBD a couple of days ago, I have a question about the delbrueckii yeast which Wyeast packages in their 3056 packets. I have similarly colony-purified yeast from this packet

which will give the characteristic cloviness which a friend of mine was looking

for. As you stated, other colony isolates give a maltiness which is similar

to many lager yeasts, while colonies of another larger appearance are obviously delbrueckii. The problem is that when he attempted to ferment with yht this

tyeast (please excuse typos, I don't know how to edit on this terminal!  
t)

it stopped about halfway to the expected terminal gravity. Is this characteristic

it stopped about halfway to the expected terminal gravity. Is this characteristic

it stopped about halfway to the expected terminal gravity. Is this characteristic

(sorry) of this yeast, and does it need the other strain to finish out?

It is possible that I simply have a mutant, and could pick more colonies if this is the

case. Perhaps it is this particular strain from Wyeast?

I cannot completely eliminate the possibility that this merely a stuck ferment due to some other factor than the yeast itself. However, he says he has used the 3056 before without this problem. I certainly welcome any comments on this subject.

Thanks,  
tim Fahrner (apprentice typist )y

From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: Bananas

To add another data point, my Chimay-clone using the Wyeast Belgian ale yeast was fermented at 58-60 F (measured on the glass outside the carboy)

It was an all grain batch that turned out great but produced copious amts of banana and bubble gum esters during the ferment.

Now four monthes later the fruitiness has subsided to the pleasant level and is very enjoyable. I think it is a characteristic of the yeast and definitely not due to sanitation, especially since the banana aroma is subsiding with age. This yeast was *\*very\** vigourous even at 60 F.

Chimay flavor for \$2.00/gal., I can't complain =:^)

Subject: cooler for lauter

Nick Zentena sez:

Hi,  
>I just finished making a new lauter-tun  
>based on a picnic cooler. Does anybody have  
>any hints on using this versus my old  
>zap-zap unit?

>Also whats the best way to clean the pipe.

I have some hints:

When you get ready to sparge, pour into the cooler your equivalent amount of sparge water at boiling temperature. Add the mash which will be at about 150 F, and stir. The resulting mixture will be reduced in temperature to about 170-180 F. Hot Dog! No fiddling with mash-out!

Leave the mixture with the cooler lid on for about half an hour. Perhaps longer. Then re-circulate about a gallon of the water. It should be very clean. Go ahead and run off the wort as fast as you want to. Be bold! If it slows up, take a kabob skewer and poke the filter bed, or drag across the surface to break up the fine sludge on the top of the filter bed. After all, this is what the big guys do.

Start heating the wort as soon as you have 2 gallons or so. Use a second kettle to catch the remaining runoff. Don't bother with sprinkling sparge water over the bed after it's all run off. If you are worried about the loss of a few sg points, simply add another half pound of grain next time.

The best way to clean the pipe is to disassemble it if it's made of 1/2" fittings and rinse it with cold water. If you do this right away without letting the gunk dry on it, you can get it very clean.

Enjoy the rewards of easier all-grain!

Florian

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Head retention from Micah Millspaw

There have been some questions about both head retention (beer) and chill haze problems. I think that a large portion of the problem is a lack of lipids in the wort.

Lipids are very important elements for proper beer stability. Lipids are unsaturated fatty acids, this means that they are available to form new bonds with other elements of the wort. Although only a few ppm of lipids are present in finished wort, they can have far reaching effects on factors such as yeast viability, ester formation, gushing and flavour staling. Small variations in brewhouse procedure can produce large variations in wort lipids. Lipids adhere to trub particles ( trub contains up to 50% lipids) and to filter materials. Spent grains are high in lipids. A turbid top runoff from the lauter tun can contain 5 times, and even 40 times as many lipids as the clear wort runoff from the same mash. Also yeast will autolyze if it does not receive small amounts of ergosterol or unsaturated lipids.

North American grown barley malt contains very small amounts of free fatty acids (3.2-3.5 mg/l) opposed to european malts (18-26 mg/l). Insufficient fatty acid levels can result in high esters in the finished product and can also be responsible for gushing problems in the finished beer. The addition of unsaturated fatty acids can cure gushing. While the addition of saturated fatty acids tends to increase gushing. The content of unsaturated fatty acids has a strong influence on the formation of fermentation volatiles, notably the acetate esters. A wort that has been stripped of lipids could produce a beer too high in esters.

I beleive that a shortage of lipids may be a problem that homebrewers encounter because of their obsession with mash extraction yields. This need to eke out every trace of sugar from a mash, leads home brewers to practice wort recycling and or flaufing. These can be risky sparging techniques with regard to hot side aeration as well as stripping lipids from the wort. Recycling is the collecting of the wort as it runs out of the lauter tun and pouring it back over the grain bed. Many brewers

claim that recycling should be done to settle the grain bed. Flaufing is the collecting of the wort as it runs out of the lauter tun, boiling it and then returning it to the top of the grain bed. These practices not only give oppurtunity for hot oxygen and wort reactions, but also strip out fatty acids (which North American grown malts are low in) that are essential for proper yeast nutrition.

I have long felt that mash recycling was a bad thing, in that it tends to remove a lot of large particulate matter that would otherwise be in the boil. I feel that these particles ( husks and grits mostly) provide a place for proteins to clump onto during the boil and then settle out more effectively in cooling.

I have observed much clearer finished wort (cooled) from my boils, when the mashes were conducted with no recycling of wort than from those of other brewers whose worts were made by recycling the mash.

Micah Millspaw 3/31/92

A lack of sufficient lipids will cause the finshed beer to have stability problems one of which is head retention. Above it was mentioned that additions of lipids could cure gushing, I would make it clear that gushing is a head retention problem, and that it causes acn be the same as those responsible for no head formation at all.

Micah Millspaw 6/3/92

ps. Look for more about how chill haze and haze in general ties in with this in future HBDs.

From: Shirley Thompson <DUSTHOMP@idbsu.idbsu.edu>  
Subject: Problems

I made up two batches of beer about 10 days ago. The first batch (a wheat beer) has been bubbling merrily along. The second batch (a lite ale beer), the yeast is working very very slowly. The first yeast did not appear to work, (I might have added it too soon, before it was cool enough), so I added more yeast. It doesn't appear to be working at all, except the bubbler is raised up. The temp is 65 degrees on the outside of the carboy this morning. Can the yeast be working so slow that I never see the bubbler move? I only time I saw the bubbler move is when I got worried and replaced the bubbler with a cork and shook it up really good. It bubbled for about 10 minutes and then quit. It is inis is only my five and sixth batches of beer. Am I just a then quit. It is in a 7 gallon carboy. This is only my fifth and sixth batche s of beer.

The recipe I used was:

6 lb Malt Brewcon Pale  
1 lb Hop Lite dry malt  
20 gm Tett hops  
15 gn Fuggles Hops  
2 pkgs Mutton/Fison

Am I just a worry wart or should I dump the second batch out and start out?

From: fjdobner@ihlpb.att.com  
Subject: Wort Chillers

Some practical questions about using immersion-type wort chillers:

1. How does one go about cleaning a wort chiller? When I say clean I mean making sure that any solid or liquid foreign matter are removed from the inside of the coils? Initially, I am concerned because I have new equipment (1/2" copper coils and hose) and want to get rid of any possible manufacturing debris or oil present. Would you really want to use detergent (for the same reasons as not using detergent for beer glasses)? If not, what?

2. As far as cleaning on an ongoing basis, would you just do the same thing as recommended for 1) or a reduced instruction set.

There is no thrill greater than making beer from new equipment and drinking it.

I almost underwent a full collapse of both lungs standing in my basement and sucking through 15 feet of vinyl hose and 35 feet of copper coil from a pot of boiling water in the kitchen above. I have improved the siphon process (luckily on a trial run with no real batch at stake) and gave my wife a good belly laugh all at the same time. Up until that my only experience of siphoning was from gas tanks and from primary and secondary fermentation vessels with a meek 4 or 5 feet of hose. The key with these larger scale siphoning jobs is to ensure that the hose has no air pockets of significant size. I would have not relaxed, and worried plenty had this been a full production batch.

This question and all the followup have got to be in the same class as  
the hops wine stunt.

Surely this is a jest!

>From: tahoma!dgs1300@bcstec.ca.boeing.com (Don Scheidt)

>Yes, the Whitbread ale yeast is a combination of several strains, not a  
pure  
single culture. I'll gladly pay extra for Wyeast's liquid cultures for  
this  
very reason;

Yes, if one really wants such a combination, it seems a bit of an ordeal  
to  
replicate it.

> you don't get that funky 'homebrew' nose that you get with the  
dry yeast.

I separated your statement into two parts because it is NOT necessary to  
"pay  
extra for Wyeast" to solve the second problem. One can "clean up" dry  
yeast  
with very simple culturing techniques I have described in previous  
articles.  
I defy anyone to find a "funky homebrew nose" in my beer and I have  
never  
used Wyeast or any other commercial "liquid yeast".

BTW, those going to the AHA conference in Milwaukee will have an  
opportunity  
to taste ARF's Generic Ale made with pure cultured, wild yeast. In  
addition  
to a few MALTMILLS, I will be bringing a keg or two of the "WORLD'S  
GREATEST  
BEER". Unfortunately, we have been asked to limit the serving size to  
three  
ounces.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: toilet humor

No, Jack, my question about using dehumidifier water was not a joke. My initial feeling was "Ugh, scary stuff", but then I realized it might have some nice qualities, such as never being exposed to chlorine and being very soft. I would certainly use a new clean catch basin, and I would obviously boil the hell out of it before I would use it. So I tossed the question out, and got some good responses. I've decided not to use it, because it will probably have a metallic taste, and there's a question of microorganisms that I don't want to deal with, even with a boil. I'm sort of surprised, though, Jack, that such a passionate "standard brewing practice" debunker as yourself would dismiss a real question about a "non-standard" practice as a joke.

Re. cleaning copper: One of the best pieces of advice I've received from this HBD is to boil copper tubing in a water/vinegar mixture to clean it. About a cup of vinegar in 5 gallons is enough. The tubing comes out shiny. For an immersion chiller, you don't really care about the inside of the tubing. I give it a once over with a steel wool pad and hot rinse after each use.

Micah sez don't recycle the mash. Hmmm. That'll shorten sparging time too. What the heck, I'll give it a try this weekend. Thanks, Florian, too, your dump in boiling water to mash out should speed things up too. (I got sh\*t last weekend for spending too much time in the cellar. :-/

Subject: michigan

Lots of homebrew here in Michigan. There are several good supply stores in the area. For quick "pick ups" I go to a local "party store" that has a good selection. For major shopping trips, I go to the G.W. Kent retail outlet (they're wholesale only by mail-order), where prices tend to be a little lower (two data points: Coopers Light Extract was about 25% cheaper, and I got Fix's book for near wholesale). If you want grain, there's a supply shop about 20 minutes south of Ann Arbor that has a roller mill in the back, and will sell you crushed grain for the same price that Kent sells it uncrushed (in small quantities).

We have an active homebrew club, the Ann Arbor Brewer's Guild, with about 70 members, for which I serve as the e-mail contact. Josh Grosse (a frequent HBD contributor) and I are now co-editing the newsletter, as well. July will see our annual BeerBQ, complete with a pig roast.

From: pyle@intellistor.com (Norm Pyle)  
Subject: Re: Wyeast Belgian revisited

This thread brings up a valid point about problem solving via the hbd. Problems can often be attributed to technique, but also to bad luck. A good technique may work well for years before a particularly hearty wild yeast or bacteria infects your brew. I say the technique is "good" because it worked for years. Often, a single variable will change for the instance the brew turned bad, and the brewer will blame that variable, when it may have nothing to do with the problem.

I guess the point is that if you have a problem, try to be as scientific about it as possible (i.e. don't jump to conclusions). If you're commenting on someone else's problem, do the same. We don't need to run off half-cocked (or half-crocked) yelling "fire" in a crowded theatre house.

As far as Wyeast related problems go, I'm inclined to believe slow starts are much more of an issue than purity. Just MHO.

From: BOB JONES <BJONES%NOVAX@NOVA.llnl.gov>  
Subject: Immersion chillers and long siphons

In response to Frank Dobner questions :

Twice this month I have heard similar concern about cleaning the inside of an immersion cooler. After further questioning, I discovered that some brewers wrongly think you should place the cooler in a bucket of ice water and flow the hot wort through the inside of the cooler. Listen up brewers, you immerse the cooler IN the hot wort and run the cool city water through the INSIDE of the cooler. That way you don't need to worry (assuming any of REALLY worry) about cleaning the cooler. I ask the first person who was doing this if he had a hard time connecting up to the 3/4 inch hose fittings and he said. yeah. I ask if he stopped to think about why there were garden hose fitting on the cooler to start with? He had no comment, just this pie in the face look. On you other problem, Frank, of long siphoning. Why don't you just start the siphon close to the brew pot, through a short piece of hose. Then just connect that hose to the long hose that leads to the basement or wherever. Gravity will do the rest of the work for you. Also you should be cooling with your immersion cooler in your brew pot BEFORE you transfer to your fermentation vessel to avoid hot side aereation problems.

From: tbarstow@suneast.East.Sun.COM (Tom Barstow - Sun BOS Software)  
Subject: Stuck lager

I brewed two batches of honey-ginger lager back in late February (see recipe at end), the only difference being the type of yeast used. Wyeast #2007 (Pilsener) is in one; Whitbread Lager Yeast is in the other. The two-stage fermentations seemed to proceed normally, although the colors differed substantially until recently.

I decided to bottle last night and found that the Whitbread-based batch seems to be stuck at 1.019 whereas the Wyeast batch was down to 1.008. I went ahead and bottled the Wyeast batch and boiled 2 tablespoons of yeast energizer with a cup of water and dumped that into the Whitbread batch to see if I could get the fermentation started again. Nothing as of this morning, however.

So what do I do if it is stuck? Electro-shock? Threats? Therapy? It's too sweet to drink (and presumably wouldn't carbonate, either). Please send replies to me directly at tbarstow@suneast.East.Sun.COM since I'm not currently getting the digest itself.

Thanks.

-Tom

Recipe:  
3.5# M&F light DME  
2.5# clover honey  
2t yeast energizer  
2.5 oz ginger root, grated  
1.5 oz Cascades hops (65 min.)  
0.5 oz Cascades hops (3 min.)

From: rwinters@nhqvax.hq.nasa.gov  
Subject: mead questions

I bought a mead kit at the recent "Beer Expo" in DC. The instructions were almost non-existent, and questions abound:

- What kind of O.G. should I expect when adding water to 12 pounds of honey to make 5 gallons?
- Is my 7 gallon plastic brew-bucket OK for a primary, or should I endeavor to clean out one of my old carboys?
- The kit came with Red Star champagne yeast. Can I do better? Should I? Where will the S.G. end up, and how long is it likely to take?
- How does champagne yeast behave, anyway? Should I make a starter?
- What about temperature? I don't have any facilities for lagering, but should I attempt to keep it cool, or just let it go at room temperature?
- I was going to put it in capped champagne bottles. Will this work okay? I think I have a corker (it's sorta inherited, like the carboys), but I've never used it.
- If I wanted to prime this so that it would be a sparkling mead, what should I prime it with? and how much? 3/4 cup corn sugar? Another 1/2 pound of honey? Will the bottlecap keep it in the champagne bottle?
- I was also thinking of adding something for aroma; maybe a nice, fragrant finishing hop, or something herbal. Any suggestions about what to add and when to achieve a nice effect?

Thanks for any and all suggestions!

Date: Fri, 5 Jun 92 10:18:03 EDT  
From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Maple beer information

After the thread about using maple syrup began a while ago, I thought that it would be good if I could dig up a book which has relevant information on the subject. I'm sorry that I took so long, but my book collection is a mess.

The source is: Wines and Beers of Old New England: A How-to-Do-It History (1978), fascinating even if you never plan on following any of its recipes. The author is Sanborn C. Brown, who has taught many classes on homebrewing at MIT. I don't know if this book is still in print (part of the reason why I feel it would be useful to copy out some of the info), but it's somewhat easy to find used.

The quotes are taken out of order.

"Since maple syrup is about one third water, to use maple syrup as sugar for beers, wines, or ciders increase the volume of the syrup by that amount (1 1/2 cups syrup = 1 cup of cane sugar).

"You can make good 'middle beer' by using the sap just as it comes from the tree in place of the water in the basic beer recipe.... To make a colonial strong beer, boil the sap to one half its volume and use it in place of both the water and the sugar in the basic recipe.... It makes a good light beer."

[the basic recipe is: 1 gal. water, 3# hopped malt extract syrup, boil, six cups sugar dissolved, water added to make five gallons, yeast.]

"When maple beer was made in the old days, it was an early spring beer and was made right along with the syrup and the sugar. This was because sap does not keep well. It molds easily. Its pectin content is high, and if kept for long, it can turn to a soft jelly which inhibits fermentation. However, fresh sap boiled to one half and used in place of water in the usual process of making beer gave the early settlers an excellent strong beer made totally from the products of their own farm. They also made a wine, which they called 'maple mead,' by boiling the sap to 1/10th\*, adding yeast, and fermenting."

[\* Elsewhere, Brown indicates that commercial syrup is sap reduced to 1/40 or 1/50 original volume.]

There is also several pages about collecting maple sap and making maple syrup. I'm intrigued by the idea of making beer directly from slightly reduced maple sap (it makes diluting maple syrup an unnecessary step), and meant to talk to some of the commercial maple producers last winter about buying the unreduced sap. There is also intriguing information about birch sap being collected for its sugar. Some recipes and ideas are included in the book.

There is information on buying and keeping oak storage barrels, making wines, ciders, and beers of all kinds, and lots of historical information on how and why things were done. At the end is a collection of recipes for drinks made with the proceeds of the previous chapters. I highly recommend this book, and if it is out of print, it ought to be put back in print.

Mike> or a local place in the Balto-Wash. area to buy bulk honey?

Mike,

I was recently in the same boat, and asked about sources for honey. Many of the responses I received recommended trying a health food store. They often sell honey in bulk (which is a good thing, because you may be buying anywhere from 5-10# depending on batch size and sweet/dry style), and their product is usually raw, unfiltered, unblended honey, another plus.

I brewed up a "sack" mead (strong, sweet style) about 5 weeks ago, using 50/50 wildflower and clover honey. I think I used 8 or 8.5# of honey for a 3 gallon batch, and used Prise de Mousse dry yeast (a wine yeast). Original SG was 1.110, and when I racked it to secondary after 4 weeks it was down to 1.020. It seems to be just about finished, but I'm going to let it sit another 4 weeks or so to clear, and make sure that any warm weather that comes along doesn't cause fermentation to kick in again.

Good luck and happy mead making,

Brian

Bob Jones says:

>...some brewers  
>wrongly think you should place the cooler in a bucket of ice water and  
flow  
>the hot work (sic) through the inside of the cooler. Listen up brewers.  
..

Bob, ease up, it's a perfectly reasonable thing to do. It has its  
advantages and its disadvantages just as any other method. I depends on  
what you want/need to do.

Advantages:

- the wort is cooled very quickly like in a counterflow cooler, giving  
a good cold break.
- it's a sure thing that the wort is not exposed to infection during  
its most vulnerable time ( 170F < wort > 70F )
- the materials are mostly easy to get (a pot, ice, a coil of copper  
tubing) and there's not alot of permanent`construction' to be done

Disadvantages:

- you need to concern yourself with the cleanliness of the inside of  
the tubing
- you have to jockey yet another pot of water
- you have to come up with an intake tube that will stand up to boiling  
wort
- you have to figure out how to plumb the whole thing together

Subject: re sweet beers from delbrueckii

wrt to comments that isolated *S. delbrueckii* doesn't seem to ferment as far:

after the Red Star lager yeast tests (single-cell cultures showing that the basic yeast is sound, suggesting the off-taste comes from contaminants---done in Boston 2 years ago and reported a few times in previous HBD's) one of the people involved reported other culturing tests that had found (as this one had) that freshly-cultured yeast generally seems less attenuative than yeast that's been through at least one batch of beer. Have any of the people who cultured *SdelB* tried repitching? If so, did you get the same results?

From: "Theodore R. Jackson Jr." <tj2d@mtaac.bme.Virginia.EDU>  
Subject: Wyeast problems (Re: Wyeast Belgian revisited)

I have also encountered problems (infections) using Wyeast liquid cultures. At first, I attributed the problems to poor sanitation techniques although I never had a problem in any of the 18 previous batches brewed with Whitbread ale yeast. However, a recent attempt to culture Chimay yeast directly from the bottle has lead me to believe otherwise.

The three times I used Wyeast cultures, I produced beers with a horrible aftertaste (one that would stay with you for 1-3 days). The attempt to culture Chimay produced the same aftertaste in the starter. I tossed the starter down the drain. The Chimay yeast was presumably dead and something else started growing.

This leads me to the point that no matter how well one sanitizes equipment, the yeast population still has to be large enough to out-produce anything else living in the fermenter. I really already knew this, but disregarded advice to first pitch the Wyeast into a starter before pitching into the main fermenter. I ruined four batches of beer because of slow starts.

It might be worthwhile to prepare a small (starter size) batch (usual sanitation procedures) and allow it to sit with a fermentation lock and no yeast. If the resulting infection is similar the problem infection (method to be determined by you, taste was enough for me), you can point a finger at the wild things living in your kitchen.

From: NCDSTEST@NSSDCA.GSFC.NASA.GOV  
Subject: propane questions & esters from low lipids

Ive got a question about propane regulators, flow rates and freezing I am building a kettle burner that will fire my kettle/mash tun as well as heat the sparge water. My burner supplier (Solarflo) states a maximum input fuel rate of one gallon per hour. This is supposedly regulated by a 10" water column pressure regulator (the manufacturer claimed this was about .5 psi). I have seen (and own) a backyard BBQ with a regulator rated at 11" water column pressure. I assume these are not compatible, comments. Also of concern is the ability of the regulator and couplings to supply 1 gal of propane per hour without freezing up. I am trying to gather information on regulators and flow rates so I build the optimum setup. Any info is appreciated.

Re: Micahs Ester post

Its very satisfying to read some technical discussions about brewing in this digest and I thank Micah for contributing to this. I have to question some of the statements, though no flames. I dont see how you can brew well made clear beer without recirculating some runoff from the lauter tun. I am currently using slotted sheet as a false bottom and a 20 minute recirc is mandatory for remotely clear runoff. As for oxygenation and browning reaction of hot wort, it doesnt affect flavor, and unless you are making a very light lager (pils) the resulting darkening of the wort is not significant. I follow the reasoning of particulate matter flocking to the proteins, but why add particulate matter thereby adding hot trub and reducing hop utilization. If you have sufficient amounts of calcium in the boil, the proteins will flock well anyway. As for yeast autolyzing from lack of lipids: this is irrelevant if you are maintaining healthy viable yeast stocks. Yeast need to synthesize (sp) sterols to transition from the respiration phase to the fermentation phase. Yeast will use stored glycogen reserves from the cell interior, respire oxygen and produce the required sterols. The important ingredients are oxygen (which most homebrewers can never get enough of in the wort by shaking) and glycogen stores. Stored yeast (ie Wyeast) deplete glycogen during storage without food and are thus in a position to display inordinant lag times. This coupled with the low O2 in the wort leads to the poor Wyeast ferments. Without adequate supplies of O2, the yeast can feed on the fatty acids present in trub (from the cold break). This is how yeast synthesizes sterols in a low O2 environment (read homebrewing). This is why it is a poor idea to rack off the cold break prior to the end of the respiration stage. This is also why you need a clean, glycogen rich supply of yeast slurry at pitching time. On a related topic, anyone use an oxygen injection system on their chillers? I am designing one now and am looking for tips, ideas that is.

Subject: Eau de Toilette, Whitbred Yeast

To: Homebrew Digest  
Fm: Jack Schmidling

>From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

> No, Jack, my question about using dehumidifier water was not a joke.  
My  
initial feeling was "Ugh, scary stuff", but then I realized it might  
have  
some nice qualities, such as never being exposed to chlorine and being  
very  
soft..... I'm sort of surprised, though, Jack, that such a  
passionate  
"standard brewing practice" debunker as yourself would dismiss a real  
question about a "non-standard" practice as a joke.

I sort of suspected it was not a joke but having been sucked into two  
others,  
I didn't want to seem like I was taking the bait.

However, although your motivation may be in line with my passion for  
experimentation, the reality of dehumidifier soup as a serious  
possibility  
for brewing really does stretch credibility. It would be fun to streak  
a  
petri dish with a drop of that water but like you said most of that  
stuff  
would be killed by boiling.

That aside, the volume of air that passes through a dehumidifier to  
produce  
five gallons of water is staggering and most of the particulate matter,  
dead  
or alive, ends up in the water.

What seems like a free water distiller at first glance also happens to  
be an  
air filter by default. I think I would rather take my chances with rain  
water if I had a water problem and could not afford to buy distilled  
water.

.....

#### PURE CULTURING WHITBREAD YEAST

I recently pure cultured some dry Whitbred yeast and the following is  
what I  
learned.

First of all, I would not have started the project if I had known that  
is  
consists of three different strains. I was simply looking for something  
different to try.

The initial results of the streak plate were colonies of a typical,  
white

yeast with no detectable, visual difference. I made some slants from this and brewed a batch of beer that was nominal in all respects. This was about the time I learned that there are supposed to be three strains in there.

Within about a week, both plates developed one colony that is best described as looking like a nipples breast with coarse striations. I assumed this was mold but the striations never developed into the typical fruiting bodies of a mold. The colony just kept growing but kept looking like a yeast.

I discarded the plate from which I took the sample because it could have been contaminated during the process of innoculating the slants. The other plate has never been opened.

The second plate, also developed a slow growing colony of what seems like a yeast and is only differentiated by its very yellow color.

If these two odd balls represent the other "strains", they are a joke because the one in a zillion ratio has got to put there effectiveness in the noise.

I would also suggest that such drastically different morphology would indicate more than different strains, more likely different genera.

Now the most interesting data is that the entire plate is now (day 17) almost completely covered by mold that has developed in the past several days from about 4 colonies not previously identifiable.

As an additional experiment, I sprinkled yeast granules right from the packet onto two plates several days after I prepared the other two plates. Both of these plates now have several mold colonies that are taking over and neither has been opened since inoculating.

The bottom line here is that Whitbread dry yeast seems to be seriously contaminated and there is a possibility that the three strain claim is a hoax. If anyone has cultured this yeast, I would be interested in hearing from you. I am particularly interested in knowing if the yellow yeast and the hairy breast are the other "strains" or just random junk.

Just for the record, similar experiments with Edme never indicated any contamination.

>> Otter Creek  
>> 2 others in brattleboro I believe, but only counting the 4 above,  
>> we get about 1 micro/brewpub per 150,000 residents.

The two in Brattleboro are Dewey's Ale house and Latches'. Latches beer is fairly ordinary. Dewey's had shut down operations to renevatate their brewery to make it larger -- after only 6 months in business. Guess those Vt's like to drink :^)

Anyway, that makes 6 brewpubs that I \*know\* are in Vt, which works out to 1 per 91,600 residents. Which beats :

>Oregon ---  
>  
[list of brewpubs deleted]  
>  
>here maybe 2 others I believe, but only counting the 22 above,  
>we get about 1 micro/brewpub per 147,000 residents...  
>

>If you just look at Portland metro area alone:  
> 15 Micros/BrewPubs/1.5 million people, you get 1 micro/brewpub per 100,000 residents.

Well, if you consider just the Brattelboro area, which can't have more than 20,000 people, with 2 brewpubs, you get 1 per 10,000 residents!  
Not that it's a contest or anything :^)

From: Jacob Galley <gal2@midway.uchicago.edu>  
Subject: Mead Recipe

I'm so happy with my second mead (already!) I thought I'd tell you-all about it.

2ND MEAD (5 gallons)

7 lbs clover honey (60 min boil)  
5 lbs orange blossom honey (60)  
1 lb chopped raisins (dark) (30)  
1 tsp thyme (30)  
1 pak Red Star champagne yeast  
0 yeast nutrient

I don't have my notes with me, but I whipped this up in late February. I have yet to rally up enough wine bottles to bottle it all. However, I did bottle one gallon two weeks ago, priming with half a cup of Welch's 100% grape juice (one additive: ascorbic acid <-- any comments?). I was entertaining last night, and it was so good we opened and finished two bottles. None of my guests had ever tried mead before, and they weren't just being friendly (not even the one who doesn't like wine).

This stuff smells incredible -- slightly orange, slightly fruity, very much like flowers. The grape juice had not fermented out completely (it's not explosive, yet), but neither was it noticeably sweet. The grape masks whatever young-taste the mead still has in it (not much). After two weeks it was lightly carbonated and a very clear pink.

As my first batch of mead (a clovey metheglin) is only about seven months old and not very tasty, I don't have any experience with mature mead yet. Actually, the first one used to taste better, before most of the non-clove flavors aged away. I'm now somewhat skeptic of the theory that you have to age mead a full year. Does anyone else have anything to say about this?

Wassail,  
Jake.

Subject: Recent Steam Beer Clone & McEwan's Scotch Ale

I recently made a steam beer clone using a 'Reasonable recipe' (Extract)  
i used a 2 stage fermentation the first stage lasted about 3-4 days and  
due to the long bottling process i let the second stage go almost 3 weeks  
i use the 90 second airlock test instead of S.G. it was up to about 120  
sec.

between 'blurps' when i bottled. I used 1 cup of DME in boiling water  
(cooled)

for the PRIME (5 gal). This stuff has been bottled and stored at 65-68  
deg.

for about 3 weeks now it is starting to show visible fermentation but  
little

or no head. The taste is wonderful.

The question ..... how is head related to Carbonation ( ^^ replace  
Carbonation).  
??????

The second topic...

McEwan's Scotch Ale - I only got one reply on my post ....

Has no one tasted this stuff ???

This beer has little or no head is this related to my other problem ???

I want to 'Clone' this stuff but I don't want a Steam Beer with no head !  
!

will my steam beer become more carbonated the longer I leave it.

Should I raise the temperature ??? Lower ?? Relax And have another ?

-John Yoost Brewer/Programmer

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: no recycle

I brewed a batch this past weekend, using Micah's advice to not recirculate the first runnings of the sparge. The sparge did run clear after a couple of gallons. There was more break material than a similar batch done the weekend before, in which I did recycle the runnings, but not as much as I expected (although seeing a whole uncracked grain in the trub was a new experience). I'd estimate the no-recycle batch had twice the trub of the recycle batch, but the recycle one had very little trub to begin with. The NR batch seemed clearer going into the carboy, but was still very cloudy. It should be fermented out this week. The R batch is already kegged, and is still cloudy. The NR batch won't be touched until the end of next week.

I'm trying to keep the technique for the two batches as close as possible, with the exception of the recycling, but they're not exact copies, so nothing could come of this. I'll get back to this thread in a couple of weeks with all the gory details.

FWIW, I heard that Dewey's in Brattleboro, VT temporarily closed down because of infection problems, not to increase the brewery size.

From: gjfix@utamat.uta.edu (George J Fix)

**Subject: mead**

Subject: Origin of Calorie Formula; Numerical Examples (George Fix)

The calorie formula I quoted was derived by the committee on analysis of the European Brewing Congress (EBC). They started with the postulate that the formula should have the following form:

$$\text{cal.} = 3.55 * (c1 * A + c2 * (\text{RE} - 0.1)).$$

In this formula A is the % alcohol by weight (they report this as grams per 100 grams which is our degrees Plato). RE is the real extract measured in the same units, and the term RE - 0.1 represents the residual extract corrected for the ash content. The number 3.55 was a factor associated with the units used (i.e., grams and kcal). It was introduced so that the numbers c1 and c2 would be dimensionless. The latter were determined by a least squares fit using standard mathematical techniques.

The unit used for calories was kcal/1000g (calories per kilogram). This is how beer calories are reported in EC countries. All I did was to convert it into other units. Multiplication by FG (beer specific gravity) takes it to kcal/l, and the liter-oz. conversion factor takes it kcal/12 oz. This is the form I reported, which I rewrite as follows:

$$\text{cal.} = (24.495 * A + 14.2 * (\text{RE} - 0.1)) * \text{FG.}$$

The problems that bothered many was the nonlinear formula for A. Rob Bradley brought this out nicely. Boy if people get worked up by the alcohol formula, they should see what we use for hops. There is not anything even remotely linear about any of them.

As far as the other issue is concerned, I personally do not see anything wrong with the "factor of 4" conversion from Plato to spec. gr. The only point I wanted to make was that it was not exact. In particular, Mike Hall's analysis seems entirely reasonable.

Perhaps the following examples might clarify these issues a bit. The data was taken from the German trade journal Brauindustrie. Their column "500 Biere aus aller Welt" gives numerical profiles of beer brewed throughout the world. The measurements were done at Weihenstephan so the numbers are very good. The only exception was Michelob whose data I got from AB. The numbers are in % by weight (grams per 100 grams), except those for calories.

Paulaner Salvator

- - - - -

Measured data:

OE = 18.3 (1.076 or 1.073 for the factor of four types)

RE = 6.78 (1.027)

AE = 4.24 (1.017)

A = 6.17% wt.

kcal/1000g = 693

kcal/12oz. = 693 \* 1.017 \* 12 / 33.8144 = 250.1

Balling's formulas:

RE = .8192\*4.24 + .1808\*18.3 = 6.78  
A = (18.3 - 6.78)/(2.0665 - .010665\*18.3) = 6.16% wt.  
EBC formula:  
kcal/12 oz. = (24.495\*6.16 + 14.2\*6.68)\*1.017 = 249.9

By the way the linear wine formula  $A=100*(OG-FG)$  gives

$$A = 100*(1.073 - 1.017) = 5.6\% \text{ wt.}$$

I frankly feel most homebrewers could have gotten a better estimate by actually tasting a glass of Salvator and guessing. The wine formulas do better at lower OGs, but my interest in accuracy wanes as well. Having said this I should also say that "acceptable accuracy" falls into the area of personal opinion, and thus is not amenable to rational analysis.

My main interest in formulas for alcohol and calories is for dopplebocks and barley wines. I wanted something better than "sloppy Joe" numbers not only to monitor personal consumption, but also as a reference for friends and neighbors who help me drink the beer I brew.

Michelob

- -----

Measured data:

OE = 12.0  
RE = 4.53  
AE = 2.89  
A = 3.81% wt.  
kcal/12 oz. = 156

Calculated data:

RE = 4.53  
A = 3.85% wt.  
kcal/12 oz = 158

EKU 28 (!):

- -----

Measured data:

OE = 28.8 (1.124; here the factor of 4 gives 1.115)  
RE = 12.22  
A = 9.42% wt.  
kcal/12oz. = 416.5

Calculated data:

You are not going to believe this, but the formulas for A and kcal/12oz. are almost exact. I leave this as a homework exercise!

The nonlinear term in Balling's formula is also of historic significance. The classical Gay-Lussac theory (see page 161 of my book) predicts a formula like

$$A = (OE - RE)/c,$$

where c is a constant near 2. (Note that OE - RE is the amount of extract fermentated in grams per 100 grams). This is only the case for liquids like wine, which for this purpose may be considered as a simple mixture of glucose (dextrose) and water. Beer wort is far more subtle! This lead to the modern Embden-Meyerhof-Parnas theory of fermentation (pages 175-184)

.

There is a practical issue here as well. Note that the denominator

$$c = 2.0665 - .010665*OE$$

decreases as OE increases. Folks, there is more alcohol in our homebrews than many may realize, especially those with high OEs. Take care.

Off to Milwaukee!

From: "DRCV06::GRAHAM" <graham@drcv06.decnat@drcvax.af.mil>  
Subject: Keg pressure release valve question.

Ah, struck it rich, keggewise, that is. A friend owns a root beer concession truck and is giving me a good used regulator, tank and hoses, not to mention kegs. He just brought over two Coke pin lock kegs. I'm gonng have to replace the O rings, of course, don't like root beer flavored beer, but I have a question.

I've never had my hands on a soda keg before. There are two connections, as I would expect. In the center of those valves, is an area that I can press on and the pressure is released, or I get squirted with old root beer, depending on which one. There is a bail-like handle to release the top. Is there supposed to be a separate pressure relief valve, something other than the centers of the two and three pin valves? Is it supposed to be in the lid? Have I gotton very old kegs that I shouldn't use? Can I get replacement lids with valves, or am I on the wrong track completely. I'm doing this blind, so to speak, 'cause I'm really blind and got tired of bottling and spilling. Let's hear it for kegs, assuming I can get these to work.

Now, if I've gotton the wrong kind of kegs, let me down easy like, huh?

Subject: Re: immersion chillers/Wyeast lag time

Carl writes (regarding the "coil-in-icewater" chillers):

>  
>It has its  
>advantages and its disadvantages just as any other method. I depends on  
>what you want/need to do.

>  
>Advantages:  
> - the wort is cooled very quickly like in a counterflow cooler, giving  
> a good cold break.  
> - it's a sure thing that the wort is not exposed to infection during  
> its most vulnerable time ( 170F < wort > 70F )  
> - the materials are mostly easy to get (a pot, ice, a coil of copper  
> tubing) and there's not alot of permanent`construction' to be done

Also:

- uses a lot less water than either an immersion chiller or a  
traditional  
counterflow (some use a closed loop with icewater on the chiller side)  
-- very important in drought-stricken areas!

>  
>Disadvantages:  
> - you need to concern yourself with the cleanliness of the inside of  
> the tubing  
> - you have to jockey yet another pot of water  
> - you have to come up with an intake tube that will stand up to boiling  
> wort  
> - you have to figure out how to plumb the whole thing together

Also:

- the cold break ends up in the collection vessel -- you need to siphon  
off the trub again, this time at 70F (increased risk of infection)

>  
>  
>Carl  
>

I'd also like to point out that it's the head (the weight of the column  
of liquid above the level of the source vessel of the siphon system) and  
the 50 feet of tubing that make starting the siphon so difficult not the  
10 feet of hose running down to Frank's basement. Starting the siphon in  
the kitchen with a short length of hose would not help much. What would  
help is lowering the chiller. How about putting the chiler in the  
basement? Once you see the wort in the tubing, you can let gravity  
fill the chiller. I suggest PE tubing for the hot side -- it stands up  
to heat \*much\* better than the clear tubing.

>culture Chimay yeast directly from the bottle has lead  
>me to believe otherwise.

Then Ted goes on to suggest that slow starts and not using a starter probably caused some nasties to take hold before the Wyeast did. I concur. I like Ted's suggestion for testing your "environment." Good idea.

I'd like to point out that timing is essential when not using a starter with Wyeast. I've successfully made 15 or 20 beers using Wyeast \*without\* starters and have not had any infections with those batches. (I've since begun using starters for even faster starts and for cost savings -- I split a package of Wyeast between three batches -- three 16 oz starters.) The key, I've found, is to pitch after the correct amount of incubation. When I've used packages that were \*completely\* swollen (almost to bursting) I've had slow starts (48-60 hours). Twice, having pitched 1 month old packages, after only 18 hours of incubation, where the package was only about an inch thick, I got active fermentation in about 12 hours.

I theorize, that as in any starter, there is a limited amount of sugar. If you pitch the yeast into the fermenter when the yeast is most active (high krausen, if using a starter container you can see through) your lag time is minimized. If you wait too long, the yeast runs out of sugar and goes dormant again. Another important factor is the temperature difference between the starter and the wort. I've noticed an increased lag time from a five degree difference (colder wort than starter).

Granted, there are other variables, most notably the strain of yeast, but I think that the importance of timing the pitch with high krausen has not been given the proper attention.

Proper timing and matching the wort temperature to the starter temperature can give lag times close to those of dry yeast.

I guess I've been blessed with a relatively nasty-free basement, since the long lags have not been a problem.

Date: Mon, 8 Jun 92 13:40:26 PDT  
From: tpm%wdl158@wdl1.wdl.loral.com (Tim P McNerney)  
Subject: An easier way of brewing?

I have recently started using a method for brewing which I find to be easier than what I was using before and I would be interested in comments, suggestions or problems people see with it.

Basically, the main change was to start buying one of those 2.5 gallon plastic water jugs. I use the jug itself to ferment in, then I just get rid of the jug (my apartment recycling bins won't take it (only the 2 liter plastic bottles. Are they recyclable?)).

Advantages I've found:

1. Cleanup is much easier.
2. I prefer 2.5 gallon batches since it lets me brew as often as I did, but I don't end up with the backlog of beer I had before.
3. No fear of two foot long glass shards.
4. In general, easier to move around.
5. No need to wait for cooling to add to carboy.
6. I can fit the whole thing in the freezer to get it down to pitching temperature.
7. Easier to fit in the fridge. Before, brewing a lager was not a possibility.
8. I don't have to use Mountain View sparkling tap water.
9. Faster ferments, quicker settling (I believe this is true, though I don't have a large enough sample yet.
10. Since this is a one-shot deal, no problem with getting scratches in the jug.

Disadvantages:

1. Cost. Though most ingredients are scalable, yeast isn't, so the cost (if using Wyeast) would be twice as much per volume. Also, brewing time is not cut in half. The first isn't a problem since I culture my own (actually, it is an advantage as I do not have to make a fullsize starter) and the second doesn't bother me. There is the cost of the water and jug, though.
2. If I make a really good batch, then no one else gets to try any.
3. Somewhat strange shape of bottle makes blowoff less effective.
4. Most equipment not made for the Alhambra water bottle (new stoppers, etc.).
5. Temperature fluctuations more likely.
6. No obvious way for two-stage fermentaion without taking away some of

the advantages (ie. I would have to clean out some of the older jugs)

Some questions:

1. How clean are these bottles likely to be (do I need to give them a quick bleach soak)?
2. I know these bottles are water safe, but are they also beer safe?
3. Can I recycle these water bottles?
4. Do I need to preboil the water (I am an extract brewer and I have been brewing with 1.5 gallons of water while putting the other gallon or so in the freezer, making for a quick pitch)?
5. Any other problems which come to mind?

Thanks.

From: GC Woods <gcw@garage.att.com>  
Subject: Stoudt's Beer Festival

The following is a post from rec.food.drink:

>June 13: Great Eastern Invitational Microbrewery Festival  
>1-5pm Stoudt's Brewery Hall  
> Route 272  
> Adamstown, PA  
> "Participating breweries: Wild Goose (MD), Oldenberg (KY),  
>New England (CT), Brasal (PQ), Old Dominion (VA),  
>Buffalo (NY), Pennsylvania (PA), Otter Creek (VT),  
>Samuel Adams (PA), Vermont Pub (VT), Boston Beer (MA),  
>New Haven (CT), Niagara Falls (NY)"  
> Admission: \$15 (includes wurst buffet & beer samples)  
> Info: (215)484-4387 [Stoudt's Black Angus]

We received our tickets around a month ago and 700 out of 1000 had already been sold. One of the stipulations Stoudt's placed was that all the beer had to meet the Reinheitsgebot standard, so if the above list is correct I wonder what Oldenberg makes that would pass this test - certainly not Little Kings.

I would guess that the Pennsylvania brew is (hopefully) Dock Street and of course Stoudt's has been left of the list. Also what the hell is Brasal (PQ)?

If the Best of the Wurst buffet is anything like what is served at the Black Angus it should be excellent. The Black Angus features steak and a great raw bar - but watch out enties are around \$20, but well worth it.

From: florianb@chip.cna.tek.com  
Subject: Question on V/M/Okt. for Dr. Fix

I have been enjoying reading Vienna/Maerzen/Oktoberfest. Having lived in Southern Germany for 1.5 years, I learned to appreciate the infinity of variations of southern German lagers, including the festbiers. I have attempted this style at home with good results, but I have much to learn. Particularly in the area of fermentation, packaging, and lagering I have a distance to go. In reading the book, I was intrigued by your mention of the use of Cornelius kegs to lager the beer. I too have used Cornelius kegs for lagering recently. Having made my own refrigerator controller, I can maintain +/- 2 deg F quite easily. In the book, you do not mention the use of priming sugar. Did you in fact use a priming method, and if so what? Is it possible to charge the keg with CO2 periodically during the lagering stage and obtain a good carbonation or is it necessary to prime the beer first? I have never tried not priming and would be delighted to see whether this step can be skipped in order to preserve the clarity and quality of the beer which has completed secondary fermentation.

I posted here so that your comments might be of assistance to others on the hbd. Thanks.

Florian

From: Peter Kester <pkester@hooville.mitre.org>  
Subject: Adamstown PA Beerfest

Stoudts Brewery in Adamstown, PA is holding a beer festival this Saturday, June 13th with over 50 microbreweries promised to be in attendance. Admission includes the "Best of the Wursts Buffet". The bad news is that the festival is sold out, so if you don't have a ticket or don't have a way of getting a ticket, you're out of luck. The phone number for the brewery is (215) 484-4387.

The good news if you live near Washington, DC or Baltimore, MD is that the DC area homebrew club BURP (Brewers United for Real Potables) is running a bus up to the festival and there are still some seats left! The price for the bus is \$25 per person which includes a ticket to the festival. The bus will be leaving from the New Carolton Metro stop near DC and will also be making a quick stop just north of Baltimore. We have exactly one ticket for each bus seat. Because we need to almost completely fill the bus to break even, BURP will not sell the tickets separately.

For more information or to reserve a space on the bus, contact Peter Kester at pkester@mitre.org or (703) 849-9475.

**Subject: Fruit Flavored Beers**

I recently tasted two fruit flavored beers, Raspberry Ale and Blueberry Ale, at the Boston Beer Works, not to be confused with the Boston Beer Company, and found them to be quite good , a hint of fruit flavor without sweetness. My friend Elise remarked "why can't you brew something like that?" Hence this posting:  
I would be intersted in recipes but more importantly process.  
Must I use fresh fruit?  
How much for a 5 gallon batch?  
I have noticed that some wine/beer shops sell "fruit flavor" and "fruit concentrtate" can I use these?  
How much for a 5 gallon batch?  
When do you add the fruit, flavor or concentrate ?

Color is not that important the ales at BBW were light golden colored.

I will post a compilation of responses.

Date: 09 Jun 92 16:06:21 EST  
From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
Subject: Technique

After reading the Digest for some time, I thought I should solicit advice on what I might do next to improve my technique. In short, there are a number of things that I plan to do sometime, but I should like your thoughts on what will give me the best return.

First, this is what I now do: the day or more before brewing I start Wyeast and eventually make a 750 ml starter with light dry malt extract (or sometimes I repitch from the secondary and avoid the starter) and I also boil 1.5 to 2.0 gallons of cold tap water (it's quite soft in Philadelphia) and then freeze in a block; on the brewing day I bring about 4.5 gallons of water to around 170x F., turn off the heat, add 6.6 lbs. NW malt extract syrup, stir to dissolve, start heating again and bring to a boil, add hops at one or more times, and boil for 60 to 90 minutes or until volume falls to about 3.5 gallons, cool from 212x F. to about 170x F. by putting the pot in a sink of cold water and then cool to yeast pitching temperature by adding the 1.5 to 2.0 gallon block of ice, pitch yeast into the pot and let stand one to two hours, rack wort off of the settled trub into a carboy or plastic fermenter while waving the siphon hose to aerate the wort, fit a fermentation lock, ferment two to three days until kreusen falls and then rack to a carboy for a one to three week secondary fermentation, rack to a plastic fermenter with priming sugar (preboiled corn sugar), and then bottle. Sometimes I bring crystal malt or other specialty grains to 170x F. in the brewing pot and then skim it out before adding the malt extract syrup. Sometimes I treat my brewing water after the boil with Burton water salts (for pale ales) and sometimes I add .5 tsp. of Irish Moss at the end of the boil.

Among the things I have considered doing to improve this technique are: (i) use an immersion wort chiller so that I could do a full boil instead of using the block of ice (this will help when I get ready for all grain, too), (ii) use a bottle of oxygen to aerate the wort before pitching, (iii) use a 7 gallon carboy instead of a plastic fermenter for primary fermentation (where can one get a 7 gallon carboy?), (iv) use kegs of some sort rather than bottles (this would make life easier, I think, but shouldn't improve the beer) and (v) use a larger volume of starter, say one liter.

What of these items would you do, and in what order? Is there something else that I should do? Perhaps wait longer before racking the wort off the trub into the primary fermenter?

You may answer to the list, or directly to me at RKarras@PennSAS.UPenn.edu, as you choose. I will summarize to the list useful comments. Thanks!

Chris Karras

From: CW06GST <CW06GST%SJUMUSIC.bitnet@CUNYVM.CUNY.EDU>  
Subject:

Hello to all of you Homebrewers,

I have recently become interested in making my own beer and figured that this would be a good place to start. I have read a few issues of HBD and I can tell that there are quite a number of knowledgeable brewers out there. What I am looking for right now is a way to get started. Many of you are mentioning terms that I am not familiar with even though I have been a beer drinker since I was 12. (That's 105 in dog years) Anyway I think the best place for me to start would be with a couple of good books, so if anyone could suggest some reading material for the novice brewer, it would be greatly appreciated.

Recently I was in England and spent as much time as possible going into the local pubs of each town I was in. I tended to like the bitter much more than ales and lagers, so if you could steer me in that direction that would be great. Also, if anyone knows of any commercial beers that would be similar to the great bitters of England, I would be very interested in finding and drinking those. I found a "pub" in NYC called "The Slaughtered Lamb" and they serve an ale there called "Full Moon" that was quite what I was looking for, but it is only available on tap in their bar.

Unless you think that there are other novices out there like me you can send any information to my e-mail address.

Erik Zenhausern

Date: Tue, 9 Jun 92 15:12:20 PDT  
From: tpm%wdl158@wdl1.wdl.loral.com (Tim P McNerney)  
Subject: Evil water jugs.

I have had a number of replies to my posting yesterday warning of the danger of using the plastic water jugs for fermentation. I had heard these also (which is why I asked about it), but I haven't received any information more specific than that it was bad.

Does anyone know what these jugs are made of?

Any specific references to articles/warnings against using them?

I've seen similar containers which contain orange juice, which would lead me to believe that it isn't the pH of the beer that is bad. I would guess then that the alcohol could act as a solvent which could cause problems. But one would expect that only innocuous additives to the resin would be allowed if it were used in any type a food packaging.

If anyone can shed some light on the subject, it would be greatly appreciated.

Date: Wed, 10 Jun 92 8:26:45 EDT  
From: gkushmer@Jade.Tufts.EDU  
Subject: Mildew

Hello everyone, I've a question on airborne nasties:

Starting next week, I'm moving into another house. This house has a basement that stays cool all through the summer (or so I've been told by the current occupants) so that I can make ale without needing to worry about heat.

BUT (there's always a hitch) the basement floods on occassion meaning that it can be very humid. Because of that, there is an ongoing battle against mildew and mold.

My question is - how safe would it be to put a carboy in the basement with an airlock? My initial impression is that the carboy with an airlock would be a sealed environment. However, the mildew and mold spores are everywhere. When I go to bottle/keg or generally open the carboy for readings, don't I risk airborne contamination?

Advice/suggestions will be most appreciated!

From: "Roger Deschner " <U52983@UICVM.UIC.EDU>  
Subject: Evil water jugs; supplies in Boston area

The plastic water jugs are made of PETE, a modern polymer. The problem is not that the beer can do ANYTHING to it - in fact, PETE plastic was designed to resist almost anything you could put into it. The problem is that, in the cleaning process, there will always be microscopic scratches, which will harbor miniscule residues of wort and bacteria, and which can easily infect your SECOND batch made in the jug. The same problem can affect any plastic equipment, especially the plastic tubs (made of softer HDPE plastic) which are common in homebrew starter kits. This is also a reason to periodically replace your plastic hoses. Glass does not scratch like plastic, and is therefore more easily sanitized. You'll just have to put up with its weight, cost, and the possibility of breakage, but these are manageable issues.

In the Boston area, I recommend THE MODERN BREWER in Cambridge. Phone number is 1-800-SEND-ALE. (catchy, eh?) Even though I'm in Chicago, I buy from them by mail order.

Subject: berries and chlorine

Good'day fellow brewers;

I have been brewing beer for over a year now and have finally decided to get a bit more adventursome. In some of the Beer guides that I've read there is mention of adding fruit to beer, especially the likes of raspberries, blueberries (here in the great white north we have another berry called saskatoons, very much like a blueberry but tarter), strawberries, chokecherries etc. So I would ask that anyone having recipes or

knowledge of such a method of beer making to send me some information. I will submit a compilation of info and recipes. As I sometimes do not have time to read every issue of HBD personal messages would be appreciated

at bitnet: portersc@ureginal

Another question that has had me wondering for some time is sterilization

at present I am using the Hydrogen Metabisulphite recommended by the local

brewstore. However, I have read of using simple bleach. Has anyone out

there done this? If so what strengths of bleach! Rinse after!! I read

the discussion a few digests ago on the diff between sterilized and sanitized

but I don't believe I saw any mention of the use of bleach. Let me know if

I'm wrong. Again please send responses to my personal address.

Thanx, Steve

Subject: Brewing in Plasic Water Jugs

I guess I can claim to be something of an authority on this subject. I brewed 50 batches of beer this way. The first thing I would say is don't worry about toxicity too much. I'm not dead yet :-). The second thing I would say is don't do it. The big problem is sanitization. In our first 50 batches my brewing partner and I had quite a few contamination problems.

Some of this stems from the fact that we had inadequate knowledge about sanitization. For example we tried to sterilize with sodium metabisulfate which isn't the best thing to use. We also never sterilized the water jugs before using them figuring that they'd only been exposed to pure water. Of

course this isn't really true. Sure some of the water was purified by reverse osmosis but some of it was just spring water. Even the purified stuff doesn't guarantee that the jug was clean before the water was put in it.

You can probably use these jugs without infection if you treat them with bleach water and don't re-use them but I wouldn't count on it. Glass is much more reliable. Another problem is that the jugs aren't that sturdy. You haven't lived until a full one has rolled off the counter on a warm day and exploded all over your kitchen or laundry room!

If you really want to make small batches that will fit in your refridgerator why don't you use 1 gallon apple juice bottles or something? You might even be able to find a 2-3 gallon bottle somewhere.

Finally, why are you worried about Mountain View water? I brewed in Menlo Park and the water was pretty good for brewing and great for drinking. Does Mountain View get Santa Clara well water instead of Hech Hechy (sp) reservoir water?

> danger of using the plastic water jugs for fermentation. I had heard  
> these also (which is why I asked about it), but I haven't received  
> any information more specific than that it was bad.

Although I can't tell you specifically about the 2 gallon water bottles you are buying, I can tell you that there is a strongly held prejudice against any form of plastic in the homebrewing world.

The things to be aware of:

- \* Many plastics are much more permeable to oxygen than glass
- \* Non-food grade plastics may be made with plasticizers that can be leached out by ethanol, and besides what these may do to you after years of imbibing, they can taste pretty bad.
- \* Plastic scratches easily, and those scratches can harbor infectious organisms. It may therefore, be difficult to sanitize with contact sanitizers like iodophor, b-brite and bleach.

Ignore the AHA statistic that indicates that glass is over represented and plastic is under represented in the winners circle. Although true, this does not necessarily mean anything about the qualities of glass and plastic.

I use a food grade trash can for my primary and 5 gallon plastic water bottles (made from polycarbonate, which is safe from attack by ethanol, although it is somewhat oxygen permeable) for secondaries. I sanitize with boiling water, which doesn't need direct contact to work (the heat will get the little suckers), and doesn't need any kind of a rinse afterwards, either.

Glass is a good way to go, and I do use it for starters (although I just acquired a plastic baby bottle that I can pour boiling wort into and allow to cool). But it can be dangerous to handle in wet and slippery environments, and the chemicals used to sanitize can be difficult to remove without compromising the sanitization.

My advice is to choose a method that fits in with what you want to do and then work to eliminate any problems that occur in your environment.  
Good luck, and good brewing,

--Darryl Richman

From: Sean J. Caron <CARONS@TBOSCH.dnet.ge.com>  
Subject: dry hopping rates

Ok, you dry-hoppers (YOU KNOW WHO YOU ARE):

I'm biting the dry-hop bullet. Sign me up, i want that awesome dry-hopped aroma. I ordered the ingredients for my latest batch and ordered a package of Hersbrucker compressed hop plugs. I brewed up my batch last night as follows:

6lb Laaglander extra-pale DME  
1lb corn sugar  
.5oz fuggles pellets a=4.0 (begging of boil)  
.5oz Willemette leaf a=4.2 ( @ 20 minutes)  
.5oz" "" ( @ 40 minutes)  
#1056 - American Ale

OG = 1.060

The boil was a full 6 gallons (in my shiny new 10gal ss brewkettle! ;-), yeilding 5 gallons after the boil. It's merrily fermenting away in the primary now.

So how much of the Hersbrucker (a = 2.6) do i throw in the secondary? Is there some rule-of-thumb for amount of malt (SG?), amount of bittering hops, and amount and/or alpha of the dryhop being used? Or is it as simple as just throw in 1oz at transfer to secondary?

thanks!  
sean

OFFICE MEMOgrowth curve

Date:6/10/92

John Cotterill asks:

>Whenever I use Wyeast, I prepare a 12oz starter. Timing when to pitch a  
>starter has always been a mystery to me. The general recommendation  
is  
>to pitch at high krauesen. The trouble is determining when high  
krauesen  
>occurs. With my starters, I am lucky to get 1/8 inch of foam on top,  
and  
>that is a best case! What sort of krauesen do you get, and at what  
point  
>do you pitch the starter?

John, the idea behind this is that you want to pitch when the yeast are most active. Here's a quicky on how yeast (and other microorganisms) grow (usually):  
(monospace)

```
# |  
C |-----  
E |  +++  
L | ++  
L |  +  
S |  +  
  | ++  
  |=====  
-----  
TIME  
= lag phase  
+ log phase  
- stationary phase
```

High krausen will occur during mid- to late-log phase, evidenced by the healthy head. During this period, the yeast is gorging on all that nice sugar, and dividing rapidly. Consequently, it will be able to take over the wort very quickly. Thus, the yeast will be happy, and risk of infection minimized. Happy brewing!

From: CHUCK <UNDERWOOD@INTEL7.intel.com>  
Subject: Partial mashes

Hi all,

The other day I was able to help out on a friends first full mash. I was suprised as to how easy it was! The whole process took about 6 hours and aside from the fact that I don't own a 8 gallon brewpot I know I could do it now with no problems. However...

All I have is a 4 gallon brewpot. So I'm thinking of moving up to a partial mash. (I've been all extracts up till now) Papazian didn't go real deep into them and all the recipes were lagers. Anyone care to send me some hints? Recipes, how much grain, water, extract, etc. Also all of Papazian's recipes called for a step mash compared to the straight 150 deg mash? He also mashed the crystal, specialty grains, too. Why?

Any help would be appreciated.

Cheers, Cu

 Subject: Growth curves

Brett Lindenbach wrote a great piece on the growth of yeast that deserves repeating:

John, the idea behind this is that you want to pitch when the yeast are most active. Here's a quicky on how yeast (and other microorganisms) grow (usually):  
 (monospace)

```
# |
# | -----
C |      +++
E |     ++
L |      +
L |     +
S |      +
# |     ++
# |     ====
# | -----
# |
# | TIME
# | = lag phase
# | + log phase
# | - stationary phase
```

High krausen will occur during mid- to late-log phase, evidenced by the healthy head. During this period, the yeast is gorging on all that nice sugar, and dividing rapidly. Consequently, it will be able to take over the wort very quickly. Thus, the yeast will be happy, and risk of infection minimized. Happy brewing!

(end)

I wanted to comment that this curve (when modified slightly) applies to populations of people as well as yeast, though the time frame is expanded significantly. Thus:

```
# |
P | -----
E |      +++      ooo
O |     ++oooo
P |          +  ooooooo
L |         +
E |        +
# |       ++
# |       ====
# | -----
# |
# | TIME
# | = lag phase   The current earth situation contains
# | + log phase  geographic locales that fit all of these
# | - stationary phase  phases, as shown below:
# | o decay phase
```

```
# | Calcutta
P | -----
E |      +++      ooo
O |     ++ ^     oooo
```

```
P |      +   NY City ooooooo
L |      +^ ^
E |      + PhoenixCampden, N.J.
  |      ++
  |      =====
  |      ^
  |      Antarctica
```

-----  
TIME

It should be noted that yeast also have a decay phase, and the junk at the bottom of a well-aged bottle of home-brew more closely resembles Campden than the Big Apple.

Roger Deschner says:

>The plastic water jugs are made of PETE, a modern polymer. The problem is  
>not that the beer can do ANYTHING to it - in fact, PETE plastic was  
>designed to resist almost anything you could put into it. The problem is  
>that, in the cleaning process, there will always be microscopic  
>scratches, which will harbor miniscule residues of wort and bacteria,  
>and  
>which can easily infect your SECOND batch made in the jug. The same  
>problem can affect any plastic equipment, especially the plastic tubs  
>(made of softer HDPE plastic) which are common in homebrew starter kits.

Ho, hum. Yeah. I have heard this more times than I can count. I still don't buy it. I have been brewing for over 10 years and have always used plastic fermenters. I clean them with greenies (green scrubbing pads) as often as not and I am sure they have scratches in them. While I have no doubt some bacteria could hide in them, I am under no impression that I have a sterile environment. Period. Not only does sanitizing not kill everything, but when you put your beer in the fermenter (and especially when you aerate it) you will \*undoubtedly\* get some bacteria in it. Now, if I had an infected batch I might think twice about reusing the bucket if it were scratched, because we are now dealing with a known problem source. But until then I see no reason to believe that nasty bacteria will spontaneously grow in scratches in the plastic. If they come in, they will come in from the air (from which we have no protection in any event).

Geoff Sherwood

(and [knock on plastic] I have \*never\* had an infection in my beer)

Sean, I don't have any rules of thumb based on SG etc., but I will say 1  
oz.  
will overpower any brew I can think of. Half that amount has proven to  
be on  
the verge of "too much" for me in a few different brews (and I love hops!  
).  
I'd start with about 1/3 oz. for full hop aroma. Just MHO.

>water?

As a homebrewer who's located in Mountain View,CA, I'd like to share my  
opinion. Let me state first, I've never asked the water company for a  
report  
on the water. I \*DO\* know that I don't like the taste of the water that  
comes  
out of the tap, so we get bottled water for drinking. My partner and I  
use the  
same bottled water for our beer. The rationale -- if it doesn't taste  
good,  
don't use it. Works for us. We get our bottled water at a local store  
(Pure  
Water is the store name) for only \$.25/gallon. There's probably isn't  
any  
safety hazard in using the tap water, we just choose not to! Anyway  
there's my  
two cents worth:-)!

Damn it Jim, I'm a homebrewer, not a scientist,

>concern is the ability of the regulator and couplings to supply 1 gal of  
>propane per hour without freezing up. I am trying to gather information  
>on regulators and flow rates so I build the optimum setup. Any info is  
>appreciated.

1 gallon of propane = about 92,000 btu, I believe. When my regulator for  
the house froze up I temporarily substituted the one from a barbecue. The  
BBQ is 40,000 btu, and the regulator worked ok with the 60K drier, or the  
range, but the flames started getting lower if I tried both. From that I  
would guess that you won't be running full pressure with a barbecue  
regulator.

Of course, yours could be more overbuilt than the one I used.

Subject: soda kegs in HBD#898

In HBD#898 Dan Graham asked some questions about using soda kegs without pressure release valves. [I would have responded to you directly Dan, but your email address is pretty ugly :) and I'm sure my mail program wouldn't be able to digest it.]

Two fellow homebrewers and I have been using soda kegs with and without the separate release valves that you are looking for. Don't worry, you don't have the wrong kinda of kegs! The difference is in the lids, and lids with release valves are available (our homebrew shop sells them, but they are pricy, about \$18-19 just for a new lid!). We use both kinds of lids (acutally 3 kinds, one has what looks like a one-time pressure valve that would only open if the presure got too high, and then probably need replacing) interchangably, without much preference. We always figured that the kegs are rated to withstand 130 psi, and our beer is not primed to come anywhere close to that. If we are ever concerned about the internal pressure getting to high, the little valve in the top of the 2-pin stem always works to release a little CO2 (unless the keg is very very full). Note, it's the 3 pin stem that ususally goes to the feeder tube for the liquid, and thus results in the showers of brew/soda-syrup.

I hope this helps.

John Fitzgerald

BTW, the kegs also make great mini grain silos! We buy grain in bulk, and store it in a keg, pressurized with CO2. So far it seems to keep pretty well.

Nils,

Try Anchor's Liberty Ale! From the same people who make Anchor Steam and Anchor Porter. I've had this many times and really liked it because it's very hoppy. They use dry-hopping in brewing it and 3 kinds of hops. I've been able to get it a Leary's in Newburyport MA (Only 35 mins from York Me.) but you should be able to get it in any store that has a good selection of Gourmet/Import beers.

By the way, I live in NH on the seacoast. Where in ME do you live? Do you belong to any brewing clubs? Where do you buy supplies? There are about 10 people here at UNH (where I work) that brew and sometimes we get together for an informal tasting. Not really a club but we're toying with the idea of starting one. Interested?

Subject: hopeless hops

hey now- did anyone else get hop rhizomes from matucheski farms in wi this year? a friend and i ordered a bunch at the end of march and received them at the end of april. there was a problem with the weather in wi at the time so their harvest was late. anyway, we've had these things in the ground for like six weeks now and have seen no signs of life. i even dug one up yesterday to see what was going on and the rhizome looked the same as it did when i planted it!

now this really bums me out. all i wanted out of life was to be able to sit on the patio next to my hop garden, slurp homebrew, and listen to dead tapes. i'm easy to please. i've got the brew and the tapes but no hops. my friend has had the same results (or lack thereof). so what is it? is it da hops? is it da good piscataway soil? is it da shoes?

i never saw a rhizome before these arrived, so i don't know how thick they're supposed to be. the ones we got were really skinny, like much thinner than my pinky. were they anemic or something? if anyone has had problems with hops from this place, lemme know...

later

From: oconnor@ccwf.cc.utexas.edu (donald oconnor)  
Subject: hop tea vs dry hopping

Several hdb'ers have commented on the great hop aroma and flavor they get from dry hopping. the method that lynne and I use most often is to make a hop tea at bottling. The results seem very similar to dry-hopped beers of our friends. I think hop teas are a little trickier but perhaps give the brewer a little more control over the amount of flavor vs aroma. Our experimental approach has led us to conclude that there are several important variables in hop teas.

1. steep time 6-8 minutes seems to be best. too long and you lose the aroma; too short and you don't get much of anything.

2. amount of water. 1/2 gallon seems to be about the minimum. too little water prevents the components from dissolving.

3. obviously, the amount of hops. we use 1/2 to 2 ounces. i usually suggest 2 oz as a place to start with either hallertau or cascade because you will have no doubt about your success. then step down to suit your taste.

Does anyone know of commercial breweries that use dry-hopping? my recollection is that Sam Adams and Liberty Ale dry-hopped. any others? In the video the Beer Hunter, Michael Jackson tours an English brewery (whose name escapes me) and they effectively use a hop tea. The hot wort is poured over hops on the way into the chiller. Seems like the same idea as a hop tea. I think I recently read that Sierra Nevada does this as well. Is that true?

From: tooch@auspex.com (Michael J. Tuciarone)  
Subject: Re: Water opinions

Although I, too, am a Mountain View (CA) homebrewer, I'll try to make my comments as general as possible to avoid boring and irritating most of you out there in the heartland.

First of all, if you're genuinely interested in the fine points of your brewing water, you should get a water report. If you get city water, then you may get an annual water quality report automatically in your bill. That's the case in Mountain View, and I wouldn't be surprised if that's common elsewhere. Even if you don't, I'll bet your water company will mail you one if you ask them.

If you have a well, then you're on your own, but you should still have your water analyzed periodically anyway. (My Dad used to have it done every ten years or so; I don't know what the official recommendation is.) You'd hate to discover someone's septic field seeping into your well supply, for instance.

The report can tell you all sorts of interesting things like mineral content and so forth. But you should take it with a big grain of salt, since it really represents averages or typical values. In Mountain View, like many other places, the city water supply is created by blending water from the SF Water Department (Hetch Hetchy--which is \*really good\* water, by the way), the Santa Clara Valley Water Department, and sometimes from city wells. The water that comes out of your tap depends on where in the city you live and what's going on in the pipes that day. So the actual tap water is very variable, and this is likely to be the case in your community if your city is not blessed with a large and consistent natural water supply.

City water is chlorinated and treated to a greater or lesser degree (see above), often noticeably. I think this is the most important consideration..."it's the water," after all, isn't it? This is the main reason I use bottled water for brewing. It's very consistent and clean-tasting. (Maybe I could get the same effect by just bottling the tap water and letting it sit for a week. Hmmm.) I also don't think it makes that much difference to me, since my tap water isn't that bad, but there are people living in places where the tap water has a lot of sulfur or alkali or god-knows-what in it. You choose.

Subject: RE: Homebrew Digest #890 (May 28, 1992)

Mark Easter is brewing a batch with:

- > 4 oz cocoa powder
- > 4 oz freshly ground coffee (Costa Rican)
- > 1 cup unsulphered blackstrap mollasses

That's a lot of strong flavors for one batch. I used two ounces of coffee beans (unground) in 5 gallons of stout: the coffee was easily noticeable (and good), but another ounce would be pushing it. Experience from others on this digest says that 1/2 lb. would make your entire batch taste like fermented coffee.

- > (Anybody
- > done it?)

In the batch mentioned above, the two ounces of coffee beans were added when the yeast was pitched. The stout develops a great head; head retention isn't very good though. Coffee aroma is noticeable, and taste is pronounced.

- > Now for a question. I've got a weizen in the secondary which I

- > Ooogy wawa,
- > Dr. John

In a batch of bitter, I added black patent "tea" to darken the brew several days before pitching and achieved the desired results. If you try to add it at priming/bottling time, you'll have to decrease priming sugar to allow for the extra fermentables in the bottle to avoid overcarbonation.

Cheers,

From: "John Cotterill" <johnc@hprpcd.rose.hp.com>  
**Subject: Yeast Growth, Krauesen**  
Full-Name: "John Cotterill"

Thanks to all who have responded to my questions regarding yeast growth in starters (etc). I had a pretty good idea of the growth process that yeast undergoes during the brewing process. However, the difficulty I am having is determining when (or how to tell) a particular phase is occurring. Specifically, how can you tell when 'high' krauesen occurs in the yeast starter. As I watch my starters progress, its kind of like watching grass grow (or a golf game on TV). Not a whole lot happens. In fact, it is difficult to really see anything going on. I definitely don't get any foam cap on top of the base starter. At most its a few floating bubbles. All the information that I have come across suggests that it is 'very' obvious that high krauesen is occurring by the large amount of foam on top. This is true in my batch of brew, but I have never seen anything remotely close to 'a lot' of foam on top of my starter. I just usually pitch after 1-2 days of starting. So whats the deal? Does anyone out there get a good head in a 12oz starter. Not worrying, just curious (and feeling a bit insecure).

From: Dave Herd <kai@palace.ign.island.com>  
Subject: mashing

CHUCK <UNDERWOOD@INTEL7.intel.com> writes:

> The whole process took about 6 hours [...]

Yea, sounds about how long it takes me. I think you can do it a lot faster if your using a big gas burner -- I'm using an eletric stove top, which is damn slow at heating anything that big.

> Anyone care to send me some hints? Recipes, how much  
> grain, water, extract, etc.

I use between 2 and 4 hoppers\* of pale, along with at least one hopper of medium (~40 l) crystal, in 3 or 4 gallons of water to mash, and I sparge with a similar ammounht. Also, I often add to my mash a mixed hopper of wheat malt and rolled oats. I very seldom use any extract.

\* A "hopper" is my unit of measure for grain. It's however much it takes to fill the hopper of a Corona grain mill to the top. This is somewhere between 1 kilo and 2.5 pounds.

I heat the stuff to 150 deg F, or a little more, as fast as my stove will allow (this takes an hour and a half, or so). Once the mash is up to the temperature I want, I put the whole thing in the oven, preheated to 150 - 200 deg F. I turn the oven off \*before\* placing the mash. (My intent in preheating the oven is not that the oven should heat the mash, but rather that the mash should not have to heat the oven.) Anyway, the oven, being an insulated box, can keep the mash temperature stable for hours and eliminates the need for constant attention (stirring).

> Also all of Papazian's recipes  
> called for a step mash compared to the straight 150 deg mash?

The model I've got for enzyme and related activity isn't too well developed yet, but it does include a fair set of heuristics.

-- Reactions go faster when it's hot because all of the molecules are moving faster, and so can find their appropriate partners in crime more quickly.

-- Enzymes are big, complex, and therefore delicate things; they are easily dammaged by high temperatures.

-- Starch turns into dextrin (thick, clear, non-fermentable, gooey stuff) when it gets too hot.

-- High temperatures tend to produce thick, sweet beers, while low temperatures tend to produce thin dry ones.

-- If the temperature's way too low, stuff'll grow in it.

A straight 150 deg mash isn't really just 150 deg's (unless you go to a lot of trouble to make it so); you get the cumulative effects of mashing at \*all\* of the temperatures your wort passed through on its way to 150 deg. By doing a stepped mash, you're

just making for a larger porportion of the time being spent at a few selected temperatures. The purpose of this is so you can come a little closer to being able to choose which kinds of sugars and dextrans will be in your wort. To do this really well, you need either a way to change the temperature of your mash quickly and precicely, or you need to be able to calculate the effects that not being able to do this would include, or both.

> He also mashed the crystal, specialty grains, too. Why?

All of the grains, except for the really dark ones, can add to the total yeald of sugar, if you put them in with your mash.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: mild ale malt, regression (long)

Has anybody out there had much experience with `Mild Ale Malt'. I have purchased it from Lil' Ol' Winemaking Shoppe in the Chicago suburbs on two occasions.

At first I bought enough for one batch, just to try it out. Having drunk mild ale in the north of England (the first time was in Carlisle during a blizzard, heading from the Lakes to the Highlands), I was expecting a dark malt. Dave Line (\_BBB\_) describes it as: "malted barley roasted slightly more than pale malt. The higher kilning temperature tends to give a fuller flavoured beer and results in a darker coloured malt with a slightly restricted diastatic activity".

The stuff turned out to be much paler than I had imagined. To the eye it was only just noticeably darker than pale malt. It smelled nutty and toasty, though. It was easy to differentiate from pale malt with the sense of smell. I believe it to be 2-row.

Dave Line's recipes call for a total of about 2/3 lb. of darker malts to make a 5-pound batch. I tried the following, and it turned out extremely well:

Mid-West Mild Ale

-----  
6 lb. Mild Ale Malt  
4 oz. Chocolate Malt  
1.5 oz. Fuggles (pellets) - boil  
0.5 oz. Fuggles (pellets) - finish

5 gallons @ 1040 (!)  
final gravity 1014

Bottled on day 13. At it's best fresh; weeks 3-6.

I believe the original gravity figure (which suggests more than 80% efficiency) was in error. Around 1037 seems more likely (see below).

This took place in the winter of 90-91. In September 1991, gearing up for the season that has just passed [no basement or air conditioning :-(  
]

I ordered 30 pounds more. I used it in 6 batches, sometimes alone and sometimes in combination with US 6-row (much cheaper). I used it as I would have pale malt in 3 pale ales, a stout, a Scotch Ale and a winter warmer. In all cases (except possibly the stout), it added extra character and complexity to the beer: a sweet maltiness and a slight roastiness in the nose, a nuttiness in the flavour. It shone best, perhaps, in the scotch ale (which was unfortunately over-hopped and so not really true to style; more like a pale ale).

Because my mash/sparge technique was the same in all 6 batches and the array of other ingredients was limited, I thought this would make a good data set for estimating the yield from mild ale malt. I got 30 gallon-points per pound, by which I mean that if I brewed a 5 gallon batch using 8 pounds of mild ale malt, I would get expect

(8 lb. x 30 gal.-points/lb.) 240 gal.-points  
----- = ----- = 48 points,

5 gal. 5 gal.  
or an original gravity of 1048.

This rule-of-thumb method for predicting OGs has been widely discussed in past issues. It is a reasonable linear model of a non-linear process, but its reliability depends upon the numbers being calibrated for your process. Depending on how you mill/mash/sparge, you may well get more or less than 30 gallon-points per pound.

The best way to come up with numbers is to run a linear regression. This way, errors in measurement (both of weights and OG) will tend to cancel out. The larger the sample size, the better, but you must always have more batches than numbers of ingredients: that is, if you use 2-row malt, 6-row malt, crystal malt and black malt, you must get data from at least 5 batches...more if possible. On the other hand, since you are measuring an aspect of your brewing process, you should only include data from batches where the method is the same. If you change your lautering system or your mill, or you start using more sparge water, you won't get reliable figures using data from old batches.

There are many software packages, including Mathematica, which can do the calculations for you. (Always run the regression without constant term!!!) If interested on how to do it with mathematica, post to me.

With my 6 batches I used 4 ingredients and got the following data:

Ingredient gallon-points per pound

```
-----  
mild ale malt (2-row?) 29.8  
6-row US pale malt 28.8  
6-row UK crystal malt 25.0  
roasted barley 15.6
```

The accuracy of a homebrewer's procedures suggest we round to 30, 29, 25 and 16 respectively. If you brewed a batch with 3 # mild, 4 # 6-row and 1 # crystal, you would expect:

$$\frac{(3 \times 30) + (4 \times 29) + (1 \times 25)}{55} = \frac{231}{55} = 46.2 \text{ points.}$$

55

In fact, I got an OG of 1046 with this brew (lucky!).

My best batch of the winter, highly recommended:

Long Island Winter Warmer

```
-----  
7 lb. mild ale malt  
3 lb. US 6-row malt  
2 oz. Cascade (leaf) - boil 75 min.  
1 oz. Cascade (leaf) - boil 30 min.  
0.5 oz. Cascade (leaf) - boil 15 min.  
0.5 oz. Cascade (leaf) - steep for 15 min. after the boil  
0.5 oz. Cascade (leaf) - dry hop in the secondary  
ale yeast
```

5 gallons @ 1057  
final gravity 1020

The Cascade hops were fresh and very aromatic, from the fall '91 harvest. Alpha acid was about 5%; alas I didn't write it down. I used Edme yeast, although I doubt if I would ever again use dried yeast on a beer like this (or any beer?). Fortunately, I got no infections. I drank the last bottle on June 6 (brewed Jan. 25).

It was still in great shape: spicy on the nose and `creamy' and full-bodied in the mouth.

Try this mild ale malt stuff....it's really good!

Cheers,

Rob

Subject: UPLOAD: AHA.CON

1992 AHA NATIONAL AWARDS AND CONFERENCE TRANSCRIPT

(This is the transcript of CompuServe Beer Forum's live online report from the American Homebrewers Association's annual National Awards presentation at Marc Plaza Hotel in Milwaukee on June 12, 1992. Beer Forum Associate Sysop Robin Garr was on hand for the presentation, reporting "gavel-to-gavel" coverage in the Beer Forum's Conference Room 5 (The Brewery) using a portable computer set up alongside the dais.)

<Transcript begins>

Charlie Papazian has JUST walked up front. He's wearing a tux! and a... tall silk hat like Abraham Lincoln!  
OK! We're under way here, gang.  
Charlie has just asked if we're relaxed, not worrying and having a... homebrew. The crowd is pleased.  
Charlie is going through some routine announcements, and the crowd... is getting a little unruly.  
Charlie called up Jeff Mandel, of the AHA, and is giving him a round... of applause for all his work ... he's driven 2,000 miles around the... Upper Midwest this week, collecting all the FREE BEER for the... convention. The crowd, of course, is giving Jeff a \*\*\*Standing... O\*\*\*.  
Now they are chanting, MORE BEER! MORE BEER! MORE BEER!  
Charlie is now recognizing Karen Barela of the AHA. "I want to make... sure everyone knows, Karen is the one who's responsible for... everything that has happened here during the past four or five days... and including tomorrow. Karen, I want to give you a hug." <he does so>  
The crowd likes it. :-)  
Charlie is now making an announcement about tomorrow's Just Brew It... festival in Milwaukee's Old Heidelberg Park, 11-5. Shuttle buses... from the hotel, etc.  
More announcements: AHA's new Competition Committee meeting tomorrow... morning.  
Charlie: "If you haven't had enough beer by the time this is over,... there are three Hospitality Suites tonight." <cheers> He announces... their locations.  
There is a LOT of homebrew around here, folks.  
Continuing, Charlie makes more announcements. A wort chiller is... being raffled off tonight. It goes to the person who has a STAR on... their menu. Some guy in the back yells, "Yeah!"  
Now everyone's applauding Michael Matuchev <sp?>, who made the... special conference beers, served with dinner: Two raspberry... lambics, one called "Wild Rose," one called "Dirty Rose." More... applause.  
All these announcements are preliminary to the awards. We're... coming up on them in just a couple of minutes.  
Charlie is explaining to the group right now that we're on... conference. (Jeff Frane, looking over my shoulder, says "hi"... to the online participants.)  
And now.... Charlie is speaking:

"Without any further delay, Mr. Hombrew Competition himself, Dave... Welker."

Dave, competition director for the past five years, is coming up to... the front now. The awards ceremony is under way.  
(Russ W. just walked up and said howdy to the gang online.)  
Dave is taking the mike and shuffling his notes. This is Dave:  
Welcome, everyone! I'd like to start off with Karen, who gave me... some statistics at lunch. Anyone want to hear em?  
<mumbles from the audience>

I think they're really interesting. (This is Dave talking)  
There were 2,400 entries, double last year.  
56 from Canada, Australia, Japan, Sweden and the Virgin Islands,... most of them from Canada.  
California had the largest number of entries, 636 -- one-fourth the... total. <hisses from the audience>  
Colorado was next with 200. <cheers>  
Dave: I know you guys. Bunch of drunks.  
Illinois was next with 140. Then Wisconsin with 133.  
One of the things we've enjoyed here is how friendly everyone from... Wisconsin has been. Thank you very much.  
Every subcategory had entries, even the dry beer this year; none... last year, had four entries this year. <hisses>  
901 different brewers were responsible for the 2400 entries, an... average of 2.6 per brewer. One brewer entered 27 beers: Ron Page,... from Connecticut.  
First round, we had 150 judges in 26, three-hour judging sessions,... around 12,000 judging hours.  
As far as receiving, unpacking, sorting, registering, that consumed... about 920 hours and distributed through the four different sites.  
Total number of hours related to the judging, over 13,000, or about... 5 12 hours per beer.  
The crowd is getting a little tired of this, starting to rumble.  
Dave is naming all the best-of-show judges.  
Now, I'd like to get into the actual winners!

#### THIRD PLACE WINNERS:

Barleywine, Harry Clayton, Seymour, Conn.  
Belgium-Style, David Suda, Boulder, Colo.  
Brown Ale, Ron Page, Middletown, Conn.  
English-style Pale Ale, Rick W. Guthrie, Livermore, Calif.  
American-style Pale Ale, Steven and Christina Daniel, League City, Texas.  
English and Scottish Bitter, Alex Puchner, Hermosa Beach, Calif.  
Porter, John Arends, Calistoga, Calif.  
English and Scottish Strong Ale, Don Gosselin, Winthrop, Mass.  
Stout, Paul Hale, East Northport, N.Y.  
Bock, Brian and Linda North, Franklin, Wis.  
American Dark, Christopher Hansen, San Luis Obispo, Calif.  
Dortmund Export, Bill Murphy, Brookline, Mass.  
Munich Helles, Chris Harding, Ketchum, Idaho.  
Classic Pilsener, Richard Rosen, Andover, Conn.  
American Light Lager, Jim Lopes, Fresno, Calif.  
Vienna/Okfest/Maerzen, Tom O'Connor, Rockport, Maine.  
German-style Ale, Donald Weaver, New Freedom, Pa.  
Fruit Beer, Thom & Diane Tomlinson, Boulder, Colo.  
Herb Beer, Ron Page, Middletown, Conn.  
Specialty Beer, Neil Gudmestad and Ray Taylor!!!! of Fargo, N.D.!!!!  
Yeeah! (Ray and friends are online from Fargo.)  
Smoked, Tom Altenbach, Tracy, Calif.  
California Common, Larry Ferguson, Brooklyn, N.Y.  
Wheat Beer, Harry Clayton, Seymour, Conn.  
Traditional Mead, Micah Millspaw, Oakdale, Calif.

Melomel/Cyser/Metheglin, Walter Dobrowney, Saskatoon, Saskatchewan,  
Canada  
Cider, Robert Gorman, Waltham, Mass.  
Sake, Fred Eckhardt, Portland, Ore.

#### SECOND-PLACE WINNERS

Barleywine, Rob Brunner, Windsor, Colo.  
Belgium-style, Rick Larson and Paddy Giffen, Sebastapol, Calif.  
Brown Ale, Charlie Milan, Baton Rouge, La.  
English-style Pale Ale, Robert Drousth, Madison, Wis.  
American-style Pale Ale, Michael Chronister, Norristown, Pa.  
English and Scottish Bitter, Ross Hastings, Edmonton, Alta., Canada  
Porter, Jack Spence, Alexandria, Va.  
English and Scottish strong ale, Dale James, Fresno, Calif.  
Stout, Randy Gremp, Calistoga, Calif.  
Bock, Vern & Darlene Wolff, Esparto, Calif.  
Bavarian Dark, Steven and Christina Daniel, League City, Texas  
American Dark, Steven and Christina Daniel, League City, Texas  
Dortmund Export, Greg Walz, Pittsburgh, Pa.  
Munich Helles, Steve and Christina Daniel AGAIN.  
Classic Pilsner, James Cannon, Williamsburg, Va.  
American Light Lager, Steve and Christina Daniel  
Vienna/Okfest/Maerzen, Ray and Maureen Taylor, Fargo, N.D.  
German-style ale, David Rose, Yountville, Calif.  
Fruit Beer, Daniel Jodoin, Livonia, Mich.  
Herb Beer, Wayne Greenway, Oakland, Calif.  
Specialty Beer, Rob Lillard, Lyons, Colo.  
Smoked, David Woodruff, Sebastopol, Calif.  
California Common, Rob Reed, Kokomo, Ind.  
Wheat Beer, Rick Larson, Sebastopol, Calif.  
Traditional Mead, Mark Quade, Port Aransas, Texas  
Melomel/Cyser/Metheglin, Dave Resch, Colorado Springs, Colo.  
Cider, Steve Mclaughlin, Orwell, N.Y.  
Sake, Jim Long, Sacramento, Calif.

And NOW!

#### FIRST-PLACE WINNERS!

Barleywine, Greg Leas, St.Charles, Mo.  
Belgium-style, Mark Richmond, Springfield, Ohio.  
Brown Ale, Randy Gremp, Calistoga, Calif.  
English-style Pale Ale, Kevin Johnson, Pacifica, Calif.  
American-style Pale Ale, Bill Draths, Chicago, Ill.  
English and Scottish Bitter, John Arends, Calistoga, Calif.  
Porter, Dennis Kinvig, Toronto  
English and Scottish Strong Ale, Jim Campbell, San Jose, Calif.  
Stout, Dick Van Dyke, Park Forest, Ill.  
Bock, Steve Dempsey, Fort Collins, Colo.  
Bavarian Dark, Stu Tallman, Rochester, Mass.  
American Dark, Craig Beifus, Milford, N.J.  
Dortmund Export, Norman Dickenson, Santa Rosa, Calif.  
Munich Helles, Brian and Linda North, Franklin, Wis.  
Classic Pilsner, Patrick Drigans, Buffalo, Minn.  
American Light Lager, Steven & Christina Daniel, League City, Texas  
Vienna/Okfest/Maerzen, Keith Weerts, Windsor, Calif.  
German-style ale, Tom Young, Loyaltor, Calif.  
Fruit Beer, Dan Robison, Salt Lake City.  
Herb Beer, Eric McClary, Carson City, Nev.  
Specialty Beer, Bob Barson, Chicago, Ill.  
Smoked, James Cannon, Williamsburg, Va.

California Common, Phil Rahn, Cordova, Tenn.  
Wheat Beer, Eric Warner, Lafayette, Colo.  
Traditional Mead, Byron Burch, Santa Rosa, Calif.  
Melomel/Cyser/Metheglin, Vern & Darlene Wolff, Esparto, Calif.  
Cider, Charles Castellow, Edmonds, Wash.  
Sake, Tina Long, Sacramento, Calif.

(Suddenly, scores of people in the ballroom strap on Charlie Papazian masks!

This is really weird! A looney figure in in white mental-hospital garb and...

a fright wig has just rushed on stage, yelling, "I need a beer! FREE... BEER!"

Charlie is nowhere to be seen.

More Papazian masks are breaking out all over the room.

They hustle in a gigantic beer keg ... and out pops the REAL...

Charlie, wearing a velvet cape and pouring himself a homebrew.

This is real, stone strange, folks. ;-)

All of this, of course, is aimed at building up the tension before... they announce the Best of Show winners.

#### CLUB AWARDS

Charlie now takes the podium, and they break away to announce the... nation's top homebrew clubs, based on competition points, before... naming the best-of-show winners.

Here's Charlie:

"Over 25 clubs entered this year's competition as a club to gather... points for the coveted trophy sponsored by De Falco's of Texas."

Charlie will announce the top 10 clubs, based on judging points,...

starting with 10. To put us on the edge of our seats, he says, the... top two were separated by ONE point.

Starting in tenth place, the Brewers of South Suburbia, Brewtown...

Brewmasters and Ithaca Brewers Union, all with four points.

Then, the Gold Country Brewers Assn Calif, and Underground Brewers of..

Connecticut, tied with 5 points.

With 6 points, Washoe Zymurgists.

With 7 points, San Andreas Malts -- they're No. 4.

In third place, with 8 points, Hop Barley and the Alers, Boulder, ... Colo.

And in second place, with 25 points, The Boston Wort Processors

In first place, with 26 points, for the sixth or seventh year in a... row, the Sonoma Beerocrats (Calif.) <cheers, mixed with a few boos>

Byron Burch comes up to receive the award.

It's a silver cup, big enough to hold a jug-o-wine.

No hisses now, just a big round of applause.

#### BEST OF SHOW

Now, Charlie presents the the major awards.

"Dave, do you have an envelope for me?"

SAKE MAKER OF THE YEAR: from Sacramento Calif., Tina Long.

CIDER MAKER OF THE YEAR: from Edmonds, Wash., Charles Castellow.

MEAD MAKER OF THE YEAR: (Sparkling Traditional Mead), from Santa... Rosa, Calif., Byron Burch.

Byron sez: "Charlie tried to get me interested in mead several...

years ago. I wasn't interested at that point. He was right. I was... wrong."

This year, Charlie says, "We have a new award, the NINKASI AWARD...

(named for the ancient Sumerian goddess of brewing). In addition to...

the Best of Show, for homebrewer of the year, the Ninkasi Award goes... to the person who won the most ribbons in this competition, based on... three points for a first, two for second, one for third. With 14... points, it's Steven and Christina Daniel.

Charlie: Well, there were 2,400 beers, and this is what it all boils... down to: Best of Show, sponsored by Munton & Fison. The judges... really had a hard time picking 'em, more than ever. This year's award goes again, second year in a row, to the dunkel... category, Bavarian Dark, Munich Dunkel. Stu's Brew, the Boston Wort Processors, Stu Tallman, the 1992... HOME BREWER OF THE YEAR!

This concludes the presentation, the first LIVE Beer Forum conference coverage from the AHA Nationals. Thanks to all who attended the online session.

Subject: \$Agar?

Hi,

Does anybody know of anyplace that sells agar at reasonable prices? A local place wants almost \$100 for one[1!] pound of Malt extract Agar. They also want \$50 for a pound of DME.[This isn't a homebrew place put a chemical supply house]

If this doesn't pan out has anybody in Canada ordered from the Brewers Resource? How long did it take to clear customs?

Thanks  
Nick

From: envkas@sn634.utica.ge.com  
Subject: sediment in wine

To any of you wine makers out there:

After learning how easy and fun it is to make beer, my wife said "now if you could only make wine too...". This past summer I fermented 10 g of grape juice following directions from friends, books, and tips from a "quick" wine kit. Everything went smoothly. I bottled the white wine in December so that I could use my caraboys again for some beer. The wine seemed clear, so I did not use any finnings before botteling. Now I have sediment on the corks (bottles stored upside down) so when the wine is poured into glasses, the otherwise clear wine is degraded (at least visually, maybe in taste). The wine tastes great straight out of the bottle, but we want to serve it to friends and would like to have it clear.

My question is what should I do with about 40 bottles of wine that all have some sediment on the corks? I tried filtering some thru coffee filters which removed the particles, but the wine seemed to oxidize badly. Any ideas???

Thanks in advance!

Subject: Conference + Re: Technique/HighKrauesen/Dryhopping/MOREBEER

Having just returned from the AHA National Conference, I'd like to comment

on a number of posts received while I was away. By the way, I strongly urge everyone to try to attend the next Conference which will be held in Portland, OR, next summer. Not only are there \*barrels\* of information to be gained from the sessions (my favorites were the session on Yeast by George Fix and the session on Brewing Lambics by Martin Lodahl and Mike Sharp), but you also get to taste \*hundreds\* of homebrewed beers while standing shoulder-to-shoulder with such brewing luminaries as Charlie

Papazian, George Fix, Dave Miller, Byron Burch, and Fred Eckhardt.

>From the matching faces with logins file: everyone is much younger in person than they seem on the net. Given the amount of knowledge that HBD members have, you would expect them to look like old, grey-haired brewmasters. Not so. In addition, homebrewers are the friendliest people in the world. Period. If you stepped up to a homebrewer at the conference who was pouring a vintage 1967 Thomas Hardy's Ale, and they noticed your glass was empty, they would pour you some... nevermind that they haven't even had a chance to read your nametag.

Chris writes:

>Sometimes I treat my brewing water after the boil with Burton  
>water salts (for pale ales) and sometimes I add .5 tsp. of Irish  
>Moss at the end of the boil.  
>

So far, you have excellent technique.

>Among the things I have considered doing to improve this  
>technique are: (i) use an immersion wort chiller so that I could  
>do a full boil instead of using the block of ice (this will help  
>when I get ready for all grain, too),

Yes. I think this should be your first improvement. Note that when you increase your boil volume to the full 5 to 6 gallons,

you will get better hop utilization due to the lower boil gravity, so be careful. See the article by Jackie Rager (who I got to meet and with whom I shared a Blueberry Porter provided by one of the New York area homebrew clubs) in the Hops Special Issue of Zymurgy to see what kind of change you can expect from your full boil.

>(ii) use a bottle of oxygen to aerate the wort before pitching,

I would call this overkill. Good aeration is enough. (Ironically,) Alberta Rager will have an article in the Conference Transcripts on aeration -- she suggests using a bubbler stone, an aquarium pump and a 2micron inline filter for aeration, but I would leave this improvement for later.

>(iii) use a 7 gallon carboy  
>instead of a plastic fermenter for primary fermentation (where  
>can one get a 7 gallon carboy?),

Even a 5 gallon carboy will help you keep things more sanitary than plastic, but as noted by Darryl Richman recently, he's been using an HDPE fermenter for years and has brewed prize-winning beers with it.

>(iv) use kegs of some sort  
>rather than bottles (this would make life easier, I think, but  
>shouldn't improve the beer) and

>(v) use a larger volume of starter, say one liter.

The difference between 750ml and 1 liter is minor. Personally, I think that 750ml is enough if you pitch when the starter is most active.

Additional improvements:

- try adding specialy grains, like Crystal, Chocolate, Black Patent (I simply crush them, put them in a grain bag, and suspend the bag in the water as I bring it to 170F, then remove the grains.) The grains will give your beer a more malty flavor and aroma than just simply using extract.
- try some different malt extracts. I've found that Northwestern Extract seems to give a high terminal gravity. Other extracts give slightly different flavors too.
- Dryhop. Try 1 oz of Willamette or Goldings or Fuggles in the secondary (the last 10 days before bottling). Try Liberty Ale of Young's Special London Ale to see what dryhopping can do for beer bouquet.

John writes:

>Whenever I use Wyeast, I prepare a 12oz starter. Timing when to pitch a  
>starter has always been a mystery to me. The general recommendation is  
>to pitch at high krauesen. The trouble is determining when high  
krauesen  
>occurs. With my starters, I am lucky to get 1/8 inch of foam on top,  
and  
>that is a best case! What sort of krauesen do you get, and at what  
point  
>do you pitch the starter?

I think it may have to do with the low gravity of starters (I use 1018), but high-krauesen is really, at best, 1/8 inch, sometimes none at all.

I know I wrote "high krauesen" in a hurry and I really hadn't thought-out my post properly or explained myself thoroughly. Usually, I just time the bubbles and scale down from a 5 gallon batch -- 1 bubble per 80 seconds in a 16 ounce starter is (for practical purposes) 1 bubble per 2 seconds in a 5 gallon batch. I consider anything approaching 1 bubble per 2 minutes to be "high krauesen" in a 16-32 ounce starter.

Sean writes:

>I'm biting the dry-hop bullet. Sign me up, i want that awesome dry-hopped  
>aroma. I ordered the ingredients for my latest batch and ordered a package

> .5oz fuggles pellets a=4.0 (begging of boil)  
> .5oz Willemette leaf a=4.2 ( @ 20 minutes)  
> .5oz" " " ( @ 40 minutes)  
> #1056 - American Ale  
>  
> OG = 1.060  
>  
>The boil was a full 6 gallons (in my shiny new 10gal ss brewkettle! ;-)  
,  
>yeilding 5 gallons after the boil. It's merrily fermenting away in the  
>primary now.

I feel that you have underhopped. 1/2 oz of 4.0% Fuggles is quite low for a 5 gallon batch of 1060 Ale. I would have used 1.5 ounces.

>So how much of the Hersbrucker (a = 2.6) do i throw in the secondary? Is there some rule-of-thumb for amount of malt (SG?), amount of bittering hops,  
>and amount and/or alpha of the dryhop being used? Or is it as simple as  
>just throw in loz at transfer to secondary?

I suggest 1 ounce for the last 10 days in the secondary. At first, the dry hop bouquet may be overpowering (if that's possible, but I'm a hophead) at first but will mellow out in a week or two. Note: I heard at the conference, that Smartcaps(tm) will make your hop bouquet last much longer. If this is true, then you may want to try Smartcaps and use 1/2 ounce of Hersbrucker.

Subject: Bitter Commercial Brews

Nils/John:

Last year at the WBUR "Brewers Offering" my brew partner and I compared side by side the two beers we considered the hoppiest in the neighborhood. My palate my have been a little impaired but we found Geary's Pale to be the second in bitterness to Post Road. I would imagine that you can get it in Maine... it's brewed for the Marlborough Brewing Company by our friends in White River Junction.

> beers I've tasted are from Grant's in Yakima, WA. I think I read a  
claim  
> that their Imperial Stout is the hoppiest beer in America...

Perhaps surprisingly, Grant actually reduced the hops in his beers just a bit from the early days. Bert Grant worked in the hops trade (I don't recall just what he did) before he started brewing commercially. The man *\*really\** likes hops. I still remember the first time he brought his beer to the Great American Beer Festival--the India Pale Ale (which is supposed to be a hoppy style anyway) was overwhelming. It *\*was\** good, though.

I wonder if Sierra Nevada's Celebration Ale was counted in that "hoppiest beer in America" comparison. (Maybe not, because it's seasonal.) It's certainly been one of the hoppiest beers I've had over the years.

> ...Samuel Adams Boston Lager, which is as hoppy as  
> anything you're likely to find in general distribution.

It's hard to draw the line for "general distribution" though. The growth in the numbers of people who like substantial beer has been enough that Anchor and Sierra Nevada are almost common...and they're quite a step up from SA in hops content.

From: James Hensley <jpaul@barge.sd.locus.com>  
Subject: Box 'o beer

My friend went to the PB brewhouse here in San Diego, and saw several boxes haning from the ceiling. He asked what they were, and was told they are take-home gallons of beer! He brought me one (nice guy -- cost \$16.00 !! Anyway, I had never heard of this before and was wondering if anyone else has seen this sort of thing. It was quite good. Cardboard box with 1-gallon plastic container inside, came along with a plastic tap that you replace the lid with.

Cool packaging!

James

> Does anyone out there get a good head in a 12oz starter. Not  
worrying,  
just curious (and feeling a bit insecure).

Not sure what you are starting in what but.....

After 24 hours, I get a ring of bubbles around a half inch of wort in a  
slant  
tube.

This gets poured into 50 ml wort and 24 hours later will foam when  
agitated.

This gets poured into 200 ml wort which will foam up just like  
fermenting  
beer within 24 hours.

If I have the time and motivation, this I pitch into 500 ml wort and it  
foams away in 24 hours.

I guess the bottom line is, it takes four days to do it right.  
.....

I would like to express my good will and warm feelings to all the great  
people I met at the AHA conference in Milwaukee last week. I even  
extend  
that to the HBD celebrity who refused to shake my hand or taste the  
"World's  
Greatest Beer". After composing my flaming expose' of the twit I  
decided to  
give it one more try and flatter myself in thinking that I must still be  
the  
world's greatest salesman. Finally, with great condecension, he tasted  
the  
"World's Greatest Beer" and couldn't find anything wrong with it.

From: Jon Binkley <binkley@beagle.Colorado.EDU>  
Subject: Gravity of Starter Cultures

Why is a relatively low gravity (1.020) recommended for yeast starter cultures?

The last few batches my friend and I made were from higher gravities (~1.040-50), first by accident and then on purpose. The cultures seemed very happy, and the lag time after pitching seemed shorter (very subjective observations).

Is there any problem with this, other than using more malt extract than is absolutely necessary?

Jon Binkley

Subject: RE: Homebrew Digest #903 (June 16, 1992)

1) Beer in Alaska. I can't offer much information concerning brewpubs, but I strongly recommend the beers produced by the Alaskan Brewing Co. in Juneau (see Jackson's pocket guide for a thumbnail sketch). They produce a wide variety of beers, with only the pale ale being a bit pedestrian. Of particular note is their amber, which is far and away the most Belgian tasting beer made in America (you can tell where my heart lies. . . . could you bring me back a case?)

2) Oranges. I'd like to use orange zest in my secondary for some orange flavor and aroma (again, a Belgian-type brew). The question is, how much? The beer will be about 1.070, using a rather fruity yeast stolen from a Belgian bottle. Also, should I avoid dry-hopping with hops at the same time?

Subject: Milwaukee Goodbyes

Subject: Milwaukee GoodbyesTime:7:50 AMDate:6/16/92  
I'd like to say that I found the 1992 Conference to be very useful. All the sessions I attended were well prepared, presented, and interesting. The general session speakers and events were equally well designed. There were one or two rough spots, but that's to be expected when planning an event of this size and complexity. The food and drink were never lacking, and that includes what was supplied by the local (some not so local) clubs in the hospitality suites. We got to see two of the most inspiring breweries for "seat-of-pants" homebrewers. Both Sprecher and Lakefront were built with a minimum of up-front investment and serve as shining examples of what can be done with inspiration and "sweat equity". All in all I think Karen Barela and the AHA staff deserve our high praise for bringing off the event so smoothly. "Thanks!" to all of you in Boulder.

Meeting so many "Electronic Brewers" face to face after as much as 3 years of keyboard contact was very exciting. The added dimensions of the personalities of those I got to spend some time with was certainly the most intriguing aspect of getting to know people who I thought I could anticipate. Beyond the obvious miscalculations of age and appearance, I found peoples' sense of humor and warmth (often difficult to see on-line) served to cement many electronically formed friendships. My only regret is that I didn't get to spend more time with these people.

To those of you who I didn't get to say "goodbye" to, I look forward to continuing our discussions here and to seeing you again in Portland. Thanks for making Milwaukee so memorable.

Subject: Re: hopeless hops

I purchased some hops from Michael Matucheski and they worked out fine. I happened to be in Antigo Wi during the bad weather. the last day we were in town things warmed up and Micheal was able to dig mine up. All of the rizomes had buds - the fuggles had a 4" sprout on it when I planted it. I must admit, I didn't get around to planting until almost a month after I recieved the rhizomes. They were in plastic baggies at room temp. Perhaps that is why they were so vigorous? I don't remember how thick they were. Something like my pinky and about six inches long is what I remember. They all came up within a month of planting. Also, Seattle has had \*very\* warm weather this spring. Everything is early. A friend reported his hops already are forming flowers!

As an aside, the fuggles is most vigorous, the Cascades next and the Hallertauer least vigorous. I presume next year things will even out after they adapt to their new homes.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: \$Agar? and sediment in wine

Agar

Nick,  
Check out your nearest oriental grocery store, you'll find agar-agar in at least one of several forms; powder, noodle-like strips(looks like rice noodles), or puffed square sticks that look like they're related somehow to fried pork rinds. Unless you're planning on doing heavy-duty microbiological studies on your yeasts this stuff will work fine for you.

Sediment in wine

>My question is what should I do with about 40 bottles of wine that all have  
>some sediment on the corks? ... Any ideas???

I don't do wine but, you asked for ideas, here's mine:  
Stir/shake a bottle up to get the sediment off the cork, and store it on its side, allow the sediment to settle to the side of the bottle. When serving, carefully and gently decant all at once into a decanter, then pour for your guests.

Carl

Date: Tue, 16 Jun 92 10:47:13 CDT  
From: gjfix@utam.uta.edu (George J Fix)  
Subject: Larging, Milwaukee, Questions about England (George Fix)

Florian asks in HBD 899 about priming festbiers in cold storage. We followed the traditional process, still widely used in Germany, of having a long, cold secondary fermentation in a gas tight vessel. No attempt at priming was made in this process. In particular, we allowed the fermentation to go 2/3rds of the way in the primary, and let the last 1/3rd finish off in the secondary.

We took periodic samples to determine the state of carbonation. Very often it was necessary to bleed off some CO2 to prevent overcarbonation. If anything, it is possibly best to stay slightly on the low side, and then make minor upward adjustments at the end with direct CO2 injection. This practice is also widely used in Germany.

Laurie and I really enjoyed Milwaukee. The biggest treat of all was meeting old friends, and relating faces to e-mail addresses of people we had not meet before. I just wish there were more time for everything, especially informal discussions. What would be great is to follow something like Jay Hersh's seminar with sessions where homebrews were tasted by a group of interested brewers. The beers could be served anonymously to prevent excessive ego deflation or inflation. This would also allow people to talk more freely about what they are actually tasting, and perhaps talk about their own personal experiences. (By the way, Jay really worked hard to get the doctored beers right, and despite of the hectic ending which was created by time limitations, I think he did an outstanding job.)

Jack Schmidling's generic ale was indeed clean as a whistle. I did, however, have some stylistic quibbles with it. Jack, those high alpha Chinooks need a generous malt charge to balance them off. I hope you had a chance to taste Bob Jones' Brown Ale. It clearly showed how really delicious a clean well balanced beer can be. Also, since you and Al Korz. live in the same city, I hope you get a chance to taste his beers as well. They too are excellent models. The larger point, however, is that yeast culturing works, and it can do so for any type of brewer. One does not need fancy equipment to brew tasty beer. Good yeast, a good recipe, and sanitary brewing conditions will do the trick every time. One final point. Jack, when you discard yeast after they make a clean brew (well formulated or otherwise), then you could be chunking THE WORLD'S GREATEST YEAST SLURRY.

Laurie and I are going to England at the end of this month. It is alas a work trip, but there should be some spare time on weekends. We would be grateful for any tips concerning pubs, brewpubs, and micros in or around Cambridge. These can be sent directly to [gjfix@uta.utamat.edu](mailto:gjfix@uta.utamat.edu).

> improvement for later.

Well I tried using a 1 micron inline filter with an aquarium pump placed in my wort and the pump produced so much air that my wort bubbled out of the carboy!!! I don't know if the bubbler stone (which produces fine bubbles compared to just the end of the 1/8" tubing) doesn't have this problem or are they using a 15 gallon fermenter with 5 gallons of wort in it...

Anyone who saw the demonstration at the Conference or know how to get around the problem care to comment??

By the way, how did they sterilize the bubbler?? Put it in bleach?? All of those little pores in the stone would be a menace to get clean it seems like...

From: Chris Goedde <goedde@shape.mps.ohio-state.edu>  
Subject: Questions from a novice

Hi. I'm a novice brewer (just racked my second batch to the secondary), and I have the following questions.

- 1) Is there a simple conversion between pounds of liquid malt extract and pounds of dry malt extract?
- 2) I'm thinking of brewing some half batches (2.5 gallons). Papazian gives a table for hop utilization for bittering as a function of the gravity of the boil, and I was wondering if there are similar adjustments for finishing hops also, or should I just cut them by 50%?
- 3) That little lid that comes with your fermentation lock. Do you attach it securely while fermenting or do you just set it on top? Or do you throw it away? In other words, what's it there for? I made a starter for my last batch, and it was slightly carbonated because I had the lid to the lock on, which didn't seem quite right.

Thanks,

chris goedde

>Sometimes I treat my brewing water after the boil with Burton  
>water salts (for pale ales) and sometimes I add .5 tsp. of Irish  
>Moss at the end of the boil.

I like this technique! The idea of letting the trub settle in the brew kettle is nice. Typically I sparge the wort immediately into the primary and end up getting a good portion of the trub in the primary. Just a few questions:

- 1) Does pitching the yeast into the brew pot (@80F) and siphoning 2 hours later disrupt the fermentation process?
- 2) Is a significant amount of yeast left behind in the brew pot along with the trub?

I have been looking for such a technique and your additional comments would be appreciated.

From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
Subject: Technique; Chillers; Kegs

Thanks to all who responded to my post on brewing technique and suggestions for improvement. The leading suggestions were to use a wort chiller rather than the block of ice made from brewing water. This change would allow a full boil (with its better hop utilization)--more on this later.

Although several respondents recognized the difference of views expressed in this forum from time to time, the consensus was that a plastic primary fermenter was fine. I do rack to a glass secondary and that won approval. No one thought that using oxygen to aerate the wort prior to pitching was sufficient bang for the bucks and a one liter starter was thought to be little better than the 750 ml starter I now use (although I suspect that I should be giving the starter more time to get to high krausen).

At least two respondents thought that keggins WOULD improve the brew, providing better conditioning. Several more agreed that it would make brewing easier. More on this later, too.

And of course just about everyone noted the benefits of going to all grain. If I can collect the additional materials, I plan to give that a first go this weekend in celebration of Father's Day (but my daughter has opted to feed my computer hobby so no wort chiller there). Finally, one respondent noted the inadvisability of doing more than a 60 minute boil for extracts, something I now recall seeing here some time ago but had not remembered.

Wort Chillers. OK, I am ready to take the step. The immersion variety seems more practical from a sanitation standpoint. I like the idea of keeping it clean, but sterilizing it just before use by inserting it into the boil for a few minutes before turning the water on. The most detailed description I have found here of making an immersion wort chiller was by Patrick Volkerding (volkeri@mhd1.moorhead.msus.edu) on 3/26/92. He used 25 feet of 3/8 inch outside diameter (O.D.) copper tubing with compression fittings to connected to a garden hose. His tips included using a snap-connect fitting for easy connections. Washing machine hoses can be used for connections. The plumbing supply stores I talked to today say that the 3/8 inch O.D. tubing has a 1/4 inch inside diameter, and comes in two varieties, the one that I would want for easy bending being the soft variety. \$1.05 per foot in Philadelphia. Patrick used 25 feet--should I use the same?

Kegs. My wife brought back from England a couple of weeks ago a copy of Home Brewing--The CAMRA Guide by Graham Wheeler (Alma Books, Ltd. 1990)

It is a 172 page cross between the books by Miller and Papazian, but with an English bent that I found really useful (for example, I just never understood before that copper finings were fining agents added to the brewpot, which is called a copper in England due to its historical construction material). As the book describes all grain only, I have certainly not digested it, but I am intrigued by the plastic barrels used in England for keggering. They have a tap set into them and can take a carbon dioxide charger to protect against oxidization. Can anyone compare them to the soda kegs used by many homebrewers here?

Thanks again for the help of this Digest. Next year I hope even to go to Portland!

Subject: Los Angeles Brewing Company

I got some more news on the Los Angeles brewing company, who are the folks that make Eureka beer.

The brewpub closed down during the L.A. riots, and then never opened up again. The official word was 'financial troubles' and that the brewery would continue to brew beer, but the pub would remain closed for a while.

The story has now changed for the worse: The brewery will close and the pub will stay open...

Seems stupid to me...

That's 0.2 micron by the way. It is to filter out airborne beasties,  
so you need an extremely fine size.

> . . . the pump produced so much air that my wort bubbled out of the  
carboy!!!

Keep an eye on it and turn it off periodically to let the foam subside.

Subject: questions asked and answered

Morning folks.

Chris Goedde asks ...

>1) Is there a simple conversion between pounds of liquid malt  
> extract and pounds of dry malt extract?

My understanding is that .8 lbs DME = 1 lbs LME, with the extra .  
2lbs  
of LME being water content.

>3) That little lid that comes with your fermentation lock. Do  
> you attach it securely while fermenting or do you just set  
> it on top? Or do you throw it away? In other words, what's it  
> there for? I made a starter for my last batch, and it was  
> slightly carbonated because I had the lid to the lock on, which  
> didn't seem quite right.

Assuming your using one of the "tripple-ripple" locks with the orange  
plastic cap, the lid stays on. It is supposed to have ridges molded  
into  
the plastic which provide room for the co2 to escape. In pratice,  
i've  
had the same problem. Make sure the air spaces between the ridges are  
not  
clogged, and dont jam the cap on tight, and it should work.

Chris Karras is ...

I looked into these as an alternative to the expense of a full-blown  
kegging system, and I was told they are fine for party-type  
situations,  
but are very prone to leaking, making them less than suitable for any  
kind  
of longer term storage. Anybody actually use one?

Subject: Beer Barrel

Thanks to a system crash, I can't quote who mentioned the beer barrel in the last HBD. But I wanted to say this:

I've tried Beer Barrel beer once when I was visiting a homebrewer in England. The beer tasted fine - I didn't taste or smell plastic. I've been dying to get my hands on one ever since and recently found one at a place in Woburn for \$77 (Beer & Wine Hobby in Woburn, MA - and I'm not affiliated in any way except that they've gotten large chunks of cash from me).

>From what I've seen, there is much less hassle in this approach and I am looking forward to trying it out.

If anyone knows a place with these things for less than I cited above, please let me know.

Alberta mentioned this phenomenon also. The only solution, as I recall,  
is (as you said), to have a lot of headspace.

>By the way, how did they sterilize the bubbler?? Put it in bleach?? All  
>of those little pores in the stone would be a menace to get clean it  
>seems like...

I believe Alberta said to get a non-plastic bubbler, so you can boil it.  
If you use PE tubing (generally the "suitable for drinking water" tubing  
is  
PE), you can boil that too. That seems like the easiest method of  
sanitation  
to me.  
Al.

From: sami@scic.intel.com  
Subject: Homemade Wort Chiller

In answer to Chris, we made a wort chiller following the directions from an article published in Zymurgy that we heard about in the Beer and Wine forum on Compuserve. A rough summary of that article is as follows:

Go down to your friendly home handy-man supply center and buy the following: 15 to 20 feet of 3/8" o.d. coiled copper refrigerator tubing. (\$20), 2- 3/4" pipe clamps (\$.75 ea.), 1- 1/2" i.d. garden hose (50ft was the shortest I could get, \$8), and I'll assume you have 3/8" i.d. plastic hose already. If not, you'll need about 2 inches of the stuff. Now, take the 3/8" copper pipe and start to carefully bend it. Make a J type bend, much like a racking tube, at one end. This will hook on to the side of your boiling kettle. Then allow a straight length to any depth you might desire (mine's about a foot). Then start to coil the pipe to fit inside a 5 gallon pot. You can customize the size to your situation. After coiling, leave enough pipe left to come back up to match the first J bend. Be careful throughout not to kink the pipe! When you are done, you should have something that looks like the guts of a commercially available wort chiller. The J type bends at the two ends allows it to hook on to the side of a pot or bucket and keep the hard to sanitize garden hose completely out of any possible contact with the wort. Now decide how much garden hose you want on the end. I used 10 ft. Measure from the female fitting end and then cut the hose there. Now take about an inch of 3/8" i.d. tubing and shove it on to one of the ends of the copper pipe. This will act as a spacer to interface with the garden hose. Now slide a hose clamp onto the hose and then put the cut end of the hose over the 3/8" plastic hose spacer. The 1/2" i.d. garden hose should fit perfectly over the 3/8" plastic tubing on the copper pipe. Simply tighten the hose clamp on the joint. Now cut another 10 feet of hose and repeat on the discharge side of the wort chiller. Voila you have a wort chiller. Now if you want, buy a new female fitting for the 30 ft hose you have left over (about \$1.50) and you also have a perfectly good 30 foot garden hose! The female hose fitting works on my kitchen sink. This contraption will bring 5 gallons of wort to pitching temperature in about 20 min. The chiller is very easy to make (took me about 20 min.).

the  
>same time?

well, considering that my latest mead was light, sparkling, and  
had 5 lbs of oranges squeezed into it, yet one could barely discern  
the orange flavor I'd say... a lot. Oranges (and strawberries, too)  
don't seem to ferment a way and not leave much flavor in the final  
product. Definitely avoid dry hopping it. maybe try adding orange  
flavored extract - that way you could split the batch into 2 or 3 parts  
with varying amount of orange, and pick the one you liked best.

Subject: wyeast?

This weekend I crossed a new boundry; I tried wyeast instead of dry yeast.  
I am attempting to make triple stout. I made a starter for the yeast with one small can of Alexander's dark extract in about 2 quarts of water with 1/2 oz of northern brewer hops. When down, I split the what was left after the evaporation into two wine bottles. The yeast took off. By the time I was done with my real batch, the yeast was coming out of the air lock of one bottle and almost out of the other. My brew consisted of specialty malts and nine pounds of syrup and dried extracts; oddly enough, I came out with a sg reading below what I expected. I threw in both bottles of yeast, slapped on the air lock, and was on my marry-ol' way. I checked my 5 gal batch the following night. Foam was coming through the lock. I took the lock off and put in a hose to a bucket of water. Later that night when I checked it, the lid had popped off, 6 gal plastic bucket. I put the lid back on, went back upstairs, sat down, turned on the tv, BOOM. I put the lid back on three times that night before I gave up for the night. It is now fermenting actively but not blowing the lid anymore. Now, how much wyeast do you put in for 5 gal of what should a very sugary brew?

Subject: Midwest HBers Unite at Oldenberg Brewery (long)

The 4th Annual Bloatarian Brewing League's BEER & SWEAT '92  
=====

That's right, it's Beer & Sweat time. On Saturday evening, August 15, 1992, the festivities for homebrewing enthusiasts begin at suites 5110 and 181 at the Oldenberg and Drawbridge Inn Complex, I-75 and Buttermilk Pike exit in Ft. Mitchell, Kentucky. (Just a few miles down the Interstate from Cincinnati, OH)

During the day there's the amazing Oldenberg breweriana collection, several pools, other homebrewers from at least 15 clubs (our estimate is up to 300 people) from the Midwest area, brewery tours, good restaurants, and hot weather to enjoy. This event is for you if you're into homebrewing or just like being around those who are. The only guarantee is that you will sweat and there will be beer.

Bring your favorite homebrewed beer, commercial beer, etc. to the festivities for you and others to enjoy. The Drawbridge Inn has donated the use of a hospitality suite 181 by the main pool. Please keep in mind that no glass or bottles are permitted in the pool area. No problem--just pour your homebrew into plastic cups. There will be plenty of kegs and ice but please bring extra coolers.

So RELAX and enjoy this opportunity to meet many people from all levels of brewing and to share in what we at the Bloatarian Brewing League believe is the greatest time of the year.

Friday August 14  
=====

7:30 p.m.-? Those who arrive early (aka: party animals) can get started at the Oldenberg Beer Gardens with the opportunity to party later too.

Saturday August 15  
=====

a.m. You should be on your way or already there!

Noon Hospitality suites open (Suites 181 and 5110, Drawbridge Inn Complex)

3 p.m. Check in to your room at the Inn

3:30 p.m. Keg check-in at the hospitality suite

5-6 p.m. Meeting of the top dogs from the different clubs in Suite 181. If you consider yourself a mover and a shaker and are interested in making next years Beer & Sweat bigger and better, then stop by and put in your 2 cents. We would like to have each

club represented.

5-7:30 p.m. Dinner on your own. Some groups are going to the show at the Oldenberg Greathall. There are many fine restaurants in the complex and nearby.

7:30 p.m. 'till midnight Beer & Sweat at the Oldenberg Drawbridge Inn, Suite 5110. This will be the main gathering of the homebrewers and clubs. Typical draft brews from last year included: Ginger Lager, Super Steam, Not quite Munich, Sheldon Macadoo Spice Ale, Pilsner, Brown Ale, and many more..... Some of the best beers you will ever drink will be there for your consumption. Reminder: Plastic cups are the requirement.

Sunday August 16

=====

Crawl home with a real goodnbad feeling!

For information on rooms, call the Drawbridge Inn at 1-800-354-9793 and mention the Beer & Sweat activity in order to get the \$50/night room rate. A special THANKS to the Drawbridge Inn and Oldenberg Complex for all their help and support.

Subject: Lupulophobia in Milwaukee

George Fix writes:

> Jack Schmidling's generic ale was indeed clean as a whistle. I did,  
however,  
> have some stylistic quibbles with it. Jack, those high alpha Chinooks  
need  
> a generous malt charge to balance them off. I hope you had a chance to  
taste  
> Bob Jones' Brown Ale. It clearly showed how really delicious a clean  
well  
> balanced beer can be.

I was not present nor have I tasted THE GREATEST BEER MADE WITH RECYCLED  
AMERICAN MATERIALS (insert small US flag icon here :-)).  
Nevertheless, this brings up a pet peeve of mine:  
the seeming obsession with "balance" by certain figures in the AHA.

Let me say first that I respect George highly in matters of science  
(I have to, I'm not a physical scientist), but  
we part company when taste comes into the picture. To make a point,  
let's assume for the moment that Jack did NOT approach George and say,

"George, I have here a bottle of <insert AHA style category here>  
beer, how do you think it would do in competition?"

or

"George, I seem to be having a problem with mash extract, do you think  
this beer is out of balance?"

Under these assumptions (and from my experience with Jack Schmidling's  
outlook, I find it difficult to imagine him asking for such feedback)  
I find George's fatherly advice about beer styles rather inappropriate.

Bear in mind  
that I am extensively self-educated in these matters but  
I have not been through the Beer Judge Certification Program, and hence  
am not "Politically Correct". Consequently,  
when I taste such a beer, I'm able to say either "Man, that's bitter...  
I like it!" or "Man, that's bitter... I don't like it!" without feeling  
ashamed of myself. If Jack had the temerity to put a style-name  
on his beer, the better comment would be "I don't think you brewed what  
you tried to brew", although again, I find it difficult to believe that  
Jack would call his beer anything other than "THE GREATEST".

Sadly, I think the AHA in general  
is dominated by this obsession with beer style  
at the moment. What is worse, it is my unscientific impression that  
the majority of the styles are skewed toward maltiness (most AHA figures  
call this "balance").  
I have christened this obsession with balance to the detriment of  
hop bitterness, flavor and aroma "lupulophobia".

Anecdotally, lupulophobia  
seems to be \*somewhat\* more common in the Midwestern United States

and relatively rare in the Pacific Northwest. Note the number of small breweries brewing lagers in the Midwest vis a vis the P. Northwest as support for this view. I was recently enjoying a pint of the first Pilsner microbrewed in Portland, and reflecting that the impressive hoppiness would probably not be attempted in many other markets.

(Sadly, I've heard that the brewer intends to "tone it down". Commercialism rears its ugly head even here).

Finally, I wonder why George advises Jack to taste a brown ale. Was it because Jack was trying to brew such a beer? If not, I translate the comment as, "I wish you had brewed me something more like this". This is not necessarily inappropriate, since I take such things into account when I brew a beer I hope my friends will like. But again, if Jack wanted the AHA thought police to like his beer, he's not the person he seems to be on HBD.

Basically, I'm impressed by the report that Jack's beer is clean (and unoxidized?). I wish I had been around to taste it (and to get a load of the brewer's world view, no doubt :-)).

I'm looking forward to seeing HBD'ers in Portland OR next year at the AHA conference and subjecting you to a healthy dose of IBUs :-).

**Subject: AHA conference**  
Full-Name: Ted Manahan

I have enjoyed reading the notes other people have written about the AHA conference. It's always fun to have your own perceptions reinforced! In that vein, I offer my own impressions of the conference.

This was my first AHA convention. It exceeded my expectations, which were pretty high.

I was surprised by the tremendous amount of BEER at the conference! What a dummy I am, you may think - that was the whole purpose of the conference! But no, I mean really vast amounts of excellent beers, both commercial and homebrewed. Imports and domestics. Left over bottles from the national convention. Ales, lagers, lambics, dark, amber, light, wheat, fruit. Pretty much every style you can think of was represented. Let no one go thirsty! The AHA really did an excellent job getting donations from brewers and distributors for this conference. Yes, most or all of that beer was donated! More free beer than you could shake a stick at.

One of the best parts of the convention was meeting many of the well known names in our hobby. I talked at some length with Martin Lodahl and Fred Eckart, and met Chuck Cox, Kinney Baughman, Charlie Papazian, and Byron Burch. I also had the pleasure to talk with dozens of other brewers. There was a tremendous atmosphere of good will with everybody I met. Everyone was very friendly and having a great time.

The conference sessions were informative, but much of that information can be gained by reading the conference proceedings. My favorite talks were the session on Yeast by George Fix and the session on Brewing Lambics by Martin Lodahl and Mike Sharp. Other good sessions were cooking with beer, bock recipes, and ideas for running homebrew clubs. I may try out some of these ideas on our local "Heart of the Valley Homebrewers" club!

Club night was a blast! There were about thirty booths representing both clubs and vendors. There were many booths from midwest clubs, as well as booths from some of the larger clubs across the nation. Most of the club booths had good to excellent beer for tasting. I bought a beer glass from the San Andreas Malts, and was tempted by yeast cultures (50 cents each) from the Boston Wort Processors. I bought a commercial yeast culturing kit, and will offer my services to our club as a yeast bank when I figure out how to use the thing!

I'm looking forward to next year's conference in Portland, OR. As a "local", I feel a moral obligation to do my part in providing enough beer for all the thirsty conference attendees!

From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Cherries in beer

A friend has far too many cherries in her freezer, since she wants to start putting up this year's crop. I've offered to take them for adding to beer and return a six-pack or two of the results in exchange.

Given that I'm making five to six gallons:

1. How many pounds of cherries should I use in a basic pale ale recipe?
2. Should I cut back on the hops for bittering, flavoring, or both? (generally, my hoppier beers are more popular)
3. Papazian specifies that fruit ought to be added at the end of the boil. Would it be unwise or pointless to add any in secondary ferment?

Thanks for your answers in advance,

AjD

Subject: Re: English bitter info/examples

Paul Stafiniak asks about English bitter. Though an American, I travel to England quite a lot and drink prodigious quantities of the stuff, so I think I can answer some questions.

(To explain the context of my answer, I should point out that people in England, even CAMRA, don't get into the very precise definitions of beer style that Americans in general and the AHA in particular does. A beer style over there is much more likely to describe a range of characteristics, which may overlap with other beer styles. "Bitter" is a continuum, not a point.)

Bitter is the default drink in most pubs in England. Bitter is basically draught ale. Bitters tend to have roughly the characteristics that we associate with your basic ale. They are generally darker in color, lower in alcohol, and fruitier than light ales. They are usually not as sweet as milds. They are fairly well hopped, but this varies. They are bitter from both the hops and the hard water used, and they usually have a tang which is hard to describe. None are heavily carbonated. In London, beer is served practically flat. Go up North and it gets fizzier, but never so fizzy as any bottled ale.

There are several kinds of bitter that you can get in pubs:

- 1) Ordinary: O.G. around 1028-1032, not much malt flavor, not sweet, well but not overpoweringly hopped. E.g. Young's Bitter
- 2) Special or Best: O.G. around 1035-1045, a bit more malt flavor, a bit sweeter, about the same hoppiness. E.g. Courage Directors
- 3) Name varies depending on location: O.G. higher than 1040, lots of malt flavor, sweet, hopping varies. E.g. Ruddles County, Greene King Abbott.

The flavor varies a lot within each style. Webster's Yorkshire Bitter, for example, has enough hops to preserve an elephant.

The only way I have found of making something that tastes like bitter is to make a generic ale and allow it to condition in a vessel that bleeds off pressure. Those little 5 liter party cans with a spout stuck in the cork work well, but they're a pain to keep clean. One more thing: do not use Cascade hops under any circumstances. Use Northern Brewer or something like that.

The only American beer I have ever tasted which comes anywhere near to a real bitter is the bitter at the Commonwealth Brewery in Boston, MA. It is really hard to get the flavor in a bottle, but Sam Smith's Old Brewery Bitter comes close.

Subject: The World's Greatest Beer Review

Well for all those that didn't get to attend the AHA conference and are just dieing to know what J.S.'s Worlds Greatest Beer from The Worlds Greatest Brewer tasted like, I can assure you all it was not the World's Greatest. It was also not the world's worst. It tasted clean, thin and rather bland and very generic. I don't know if this was Jack's best example of his brewing technique, I assume it is since it abviously was labeled as such. I was really expecting to have to spit it out. I didn't, I just didn't finish the other 1 oz.

From: tony@spss.com (Tony Babinec)  
Subject: brewing ersatz pilsner urquell

Here are some ideas on making an all-grain ersatz-Pilsner Urquell. As this is a light-colored world-class lager, good ingredients and process are even more important than usual.

You can try one of two grain bills.

Following Dave Miller:

8.5 # 2-row pilsner malt  
0.5 # crystal malt 20L  
0.5 # cara-pils malt

OR, following Greg Noonan:

8 # 2-row pilsner malt  
1 # light Munich malt  
0.5 # cara-pils malt

Each recipe assumes 75% extract efficiency. Use the best German or Belgian pilsner malt you can find, rather than U.S. 2-row or U.S. 6-row malt. Likewise, use German or Belgian Munich malt if you can find it. In the recipes, the crystal malt and Munich malt impart some color, but otherwise will have slightly different flavoring properties.

For hops, use Saaz hops exclusively. Following the traditional German hop schedule, you can use 3 additions:

60 minutes until end of boil: 2 oz Saaz (3% alpha)  
30 minutes until end of boil: 1 oz Saaz  
10 minutes until end of boil: 1 oz Saaz

Do your HBU or IBU calculations. You could probably hop a bit more aggressively than indicated. You might make a final aroma addition of another 0.5-1 oz of Saaz right before end of boil. You also might consider dryhopping.

For yeast, use Wyeast "Bohemian" lager 2124 or "Munich" lager 2308.

Water should be soft.

For starch conversion, aim at 153-4 degrees F for 90 minutes.

Pilsner Urquell cold-conditions for months, so you might try an extended lagering.

Sj: Pubs in Cambridge

---

-----  
George, I could not mail to your address so I am making a general post. I read your post regarding pubs in the Cambridge area. I have regular business in the area and can make some recommendations.

1. There is a place called The Mill (also has a sign called Tap and Spire)  
which is located on the river Cam just down the street from the Garden House hotel. They support CAMRA and always have a rotating variety of real ale. Occasionally you might find the CAMRA Newspaper there for your reading pleasure.
2. Nearby is The Anchor. More of a college hangout (it is a college town) and they have live jazz during the week. The Boddington's and Abbott Ale are good.
3. There is a brew pub in Cambridge (I can't remember the name). I have never been there since the locals did not have much good to say about it.

In general, a good strong ale from that area is Abbott Ale made by Greene King. It has been a favorite of mine for some time. Pints of beer range from 1.25 - 1.65 pounds depending on brand and gravity. England is expensive, be prepared. Cambridge is about 1 1/2 to 2 hours by car from London. You get used to driving on the other side of the road pretty quickly.

I could go on, but Cambridge is a beautiful town and there will be plenty of exploring you'll do on your own. Cambridge is a small place and you can easily walk all over town.

Have a good trip

cheers,  
chuck mryglot

ps.  
I appreciate all the information/advice you post. I am just getting into brewing festbiers and look forward to reading your book.

From: djt2@po.CWRU.Edu (Dennis J. Templeton)  
Subject: Copper tubing lengths

Chris... here's a data point on the immersion chiller.

I made one recently with 16 feet of 1/4 copper tube (that's the longest piece they had in stock). There are probably 14 feet in the wort.

This will chill a 6 gallon boil to pitching temp (probably 80 degrees; I have been loath to put in a thermometer) in 25 minutes.

The water flow rate is about a gallon a minute; even at this low flow the water coming out is pretty cool. It warms considerably if you move the tubing or swirl the pot. I get the idea that the liquid immediately around the tube is chilled quickly and that the limiting factor is mixing.

Were I to do it again, I'd use 25-30 feet of 1/4 inch, and I think the chill time would be closer to 15 minutes. I don't see the advantage of 3/8 inch tubing since the effluent is not fully warmed. I think maximizing surface area (small tubing) is more important than total flow (large tubing).

good luck,

dennis

Subject: Re: Cheap Kegs and related hardware

u\_banzai@mcl.mcl.ucsb.edu writes:

>I have tried unsuccessfully to find cheaply the few items it takes to  
>complete a home keggng setup.

Our local homebrew club came up with the following prices.

1. 5gal used Cornelius\$35.00  
1 keg inlet connector \$ 5.25  
1 keg outlet connector \$ 5.25  
5 feet air hose \$ 2.15  
5 feet liquid hose \$ 2.15
2. Single gauge regulator, 3-D-409 \$30.00  
Dual gauge regulator, 3-D-407\$36.00  
1 tap faucet, 3-P-258 \$ 1.90
3. 2.5 lb. CO2 tank \$25.00  
5 lb. CO2 tank \$35.00  
10 lb. CO2 tank \$45.00

So for \$106.70 (excluding tax) a keggng system can be owned.

1. Brew&Grow (612)780-8191
2. Superior Products (800)328-9800
3. All-Fire Test Co. (612)332-6268 (this is a Fire extinguisher  
store, check the yellow pages for one similar near you).

BTW, don't bother calling Cornelius for kegs, they are wholesale only.  
Try looking in the classifieds under Restaurant Equipment (or Brew&Grow)

Anyone know of other places for kegs?

Hope this helps,  
rick

From: "Stephen E. Hansen" <hansen@Sierra.Stanford.EDU>  
Subject: Listserver now available at HBD Archive

In HBD 878 I announced that I had copied the HBD archives from Mthvax and had set up a new archive at Sierra.Stanford.EDU. At the time I did not have a listserver set up for those of you without ftp access. I have just finished setting up the listserver at Sierra so that you can retrieve archive files via e-mail.

Please send requests to listserv@sierra.stanford.edu. There are only a few of the possible listserver commands enabled, i.e. help, index, and get. If you are unfamiliar with listserv commands, you put one or more requests in the body of the message, one per line, and the results are mailed back to you.

For example, send

```
index homebrew
```

to get the complete listing of the Homebrew archive or send

```
get homebrew incoming/904
```

to get issue 904 of HBD.

If you have problems with the listserver send mail to

```
listserv-manager@Sierra.Stanford.EDU
```

Please be patient. The listserver on Sierra is a new beast and is not fully automated as yet and new files may not be immediately accessible.

Thanks,  
Stephen

I have heard that, but not experienced it. My process starts with throwing the fruit in the freezer at least several hours before brewing, sometimes the night before. People tell me that this breaks down cell walls, making it easier for the essence to get into your beer. I then toss this in as soon as I turn off the heat and let sit for 15 minutes. So, it may be that by starting frozen and adding to boiling-hot wort, the result is really a steeping at 170F or somesuch and thus avoiding any pectin haze--I don't know.

>>Brown Ale. It clearly showed how really delicious a clean well  
>>balanced beer can be.

>Nevertheless, this brings up a pet peeve of mine:  
>the seeming obsession with "balance" by certain figures in the  
>AHA.

Let me add my own perspective here. When I go to a meeting of my local homebrewers club and taste a homebrew, my remarks will be tailored to the skill and experience of the brewer. If it is someone more skilled or at least more experienced than I, I might say "Hmmm, how did you get it so hoppy? Ten pounds of high alpha acid hops?" and go on from there. If I am talking to someone who has only had Budmillob, maybe Guinness, and is now brewing a pale ale or bitter, I will very often suggest that they taste several other beers (commercial or fellow homebrew examples) and see if there is something there they would prefer. Then I can make suggestions on possible changes to recipes or processes, if they desire.

In Jack's case, I would have also recommended he try other beers that I thought were good, because he has only recently been exposed to good homebrew.

Finally, whenever the issue of "stylistic quibbles" comes up, you can expect that ten people will have at least a dozen opinions on it. As a general rule, balance is a good thing, though it can certainly be overdone. Luckily, the local homebrew club has plenty of people who know nothing of balance and brew that way, just to keep the rest of us in line.

From: cook@uars.DNET.NASA.GOV (Chris Cook, NMOS Quality Engineer - (301) 386-7807)

**Subject: Spruce Beer Questions**

I have made many beers using spruce extract and I like them a lot, but I've got some questions about technique.

The first spruce-flavored beer I made was Papazian's Goat Scrotum Ale, simply as a lark. I added the spruce essence (1 oz) at the beginning of the boil, as directed, and the kitchen was filled with this marvelous aroma that I'd never have connected with a tree.

The beer was great. The spruce was surprisingly subtle, and I strongly recommend it for those who like richly flavored beers. I've made a batch every year or so since then.

This year I had a brainstorm. Hey, I said, I love the smell during the boil, but am I boiling off all those great aromatics? What if I added the essence at the end instead of the beginning?

So it goes. I added the essence with the finishing hops (shedding a manly tear for the lost smells) and proceeded as usual, although I did a little dry-hopping this batch. Looked good so far. When I sampled the ale a week later I realized that I had been right - the batch was more aromatic.

Much more. I still like it, but I'm afraid that it'll be too strong for my guests. This is a major disappointment, since this style was always one of my 'show-off' beers for new homebrew drinkers. I hope things mellow with age.

My question is about timing. When should I add the essence and how much should I use? Are there two options (add lots early or a little at the end)? Anyone played around with this?

Subject: English Bitter

In HBD #905 Eric Pepke gives a good overview of English Bitter. I would like to add two things:

1) Eric Says:

> One more thing: do not use Cascade hops under any circumstances. Use Northern Brewer or something like that.

Also try Fuggles for bittering and Kent Goldings for Finish. Both are excellent.

2) He also says:

>The only American beer I have ever tasted which comes anywhere near to a real >bitter is the bitter at the Commonwealth Brewery in Boston, MA.

I cannot agree more! Since my only trip to England (darn!) I have been on an unending quest for English style ales especially Bitters. This quest alone started me homebrewing. Only a week after my trip to the U.K. I had a chance to go to the Commonwealth Brewery in Boston and tried their bitter. It is very good and the best at emulating real English bitter that I have found in the U.S. TRY THIS BEER!

No, I'm not even lucky enough to work for them! I just like the beer.

Cherries, on the other hand, do not totally ferment away.  
I brewed up a 6 gal batch of Cherry Bock with 10 lbs of Dark X  
and 6 lbs cherries, and you can definitely taste the cherries  
through all the malt. It's been aging for just over a year now.  
The beer forms a nice pink head, and if you look close, you can  
watch the red "bleed" away in little rivulets.

> 3. Papazian specifies that fruit ought to be added at the end of the

ferment?

You add it to the hot wort at the end of the boil to sanitize the  
fruit as much as possible without turning into jello by boiling it.  
If you add it after the wort cools, add a few campden tablets to  
the cherry slurry, let sit a few hours, and then mix with the  
wort, or if you haven't pitched the yeast yet, add the tablets to  
the entire mixture, let sit, and pitch.

>Thanks for your answers in advance,

>Ajd

The latest issue of Zymurgy has an entire article about this subject. I found the suggestions quite surprising compared to fruit beers I have tasted in the past. Some real interesting ideas.

He suggests something like .5 to 2 pounds of cherries per gallon. Use as light of malt as possible, and hop as little as possible. If I remember right he suggests cutting the hops down to 1/3 of what you would normally use. He makes some comments about Papazian's method of adding fruit at the end of the boil and also talks about adding the fruit after the wort has cooled and aging the beer with fruit.

Since all kinds of fruit are now available, I was thinking about trying several of his methods to see which I would like better. I was quite surprised to read that aging with fruit would probably result in a surface infection which is unsightly in the bottle. He says that if you use a keg, you draw from the bottom first and can't see the mold so it doesn't matter (!). He claims you can't taste the mold that forms. This seems to go against just about everything I have learned about brewing to date and has me really curious.

Beers of all styles should have a balance between sweetness and  
bitterness,  
malt flavor and hop flavor, malt nose and hop nose. This balance is  
different for each style of beer. For example, in the Munich Dunkel  
style,  
malt dominates and in the India Pale Ale style, hop bitterness dominates.  
Don't blame the AHA for the figures listed, they are a compilation of  
data collected from analysis of typical beers of the style. Note that  
both the gravity and IBU values in each case are a range, to account for  
differences among breweries and regions.

>as support for this view. I was recently enjoying a pint of the first  
>Pilsner microbrewed in Portland, and reflecting that the  
>impressive hoppiness would probably not be attempted in many other  
>markets.  
>(Sadly, I've heard that the brewer intends to "tone it down".  
>Commercialism rears its ugly head even here).

Actually, historically, breweries in hop growing regions have a tendency  
to  
brew hoppier beers. This is not surprising. It's not fair to say that  
the hop rates in the Pacific Northwest are the correct ones and that the  
hop rates in the Midwest are too low. There are regional differences in  
beers throughout the world. Consider Brown Ales in Northern Great Britain  
and in Southern Great Britain.

>I'm looking forward to seeing HBD'ers in Portland OR next year at the  
>AHA conference and subjecting you to a healthy dose of IBUs :-).

>

> -- R. Al Marshall

I too am looking forward to the conference, visiting Portland, OR and  
getting a healthy dose of IBUs. I love hops and hoppy beers. Also, I  
appreciate (and support) the regional differences in beers.

Al.

Subject: Reading SG from wort after it's in the Carboy?

A while back I started having problems with contaminated batches, so I switched from dry to liquid yeast and also recently switched from a plastic primary fermenter to a glass carboy... The difference has been phenomenal! I've brewed four straight batches with this setup that have all had superb results!

But there is one problem with this setup over the plastic setup: How do I take SG readings?

I've tried using the blow off to read my OG but I'm convinced the stuff that's blown off is not representative of the whole batch. (i.e. I've gotten results that must be incorrect: Stuff like <1.030 for a 5 gallon batch with 8lbs of amber extract, 3lbs of specialty grains, etc. and a very large variance (sometmes down, sometimes up (!)) over short periods of time in SG readings.)

And for FG, the blow off has stopped so I don't even have that to work with.

I can measure FG at bottling time but by that time I've already siphoned it out of the carboy so if it has not actually reached its FG I have to bottle anyway. This happened to me recently on an otherwise great Bitter, the result was a very over-carbonated beer since it had to finish fermenting in the bottle (fortunately none blew up)! If the beer isn't ice-cold it will gush and even if poured carefully it has mega-head which takes a while to dissipate to a drinkable level.

So, does anyone have any sure fire methods for measuring SG when brewing malt extract recipes with glass? I want to minimize the risk of ruining a batch since that's why went to the trouble of switching, but I still want to know when I can bottle and how much alcohol my beers contain (seeing as how this is *\*invariably\** the first question a non-brewer asks when sampling one of my beers. sigh).

Arthur,

> 1. How many pounds of cherries should I use in a basic pale ale  
recipe?

...  
> 3. Papazian specifies that fruit ought to be added at the end of the  
>boil. Would it be unwise or pointless to add any in secondary ferment?

A friend and I tried strawberry beer loosely based on Papazian's  
recommendations. We added 10 lbs of crushed frozen berries after the boil  
for the primary fermentation. Then we added 5 lbs of crushed frozen  
berries  
to the secondary. I don't know how much the second addition affected  
things, but we have received a number of good comments on the finished  
product. We also switched to Cascade hops in regular quantities.

Question: How do I get a copy of the Conference proceedings from the AHA  
this year? I was stuck on a trip and couldn't get there, but I am  
interested in several of the topics that were covered.

Subj: American Classic DME

Folks,

Please ignore the other post, I sent an old file by mistake ...  
this is what I really meant to say ...

Folks,

I recently received a catalogue from American Brewmaster. They advertise a brand of DME called "American CLassic (insert Trade Mark thingy here)". They also make a few claims that I'd like to run by all youse on the Digest for comment ...

It goes like this ...

...Our stuff is excellent, blah blah blah ... "and the worts are concentrated using the most technologically advanced, high vacuum distillation process, assuring you" blah, blah, blah ...

"... Higher quality control during the malt extraction produces a cleaner malt. You will therefore notice a reduced trub level in your primary fermentor and as much as a 50% reduction in sediment in the bottle with single stage fermentation. Trub is a major source of off-flavors in beer through the production of esters and fusel alcohols."

There was a recent thread about Trub producing off-flavors, but I seem to recall that it ended in a hung-Digest?

Has anybody got any theories as to what effects (and why) this high-vac distillation will have on the body and clarity of the finished beer? Anybody tried this stuff? It's not just American Eagle under a different name, is it?

Send to me and I'll summarize,

Later, -Chuck-

From: gummitch@techbook.com (Jeff Frane)  
Subject: Al Marshall, Hops and Balance

Al Marshall launched a typical Portland-area tirade, based on his impressions of George Fix's comments on Jack Schmidling's World's Greatest Beer. Having not only tasted WGB, but being a Portland-area hopfreak and a BJCP judge gives me a little room to move here, I think.

Al, you know how much I love hops and you also know I agree with you about the attitude toward hoppiness outside the Great NW. But... George didn't not say the beer was too hoppy, he said it was out of balance and needed more maltiness to weigh up against the bitterness. I tasted that beer and I think George understated the problem; Bob Jones was a bit crueler but more on the mark.

More to the point, I think you are wrong in general: I think bitterness is great but when it exists in a (sorry, Jack) thin and otherwise flavorless beer, you don't get good beer. It's not a question of being out of style; it's just a question of whether it tasted good or not. Jack's beer wasn't contaminated (which is good, but I would expect that of any brewer who had made more than a couple of batches) but it also wasn't tasty. As far as I'm concerned, a beer that has only one flavor element--bitterness--is missing the boat. I think it could have been improved considerably--not necessarily by adding a lot of malt--but simply by bringing in some other flavor elements. With all that bitterness, a profundity of hop flavor would have made for a better beer.

It is true, folks, that the Midwest suffers from a sort of lupuphobia; by the last night I was stumbling around, sobbing pitifully for some hops. Some creep snatched the last bottle of Liberty Ale from before my eyes at the Banquet, risking death and dismemberment. Good thing I'm a nice guy.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Wyeast/High gravity beers

In response to the query about Wyeast cultures and high-gravity beer, I'd venture to say that the problem isn't the yeast, but the procedure. You're building up a lot of pressure in the plastic bucket, and it's hardly surprising you're going to get stuff spewed all over the place. This happened to me when I brewed my batch of Elbo Nerkte (allegedly) Brown Ale.

I'd suggest doing it this way: put the wort into your bucket and place the top on but don't seal it up. That's right, just lay the sucker on there, and put a piece of tape over the fermentation-lock hole just to keep gunk from getting in. If it makes you feel better, you can put a VERY LIGHT weight on top to keep the cat from getting in. This will allow you plenty of ventilation for the CO2 to escape, and the likelihood that other stuff will get in is quite small, particularly considering that the CO2 will create a modest positive pressure in the bucket--thereby keeping various biological bugs on the outside.

Once the kreusen has fallen (or close to it), rack the beer into a carboy. By this time the most ferocious activity will be over, and you won't be losing your wort on the floor. You'll also leave behind a fair bit of scum and have yourself a cleaner beer. By the way, there's no reason you can't peek into the bucket from time to time to see how the kreusen is coming along. Some people will even use a sanitized spoon or skimmer to take the foam off (it carries dead yeast, oils, and other stuff, I'm told). And of course, relax and don't worry. Especially about having to mop the floor.

Subject: Midwest beer and a request

Greetings all,

After reading the various reports on the AHA conference, I'm sorry (mostly) that I was unable to attend this year. Lest the wrong impression, that hops are unknown in the midwest, be left with too many digest subscribers, let me suggest that all you hopheads seek out, drink, and savor both the August Schell Pilsner, and the Capital Special. Unless the recipes have been radically altered of late, I think you will find that both of these fine MIDWESTERN lagers feature an adequate hop character. A noted British beer expert has commented that Capital brews ". . . a Pilsener called Special \*\*->\*\*\* that has lots of hop taste . . ." A couple pages later, this same expert notes that Schell's "products include a good, hoppy Pils\*\*\* . . ." I'm sure that there are other hoppy beers brewed in the midwest, these just happen to be two of my favorites, and two which should give the lie to the notion that midwest micro-brewed lagers are generally lacking in hop character. On another note, I'll be travelling to Baltimore in early August for the American Agricultural Economics Association's annual meeting. So far, I've uncovered a few possibilities for nighttime relaxation and recovery from the days' presentations of esoteric research papers: Baltimore Brewing Company, Sissons/South Baltimore Brewing, and perhaps Bertha's Mussels (reputedly serving a cask-conditioned Oxford Ale from British Brewing Company on the weekends). I welcome private e-mail evaluations of all, or any, of these, suggestions for other possibilities for an enjoyable evening's beer drinking, and information on good retail beer outlets. Ooogy wawa,  
Dr. John

From: KIERAN O'CONNOR <OCONNOR%SNYCORVA.bitnet@CUNYVM.CUNY.EDU>  
Subject: Wort Chillers and Kegs

Regarding wort chillers. I'm a high school teacher and I paid (with Brew) our district plumber to make mine. I bought 50 feet of copper tubing @ 37\$. I also bought all the fittings as described in Tuesday's HBD. Two thoughts:

1) Because I have more tubing, mine cools a lot faster. I can get wort from 212 to 50 degrees in 18 minutes. That's a little faster than what I have read.

2) I have these quick connect garden hose connections (bought from my friend Dwight's suggestion). You hook them to the hoses and to the chiller. Then you don't have to worry about twisting the hoses to connect them to the chiller and to the faucet. I would get the brass ones, they are more expensive, but I would figure more durable too.

3) You might think about a counter flow chiller. It is better in that you chill parts of the wort to 50 degrees or whatever, and the rest of the mass is at 200 degrees, preventing infections. However you have to deal with filters, and sterilization etc.

On Kegs:

1) Go to a restaurant and see if they will sell them to you for a meager price. Dwight went to a local joint and they would be happy to part w/em for 10\$/keg. You may be able to do better/worse, but it's cheaper than new ones.

Subject: English Bitter styles

Hi

I had just joined this list and spotted:

> I'd like some info on the English bitter ale style. What  
characteristics  
> define an English bitter?

Eric Pepke replies well, and observes "Bitter" is a continuum not a point.

I offer the following definitions for your thoughts. It is true that precise beer style definitions are not normally produced, but the homebrewers over here do just that. The National Guild of Wine and Beer Judges (NGWBJ) is the organisation to which 'certified' amateur judges belong and they publish, for the guidance of judges and competitors, a small book which includes the these definitions:

Light Ale.

The term 'light' refers to the flavour and not colour, so with an OG of 30-35 and alcohol level of 3-3.5%, the colour may vary from straw to amber.

The beer should have a bouquet light in hop. The taste should be clean, dry and lightly hopped with no flavour components too prominent.

Pale Ale or Bottled Bitter.

OG should be from 40-45 and the colour from golden to deep copper. The aroma

of hops in the bouquet should lead to those of malt and grain. The flavour

should be full, malty and grainy with a hoppy bitter farewell and perhaps

a little sweetness from residual dextrins. Alcohol content ranges from 4-5%.

India Pale Ale.

This full bodied premium bitter has an OG of 50-60, and a rich golden to deep copper colour. The bouquet should be hoppy, alcoholic and grainy.

The flavour should be full, malty and grainy with a prominent hop and a clean bitter farewell. There should be a little residual sweetness to balance the hop. Alcohol content is from 5-6.5%.

These are, therefore, the definitions to which the amateurs work, but they do not always translate directly into the commercial arena. For example, most

pubs would regard 'light ale' and 'pale ale' as synonymous. Also, historically IPA was the premium bitter as we describe it above, but it is now often the name given to the 'ordinary' bitter in a pub.

> One more thing: do not use Cascade hops under any circumstances.  
> Use Northern Brewer or something like that.

I personally don't use Northern Brewer as it can be a little aggressive on the palate. As others have observed, it is difficult to beat Fuggle or Golding on the nose of a good bitter.

From: pbacon@CVEDG.Prime.COM (Phil Bacon)  
Subject: Beer Barrels

I am a plastics brewer(imperial measures),

Glass would be nice but so easy to loose 5 gall of sticky mess all over my kitchen floor more than enough to run all over the living room carpet.

I use a 6 gall plastic pail for primary,

For secondary i have the option of using polypins(3).

These are very handy plastic containers that hold about 36pints(when full)

they are a cube with a tap, replace tap with airlock one secondary fermenter.

They have a cardboard container which is stiff enough to carry around so they are easy to move. They compress so out goes all the air before the tap/lock goes on. NOTE : They are not PRESSURE vessels so LOW pressure only.

The source for these is my local brewery they sell beer in them(#40ish). Second hand empty about #2 (\$3.60)

I also use them for dispensing my dry still ciders. When the need arises i use them for taking larger quantities to parties "brite"(sp).

I have 3 barrels a roto-keg,edme and Boots(edme i think). They all have CO2 injector system and pressure release valves. The key to stopping leaks is to set the spring loaded valve correctly(if it leaks loosen next time)

Use without pressure release valve = leak

My process is rack into barrel prime close lid and wait, after 2 weeks check condition when ready drink. when priming sugar all used up add a little CO2 out comes some more beer when finished clean sanitize start again. (can often get away with no added gas).

The nice thing about the barrels is they have a float so you can use the clear beer at the top and follow it down to the base of the keg. Use without the float takes a little longer to clear but gives the beer more time to condition but will require more gas as the contents is used. I have had beer in the kegs for upto 6 months without any ill effects.

COST NEW about #20 for the boots keg. If anyone is realy interested i can get prices for others and accesories but there must be someone in the UK that reads this digest that knows. Second hand #5-#10 depends if the seller knows how much a new one is.

I bought my roto-keg for #15(new) the others i got from the growing number of EX homebrewers - MARRAGE + HOMEBREW = MORE Kit for me(i love weddings).

I have a co-worker who works in MA. will take any plastic kegs that are taking

up the valuable space in your garage ;-)

From: sami@scic.intel.com

Subject: Spruce Essence, etc . . .

Chris asked about timing of spruce essence. We made a batch of Papazian's Spruce Ale last February, having read what a treat it was supposed to be. The airhead that I am, I walked out of the brewing store and left the spruce essence on the counter and didn't notice 'til we were ready to add it. I called the guys at the store and they said not to worry, pick the stuff up the next day and just add it during the primary. MISTAKE!!!!

When

we opened the first bottle four weeks later, the familiar aroma of Pine Sol

floated through the apartment. This batch has mellowed somewhat since then.

I tried it two days ago and it still has a strong spruce flavor. Maybe it will mellow with the years . . . Next time I'll try it like you did.

After a week in Milwaukee it appears many have tired of malty/sulfury lagers. Jay, I think the use of Pabst with its elevated DMS levels did not get things started off on the right foot! I bet, however, after a week in Portland some will tire of the floral Cascade West Coast taste. For the record, I greatly admire good beers in both styles. Right now, I crave the original, namely cask conditioned English ales. Someone point the way to Burton!

>much alcohol my beers contain ....

Well, we've got a method, but I'm not sure it qualifies at "sure-fire."  
We use a glass turkey baster to pull out enough beer to fill a test-  
tube,  
which just fits the hydrometer. The baster has a rubber squeeze bulb  
which can be disconnected from the glass tube for easy sterilization.  
Most basters these days have plastic bodies (probably for safety reasons)  
but you could sanitize them if you make sure the bulb separates.  
I got mine at a garage sale (for 25 cents!) but it is vintage 1950's.  
Make sure you squeeze the bulb before you stick the end into the carboy  
to avoid forcefully blowing nasties into the headspace.  
Of course, after all these precautions, sometimes the master brewer then  
tosses the contents of the test-tube back into the carboy (heresy, I  
know,  
but never a contaminated batch...). Oh, and another thing -- make sure  
the extract/water is really well mixed up before taking readings. Hope  
this helps...

So am I. Don't trust SG readings based on blowoff.

> So, does anyone have any sure fire methods for measuring SG when  
> brewing malt extract recipes with glass?

Why is it any more difficult to take SG readings in a glass carboy?  
Did you formerly put the guage straight into the wort, and now can't  
do that because of the narrow opening on a glass carboy?

We take readings by sanitizing our siphon tube and siphoning out enough  
wort to fill a 100ml graduated cylinder, into which one of those SG  
guages  
fits very neatly. We don't even have to formally start the siphon,  
because  
one tube's worth fills the cylinder enough to take a reading (don't need  
to  
fill it all the way, since the guage itself displaces some). Any tall,  
thin container should work.

Other ideas:

- Avoid taking SG readings without reason, since it is just another  
opportunity for infection. We only take SG readings at pitching time,  
whenever we transfer to secondary or bottle, or if we suspect something  
is wrong.
- Go ahead and drop the SG guage into the carboy anyway! In this,  
the glass carboy is better than the plastic because you can monitor the  
SG throughout the ferment without opening the carboy again! The only  
problem is getting it out again, but a) you can wait until after  
bottling,  
at which time the carboy will be empty; or b) we have had good luck  
fishing  
it with a bottling wand. As your guage bobs proudly in five gallons of  
fermented beer, push the wand over the tip of the guage, tilt sideways,  
and gently pull the guage out.

Enjoy,

Subject: English Bitter, etc.

Allan Wright and Eric Pepke justifiably recommend a visit to the Commonwealth Brewery in Boston. The Burton Bitter is a mandatory pint for any beer-loving visitor to Beantown. Alas, many HBD'ers don't make it East very often.

Luckily, there's a Midwest alternative -- the Bishop's Bitter at the Sherlock's Home (yeah, yeah, it's a dumb name) brewpub in suburban Minneapolis, MN (in Minnetonka). It's the best (to my taste, at least) of their four standard fined and hand-pumped beers (the others are a Scottish Ale, a porter, and a stout). You'd be hard-pressed to find a more authentic British pint served in the U.S. And yes, it even has enough hops to satisfy a Portland homebrewer!

Finally, I'd also like to say how much fun it was to match the faces up with the net addresses at the AHA conference. Hell, even in those cases where we had actually met before, our network connection added a new element for lively discussions and great laughs. Hard to believe, but Jack and his Arf Generic are no longer "Chicago's Own" -- it's about time we shared him with the world...

And for those of you who did NOT mistake me for Jeff Mendel, a hearty thank you.

From: bgros@sensitivity.berkeley.edu (Bryan Gros)  
Subject: yeast starter karausen

In answer to questions from a few days ago, the way I tell when to pitch from my yeast starter is by looking for bubbles.

There is usually only a very small layer of bubbles on the surface, but if you look close at the "beer", you'll see a lot of bubbles rising through the beer to the surface. Then you know the yeast is very active. Of course if you use a dark bottle, then it will be harder to tell. Maybe hold it up to a window.

From: korz@iepubj.att.com  
Subject: Cherries lost in the snow

Regarding the article on fruit in the latest Zymurgy, which suggests 0.5 to 2 lbs of cherries per gallon, I have another data point. I used a 96 fl. oz. can of Cherry Wine Base split between two 5 gallon batches. The net weight was not given, but the gross weight of the can was 6.5 lbs. The cherries were whole with pits included. There was a medium, dark red "syrup" in the can along with the whole cherries. There was no indication as to the composition of the "syrup."

I hypothesized that if this can was meant to make 5 gallons of cherry wine, then it should have enough flavor to add some subtle cherry notes to two 5 gallon batches of beer. Not so.

The first batch was a sweet stout with 6.6 lbs of John Bull unhopped Malt Extract syrup and some crystal malt. I added the 48 fl. oz. immediately after turning off the heat. The resulting beer had no cherry flavor or aroma. In fact, I entered this beer in the AHA Competition and it scored a 38.

Suspecting that the CO2 produced during fermentation scrubbed the cherry aromatics out of the beer, I decided to add the second half of the cherries (stored in a glass jar in the fridge for 10 days) in the secondary of a lightly hopped (by midwestern standards :^) pale ale. I boiled up two quarts of water and then added the cherries to it to "sanitize." The resulting beer had a slight tendency towards an orange color, clarity was fair-to-poor, a little bit of cherry aroma at bottling time (none after conditioning at 65F for two weeks) and the cherry flavor was so slight, that if you didn't know it was supposed to be a cherry ale, you would blame esters for the fruity notes.

My contention is that, at least with canned Cherry Wine Base, 0.6 lbs/gallon is not enough and even 1 lb/gallon may not be enough either.

I'm off to Michigan tomorrow morning to pick \*fresh\* cherries, if the blasted birds haven't beaten me to them.

Al.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Beer Snobs

To: Homebrew Digest  
Fm: Jack Schmidling

> -- R. Al Marshall  
>Subject: Lupulophobia in Milwaukee

>Basically, I'm impressed by the report that Jack's beer is clean (and unoxidized?).

But of course, what you do not know is that I had previously agreed to write a glowing review of the Fix's new book. :)

From a philosophical and political viewpoint, I think your comments are most poignant. However, having been present at the tasting in person and being the Master Brewer of the beer in question, I can assure you that the comments on balance (or at least hoppiness) were probably appropriate.

First of all, watching George's lovely wife stick her nose in the beer and snort like a rhino really made one believe they were serious. When she came up for air and pronounced it clean, a new era was ushered into the world of homebrewing and church bells rang round the world.

Their comments on the hops actually were an impressive insight into their credibility as judges of beer and my own growing taste awareness. Please understand I mean judges in the common usage, not the politically correct, AHA approved type.

That particular batch of beer, AGA #23 was an experiment in hoppiness. My standard hopping rate has been 1 oz Chinook and .5 oz Saaz. Wanting to get a feel for the effect of hops in beer, I doubled the Chinook in this batch to make sure I would not miss it if the difference was subtle.

Our impression of the beer was that it is great with popcorn but if tasted with a clean mouth, it is a bit too bitter for our taste. However considering the fact that Marilyn and I usually have a bowl of popcorn with our daily glass of beer, it seems appropriate for a "popcorn style" ale. We, like most people, share our beer with lots of brainwashed Americans and most of them probably would also find it too bitter.

So the comments on hops are not surprising. We simply brought the keg that was next in line, not one specially brewed to impress convention folk.

The comments on maltiness are far more interesting to us because this batch also was a departure from our normal generic pale malt. We substituted 5 pounds (1/2 the total) of expensive, imported "Munich malt" for the .55/lb

Harrington we buy from Minnesota Malting. We were unimpressed with the difference. In fact, when comparing it with the standard, we either could not tell the difference or preferred the standard.

So, in summary, I am glad the Fix's were there to taste it and I am glad there are people out there willing to put beer snobs in their place. But you may rest assured that beer snobs, the Fix's most assuredly are not.

>From: melkor!rick@uunet.UU.NET (Rick Larson)  
>Subject: Re: Cheap Kegs and related hardware

>BTW, don't bother calling Cornelius for kegs, they are wholesale only. Try looking in the classifieds under Restaurant Equipment (or Brew&Grow)

Anyone know of other places for kegs?

I bought my first keg through the mail for \$35 plus shipping. On my next trip to the scrap yard where I buy my aluminum for MALTMILL castings, I spied a mountain of Coke kegs under a snow bank. I offered him \$5 and he glowed like I really blew it. I took two home to see if they were any good and when I got around to going back for more, they were of course, gone.

The good news is that he had a few more the next time I went for aluminum.

So I suggest checking out scrap yards, you may get lucky but start by offering a buck. Is that cheap enough?

js

Hope this helps,  
rick

From: lee\_menegoni@ptltd.com  
Subject: Fruit beers info compilation

I would like to thank all the people who responded to my post. Below is a list of common threads found in the replies regarding fruit beer which may be of help to those you planning a fruit beer.

Use a light bodied beer recipe, OG mid 30s, and light extract or grains since:

- the fruit taste is subtle and can be easily over powered.

- the fruit will also add additional fermentables.

Use very little hops since rasberies and cherries add bitterness.

- 1 oz max in 5 gallons at 60, 30 and 10 minutes Cascade, Saaz, Hallertaur

- e.g. The 1990 AHA Fruit beer recipe used 1/2 oz of Saaz in 3 1/6 oz additions for a 5 gallon raspberry beer

Use at least 1 lb of fruit per gallon brewed.

- for strawberries and peaches 2 lb per gallon is suggested

- fruit beer isn't cheap to brew if you buy the ingredients.

Do not boil the fruit, add it to the wort after the boil

- the boiling process will destroy the taste

- boiling also causes problems due to the pectin in fruit, pectin puts the gel

- in jam and jelly.

Do not add whole fruit.

- crush it or chop it up, others suggest freezing berries to cause the cell

- walls to break but why go to the expense of fresh fruit if you plan to freeze. IMHO fresh berries smell and taste better than frozen.

Other suggestions / comments:

Add pectic enzyme when you add the fruit.

- I found beer/wine stores that sold it, it is used in making fruit wine, but

- nobody knew how to use it, ie what it does, what temp, how much per lb fruit.

Add more fruit to the secondary.

- I wonder what effect adding more fermentables, fructose, will have late in

- the fermentation. The intent is to add aromatics like dry hopping.

Place the fruit in water with 1 campden tablet, for S02, for 1 hour to sanitize

- Others feel that well washed fruit placed in hot post boil wort will kill the

- contaminants and that sulfur even in small quantities, parts per billion, can

- have negative effects on taste.

Ferment the whole mess since you can't separate the liquid from the trub/solids. The trub/solids will settle out during the primary fermentation.

In principle I disagree with this since trub is supposed to cause fussel alcohol production. My expeience with 1 batch of strawberry beer, 8 lbs berries = 3.25 quarts of berry puree in 4.5 gallons of wort, was the pureed

berries and trub settled out into a thick layer which was about 1.5 gallons of trub / pulp / liquid in about 4 or 5 hours ( I refrigerated the wort trying to get near 32F per Miller's suggestion to maximize precipitates.

Date: Fri, 19 Jun 92 23:02:55 EDT  
From: jdg@grex.ann-arbor.mi.us (Josh Grosse)  
Subject: Fear, Uncertainty, and Doubt (FUD) over trub

In Friday's HBD, Chuck Kenyon asked about some marketing boilerplate for American Classic DME:

>"... Higher quality control during the malt extraction produces a  
>cleaner malt. You will therefore notice a reduced trub level in  
>your primary fermentor and as much as a 50% reduction in sediment  
>in the bottle with single stage fermentation. Trub is a major  
>source of off-flavors in beer through the production of esters  
>and fusel alcohols."

>  
>There was a recent thread about Trub producing off-flavors, but I  
>seem to recall that it ended in a hung-Digest?

A couple of months ago I'd summarized the reasoning behind Miller's recommendation:

Leave your wort sitting on top of the hot and cold break material during the respiration phase (8-12 hours), then rack off the sediment.

I'd have to go back to the old HBD to look up the specifics, but I remember the generality quite clearly:

During respiration, cell production uses lots of trub components and your lag time will be reduced. Afterwards, the trub is harmful by contributing to overproduction of fusel alcohols and esters (which are combinations of fusel alcohols and fatty acids).

>Has anybody got any theories as to what effects (and why) this  
>high-vac distillation will have on the body and clarity of the  
>finished beer? ...

The only theory I have is once again stolen from Dave Miller: higher vacuum means lower boiling point, which equals less caramelization.

Should there be less trub? I'd have to refer to Fred Scheer, Brewmaster and Technical Director of the Frankenmuth Brewery, and industry consultant. I guess all those BJCP classes paid off. I believe I recall his comment that you should have something less than 20% by volume. I hope this helps.

From: synchro!chuck@uunet.UU.NET  
Subject: BBC vs BBC lawsuit

Since this lawsuit seems to have national interest, I thought I'd let you all know the results.

Background: The Boston Beer Company (contract brewer/microbrewer) recently sued the Boston Beer Works (brewpub) for \$1,000,000 for trademark infringement. This lawsuit made the front page of at least one of the local newspapers. I wrote a letter to the court expressing my opinion that the lawsuit was baseless.

During the course of the 1 day trial, Jim Koch threatened to sue Boston Beer Brands (distributor/wholesaler) and the Commonwealth Brewery (brewpub). Why Commonwealth? Because they used the word "Boston" in the name of one of their beers.

In the surprisingly quick trial, the judge ruled against the Boston Beer Company. They have 20 days to appeal. The judge reportedly issued a 20+ page ruling stating that "Boston" and "Boston Beer" were generic names and could not be protected. For reasons that escape me, I have been asked not to read the ruling until the appeal period has expired, as I may be requested to testify if there is an appeal.

I'll let you know if the BBC is actually stupid enough to appeal, or if there is anything interesting in the finding when I get to read it.

From: Nick Cuccia <cuccia@remarque.berkeley.edu>  
Subject: Southside Steam Beer

This is a steam beer recipe that I created last month. It's not quite as hoppy as it should be; this is largely due to my not correcting my hop util. for whole hops. Nevertheless, this is my best brew to date (although the porter I've just bottled may surpass this one).

Southside Steam Beer

5 Gallons

8# Klages malt  
1# light munich malt  
1/2# 10L Crystal  
1/4# 40L Crystal  
1/4# 80L Crystal  
2 oz Northern Brewer Hops (Whole) (7.5% a)  
1T Irish Moss  
Wyeast #2112 Calif Lager yeast in 1/2 gal starter

Mash Schedule: Elapsed Time  
Mash-in @ 130F/Protein rest @ 122F :00  
Starch Conversion @ 150F :30  
Starch Conversion @ 156F 1:30  
Mash-out @ 166F 2:00  
Sparge @ 170F 2:15  
Finished 3:15 //stuck :-(

Boil Schedule:  
1/2 oz NB :00  
3/4 oz NB & Irish Moss :30  
3/4 oz NB :55  
Chilled 1:00

Ferment Schedule: Days Lapsed Gravity  
Pitched yeast Slurry 0 1.054  
Racked 11 1.010  
Bottled 16 1.010

The beer, appearances-wise, is a dead ringer for Anchor Steam; my SO could not tell the two apart on the basis of appearance. As I mentioned, the hop flavor isn't as strong as it should be. In any case, darn nice beer.

Date: Mon, 22 Jun 1992 10:45 EDT  
From: Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU>  
Subject: Sterilizing counter-flow chillers

>:Wort Chillers. OK, I am ready to take the step. The immersion  
>variety seems more practical from a sanitation standpoint. I like the  
idea  
>of keeping it clean, but sterilizing it just before use by inserting it  
into  
>the boil for a few minutes before turning the water on.

Oh, well. Thought I'd do my part to dispel the ever-present notion  
that counter-flow chillers are impractical or difficult to keep sterile.

When I finish using my counter flow chiller, I drain the chiller body  
of water and siphon boiling hot water through the coils to cut the  
malt sugars. I then follow with some of my clorox sterilant solution  
and let it sit for about 30 minutes. Drain and store.

Before using the chiller for the next brewing session, I fill it with  
sterilant again and let it sit for 30 minutes. As if this isn't  
enough, before I actually start chilling the wort, I siphon the  
boiling hot wort through the copper coils until the wort runs boiling  
hot out the bottom. (If boiling hot wort is good enough to sterilize  
immersion chillers, it's good enough to sterilize the counter-flow  
chillers or else I'm missing something.) I then fill the chiller body  
with water, return the collected wort back to the boiler and proceed  
with the chilling procedure. I've used counter flow chillers for  
eight years and have never had problems with contamination.

Add to this the fact that copper is used to sterilize swimming pools  
because it has anti-bacterial properties (or so I'm told) and I've  
never worried an iota about contamination with my chiller.

The following points are somewhat technical but I might add that  
counter-flow chillers have several things in favor of them over  
immersion chillers. (1) Shocking the wort cool produces better cold  
break. (2) Since you can start siphoning immediately after finishing  
the boil, it's a time saver. And finally (3) I'd argue that there is  
less chance of bacterial infection with the counter-flow chiller  
because any one drop of wort is going to go from boiling to pitching  
temperature in about 6 seconds.

The down-side, of course, is that counter-flow chillers are both more  
difficult to make and, if you buy one, are more expensive.

>From a purely technical point of view, I think counter-flow chillers  
win out. But from an economic perspective, immersion chillers are the  
winner.

But whatever the case, use one or the other. Wort-chillers are  
essential to any homebrewery.

The AHA conference was indeed a blast. As mentioned by others, it was  
great putting faces to email addresses. There must have been ten  
times the number of online brewers at this conference compared to last  
year so there's no way I can make disparaging comments about those I  
met like I did last year. So count your blessings. :-)

Still I'd be remiss if I didn't say thanks to Martin Lodahl and Mike Sharpe for their outstanding lambic beer tasting and the information they provided to us regarding this most unusual of all beer styles. I thought Mike's framboise was remarkably close to style. Thank you, thank you, thank you for sharing that with us. It was nectar of the gods as far as I was concerned and feel privileged to have gotten a chance to taste some of it.

Cheers, ya'll.

Subject: Comments

I am going to be off the network until next fall, so I wanted to take this opportunity to make some brief comments.

(1) Jeff- Your comments in HBD #906 were generally on the mark, except for the following to which I take great exception.

> Jack's beer wasn't contaminated (which is good, but I would expect that of any brewer who had made more than a couple of batches....

Be prepared for a real flame from me on that one via a postcard from England! For now a simple question will do. Why is it that two brewers can use the same type and amounts of malt and hops, and have very similar brewing procedures, yet one brews beers that generally score in the low 30's and the other typically gets marks in the 40's? Clearly massive infections or totally disfunctional yeast is not relevant in either case. But what about minor imperfections? Some times high hops levels and/or other things will mask these effects in beers with higher flavor profiles. However, thanks to the judge certification program, there are people out there (including yourself) who seem to be able to taste their way through such things. One should not be overly hyper about these matters, but neither should one take them too lightly.

(2) Thanks for the great info from the UK. I have not been able to respond to those whose e-mail address ends with uk. Our local mailer goes berserk when it sees this.

(3) Larry- I see you have changed your e-mail address. Our local mailer also does like "!". It is to software systems what Red Star is to yeast! Feel free to use the material I have posted for your local beer club.  
Are  
you still at Microsoft?

I have really enjoyed the lively discussion on HBD, and look forward the joining the fray in the fall.

> trouble finding these otherwise.

Maybe hard to get in single unit quantities. If you want 10 or 12 (box quantity), they can be found at Carolina Biological and Cole-Parmer, both of whom sell retail; addresses can be found in HBD back issues.

I missed Alberta's talk at the conference (had to make choices) but from recent posts, it sounds like folks are waiting until the primary is full or nearly full before aerating. This will surely cause problems with foam blowing out. I start mine as soon as there is enough wort in the carboy to cover the air stone and leave it in until the carboy is about half full of wort and half full of foam. Then the air is turned off and the foam subsides while the remainder of the wort is siphoned in.

Another useful tip when working with a .2 micron filter: don't get it wet. Once liquid gets in there, it's not coming out. The membrane area is quite small and it's only good for filtering gases. It will merely absorb liquids and expand, causing it to lock up.

Date: 22 Jun 92 13:17:41 EST  
From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
Subject: Pitch in Brewkettle

In HB 904 Chris Lyons (lyons@adcl.adc.ray.com) asks:

>> 1) Does pitching the yeast into the brew pot (@80F) and siphoning  
>> 2 hours later disrupt the fermentation process?  
>>  
>> 2) Is a significant amount of yeast left behind in the brew pot  
>> along with the trub?

As noted in HB 907, a couple of months ago Josh Grosse (jdg@grex.ann-arbor.mi.us) summarized the reasoning behind Miller's recommendation that led me to this procedure:

Leave your wort sitting on top of the hot and cold break material during the respiration phase (8-12 hours), then rack off the sediment.

Josh goes on to say that he'd have to go back to the old HBD to look up the specifics, but the generality is:

During respiration, cell production uses lots of trub components and your lag time will be reduced. Afterwards, the trub is harmful by contributing to overproduction of fusel alcohols and esters (which are combinations of fusel alcohols and fatty acids).

For this reason, I have been pitching my yeast into the brewkettle and then racking off into the primary. I have been waiting about two hours after pitching to rack, but perhaps should wait longer. . . . From what I can tell from the speed that fermentation progresses, there is no interruption in the fermentation process. I am also under the impression that the active yeast cells are in suspension (and therefore get moved with the racked wort) and only the inactive cells drop to the bottom with the trub. Of course I am only doing ales with top fermenting yeast this summer--bottom working lager yeast may be a different story.

Date: Mon, 22 Jun 92 12:18:35 PDT  
From: Richard.Goldstein@Corp.Sun.COM (Richard Goldstein)  
Subject: Priming Cherry Beer

I am calling on the collective wisdom of HBD. I made a cherry wheat beer several weeks ago, and it will be time to prime soon. Someone on the net gave me the very interesting idea of priming with cherry juice or cherry jam to add a little more fruit essence/flavor. So now the obvious question:

How much?

Clearly that depends on the sugar content. I have been having a hard time finding pure cherry juice, or perhaps cherry cider, in the bay area. I can get Dole's Mountain Cherry juice, but that is a blend of fruit juices. It lists the caloric content per fluid oz. Can someone tell me how many calories are in an oz of corn sugar? Can I then use an "equivalent" (calorie for calorie for say 3/4 cup of corn sugar) amount of fruit juice? What's faulty with this reasoning?

If I use cherry preserves/jam/etc, how much do I use? In this case I want to use a product that won't introduce fruit chunks into the final brew. However, using these products would introduce pectin, and I of course made every effort earlier in the process to not introduce pectin into the beer. So what do I do to mitigate/remove/reduce this pectin addition?

Anecdotal observations, experiences, and advice will be appreciated.  
Thanks in advance.

Rich Goldstein

Subject: Re: Jacksons 4 star beers

>Scotland  
> Traquair House Ale

I had the fortune of trying this last Saturday while visiting the Brickskeller (sp?) in DC. This is truly a great beer. If any one knows more about this beer, please fill me in. I will check my copy of Jacksons book tonight. I almost didn't shell out the \$9 for it, but decided hey what the hell, I might never see this beer again. The menu listed something about them getting most of the 250 cases sent east of the Mississippi.

On another note, has anyone ever seen Younger's Tartan Special in the states? I saw it in Toronto in early May. I had never seen it outside of Scotland. The 'skeller had a can of it, but nothing for sale. The can got my hopes up (not the metal, just the label).

All in all the 'skeller was overwhelming. I will go again next time I visit DC.

Just Impressed,  
Scott

>Raccoon Lager. However, I not setup for lagers so  
>I'll be brewing R.R. Ale. Does anyone have any  
>comments on what I should expect?

Expect a great ale. R.R. Ale is the basis for many of my brews (including my hot-pepper ale). The only change I've made with Charlie's receipe is to use 4lbs of dry malt (rather than 3.5lbs) and 2lbs of honey (rather than 2.5lbs). I've found the use of less honey and more malt avoids any cider like taste and gives a nice full flavor. Following the remainder of the receipe will result in a fantastic beer, which seems to improve with age (some how I can't seem to let it age for more than one month). Using this receipe as a starting point can lead to many interesting brews. Happy brewing!

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: Fast Sparge Truth & Consequence

I brewed a vienna lager this weekend. Since I was rushed for time I just trimmed here and there. In particular I sparged 6.25 gal in 20 minutes. In spite of the fast sparge time I achieved near 100% extract efficiency, as compared to Dave Miller's numbers. (8.5lb of grain, about 50:50 pale malt and lt munich/crystal, OG = 1.050/5.75 gal = 34 pt/lb/gal final)

My sparge technique is to open the drain cock wide and recirculate until the flow rate slows down (compact the grain bed). This typically takes 10-20 minutes. Then the sparge settles down to about 6-8 min/gal. With the lager the sparge never seemed to slow down that much.

Anyway, I have always maintained that my extract efficiency seems to be more related to the quality of my crush (the sparge rate as well!) than anything else.

Many questions:

a: are there any negatives associated with fast sparging, other than loss of efficiency?

b: Anyone have any opinions/data regarding the treatment of sparge water vs mashing water? I always have measured out the proper amount of water for my entire brew and treated it prior to mashing. Hence the sparge water is treated with salts as well.

c: Do others on the net use Calcium Chloride? The vienna lager was the first beer of mine to use CaCl<sub>2</sub> along with Gypsum. Even the small amount I used (2 gm/7gal) seemed to make the resulting wort sweeter. Perhaps it was the reduction of sulphate dryness? I used only 3gm of Gypsum in the water.

Cheers!

- Larry Barello

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: GENERIC ALE

To: Homebrew Digest  
Fm: Jack Schmidling

From: gummitch@techbook.com (Jeff Frane)

>Having not only tasted WGB, but.....

Now that my beer has not only been publicly proclaimed to be NOT the World's Worst, in addition to being "clean", I will leave the "World's Greatest" fun behind and return to what I originally was trying to produce and indeed called it, i.e. Generic Ale.

I will use Jeff's comments to illustrate my discussion.....

>Jack's beer wasn't contaminated (which is good, but I would expect that of any brewer who had made more than a couple of batches)

In actual fact, I made many batches over many years and most of them were or became contaminated. Without access to a forum such as this, I would never have known that Red Star had problems nor would I have had a clue that most of the experiments with different yeast were simply with re-packaged Red Star. So your comment is misleading to say the least.

> but it also wasn't tasty.

Now we get to Generic Ale.

>More to the point, I think you are wrong in general: I think bitterness is great but...

I discussed the reason for the excess bitterness yesterday....

> when it exists in a (sorry, Jack) thin and otherwise flavorless beer, you don't get good beer.

>I think it could have been improved considerably--not necessarily by adding a lot of malt--but simply by bringing in some other flavor elements.

As a born-again brewer, with a scientific bent and perhaps a wooden tongue, I decided that the best way to learn brewing was to start with the most basic recipe and process and find out just what basic beer, i.e. Generic Ale should taste like. Once I had that firmly established, I could then venture into other "flavor elements" using Generic Ale as a standard.

Generic Ale was defined as:

American Pale Malt  
Yeast  
Hops  
Water

More specifically, it is now for a 5 gal batch:

9 lbs 2 row Harrington  
Edme yeast (pure cultured)  
1 oz Chinook Hops  
Chicago/Lake Michigan water, pre-boiled  
OG 1.040

If that recipe produces a "not tasty, thin, flavorless" beer on the tongue of an expert, I certainly will not argue nor try to defend it other than to say that, that is what one gets when one uses those ingredients. That IS Generic Ale and it is my starting point for new adventures. Everytime I try something new, I have some GA as a standard to compare it with.

I might also add that I am glad that I am not expert enough to find it boring and tasteless.

> With all that bitterness, a profundity of hop flavor would have made for a better beer.

Just as a point of interest, I always add 1/4 of the hops after the boil so a nominal attempt at aroma is SOP.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: G. Fix/Cambridge/CAMRA Good Beer Guide

Our story so far: In issue 904 George Fix, a hearty traveler, inquired where to find a good beer in Cambridge, England. In issue 905 Chuck Mryglot suggested the Mill and also the Anchor. While I haven't been beer drinking in that part of the world (yet), I did look up the area in the 1991 CAMRA Good Beer Guide.

The following Cambridge pubs, all serving real ale from hand-pumped kegs, are recommended:

Ancient Druids (Napier Street)--a brew pub with a wide selection

Bird in Hand (73 Newmarket Road)

Cambridge Blue (85 Gwydir Street)

Cow & Calf (St Peters Street) -- "Smashing little pub"

Free Press (Prospect Row)

Panton Arms (Panton Street) -- "Excellent pub"

Tap & Spile/The Mill (13-14 Mill Lane) -- "Ever changing range of ales from independent brewers" "six guest beers"

Tram Depot (5 Dover Street)

White Hart (2 Sturton Street) -- "The landlord has won several cellarmanship awards, as reflected in the quality of the beer"

White Swan (109 Mill Road)

In addition, Cambridgeshire does have a local brewery making real ale: Elgood & Sons Ltd, in Wisbech. They make a bitter (OG 1.036, 4.1% by volume) and Greyhound Strong Bitter (GSB) (1.045, 5.2%).

This might be a good time to mention the Good Beer Guide which is published annually by CAMRA. The pub section of the guide contains detailed listings with descriptions of all the pubs that local CAMRA chapters have deemed to be zymologically correct, including information on parking, food, lodging, decor, etc. Also included is an apparently comprehensive listing of all breweries and beers in the UK, with tasting notes, original gravity, and alcohol by volume. This stuff is great reading--I mean, why can't WE have beers named Maiden's Ruin, Old Fart, or Santa's Revenge. Finally, there's a series of essays

detailing current status of the battle for real ale, and a listing of prize beers over the years. All this is packaged in a 500+ page guide that is absolutely required reading for anybody interested in British beer--and believe me, it's great fun to read. In fact, I'm using it as a tourguide to plan an upcoming trip to Suffolk (home of seven breweries making real ale, including the Greene King brewery of Abbott Ale fame). The problem is how to get a copy. I did see one at the British Travel Bookshop ((800-448-3039), and when I called today they said they still had it. They also say they are the only source for copies in the U.S. and that they may or may not be able to get more.

The cost was \$17.95. If your interested, send them a note at 40 W. 57th St., New York, NY 10019. I think they need to realize that this publication isn't just a sop for people visiting merrie olde England for a week during the summer. So how come we don't have a guide like this for the U.S.?

Thanks George, wherever you are, for this opportunity to mount the soapbox.

Subject: Dr. John is Right--Kind Of

Well, it's true that August Schell Pilsner and Capital Special are great beers. Capital Special, in fact, holds a very special place in my heart, and I managed to commandeer and disappear two bottles during the AHA banquet. Compared to NW beers, however, it's not particularly hoppy. When the AS Pilsner appeared at the Oregon Brewers Festival on draught about 3 years ago, it blew me away: an extraordinarily hoppy beer and my favorite from the festival. But the bottle version is considerably more timid; the local distributor, in fact, is convinced that AS is bottling their real pilsner as their Export and the Export in the Pilsner bottles.

And don't mistake me: I love good Midwestern Microbrewed Lagers (TM); I brought a case of Sprecher's home on the plane, and it's already almost gone. But... when you need HOPS, stick to the Left Coast.

Subject: Re: pearled barley

Yes, pearled barley is useful for brewing, and can be substituted in all-grain recipes for flaked barley. I've seen Charlie P. suggest its use in stout to help give it that creamy, Guinness-like head.

I'd try about a pound of it in a stout. It will most likely create a beer that will not clear, so I'm not sure I'd use it in a beer that wasn't opaque. It has to be cooked prior to the mash. Just boil it up with the water you plan to use for the mash. When it seems done, let it cool down to whatever your mash strike temp is (or chill it if you don't want to wait) and add the rest of the grains to start the mash. Mash and sparge as usual.

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: Bedeviled hops

Greetings all,

Seems that the HopDevil's hops are bedeviled. John, identifying the perpetrators will be a boon to dealing with them. You can knock back many types of soft-bodied critters (such as aphids) pretty handily with a soap spray. If memory serves, and I'm not sure it does exactly, a 1% solution is adequate. You can go to the trouble of buying one of the horticultural products (i.e. Safers) but plain old Ivory Liquid dish soap will do the job.

You can eradicate many other bugs with specialized BT preparations.

Bottom

line is that pest identification is the key to eradication, unless you are

willing to do the job with industrial strength chemicals and expose yourself

to all the potential risks they carry into your hopyard and your life.

On another note, I'd like to thank all who were so kind as to send private responses to my question about beer in Baltimore. Looks like there

plenty of places to get good beer there.

Ooogy wawa,

Dr. John

P.S. Good to see you online again Master Baughmann.

As an Englishman living in the Real Ale mecca of Salford/Manchester area  
(Thats NW England for those not sure !), who also drinks gallons of  
bitter,  
I commend your good taste !

>style that Americans in general and the AHA in particular does. A beer  
>style over there is much more likely to describe a range of  
>characteristics, which may overlap with other beer styles. "Bitter" is  
>a continuum, not a point.)

Absolutely right, there are many different types of 'Bitter'. Some good  
some ... Oh Oh I nearly forgot the golden rule which states that there  
is  
no such thing as BAD beer. just that some is better than others !

>a tang which is hard to describe. None are heavily carbonated. In  
London,  
>beer is served practically flat. Go up North and it gets fizzier, but  
>never so fizzy as any bottled ale.

It depends what you mean by 'fizzy'. Both Real Ale and Keg beer is pulled  
flat into 20 ounce glasses in the South of England, Whereas up north  
many pubs use 24 ounce glasses and pull the beer with a thick head on  
top.  
Keg beer always tastes gassier than Real Ale because it is chemically  
killed  
and filtered before being artificially carbonated. Real Ale uses the  
natural  
carbonation provided by the yeast and is not treated in any way, apart  
from  
the occaisional use of finings to clear a particularly stubborn barrel.

Happy brewing and tasty drinking,

Mike Smedley

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: English bitters

I'm not sure that traditional definitions of bitters correspond with current practice. As has already been observed, the term 'IPA' tends to be abused frequently. On the other hand, session bitters are an important category which don't seem to fit the definitions. They are more than a light ale; in fact, skill is required in order to perform various conjuring tricks which make the beer seem 'bigger' than it really is. The tricks include using darker malts for flavour, increasing the proportion of unfermentables (so that, for example, a SG 36 wort finishes fermenting around SG 12), and employing hop aroma and esterification to advantage. On the lager front, Pilsener Urquell is a good example of some of these techniques. Obviously, the alcoholic warmth/sweetness of high gravity brews will not be present, but that is something that can be compensated to a certain extent. The upshot is that it is possible to brew to less than 3% alcohol by volume without sacrificing too much in the way of flavour. The brew may not win competitions, but is a good alternative to soft drinks or low alcohol beers, IMHO.

If this is just regular barley I've used it with neutral results. I was struck by the same thought while wandering through the grocery store and picked up a 2 lb bag of the stuff. I've used as much as a 1/2 lb in my brews; I'm not sure if it added or detracted very much. I generally grind it in my trusty coffee grinder and add like a specialty malt.

My feeling on this is that I'm not doing it exactly right. I'm an extract brewer and not well versed in the procedures of infusion mashing, which would probably bring out more good stuff from the barley. I do have a feeling that the pearled barley contains starches and proteins too complex to ferment without correct mashing, but I understand that could add to the head.

My experience is that moderate amounts won't hurt anything, so go ahead and try it.

Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU> writes in the HBD:  
>  
> But whatever the case, use one or the other. Wort-chillers are  
> essential to any homebrewery.

I'm an extract brewer (with occasional specialty grains), on my 16th batch in about 1 year. Will a wort chiller help my brew?

I am not interested (for now) in going to all-grain; I don't have that much time for this hobby!

My current procedure is to boil only about 2 gallons of wort (from extract/H2O), adding hops/grains as necessary, and then dumping this into the fermenter with 2-3 gallons of cold H2O. The temperature drops from boiling to pitching temperature instantly, and I can pitch right away. There's no "cold break" that I can notice with this method; I imagine the trub eventually precipitates out into the primary yeast cake.

I've just started using liquid yeast (Wyeast Ale) and whole hops for aroma. Batch 15 was the best so far with these improvements. Thanks to the HBD for these suggestions!

Subject: Re: sterilizing counter-flow chillers

This comes up every so often, but at caveat for those making or purchasing a counter-flow chiller. Make sure the inside of the tubing is free of machining oils. Chemical cleaning is not sufficient in many cases...requiring actual physical scouring of the inside of the tubing before you bend it into a coil.

If you want to test your tubing for oils, swab a q-tip soaked in rubbing alcohol around the inside. If it comes out dirty, you've got a problem....if not....no problem...

Mike Zentner, who has tried to clean oil out by running 20 batches of boiling water, rubbing alcohol, beer, bleach, soap water and even lysol through an already constructed chiller...to no avail.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: Bar Harbor Amber, Cerpa

Had the chance to taste an Amber Ale from the Bar Harbor Brewing Co. in Maine, on tap. Pretty standard amber, except for having absolutely no hops aroma at all. Bitterness/malt were balanced ok, but either they forgot to add the finishing hops, or they should change their recipe. Anyone tried any of their other brews?

On a better note, I had a Cerpa pilsner from Brazil. Came in a colorful can. It's an eastern European style pilsner, very similar in flavor/aroma/color to Budvar, or maybe even the Czech version of Pilsner Urquell. A nice beer. I was told that the "generic" beer in Brazil is better than generic US Budmilooors. Oddly, Xingu lager was not to be found, and the locals had not even heard of it.

And now, a homebrewing question. Darryl Bock-man ;-) said he sanitizes his plastic with boiling water, reasoning that the heat will kill the nasties in any cracks. I've been thinking of using a zapap lauter tun (bucket in a bucket) as a hop-back, but have been concerned about exposing my chilled wort to the plastic buckets. But, if Darryl's assumption is true, then pouring the \*hot\* wort through the lauter-tun/hop-back would eliminate sanitation concerns about the plastic. It would oxidize the wort, but at this stage it would mostly just darken it. Correct me if I'm wrong on that. I'd also be concerned about handling a brewpot full of hot wort, but I can imagine a way to be careful about that. Am I forgetting anything? Any holes in my thinking?

>pitching to rack, but perhaps should wait longer. . . . From what I can  
>tell from the speed that fermentation progresses, there is no  
interruption  
>in the fermentation process. I am also under the impression that the  
active  
>yeast cells are in suspension (and therefore get moved with the racked  
wort)  
>and only the inactive cells drop to the bottom with the trub. Of course  
I  
>am only doing ales with top fermenting yeast this summer--bottom working  
>lager yeast may be a different story.

I have read with interest over the last few months the different methods  
and supposed pros/cons of the trub/no trub discussions. While admitting  
I have not done any controlled experiments (no patience) I tend to pick  
the parts that sound logical and incorporate them into my technique,  
while also trying to keep things as simple as possible.

First off, I am currently strictly an extract brewer. Rather than the  
above  
method I tend to dump the hot wort directly into a plastic fermenter  
and let it sit about 1-2 hours to let the trub settle. I then rack off  
to a glass carboy which allows me to areate the cooled wort very well  
and then I just pitch in a quart or so of wyeast starter. I get great  
results with only 2-3 hours lag time and then have no reason to mess with  
the beer once fermentation has begun. Have had excellent results so far,  
even if I do say so myself!

Questions:

Is there any problem with racking (read oxidation) after fermentation has  
begun in the kettle?

Would the use of a yeast starter reduce or eliminate the need for  
pitching  
with the trub intact?

Thanks for all the great info provided on the HBD

Brew On!

Greg

From: korz@iepubj.att.com  
Subject: Priming with grocery store juice

Rich asks about priming with juice.

I suspect that you will have great difficulty in priming with store-bought juice. Most contain preservatives to keep them from becoming what we're trying to make them: alcoholic. Read the label.

Regarding quantity (in case you find some that does not have preservatives), remember that not all sugars are alike. The fermentability of anything is dependent on what kinds of sugars you have and what kinds of yeast you have. Highly-attenuative yeasts will eat almost any type of sugar, whereas the less-attenuative yeasts will only eat simpler sugars. I'm afraid that the only way you will know for sure is to perform an experiment. Bottle five bottles worth with varying amounts of priming solution (juice, in your case) and let sit a week. See what amount of priming solution is right.

Al.

I wouldn't be surprised to find that Mike or Mary Hall answer this too but in case they don't...

There are no brew pubs in Santa Fe. Embudo Station (on the way up to Taos) is the closest. It's probably about a 45 min drive but very pretty and worth going. Santa Fe Pale Ale is brewed at the Galisto Brewing Company just south-east of Santa Fe. It's not a brew pub but they will give you a tour (I think just on the weekends unless you arrange otherwise). If you just want to try the beers you can get any that are available at The Royal Buck on Galisto Street in Santa Fe. They have a pretty good selection of beer and they carry "Santa Fe" beers from the Galisto Brewery which are not available in bottles anywhere but at the brewery. Of course there are good beer drinking establishments in Albuquerque too.

Home-made "tobacco tea" has a number of real disadvantages, and I don't recommend using it for the following reason:

- Nicotine is one of the most toxic "botanical" insecticides, weight-for-weight. It's substantially more poisonous than the commonly-used synthetic organophosphate insecticides such as malathion. Commercial nicotine sulphate insecticide is quite poisonous (I believe that it carries a Danger labelling requirement) and has been the source of a substantial number of accidental poisonings (as well as being a staple in British murder mysteries).

Although "tobacco tea" is a relatively dilute form of nicotine, it's not something to be treated casually. If you spray it on your hop vines, take precautions: wear gloves and a facemask, don't spray on a windy day, don't overspray, don't get it on your skin, and wash yourself off afterwards.

- A large percentage of commercial tobacco is infected with tobacco mosaic virus (TMV). This virus can infect most plants in the nightshade family, including tomatoes, peppers, potatoes, and certain ornamentals. It can stunt or kill these plants, and is incurable. Don't use tobacco tea anywhere around these sorts of plants, and don't use the same sprayer to spray fertilizer, etc. onto these plants at a later time (TMV can survive, dormant, for quite some time).
- Well-fermented tobacco tea can stink to high heaven.

Two other botanicals you might want to consider, as alternatives, are pyrethrum and rotenone. Pyrethrum is a fast-acting contact insecticide with a fast "knock-down", and is of low overall toxicity to birds and mammals. Rotenone is a stronger contact/stomach insecticide, but is more toxic (especially to fish) and should be treated with respect. These botanicals are sometimes used in combination. They biodegrade within a few days, and so can be used up to within a day or two of harvest (check the labels for details).

Another technique which sometimes works, is to lay down a barrier of some sticky substance (e.g. Tanglefoot) on the plant's stem and on the supports for the trellis. This isn't always practical - one cannot always blockade all of the routes by which an insect could climb up into the plant... but if it's practical in your situation, it can be an effective way to keep crawling/chewing insects from chomping your plant. [Won't do diddly if you have a problem with flying insects such as Japanese beetles].

All of this is relevant if your plants are being eaten by insects. If they're being chewed up by snails, you'll need to use other methods

(e.g. laying down a metaldehyde-laced bait).

Before spraying anything, I'd recommend catching the guilty parties in the act, so that you'll know what it is you're fighting. This will give you the best chance of choosing the right remedy, rather than simply nuking your future homebrew supplies with chemicals (synthetic or botanical) chosen at random.

Why, from CAMRA, of course! They can take Visa and Mastercard orders if you phone during UK office hours (approximately 4am-noon Eastern US time) and should be reasonably priced - I don't have that information at hand, but it should be close to the \$17.95 Phillip mentions, inclusive of shipping. The 1993 Good Beer Guide will be published in October or November of this year.

Their phone number from the US is:

011+44-727-867201

They also have a fax number; perhaps someone would like to check out the procedure for ordering from them by fax?

While you are talking to them, enquire about overseas membership - it is only 14 pounds (approx \$25) per year. This includes timely delivery of What's Brewing, the Campaign's very informative monthly newspaper. Highlights of the June issue include fears that Guinness is poised to axe its bottle-conditioned Guinness Original Stout, criticism of Greene King's acquisition policies, "The Beer Hunter Down Under" - Michael Jackson reporting on his trip to Australia, a special section devoted to the resurgence of Porter, and even some hints on where to find draught (sic) Anchor Steam in London!

I guess I should declare an interest: I'm a longstanding member myself. I hope no one objects to blatant promotion of this non-profit-making, consumer organization.

>

At the risk of sounding dumb, what is the advantage of such a complicated procedure as using aquarium pumps, micron filters and aeration stones? It seems like a lot of effort for such small gain over some other Very Simple Gadgets.

For example, I have been using a 6" length of copper tube (surplus from my wort chiller) with four 1/16" holes drilled around 1" from one end. The short end is placed in the outlet hose of my chiller. Air is sucked into the holes, mixed with the chilled wort and a nice frothy bubbly wort is dumped into my carboy. A five gallon batch o beer fills the head space of my 6.5 gal carboy with foam.

Simple, effective, easy to sterilize, cheap.

Depending on how clean your air is, filtering it may certainly be  
overkill.  
It's just one more way to eliminate potential problems.

The simple 'holes in the siphon' method of getting more of your wort  
exposed to oxygen may not be enough. A cool, high-gravity wort is not  
very receptive to O2 absorption to begin with. Most homebrewers  
underpitch  
significantly and really need a large amount of dissolved O2 for the  
best fermentation possible. For example, I know of a microbrewery that  
had problems traced to insufficient aeration (they used filtered air).  
and had to move to pure O2 injection for proper yeast respiration.  
The brewer calls it Vitamin O.

My subjective experience indicates that lag times can be reduced by  
factors of 2-4 when an air stone is used to introduce more oxygen  
at pitching time.

We're not talking about much work or expense here, either. Figure  
about \$6 cheap aquarium pump, \$1 air stone, \$3 filter, \$0.50 tubing.  
Sanitize the tubing and air stone in bleach or ethanol. Sounds to  
me like a Moderately Simple Gadget.

Subject: Sam Adams Wheat

I've had it on tap and in bottles and, although I don't mind it, I'm not particularly crazy about it. It also doesn't strike me as much of a wheat beer. The first time I had it I had it with the traditional lemon slice and the flavor immediately struck me as being akin to Bazooka Joe bubble gum. Very strange, indeed.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: bitter

Let me add my \$.015 to the recent discussion of English bitter. Drinking real ale in England during the 2 years I lived there opened my eyes to beer outside of the Molson/Labatt/O'Keefe axis (beers which my Dad assured me were the 'best in the world'). The wish to duplicate (OK, approximate) fresh English bitter is what inspired me to take up homebrewing more than 7 years ago.

Most of the comments which have appeared recently have been on the mark (continuum not point, classification of style as a function of gravity, etc.). Especially the matter of Fuggles or Kent Goldings as finishing hops (although Northern Brewer makes a good bittering hop, especially in combination with Fuggles).

I can't stress enough the importance of serving bitter on draft if you really want to experience the stuff they serve in English pubs. At very least, it should be fresh and lightly carbonated. And what's the point of bottling if that's what you want?

I used to 'keg' my bitter in the 5 gal. (20 litre, actually) collapsible polythene cubes which can be bought in camping supply (and sometimes homebrew supply) stores. I'd keg the stuff on about day 7, and serve it a couple of days later. The cube would puff out a bit during these few days. It should be checked once or twice a day -- draw off a pint if it's puffing up too much. The beer comes out quite flat but, if you're lucky, the first gallon or so will be lightly carbonated. It's best served at a party and finished off that evening (usually no problem). At the very least it has to be drunk within 48 hours of the time when the air starts bubbling into the cube. This 48-hour deadline is typical of English bitter, in which air replaces the beer which is pumped out of the keg.

These collapsible kegs come in a 2 1/2 gallon size, allowing you to keg half a batch and bottle the rest.

Another trick is to use a little sugar (horrors!). A pound of brown sugar in an otherwise all-malt batch doesn't hurt the beer and gives the sort of flavour you might find in a darker bitter. And don't forget to dry hop, or at least finish the beer aggressively.

As far as commercially available bitter, Wellington County Brewery in Ontario makes excellent bitter. Unfortunately, you'll have to travel to Ontario to get it. In the provincial beer stores, there are 4(?) varieties available in 1-litre plastic bottles. However, there are a handful of pubs in the Toronto area that serve the stuff on draft. There are two real ales: Arkell Best Bitter - lighter gravity, hoppier and made with Fuggles - and County Ale - higher gravity, maltier and made with Goldings. Perhaps a Toronto hbd'er can supply the names of pubs which carry it...it's been 3 years since I've lived in Toronto. In those days I usually drank it at the University of Toronto graduate student's pub.

Cheers,  
Rob

Phillip Seitz writes:

>This might be a good time to mention the \_Good Beer Guide\_ which is  
published  
>annually by CAMRA.  
[ stuff omitted]  
>So how come we don't have a guide like this for the U.S.?

There is one that is pretty good, called "On Tap" and put out by the  
World  
Beer Review people (Steve Johnson, I believe). It details brewpubs and  
micros  
in the U.S. with a page showing locations, directions, beers available,  
and  
info about the type of place (fern bar, yuppie hangout, sleazepit or  
whatever).  
It was put out in 1991 (I think) and there is already a supplement out.  
It  
costs about \$15 and the supplement costs about \$10. WBR has ads in  
Zymurgy, and  
is located in Clemson, SC. If anybody is really interested, and can't  
find them  
in Zymurgy, I will post the address (I don't have it with me now).

And, no, I have no connection to WBR.

Date: Tue, 23 Jun 92 11:50:53 PDT  
From: hartman@varian.varian.com (John Hartman)  
Subject: re: English Bitters--Brewing Beers like Young's they make

This recent discussion prompts to give further details of my trip. I spoke at length with two of the five brewers at Young's Brewery in London. They definitely qualify as "lupulophobic". I describe what I learned about their ales below...

They make a number of cask ales, some bottled ales, and a couple of lagers. My focus was on their ales and does not apply to their lagers. In particular I was interested in Young's Special cask-conditioned ale. As this information was given to me in the tasting room after the tour, my focus did eventually become blurred and my arm did eventually become tired. While tasting you see, I was forced to fill my own pints via hand pump;-) Also I didn't want to pry (I just wanted to know everything:-))

Consequently, the information I do have is incomplete and not well organized--sorry. On the other hand, what I did learn came straight from the brewers, who were very enthusiastic and forthcoming, so I assume it's accurate. If I wasn't sure about what I remembered I have noted so in parentheses...

All of their grists are "approximately the same". They use "only the finest ingredients they can find". The variety of malt is Maris-Otter. I have a small sample of crystal that appears to be about 20 or 40 Lovibond. Some flaked barley is also used for head retention. A certain amount of brewing sugar is used. I don't know how much nor in which beers. Contrary to what is printed in the "The Real Ale Drinker's Almanac", Young's does not use torrefied wheat in any of their brewing. In general I was disappointed with the accuracy of the information found in the almanac. Let the brewer beware that the ingredients they list have little in common with what in reality Young's uses. Oh well.

Young's Special draught should not be confused with the bottled Special London Ale sold here in the US. The draught bitter has an OG of ~ 36, draught special has an OG of ~ 46, and the bottled Special London Ale is ~ 66 OG. I don't know what IBU levels are used for the beers, but they do use a single addition of Fuggles in the kettle at the beginning of the boil. And now we come to the issue of finish hops. The draught bitter is (I believe) dry-hopped with (I believe) East Kent Goldings. The bottled Special London Ale is dry-hopped with East Kent Goldings. The draught special is dry-hopped with the Target variety in plug form. The box called them pellets, but they were in fact 1/2 oz. plugs as we know them here in the states. For each 36 Imperial Gal cask (43 US Gal.) they use a mere 2 oz. of Target! I was embarrassed to tell them how much I use and for a brief moment considered prevarication (lying, that is). When I told them that I usually use about 1 to 2 oz. per 5 US Gal., there was no uncertainty.

Young's only started dry-hopping about two years ago. The owner and most of the brewers were not interested in trying it, but once they had, they decided to make the change. I suspect the economy of dry-hopping, i.e., more aroma at less cost, played a part in that decision.

Their beers ferment in open primaries for seven days. They are then

transferred to secondary for seven more days. Then the beer is placed in SS casks. It is at this point the beer is dry-hopped and fined with Isinglass powder. In a few days the draught is drayed (delivered by horse-drawn cart) to their local tied houses. Finally after a few more days in the pub cellar it's served to the many patrons who happily slake their thirst. The beers are never primed or krausened. Their yeast strain is a slow finisher which allows them to develop a light level of carbonation in the cask without priming. I have since tried this and it works quite well. Also it makes brewing that much easier since I don't have to mess with gyle or corn sugar. They do have a kegging and bottling operation which (I believe) force-carbonates those products. I asked for an opinion on our weighty matter of whether to skim the krausen or use a blow-off tube vs. not skimming. They don't skim per se! , but do employ some technique wh

I hadn't heard of Target, so I enquired. The Target variety is a decendant of EKG. It is a 10-12% hi-alpha, hi-aroma version that I do not believe is available here. I have since called Dave Wills of Freshops to see if he carries them. He said this year he ordered 100lbs of imported EKG and sold them quickly even though he didn't advertize their availability. He plans on ordering more and so I told him to consider the Target variety. He will, depending on the interest level. If you would like to use this hop as well perhaps you might call Dave an express you interest. Freshops' number is 1-503-929-2736. I have no affiliation with Freshops other than buying lots o' hops from them. If you know where one may obtain Target here, let me know.

As an aside which has nothing to do with how they brew their beers, the owner related to me that several years ago when Fritz Maytag was reviving the Anchor Brewery here in SF he visited Young's for two weeks. He took back with him recipes and knowledge gained at the Young's brewerery. So maybe I'm on the right track... That is all.

Cheers,  
John hartman@varian.varian.com

From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: English Bitter

While it is true that the term "bitter" in England covers a wide range of beers, I do think that as a homebrewer (as opposed to a surveyor of commercial brews) it is possible to define a narrower range which could be defined as your basic "best bitter". This basic recipe can then be supplemented/substituted with different malts, mashing techniques, hops etc to produce the whole spectrum of bitters found across the UK. I'm currently in the middle of testing empirically the effect of these additions of the basic recipe to gauge the effect on the final beer.

My basic recipe for 5 (UK) galls (22.5 litres; 6.25 US galls?) consists of (from memory):

7-8 lbs crushed pale malt  
0.5 lb crushed crystal malt  
mashed in 3 galls boiled water (+ 1 tsp CaSO4) 66C for 3hrs (or overnight)  
Sparged to 4.5 galls  
Boiled 1.5 hrs with 1 tsp Irish Moss  
3oz Goldings for 60 min  
0.5oz " " 10min  
0.5oz " " soaked at end of boil  
Cooled with immersion chiller, racked and aerated: OG 42-48  
Pitched with Edme yeast (starter from dried yeast)  
Racked into secondary after 4 days (SG=20)  
Fine if necessary (gelatin or Polyclar)  
Dry-hopped with 0.25oz Goldings in secondary.  
Barrelled after 2 weeks, primed with 3oz malt extract.

This comes out tasting something like draught Bass, or Fuller's London Pride.

To this recipe I add adjuncts such as amber malt, chocolate malt, roast barley, Fuggles instead of Goldings, etc etc to yield what looks and tastes a very different beer, but has 90-95% identical ingredients. For example, my last batch was a (misconceived) attempt to brew Theakston's Old Peculier. I thought I detected some wheat malt in the commercial brew,

so my recipe was changed to:  
7lb pale malt  
2lb wheat malt  
4oz chocolate malt (for the reddish hue!)  
4oz roast barley  
4 oz Fuggles hops, timings as above  
Treacle to prime (= Molasses)

The result: a good beer, with a deep malty taste, a dense, lasting head and a wonderful reddish-black colour - but otherwise totally unlike OP. So - back to the drawing board...

P.S. My last batch of "basic bitter" was an accidental experiment in altered mashing conditions: I let the temperature rise to 75C in the first 30 minutes, so although I got a good conversion, a lot of this was unfermentable (due to excessive destruction of the beta amylase, which produces maltose from dextrins). So the starting gravity was 1.048,

but finished at 1.020. As Conn Copas noted in HBD 909, it is thus possible to produce a relatively low alcohol beer which doesn't taste too weak. In fact, it's rather good, IMHO.....

From: jp07@gte.com (James Paschetto)  
Subject: Re: CAMRA \_Good Beer Guide\_ availability

In HBD #908, Philip Seitz asked about availability of CAMRA's \_Good Beer Guide\_ in the US. I recently bought a book titled \_The Best Pubs of Great Britain, 1987-88\_ from a mail-order house. I don't have the book in front of me to check, but it appears to be a re-publication of the CAMRA guide under a "generic" name--CAMRA is mentioned throughout, the association is explained, and there is a CAMRA membership form in the back. The first half of the book talks about beer in general and details Britain's breweries and their products. The back half lists the "real ale" pubs by county and town, with brief descriptions. There are also pages of maps showing the pub locations. (Does this sound like the CAMRA guide, Philip?)  
I got it from: Edward Hamilton, Bookseller  
Falls Church, CT 06031-5000  
(There's no phone #, I guess it's mail only.)  
It's order #765317, \_The Best Pubs of Great Britain\_; \$1.95 + \$3.00 (shipping).  
(I should say that I have no affiliation with this guy; it's just where I bought the book.)  
NOTE: This is the 1987-88 guide. It's NOT the most recent!

From: rak@mayo.EDU (Ron Karwoski)  
Subject: Hops, Aeration

Greetings!

My hops have a couple of problems. I have only two plant growing and I fear I may have lost them for the year. The tops of both plants have been lost. On one, a few days of wicked storms weakened the plant where it latched on to the twine I have hanging from a tree. I'll make the twine tighter. I noticed the second top (just the top inch) was missing about a week later and closer inspection revealed an army of ANTS! marching up and down the twine. My question: Will these tops come back and the plants resume climbing or are they stuck for the year? How do I get rid of the ANTS!? Soap?

On another note, I too have wondered about wort chillers for extract or partial mash batches. I know aeration of hot wort is a problem. My method is to put the strainer into the pot after boiling and then siphon the hot wort into the cold water in the carboy. I then top off the carboy by sparging cold water through the hops left in the pot. I know cold water sparging doesn't get me much, but are there any other problems with this method? On my first partial mash last week there was a tremendous cold break.

One other note. I'll be in London in late August for a week, staying in the West End. Any pub or beer suggestions would be greatly appreciated.

From: Bob\_Konigsberg@3mail.3com.com  
Subject: Homebrew Digest #909 (June 24, 1992)

I've been using an immersion chiller for a while now, and I don't feel that they're too hard to clean.

Prior to use, I run hot tap water (~180 F) through it from the tap for about a minute (full 60 seconds) after it's hot at the far end at a fairly high flow rate. Then I fill it (with a funnel) with a Chlorinated TSP solution, and let it sit in there for about 30 minutes. Then the hot water rinse is repeated again for another full minute. The chiller is then stored with the copper tube left full of water.

I always check the first rinse water out of the tubing (smell, then taste) prior to the full first hot water rinse, and I've found no problems with it. A friend goes a little further and uses live steam from a pressure cooker to really sterilize the inside of the copper tubing. He's had no problems either.

On the rubber hose surrounding the tubing, I recommend the use of a hot-water rated hose.

I've made up a diagram and condensed instructions for a friend or two for making one of these, and since it's done, anybody who wants a copy can send me a self-addressed stamped envelope, and I'll send it back out with a copy of the instructions. Only 1 stamp, since it's only 1 page.

Send the envelope to:

>I was told that the "generic" beer in Brazil is  
>better than generic US Budmilooors. Oddly,  
>Xingu lager was not to be found, and the locals  
>had not even heard of it.

Having lived in Brazil 83-87, I can vouch for the fact that the average Brazilian beer is far better than the average US beer. More flavor (both malt and hop) and generally more character.

My personal favorite is Antarctica (comes in big 0.6 liter bottles). Other favorites were Cerpa and, of course, Xingu. Brahma, although one of the biggest sellers in the world, is generally no better than Miller.

By the way, I find a lot of confusion in this country about the pronunciation of Xingu. ItUs the name of an Indian tribe, also a major river, and the proper way to say it is: sheen-GOO.

One funny quirk of Brazilians is that they will usually order whatever beer is coldest (Jackson comments on this). They recognize that itUs silly, but still often ask for their beer Restupidamente geladaS (stupidly cold).

Be aware that the Brazilian beer exported in cans is NOT the same as what they drink there in bottles. It doesnUt travel well at all. The fact that you can often get a good can of Brazilian beer here in the US is an indication of just how good it is down there, fresh in the bottle!

Last year I tried Safer(tm) for the first half of the season and Diazinon for the second. Whatever was eating my hop leaves last year was not affected by either. This year I used Sevin and although I have some holes in many of the leaves, the plants are healthy and happy. Given that I'm about 25 miles (as the ladybug flies) from John the HopDevil, I suspect we may have similar problems. I brought sample leaves with me to the Conference and had some experts (like Vern) look at them, who immediately said: APHIDS. Unless I wasn't using enough Safer and the Diazinon was too late, I would tend to stick to the Sevin. I tried to find ladybugs in all the stores around, but could not find any. If anyone in the Chicago area knows of a store that has ladybugs for sale (or for that matter, anyone who knows of a store that will ship), please send me email.

>yeast cake.

Yes it will. You've already mentioned that you don't get a cold break. Some of what would be cold break does precipitate out, some just throws a haze when you chill your beer (heard of "cold-filtered?").

Chuck writes:

> 1. Aeration of wort. Why should I do it and how.

Yeast first goes through respiration then begins fermentation. During respiration, it takes up oxygen it uses later. This oxygen is necessary for good yeast health. Oxygen-deficient yeast can lead to stuck fermentations, low alcohol tolerance and (correct me if I'm wrong, someone) increased diacetyl production (or is it decreased diacetyl reduction?). Aeration should be done on the wort after it has cooled below 80F so that oxidation is reduced. I simply cool with an immersion chiller (I used to do partial boils and then chill with boiled cooled icewater in the kettle) and then

pour from a great height (12 - 18 inches) into a funnel in the top of the glass carboy to aerate.

> 2. Does anyone have any experience or opinion about the malt  
extracts  
> from North Western.

Yes. They are tasty and don't produce too much hot break, but are pretty high in dextrins and unfermentable sugars which means you will tend to get higher FG, sweeter beers (how sweet, depends on how attenuative your yeast is -- I use primarily Wyeast #1028 and #1056 and occasionally #1084, Belgian Ale and Bavarian Lager (I forget the #'s). I've found that #1056 and #1028 are on the less-attenuative side as are the Belgian and Bavarian. I've found #1084 to be more attenuative than most.).

>

>My feeling on this is that I'm not doing it exactly right. I'm an  
extract

Pearled barley is not cooked. Like steel cut oats, you need to cook it  
first to gelatinize the starch (i.e. make it soluble in water so the  
mash enzymes can get to it). Rolled or Flaked barley or oats are already  
pre-cooked by the rolling process and can be added to a mash as is.

Extract

brews won't get any appreciable fermentables from any of these products  
unless there are enzymes present (DME). There are other things that  
extract

and grain brewers will get from plain grains. Beta-glucans are one of  
them.

I believe Beta-glucans will add to wort viscosity.

I have used 8oz of rolled barley in light lagers using single step  
infusion

mashing with no apparent chill haze. I have used 2lb of rolled barley  
and  
roast barley in a stout and it cleared just fine (hard to tell, of  
course).

The use of rolled barley or oats is kind of a "head" insurance.

Cheers!

- Larry Barello

From: terrype@itx.isc.com (Terry Peterson)  
Subject: August Schell Pilsner & Export

You might think a brewery that's been around since the 1800's would have enough confidence in their product to leave the recipe alone, but as Jeff Frane discusses in #909:

>When the AS Pilsner appeared at the Oregon Brewers Festival on  
>draught about 3 years ago, it blew me away: an extraordinarily hoppy  
>beer and my favorite from the festival. But the bottle version is  
>considerably more timid; the local distributor, in fact, is convinced  
>that AS is bottling their real pilsner as their Export and the Export in  
>the Pilsner bottles.

My brewing partner and I USED to drink lots of AS Pilsner. In fact, it was our favorite pilsner beer. The bottled version definitely favored malt over hops, but had enough hops to make it a terrific pilsner beer. Unfortunately, our distribution channels began receiving twist off bottles of non-bottle conditioned beer (of some sort) with a new label. I agree with Jeff's distributor at least enough to say that the new "Pils" is NOT the same beer we used to drink. I've also had the Export and, although it's better than the Pils, I don't like it as well as their previous product. The Export tastes like an ale to me and so I can't believe it is their pilsner in disguise.

I'm sad to say I can't support the old brewery any more. If they'd at least continued bottle conditioning their beer the yeast would have had some value, assuming they didn't change that too. I've been meaning to write AS a letter, but haven't done it yet. I wonder if they'd give me some hints so I could try to recreate their older pilsner recipe?

I think that MOST malt extracts are concentrated by boiling under a vacuum. Any that are called "DME" (diastatic malt extract) have to be so they can lower the boiling point to a temperature which won't destroy the enzymes.

As to the value of reduced trub.. even neglecting any taste effects, you at least end up with more beer.

From: lrj@helios.TN.CORNELL.EDU  
Subject: mash/lauter-tuns; cylindrical or rectangular?

It's time to have a go at doing all-grain beers. The one item I still need to come up with is something for mashing and sparging. I currently plan to brew in 5 gallon batches, and will probably stay with that for now. I've gone through a lot of HBD back issues, but couldn't find any concrete information.

I think that my best investment for the moment would be to purchase either a 5 gallon cylindrical cooler or a rectangular picnic cooler (~54 qt.). Each would appear to have its advantages and disadvantages.

A 5 gal. cylindrical cooler would cost approximately \$30. I could build a slotted-pipe setup, or use some sort of vegetable steamer or collander. The advantage is that I would have a deeper grain bed while sparging; the disadvantage is that I would be more limited on how much grain I could use. What do people find is the limit on the amount of grain in these?

The cheaper route seems like the 48 or 54 qt. rectangular cooler, as they're available for around \$20 or so right now. I would put together some sort of forked, slotted-pipe arrangement with this system. Advantage: no problems with running into space limitations if I want to brew a stronger brew. The apparent disadvantage is that I'd have a lower extraction efficiency, especially with smaller quantities of grains.

I'd appreciate suggestions from people on which would be a better investment and why. Thanks!

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: hops bugs, copper&vinegar

Those bugs that are eating John Hop-devil's hops are likely to be Japanese Beetles. They can devastate your plants. I use a Rotenone spray (you know, mix the stuff up with water, attach the dispenser to your garden hose, and spray the plants enough so there is some white residue when it dries). It's helped keep them away, but still some of the plant gets eaten. I think the Bag-A-Bug things attract beetles as much as they catch them. I haven't used one this year, and there are a lot less beetles. It could be the cool weather, though. It's also a good idea to kill any of the beetles you see. Early morning and at night are good times because they're slower. Last year the beetles here in NH mostly went away after about a month, about the middle of July, so it's only an early summer pestilence. If they get really bad, I might cover my plants in bird netting (the kind used on fruit trees) until the JB season passes.

Mike Z. with the oily counterflow chiller: Run a vinegar/water solution through the copper to clean it. It worked *\*really\** well on my immersion version.

>Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU> writes in the HBD:  
>>

>> But whatever the case, use one or the other. Wort-chillers are  
>> essential to any homebrewery.

>I'm an extract brewer (with occasional specialty grains), on my 16th  
>batch in about 1 year. Will a wort chiller help my brew?

>My current procedure is to boil only about 2 gallons of wort (from  
>extract/H2O), adding hops/grains as necessary, and then dumping this  
>into the fermenter with 2-3 gallons of cold H2O.

If this is what you're doing then no, they aren't essential. But this does bring up the issue of whether or not one should boil just 2 gallons of wort and dump it into 3 gallons of cold water. Sure it works. But I think conventional wisdom is that you're more likely to brew a better extract beer by reconstituting the wort, that is, by bringing the wort back up to 5 gallons. By reconstituting the wort you're beginning to treat the extract more like grain-sparged wort. Following Fred Eckhardt here, extract beers are already a "cheat", if you will. In order to approach the quality of scratch beer, one should treat extract beers, as much as possible, as if they were scratch beers. Therefore one should attempt to (1) reconstitute the wort, (2) use fresh hops, and (3) use at least some specialty grains, especially crystal malt.

Because of these concerns, I recommend that beginning brewers get a 6 or 7 gallon boiling pot as soon as possible. When deciding on recipes, don't get bent out of shape trying to find a can of Northern Nowhere Amber Malt Extract. Cue in on the fact that you need amber malt extract and make your own. Amber malt is just pale malt with some crystal malt added to it. If you buy only pale malt extract, you can make your own amber or dark extract with ease. Here are some rules of thumb. Adjust quantities according to taste. Assume 5 gallons of beer.

Amber Malt 1-2 cups of crystal malt. 2 cups will add a significant sweetness to the beer. You will barely be able to taste 1 cup but you WILL taste it.

Dark Malt At least 1 cup of crystal and 1/2 to 1 cup chocolate malt for a decently strong chocolate/bock tasting beer. More chocolate and crystal for porter-ish dark beer.

My other advice is to skip extract recipes altogether and look at the all-grain ones, substituting 2 cans of pale malt extract for 8-10 pounds of pale malt and adding specialty grains as recommended in the recipe. Treat the specialty grains as follows:

Grind the grains and place them in a mesh bag and throw them into the boiler as the water comes to a boil. Lift and plunge the grains into the boiler water as often as you wish to simulate a sparging action. When the water reaches 170 or 180 degrees F., toss the grains.

When the water comes to boil, cut off the heat source, add the pale malt extract, stir into solution, then resume heating. As the wort

comes to a boil a fine, creamy head will form on the surface of the wort. Skim this creamy head and you'll never suffer from boil-over again. The head is composed mostly of proteins that will later form a big protein bubble when steam escapes from the liquid at the onset of the boil. The dreaded boilover!! Haven't you noticed how boilover only occurs in the split second between the last time you looked at your non-boiling wort and the horrified realization that it's already started boiling?!

And, of course, hop as advised with fresh hops, plugs or pellets.

Assuming this is the way you make extract beers then (and now we're back to the original question...whew!) you should be using a wort chiller because you have 5 gallons of beer to cool down in a hurry. And this was what I was assuming when I said wort chillers were essential to any homebrewery.

Then Russ sed:

>Mike Zentner, who has tried to clean oil out by running 20  
>batches of boiling water, rubbing alcohol, beer, bleach, soap water and  
>even lysol through an already constructed chiller...to no avail.

The above is well worth mentioning. Mike had a helluva time cleaning up some copper tubing he found or bought from somewhere. At the same time, if you buy refrigeration grade copper tubing from a hardware store you shouldn't have the kinds of problems Mike had, at least I never have and I've made several hundred wort chillers. It's my understanding that silicon oils are used in the extrusion of that kind of copper and are easily removed with several soaks in clorox or a couple siphonings through of boiling hot water laced with B-Brite or beer line cleaner. Where did you get that copper tubing after all, Mike?

>And now, a homebrewing question. Darryl Bock-man ;-) said he sanitizes

be  
>concerned about handling a brewpot full of hot wort, but I can imagine a  
way  
>to be careful about that. Am I forgetting anything? Any holes in my  
thinking?

I just finished writing an article for the special issue of Zymurgy that describes how to make a hop-back that avoids the issue of oxidation when using a hop-back altogether. I could post the article here in the HBD if anyone is interested and if Charlie P. doesn't mind. But for the moment, suffice it to say that my hop-back design uses a mason jar connected inline between the boiler and a counter-flow chiller. The mason jar lid is drilled with two holes, each containing a length of copper tubing, the bottom of the outlet tube wrapped in the infamous copperwound pot scrubber in a fine mesh hop bag. Stuff about 3/4 oz of the gummiest aromatic hops you can find into the jar and start a siphon. The hot wort passes into the jar of hops, picks of the aromatics, leaves the jar and enters the wort chiller where it is immediately cooled down. Having been cooled to water temperature, the hop aromatics aren't volatilized to the atmosphere and instead enter the wort where they belong. The resulting beer will have the same kind of hop character we've all grown to know and love in Sierra Nevada Pale Ale or some of the ales made by Hart's Brewing Company in Washington state.

And now for the new sig...

From: Kevin V Martin <kmartin@magnus.acs.ohio-state.edu>  
Subject: Re: Rocky Raccoon Ale

Like Michael Gildner, I'm not able to ferment lagers. Here's my version of Rocky Raccoon Ale:

1 can M&F Light Malt Extract (unhopped)  
3 lb. Clover Honey  
2 oz. Willamette hops (5.0 AAU's)  
Wyeast London Liquid Ale yeast  
1/3 c Clover Honey (priming)

The malt extract, honey, and 1 oz. of the hops were boiled in 3 gallons of water for 1 hour; the remainder of the hops were then added and steeped for 15 minutes. The wort was passed through a strainer into a plastic primary and diluted to 5 gallons. After reaching room temperature, the yeast was added. The initial SG was equal to 1.040. After 6 days in the primary (60-65 deg.F) and 10 days in a glass secondary fermentor (60-65 deg.F) the final SG was equal to 1.000. The beer was then primed with honey and bottled. After two weeks in the bottle, the carbonation had reached an acceptable level; but the taste was a little green. After another month the taste has mellowed out. This beer is turning into a favorite of my friends who don't appreciate my usual heavy ales ;). I enjoy because it has more taste and body than BudMillCors!

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Traquair house ale from Micah Millspaw

I noticed a posting about the scotch ale Traquair House. It is my personal opinion that this is one of the best beers that I have ever tasted, commercial or homebrewed! This amazing beer is available through Merchant du Vin in Seattle, WA. but the price is very high. Since I like the stuff but its not realistic to buy, I made quite an effort to copy it. The effort has gained me a lot of experience and quite a few ribbons in scotch ale (wee heavy) competitions. So I will give you all my best and closest to Traquair House recipe, do not make substitutes with inferior ingredients or the ale will suffer, and use the same yeast indicated for the same reasons.

this is for 5 gallons and is made from only the first runnings of the mash

18# british pale malt  
4# british crystal malt  
2# toasted malt (homemade in oven - 10 min. @350F)  
4oz roast barley - in mash out only  
1# chocolate malt - in mash out only  
1 1/4oz centennial hops - 11.3 alpha for 75 min.  
3/4oz tettnager hops - 4.8 alpha for 15 min.  
1 tsp salt in boil  
1 tsp gypsum in boil  
irish moss last 30 min.

wyeast 1056 culture  
OG 25B or 1100

mash @ 155F 1 1/2 hours collect first runnings no sparge  
strike with 8 gallons @ 170F  
mash out with 3 gallons @ 200F with chocolate and roast grains  
collected 8 gallons boiled down to 5 gallons

have fun

Subject: Bad Taste...

I'm a beginner at homebrewing, and so far I've only made lagers from pre-packed kits. Every brew I've made has seemed to ferment out OK, but The problem is just about every batch ends up having a bad taste in it. It's hard to explain exactly what sort of taste is is - sort of metallic. Does anyone know what could be causing this? I sterilise all equipment thouroughly using sodium met. I was told that it could be from using this chemical, but I haven't got a chance to try bleach yet.

I was wondering whether it could be from light destroying the brew. The best one we made was an English Ale, and we did it in an old tea chest. This was the best tasting brew we have made. Could this be the problem? It's not the water because I've used other types like sterilised rainwater. Can anyone help?

> the net gave me the very interesting idea of priming with cherry juice  
> or cherry jam to add a little more fruit essence/flavor. So now the  
> obvious question:  
>  
> How much?

An interesting idea indeed but I'm not convinced that it would be practical. While this won't help you now, you might consider priming with saved gyle in the future. I have had great success doing this by following Papazian's guidelines for calculating the amount to save and not being too concerned with getting \*exactly\* that amount. It takes a bit longer to carbonate and condition but the end result is worth it to me. That way, you are just adding back a little of the same ingredients that went into the batch in question and nothing more. It would, in your case, have contained some of the cherry essence that was present in the brew from the start. This in combination with adding some "fruit essence" at bottling time, as Micah Millspaw suggested in his article on fruit beers, should be right on the mark. You might try to find some cherry essence to add and prime with corn sugar, DME, or honey for this batch. I recently made a Blackberry Ale using 8 pounds of blackberries which I primed with orange blossom honey and it turned out quite well. The blackberry aroma is there even without the addition of fruit essence. It also has a slight floral aroma from the use of Cascade hops and, I think, the honey.

Subject: Watneys, Gordon Beirch, Brew Clubs

Hi all,

Just wanted to repeat a post I saw earlier, if anyone has tried to duplicate a Watney's Red Barrel recipe, I (and a few other people) would sure be interested. Please send us what you got!

Also just wanted to say I got out to the Mountain View, Ca area awhile back and got to visit The Tied House and the Gordon Beirch brewpubs in San Jose and Palo Alto. Yum! Sure wish we had a few of those down here in NM!

Finally, thanks to all those who responded to my partial mash questions. Your help is forever appreciated. I'm ready to do one!

Does anyone have any info on brew clubs in the Albuquerque area? I think there's one but forgot who to contact. What do you guys talk about in these things anyway. I'm kinda thinking about starting one, any help out there?

Always thanks in advance,

chuck

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: bottling wands (zymurgy review and question)

The latest issue of zymurgy (Summer '92) had an article comparing three types of bottling wands. The author's primary consideration seemed to be the amount of oxidation potential each had. He liked Phils Philler the best because (1) the beer doesn't spray out the bottom (so no aeration at that end) and because (2) it left very little head room (so little oxidation potential at that end).

My question: there was a discussion of Phils Philler in this list a while back (6 mo?) and I thought that the consensus was that the little air hole at the top (that allows for property 2 above) at least had the potential for introducing air into the beer as it flowed by (by Bernoulli's principle). Has anybody had any further thoughts on this or experiments to back it up or refute it?

I'm currently using one with the valve at the bottom. I think it's the second kind he reviewed. There's a little "wand" sticking out that opens the valve whenever pressed up or to the side. This allows me to easily top off bottles by holding the wand against the (in)side of the neck of the bottle. But it does "spray" beer out the bottom. Still it's better than no bottling wand, by far.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: oxidize,ants

I knew there was more reason for not oxidizing hot wort than just because it will darken. What happens is that things such as melanoidins (sp?) get oxidized, which isn't a problem in itself, but as such they will not be able to reduce oxygen later on, and so the brew is more susceptible to the post-ferment oxidation which can impart off flavors. Thanks to all who reminded me.

So, pouring hot wort into a hop-back is not the greatest idea. My plan now (at least until I get to read Kinney's Zymurgy article...amazing how great minds think alike ;-), is to pour boiling water into the plastic buckets/hop-back and let it sit while the wort is chilling as usual. The heat should sanitize the buckets. Then I can pour the cooled wort through the hop-back. No hot wort, no plastic nasties, and well-oxygenated wort as a by-product. One concern about your hot wort/hop-back/chill scheme, Kinney, is that the hops are not being used as a trub filter bed, at least not for the cold break material. But I guess that's the price you pay for all that great hop aroma that'll be extracted by the hot wort. Does Sierra Nevada hop-back with hot or cold wort?

Re. ants on hops: Ants love aphids. They actually herd them, like cows. If you've got a lot of ants on your hops, you've probably got aphids.

Has anyone used the California Common aka Steam beer yeast from Wyeast? A couple of pints of Anchor Steam last night has decided my next brew...

Subject: Re: English Bitters - Theaky's XB Anyone?

I too am one of the many who started brewing because of the want to get a decent pint of English Bitter. (That and I had this 'calling' to do so :).

My favorite example of the style is an English ale made by Theakston's. These same people make Old Peculiar, which I know many of you have tasted.

However, their Theakston's XB, available on tap mainly in Lancashire and York, is one of my favorite beers. It's hoppy, smooth, and just slightly creamy.

Of course, I've come nowhere near duplicating it yet, but if anyone out there has some malt/hops/brewing tips on how I can get close to it then I am all ears.

So far, my best results have come from 6 lbs of amber extract (don't mash yet, but I still brew :), a half lb. of crystal, a 1/4 lb. of roasted malt, and long-term dry-hopping.

Cheers,

- --gk

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Sierra Nevada crib notes

This past Tuesday and Wednesday the Brickskeller held its Sierra Nevada beer tasting, and it was definitely the place to be if you're one of those HBD mad-dog left-coast Death-by-IBUers. All the beers were on tap (except the Celebration Ale), and all were frighteningly fresh. How hoppy was it? Well, by the time we got to the Bigfoot all six of the hearty beerdrinkers at my table were chewing on the tablecloth and wiping their tongues on the carpet to try to cut through the impenetrable hop-oil coating in our mouths. I heard that after the open keg five people required first aid for bitterness burns and three were hospitalized for IBU overdoses. Must have been left-coasters. (And, no, I'm not from the Midwest.)

Anyway, Sierra Nevada's sales manager Steve Harrison was in attendance, and shared the following information with us (please accept my apologies for the gaps--perhaps someone who was there on Wednesday can fill them in?):

- 1) All beers are made with 2-row klages malt. A single-temperature mash is done at 156 degrees.
- 2) SN uses open primary fermenters so they can recover their yeasts from the krausen. Harrison claimed they can usually reuse the yeast for 30-40 batches before it goes bonkers, though they've found that the yeast collected from Bigfoot and Celebration Ale is close to useless.
- 3) The beers:
  - --Summerfest (a lager). OG: 11.5 Balling, FG 2.7 Balling, using only 2-row klages. Hallertauer for finishing.
  - --SN Pale Ale. OG: 13 Balling, FG 3 Balling, using klages, crystal, and dextrin malts. Perle hops for bitterness, cascade for finishing.
  - --Pale Bock. Sorry, folks, I blew it. Must have been in the bathroom.
  - --Celebration Ale. OG: 16 Balling. Hop schedule usually includes Chinook in the boil, cascade for finishing, and centennial as a dry hop. However, Harrison says they're willing to change the recipe in accordance with availability of the hops most likely to hit people squarely between the eyes.
  - --SN Porter. OG: 14 Balling, FG: 4 Balling. Either Perle, centennial, or Hallertauer in the boil, with Tetnanger and Willamette in the finish.
  - --SN Stout. OG: 16 Balling, FG: 4 Balling. Chinook in the boil, cascade finish. Malts include black patent and chocolate, but NO roasted barley. (Hmmm. . .)
  - --Bigfoot. Must have been in the bathroom again (don't shoot!)

Also served was the Richter Scale Ale from the San Andreas Brewing Co. in Hollister, CA. This is a cranberry ale, and our table agreed it had

the best fruit flavor of any American commercial beer (not that there are a lot of choices).

On the recommendation of Scott Leno (HBD 907) I also tried the Traquair. Good call, Scott. The beer is very richly malty, with a nearly silky mouth feel. Taste rather reminiscent of Belgian triples (Rochefort comes to mind) but without the alcohol taste. VERY restrained carbonation (I'd say there were about six bubbles in the entire bottle.) Definitely an enormous, great beer. However, right-coasters not living near Washington might take some comfort in the fact that a small-business loan is required just to drink a bottle of this stuff: at \$9.95 for an 11.2 ounce bottle this is vastly the most expensive beer I've ever consumed. At about \$1.00 a sip you gotta wonder.

Anyway, those frothing-at-the-mouth hop-crazed left-coasters wouldn't like it anyway. It's practically unhopped. So there.

From: Gordon Baldwin <hpubvwa.nsr.hp.com!sherpa2!gbaldwin>  
Subject: Low sparge yield

I posted here about 2 months ago complaining about low yield. The general concensus was to slow down my sparge, and that helped, but I am still not up to where I think I should be. Here are the details:

8 lb klages  
.5 lb munich  
.5 lb crystal  
1.5 oz cascade beginning of boil  
1 oz fuggles middle of boil  
1.5 oz saaz fininshing  
Wyeast German ale yeast.

I use a one step infusion mash at 155 for 45 minutes. It looks like I get complete conversion testing with iodine. I tested before so I know what to look for when conversion was complete. I sparge with about 4 gallons ~170 water until it no longer tastes sweet, about 6 gallons. I sparge in the Zap-pap lauter tun (nested buckets with the inner bucket drilled with about a thousand holes.) Sparge now takes about 45 minutes to complete. The boil is for 1 hour and I boil the 6 gallons down to about 5. The starting gravity is 1.036 and finishing is 1.006. With 9 lb of grain I think I should be getting around 1.040. I just brewed a similar receipe using 12 lb of grain and I only got 1.042. My grind seems good, I get my grain from The Cellar in Setttle, (They are only about a mile from my house). They have a good roller mill there that I use, and they checked the grind and thought it looked fine.

Any pointers to what I should try next would be greatly appreciated.

Subject: DMS vs DME

Whoa! Two people in the same issue refering to the extract which still has active enzymes as "DME." DME is the common acronym for Dried Malt Extract. Let's not confuse beginners here! Edme makes a product they call DMS which stands for Diastatic Malt Syrup and does have active enzymes. DMS is also an acronym for Dimethyl Sulfide which we all know as "that cooked-corn aroma." I know that Munton & Fison also makes a Diastatic Malt Syrup and they might even call it DME, but lets reserve the acronyms DME and DMS to Dried Malt Extract and Dimethyl Sulfide and spell out Diastatic Malt Syrup (or Extract) so there's no confusion. Al.

> from boiling to pitching temperature instantly, and I can pitch right  
> away. There's no "cold break" that I can notice with this method;  
> I imagine the trub eventually precipitates out into the primary  
> yeast cake.

Steve, I have also been an extract brewer for about one year,  
but have not had the experience that the temperature drops from  
boiling to pitching instantly. Indeed, even if you mix 2 gallons  
of boiling wort at 212 degrees F to 3 gallons of ice cold water  
at 32 degrees F you get 5 gallons in the fermenter having a  
temperature of

$$T = (2 * 212 + 3 * 32) / 5 = 104 \text{ degrees F.}$$

Piching at such temperatures can cause your yeast (even Wyeast) to  
do wierd stuff. Even worse, my cold tap water in the summer  
(in Maryland) is about 68 degrees F. I cool the ingredients  
in the fermenter by immersing the entire fermenter (covered)  
into a large container filled with ice water. This cools  
my brew down to pitching temperature (about 75 degrees F) in 40  
to 75 minutes depending on the temperature of the tap water.

However, I am planning to move on to all grain and am planning  
on building a wort-chiller using some of the excellent ideas that  
I've read in HBD.

There has also been a lot of articles on hop pests recently. In  
HBD910 Ron Karwoski writes:

> My hops have a couple of problems. I have only two plant growing  
> and I fear I may have lost them for the year. The tops of both plants  
> have been lost. On one, a few days of wicked storms weakened the plant

> marching  
> up and down the twine. My question: Will these tops come back and the  
> plants  
> resume climbing or are they stuck for the year? How do I get rid of the  
> ANTS!? Soap?

No, ants will not harm your hop plants. Ants, however, are  
attracted to a secretion (honeydew) of aphids. If you look  
carefully, you should also be able to find aphids. In their nymph  
stage they are light green in color, with roundish bodies about  
one sixteenth to one eighth on an inch long, and are soft bodied  
(will squish easily if you touch them). They will change in time  
developing small wings and become darker in color.

Two additional ways of controlling these pests are

- 1 Squish them between your fingers (they tend to cluster).
- 2 Mist them with water, then dust them with household flour.

One problem with these methods and the other organic treatments of using rotenone, pyrethryn (sp?) or insecticidal soap is that each method is a direct contact method only, (rotenone breaks down quickly) and if you have bad aphid problems you may have to treat them almost every day. This is probably why Al Korz mentioned in HBD910 that Sevin worked better than Safer's soap for him. Sevin is not organic, and will last a few days so it is not needed as frequently. I myself try not to use inorganic compounds, but Sevin isn't too bad, and its the only thing I've found effective on Japanese beetles. (A friend of mine, who is a fanatical cat lover, dips his cat in a Sevin solution to rid it of fleas. He's so careful about the health of his cat that he'll take his cat to the vet whenever it sneezes!)

Also, don't worry about losing the tops of the hop plants. Last week, while increasing the height of my hop trellis, I accidentally cut off the top of a hop plant. It now has grown two branches near the top and both are already over a foot long.

Bill Szymczak

> Then the hot water rinse is repeated again for another full minute.  
> The chiller is then stored with the copper tube left full of water.

Er, ah, I don't really want to tell you this Bob, but you're not using  
your chiller correctly. There is no need to clean the inside of an  
immersion  
chiller...the cold water runs through it, and you dip the whole mess down  
inside your kettle. Thus, the name "immersion"...the only thing you need  
to clean is the OUTSIDE, not the inside.

Don't feel bad, you're not the first person to do this, I heard some  
people  
even bought pre-manufactured ones, only to have to change all the  
fittings  
to get it to work like they thought it was supposed to. I'm posting this  
to the digest directly because there are more people than I realized  
doing  
this...

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: cylinder vs. square

I've used up to 12 pounds in my cylindrical cooler.

It was real easy to get the 3/8 to 3/8 right angle compression fitting, 6 feet of copper tubing (coiled and slotted on the bottom) and the right angle 3/8 spigot (look under your sink, the oval knob kind you find in plumbing stores) in local hardware stores, all for under \$10.

I think the square cooler setup is a little more complicated, but I'm basing that on one rig I saw made with plastic tubing of some sort in a E shape.... Still it's probably no big deal.

My preference for the cylindrical cooler holds since I brew 3 or 5 gallon batches. If you wanna brew bigger ones you'll surely need the rectangular coolers...

Subject: Dry Yeast Update

I've some news of interest to active dry yeast users and detractors, alike. First of all, some business news:

- o I can confirm the rumor that Whitbread is no longer producing dry yeast, production stopped earlier this year.
- o I can also tell you that Red Star has been out of the beer yeast production business since last year.

I've once or twice seen the question, "Who makes the dry beer yeast that's private labelled by G.W. Kent?" Answer: Lallemand Inc., who are known for their 70+ strains of dry wine yeasts, usually under the "Lalvin" trade name. They now produce both a lager and an ale dry beer yeast, at plants in Canada and Denmark.

This information comes from the owner of G.W. Kent Inc., a major brewing and vinting wholesale supplier, and the U.S. Agent for Lallemand. Some highlights from Lallemand marketing literature they shared with me:

Until the 70's, the wine industry all used spontaneous fermentation. About that time, experimentation began on isolating single cell cultures that would provide individualized and consistent characteristics. Single cell strains were successfully isolated, but there were problems developing commercial cultures. This was due both to limited culture lifespan and short unpredictable grape harvest seasons.

If you use dried yeast for brewing, you may be interested in these rehydration recommendations from Lallemand:

"Three factors seem responsible for the effects of rehydration on subsequent activity. The first is a loss of cell constituents, which results in poor growth and activity. Secondly, improper rehydration creates a condition of poor dispersion of cells which results in clumping of cell groups thereby reducing the efficiency of oxygen and nutrient transfer to the cells. The net result, poor activity. Finally, the effect of "cold shock" can also be devastating. When dry yeast is added to cool must, water or wort, the viable cell count can drop by as much as 60%! Petite mutants can be formed which may produce off flavors. Although these mutants generally have a limited life during normal fermentation, their effect can be magnified because of the sluggish nature of the remaining recovering cells."

Guidelines:

- o Use 5-10 times the amount of water to dry yeast.
- o Use water between 105-114 F.

- o Add yeast to water, not water to yeast, to avoid uneven rehydration.
- o Let the yeast sit for 5-10 minutes before stirring, and pitch within 30 minutes.
- o If your wort is over 50 F, gradually add small quantities of wort to the rehydrated yeast, in 5 or 10 minute intervals, to allow for temperature matching.
- o Rehydrate in water, not wort, due mainly to wort components that are lethal during the rehydration period, such as SO2 and hop components.

In summary, Lallemand dry yeasts are selected for fermentation characteristics (as well as dehydration survivability), and they recommend rather more complicated rehydration procedures than the published homebrewing literature I've seen. It is possible that many of the off flavors I've had over the years of brewing with dry yeast came from improper pitching technique, such as opening the package and dumping the dry yeast directly into my wort.

I hope you've found this information helpful.

Disclaimer: I've never used Lallemand yeast, and for the last 18 months have been using nothing but liquid cultures. I don't plan to go back.

Subject: Samuel Adams Boston Ale

Does anyone have a recipe for Samuel Adams Boston Ale? I'm looking for an all-grain recipe to mimic this. The label says it the hops included Kent Golding, Fuggles, and Saaz. Any idea which is used for bittering, flavoring, and finishing?

Thanks,  
rick

Subject: Priming with DME

Yes I Know this is a FAQ, but I never pay attention to such things until it has to do with me :-)

I am making a brown ale, and plan to bottle on Tuesday. In the past I have used 3/4 cup dextrose dissolved in one quart boiling water. This time I want to use DME for the priming (even though I have about 2 pounds of dextrose from earlier supplies). SO... how much DME is equivalent to 3/4 dextrose?

Thanks,  
John

Something I've seen that occurs in particular species of ants is a peculiar behavior called "aphid farming" The ants will transport aphids to suitable "grazing areas", then "milk" the aphids for "honeydew", an aphid secretion rich in sugar. It might be a good idea to look closely for aphids if ants are observed on the hop vines, and treat accordingly. Ladybugs are hell on aphids, if you can convince them to hang around. In any case, I'm not aware of any common species of ants that like to chow down on hops.

From: Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU>  
Subject: More on hop backs. Mash efficiency.

Russ sez:

>My plan now is to pour boiling water into the plastic  
>buckets/hop-back and let it sit while the wort is chilling as usual. The  
>heat should sanitize the buckets. Then I can pour the cooled wort  
through  
>the hop-back. No hot wort, no plastic nasties, and well-oxygenated wort  
>as a by-product.

True. But, as you note below, I don't think you will extract as many hop oils from the wort by circulating cooled wort over them. Moreover, I'd worry some about bacterial contamination. Since you're running cooled wort over fresh hops you're basically dry hopping. But dry hopping in the secondary is safer than what you propose here because some alcohol has already been generated during primary fermentation and therefore lessens the risk of contamination.

>One concern about your hot wort/hop-back/chill scheme,  
>Kinney, is that the hops are not being used as a trub filter bed, at least  
>not for the cold break material. But I guess that's the price you pay  
>for all that great hop aroma that'll be extracted by the hot wort. Does  
>Sierra Nevada hop-back with hot or cold wort?

You know me, Russ. I'm the infamous pot-scrubber-in-a-mesh-bag guy. With that technique, I filter the wort up front. Your point about the cold break material is true but all hop backs assume the circulation of hot wort over the hops prior to the wort entering the wort chiller. Letting the wort sit on the cold break is another issue and one that I, frankly, don't worry too much about. I figure I'm doing such a good job of filtering off the hot break, a little bit of cold break can't be too detrimental to my beer, discussions about the pros and cons of this notwithstanding. Plus, with the ol' BrewCap system, I can drain away the cold break immediately upon the cessation of primary fermentation. I figure that's the time to get the beer away from the cold break anyway since allowing the beer to sit on the break appears to be advantageous during the respiration phase of the yeast. I know some would disagree but my beers have been turning out just fine.

Sierra Nevada hop-backs with hot wort.

And Gordon worries about the low yield of his mashes:

>I use a one step infusion mash at 155 for 45 minutes.

Mashing at 155 will not convert as many of the sugars as would mashing at 150. Mashing at 155 will promote a dextrinish wort. You'll miss the maltose since the enzymes for converting these are inactive if not destroyed at the higher temps.

>It looks like I get complete conversion testing with iodine. I tested  
>before so I know what to look for when conversion was complete.

I usually see starch conversion at 45 minutes, too. But Dave Line recommends letting the mash continue for another 45 minutes past starch conversion for an even more complete conversion.

>I sparge with about 4 gallons ~170 water until it no longer tastes  
>sweet, about 6 gallons. I sparge in the Zap-pap lauter tun (nested  
>buckets with the inner bucket drilled with about a thousand holes.)

Again, following Dave Line, I use a sparge bag. He points out that  
sparging in a plastic bucket will promote capillary action along the  
sides of the bucket thus wasting all that water. The coarseness of  
the sides of a sparging bag reduces this tendency. Although I've  
never done a side by side test, I had a customer who did and he  
reported an increased yield with a sparge bag. FWIW.

>Sparge now takes about 45 minutes to complete.

That's plenty of time.

Cheers ya'll,

> had the potential for introducing air into the beer as it flowed by  
> (by Bernoulli's principle). Has anybody had any further thoughts on  
> this or experiments to back it up or refute it?

I have a Phil's Philler. The hole at the top is closed when the main  
valve opens. There are no apparent bubbles at the exit of the filler  
(no bubbles floating to the surface) during filling. The filler is  
designed very well and does a great job.

> I'm currently using one with the valve at the bottom. ...  
> But it does "spray" beer out the bottom.

This is the primary source of oxidation in bottles, followed by  
excessive head space. The spray creates great turbulence in the  
presence of air and can oxidize the beer. You may as well pour  
an ounce of beer in the bottle and shake it up before filling the  
remainder. If you could purge your bottles with CO2 before filling  
with beer, this problem would be eliminated, but that's obviously  
too much work.

> Still it's better than no bottling wand, by far.

I disagree; a spring clamp on the siphon hose can work just as well  
for controlling/stopping the flow and produces no splashing or spraying.

From: korz@iepubj.att.com  
Subject: Phil's Philler

I tried Phil's Philler at the AHA Conference. It does not suck air as Spencer suggests since (I believe) the air hole is covered when the "valve" is open. Stopping and RESTARTING the philler \*does\* introduce a big bubble. The guy behind the counter (Mr. Listerman, I believe) said that with proper practice, you will never introduce air like that. It's true that when he filled the bottles, he very rarely had any bubbles and probably only because he was hurrying and leaning over a table. For those with shaky hands, Phil's Philler could prove difficult to use, but with practice, you could probably avoid air 95% of the time. Incidentally, when I do splash the beer around as I fill or if it's one of the first 10 or so bottles, I mark the bottle as "NOT FOR COMPETITION." It would really be terrible if the one bad bottle of my finest beer made it into (and quickly out of) a competition.

Regarding spraying (with any variety of filler) while the level of the beer is below the end of the wand, there is a simple way to slow the rate of filling till the end is submerged: change the height of the bottle. I use the dreaded "orange tip" filler and I like it. When I begin, I have the bottom of the filler about 6 inches below the level of the beer in the priming tank. Once the end is submerged, I lower the bottle to the floor and the bottle fills up quickly. Note that the "orange tip" filler now leaks. I used to curse this, but not anymore... I use it to my advantage. When the bottle is filled to the very top, and I remove the wand, the level, of course, drops. But since the "orange tip" is slowly leaking, it still is filling slowly. I can get easily the level in the bottle at 3/4 to 1 inch from the top, which is what I believe is ideal.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: dry-hop?

I've got some question that pertain to chillers, hopping, and all this sort of stuff we've been talking about. Isn't it a good idea to allow the steam from the hot wort to escape to disperse DMS (dimethyl sulfide, the cooked vegetable smell)? If so, do you counterflow-chiller users wait a while before you start chillin'? How long is "long enough"?

Now, why is the hot-wort/hop-back/counterflow-chiller combo any different or better than just adding finishing hops to the hot wort and quickly immersion chilling? The counterflow method should keep more of the volatile hops oils in the brew. But the standard finishing hops method allows for longer hop/wort contact time, and so should allow more hops oils to be released to the wort (and the air). Seems like the two methods might end up being more or less equal, except one makes your house smell like hops ;-)

From: hartman@varian.varian.com (John Hartman)  
Subject: re: English Bitters--Brewing Beers like Young's they make. AGAIN

Dear Readers--

I understand that this recent submission was unfortunately garbled and am hereby resubmitting it with nice, well-behaved newlines. I believe the problem is fixed. My email karma has not been good lately... The mailer I used apparently feels that no paragraph should contain more than one newline nor should a paragraph be longer than 1024 characters. That mailer was yesterday unceremoniously shot to death. My apologies. Enjoy the tour.

- - - -

This recent discussion prompts me to give further details of my trip. I spoke at length with two of the five brewers at Young's Brewery in London. They definitely qualify as "lupulophobic". I describe what I learned about their ales below...

They make a number of cask ales, some bottled ales, and a couple of lagers. My focus was on their ales and does not apply to their lagers. In particular I was interested in Young's Special cask-conditioned ale. As this information was given to me in the tasting room after the tour, my focus did eventually become blurred and my arm did eventually become tired. While tasting you see, I was forced to fill my own pints via hand pump;-) Also I didn't want to pry (I just wanted to know everything:-)). Consequently, the information I do have is incomplete and not well organized--sorry. On the other hand, what I did learn came straight from the brewers, who were very enthusiastic and forthcoming, so I assume it's accurate. If I wasn't sure about what I remembered I have noted so in parentheses...

All of their grists are "approximately the same". They use "only the finest ingredients they can find". The variety of malt is Maris-Otter. I have a small sample of crystal that appears to be about 20 or 40 lovibond. Some flaked barley is also used for head retention. A certain amount of brewing sugar is used. I don't know how much nor in which beers. Contrary to what is printed in the "The Real Ale Drinker's Almanac", Young's does not use torrefied wheat in any of their brewing. In general I was disappointed with the accuracy of the information found in the almanac. Let the brewer beware that the ingredients they list have little in common with what in reality Young's uses. Oh well.

Young's Special draught should not be confused with the bottled Special London Ale sold here in the US. The draught bitter has an OG of ~ 36, draught special has an OG of ~ 46, and the bottled Special London Ale is ~ 66 OG. I don't know what IBU levels are used for the beers, but they do use a single addition of Fuggles in the kettle at the beginning of the boil. And now we come to the issue of finish hops. The draught bitter is (I believe) dry-hopped with (I believe) East Kent Goldings. The bottled Special London Ale is dry-hopped with East Kent Goldings. The draught special is dry-hopped with the Target variety in plug form. The box called them pellets, but they were in fact 1/2 oz. plugs as we know them here in the states. For each 36 Imperial Gal cask (43 US Gal.) they use a mere 2 oz. of Target! I was embarrassed to tell them how much I use and for a brief moment considered prevarication (lying, that is). When I told them that I usually use about 1 to 2 oz. per 5 US Gal., there was no uncertain amount of surprise and

disdain. I believe this "lupulophile" lost some credibility here. Oh well. I still hop most of my beers at such a rate.

Young's only started dry-hopping about two years ago. The owner and most of the brewers were not interested in trying it, but once they had, they decided to make the change. I suspect the economy of dry-hopping, i.e., more aroma at less cost, played a part in that decision.

Their beers ferment in open primaries for seven days. They are then transferred to secondary for seven more days. Then the beer is placed in SS casks. It is at this point the beer is dry-hopped and fined with Isinglass powder. In a few days the draught is drayed (delivered by horse-drawn cart) to their local tied houses. Finally after a few more days in the pub cellar it's served to the many patrons who happily slake their thirst. The beers are never primed or krausened. Their yeast strain is a slow finisher which allows them to develop a light level of carbonation in the cask without priming. I have since tried this and it works quite well. Also it makes brewing that much easier since I don't have to mess with gyle or corn sugar. They do have a kegging and bottling operation which (I believe) force-carbonates those products. I asked for an opinion on our weighty matter of whether to skim the krausen or use a blow-off tube vs. not skimming. They don't skim per se, but do employ some technique which has the same effect. The brewers definitely recommend skimming. They said it improves the "brightness" and stability of the beer, not necessarily the flavor.

I hadn't heard of Target, so I enquired. The Target variety is a descendant of EKG. It is a 10-12% hi-alpha, hi-aroma version that I do not believe is available here. I have since called Dave Wills of Freshops to see if he carries them. He said this year he ordered 100lbs of imported EKG and sold them quickly even though he didn't advertize their availability. He plans on ordering more and so I told him to consider the Target variety. He will, depending on the interest level. If you as well would like to use this hop perhaps you might call Dave an express your interest. Freshops' number is 1-503-929-2736. I have no affiliation with Freshops other than buying lots o' hops from them. If you know where one may obtain Target here, let me know.

As an aside which has nothing to do with how they brew their beers, the owner related to me that several years ago when Fritz Maytag was reviving the Anchor Brewery here in SF he visited Young's for two weeks. He took back with him recipes and knowledge gained at the Young's brewery. So maybe I'm on the right track... That is all.

Cheers, John hartman@varian.varian.com

Subject: Re: Wort Chillers for Extract Brewers?

homebrew@lupulus.ssc.gov writes:

>I'm an extract brewer (with occasional specialty grains), on my 16th  
>batch in about 1 year. Will a wort chiller help my brew?

I would say the answer is an unequivocal YES. I regularly teach a beginning homebrewing class, in which I use the basic method of adding dense wort to water. When I compare these beers to the pilot beers I make doing a full-wort boil (with wort chiller), the difference in flavor is pretty extraordinary.

The downside, of course, is that you need to buy a bigger kettle and that you need to spend a little time and money on a wort chiller. You have to decide for yourself whether the tradeoff is worth it, but I think you will definitely make better beers this way.

From: Kent Dalton <kentd@bach.ftcollinsco.NCR.COM>  
Subject: Reading SG from wort in Carboy: SUMMARY

I'd like to give a big "thank you" to all the HBDers who helped me with suggestions on techniques for reading SG from wort in the carboy. The response was exceptional! You folks are great!

In appreciation, I've prepared a summary of the ideas I received so others might benefit...

Summary of SG Reading Techniques:

=====

1. Use a Turkey Baster to remove wort from carboy and take reading- This was *\*by far\** the most suggested technique. Most folks suggested trying to hunt down a glass or pyrex baster rather than the garden variety plastic types for ease of sanitation. Some mentioned that metal models might also be available.
2. Use a "wine thief" or a large glass pipette to remove some of the wort for SG readings - This has the advantage of easy sterilization. Some said that a drawback was that some wine thieves required a couple of "thefts" in order to get enough wort to take a reading. They should be readily available at brewing stores which also carry wine making supplies.
3. Use the "BrewCap" - Apparently the brewcap is a commercial product which has a collection hose which allows one to judge whether fermentation has completed based on the rate of yeast deposit in the hose. I would like more information on what exactly this product does and if any other benefits are gained from its use. If anyone knows more, please let me know.
4. Measure SG in the carboy itself by lowering the hydrometer into it - I probably will not use this because of the size of my carboy neck and the amount of blowoff is usually enough that I wouldn't be able to get the hydrometer out once it was inserted. Plus I don't sterilize my hydrometer very often.
5. Siphon some wort out into your graduated cylinder for reading the SG

General SG reading tips:

=====

SG readings from blow off are inaccurate.

Never return wort to carboy after taking an SG reading.

Note that one HBD'er reported different OG's at different sample levels (depth); this would be a good way of testing whether you shook up the beer adequately when pitching....

Avoid taking too many samples, watch the airlock and the wort to determine how far a long you are to avoid having to do SG readings too often. Many HBDers reported similar experiences to the following:

What you do though is watch the fermentation lock.  
If it goes more then 1min between gulps it's done.

Make sure to hang a thermometer in the area though  
since fluctuations in temperature can affect CO2.

Subject: Filler, Mash Yield

To: Homebrew Digest  
Fm: Jack Schmidling

>From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>

>He liked Phils Philler the best because (1) the beer doesn't spray out the bottom (so no aeration at that end) and because (2) it left very little head room (so little oxidation potential at that end).

Phil was in Milwaukee and when he demonstrated the filler to me, it seemed to squirt beer around the top somewhere. I left with the general impression that it is a bit messy.

>I'm currently using one with the valve at the bottom.... But it does "spray" beer out the bottom.

There are two simple tricks to minimize the spray. First of all, you raise the bottle to reduce the head pressure when starting and secondly if you tilt the bottle, you quickly cover the end of the wand with beer. Once it is covered, put the bottle back down to the normal filling location.

.....

>From: Gordon Baldwin <hpubvwa.nsr.hp.com!sherpa2!gbaldwin>

>I posted here about 2 months ago complaining about low yield. The general concensus was to slow down my sparge, and that helped, but I am still not up to where I think I should be. Here are the details:

8 lb klages  
.5 lb munich  
.5 lb crystal

>I use a one step infusion mash at 155 for 45 minutes.

> The starting gravity is 1.036 and finishing is 1.006. With 9 lb of grain I think I should be getting around 1.040.

> I just brewed a similar receipe using 12 lb of grain and I only got 1.042.

I have no experience with plastic bucket brewing, but the second figure is more of a problem than the first which is in the ball park. You may be getting all you can get by dumping hot water onto a bucket full of malt.

I use an active mash, i.e. in a kettle on the stove. This allows a mashout at 178F and I sparge with boiling water. My typical yields for six gallons are 1.040 with 9 lbs and 1.055 with 12 lbs.

I have tried stirring the mash after extracting 5 gallons and get real excited to see the gravity of the next sample take a quantum leap but the net extraction does not seem to be effected.

The initial sample out always seems to be around 1.080 no matter how much grain I use.

I would be interested in comparing notes with others on yield just to see what the mean values really are.

>My grind seems good, I get my grain from The Cellar in Setttle, (They are only about a mile from my house). They have a good roller mill there that I use, and they checked the grind and thought it looked fine.

There are those who claim that fresh is where it's at. For example, one brewpub claimed they had to increase the amount of malt by 10% if it sat over night after milling. I rather doubt this but people have also claimed their yields went up by 10% when they used a MALTMILL. So who am I to argue.

From: (Mike Fertsch) hopfen!mikef@synchro.com  
Subject: Crazy Horse Amendment

To: Beer Aficionados  
From: Marlene Spears (reply through Mike Fertsch)

Date: 1992 June 28

Subject: Write Your Congress Rep!

**Subject: Crazy Horse Amendment**

URGENT! Just because certain people have been offended by Heileman's Crazy Horse malt liquor, Congress wants to force Sam Adams, William Penn, and maybe even Buffalo Bill, to change the names of their beers! Think that's over-reacting? Then:

Write your Representative and demand that the "Crazy Horse" Amendment be stricken from Bill HR 5488!  
Better yet, FAX your letter: THE BILL GOES TO THE HOUSE ON JULY 1ST!

Thursday, 25th June, the US House Appropriations Committee voted to add the "Crazy Horse" amendment to HR 5488, a Bill to authorize \$22.8 BILLION in appropriations for -- look at this! -- the US POSTAL SERVICE, the BUREAU OF ALCOHOL, TOBACCO AND FIREARMS, and other TREASURY DEPT. agencies! The "Crazy Horse" amendment forbids manufacturers and distributors of \*all\* alcoholic beverages from using the names of DEAD historical figures to sell their products. [BATF already forbids the use of names of LIVE historical figures without their permission, protecting us from, say, "Dan Quayle Potatoe Beer".] The amendment was approved by the Committee on a show of hands by 29 to 11 votes, with the advocacy of Mr. Frank Wolf (R-VA), so it has considerable support on the Committee.

The Committee also by-passed other House Committees, such as Commerce, with this amendment. It's another case of a small group of people making a knee-jerk reaction to a genuine issue and trying to slap on a band-aid without considering the full cost of their actions. This is typical of the real machinations of our Congress, with so much to do and so little time. The name that a brewer gives to his beer is not directly relevant to the amount of money the Postal Service and the Secret Service and the BATF should receive for the next fiscal year. But it will be restricted by a three- or four-paragraph amendment to a several-hundred-page Bill, and probably will receive no more consideration than a sneeze unless somebody calls Congress's attention to it!

I see some fundamental problem with this amendment (yes, I have contacted my Rep., Mr. Ed Markey). Regardless of how I personally might feel about the makers of Sam Adams or Crazy Horse, I believe Congress cannot legislate taste! The market, we who buy beer, should decide. We can put pressure on the G. Heileman Brewing Co., of LaCrosse, WI, without passing laws that violate First Amendment rights. And the wording is too vague. Deciphering the meaning of the words "deceased historical figure" might tie up the court system for years without serving the public's best interests.

Before this amendment becomes law, we can stop it and thereby save taxpayers' money that will otherwise be spent challenging it in court. The "Crazy Horse" amendment is unjustified censorship. Congress should focus its attention on larger issues and stop micro-managing public opinion. The last thing we need is the BATF conducting a

"pedigree search" on every beer name!

I'm trying to get my hands on a hard copy of the text of the amendment itself. If I get it, and there's any response to this posting, I'll type it in. But if you're going to write, DON'T WAIT. Tell your Representative that you care about this trivial and petty amendment and want it deleted from the Bill. Believe it or not, JUST ONE LETTER FROM ONE CONSTITUENT might be enough to call it to your Rep's attention. And it will only take one or two Representatives asking that the item be brought up for consideration to get the full House to challenge the amendment.

It's a little thing, yes, but it's a question of freedom. Remember, it's just such a little thing that allows us to brew our beers legally, for those of us who don't live in states that forbid it. We can lose that freedom, too, if we don't defend it. Or we can make a little noise once in awhile and prevent a knee-jerk reaction against beer and alcohol from becoming an amendment to another House Bill.

[My information comes from an article that appeared in the Boston Globe on 26th June 1992. Ms. Adrian Seibert (sp.?) of States News Service, in Washington, DC, graciously provided me with the number of the Bill and additional information about it. I'm not on the HBD net, but you can zap Mike Fertsch at <mikef@synchro.com>. Unfortunately I can't tell you who your Representative is; call your Public Library or City/Town Clerk.]

Subject: Re: low yield

I missed Gordon's original post, so these details are snarfed from Jack's reply. Gordon says:

> I posted here about 2 months ago complaining about low yield. The  
> general concensus was to slow down my sparge, and that helped, but I am  
> still not up to where I think I should be. Here are the details:  
>  
> 8 lb klages  
> .5 lb munich  
> .5 lb crystal  
>  
> I use a one step infusion mash at 155 for 45 minutes.  
>  
> The starting gravity is 1.036 and finishing is 1.006. With 9 lb  
> of grain I think I should be getting around 1.040.  
>

I'd expect to get still more than that. I mash in three gallons, sparge with three gallons, and with 9lb of grain usually get around 5.5 gallons at 1042. Based on what the books say I would say I have room for yet further improvement.

I've also had problems with poor yield and was interested in the replies. All I'd agree with:

Jason says check the pH. Dead right. The enzymes will slow unless you get it right. Check what the correct figures should be because I'm going from memory here, but I think you need to be between 5.0 and 5.5. Lower pH favours one enzyme, alpha amylase I think. Higher pH favours the other.

Kinney says the temp is a mite too high. I agree, 155 is fine for starting but you might do well to drop it to 150 after starch conversion, to assist the beta amylase.

Then Kinney says 45 mins is not really long enough. I think he has put his finger right on your problem here. I find 45 mins nowhere near enough when mashes are being stubborn. The greatest amount of conversion happens early, yes, but you need at least 30 mins more for dextrins to convert to maltose and to wring the rest of the starch from the grains. On occasions when I've reluctantly had to make do with poorly crushed grain, the mash has taken over 4 hours. Dave Line even suggests mashing overnight! My next move in your situation Gordon would be to double the mash time to 1.5 hours. Furthermore, if your temp and pH are a bit off you will need more time still.

Lastly Kinney suggests a sparge bag. Yes again, I wouldn't be without mine.

Desmond Mottram.

From: tcm@moscom.com (Tom Maszerowski)  
Subject: Dry yeast recommendations

I was in my one of my local homebrew outlets (Maier's in Webster, NY) this weekend looking for nothing in particular when I happened to notice that the yeast selection was terrible. Maier's at one time was a distributor of MeV (sp?) liquid cultures but since they have stopped production Maier's no longer has any liquid yeast. I have used Whitbread dry yeast in the past with excellent results but now I hear that it is no longer being produced. I prefer to use dry yeasts because my brewing schedule is at best haphazard, I usually can't plan more than a day ahead. My question is: is there a good, generally clean ale yeast available in dry form or will I be forced to go to Wyeast?

Subject: The Birmingham Brewery

The following AP article appeared in Sunday's Huntsville Times:

Birmingham Brewery has sellout debut

Until last weekend, beer brewed in Birmingham went down the drain. But Red Mountain Red Ale had a better fate.

Birmingham Brewing Co. offered the beer for the first time at the City Stages music festival, which began last Friday night in Birmingham. By 9 p.m. Saturday, the brewery had sold the last of its intitial production of 1,147 gallons.

"It was a big deal for us, a big deal for Alabama," said John Zanteson, head brewer. "We worked until 3 a.m. Friday morining filling kegs."

The brewery is the first in Birmingham since 1907, when politicians banned alcohol and forced the original Birmingham Brewing Co. to pour 300 barrels of beer into the street.

The brewery is one of a growing number of microbreweries that each produce a few thousand gallons a year. Today, there are more than 200, many in California and the Pacific Northwest, Zanteson said.

Officials at the state Alcoholic Beverage Control Board said Birmingham Brewing Co. is the first microbrewery in the state, although there has been talk of starting one in Mobile.

Zanteson worked for a microbrewery in California (Hopland, ed.) before joining the Birmingham firm. It began building its brewery in February and has been installing equipment to brew the ale and a lager. The lager takes longer to go through the fermentation, Zanteson said.

The company is owned by Lee Nicholson, the brewmaster, and Ben Hogan, a Birmingham attorney.

From: JOHNREED@BOSTON.VNET.IBM.COM  
Subject: WYEAST CA Common

A couple of days ago, Russ posted a question about WYEAST California Common Beer (aka Steam Beer yeast). Well, I just brewed my second batch using it, and I can say that it produces clean beer. Probably my best batch so far.

Here are a couple of items I noticed. During primary fermentation at 65 F. a sulphur-like odor emanated from the airlock. This went away after a day or two. After secondary fermentation of 3 weeks, I bottled and noticed no off flavors or odors. But when I sampled a bottle (admittedly soon-- after 6 days) I again noticed the sulphur smell. Now, however, three weeks since bottling, it's very clean with no sulphur smell. It's a light bodied beer (too light for a steam beer, IMHO) based on Papazian's first "The Sun Has Left Us On Time" recipe. There is a citrus (grapefruit-like) flavor which might be from the Cascade hops. I'm not sure. It could also be from the 2 oz of loose K Goldings I used to dry hop.

My second batch is in the secondary now. This time, however, I used Papazian's second "The Sun Has...." recipe. The difference is that it calls for a lot more Alexander's Pale extract. This recipe should be truer to the Anchor Steam style with more body.

At any rate, the WYEAST seems to be a good strain. The second batch, by the way, did not produce that sulphur odor as a by-product. Something I did or maybe just more nutrients available for the yeast with a higher OG?

From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
Subject: First Mash

Well I did my first mash yesterday. It was surprisingly easy, considering that I needed to fabricate my mash/lauter tun and wort chiller. Here is what I did.

For a mash/lauter tun I used a five gallon cylindrical water cooler, Rubbermaid Gott brand. These are available at Sears and home center stores and maybe K-Mart. I got mine in New Jersey, but they are available closer to Philadelphia. About \$20. I did not get the squarish Coleman brand, though, because it would not work as well with my sparge system described below. I also got a plastic drum tap from Home Sweet Homebrew (HSH) in Philadelphia for a couple of dollars. Then I unscrewed the push button tap on the Gott cooler, using a pencil soldering iron I melted a larger opening in the outer wall of the cooler where the tap is inserted and scraped away the insulation from between the walls. I had to enlarge the opening to the inner wall of the cooler, but much less than the outer wall. The drum tap then screws into position with the two washers supplied and a bit of formable washer (a thin strip of sealing compound used to pack leaky faucets). The washers may be enough, but my inner hole was not quite circular and I feared a leak during the mash. I may seal the whole thing with silicone sealant if I ever get a leak, but for now the tap is removable.

To complete the mash/lauter tun setup, I set into the bottom of the tun a vegetable steamer of the sort that opens like petals of a flower. It is designed to hold vegetables in a pot of boiling water about 1/2" off the bottom of the pot. It costs about \$10 at HSH, but got mine on a whim at Ikea in Plymouth Meeting a while ago for about \$2. It is made of stainless steel. Finally, I got a nylon grain bag at HSH for about \$10 that fits inside the tun.

The wort chiller was really easy. I got 20 feet of L 3/8" O.D. refrigerator copper tubing at Hechingers in Narberth for about \$12 and, for about \$2.50, a compression fitting that takes the tubing to 1/2" threads and an adapter that then goes to 3/4" garden hose size (which connects to the adapter on my kitchen faucet that I got with my bottle washer). Before installing the fittings, I re-coiled the tubing around the outside of a pot that was smaller than my brew kettle and then bent the ends up into an inverted "J" so drips from any fittings fall outside the brew kettle. On the intake side I used a spare washing machine hose and on the discharge side I stuck some old siphon hose over the tubing (it was a tight fit).

I then dumped 7-1/2 lbs. of my pre-crushed British 2-row grain and 1/2 lb. of 40 L. pre-crushed British crystal malt into the grain bag in the tun (which sits on top of the steamer), turned the tap off, and put in two gallons of 170 F. water. (I used the water charts for a single step infusion mash from Papazian's book.) Stirred vigorously and checked that my mash temperature was between 150 and 155 F. (I hit about 151 F.) I did an iodine test (it worked!), screwed the top of the tun on and let it work for about 90 minutes.

After mashing, I drained the first runnings from the tun and

added 4 gallons of boiling water, stirred again, and let sit for 30 minutes. I then drained off the second runnings and proceeded as I have with extract brews. This simple "mash out and sparge" technique seemed to work well, although I have not calculated efficiency. I will try to measure that next time when I have a better idea what I am doing and do not need to make up the tun and the like. George at HSH suggested that to sparge in this setup a colander could be set over the top of the tun to spread out the sparge water as it is poured in. I hope the easy "sparge" will be sufficient, and not release too many tannins from the hulls of the grain. Since I read about this technique in HBD, I would be interested to hear about your experiences with it.

From: korz@iepubj.att.com  
Subject: chillers

The original poster, accidentally wrote "immersion" instead of "counterflow" in his post, but that's it. For the record, there are basically two major types of wort chillers used by homebrewers:

1. Immersion -- run cool water (usually tapwater) through a coil of tubing which is immersed in the kettle of hot wort. A water-saving option is to use a pump and recirculate icewater through the coil. Some immersion chillers have an pre-chilling stage in which the tapwater runs through an additional coil first which is submerged in a tank of icewater. Advantages are: lower cost, most cold break left in kettle, easier to hit pitching temperature, and the surface that touches the wort is visible and thus easily cleanable. Disadvantages: entire volume of wort (simultaneously) cools slowly, efficiency dependent on tapwater temperature (i.e. not efficient in say, Florida, where the tapwater is not cold), and there is a slightly higher risk of infection since the wort spends more time between boiling and pitching temperatures.

2. Counterflow -- tube-in-hose chiller. Hot wort is siphoned or pumped through a tube which is surrounded by a hose carrying cool water (usually tapwater). Again, a water saving option is to recirculate icewater through the hose. Another option, which is based upon the same principle, is to substitute a bucket of icewater for the hose -- basically siphoning or pumping hot wort through a coil submerged in a bucket of icewater. The plate chiller which many brewpubs and micros use is a version of this type (some also use glycol for coolant). Advantages: wort cools (serially) suddenly (better cold break), higher efficiency even with warmer tapwaters, and slightly less chance of infection since the wort immediately goes from boiling to pitching temperature. Disadvantages: higher cost, cold break separation requires additional siphoning or filtration, wort outlet temperature more difficult to predict and adjust, and (unless you use a pump) requires you to siphon boiling wort.

For more information, see Zymurgy - "Brewer's and Thier Gadgets" and Jeff Frane's paper in the 1992 AHA Conference Proceedings. There was also an article on Wort Chillers in one of the last two issues of Zymurgy.

I use an immersion chiller mostly because I, personally, don't like the idea

of siphoning 200F wort and feel its easier to use.

NOTE: From Jeff's session at the Conference I learned that cold break really begins at 65F, which is a little colder than I would like for pitching temp. What I plan to start doing, is to cool down to 60F and then turn on the hot water to bring the wort back to 70F. Try \*that\* with a counterflow chiller!

A1.

>allow the steam from the hot wort to escape to disperse DMS (dimethyl  
>sulfide, the cooked vegetable smell)? If so, do you counterflow-  
chiller  
>users wait a while before you start chillin'? How long is "long  
enough"?

>

Per George Fix, in "The Principles of Brewing Science", DMS precursors  
have a 45 minute half life at boiling temperatures. DMS is volatile and  
is quickly removed in the vapors of your boiling wort. A typical  
American

2 row malt will have the precursors reduced below the sensory threshold  
after 2 or three half lifes. I guess that is why a 90 minute boil is  
a good thing. Anyway, the conversion of precursors to DMS halts when  
the wort is chilled. So all that is needed is to have the hot wort  
vented  
until chilled.

In my case, I put the lid on my wort until ready to chill (about 10  
minutes  
waiting for the swirling to stop) and I had a pretty consistent DMS  
problem. Since leavign the top off my kettle, I have not had a problem.

From: dplatt@ntg.com (Dave Platt)  
Subject: Ants on hops...

> It might be a good idea to look closely  
> for aphids if ants are observed on the hop vines, and treat  
accordingly.  
> Ladybugs are hell on aphids, if you can convince them to hang around.

The best way I've found to encourage ladybugs is to plant some cilantro  
(coriander, Chinese parsley) in the garden. Adult ladybugs feed on  
nectar,  
and seem to prefer the small, compound flowers found on plants in the  
carrot  
family. They seem quite partial to cilantro flowers; fennel, dill, and  
other members of that clan should work out well, also.

I used to have aphids in my garden every summer, and I rarely saw any  
ladybugs. Since I started planting some cilantro around the edges of  
the garden, I've had ladybugs, and no aphid problems. My experience  
seems to match that of other gardeners... if you plant annuals which  
attract beneficial insects, you'll have fewer pest problems.

From: dcdwest!titus@UCSD.EDU (Matt Titus)  
Subject: Availability of acid carboys in California (No more?)

Has anyone had difficulty getting hold of 7 gallon sulphuric acid carboys?  
The proprietor of the local brew shop claimed that none had been available for four months. He said that a new law has been passed that requires users of such carboys to recycle them. Apparently acid carboys were used once and then thrown away, which accounts for their wide availability. Note that this (possibly inaccurate) data point comes from San Diego. What's the scoop? Have the reagent distributors changed the material used to make carboys? Are there still glass carboys available for purchase by homebrewers, and if so, is the price still reasonable? Was this guy full of it?

Not worrying,

From: srussell@msc.cornell.edu (Stephen Russell)  
Subject: Business sponsorship of brew clubs?

Homebrew club members,

Does your club solicit local businesses as sponsors?

I am seeking to boost our own club's revenue (the Ithaca Brewers' Union, or IBU) by getting local businesses to become club sponsors. I would like to get advice from other clubs in order to avoid reinventing the wheel.

Among the ways I envision this being done:

1) Providing club meeting space.

Our club meets at the local brewpub, which saves us \$ we might need to pay at another place, so this is a form of sponsorship we have at the present time.

2) Donation of merchandise (or cash) for raffles or competition winners.

We did this at our spring competition; the local homebrew shop donated merchandise and two local retailers -- one a restaurant, the other the brewpub mentioned earlier -- donated cash for ribbons.

3) Donation of beer for tastings.

I don't know about the legality of this one, but I am considering it for future IBU tastings. Basically, if a local retailer donates 3 or 4 six-packs to the club, we turn around and hold a tasting of 3-4 commercial and 3-5 homebrews and charge a nominal fee. The club keeps the proceeds. The quid pro quo for the retailer is that the club members are informed of who provided the beer (and therefore know where to get more of the same). Anyone do something like this? Is it legal?

By the way, right now we hold tastings like this and charge a nominal fee, but we go out and buy the beer from a retailer instead of getting it donated. I realize that the tasting itself is probably illegal, but what about the retailer's donation?

4) Direct, unspecified sponsorship.

Give the club \$ (I'd like to hear what is reasonable) outright and get listed as a sponsor in the club newsletter. Annual basis.

5) Newsletter advertisement.

I've seen this in certain club newsletters but also know of many clubs that have a stated policy of not taking ads. Does your club do this? If not, why not? If so, how much/page?

Obviously, some of these our club has tried, but I would like to hear what your club does. Please send me e-mail directly (srussell@msc.cornell.edu or srussell@crnlmsc2.bitnet) and I will collect, edit and post if there seems to be sufficient interest.

Thanks very much,

STEVE

Date: Mon, 29 Jun 92 09:50:36 EDT  
From: oehler@smpvax.dnet.ge.com  
Subject: A series of questions on Sparging

Good Morning All,

I have a question regarding sparging. I've been brewing extract for four years now and recently attempted my first all grain. Everything went fine, and the stout was excellent, but I'm not sure we sparged correctly. Here's what we did:

After the conversion we added about about 2 gallons of 170 F water to a Zap-  
Ap (Bucket w/ holes in a bucket type) lauter tun. We spooned in the mash from the Brew Kettle being certain that the water was always above the grain. When all of the mash was in the lauter tun, we sprinkled the remaining sparge water on top. We opened up the spigot on the bottom bucket and let the wort flow out. When all of the wort was filtered through the grains we had about 5 1/2 gallons. The mash used 10 lbs grain, and the wort had a 1.048 SG. We placed this on the stove and boiled.

I have recently aquired a 48 qt cooler to use as a mash and lauter tun, so I will no longer need transfer the mash. Also, I've heard a lot about sparging slowly lately, so I'll go slower next time.

I'm soon to brew again, but would like more info on sparge techniques. Does the above procedure sound reasonable? Does the wort get run through the lauter tun a second (or third) time to extract more of the sugar? Does all of the sparge water get added to the grain at once? Do I need to try to keep the sparge water hot throughout the process to stop conversion or ease extraction of the sugars? Am I missing anything?

Subject: trouble with a roto keg

Hi

I have a question for anyone with experience with Roto kegs. I got a spherical one for my birthday. It had a strong plastic smell like it had been closed up for a long time. I followed the directions for sterilizing and getting rid of the odor; 24 hour soak in a strong TSP solution.

I did not smell the plastic odor when I rinsed it out; so I put 5 gallons of I.P.A. in to ferment. I just tasted it tonight and the beer tastes fine except for a pronounced plastic taste.

So I have two questions. Is there any hope for the beer now in the keg? Will the taste go away or get stronger? If not, I'll just pitch it to experience. Secondly, how do you get the smell out of the keg? It will work great for me once it stops ruining the beer.

Thanks in advance for the ade.

John

From: caa@com2serv.c2s.mn.org (Charles Anderson)  
Subject: First All grain, Low Yield

I made my first attempt at an All-Grain brew yesterday using a simple recipe from Cat's Meow 2, which was 8lbs of British Pale, 1lb of British Crystal, 3oz Fuggles, and 1oz of Willamette. I mashed for 90mins w/2.25 gals in my electrim-bin, and I had a hell of a time getting the temp to stay constant at 150. This was a single step infusion mash, I think my temps varied from about 145 to 160, with various hot spots around the heating element. I'm not sure how long the sparge ran, about an hour maybe with 4.5 gals, of water that I started with at about 170, but by the time I was done had probably cooled to 140 or so. After boiling 60mins I had about 4-4.5 gallons (should I have sparged more?) and a SG of 1.040. After sparging the grains at the top of the grain bed were still pretty sweet while the ones in the middle were not. My questions are how do you keep the temp consistant, and is it really important to keep it exactly on target? I stirred every 10 mins or so, and for a while it stayed at around 150 maybe the first 1/2 hour, then it cooled off, and I cranked up the temp some to try to get it to recover. Should my sparge water be boiling when I start, TCJOHB says 170, does it matter? When it was all done it looked kind of cloudy, but smelled great. I'm not worrying, just wondering, trying to make my next batch better.

from  
> about 145 to 160, with various hot spots around the heating element.

I use an Electrim bin with a sparge bag. This means you have to use  
rather  
more water, about 3 gallons, but you don't get problems with grain  
sitting  
on the element and hot spots are easy to stir in. I stir it about every  
30  
mins. Every 10 mins is likely to do more harm than good - you're going to  
cool it excessively.

I have had no problems with getting the temp to stay completely steady  
but  
it is a bit cooler at the top. I get 155 near the element, 150 at the  
top.  
I've found it's best to leave the stat set between the two 'M's of the  
word  
"SIMMER" above the knob. If it needs boosting turn it up to 6 for five  
minutes, set back, stir and check the temperature. If it needs cooling,  
splosh in half a cupful of cold water, stir and check. But don't get too  
fussy,  
you are more likely to make matters worse. There is a lot of thermal  
inertia  
in 9 lbs grain plus 2.5-3 gallons of water and you are likely to keep  
over  
correcting. Give it 20 minutes to settle between trying to make  
adjustments.  
When it's about right, leave it.

Temperature is important but it won't ruin the beer if you are a few  
degrees  
out, it just means you have to give it a bit longer. It is supposed to  
affect  
the taste slightly - warmer mashes leave more dextrins so sweeter beers,  
but  
I'll bet there aren't many who can honestly say they can tell.

[choppity chop]

> Should my sparge water be boiling when I start, TCJOHB says  
> 170, does it matter?

Hot (170-180) but don't bother boiling. It's not crucial but malt sugars  
dissolve better if the water is really hot. Boil up a few kettlefuls as  
you  
are sparging to keep it hot.

> I'm not worrying,

Definitely the right attitude! I'm sure you'll get the best beer you've ever made.

Howdy folks!

I would like to convert an upright freezer into a cool place for my brew for ferment and age. I have looked for "conversion" kits in this area, and have found only one available. Unfortunately, it costs \$75. Does anyone out there in netland have a cheap (less than \$40) solution to my problem? If so, I'd love to hear from ya!

Subject: Lagering and priming

Hi,

I've been lagering two batches o' beer for about two months in Cornelius kegs at 32 degrees f. Its about time to bottle them (I dont have the equipment to keg 'em) and I need to kow about priming.

I made a culture from 2206 Bavarian Lager yeast. If I warm up the two batehs to 60 degrees before bottling, will there be enough active yeast so that i can just do the 3/4 cup of corn sugar thing? I'd rather not do another culture if I dont have to--but I will if necessary. Any thoughts?

>I have brewed a couple of weissen beers and they were great. recently I  
was  
>reading Dave Miller's book and he mentioned a hefeweissen. What's the  
>difference?

The hefe part just means that there is yeast in the bottle, most likely  
you are  
already making it this way, unless you're filtering the brew. I usually  
buy  
these types of (import) beers because I feel that it travels better if it  
has  
some yeast in it.

Oh, and BOB JONES <BJONES@NOVAX.llnl.gov> writes:

>Does anyone know of a chemical that will cut the hop residue inside a  
>blowoff tube.

Since my blowoff tube never contacts the wort/beer (at least not the brew  
I  
drink), I just soak it in a real strong Tide tm detergent (no scent) and  
hot  
water and it comes right off, then I rinse it really well, then I clorox  
it.  
I used to use count-off,alconox, and micro brand cleaners but Tide works  
just  
as well and its cheaper too.

From: copeland@calypso.atmos.colostate.edu (Jeff Copeland)  
Subject: Berkeley Brewpubs (and the greater Bay Area)

Here's a list I got from Rec.crafts.brewing on June 18 1992. Its more than just Berkeley, but a number are accesible via BART or other mass transit.

(kudos to Nick Cuccia [cuccia@mica.berkeley.edu](mailto:cuccia@mica.berkeley.edu) for the list)

Anchor Brewing Company  
1705 Mariposa Street  
San Francisco, CA 94107  
415 863 8350

The nation's first modern microbrewery, home of Anchor Steam, Liberty Ale, Anchor Porter, Anchor Wheat, seasonal Holiday beers, and Old Foghorn Barleywine. Tours on weekdays, by appointment.  
ACCESS BY MASS TRANSIT: BART Civic Center; catch MUNI 19 Polk south at Hyde/Eighth and Market; get off at Rhode Island and Mariposa; walk two blocks east.

Bison Brewery  
2598 Telegraph Avenue  
Berkeley, CA 94704  
510 841 7734

Originally opened by "Buffalo" Bill Owens, now run by Eric Freitag and Scott DeOca. Scott likes to experiment with herbs and flavorings in his beers; I remember an espresso stout that he made last year as being particularly interesting. Postmodern building with art by local artists. Sandwiches; salads; coffee drinks (This *\*is\** Telegraph Ave. in Berkeley, after all).  
ACCESS BY MASS TRANSIT: BART to Berkeley Station, transfer to AC Transit #40. Bus stops right in front of Bison.

Boulder Creek Brewing  
13040 Highway 9  
Boulder Creek, CA 95006  
408 338 7882

Beers include Tall Tale Pale Ale, Redwood Ale, and Lorenzo Logger Lager. Not far from Big Basin Redwoods State Park.  
ACCESS BY MASS TRANSIT: CalTrain Santa Cruz shuttle from San Jose BART station; get off at Santa Cruz transit center; transfer to Santa Cruz transit #35. Note: last shuttle from Santa Cruz leaves Santa Cruz at 8:50p.

Brewpub on the Green  
3350 Stevenson Blvd  
Fremont, CA 94538  
510 651 5510

Haven't been to this one. Menu by Narsai David, one of California's best-known cooks. "Buffalo" Bill Owens is a partner in this pub.  
ACCESS BY MASS TRANSIT: Fremont BART; roughly 3/4 mi. walk/cab ride from there.

Buffalo Bill's Brewpub  
1082 B Street  
Hayward, CA 94541  
510 886 9823

First brewpub to open in Bay Area since Prohibition. Also home of American Brewer Magazine. Nice amber ale, Yakima Cider on tap, and one of my favorite brewhouses--all recycled dairy equipment.

Also home of American Brewer magazine.

ACCESS BY MASS TRANSIT: BART to Hayward Station, walk three blocks east on B.

Dempsey's Ale House  
50 E. Washington St.  
Petaluma, CA 94952

ACCESS BY MASS TRANSIT: Golden Gate Transit from SF/San Rafael to Petaluma.

Golden Pacific Brewery  
5515 Doyle St.  
Emeryville, CA 94608  
510 547 8270

Produces draft and bottled beers for the Berkeley area. Arranged to contract brew Thousand Oaks products after TO ceased production.

ACCESS BY MASS TRANSIT: BART MacArthur Station; transfer to AC Transit #57 (Emeryville Marina direction).

Gordon Biersch #1  
640 Emerson  
Palo Alto, CA 94301  
415 323 7723

Specializes in German brews--their standards are Export, Maerzen, and Dunkle; weissbiers in summer and bocks in autumn. Mmmmm!

ACCESS BY MASS TRANSIT: CalTrain to Palo Alto Station, east on University to Emerson (2-3 blocks), south on Emerson.

Gordon Biersch #2  
33 E. San Fernando  
San Jose, CA 95113  
408 294 6785

See Gordon Biersch #1.

ACCESS BY MASS TRANSIT: SCRTD Light Rail-able.

Gordon Biersch #3  
2 Harrison St.  
San Francisco, CA

See Gordon Biersch #1. Opened last week of March 1992.

ACCESS BY MASS TRANSIT: BART to Embarcadero station, south along the Embarcadero for about 4-5 blocks; in the old Hills Brothers building.

Hogshead Brewery  
114 J Street  
Sacramento, CA 95814  
916 443 BREW

ACCESS BY MASS TRANSIT: Amtrak from Oakland, Berkeley, or Richmond station/stops to Sacramento.

Kelmer's Brewhouse  
458 B Street  
Santa Rosa, CA 95401  
707 544 4677

ACCESS BY MASS TRANSIT: Golden Gate Transit to downtown Santa Rosa.

Lind Brewing  
1933 Davis #177  
San Leandro, CA 94577  
510 562 0866

Microbrewer; Roger Lind is an alumnus of Triple Rock, Golden Gate (RIP),

and Devil Mountain (RIP) breweries. Local distribution; his ales (Drake's Gold and Drake's Amber) are especially nice.

ACCESS BY MASS TRANSIT: unknown.

Marin Brewing Company  
1809 Larkspur Landing Circle  
Larkspur, CA 94939  
415 461 4677

After Gordon Biersch, my favorite brewpub. Don't think they have a bad brew in the bunch (Marin Weisse, Mt. Tam Pale Ale, Albion Amber, Point Reyes Porter, Raspberry Trail Ale (Mt. Tam with raspberries--yum!), Old Dipsea Barleywine (smoooth; blows Old Foghorn Away), San Quentin Breakout Stout, Point Reyes Porter).  
ACCESS BY MASS TRANSIT: Across Sir Francis Drake from Golden Gate Ferry's Larkspur terminal.

Mendocino Brewing Company  
13351 Highway 101 S.  
Hopland, CA 95449  
707 744 1015

Every homebrewer must make the pilgrimage: not only is it the first legal brewpub since prohibition in California, but its original  
brewing

equipment came from the late New Albion Brewery (the first startup micro in the US). All of its beers--Pale Ale, Amber, Specialty Ale (Eye of the Hawk--nectar in a bottle), Stout, Christmas Porter--are excellent. Worth the trip from San Francisco.

ACCESS BY MASS TRANSIT: Greyhound from San Francisco.

Pacific Coast Brewing Company  
906 Washington  
Oakland, CA 94607  
415 836 BREW

Been a while since I've been there. Nice old Victorian-style bar, with downstairs brewery. Also serves microbrew from other makers.  
ACCESS BY MASS TRANSIT: BART Oakland, south on Broadway to Ninth Street, west on Ninth to Washington.

Rubicon Brewery  
2004 Capitol Avenue  
Sacramento, CA 95814  
916 448 7032

Phil Moeller was once an award-winning homebrewer. Now his brews win medals at GABF. His Amber Ale is particularly yummy.  
ACCESS BY MASS TRANSIT: Amtrak from Oakland, Berkeley, or Richmond stations/stops to Sacramento.

Hogshead Brewery  
114 J Street  
Sacramento, CA 95814  
916 443 BREW

ACCESS BY MASS TRANSIT: Amtrak from Oakland, Berkeley, or Richmond stations/stops to Sacramento.

San Francisco Brewing Company  
155 Columbus St.  
San Francisco, CA 94133  
415 434 3344

Great looking copper brewkettle, pretty good lager, mediocre amber. Pubfare.

ACCESS BY MASS TRANSIT: BART Montgomery, catch MUNI #30 at Market and Third, get off at Columbus, walk towards the Transamerica Pyramid  
until

you get to Pacific. Look for the kettle.

Seabright Brewery

519 Seabright Av.  
Santa Cruz, CA 95062  
ACCESS BY MASS TRANSIT: CalTrain shuttle from San Jose CalTrain station. Note: Last shuttle leaves Santa Cruz at 8:50p.

Santa Cruz Brewing/Front Street Pub  
516 Front Street  
Santa Cruz, CA 95060  
408 429 8838  
ACCESS BY MASS TRANSIT: CalTrain shuttle from San Jose CalTrain station.

Last shuttle to San Jose leaves at 8:50p.

Sudwerks Hubschbrau  
2001 Second Street  
Davis, CA 95616  
916 756 BREW  
This brewpub specializes in the best German-style brew in the Bay Area. Their wheat beer is my favorite next to Anchor's, and their pilsner and bock are the best in the Bay Area. Period.  
ACCESS BY MASS TRANSIT: Amtrak Capitol Special from Oakland, Berkeley, or Richmond stations/stops to Davis.

Tied House Cafe and Brewery #1  
954 Villa St.  
Mountain View, CA 94041  
415 965 BREW  
20 Bbl brewery. Pale Ale, Amber, Dark, Doppelweizen, and I believe a low-calorie amber. Good food.  
ACCESS BY MASS TRANSIT: CalTrain Mountain View. East on Castro, north on Villa.

Tied House Cafe and Brewery #2  
65 N. San Pedro  
San Jose, CA 95110  
408 295 2739  
ACCESS BY MASS TRANSIT: Unknown.

Tied House Cafe and Brewery #3  
#8 Pacific Marina  
Alameda, CA  
510 521 4321  
ACCESS BY MASS TRANSIT: BART Oakland 12th St. Station. Transfer to AC Transit #12; get off at Marina Village Parkway and Challenger. Walk towards the water and look for the signs.

Triple Rock Brewery  
1920 Shattuck Avenue  
Berkeley, CA 94704  
510 843 2739  
First Berkeley Brewpub. Pinnacle Pale Ale, Red Rock Ale (my fave), Black Rock Porter. Sandwiches/chili/nachos.  
ACCESS BY MASS TRANSIT: BART Berkeley station. North on Shattuck 4-5 blocks.

Twenty Tank Brewery  
316 11th Street  
San Francisco, CA 94103  
415 255 9455  
Third brewpub opened by owners of Triple Rock (#2 is Bigtime Brewery and Alehouse in Seattle). Mellow Flow Pale Ale, Hi Top Amber (dry), Kinnikinnick Amber (malty), Kinnikinnick Stout. Sandwiches/chili/nachos.

Subject: extraction rates / hefeweizen

> I use a one step infusion mash at 155 for 45 minutes.  
>  
> The starting gravity is 1.036 and finishing is 1.006. With 9 lb  
> of grain I think I should be getting around 1.040.

I've noticed that one-infusion mashes seem to take longer than using a protein rest, also. I believe the difference is just the time it takes for the grain to get thoroughly soaked in the mash water, which can be a good 10-20 minutes. With such mashes, I've also had much better luck enough adding hot water to bring the temp to 140-145, and then slowly raising it to the desired temp, rather than immediately raising the temp with water to the lower 150's. anyway, the iodine test should tell.

>I'd expect to get still more than that. I mash in three gallons, sparge  
>with three gallons, and with 9lb of grain usually get around 5.5 gallons  
at  
>1042. Based on what the books say I would say I have room for yet  
further  
>improvement.

$5.5 * 36 / 9 = 22 \text{ pts/lb}$

which is the lower end of the acceptable range for me. The only time I usually get more than 25 pts/lb is when I use wheat malt and get into 3 hr. sparges.

As for the rest of my technique, in summary, Corona grain mill, Zapap lauter tun with sparge bag, grind the grain the day before, I try to check ph, but I usually make dark beers and they stain the ph paper enough that it's practically useless, mash for 2 hrs, and my final extraction rates are based upon how much I got after I siphon the beer off the .25 - .75 gal of hot break.

Which brings up another question, why do my hydrometer readings go up after I let the hot break settle out? The stuff is heavier than the wort (it sinks)... what gives?

- -----

>I have brewed a couple of weissen beers and they were great. recently I was  
>reading Dave Miller's book and he mentioned a hefeweissen. What's the  
>difference? Does anyone have recipe that I can use? Neither Miller nor  
>Papazian have one listed that I could find.

"hefe" means yeast, and hefeweizen contains a significant amount of yeast in solution, whereas a krystallweizen does not, usually due to filtering. Most homebrews are considered a hefeweizen (unless the brewmaster has a filtering system). Most commercial hefeweizen have had (the brewing yeast possibly filtered out and) a non-flocculating strains added prior to bottling, which is especially necessary if the beer is pasteurized. Has anyone tried this, and what did you use for the non-flocculating yeast? Wyeast 3056 seems to flocculate more than I want; I would prefer more yeast in

my hefeweizen. (I guess I could just stir up the dead yeast on the  
bottom  
of the fermenter prior to bottling, and pour out all the sediment at  
serving time...)

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Cleaning hop residue

Bob,

Run a long string or rope through the tube (use a weight or stream of water to help if necessary), tie a piece of cloth into the middle of the rope, (make sure that the cloth is big enough to make a tight fit in the tube), stand on one end of the rope, hold the other end up high in your hand and with the other hand move the tube up and down thus scrubbing the inside of the tube. You could use a bottle or carboy brush for this instead of the cloth. Cheaper than those brushes is taking apart a \_new\_ toilet brush, straighten the bristle-wire out and pull that through the tube.

Works on mine.

Carl

From: Darren Evans-Young <DARREN@ualvm.ua.edu>  
Subject: Low yield

With 9 lbs of pale ale malt, I get a SG of 1.055.  
All my water is preboiled to remove chlorine.  
When I add the grains to 170 deg water, the temp drops to 153 deg.  
The pH is too low (4.7). I was adding CaCO<sub>3</sub>, but it had very  
little effect on pH and my mash wasnt completely converting.  
I then started adding 1 tsp gypsum to my mash and the effects  
were very noticable. I mash for 2 hours and even though the  
pH is too low, it converts completely.

As for grain bags, I dont use one. I keep my water level at  
least 2" above the grain bed. I dont see how a grain bag  
will help me. I take a full hour to sparge. Sparge water  
treated with lactic acid to pH 5.7. I have even had a SG of 1.057  
with 9 lbs of grain.

Date: 30 Jun 92 10:45:00 -0700  
From: SHERRILL\_PAUL@Tandem.COM  
Subject: Paul's Peppered Pils

Hi All,

I thought I'd report on my pepper beer experiment that I queried you all about. Most recommendations leaned towards adding the pepper as late as possible in the process. Here's what I did.

Recipe (for 4 gallons)

6 lbs light liquid extract  
1.0 oz Hallertauer hops (~ 4.8 AAU) boiling 50 minutes  
1.0 oz hallertauer hops steep 15 minutes  
Wyeast Pilsen yeast (I don't have my notes with me can't remember number) Serrano chile added at bottling

Ferment at 50 degrees for 1 week. Then ferment at 45 degrees for 3 weeks. At bottling cut up serrano and add slices to each bottle.

What I did was cut up one chile and set aside 6 bottles for dry peppering. The rest of the batch was just bottled as is. I labeled my 6 bottles 1 to 6 and put a little more pepper in each beer.

Taste results: The non peppered beer is way malty but it has mellowed nicely after 3 weeks at 40 degrees. Dare I say it is not balanced. The peppered bottles are good. The ones with the least pepper (one thin slice 1/8 inch) don't have any pronounced heat but have an incredibly dry and abrupt finish. You wouldn't know it was pepper that added the strangeness. The ones that were more highly peppered (two 1/8 inch slices) begin to feel the heat. This seems to be the right amount to use to get the flavor and slight feel of the pepper with burning a hole in ye gut. The flavor only comes through in the finish and you can tell it's pepper. The last two bottles are waiting for our next homebrew meeting. Hopefully it'll have the good slowburn. By the way, the peppers did not seem to have any effect on the physical characteristics of the beer (head or color).

When I do this again I will go for the 1/4 inch slices in some sort of ale. In fact the IPA in primary could turn into India Peppered Ale. Also on the agenda for the future would be attempting a pepper tea at bottling. The problem with this is the extrapolation of the number of peppers to use and the pepper extraction rate when made into a tea.

Overall I really like this beer and I think that it could be a good subcategory for just about any beer style.

Now how can I figure the pepper extraction rate in IPUs (International Peppering Units) ?

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: Low yields

In HBD #913, Larry Barello writes

> Regardless of the dextrine maltose balance, the OG should be pretty  
> consistent.

In reply to Kinney Baughman's claim that a high mash tempreature in the mash might be responsible for a low yield. If my understanding of the workings of the enzymes is correct, then Larry is right. If Kinney is right, sould some kind soul please e-mail me (or the HBD) to explain why a higher proportion of dextrans lowers the SG? I have often mashed at temperatures higher that 150 for the purpose of getting higher fianl gravity and have never noticed a statistically significant ddecrease in yield.

Desmond Mottram elaborates on the issue of mash time (also first brought up by Kinney). Again, if this is a factor, I have to go back to drawing-board. It seems to me that once the starches have been glutenized and dissolved, the OG is essentially determined. What proportion of the dissolved material is fermentable sugar, unfermantable sugar and unconverted starch is abviously a matter of great concern, but is in no way reflected in the density of the solution.

IF THIS IS WRONG, PLEASE LET ME KNOW!

I have always believed that lower-than-expected yields come from grinding too coarsely, from sparging with too little water or from using different ingredients (e.g. US malt for a British recipe) than called for in the paradigm.

Cheers,  
Rob Bradley

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: Young's and lupulophobia

While I don't disagree that if your info is accurate Young's hopping rates are quite low, you should still realize that there is an inverse and quite counter-intuitive relationship between hopping rates and batch size.

Because the wort quickly saturates with bittering acids in small batches (of which you could consider 5 gallons) it becomes necessary to add quite a bit more hops to achieve the desired bitterness than in larger batches.

This non-linear effect can be shown by doubling your batch size and exactly doubling your recipe. I think you will find that the bitterness of the beer actually undergoes a substantial increase, and that to preserve the recipe you'll have to cut back on the hops.

This being a non-linear effect I don't know a formula off hand. Perhaps George does and can provide us one on his return. I first became aware of this phenomena when attending a talk by Finn Knudsen of Coors who spoke at the AHA National Conference several years ago on scaling up recipes from 5 gallon test batches to a pilot brewery, to full production. The effect is deemed brewing to scale, and I expect many a homebrewer turned pro has encountered this.

All that said, the hopping rates quoted for Young's still seem truly low.

From: ithaca!amber!phoebe@uunet.UU.NET (Phoebe Couch)  
Subject: Mash and Hops

First I'd like to thank everyone out there for all the advice on the net, I didn't ask the questions but read the answers all the same. Thought I will tell y'all about my setup, I recently started doing all grain,  
and we have 2 setups:

- 1) Mash in the oven in a stainless pot  
sparge in 2 plastic bucket with holes in bottom of the inner bucket and spigot on outer bucket.
- 2) Mash in a 48 qt cooler with slotted copper pipes(15 ft) and faucet fitted to it. (The leftover copper tubing (~30ft) became a 2 layer wort chiller and it works fast too. )  
sparge in same.

I don't know if we were too impetuous and checked too often, but setup2 can't seem to keep a constant temp and we ended to having to reheat the grain a lot and ended up putting all the stuff in the oven. But either way it came out good, the mashing process took about 6 hours the first time (cooler) because of all the hassles and 4 hours the second time because it kept tasting sweeter everytime we checked on it.

IMpale ale was made with setup2 and was dry hopped with Saaz pellets(cos I like the smell, but can't buy it freash)  
The beer that came out was a lot clearer and smoother than extract brewing. I will highly recommend all-grain brewing, we had a BBQ outside while the enzymes were working, so that wait was no problem.  
IMpale ale was very tasty, but the hop flavour seemed to have become stronger as it developed in the bottle. It's like drinking malty flower juice.

Anyway I have a question about hops, I am growing cascades, williamette, nugget and Mt Hood in the backyard, the cascade is the only one with what ressembles flowers, but they are small bases with white spikes sticking out and not leafy like the stuff you buy. I am worried that I may have been sold a male plant instead of a female plant (if there is such a thing for Hops)  
Does anyone out there know?

P.

Subject: Brewpubs in Berzerkley (summary)

Such an inpouring of (conflicting) information! How will I ever digest it all!? How will I ever go all those places in one short afternoon!?

Lots of folks noted that the Golden Gate brewpub is gone. Several strongly recommended that I take the extra hours (2 each way!) to drive up to Hopland and visit the Mendocino Brewing Co. Seems impractible for this trip, unless I can reschedule my flight several hours earlier. Comments the pubs actually in Berkeley included:

Triple Rock:

You'll definitely want to visit [it].  
First Berkeley Brewpub.  
For sure!  
Popular close-to-campus hangout, but beware: they make lousy beer. Good, but staid... (same 3 house brews, no rotation)  
Great place to hoist a few, especially in summer, when it's not packed to the rafters with [students].  
Great beer and a great ambience.

Bison Brewing:

Likes to experiment with herbs and flavorings ... espresso stout last year... Postmodern building  
Popular close-to-campus hangout, but beware: they make lousy beer. Good, but artsy and experimental ...(sage pale ale)  
Still exists, but I have never figured out why. ... sour and unpleasant, though others like it.  
I dunno what kind of people you like to hang out with, ... maybe I should dye my hair black and look bored to fit in.  
The beer was baaaaaaaaaaaaaaaaaaaaaaaaaad ... underhopped, sweet and boring.

Thanks to all. Now I have to decide whether to try take extra time to go up to Mendocino Brewing Co, or maybe try to visit Anchor (will they take just one on a tour?)

From: bob@rsi.com (Bob Gorman)  
Subject: CAMRA & Beer Drinkers of America

Hi All,

I'm looking for North East based CAMRA type of organization.

Is anyone aware of a political organization primarily dedicated to the promotion of beer?

This could either be an extension of CAMRA or another organization, independent of any beer company.

I've recently become aware of The Beer Drinkers of America but I know very little about them. I have a gut feeling that this may be just an organization which is sponsored by BudMilLob but set up to appear as a grass roots organization. Does anybody know anything about them?

I ask all of these questions because there seems to a fair number of people at least in the Boston area who are interested in the politics of beer. I would like to find a way to get all of these people united into some form of organization.

So rather than trying to start up one on my own I thought it might be better to merge in with an existing organization, like CAMRA.

Does CAMRA have a North East affiliation?

Can somebody please enlighten me, or point me in the right direction?

Direct email responses would be preferred.

Thanks!

From: Dances with Workstations <buchman@marval.ENABLE.com>  
Subject: Long time in the primary

Greetings, fellow HBD'ers,

A friend of mine, who is a former brewer, has an interesting question which he asked me to pass on to someone who knows about home brewing:

>From: park@h2sun5.sph.jhu.edu "L. Park" 30-JUN-1992 14:37:28.07  
>To: buchman@marval.ENABLE.com

>  
> Hi Jim -

> I have been inspired to resume the fine art of brewing.  
>I have a quick question. I have a batch of beer which is  
>about 5 years old and still in a sealed primary fermentor.  
>I recently bottled a small sample of this brew with little  
>expectation of any live yeast. To my surprize, the stuff  
>is well carbonated. The flavor is about what I expected,  
>except that there is a bit of an edge of a funny flavor  
>present. My concern is that it is some alcohol congener,  
>perhaps propanol, or worse, methanol. Have you ever heard  
>of beer being kept so long? Or are you aware of the ability  
>of yeast to produce alcohols besides the friendly ethanol?

>  
> I have considered trying to get some of this information,  
>but I am not sure where to try. Is there a beer brewing  
>group out on the net? If so, have you ever consulted any  
>of the information out there? I look forward to hearing  
>from you. Thanks.

>  
> Larry

I'm giving him information on joining the digest, so expect a new Baltimore area subscriber soon.

As to his problem, my feeling is that he is probably okay. I'm not sure, but I think the beer he is talking about is a porter. It would be intriguing to see what this brew tasted like after a five year primary, if it were safe.

On the one hand,  
- alcohol acts as a preservative;  
- wines are commonly aged for years or decades;  
- Thomas Hardy ale is often aged for years, in the bottle; and  
- I've talked with other subscribers who regularly age their stouts for 18 months or more.

On the other hand,  
- this is in the carboy, not the bottle, and  
- it has been sitting in Larry's basement, but almost certainly has been subjected to fluctuating temperatures during that period.  
- it has had lots of opportunity to get infected.  
- my father's golden rule of spoiled seafood survival is "When in doubt, throw it out".

So what would you recommend? Is it possible that other, nastier alcohols have been produced during this time? Or should he bottle and drink it

with careless abandon if it shows no obvious signs of infection?

Thanks!

Jim Buchman

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: Ladybugs

Ladybugs are ruthless when it comes to consuming aphids. Ladybugs also prey upon a host of other pest insects as well. There are quite a number of mail order businesses that deal in ladybugs. They are sold (usually) by the 1/2 pint, pint and quart. 1/2 pints are around \$11 and full pints around \$15. Some businesses go the extra mile and ship the bugs with a piece of dry ice to slow the bugs metabolism and to help prevent mortalities. These businesses advertise in the back pages of most gardening magazines. Check your library's magazine rack if you like. If anyone has trouble finding sources for ladybugs, send me private email and I will dig up some catalogs for the info.

The only complaint about ladybugs is that most if not all eventually fly away. It has to do with mating and such. Your money literally flies away. Its kinda neat to watch. If there is food present for the ladybug, alot will hang around until the food (aphids, weevils, red spiders and the like) source is depleted.

A way to trick the ladybug into not immediately flying away is to give the insect a splash of 7-UP just prior to placing the bug on the plant. The water in the soda wets their wings, thus grounding the insect until the wings dry out. The mentality is ". . . can't fly so I might as well eat someting. . .". The reason for 7-UP and not water is because after the water evaporates, the sticky sugar thats left behind will further make the ladybugs wings inoperative. The sugar eventually will disappear and the ladybug will regain flight but hopefully by that time your aphids are history. This method of using 7-UP is not harmful to the ladybug. I seem to remember that California has organic farming laws or regulations or someting like that which also specifies this method.

Subject: Electrim Bin / sparge water

Charlie Anderson asks:

> ...I mashed for 90mins w/2.25 gals  
>in my electrim-bin, ... had a hell of a time getting the temp to stay  
constant  
>at 150...  
> ...is it really important to keep it exactly on target?

Yes, Charlie, it's VERY important. There are two solutions to your problem. 1) STIR. Every minute or two. 2) USE A GRAIN BAG. This will keep the grain off of your element so it doesn't burn, allows you to sparge right out of your mashing tun, and forces you to use more water, which would also help your temperature stability.

> .... Should my sparge water be boiling when I start, TCJOHB says  
>170, does it matter?

At 172 or higher, you may begin extracting tannins which can cause undesirable off flavors. I use 168. JS uses boiling water, though he has reported his grain-bed temperature ends up a lot lower than that.

Good luck!

From: Jim Grady <jimg@hpwalq.wal.hp.com>  
Subject: Cleaning Blow-off tubes

Bob Jones asks about cleaning out blow-off tubes:

I use 'B-Brite' to clean mine. I get it from my homebrew supplier (generally Beer & Wine Hobby in Woburn, MA & sometimes Modern Brewer in Cambridge, MA). It's a sterilizer and cleanser (in probably the loosest senses of those terms) and works very well. It is kind of expensive so I use bleach when I just need to sterilize but B-Brite works great at cleaning out blow-off tubes, the neck of the carboy after blow-off & getting labels off a new batch of bottles. The label on the bag of B-Brite says to use 1 TBS/Gal but I usually use a little more than half that amount. I have never found it necessary to scrub the gunk out; just soak for a while and rinse.

Date: Wed, 1 Jul 1992 9:44:32 -0400 (EDT)  
From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: hydrometer, methanol

Hydrometer readings will go up even while the heavier trub material is settling out because the wort is cooling. Cool wort has a higher SG than hot wort. Think of it as a syrup; cold syrup is thick, hot syrup is thin, and in a simple sense, that's what SG is a measure of, liquid thickness.

Now, once and for all, can someone definitively answer whether it is possible to produce truly "bad" alcohols (like methanol) in homebrew, in any way? I mean by "normal" fermentation, very hot or very cold fermentation, very long (like 5 years) fermentation, pasteurization, storage at very high temps, exposure to various frequencies of light, distillation, or any other strange thing we might do to our beer.

Subject: IPU

Paul Sherrill asks:

> Now how can I figure the pepper extraction rate in IPU (International  
> Peppering Units) ?

If you are concerned with the "heat" of the peppers, there is an accepted scale called the Scoville level. It assigns a numeric value to each variety of pepper, going from a value of 1 for a green pepper to tens of thousands or higher for very hot peppers. I remember that the scotch bonnet and haberno are over 100,000!

Just like hops, you should be able to mix different strains of peppers to give the desired flavor + heat. That is, use a pepper with more of the vegetative flavor to combine with a high heat pepper.

Bob Devine

Date: Wed, 1 Jul 92 17:34:56 EDT  
From: pdk@pyrnj.nj.pyramid.com (Paul Kramer)  
Subject: Some thoughts on Hot peppers and beer

With regards to Paul Sherrill's article on pepper beer, I submit the following tangential musings:

> When I do this again I will go for the 1/4 inch slices in some sort of  
> ale. In fact the IPA in primary could turn into India Peppered Ale.  
> Also on the agenda for the future would be attempting a pepper tea at  
> bottling. The problem with this is the extrapolation of the number of  
> peppers to use and the pepper extraction rate when made into a tea.  
>  
> Now how can I figure the pepper extraction rate in IPU's (International  
> Peppering Units) ?

As a devotee of fine beer & an enthusiastic pepper eater, I am pleased to hear how well Paul Sherrill's pepper beers are coming out. His comment about IPU(International Peppering Units), whether jesting or not, is a reality. The Scoville Heat Unit has been around for years as a measure of the amount of Capsaicin in a pepper. Because the quantity required for taste perception was almost immeasurable, the scale originally relied on human taste testing, but now through the wonders of "High-performance Liquid Chromatography" a much more accurate method is available to assay this chemical. The Scoville scale runs from 0(Bell pepper land) to 15,000,000, which is pure Capsaicin.

The peppers themselves have different ranges of heat going up to almost 300,000 Scovilles for the hottest Habaneros. At 1 part per million, the warmth of pepper is perceptible on the palate. At 1 part per 100,000, there should be an obvious burning. Now the extraction would not be 100% on any given pepper, but I would think that a little testing with a couple of varieties of peppers could produce some rule of thumb, given the original Scoville heat rating and its potential effect on ones tongue.

Since individual peppers vary in heat(within a range for their type), & different parts of a pepper also vary greatly in their heat potential, special preparation is necessary for controlled testing. The area around the seeds is the source of the Capsaicin, therefore making a pulp of one or better yet several peppers, and then using a portion of that to flavour the beer would have more predictable results than using strips from a single pepper. Another and possibly better method would be to use a packaged, ground red pepper, such as Cayenne or Paprika. These are made in larger quantities, and would be more uniform in heat from sample to sample within a single brand. This ground pepper could be made into a tea.

Since Capsacin has been used as an emetic, it is conceivable that it is available in solution from a pharmacist. If this is true, one could have excellent control of the dosage per bottle or keg.(Remember, the burn is not a taste perception, it's teh pain receptors in your mouth which get stimulated. And Capsaicin has no flavour on its own.)

Although I have never done any of the above, I have the greatest confidence in the skills of the HBD audience, and offer myself as a taster wherever & whenever convenient.

As an aside, I think that when I go home I'll put a measured splash of a hot sauce, which has few adjuncts, into a beer to see what it tastes like. Since the peppering could be accomplished after the brew is cooled off, it may not matter when it goes into the beer.

cheers,  
paul davis kramer

From: dwatson@as.arizona.edu (Dan Watson)  
Subject: kegs

Fellow Brewophiles,

A while back, I asked about soft drink kegs and have recieved lots of info since. This probably falls into the realm of FAQs, but I thought a summary might help beginners like myself.

My original question was about the relative merits of pin-lock versus ball-lock. There was no consensus on this. I now have both, and see no particular advantage of one or the other. The pin-lock is mechanically simpler, but not by much. One writer speculated that one type was used by Coke, and one by Pepsico. This is apparently not the case. I have kegs marked Coke with both. A Coke truck driver (excuse me, a sales associate) told me that ball-locks were the old standard, and that everyone had changed to pin-locks. Because the buggers are nearly indestructable, the attrition rate was slow. He also told me that pin-locks were on the way out too, and that the industry was going to a "post-carbonation system" which uses a bag-in-a-box syrup. This is probably good news for us, since there will be a steady supply of used kegs for the next few years at least.

People generically refer to these kegs as Cornelius, (the largest manufacturer), but many that I've seen are made by Firestone. They appear to be very similar, and the top plates and hardware are interchangeable on the ones I have. There are several variations of pressure relief valves on the top plates, I like the ones that can be bled easily by hand. (I have one with a litle ring you pull, and another with a lever.)

The best price that I found on a keggng system was from St. Patricks of Texas, where I bought my CO2 tank, one keg, two-gauge regulator, hoses, tee, two pin-lock air-in fittings, two beer-out fittings, and two faucets for something less than \$180. I had one keg that was found under the University football stadium, dented but apparently OK. After a recent post about buying them at a scrap yard, I checked my local scrap purveyor and found two more in perfect shape. I bought both for scrap Stainless price of \$0.80/lb. or about \$13.00 for both. Now I'm really stoked, and am going to build up an inventory!

At the moment I have three of the four full of liquid delight, and am looking for a larger fridge! I also bought a "stem" from St. Pats, and put it through the fridge door. I found a fine tap faucet for four bucks at a used restaraunt supply place, and now keep the "common" beer (brown ale usually, or bitter) easily accessable. The "specialty" beers you have to open the fridge door for. I plumbed the CO2 line through the top of the fridge, and keep the tank up there beside the cheap temperature controller which was bought from Johnstone Controls (sorry, I don't have the model # handy, but they have several applicable ones from \$29.00 on up to \$50 or so, I had this one on hand from an old project.) I just wired a duplex recepticle to the controller, and plugged the fridge into it... seems to work OK. Mine controls to +/- 5 degrees or so.

About the plastic "roto-kegs". I bought one of the spherical ones cause I thought it would be cheaper (@~\$50), but have not been happy with it. None of the seals sealed well, and I had to take the thing apart and replace the o-rings, and coat all the threads with vasilene

before it stopped sucking up "sparkets" right and left. I also found it difficult to clean and sanitise properly. The biggest problem though, is it's shape! it takes up lots of room in the fridge, where the SS kegs use only a 9 in. round fotprint. I will keep it around to use for parties (sigh... live and (\$) learn.)

I want to thank all of you for the ongoing stream of good information. I may never cap a bottle again! :-)

You can tell if you got the sparge too hot by the little chunks of  
coagulated protein in your sparge which don't filter out very well.

>liquid thickness.

To clarify: My hydrometer readings go up when the hot break settles  
out, even after I adjust for temperature.

As for SG being a measure of thickness: Go stick a tablespoon or  
two of starch in a hydrometer flask full of water. You will wind  
up with a thick gooeey mess, but the SG is quite low.

>safe at mash temps/PH? Is anything better?

All the variations of silicone RTV they sell in automotive stores  
are rated to temps between 350 and 700 F, and the caulking isn't  
that much different. They will not dissolve in oil or most harsh  
cleaners (gasoline aside). If you're worried about ingesting any of  
the stuff (If it does dissolve, it comes off in chunks which wouldn't  
make it through the sparge), I suggest you try using bubble gum.

- - - - -

>Hefty Weiss for all

I bottled a (hefeweizen) batch last night at 1.061 OG, 1.027 FG.  
That should qualify :-)

Subject: Methanol

I asked a Chemist friend is there any chance of making Methanol when making beer. My concern was that methanol is also called "wood alcohol" and that I was planning to brew (another pseudo-lambic) in an oak cask. He also happens to be a brewer, so he's familiar with yeast and their products, so I think this should be pretty credible. He said that a small amount of methanol may be produced, but in such a small quantity that we needn't worry about it. Distillation concentrates the alcohols and each has its boiling point. If you don't know what you are doing, you can bring methanol concentrations up to where they can harm you. I, personally, cannot see any way that aging, pasteurization, or light can create more higher alcohols. I believe (speculate, actually) that higher fermentation temperatures can increase the production of higher alcohols. Another variable in my fusel alcohol test which I keep putting off.

>SG than hot wort. Think of it as a syrup; cold syrup is thick, hot  
>syrup is thin, and in a simple sense, that's what SG is a measure of,  
>liquid thickness.

I hate to nitpick, but SG is *\*not\** like liquid thickness. Specific Gravity is like liquid *\*density\**. Viscosity is like liquid thickness. For example, think about malt extract in a can: at room temperature, it's very thick (viscous) so you heat it up in the can to make it thinner (less viscous). Heating also has an effect on the density, usually decreasing it. The malt extract may have a slightly different density at the higher temperature, but it will have a very different viscosity.

The difference between density and viscosity can be seen by comparing mercury (aka liquid silver) and maple syrup. Which is the most dense at room temperature? Mercury has an SG of about 13.5, where maple syrup would be about 2 or 3 at the most, so mercury is by far the most dense. Which is most viscous at room temperature? Mercury has a viscosity which is similar to water, but maple syrup is much more viscous. This is one case which shows that density and viscosity are definitely not the same thing.

Subject: re: methanol

In response to Russ Gelinias' question about methanol and other "bad" alcohols. I'm not sure about the overall possibility of producing any signifiacan quantities of fusel ("bad" alcohols) from normal (or abnormal) fermentation but I suspect its very very low.

One thing I do know is that "wood alcohol" or methanol is not the result of fermentation of any kind. The term originates from the fact that methanol is one of the products derived from the destructive distillation of wood. Basically they would heat wood to very high temperatures and condense and collect the vapors, mostly water, and small quanties of organic solvents (I think this included acetone and formaldehyde and all sorts of things). These liquids were then seperated from each other. As I recall only about 3% was actually methanol.

From: NCDSTEST@NSSDCA.GSFC.NASA.GOV  
Subject: Wyeast viability, O2 and cultures (Jim Busch)

With summer here again (90+ degrees in DC) I have to wonder about the viability of the packaged Wyeast after shipping. From what I have learned, yeast stored without food depletes its glycogen stores. This delays the synthesis of sterols in the respiration phase, leading to longer lag times. Now, maybe this isnt a problem since I'm sure most of the HBDers make a 1 litre starter, and maybe this obviates the respiration problem, but what about the overall health of the yeast that is being grown? Wouldnt there be more mutants/autolized cells?

I am currently using cultured yeast from The Yeast Culture Kit Co, and my one litre starter has about a 3-4 hour lag time (or less). With brewers yeast off a Unitank, I get a 2 hour (or less) lag time. Any comments on lag times from Wyeast starters, and do they change with the season?

I dont inject oxygen yet. I intend to get a bottle from the hardware store and a stone from the fish store for next batch. I have been told that bottled O2 cannot support contaminants due to the high pressure exploding the cell walls. Any comments?

Another interesting thing I wanted to note is that various people are obtaining cultures of yeast directly from draft samples of beer in Europe. Using a 1.5 ml mini-tube of solid UV sterilized wort, the yeast is transported back to the states and plated. (If anyone would like to share any harder to find strains of yeast I would be very interested in hearing from you).

As always, if anyone wants info on Dr. Schillers yeast company, email me and I will hook you up. I am in no way affiliated with this effort other than a satisfied customer and brewing friend.

>where do you get food grade lactic acid?  
>  
>Thanks,  
>Jon Binkley

Yes, it is Miller's treatment. I use food grade lactic acid to get my sparge water down to the proper pH. I got my lactic acid at Greater Fermentations of Santa Rosa. I forget what percentage the acid is. It is strong stuff!!!! I doesnt take much to do the job. What I do is mixed 1/2 tsp of lactic acid in 1 Cup of preboiled water. Usually 4-5 tablespoons of this mixture will get my pH down to 5.7. This is for 5 gallons of sparge water. When I first got the acid, I ignorantly added 1/2 tsp directly to the sparge water. It brought the pH down to 3.2! So dont make that mistake. Start with a very small amount and work your way up.

From: Pat Lasswell <patl@microsoft.com>  
Subject: Re: Long time in the primary

Back when I was a wee lad, my dad would brew beer in a big 15 gallon crock. He had used nothing but ordinary bakers yeast, home-made malt, and home-grown hops. When I began to brew my own beer after I graduated from college, I took the time to sample some of his beer, which had been in 32 ounce Coke bottles in the dark of an uninsulated shed. The result was a light-bodied barley-wine, that after nearly two decades in the bottle, had a dry malty finish. Some bottles were infected with lactic acid bacteria, but the ones that were clean were mellow and smooth, almost no trace of hops. All of the bottles had a heavy sediment of yeast, which seemed to have survived a wide range of temperatures without autolysis: the temperature in the shed would go from freezing in the winter (occasionally with exploded coke cans) to eighty degrees or above during the hotter summers. It is true that this is not the same as sitting in the primary upon a heavy layer of trub and old yeast; however, it does demonstrate that beer can have a surprising longevity. Therefore, I would say, "If it tastes fine, then it's probably harmless." My dad's old stuff hasn't hurt me any. (I think :-)

Subject: rolled oats  
Greetings brewsters,

Sitting somewhere amongst my brewing supplies is a 5 gal carboy. Upon further inspection one will find that it contains a full load of some crystal clear mead (yummy!). A little research will show that it was actually brewed about 2 years ago, and after a couple weeks of primary fermentation, the mead was racked to the secondary where it still sits today. But this is not a history lesson...

Here's the problem - due to a combination of the bottling blues and negligence, this batch has been left sitting for these past 2 years, and on more than one occasion, I had noted that the water level inside the airlock had run critically low - as in empty! Of course I immediately refilled it and followed with a quick ritual anti-infectionary dance/chant

session and prayed for the best. Alas, I have asked too much of the gods.

..

floating obnoxiously on the surface of my unfortunate mead is a layer of (for lack of a more poetic term) SCUM. A quick nasal scan shows that nothing smells afoul however. Since this mead was made with 7.5 lbs of honey for a five gallon batch, and was "safely" fermented in the primary at least, with champagne yeast, I'm assuming that there is a healthy dose of alcohol present to protect it. I also know from experience, that two years in the life of mead is equivalent to the adolescent stage, so its nowhere near its expiration date.

What I'm looking for are possible suggestions as to what that SCUM is, and any ideas on how to go about bottling this. It appears that whatever is currently living off my mead can only due so at the surface, so I've had thoughts of ever so gently siphoning the mead from the bottom, and at first sign of SCUM in the proximity of the siphon head, shutting it down and using the remains to appease the great spirit of the garbage disposal.

Thanks in advance for any suggestions.

Mark

From: parsonsl@husc.harvard.edu  
Subject: Silcone again

Persons of discriminating taste,

I've been reading this magazine for almost two years now, without contributing any words of my own. I have controlled myself, because all I really have to offer are some recipes, and everyone always has enough recipes already. But I can't resist contributing these two.

The first, in response to the recent popularity of Weis beer, is a recipe of my own. It is not as heavy as the German varieties, and does not have the clove-like taste: instead, I made it in pursuit of the taste of Grant's Weis Beer, which is much paler, and lighter of body; with a hoppier aroma; and drier, but not bitter, to the taste.

Hefeweizen, for 5 gal:

5# wheat  
3# 6 row lager  
1 oz Tettnang (45 min before end of boil - alpha 4.7%)  
1/2 oz Saaz (25 min - 3.8% alpha)  
1/2 oz Saaz (10 min - 3.8% alpha)  
Wyeast 1056 ("American Ale")

Mash in 11 qts and protein rest 30 min @ 130 F  
Starch conversion 90 min @ 149 F  
Mash out and sparge 1 hr. @ 168 F  
Boil 1 hr., adding hops as specified above.

Starting Gravity 1.042 @ 72 F

While I'm at it, I also want to offer this recipe. It is time to start thinking about this Winter's beer, so here is a Scotch ale recipe which yields, I think, superb beer.

for 5 gal.

9# pale ale  
1# crystal  
1# Munich  
1/2# chocolate  
1/2 oz. Bullion (60 min - 9% alpha)  
2 oz. Fuggles (30 min - 4.5% alpha)  
3/4 oz. Golding (10 min - 4.9% alpha)  
1 tsp. Irish moss (30 min)  
Whitbread or Wyeast 1007 ("German Ale")

Heat 14 qts for 140 F strike heat  
Mash in, starch conversion 1 1/2 hr. @ 154 F  
Mash out and sparge with 5 gal. @ 168 F  
Boill 1/2 hr., adding hops and Irish moss as scheduled above.

Starting Gravity 1.055 @ 72 F

I am very fond of both these styles, and should be pleased if anyone would offer his own recipes. So much for my 15 minutes of fame. Thanks.

P.S. nec parce cades tibi destinatis

Subject: Book Review: Belgian Ale by Pierre Rajotte

Review: Belgian Ale by Pierre Rajotte

Copies of the Association of Brewers' newest publication, Belgian Ale by Pierre Rajotte, are now available. Despite it's defects (most of them editorial) this will undoubtedly be the bible of Belgian-style brewing for some time to come. Anyone interested in brewing Belgian beers must read it.

While it's a matter of (well founded) opinion that the Belgians are the world's best brewers, the specifics of Belgian-style brewing will come as quite a shock to many: these include obligatory use of large quantities of sugar, high-temperature fermentations (up to and over 85 degrees fahrenheit), microscopic hopping rates (take *that\**, hopheads!), and deliberate production of sour and high-ester beers.

The book's strength lies in Rajotte's clear explanations of the ways these can be used to generate great beers, and he does so with an eye to the practical needs of brewers at all levels.

Rajotte himself is a Canadian, with a degree in mechanical engineering. He help found Montreal's first brewpub, and is a regular contributor to zymurgy. Chapter 1 of this book provides an historical overview of Belgian brewing and its traditions. The Belgians continue to use many procedures and ingredients that were long ago abandoned by more "progressive" brewers, yet produce the world's most stunning array of beer types and flavors. Rajotte doesn't lay his cards on the table, but obviously thinks this is not a coincidence. He also emphasizes, however, that even in a within a conservative atmosphere Belgian brewers have a continued tradition of innovation and experimentation. Despite centuries of brewing, most Belgian beers on the current market are relatively new; even their distinguished Trappist brews were only developed in the early part of this century. Chapter 2 profiles the various Belgian ale styles.

This includes statistical information on gravity, color, IBU, and more, but also emphasizes that style isn't all that important; as Rajotte says, "People who like to categorize everything in an orderly manner will not feel secure in the way Belgian beers are classified." Even so, his classification system is more practical and realistic than Michael Jackson's, and better fits the categories controlled by Belgian law. In all, the discussion covers trappist and abbey beers, special beers, ales and saisons, white beers, and oud bruins (tart brown beers such as Liefmann's Goudenband).

Chapter three concerns the materials and equipment and materials used in Belgian brewing, providing detailed information on malt selection and use (almost no use of colored or specialty varieties), sugar types, hops (noble types mostly, and in minute quantities), and equipment for boiling, cooling, and fermenting.

Chapter 4 continues with an overview of the various Belgian brewing processes, beginning with a description of a joint brewing project between Rajotte and Pierre Gobron,

master brewer of La Brasserie D'Achouff. There's excellent information here, but the book's sloppy editing makes it impossible to tell which quotes are Rajotte's and which are Gobron's.

This chapter also includes a section on bottle conditioning, in which Rajotte explains why the homebrewing version (add more sugar) won't work with high-gravity Belgian-style beers. The Belgians add sugar too, but also extra yeast to replace the yeast cells worn out during high-gravity primary and secondary fermentation. Unfortunately, this technique has some dangerous implications for the inexperienced, as differences in attenuation between the two yeasts might lead to unpleasant CO2 pressure levels. It's possible that anyone who gets into this technique will risk a few explosions before mastering it.

Chapter five includes recipes. Yup, lots of 'em, with information for extract and all-grain batches of five gallons, as well as all grain batches of 1 barrel (31 gallons). Hopheads be horrified to find bittering hop levels as low as 4 to 7 Homebrew Units (18 IBU) in beers with original gravities as high as 1.088. More than hops or even malt, the secret to Belgian beer flavors appears to be the yeast, and practical advice is offered on ways to collect cultures from bottles of Belgian imports.

A variety of appendices are also included, one of which offers descriptions of the various commercially-available beers that illustrate--and vary from--the various styles.

Overall Rajotte has done a marvelous job. He is obviously very knowledgeable about beer and brewing and has done a great deal of historical and on-site research. His information is reasonably well organized, and deep appreciation of the somewhat idiosyncratic nature of Belgian beer is apparent. He understands that Belgium is a place where unusual flavors and aromas are big selling points, and makes an excellent case for judging these beers on the basis of their inherent merits and pleasures rather than with respect to style adherence or perceived deviance from a theoretical standard of taste and character.

Unfortunately the book is riddled with typographical errors and other production problems--an apparent trademark of the Brewers Publications series. It wouldn't be hard for Charlie Papazian and the Association of Brewers to turn out better, more carefully produced publications, and there's no question that authors like Rajotte deserve better. Are you listening out there, Charlie?

Belgian Ale is available from the Association of Brewers (PO Box 1679, Boulder, Colorado, 80306) for \$11.95 plus \$3.00 shipping. Copies can also be ordered by calling (303) 447-0816.

Disclaimer: I am a member of the American Homebrewers Association, which is a division of the Association of Brewers, and have no financial, editorial, or authorship interests in this book.

100 MALTMILLS

I gives me pleasure to announce the recent shipment of the 100th MALTMILL. We are currently shipping 2 a day and have a two week backlog of orders with no end in sight. Needless to say, the success of the MALTMILL has put a crimp into my retirement plans. However, in light of Greenspan's program to pauperize retirees, the new source of income is most welcome.

The initial success of the MALTMILL was due, in no small part to the free publicity received on the Home Brew Digest and the flattering reviews published therein by several intrepid, early buyers.

To help overcome the hostility toward my alleged commercialization of the Digest by product announcements and progress reports, I would like to show my appreciation by giving a MALTMILL to one randomly selected participant of the Home Brew Digest.

To avoid more criticism for collecting names and building mailing lists, I am simply going to give a MALTMILL to the author of the 100th article following this announcement. The next article is Number 1 and you can all help me count to 100.

Thanks and good luck,

js

Mark asks about:

>floating obnoxiously on the surface of my unfortunate mead is a layer of  
>(for lack of a more poetic term) SCUM. A quick nasal scan shows that  
nothing  
>smells afoul however.

If it started as a white film that gradually got thicker but still  
basically  
white, it is probably *Candida mycoderma*. If so it has a nasty habit of  
converting alcohol to CO<sub>2</sub> and water. If caught early, little harm will be  
done. Carefully remove as much scum as possible from the surface, siphon  
off  
(filtering is helpful) and treat at 50ppm with SO<sub>2</sub> (If problems persist  
try  
100ppm SO<sub>2</sub>). If you find sulphite undersirable, you need to find some  
other  
way of knocking out the *Candida*, or bottle and drink it.

The problem is often associated with neglect, so, again, it is often  
accompanied by oxidation and other related niceties. Good luck.

Subject: re: rolled oats

>In issue 910 Larry Barrello was replying to Chris Estes re. Pearled  
Barley.  
>Larry mentioned the use of rolled oats and barley. I tried mailing to  
Larry  
>directly but could not get anything through.  
>  
>My question is this. Are these regular, grocery store, rolled oats? How  
much  
>and when would you add these? Do they add to head retention? Are  
>Beta-glucans harmful?

I do not have anywhere near as much brewing experience as Larry.  
However,  
I personally would not recommend using rolled oats (at least in extract  
recipes). I used them in an oatmeal stout several months ago when I could  
not find steel-cut oats. I included them in an extract-based recipe in  
the  
standard manner of adding them to the boil water as it was being heated.  
I was quite nervous (but not worried !) that they would turn into oatmeal  
so I made sure not to let them boil and even removed them earlier than I  
normally would have removed specialty grains. I cooled the wort before  
transferring to the primary and after cooling I could see in the wort  
very  
viscous thick whitish trub that took many days to settle out. When it did  
it left a 3-4" layer on the bottom of the carboy. When I racked to  
secondary  
I was not too surprised to find what was basically oatmeal sans oats, the  
same glutinous whitish paste that's in cooked oatmeal. Unfortunately  
while  
in the primary this "oatmeal" swelled and sucked up about 1/2 gallon of  
my beer.  
In addition, the head retention of my stout is pretty poor, it only lasts  
for 0.5-1.0 minutes. This may simply be due to the oils in the oatmeal  
and  
may have nothing to do with using rolled oats. I, however, will not use  
rolled oats again. I have since found steel-cut oats in local health-  
food  
stores.

Subject: how thick is thick?

Well, that's what you get with \*scientists\* on a mailing list ;-)  
Density(SG) and viscosity(thickness) \*are\* different things. But, most  
people think of dense syrup as "thick", and most people have experienced  
cold syrup as being "thicker" than hot syrup. It may be technically  
incorrect, but the mental picture of the "thickness" of syrup with  
respect to its temperature is clear.

Russ

Hey js, is this #100, or should I post another 99 one-liners to make  
sure?

Subject: Hot peppers, Root beer

Another note on Hot Peppers: I have used hot peppers ginger ale for years with nothing but satisfaction. I usually use homegrown jalapenos for this, blending them first to homogeneity using a blender at the highest speed setting.

... And about root beer ...  
Beware that "naturally" flavored root beer from home recipes may contain carcinogens. This is why the commercially available root beers are generally artificially flavored.

From: sami@scic.intel.com (Sam Israelit)  
Subject: Peach Weizen

I was up until 1:30 this morning putting my attempt at a Peach Weizen comfortably to bed. I used a modified version of the TCJOHB recipe for weizen and 11 lbs of California white peaches (pitted and crushed with skins). Ended up with an OG of 1.061 and the yeasts were frolicking wildly by 7:30 this morning.

I plan to rack this hopeful brew after the primary and leave in the secondary for roughly 2 weeks. I have two questions:

1). Is there any consensus as to whether there is a benefit to adding more in the secondary?

2). I can get a jar of Widmer hefeweizen which has a large amount of yeast in it. I have been told that they add their yeast as a second strain later in the process. It is a more flocculent (Why does that word always bring images of gaunt monks in cold-floored stone cells in the mountains?) strain from what I have heard. I was wondering if I should try to form a starter of this yeast from the dregs of a jar and pitch this with my brew. When do I pitch the second strain? What are the advantages to this? Are there any disadvantages? Is this a dumb idea all together?

Any and all coments will be summarized to the net. Thanks in advance for any remotely constructive advice.

Subject: Silicon

There have been a number of post about using Silicon as a sealer for homebrew projects. Some folks have suggested using automotive silicon sealer because of temperature requirements, as a former auto mechanic I think this would be unwise. All of the automotive grade silicon sealers I have used have a high level of solvents in them. Granted, once they are dry they will hold up to almost anything, I would still be quite worried about contact with things I that I might eat or drink. Perhaps someone out there knows of a food grade silicon sealer which would have the same kind of properties but we would know it was safe for contract with food.

Happy Brewing  
Tom Feller

PS I will be working and drinking at this years Oregon Brew Festival and would love to see some other HBDer's. Send me mail and we well try to set something up.

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Scum on old mead

An aerobic scum on a high alcohol brew suggests you could have something like a sherry flor. It typically oxidises the alcohols to aldehydes, although apparently with far more refined results than is achieved by over-aeration.  
>From memory, it also metabolises certain acids in the brew. Even amongst the professionals, production of a flor is something of a random affair. Those brews which fail to develop one are sweetened and sold young. Those brews which develop one are allowed to ferment as long as possible until the flor drops by its own volition. Provided it is not some nasty which is souring the brew, it could result in some interesting accelerated ageing effects.

From: Brian\_Carroll@3mail.3com.com  
Subject: Kegs

I've picked up two ball lock soda kegs at the scrap yard for \$3.00 ea. and have some questions about cleaning, and the carbonation in brew use.

1)When you place new gaskets in them do you need to take the ball lock studs off and replace their gaskets?

2)Is soaking them in a TSP chloride solution sufficient for cleaning, and

will that get out the soda taste?

3)How long (if #2 is correct) do I need to soak them to get rid of the soda taste?

4)I've know that you need not to prime with corn sugar, hence the carbonation is added thru the co2 tank. But would it not help get rid of unwanted oxygen while aging?

5)After tapping how long will the beer stay good? Can you fill the keg with co2 to make it last longer?(Oh, I forgot to mention I don't have the facilities to keep it cold after tapping.)

6)Sense the soda kegs take the beer from the bottom how much of the beer will have the yeast in it?

7)Should I use some type of filter while racking into the keg? If so what

type of filter is easily used in home brewing, and how can you make sure of

sterilization? (I've thought of cheese cloth but have no clue on how to sterilize it.)

8)(this isn't really a question I'd just like to get some feedback and maybe some better ideas for cooling the beer to drink)

Ok, here is how I plan to cool it. I bought a 20 qt. cooler and 25 ft of stainless steel tubing in a coil that sits inside the cooler.

The beer comes from the keg thru a plastic tube to the cooler into a coupler shank into the stainless steel tubing into a faucet and shank set.

Wala! beer!

I figure 5 min after I place ice on the coil I should have cold brew in the mug. I'll use silicone to prevent leakage were I drill out the cooler.

I have ordered most of the equipment for this project for under \$100.

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Belgian Impressions - Part 1

Greetings Brewers,

I've just returned from the WORLD'S GREATEST BEER SAFARI, a one week tour of Belgium. In my six days there, I visited nine breweries (but was unable to tour two of them), and three times that many cafes. I tasted lots o' beers, met many friendly people, and learned a wealth about the brewing scene in Belgium.

The good news is that Belgium has by far the greatest variety in its beers of any country in the world. They take their beer seriously and it is served with respect. Each beer is served in the appropriate glass, often with its own coaster. Beer is considered the ideal accompaniment with a meal, and many dishes are prepared with beer. If you are looking for unique and interesting beers, nowhere will you find more than in Belgium.

On the down side, the oft repeated theme of the Big Guys swallowing up the little guys is running rampant in Belgium today. This past year has seen the closure or takeover of 15 small breweries, including two brewers of Lambic in Pajottenland. The two major brewers of industrial Pils, Jupiler and Stella, have merged to form a large brewing consortium called Interbrew. Maes, another large brewer is part of a larger French company. Furthermore, Heineken appears to be flexing its muscles as well. Each year, more of the small traditional breweries are forced out of business by the consortia.

The three largest lambic brewers have already succumbed to this. The largest is Belle Vue, with an annual production of about 250,000 hectoliters. They are now a part of Interbrew. Next is Mort Subite (100,000 HL), which is owned by Maes. Third on the list is St. Louis (50,000 HL), which some industry sources claim is backed by Heineken. Against these odds, the smaller, more traditional brewers of lambic are fighting for their very existence.

The remaining little guys are producing some wonderful products. My standard of comparison between lambic brewers is their gueuze. Gueuze is a blend of one, two, and sometimes three year old lambics. It is traditionally refermented in the bottle, though the larger brewers no longer do this. The examples I sampled are listed below in order of my personal preference.

1. Frank Boon (pronounced Bone)
2. Cantillon
3. Vander Velden

4. Girardin
5. Timmereman's
6. Mort Subite
7. De Neve
8. Lindeman's
9. St. Louis
10. Belle Vue

Being a lover of the traditional stuff, I did not expect anyone to produce a gueuze that I'd prefer to Cantillon, but Mr. Boon has done just that. His product is extremely complex.

It has the cutting sharpness of lactic acid, but is rounded by the richness produced by *Brettanomyces* and other wild yeasts. Mr. Boon revealed that his beer's complexity was due not only to the Brett. and *Pediococcus*, but to a host of other micro organisms as well. I had made it clear to him that I intended to publish an article based on our interview, and he declined to discuss just what these other critters were. I described to him the "Guinard Method" for making lambics outside of Pajottenland. While he was fascinated that people were doing this at home, he contended (as does Michael Matucheski) that a fully developed gueuze could not be produced using *Sacharromyces*, *Brettanomyces* and *Pediococcus* alone.

Furthermore, he confirmed what Mike Sharp's and Martin Lodahl's experiments suggest, that aging in wood is crucial to the development of *Brettanomyces* character.

By comparison, the gueuze made at Cantillon seemed rather one dimensional. It was extremely acidic, but lacked the fuller flavor of FB gueuze. If other lovers of lambic out there get the opportunity to sample both, I'd like to compare tasting notes.

When I discussed the sourness of Cantillon's beers with JP Van Roy, the head brewer there, his attitude was that it was a traditional process subject to the whims of mother nature. You basically got what you got. Mr. Boon disagreed. He maintained that within the constraints of the traditional process, one could vary the product greatly. For example, he felt that thru proper treatment of the barrels, one could favor some microbes over others, thereby effecting changes in the final product. He has worked hard to fine tune a complex process, and it shows.

Another bit of good news, sometime later this year we can expect to see limited quantities of Frank Boon Gueuze and Kriek available in the US on the East Coast. His Kriek is the best lambic beer I've had.

Cheers,

CR

Subject: Re: Dave Miller's New Book

Norm Hardy asks about Miller's new book, "Brewing the World's Great Beers". I've had my copy for almost a week, but haven't had time to do any serious reading. I've been too busy brewing to have time for reading.:-)

The book seems very approachable, in contrast to his earlier book. He makes it very easy for the novice to get started. The recipes start as all-extract using dry yeast. They become extract with specialty grains and liquid yeast, partial mash/extract/liquid yeast, and finally all-grain/liquid yeast. Most of the recipes are shown in all forms.

The book also covers such topics as wort chillers, kegging, filters, and counter-pressure bottle fillers.

On the down side, the recipes call for specific yeasts, but there is no discussion (that I've encountered yet) on what to expect from various strains. That shouldn't be too much of a problem, since that information is available from Zymurgy (and was also covered in HBD #742 by Daniel L. Krus), but its always nice when somebody includes everything you ever really need in a single book.

An advanced brewer may find some of the discussions superficial, since Miller doesn't go into the chemistry that you'll find in his early book (or many of the technical books available). I would recommend the book to novice and intermediate brewers because of the breadth of information, put together in a readable format.

Happy reading.

Subject: Question on mead (Have I won it? :)

I recently posted this to a local mailing list but seeing that I too might get the beloved MALTMILL I've got to buy my lottery tick--um--repost this thing here for the wider audience.

I've noticed that mead, when purchased in stores or in restaurants, is a rather expensive drink. The Boston Beer Works sells it for \$3.95 a glass (and the glasses are wine-size thingies) while a friend of mine buys it for \$90 a case.

Meanwhile I throw in some honey and yeast and spend a total of \$12.50 to make what is so far 5 gallons.

Is there something more at work here than market forces in keeping store-bought so high? Or is this a grab-your-ankles routine?

From: smith%8616.span@Fedex.Msfc.Nasa.Gov  
Subject: mead, JSbashing

hey folks--

For various reasons, I've been making quick meads lately instead of beers, using a base of 5 lb honey for a 5 gallon batch and throwing in various spices and/or fruits. Now, this stuff is good in its own way (not having tasted anybody else's mead, I can't compare it), but it seems quite thin. How can one add "body" to a quick mead? Add a little DME? More fruit? Is this a fruitless quest? \*ducks\* Note that I don't give a FFAARD about standard styles, I just want a nice summer beverage that doesn't take more than a month to complete. 1 1/2 gallons of frozen blackberries, a jug of honey, several million yeasties and I await your suggestions...

Oh, yeah. Why exercise your sarcasm on Jack's maltmill giveaway? Sheesh, you can hardly call it commercialism when he's giving something away for nothing! And congrats Jack, I had no idea you'd sold 100 of them. Want to make fun of something? How about the summer MajorBeer ads? "Miller Lite - It's \_\_\_it and that's that!" Pfui.

> this area, and have found only one available. Unfortunately, it  
> costs \$75. Does anyone out there in netland have a cheap (less than  
> \$40) solution to my problem? If so, I'd love to hear from ya!

Mitch,

Check the back of Zymurgy. I don't remember the company, but they offer a programable controller for about \$29.99. I believe that you plug the freezer/frig into the controller, which plugs into the wall. There must be some type of thermistor or something you slip inside the unit to monitor temperature. I will check on the company and e-mail you with the info.

. In  
addition, the head retention of my stout is pretty poor...

Well Brian you got just what you thought, oatmeal made with wort.

Oats are not the same as specialty malts like chocolate, black patent, or roasted barley. Oats MUST BE MASHED otherwise all you get is starch in the beer. In order for the starch to be available for the mashing the oats must be cooked (like rice) hence the milling process. Either "rolled" or "steel-cut" will work equally well if you mash them. Flaked barley is a similar animal and must be treated the same way. Flaked wheat is also available from some shops, works the same way.

Mini-mashing isn't hard, just take equal amounts of the oats and 2 or 6 row malt and combine with about 1 qt. of water per lb. Bring this to 155 degrees for an hour and then rough sparge into your extract through a colander or grain bag with an amount of water equal to what you mashed with. By "rough" I mean just a simple rinse, no recirculation or trickle since you are looking for the oat character and not a significant yield. Oats get pretty gummy so when in a 1 to 1 grain bed a stuck sparge is almost guaranteed.

Don't give up on them yet, just mash them next time!

Homebrewers:

I'm new to the homebrewing hobby (on my third batch). Thus far, I have used only a single stage brewing method-- my primary is a closed 6.5 gal food-grade plastic pail.

Will I achieve better tasting beer by switching to the "blow-off" carboy single-stage system as described in Papazian's COMPLETE JOY OF HOMEBREWING?

I made a "kit" beer by Brewmart that included a fining agent called isinglass. I am unfamiliar with this stuff: it claims it contains sulphur dioxide preservative--should I use it?

I am also interested in brewing beers that are similar in flavor to Grolsch and Heineken. I would appreciate any recipes that would approximate these beers.

Thanks,

- --Jeff

Subject: Sealing mash-tuns

Hey now!

With all this talk about horrible potentially toxic glues and sealers getting used in mash tun construction, I thought I'd offer an alternate approach. First off, if your cooler already has a drain in the bottom, I wouldn't try to modify it. My impression is that it's a lot easier to make a leak-proof drain from scratch. Get a 15/32" drill bit and file the sharp edges near the point dull. This will help it to scrape through, preventing the plastic from chipping or shattering. Drill carefully through a flat section of the inside of the cooler, and then shove a piece of 1/2" OD vinyl hose through it. It will fit snugly enough that it won't leak. You can then fit 3/8" OD copper tubing to either side by just sticking it in the tube.

food  
>stores.

you must mash oatmeal or any other adjuncts before you add them to the  
boil.  
In fact, I won't even add malted specialty grains anymore unless they are  
mashed. If I'm trying to do a quick and dirty job and just want to add  
a half lb. of crystal malt or so, I'll steep it in 150F water and add an  
oz.  
of amylase enzyme. If you add all the malt extract at this point you'll  
also notice that the infamous boil-over problem is alleviated.

Anyway, I made the same mistake (not mashing oatmeal) when I first tried  
it.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: Silicones, implants, and toxicity

A key factor in the current fuss about silicone implants is that the salesmen/demonstrators were specifically taught to conceal that the envelopes leaked; the toxicity of implants relates substantially to the effects of loose liquid silicone in contact with muscle or fatty tissue for periods of several years. This is not likely to happen with anything used to seal a brewing vessel rather than a brewer.

The relative internal toxicities of the liquids used in implants and the solids used in caulking are also unclear.

Neither of these mean silicone caulks are /safe/, but the comparison raised by Al Taylor may not be valid.

I would also be suspicious of aquarium caulks; standards for pets are often looser than standards for people.

Tom Feller's post raises an idea: just as for large boiling kettles, food-safe caulks (if they exist and whatever they're made of) should be findable in cooking supply houses. Try your local yellow pages....

Subject: sparge method

Some history: It was suggested by Micah M. that it is better to not recycle the sparge runnings at all, but rather to just allow the mash to rest for a period of time, and then allow the lauter-tun to drain. His reasoning is that the extra particles in the wort that result will give a clearer final product, as there will be more surface area for flocculation.

What I did: Unfortunately, this is completely un-scientific, and really proves nothing. With that caveat.....I brewed 2 (actually 3, but I'll get to that later) similar batches: 10 lbs 2-row pale with another pound of specialty malt. All 20+ lbs. was ground at the same time. Both batches were mashed at 154 deg. Both were mashed-out and sparged by pouring the mash into a 10 gallon water cooler fitted with a straining bowl, and then filling the cooler with boiling water. The sparge set at 170 deg. Let sit for 30 minutes. I recycled the wort in the first batch until it ran clear, probably about 1 gallon. For the second batch, I just opened the drain and let it run. Big chunks of stuff could be seen in the second batch. Both batches were then boiled up (90 min), with hops in a hop bag (mistake!)

The result: Batch 2 was \*slightly\* clearer going into the carboy, and after fermenting out. Unfortunately, both batches were quite cloudy, and truthfully, so is the result. I attribute the cloudiness to the use of a hops bag, because....

In batch #3 (I told you I'd get to it), I mashed the same way, with similar ingredients and grind, mashed-out and sparged the same way, but with recycling the first 1/2 gallon or so. I got a stuck sparge after about 6 gallons. (?) I poked some holes in the mash, and got out another .5 gallon. Boiled with loose whole hops (no hops bag), and the wort was crystal clear. The obvious next step is to do it the same way again, but with no recycling at all.

So, what does it all mean? It seems to imply that the resulting wort is clearer if there is \*something\*, whether chunks of stuff from the mash or hops, for easy flocculation, and that hops might be more important in the clearing than the mash stuff. But, again, this is really all just speculation, and I'm only posting this in hopes of getting a maltmill ;-)  
I'll let you know how comparative batch #4 turns out (in about a month).

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Silicones Again

I don't want to beat this subject to death but I think I need to make a couple of points about my last post on automotive grade silicone sealers. We have been talking about silicone as if it were some standard product but in the automotive field the number different kinds of silicone sealers is large, each with different properties. Some resist gas and oil, some can fill large gaps, some can fill very small flat surfaces, and some can take very high temperatures. The point I am trying to make here is that these sealers have different formulas, things are added to the sealer to get the different features. These sealers are tested on cars not on people, so because it will not breakdown exposed to gas does not mean that it is safe for contact with food. As I said before I am sure there must be some tested and approved food grade silicone sealer out there which would be far better to use for brewing.

Looking forward the the OBF and over 40 different microbrews, July 17, 18, & 19

> So I guess the general concensus is that Silcone is  
> 1) Reasonably inert chemically  
>2) Won't kill me?

I hate to throw cold water on this otherwise wonderful stuff but several  
years ago there was TV news story about a whole family that got deathly  
sick  
and I believe, at least one member died, resulting from the use of a GE  
Silicone Sealer in a repair job on the dishwasher.

For some strange reason, little was made of it but be advised that an  
aquarium is not a mash tun and heat has a profound effect on chemical  
activity. I would not use that stuff on anything that gets anywhere  
near my  
mouth.

.....

Ale yeast.....

Based on the accepted fact that ale yeast ferments down to near  
freezing, I  
am curious to know what happens to wort/agar slants of yeast cultures  
stored  
in the fridge.

Presumably, they would happily ferment to depletion and/or till the tube  
explodes if it is the screw cap type.

Seems like in the best of cases, one would end up with tired out old  
yeast if  
it was stored for more that a couple of weeks.

Hmmmmmmmmmmmmmmmmmm?

>disadvantages? Is this a dumb idea all together?

In general, modern Barvarian weizens have the two ale yeasts (S. cerevisiae and S. Delbrucki) filtered out and a lager yeast is added at bottling because, as you noted, it is more flocculent (and possibly less prone to autolysis). I recommend that you simply bottle as usual mostly because of sanitation risks.

Brian writes:

> I've picked up two ball lock soda kegs at the scrap yard for \$3.00 ea.  
>and have some questions about cleaning, and the carbination in brew use.

Note that I bought my 5 kegs new from Foxx so I can't comment on cleaning old ones.

> 1)When you place new gaskets in them do you need to take the ball lock  
>studs off and replace their gaskets?

I suggest that you do replace them. They only cost a few pennies.

> 4)I've know that you need not to prime with corn sugar, hence the  
>carbonation is added thru the co2 tank. But would it not help get rid of  
of  
>unwanted oxygen while aging?

If the conditioning (carbonation) vessel, keg or bottle, is sealed, then your only hope for getting rid of oxygen is something like SmartCaps(tm)

.

> 5)After tapping how long will the beer stay good? Can you fill the keg  
>with co2 to make it last longer?(Oh, I forgot to mention I don't have the  
the  
>facilitys to keep it cold after tapping.)

You had better find a way to keep it cold. You also had better buy a CO2 tank and regulator (it sounds like you don't have one). Refrigerated (if you have good sanitation) your kegged beer could stay good for a year.  
Unrefrigerated, well, I wouldn't recommend it.

> 6)Sense the soda kegs take the beer from the bottom how much of the beer

>will have the yeast in it?

I cut off 3/4" of the pickup tube with a tubing cutter. After three weeks of conditioning (two at 68F one at 50F), the very first beer is crystal clear.

> 7)Should I use some type of filter while racking into the keg? If so what type of filter is easily used in home brewing, and how can you make sure of sterilization? (I've thought of cheese cloth but have no clue on how to sterilize it.)

You can use a filter, but you don't have to. I recommend leaving that for later.

> 8)(this isn't really a question I'd just like to get some feedback and maybe some better ideas for cooling the beer to drink)  
> Ok, here is how I plan to cool it. I bought a 20 qt. cooler and 25 ft of stainless steel tubing in a coil that sits inside the cooler.  
> The beer comes from the keg thru a plastic tube to the cooler into a coupler shank into the stainless steel tubing into a faucet and shank set.  
>Wala! beer!  
> I figure 5 min after I place Ice on the coil I should have cold brew in the mug. I'll use silicon to prevent leakage were I drill out the cooler.  
> I have ordered most of the equipment for this project for under \$100.  
00  
>>From SuperiorProducts out of St.Paul Minn.(no affiliation)

A used chest freezer with a Hunter Airstat thermostat is the best way to go. I suspect you will have trouble with carbonation since the solubility of CO2 varies greatly with temperature. I've tried dispensing cool beer through a jockeybox (what you described) and had a heck of a time getting the CO2 to stay in the beer.

From: "C. Lyons" <LYONS@adcl.adc.ray.com>  
Subject: Question on sanitizers.

I have recently moved to a new location and the water here has a high iron content. I typically use bleach (chlorine) to sanitize my equipment (bottles, buckets, carboys, etc.) and now find that iron precipitates out of the water when I let my equipment sit in the chlorine/water solution. This has unfortunately resulted in giving some of my equipment redish-brown stains. I'm calling on the experience of the HBD readers for advise on alternative sanitizers. In HBD#917 Al Taylor mentioned the use of B-Brite, and hinted that dishwashing powder is essentially the same with a small amount of chlorine added. Since I'm trying to avoid chlorine, I'm asking for advice on another affordable alternative. I typically buy a gallon of bleach for \$0.89. I don't expect to find such an affordable solution, but would appreciate any advise on the purchase of non-chlorine based sanitizers (hopefully in bulk, like Al Taylor's dishwashing powder solution). Any advise would be greatly appreciated, as I will be ready to bottle a batch of pale ale in two weeks.

Thanks in advance,

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Origins of Lambic?

Although no one is certain of the exact historical origins of lambic brewing, there is a body of evidence connecting the roots of the lambic technique to the village of Lembeek. Lembeek is a small village (pop 4000) in the Pajottenland. In its heyday, it boasted somewhere between 40 and 45 breweries, today it has one. The following account was told to me by that solitary brewer in Lembeek. While I can't prove or disprove its historical accuracy, it does make a good story.

Lembeek is situated on the river Zenne (Senne in French), southwest of Brussels. The river takes a sharp bend, encircling the enclave of Lembeek and bestowing upon it a certain strategic importance. Whoever controlled Lembeek, controlled the Zenne, which was the main shipping route thru the region and up to Brussels. Consequently, many wars were fought over the control of this small village. In an attempt to bring peace to the region and assure that the river was accessible to all, Lembeek was established as a sort of neutral zone.

Because of its status, Lembeek was not taxed like the rest of the region. While the nearby villages were required to pay taxes to one crown or another, Lembeek was exempt. Then as now, such favorable tax laws tend to attract businesses.

Meanwhile, the brewers of Lembeek, who had established a trade guild by the 1400's, were refining their brews. The peace brought to the region allowed them to pursue their efforts more readily, and the tax laws allowed brewing to flourish. Utilizing the natural microflora of the region, they began to develop a brewing and aging technique that allowed their brews to keep for up to three years. By comparison, brewers in nearby villages were typically able to keep their products for only about three weeks before they soured, and were of course taxed on what they produced.

Utilizing their advantage, the brewers of Lembeek began to "export" their goods, first to the nearby village of Halle. The brewers of Halle were none too happy about this, and protested to the authorities. However, the authorities deemed that it was more important to preserve Lembeek's neutral status than it was to appease the brewers of Halle, and so the market for the beers of Lembeek grew. They continued to export further north along the Zenne until lambic became the popular drink in Brussels. There came to be many gueuzestekers (gueuze blenders) in Brussels, who would buy young lambics from the brewers in Lembeek, aging and blending the beers themselves.

Then with the French Revolution, came the abolition of taxes everywhere in the region. Although the tax laws have changed many times since, the scales

have never been so tipped in the favor of the brewers of Lembeek. They lost one of their big advantages, and the brewing industry in Lembeek began to decline. The gueuzestekers of Brussels became brewers themselves, and many lambic brewers moved to the big city to have easier access to a larger market. Even the hallowed traditions of Cantillon were born in Lembeek where Paul Cantillon founded the brewery. It was moved to Brussels in 1931.

There was a period after WWII, during which there were no breweries left in Lembeek. In 1988, Frank Boon moved his brewery to Lembeek, where he keeps the noble traditions alive.

Cheers,  
CR

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: smoked beer

Well, gang. Before the summer's gone, I want to try smoking some grain for a Rauchbier or other smoked beer. Unfortunately, I've found very little written about it, and I've only tasted smoked beers twice. Once was the Alaskan smoked porter from the Alaskan Brewing Co. (?), and one was an import from Germany that I stumbled across in a grocery store. Hoo boy was that smoky. All my friends hated it, but I loved it. Here's what I've gathered so far:

Dan Fink's article in the Zymurgy beer styles issue says that Rauchbier is similar to Oktoberfest. He says to use all German ingredients, and hops like Hallertauer, Tettnanger, and Saaz. Hop bitterness, flavor, and aroma are all low. He suggests a good starting point is to use 1 lb of heavily smoked malt.

In the same issue, Dave and Judy Lipitz, and Lynn Patterson have a recipe that uses 2 and 1/2 lbs. of smoked Munich malt. They hop with Northern Brewer and Mount Hood, and use Wyeast Bavarian 2206.

Ken Weiss' recipe in Cats Meow II uses liquid smoke.

Quentin Smith, in the hops special issue of Zymurgy says the smoke overwhelms the hops, so "any hop will do" (p. 59). He suggests 28-38 IBUs.

Charlie II says that the OG is 1.050-1.060, with 20-30 IBUs, and a color of 12-17 SRM. His recipe is 7 lbs. of light DME, 1 and 1/2 lbs smoked crystal, a little bit of chocolate, with Hallertauer for bitterness, flavor, and finishing.

So, I'm interested in ideas. Some constraints: I'll be using extract (because I'm not yet up to all-grain), ale yeast (because my basement's too hot for lagers), and NO liquid smoke (because I've got my own smoker and want to smoke my own grain). I know that beechwood is traditional, but I'll probably use something else. Easy for me to get are hickory, mesquite, cherry, apple, pecan, and maple.

If you've actually made a smoked beer before, I'd be really interested in hearing from you. But even if you haven't, I'd still like your opinions on yeast, hops, recipes, approaches, techniques, etc.

From: "Franklin R. Jones" <FRANK@VA5549.Colorado.EDU>  
Subject: malts...

Greetings,

I've been a reader of this digest for almost two years, and now seem to have the space, time and almost the money to set up a brewery kitchen (in its own room in the garage) to do full mash, all grain brewing. Most of the reading/research has been confined to Dave Miller's Complete Handbook of Home Brewing, and this Digest. (thanks all!) Dave's book gave the best information of the 6 or so books I own on brewing. In the research to undertake this I have come up with a few questions about malting that I would like more info on:

1> What temperatures are used to make roasted malts? Dave's rather vague on temperature's needed to make roasted malts what they are ("roasted at high temperatures..." High? when most temps with regard to malt rarely exceed the boiling point of water, what is high? 250... 400?)

My interest is in the description he gives of Brown Malt "kilned over a hardwood fire, which imparts a smokey flavor". As my main focus is Dark sweet Ales, this would seem useful.

2> He states that this malt (brown malt) is "very hard to find..." Anyone know if this is still true? Sources?

3> Has anyone out there tried making malts? Any publications on this?

Almost lastly: This digest is in fact the reason, my questions about "first mash" aren't about the process, but more of the "I wonder" type. This forum has been an invaluable source of knowledge. (you are all now obliged to get a cramp in your shoulder, by patting yourselves on the back.) I'm *\*sure\** I be back to tap the source, in the future.

Lastly: to Jack Schmidling: re: maltmill giveaway... All the systems/network managers want to thank you for stress testing their mailers.

My system just *\*loves\** processing 4M Homebrew Digests! But Seriously, Thanks for the offer. A few words of "comfort"? My father, when he retired, found that he had to retire about four more times over the next few years from the full time "amusements" he built for himself. Best of luck.

My understanding is that Widmer does NOT use a second strain of yeast, and that on the contrary their yeast is "fluffy" and anything BUT flocculent. I don't see any reason to use this as a second strain, although it would certainly be worth trying as a primary yeast. My impressions are garnered, by the way, from discussions with Frank Commanday (head brewer downtown) and a couple of other people who work there.

Also, this is not a specifically weizen strain of yeast but is the same stuff they use in all their beers; in other words, primarily a German-style top-fermenting yeast.

The big German breweries repitching at bottling with a lager yeast, to get a brighter beer. Whether they help flocculate the weizen yeast or if that primary yeast has been dropped out by cold-conditioning, I don't know.

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: IPA recipe

I just brewed my fourth batch of IPA based upon a recipe that Darryl Richman gave me. Since it is such a fine beer I thought I would share my latest effort with the HBD. The latest was modified a tad due to material shortages - the changes shouldn't affect the results too much.

7lb GWM Pale Malt  
14oz 36L Carastan (Huge Baird)  
.5oz chocolate

7.25 gal supply water treated with 14gm gypsum, 1.5 gm chalk

Mash in with 8qt@170f for a target of 153-155f. Conversion done in 30 minutes. Mash out at 168. Sparge with remaining supply liquor to collect 6.25 gal. 90 min boil.

12gm chinook pellets for 60 min  
10gm willamette pellets for 5 min  
20gm kent goldings for 5 min

1/4tsp irish moss for 10 min.

OG 1.051 in 5.5 gal (needed to add a qt to bring the volume up)

Ferment with Wyeast 1028 (london ale) at around 68f

Rack to secondary after fermentation dies down and dry hop with 10gm cascade pellets and 20gm Kent Goldings. Let sit until fermentation completely done (e.g. pellet crud sinks) - about a week or two.

Prime/bottle/keg in the usual manner.

The original recipe used 20gm each of willamette and Kent Goldings instead of the chinooks, and used cascade instead of the willamette in the second addition. Also, it used 12oz of 16L and 4oz of 70L crystal instead of the 36L stuff, above. The changes should yield the same color and bitterness. The aroma and body will be a bit different, but with all that dry hopping I doubt many will be able to tell the difference. With the above hopping levels this beer is not as bitter as, say, Grants IPA - but then I don't like overly hopped beers (shields up) - yet it is bitter enough to make it an IPA and not just a random pale ale.

Cheers!

- Larry Barello

From: ithaca!amber!phoebe@uunet.UU.NET (Phoebe Couch)  
Subject: Re: Mendicino Brewing Company

4 of July and I found myself at the door accidentally. (driving by on my way up North)  
They were having a big party in the back with a keg throwing contest. The back was an outdoor beer garden with grape and hops growing all over. The bartender told me that the hops outside were Cluster, and they were full of fragrant cones.  
The brewmaster was running the keg throw and it looked pretty bizarre. In a long sandbox, the contestant picks up this keg (75lbs for women, I estimate 150 for men) and hurls it forward and it crashes into the sand! (The high score was 115 inches)  
At one point, Someone egged me on to try it. Being on the scrawny side, I could only lift it up over my legs, and I gave up (dislocated shoulders are no fun!).  
The women hi score was 86 when I left the pub.  
They had Eye of the Hawk on tap (Red Tale X 2) and it was delicious. All the other beers were good too, especially on tap.  
Since everyone was busy having a good time, I didn't pester them about their brewing procedure, but I found out that they don't dry hop! and they use cascade and cluster (1/3, 2/3 or is it the other way)  
Went back there on my way down (July 5) and they ran out of beer on tap except for Red Tail and Black Hawk Stout.  
Its a great place!  
P.  
p.s. At their gift store, they have a poster on the door that was given to them. It has a map of California and a list of all the brewing company in CA plotted on the map, on each side of the poster are the name/address/phone number of each brewing company or brewpub. The name of the printing company was somewhere in san Jose. I forgot to copy the name. Have anyone seen this poster? Do you know where I can get one?

From: hartman@varian.varian.com (John Hartman)  
Subject: Get-together at Oregon Brewer's Festival

Six people responded to say they are interested in gathering at the Fest.  
Here  
is when and where we will meet:

Where: The Bridgeport Stand (where Bridgeport Brewery is pouring  
their beers) at the Festival location. The Festival location  
is the Waterfront Park located along the river in downtown  
Portland.

When: Saturday, July 18, at 3PM

The Festival opens that day at noon and goes 'til 9PM. I'm leaving for  
Oregon on July  
10, so unfortunately I don't have much time to consult with the  
respondents.  
The above time seems to work for everyone. If someone has an alternative  
suggestion,  
let me know soon. Otherwise this is it.

See you there!

John hartman@varian.varian.com

John,

I will be working at the Brewers Festival Friday night and probably be attending for the purpose of consumption early Saturday afternoon. I've found eqq early attendance beneficial as the more popular (and often better) brews tend to run out early in the day.

Anyway, as the event approaches, we can set out specifics to meet.

Jim Larsen

John:

I will be going to the Oregon brewer's Fest all 3 days. I live in Southern Cal. and have airplane reservations for the morning of the 17th. I haven't made any hotel reservations, I will be doing that tonight. I'm also not sure yet if I am going to rent a car. I plan on calling one of the Brews Brothers to help me work out the logistics. I am also going to volunteer to help. I hope to see other Homebrew Digest subscribers there also.

The return address on the header of my message will not work since it is a new system and not in the nameserver tables yet. You can try:

haberman@192.42.141.199 (numeric address for system in header)  
or  
habermand@pl-edwards.af.mil (another system I use frequently)

From: Russell Owen <OWEN@VAXE.NIEHS.NIH.GOV>  
Subject: ROOTBEER

My note on the possible hazards of genuine rootbeer elicited a response from D. Popowich asking for details. I lost his email address and this is tangentially related to homebrewing, so here goes ...

Root beer is flavored with a distillate of the young shoots or root bark of Sassafras variifolium, a member of the laurel family. (I remember shaving off pieces of bark to chew upon as a child in Trumbull, CT.) Sassafras has also been used to make tea for medicinal and enjoyment, and to make a yellow dye. In addition, an oil from sassafras fruit has been used in perfumery.

The trouble with sassafras is that it contains safrole, a carcinogen (see the NTP 85-002, 1985). Safrole (aka 5-(2-Propenyl)1,3-benzodioxole, aka allylcatechol methylene ether, aka 4-allyl-1,2-methylenedioxybenzene, aka allyldioxybenzene methylene ether, aka m-allylpyrocatechin methylene ether) is about 75% of oil of sassafras. It has been used as a topical antiseptic and a pediculicide (lice treatment). Its oral toxicity in rats is 50% lethality at a dose of 1.95 g per kg.

So, if you must indulge, do so in moderation!

Subject: US book on Porter

I recently had the pleasure of meeting Bob Grossman at the Durden Park Beer Circle, whilst he was over in London courtesy Young's brewery. I believe it was his prize for being master brewer at last year's AHA. He had with him a book entitled 'Porter' and I would be interested in getting a copy. Can anyone give me more details, as in Authors, correct/full title, publisher, etc.

I would also be interested in knowing what other books are recommended reading for the US homebrewer (full details please including ISBN)

Many thanks  
Geoff

From: Russell Owen <OWEN@VAXE.NIEHS.NIH.GOV>  
Subject: Al's Jockeybox

Al (korz@iepubj.att.com) wrote  
"I suspect you will have trouble ... since the solubility of  
CO2 varies greatly with temperature," saying that he had  
trouble keeping the cold beer carbonated.

Gases are \*more\* soluble in water as temperature drops,  
and I suspect that beer is enough like water for this to hold  
true in brew.

Specifically, the solubility of CO2 in H2O (ml per 100 ml @ 760 mmHg)  
is 171 @ 0 degrees C,  
is 88 @ 20 "  
and 36 @ 60 ".

Perhaps the length of the tubing in the "jockeybox" is the problem.  
The amount of beer sitting in the tubing and the amount of time  
any sip of beer spend sitting in the tubing increase with tubing  
length. 10 feet of tubing with a cross-sectional area of 1 cm<sup>2</sup>  
will easily accommodate an entire glass of beer.

Cheers

From: "Roger Deschner " <U52983@UICVM.UIC.EDU>  
Subject: \$40 Fridge Controller

An article in Zymurgy a couple of years back described a "Honeywell T6031A 1029 Refrigeration temperature Controller" which is available for less than \$40 at any wholesale heating/cooling supply. You get this gizmo, which comes complete with a temperature probe, and wire it using a 3-prong heavy-duty air conditioner extension cord. Synopsis of wiring diagram: Those types of cords have three wires - a ribbed one, the center one, and a smooth one; cut the smooth one to wire it into the controller. If you've got a round cord with colored wires, cut the black one. (Or else look up the Zymurgy article for a real wiring diagram.) The article even described how you can use self-adhesive hook gizmos to keep the temperature probe line orderly. That's all - and all parts are available locally.

From: richer@ionic.HQ.Ileaf.COM (Al Richer)  
Subject: Kegging basics

I have seen the light, and it is made of stainless steel....

Greetings. After having asked several dozen stupid questions about keggering,  
I have decided that I should pull all of this information together into one  
article for the amusement and edification of the Digest.

#### I. Items needed for a keggering setup

Keggering is the process of packaging beer so it may be dispensed. To this  
end,  
you need a package. The normal container for the homebrewer is the  
Cornelius  
or Firestone stainless-steel premix soft-drink container. It is available  
from  
many sources, including restaurant auctions, scrapyards, cooperative  
soft-drink  
retailers, and other sources. Use your ingenuity, and you will seldom go  
wrong.

The other items to go with your keg are used for the dispensing process.  
They  
allow you to dispense the beer under gas pressure, and to connect and  
disconnect  
the equipment from your keg.

These items are:

A CO2 cylinder. Most hobbyists purchase a 5 Lb. one.

a pressure regulator. This reduces the 800 PSI of gas  
pressure in the CO2 tank to a manageable dispensing  
pressure (usually 5 to 7 pounds).

Hose with gas-in fitting. These items conduct the gas to  
the keg from the regulator, and allow you to connect the  
gas line to the keg. The gas-in fittings come in either  
ball or pin lock. Buy whichever fits the keg you obtain,  
as one is as good as the other for the homebrewer.

Liquid-out fitting and beer faucet. This is the part that  
the beer actually comes out of. It has a fitting like the  
gas-in one, but keyed differently to prevent interchange.  
On the end of the hose from this fitting is a spigot to  
control the flow.

When it comes to the pressure-regulating items and the gas bottle, don't  
scrimp, as cheap or defective fittings can be very dangerous. Gas at 800  
PSI is not trivial to handle, and an accident could be fatal.

#### II. Preparing to keg - How to get ready.

If you buy all of your equipment new, than you can skip this part. What I am going to go into here is the cleaning and overhaul of a standard pin-lock Firestone keg. Cornelius kegs are similar, but I have not worked with them and would not speak of them without personal experience.

With a keg that has been used for soft drinks, the rubber parts that are in contact with the drink become impregnated with the sugar syrups. These will then flavor any beer you might bring in contact with them, so they need to be replaced as part of the cleaning and preparation process. These are located in the bases of the gas-in and liquid-out fittings, and around the lid of the keg.

Remove the gas-in and liquid-out fittings, using a 13/16" open-end wrench inserted through the gaps in the handle surround. Once loosened, these should remove easily. Once unscrewed, set these aside, and remove the dip tubes from the fittings welded to the tank. The gas dip tube is rather short, and the liquid dip tube is the long one that extends to the bottom of the tank. Remove the o-rings from both of these and replace them with new ones from the hardware store. O-rings of the proper size are easily available in the plumbing area of most good hardware stores. Reinsert the dip tubes and reinstall the fittings, tightening them with the wrench. Do not overtighten, as it is unnecessary and will make it more difficult the next time.  
NOTE: The gas-in fitting is the one with two lugs. The liquid-out fitting is the one with three lugs. I got them mixed up too...8\*)

Replacement of the top gasket is easy. Just open the head by lifting the bail, then drop the head down into the keg and rotate it to remove the lid from the keg. The O-ring should come out with the lid. Simply remove it from the lid and replace it. New ones of these should be available at your homebrew supplier, or try a pool supplier for a pump O-ring of the proper size. Bring the old one as a comparison sample.

Cleaning the keg is rather simple. I usually prepare a solution of washing soda and soak a new keg full of it for 24 hours, followed by purging the solution with CO2 through the fittings on the tank. This is followed by 2 gallons of boiling water, well-agitated in the tank to clear the residue, and purged thru the fittings with CO2. The boiling water rinse is also a god way to clean out a tank before use, along with a weak chlorine rinse for sanitizing.

### III. Kegging - The process

Kegging is considerably simpler than bottling, but has a set of gotchas all its own.

The first step is sanitizing the keg. I personally do this with a rinse of hot water and B-Brite of a gallon or so, shaken in a sealed keg, then expelled through the keg plumbing with CO2. After this, I do the same thing with boiling water, again expelling through the plumbing, to clear the B-Brite residue. One pass is usually sufficient, though if I'm being paranoid, I'll do it twice. After this step, you must handle the keg in a manner to retain the sanitation. This means not taking out the lid and laying it down on the work-bench in the basement. Treat the keg as you would a sanitized bottle ready to fill.

Next, add the priming syrup to the keg. I usually use 1/2 cup of sugar to 1 qt. water, boiled for 10 minutes for sanitation. I cool this to blood temp, then add it to the keg. Next, with a sanitized siphon hose, siphon your finished beer into the keg, being careful not to splash, but swirling enough to get a good mix on the priming sugar. Once filled (keep the beer level below the CO2 inlet, otherwise don't worry), reinsert the lid and cinch it closed. Before doing this, I usually turn on the CO2 to the keg and purge the airspace above the beer to clear the residual air in the tank.

With the keg sealed, pressurize it to 5-6 PSI to seat the head. If it begins to leak, open and reseal it, which usually cures the problem. Make sure that the lid isn't angled, which is easy to do and can cause leaking.

Allow the beer to carbonate for 1-2 weeks before drinking. I usually discard the first 1/2 mug out of the keg, as it brings the yeast out with it. After that, it's home free.

I need a beer after all this typing...

ajr

From: c\_vandev@hwking.cca.cr.rockwell.com (Craig Vandeventer)  
Subject: Adjusting ph of sparge water

I am an extract brewer who is looking into doing full mashes. I have been reading up on the subject and, even better, reading all the old digests (a gold mine of info). A couple of posts recently have confused me about the whole mashing process. As I understand it, adjusting the ph of mash water is so that the enzymes can convert the maximum amount of starches to sugar. If this is so (correct me if it is not), after conversion is complete what purpose does adjusting the ph of the sparge water accomplish? If the enzymes are done why make the sparge water more acidic? Is there some other good reason for doing this?

On another topic, I will be traveling to San Diego soon and would like up-to-date info on brewpubs and bars with great tap beer. I searched through the old digests and came up with these brewpubs:

Pacific Beach Brewhouse  
La Jolla Brewing Co.  
Callahan's  
Old Columbia Brewing Co.  
Mission Brewery

If anyone could send me any more info on these or newer brew pubs it would be greatly appreciated.

Craig Vandeventer - Reason #326 for drinking homebrew:

"Homebrew beer belches taste better."

P.S. Jack, I just received my KitchenAid grain mill in the mail. If you'll give me the freebie(if I'm not #100) I'll do a side by side comparison and post the results here. If I like the Kitchenaid mill better I'll return yours; otherwise, I'll sell my Kitchenaid mill.

From: tony@spss.com (Tony Babinec)  
Subject: smoked beers

Liberty Malting of Seattle (see their ads in Zymurgy) carries a rauch beer malt. Their malts aren't cheap, and unless you're local, you'll have to have them ship it to you. But, it's an excellent malt. A couple pounds of it in your favorite recipe will impart a sweet, smoky flavor.

You can smoke malts on your backyard grill. Use hickory, mesquite, or fruit tree wood such as apple. Wet the grain and dry it over the charcoal and wood fire. You'll have to turn the grain to dry it evenly. Those of you who attended AHA National in Milwaukee might have visited the Chicago Beer Society table or hospitality suite, where we were serving a Russian Imperial Stout (first runnings) and a Porter (second runnings) made with some smoked malt.

The commercial Rauch Biers most of us have access to are said to be in the Vienna style. Some German brewers also make a seasonal smoked Bock. I also read somewhere in the Michael Jackson Pocket Guide that there are a number of smoked wheat beers. Other styles that would seem to benefit from some smoked malt are Scotch Ale, in addition to the above-mentioned Porter and Russian Imperial Stout styles.

If you're an extract brewer, use a simple partial mash technique and some smoked barley malt. If you start with some smoked malt, crack it, steep it, strain the water, and continue with your usual brewing process.

Subject: highly modified malts

On the prompting of local friends, and recent discussion in this forum, I made a visit to the Sherlock's Home brewpub outside of Mpls. (interesting that I just \*happen\* to live here...he..he..) Very, very good....

Very smooth. Perhaps I should visit England some day.....

But I digress. I got hold of the Brewmaster ( great fellow!), and he made

quite a point that they use only English 'highly modified' malt. From Papazian

I understand that this refers to grain that has been allowed to 'sprout' more,

increasing the enzyme content and reducing the starch content (it goes into

forming the rootlets, which are discarded).

Now the question: has anyone out there experimented with USA versus English malt, and if so can you describe the difference in character they give to a brew?

The Brewmaster at Sherlock's said forcefully "you CANNOT make english-style

brews using USA malt." Is it the highly modified malt that gives their brews their smooth character, or is it brewing skill, etc. etc....?

Subject: Re: Homebrew Digest #919 (July 08, 1992)

In Homebrew Digest #919 (8-Jul-92), smith%8616.span@fedex.msfc.nasa.gov asks:

> How can one add "body" to a quick mead?

In my experience, adding more honey (two to four pounds per gallon) helps make the flavor more "real". In addition, remember to skim off the white and brown foam when it is heating/boiling - that helps keep the taste clean.

I've found that adding bay-leaf and marjoram as spices with some fresh ginger root and some lemon peel makes a really flavor-ful drink that doesn't have that "thin-ness" that simple honey/water mix makes.

My basic recipe is lemon peel and ginger, and I've found that it is refreshing in a "ginger-ale" way, but adding the bay-leaf in small amounts (one bay-leaf or two per 5-gal batch) adds a "woody" flavor to make it more beer-like. The marjoram (or rosemary) adds a light flower-scent which enhances the honey-nature of the drink.

Another way to improve body: use darker honeys - if you use a really dark honey, such as a "raw" wildflower honey, you can get something like a "dark" mead.

Good luck!

Silicone rubber caulks, unless marked "safe for aquarium use",  
contain  
poison (cyanide? arsenic compounds? I don't remember) to resist the  
formation of mold and mildew when used outdoors or in dark, damp  
places.

This poison will leach out over time and kill your fish if you use  
the  
standard caulk in an aquarium. I would not use it in beer-making.

The  
"safe" kind should be all right. The "solvent" released during  
curing  
is acetic acid, and is common to all silicone caulks. It shouldn't  
do  
any worse than sting your eyes if you get too close while the caulk  
is  
setting up.

> "Aquarium Seal" is likely to be slightly more costly than other  
types  
> of silicone rubber caulking.

If you buy it as "Aquarium Sealer" in a pet store, then yes, it will  
be  
much more expensive. If you just go to the hardware store and get a  
tube that's marked "safe for aquaria", then it shouldn't be any more  
expensive than the standard mildew-resistant stuff.

Subject: Load of questions...

Howdy,

First of all, this mailing list is awesome. It's the first thing I read each morning, and makes my day usually.

I am a novice brewer, with about 20 batches under my belt, and am interested in getting a load of new recipes to try. Does anyone have an archive of recipes they can send me? Hypercard stacks? I use extracts now, but will be switching to all-grain next month.

What is a cold break? Hot break?

Why didn't my lager ferment after nearly a month in the fridge? I suspect that the temperature was around 38-42 degrees in there? Is this too cold? It's sittin' on the counter now, having fermented at about 70f for a week, and is finally ready to bottle. Glad I took a "final" gravity after I took it out of the fridge.

It there anyone else out there who brews 10 gallons at a time? Do you do anything different because of that?

Is there anyone else in the Raleigh/Durham/Chapel Hill area reading this?

Thanks for the time and the raffle ticket!

Phil Calvin DoD #242

Subject: Moet Liquor (mead???)

Greetings,

Has anyone tasted an after dinner drink produced recently by Moet et Chandon?

I can't remember the exact name but it comes in a small version of a regular Moet champagne bottle. This stuff is great! Sweet and alcoholic but not cloying like liquors - due at least in part by the carbonation.

Two questions:

- 1) Is this stuff a sparkling mead?
- 2) Does anyone know how to make it?

Note:: what HBD posting number are we up to?????

thanks in advance,

Joe P.

I also have a very high iron content in my water. I use a water filter which filters out most of the iron from the water. The one we use is for the whole house, however you can purchase filters that hook up under the kitchen sink. Sears has a good selection of filter holders and filters specifically for iron removal. Also, most home building supply stores carry these. Prices are usually less the \$50.

If you get one of these, you can then use sanitizer you like.

Does that mean you advocate not introducing oxygen into the keg?  
I know some people say that they flush the air out with CO2  
before racking into the keg. If this works, it should answer the  
original question.

>> 5)After tapping how long will the beer stay good? Can you  
>>fill the keg with co2 to make it last longer?(Oh, I forgot to

I have wondered about this myself. Does anyone have an  
explanation for it? Considering that your bottled beer will last  
a year at basement temps just fine, why shouldn't a keg do the  
same? Is it because air gets in when you tap the keg? Or do  
just microorganisms get in? Or what?

>Brian

>

I think the unit Brian is describing is the Hunter Air-Stat (or something  
very close to that name). I have one that I use to control my 'fridge.  
It works perfectly well, controlling the temperature within +-2 degrees F  
of the set-point. I believe the lower limit on the temperature is 35  
degrees and the upper limit is 99 (but don't quote me on it :-). I'm  
sure  
it would work as well with a freezer. It works just like Brian describes  
it. This unit has been discussed many times in this digest. I found  
mine  
at a semi-local hardware store called Home Depot. I think these are in  
several regions around the country. It cost about \$25. You may be able  
to find it in many do-it-yourself stores.

Has anyone else noticed that the Wyeast #3056 (Bavarian wheat) seems to be less "clovey" and rich since they changed their packaging? I make weizen quite a bit, and lately my batches just haven't been as rich as they used to be. Perhaps Jeff Frane knows something about this.

> Since I know of no access to pure *S. delbrueckii* and am not too interested  
> in plating it out, has anyone out there tried adding cloves to either the  
> primary or secondary?

I've used cloves for spiced ales, and my advice would be \*go easy\*. It doesn't take much to add that character. I had good luck by simmering 3-4 whole cloves (not crushed) in water, then adding the whole thing to the primary.

In fact, I'll post the recipe. I'm normally an all-grain brewer, but this is a twist on a kit beer. I find that spices tend to mask any sort of "canned" flavors, and with the time you save you can brew a lot of it, like for a party. The spices balanced perfectly after a few weeks in the bottle.

#### Easy Spiced Brown Ale

MountMellick Brown Ale Kit  
3-4 whole cloves  
3 whole cinnamon sticks  
1/4 tsp ground nutmeg  
4 oranges  
1/8 cup Hallertau hops (fresh)

Simmer spices, hops, and zest of 1 orange in 1 qt water for 30-45 minutes. Make Brown Ale according to 3.6 gallon recipe. Add spice mixture (do not strain) and zest of other three oranges to wort. Ferment, strain, and bottle according to kit instructions.

Subject: Bottled California Beers

Subject: Bottled California Beers Time:8:26 AMDate:7/8/92  
Mike Daly asks about where to purchase bottled California beers while visiting San Francisco. The following are all in San Francisco in various parts of the city.

The Jug Shop  
1567 Pacific Ave (at Polk)  
Good selection of locally produced beers including Marin Brewing Co.

Cannery Wine Cellar  
The Cannery at Fisherman's Wharf  
Large selection of local and international beers. Expensive. Also great selection of Single Malts.

Coit Liquors  
Columbus Ave. and Union St.  
OK selection of local beers. Very well priced. (You might still find some SN Mai Bock if you are here in the next two weeks or so)

Liquor Barn  
201 Bayshore Blvd.  
OK selection of local beers. Poorly handled.

Almost all Safeways have some local stuff these days. Anderson Valley, Winchester, Rogue, Mendocino to name a few I have spied. Both the Northpoint and Marina Safeways have these and I am told selection is similar elsewhere in the city.

Enjoy the trip!

Subject: oats and other adjuncts

As I understand it, specialty grains do not need to be mashed. They could be mashed, but only really need to be sparged. Is this true? Is it better to mash them, or not mash them? Is it bad to mash them?

And what is the difference between Quaker oats, Steel-cut oats, milled oats, rolled oats etc? As I gather from yesterday's digest, they need to be mashed. Do you throw them in with the mash or cook them first?

Subject: That clove-like aroma

We've had a bit of discussion about wiezen beers and their clove aromas recently, so here goes my \$0.02 worth. I can spot the influence of S. Delbru...  
from a distance of about 2 miles. To me it is anything but sweet or estery;  
on the contrary, I would describe it to an uninitiate as something like rotten tomatoes. Alternative ways of achieving this phenolic sensation are  
(a) getting a wild yeast infection, or (b) using Vierka lager yeast (not really different from the previous option!). So what gives, am I ultrasensitive or something ?

For those looking to culture from a hefeweizen, I can recommend that Falken's  
brew (from Schaffhausen, in Switzerland) gives a culture with all the desirable (?) characteristics of its parent.

From: JLAWRENCE@UH01.Colorado.EDU

Subject: Extracts

I have recently come across a number of recipes I'd like to try that use amounts of extracts that are less than a standard can. I've found small cans (1.4 lb), large cans (6.6 lb), and middle sized cans (3.3 lb). The three bears would be proud. However, I have seen recipes that use, for example, a cup or 2 of 1 type of extract, a couple of pounds of another, etc.

So, my question is:

1. Does the stuff keep? If I were to open a can and only use half of it, how do I store the rest? I don't have enough equipment to create more than one batch at a time.
2. What's the best way to measure it? Warm it first to get it a bit less (more?) . . . um . . . viscous (right? the discussion on viscosity vs. SG was interesting, but I'm not sure I got it all)? Pour it into a bowl and weigh it on a kitchen scale? Sticky, I would think, but not impossible. Does anybody have an easier way?

On another note, I was happily washing bottles last Sunday and allowed the dreaded boilover to occur. This one was a beaut (and what a waste of perfectly good wort :- ( ). Does anybody have a good way to clean those burner pans and rings? The SOS pad didn't get it all, and I got real tired of scrubbing.

Thanks.

- Jane

>in plating it out, has anyone out there tried adding cloves to either the  
>primary or secondary?

I had the same complaint last summer so I tried what you propose. I looked  
up my favorite christmas wassail recipe and found it called for 2 tsp. of whole  
cloves for 1 gallon. This sounded very excessive so I cut it by 1/8 which  
still was about 1 tsp./5 gal. I added this to the boil with the malt.  
Result: Way too much clove flavor for anything except a christmas beer.  
I would cut this by 1/2 to 1/2 tsp./5 gal. if I was making the ale over again.

I've been wanting to make a Berliner-weiss style beer and have been unable  
to locate pure ( or mixed for that mater) lactobacillus. A Zymurgy recipe used a Stoudt's Wheat culture for this style. The judge's comments included "good lactic nose." Has anyone cultured Stoudt's Wheat yeast and tried this? I can't get Stoudt's Wheat here in Charlottesville, Va and want to know if it worth the drive to seek it out.

> secondary?

I've not done this myself, but have tasted the results in competition. The clove-\*like\* characteristic is a phenol compound produced by the yeast (but you already knew that). It's called clove-like for lack of a better interpretation of the flavor/aroma perceived by your senses. The actual clove spice is something altogether different.

The competition entry I tasted was entered in a wheat beer category, supposedly as a weizen style. The description I gave was `potpourri`; it had a sweet spicy character similar to mixed cooking spices. It was nothing like the genuine weizen beer character. If you like spiced ales, use cloves. If you want a traditional weizen with the right flavor/aroma properties, you'll have to use the right yeast.

I have used several strains of wheat beer yeasts including the pure *S. Delbrueckii* sold by the now-defunct MeV labs, and Wyeast's Bavarian Wheat. The pure culture definitely produces a stronger clove character. The Wyeast mixed culture does a fair job if fermented at warmer temperatures, e.g. 73-78F. Still, the ale yeast in the mixed culture tends to take over eventually and repitching results in progressively milder beers.

From: Steve Kennedy 08-Jul-1992 1119 <kennedy@ranger.enet.dec.com>  
Subject: "mini-mashing" oats questions / Diastatic Malt Syrup (DMS) question

Hi. I'm fairly new to HBD (3 wks) and also to brewing (~1 yr).

I am planning on making an oatmeal stout within the next week or two and so the current 'use of oats' discussion is of interest. I'm also an extract brewer, so my knowledge of mashing (etc) at this time, is limited to what I've read in passing in HBD and other related forums.

In HBD #919 Russ Wigglesworth writes:

> Mini-mashing isn't hard, just take equal amounts of the oats and 2 or 6  
> row malt and combine with about 1 qt. of water per lb. Bring this to  
155  
> degrees for an hour and then rough sparge into your extract through a  
> colander or grain bag with an amount of water equal to what you mashed  
> with. By "rough" I mean just a simple rinse, no recirculation or  
trickle  
> since you are looking for the oat character and not a significant  
yeild.  
> Oats get pretty gummy so when in a 1 to 1 grain bed a stuck sparge is  
> almost guaranteed.

I had heard/read that you need to mash the (rolled) oats, but never heard you needed to mash it with equal amounts of X-row malt -- what are the advantages to doing this over just mashing the oats by itself? is this combination necessary? in trying to determine the amount of other fermentibles to use in the recipe, how much should I expect the mashed oats and/or malt to contribute?

responding to the same question re: oats, Brian Bliss writes:

> you must mash oatmeal or any other adjuncts before you add them to the  
boil.  
> In fact, I won't even add malted specialty grains anymore unless they  
are  
> mashed. If I'm trying to do a quick and dirty job and just want to add  
> a half lb. of crystal malt or so, I'll steep it in 150F water and add  
an oz.  
> of amylase enzyme.

I tend to start with the specialty grains (ex. crystal malt) in a gallon or so of cold water, slowly bring the water up to boiling, and remove the grains from the water just before the boil (or at ~180 degrees if I happen to have the thermometer handy).

My question: how does mashing the specialty grains change their contribution to the brew vs. using the procedure I've described (and usually use)?

=====

Lastly, I have a question regarding the use/advantages/disadvantages of Diastatic Malt Syrup (DMS):

I thought I'd try using this as the basis for a light pale ale and was told that because the DMS still contained active enzymes that I should mash the adjunct pale malt (I was planning to use in the recipe) in the DMS. I guess I'm looking for a confirmation on this and perhaps a little procedural advice.

Thanks in advance to all,

/steve

>Presumably, they would happily ferment to depletion and/or till the tube  
>explodes if it is the screw cap type.

Oops! I think you mean lager yeast, don't you? Most ale yeasts  
generally  
poop-out at about 50F and would probably expire as the temp approaches  
32F.

You're right about them fermenting till depletion, though. What's wrong  
with that? What you're trying to do, presumably, is to hold on to some  
dormant yeast, so you put them at a low temp so that they are relatively  
inactive. Autolysis is the great fear here, where the yeast secrete a  
chemical that breaks down the cell walls of their surrounding brothers/  
sisters.

Then, they cannibalize. Ick!

Al.

From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: Cider and Perry making

Greg asks for advice for making cider and perry (pear cider). I've only made the stuff from kits (it was 'orrible); however, the Institute where I work was founded as the National Fruit and Cider Research Institute, although it now specializes in agricultural research (I'm a molecular biologist working on *Arabidopsis thaliana*, as un-agricultural a weed as you're likely to meet). However, the library still has cider-making books, and I've done a bit of reading.

The traditional way of making farmhouse (ie. homebrew) cider is simply to crush apples, press out the juice and allow it to ferment without any additions, even yeast. Fermentation relies on infection by wild yeasts from the air. You could try this, but I wouldn't recommend it - there is no guarantee that a suitable wild yeast will fall from the heavens, and there will be plenty of other bugs waiting their chance to turn your apple juice into cider vinegar. Your best bet is to try to sanitize the apple juice in some way, and then add a starter of pure yeast.

You may have trouble finding suitable apples - in the West of England, there are special apple varieties of cider apple. These are small and very tart to taste - inedible, in fact. You may be able to mix cooking apples (Bramleys?) with a smaller proportion of dessert apples. The apples should be ripe enough for the skin to break if you stick your thumb in hard. The cider brewery next door seems to leave the barrels of apples and pears outside until they get really squishy (and smelly). Roughly crush the apples (eg in a barrel with a wooden pole) and leave them to oxidise (this supposedly allows the tannins to cross-link with proteins which then fall out in the fermentation vat). Extract the juice using a press. The SG should be 1.045-1.065. You may then try partly to sterilize in some way. Don't try to sterilize by heating: this imparts a cooked taste to the cider. You could try a very small quantity of sodium metabisulphite for a few hours (see recipes for wine-making from fruit). Pitch the yeast (and I would add some yeast nutrient) and ferment for about 2-4 weeks. This can be drunk immediately ("rough cider") or racked into secondary for up to 3 months. Don't worry about the clarity: it's unlikely to drop clear, due to all the pectins. If you're really confident about your sterilization, cider matures well in bottle.

One way of cutting down on contamination would be to boil a small quantity of the juice and make up a starter with the yeast - this large inoculum should compete out any unwanted strains, and the cooked taste from the small volume of starter won't be noticeable.

A recipe for the best cider ("Nobs' cider") which I found goes:  
1 gall apple juice (ie 1.25 US Galls)  
0.75lb chopped muscatel raisins  
0.5oz root ginger (crushed)  
2" stick of cinnamon  
Juice of 1 orange

This would turn out more like an apple wine, probably, and I would use

a wine yeast if you can't get hold of any unpasteurized cider to culture from.

Good brewing

I've successfully been able to get very clovey aromas/flavors from  
Munton & Fison's Muntona yeast (included in their ale kits and may  
be available separately). At 70F, you'll get a LOT of clove character.

I too, did not get much cloveyness from Wyeast #3056.

From: piatz@fig.cray.com (Steve Piatz)  
Subject: Adjusting specific gravity

I recently had a need to determine the change in specific gravity due to dilution with addition water. I ended up boiling my imperial stout down to 4.75 gallons while getting my 60 minute boil after adding the hops. I decided not to dilute until I went to the secondary and needed to adjust my specific gravity measured in the primary. TNCJOHB, page 381 gives some tables for adjusting the specific gravity. Unfortunately, they didn't come close to the 1.110 gravity I had. So I decided to figure out the corrections using the following (I hope my memory of physics classes from long ago is correct):

OG = the original gravity  
FG = the final gravity  
dvp = the additional water as a percent (5% == 0.05)

$$FG = (OG + dvp) / (1.0 + dvp)$$

Using the above, the following program will produce a simple adjustment table

```
===== cut here =====
#include <stdio.h>
#define NUM_PERCENT 10 /* number of columns */
#define NUM_GRAVITY 30 /* number of rows */
#define PERCENT_STEP 0.05 /* percentage per column */
#define GRAVITY_STEP 0.005 /* gravity per row */
#define INITIAL_GRAVITY 1.010 /* gravity for first row */
#define INITIAL_PERCENT PERCENT_STEP /* percentage for first column */
main ()
[
  int i;
  int j;
  float og, fg;
  float dv;
  float dvp;
  printf (" | Dilution By/n");
  printf (" O.G. | ");
  for (j = 0; j < NUM_PERCENT; j++)
printf (" %3.0f%% ", 100.0 * PERCENT_STEP * (1 + j));
  printf ("/n");
  printf ("-----|-----");
  for (j = 0; j < NUM_PERCENT; j++) printf ("-----");
  printf ("/n");
  og = INITIAL_GRAVITY - GRAVITY_STEP;
  for (i = 0; i < NUM_GRAVITY; i++) [
    og += GRAVITY_STEP;
    printf ("%6.3f | ", og);
    dvp = INITIAL_PERCENT - PERCENT_STEP;
    for (j = 0; j < NUM_PERCENT; j++) [
      dvp += PERCENT_STEP;
      fg = (og + dvp) / (1.0 + dvp);
      printf ("%6.3f ", fg);
    ]
  ]
  printf ("/n");

]
exit ();
]
```

Can anyone add to Al's observations on this topic. I plan to start  
kegging  
with my next batch of beer. I don't have a place to keep kegs cold. I  
do have a small dorm sized refrigerator which I plan to run some tubing  
through. Effectively the same as a "jockeybox".

The kegs will be kept in my cellar at around 65 deg f.

I have always thought that the beer would keep for a time as long as it  
was  
not in contact with air.

Kevin

From: jason@beamlab.ps.uci.edu  
Subject: funny smell and strawberries

A couple of questions:

My friend and I made a quicky extract/specialty grain batch on Friday. We put 1/2 pound of ground chocolate grains in one of my girlfriends old white nylons and began to heat the water to about 170 F at about 150 F or a little less we noticed this awful plastic like smell that seemed very wrong and toxic. It eventually went away (we didn't just get used to the smell we had others come in and smell) when the water got close to 170 F. The smell seemed to come from the water and not the nylons (tested by pulling the nylons out of the water and sticking out noses on them).

Does this type of grain usually produce a disturbing odor in the process of heating? The grains were a few months old. Does this matter?

ALSO:

When it comes time to bottle, I only want to bottle 3/4 of the batch. I would like to add strawberries to the remaining 1/4.

Question: Do you think I should just leave the 1/4 in the fermenter along with the trub and settlement and just add the strawberries to this? Or Should I rack the 1/4 to a seperate container and then add the stawberries? (Will there be enough yeast in suspension?)

I have some pectic enzyme--should I use any of this?

Comments?

Ayudame, lo necesito.

From: roman@tix.timeplex.com (Daniel Roman)  
Subject: CO2 tanks and fittings

I recently inherited a couple of soda kegs (ball lock) which are in good shape. I called a couple of local soda distributors about CO2 tanks and hoses and they either did not want to deal with me or were charging \$85 for just the 5 lb tank unfilled. So, a couple of questions:

- Is a 5 lb tank adequate? I wouldn't be dealing with more than two kegs at a time. They are 5 gal. kegs.
- Can someone suggest any mail order or sources of used tanks, especially if someplace has experience with homebrewers and their particular needs.

(Now all I have to do is convince my wife that we don't need the shelves in the fridge and that two kegs and a CO2 tank won't take up that much room). Refridgerators are expensive.

Subject: Ale yeasts at cold temp

Jack writes:

Ale yeast.....

Based on the accepted fact that ale yeast ferments down to near  
freezing,  
I

am curious to know what happens to wort/agar slants of yeast cultures  
stored  
in the fridge.

Presumably, they would happily ferment to depletion and/or till the tube  
explodes if it is the screw cap type.

Seems like in the best of cases, one would end up with tired out old  
yeast  
if

it was stored for more than a couple of weeks.

Say what? Did you mean Lager yeast here, or is there something I'm not  
aware of? In any case, we have taken yeast cake from the bottom of  
primary

ferment, put it in 12 ounce bottles at about a 50/50 yeast to  
semi-fermented wort ratio, and stored these in the fridge for later use.  
The longest we ever kept one of these may have been around 6 weeks, but  
it

certainly took off like a banshee. Only in one instance did the yeast not  
take off after being stored in such a manner, and that was stored  
substantially longer, I believe.

As far as tired old yeast goes, well, how would the yeast you're  
proposing  
to freeze be worse off than something you find at the bottom of a bottle  
of  
Sierra Nevada? In either case, you need to allow the yeast to build up  
its  
cell walls again before you expect it to go to work for you. :)

Subject: Recipe: Really Bitter Dregs(tm)

Here's a recipe for a brew I've particularly liked. It's somewhat in the style of a Brown Porter, although really a little too hoppy for that style. The origins of this brew are somewhat amusing (IMO) - Martin Lodahl and I were lamenting (electronically) about our respective jobs; the condition of the world, etc., and I recalled the phrase "Oh, bitter dregs..." from the song. Some electronic musing over "bitter dregs" ensued, and the rest, as they say, is history. The recipe is toned down from the original hopping rate, but I believe even a hop-head will enjoy this brew. Tasty stuff, that!

Really Bitter Dregs(tm)  
by invitation only.  
send your resume to the Really Bitter Dregs selection committee ;-)

Ingredients -

6 lbs 2-row pale malt  
3 lbs Munich Malt  
16 oz black patent malt  
4 oz Crystal Malt (80L)  
12 AAU (~1.0 oz @11.6) Centennial hops (bittering) (Oops!)  
9.5 AAU (~0.75 oz @12.6) Chinook hops (bittering) (Oops!)  
1/2 oz Cascades (steep)  
1 oz Kent Goldings (dry hop at rack to secondary)  
Wyeast 1084 (Irish Ale)  
1.5 qt gyle (or 1/2 cup corn sugar) (priming)

Process -

All brewing water pre-boiled and decanted from sediment.  
Mash water: 11 qts @ 140F  
Mash-in: 3 min @ 135F, pH 5.0  
Protein rest: none  
Conversion: 30 minutes @ 145F (step infusion) (See Notes)  
45 minutes @ 155F (step infusion)  
Mash-out: 5 min @ 170F (See Notes)  
Sparge: 6 gal, pH ???, 170F (Increased from 5 gallons)  
Boil: 90 min. Centennial addition @ 30 minutes into boil,  
Chinook @60 minutes; Cascades added and steeped 45 minutes at  
end of boil (while chilling).  
Dry hop at rack to secondary.

Initial runnings 070 - final runnings 020.  
OG: ~046. FG: ~015.

Notes:

I overshot temperature on initial conversion ("cajun cookers" have their disadvantages!) but dropped back into range with a couple minutes in a water bath. No doubt affected extraction efficiency. Next time, I'll use the vernier rocket (hot plate) instead of the main thrusters!

Forgot to raise to Mash-out temp - had to dump back from lauten tun into the boiler. Grrrrrr.....

Additional 1 gallon of sparge was prepared when gravity of runnings was so high. Even after an addition gallon of sparge, the runnings were high, IMO. The little red worms in the compost heap were happy, though! Next time, I'll use more gypsum to bring the ph down to 5.7!

About the hops. When it came time to add bittering hops, I went to the freezer, and grabbed Centennial instead of Chinook. (What can I say? They both start with `C'. Honest, I only had consumed about 3/4 of a homebrew!) I realized my mistake later when rooting around for the Cascades. So, with still 30 minutes left in the boil, I added some Chinook for the last 30 minutes.

The Cascades were steeped longer than intended. The boil ended just at dinner time, so I put the hops in and left them while we ate. Midway through dinner, I realized that I hadn't sterilized the chiller, so that added another 30 minutes to the steep.

Chilled to pitch temperature, strained into the primary carboy, aerated, and pitched the yeast (which was at high krausen). I checked an hour later, and there was positive outflow through the blowoff tube.

Racked to secondary a week later, with the Golding dry-hopped at that time. (Put the hops into the secondary and racked onto them.) Bottled 3.5 weeks later primed with 1.5 quarts of gyle.

What ale yeast is this?? Did you mean lager yeast. All the Ale yeasts I  
have  
ever used tend to flocculate out and go dormant when I drop them to cold  
temperatures (like say below 45F), in fact I, and many many brewers  
commerical and home, rely on this behavior to stop fermentation and  
clarify the beer, it even has a technical name for it, called cold  
conditioning.

Care to enlighten us???

Subject: Re: Greg's cider question

In HBD 919, Greg asked:

> Can anyone out there in HBD-land provide me with a good recipe for  
apple  
> or pear cider. What are the pitfalls?

The most recent issue of Zymurgy has an informative article on making  
cider. I've learned quite a lot from it, and have 5 gallons of a new  
recipe bubbling away in my garage right now! :-) The Cat's Meow II  
also has some recipes that look like they're on the right track.

For what it's worth, the following recipe won the AHA cider competition  
this year:

Hard Core XXX Cider  
3 gallons cider (allegedly made from Johnagolds)  
6 Campden tablets  
3 oz. lactose  
12 oz. can frozen concentrated Seneca Granny Smith apple juice  
16 oz. can frozen concentrated TreeTop apple juice  
Vintner's Choice Pasteur Champagne yeast

Pour cider into 3 gallon carboy with 6 crushed Campden tablets.  
Add yeast after two days. Ferment for three weeks at approximately  
68 degrees.

Oops! That's a little too dry. Rack to keg, adding three ounces  
lactose. Force carbonate for two weeks.

Damn! Still doesn't taste quite right. Add some apple juice  
concentrate to get an apple taste.

Filter with 0.5 micron filter and force recarbonate. Bottle using  
counter-pressure bottle filler.

Comments:

The most important thing I've found is getting fresh juice (freshness  
shouldn't be a problem if you're pressing your own) that tastes like  
apples. This is sometimes a little harder than it might sound. In  
Washington, the majority of apples grown are "eating" apples, rather  
than juice or cooking apples. The Johnagold apple juice I used didn't  
have sufficient "apple taste", so after the sugar had fermented away,  
there wasn't much taste left. I put some apple taste in with the  
concentrates. (The current batch I'm making uses juice from Red  
Delicious and Granny Smith apples, but still doesn't have a strong  
apple taste, even before fermenting.) I'm told that blends of different  
types of apples work better than juice from a single type.

You might want to keep an eye (taste bud?) on the fermentation and  
stop it before it completes, or use a different type of yeast that  
won't take it so far. Mine was bone dry after three weeks, so I  
sweetened it up some with the lactose.

Above all, relax, have a homebrew, and don't worry about it.  
Chances are, it will turn out great.

Good luck

Charles Castellow

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Wit Beers in Texas?

There is an interesting story behind how Belgian beer came to be brewed in Texas, where the Celis brewery in Austin has recently come to market with its products. Mr. Celis formerly brewed in Belgium, and was too successful for his own good.

In previous times, the eastern part of Brabant province was a major brewing center. It is here that we find the town of Hoegaarden (pronounced who-garden), whose brewing heritage goes back at least as far as the 1300's, and probably farther. Hoegaarden was known for its Wit beers.

Belgian Wit beers are light refreshing brews made with about 50% unmalted wheat and 50% malted barley. Sometimes a small portion of raw oats is added. The beers are very pale, and given a milky appearance by a highly non-flocculant yeast strain. They are very lightly hopped, but often spiced with coriander and orange peels. They are popular summer drinks.

The usual market forces and two world wars caused a decline in the importance of this region as a brewing center. Smaller breweries were closing, consumption of mass marketed Pils was on the rise and by the mid 1950's, the last brewer of Wit beers was defunct. The style appeared to be extinct.

Pieter Celis had lived near an old brewery that produced Wit beers, and felt that the style could be revived. Acting on that idea, he purchased equipment from a defunct brewery, and in 1966 his De Kluis brewery started making Hoegaarden Wit beer. Much to Celis' surprise, the beer was extremely popular, especially among younger drinkers. Soon he was unable to keep up with demand and so the brewery was expanded.

In order to finance the expansion, Celis sought an investor to take on as a partner. The two owned equal shares of the brewery with Celis being the more active partner. A period of phenomenal growth ensued. Wit beers were becoming more and more popular, and Celis was doubling his production on an annual basis.

The growth rate proved to be too extreme, and it was hard to make ends meet. This may be hard to picture for those not close to the business world, but too much growth places excessive strain on a business' resources. For example, if this year's malt bill is twice as much as last year's, and the money available to pay this year's bills is based on last year's production, then

it's tough to cover expenses.

This is exactly what happened, and the De Kluis brewery was unable to make payments to their supplier of malt. Mr. Celis made a deal with the head of the malthouse whereby the maltster would get shares of the brewery instead of cash payments. What Celis didn't know was that the maltster (appropriately named Mr. Wolf) had ties to brewing giant Interbrew.

It seems that the little brewery had been too successful in reviving a style, and had attracted the attention of the big guys. Soon Mr. Wolf's shares were in Interbrew's hands, and they were busy courting De Kluis' investment partner as well. When the partner sold out, Mr. Celis found himself to be the minority shareholder in the brewery he founded. Interbrew felt they no longer needed Celis around, and squeezed him out of the business. His success was his own downfall.

The revival of Wit beers has continued, and they are very popular in cafes all over Belgium today. Even cafes with very modest beer selections typically offer a Wit beer. As a result, many other breweries around the country have capitalized on this and started brewing their own Wits. It has become a very trendy style of beer, and is now eschewed by hard core beer fans as no longer being the noble beverage it once was. Readers in Oregon may see a similarity to the Widmer Hefeweizen phenomenon.

Meanwhile, Mr. Celis decided that he'd had enough of his battles with Interbrew. Like so many Europeans before him, he has sought refuge in the US. He's brewing in Austin and his beers are available there. They will soon become available in California, and other selected markets. Let's hope he's not \*too\* successful this time.

Cheers,  
CR

From: mfetzer@ucsd.edu (The Rider)  
Subject: San Diego Brewpubs

Oh oh oh me! me! me! Finally a topic I'm an expert on... :\*)

>On another topic, I will be traveling to San Diego soon and would like up-to-date info on brewpubs and bars with great tap beer. I searched through the old digests and came up with these brewpubs:

>Pacific Beach Brewhouse  
>La Jolla Brewing Co.  
>Callahan's  
>Old Columbia Brewing Co.  
>Mission Brewery

PB: Nice atmosphere, but lately the beer is lousy. I've stopped going there, since I was sorely disappointed with things last time. It's close to the beach, I'd recommend stopping by for a pint of Stout, and \*do\* let me know if they improved things.

LJB: My absolute favorite in town. Great atmosphere (not many yuppies) Excellent porter, and a wonderful happy hour 4-6 M-F, \$5 pitchers! Great food.

Callanhans: a bit like a dungeon... not impressed with their bitters (but then I'm racist when it comes to beer... I'm into the black stuff, which they were out of) They serve non micro brewed beers there, too, just in case you can't handle their own.

Old Columbia: Haven't been there in a long time, I must admit. Yuppie city, since it's close to downtown. Bring a white shirt and red tie. Their beers: generally a light, an amber, and a dark. I've never been impressed with the light and dark, but the amber is quite good.

Mission Brewery: went bankrupt before they ever opened. Nice building, tho.

Others you didn't mention:

Brewskie's: Again, yuppie at hell. It's around 4th and G, but don't quote me. Beers are ok, their stout is nice. They also have a happy hour on about the same terms as LJB.

The Red Kettle? I think that's what it's called, in Encinitas. Well, they were out of everything the day I went there, and I haven't gone back. They do have Anchor (I think!) Porter on tap, so that saved the day. Other than that, hm... somehow it was lacking atmosphere, but I have friends that quite like the place and were surprised the day I went, at how different things are from normal.

Overall, LJB takes the cake. Be there any Friday around 5, find me, and I'll buy you a beer. :)

I'm the guy at the table with the 3 pitchers of porter... Seriously...  
email me if you make it down here on the weekend, we're always down  
there,  
and I'd like to meet some of these HBD folk.

Subject: Growing Hops

While I haven't started brewing yet, I accepted a hops plant from a friend of mine to see how it would grow on my farm. I planted it in a partially shaded area along a creek and it is growing like crazy. This is its third year. Last year it produced a few hops. The plant was described as a "common hops." Now for a few questions:

1. what is common hops?
2. can common hops be used for brewing or other purposes?
3. the plant has been getting a white mold on some of its leaves, is this caused by the damp, shaded location?
4. do I need to be concerned about the mold? If so, can it be treated?

Thanks for any information you care to share.

Subject: ReCycling Weizen Yeast

I brewed an (IMHO) excellent wheat beer about three months ago using a Wyeast Weizen culture. It came out so good that I've done a Raspberry Wheat and am about to do a DunkleWeisse.

I thought it would be a good thing to re-use the yeast from my first batch (in the form of bottle leavings) on my next couple of wheat beers.

As I was culturing last night (4 tablespoons dried wheat malt extract, 1 pint of water; boiled) I got to thinking, does one of the strains take dominance in the bottle? As everyone know the Wyeast Weizen product is actually a mix of two yeast strains. If one strain (say the noraml Ale strain) survives the dormacy period better will my beer be unbalanced.

So my question is; Has anyone successfully re-used the Wyeast Weizen strain?

Brew on Dude,

John D.

Subject: Digest Backlog

Hi folks, sorry about the digest delay. The volume of incoming articles finally overwhelmed my simple scheme for handling homebrew article overflow. I've just rewritten it to avoid this problem in the future, but now there is a 4 day backlog of articles to be digested. If you submit an article now, don't worry if it doesn't appear immediately- all the previously submitted articles must be sent out first.

Subject: Short Fermentation Mead

Somebody whose name I deleted wrote something like:  
>I'm looking for short-fermentation mead recipes.

Check Dave Miller's Handbook of Home Brewing for a "mead ale" recipe.  
The recipe I use, which is strictly experimental (but I like it) is:  
5-7 lb honey (usually the stuff from Sam's in the 1/2 gal. jug)  
2 cracked cinnamon sticks  
20 cracked allspice  
other flavorings like ginger, hops, orange peel, nutmeg etc.  
maybe a couple pounds fruit  
Edme ale yeast

My hypothesis, which has a little data to support it, is that boiling the honeywort reduced fermentation time (while also removing a lot of the honey essence, I imagine). Note that the above is a 5 gal. batch. I don't have a hydrometer so I can't guess the OG or FG, but this stuff is pretty thin (see my plea for ideas a couple of HBD's ago). Fermentation takes 2-3 weeks, sometimes I rack, sometimes not. Basically I don't put much effort into this stuff; hell, it's 97 degrees here and I'm not running my AC enough to get the temperature down past 80, so why try to make anything award-winning when it's doomed to failure?

Another note: Some people recommend using champagne yeast for mead. I have used Red Star champagne yeast twice. Once the nasty taste went away after 4 months; the second try is still nasty after that long. No infection (at least no obvious one), just an unpleasant taste.

Please, improve on my methods here, I'd love to get a better product for not much more work....

Okay, I'm going to show my ignorance here. It seems to me that if you have good carbonation in a warm keg, then cool the beer as it comes out, you'll have the CO2 happily in solution with no desire to come out of solution (i.e. produce bubbles). Wouldn't you need to have extra pressure in the keg with a jockeybox setup, to insure proper carbonation at the dispensing temperature? Ack, that would cause dispensing problems unless you had a second regulator between the keg and the jockeybox, wouldn't it? Hey, just because I work with applied thermodynamics every day doesn't mean I know diddly about kegging. :)

Subject: modified malts and British beers

Pale ale malt is "highly modified," but so is most widely available U.S. lager malt. The modification of pale ale malt facilitates the single step infusion mash, which is relatively easy to perform. With less modified malt, one might instead use a step infusion mash or even a decoction mash. See Greg Noonan's book for the reasons to use decoction mashes on undermodified malt. From past discussions on HBD, as well as lots of visits to U.S. brewpubs, it seems that U.S. malts are mashed in single step infusion mashes with good results.

Now, pale ale malt is also more highly-kilned than U.S. lager malt, and will pound for pound produce a "darker" beer--red-amber versus gold-straw.

Color adjustments can be made with crystal malt in small additions. Another brewing issue, if I'm remembering correctly, is that lager malts carry precursors of dms, a flavor appropriate up to a point in lagers but not in ales.

Beyond the above general points, we're treading on near-religious :-)  
ground. Some might say that in the end you should use British malts for British beers, as that's what they do and there are subtleties of flavor imparted. Most U.S. commercial brewers and pubs, you can be sure, do not import British malts, but instead use local malts. The American Pale Ale style is a consequence. Aside from malts, hops are a very important part of the style, with Americans employing Cascade, Willamette, and other Northwest hops. World-class beers such as Sierra Nevada Pale Ale are the result. But, SNPA is quite different in taste from Fuller's E.S.B!

Subject: 100 years of the Crown cap. What's being done?

William Painter was awarded 3 U.S. patents for bottle sealing devices, i.e. metal bottle caps, in 1892. While the original liners have changed over the years - slices of cork, cork composites [remember those bits floating in the brew?], plastics - , and there have been some adaptations to the cap that have come around, the Crown cap is very much part of our culture and if you look at the original drawings, published a century ago, you can't mistake it.

I know brewers think of their tradition in terms of millenia, but does anyone know if there is any special celebration of this invention? Though the cap allowed the development of the super-sized brewery catering to the vulgar palate, thereby making commercial beers in the USA less interesting as they infiltrated the nation, I expect most of us consider this small item a great boon to our hobby.

Subject: Sparging Efficiency

This is my MALTMILL lottery ticket. Perhaps, I'll do better than I normally do with contests. :)

But I do have a question: How do I find out the maximum specific gravity of different malts? I've looked at the available software programs, and I get two different answers. For example, one says Pale Ale malt is 1.036 and the says 1.032. I know it's not much of a difference, but I'm trying to figure out my sparging efficiency. It can make as much as a 10% difference!

If you point me in the right direction (books, magazines, articles, experience, etc.), I'll summarize for the digest. Thanks!

Subject: Brewing with fresh hops...

I'll be picking fresh hops in about a month or so and am wondering if anyone knows a rule of thumb in terms of how many oz(s) of fresh hops is equivalent to 1 oz of hop plugs/leafs/pellets. I'm assuming the weight of fresh hops cones is greater than what you buy at the homebrew store since there is more water (not as dried out.)

Is this a true assumption or can I just measure out my standard oz(s) is not get too bitter of a beer?

No, this isn't a silly question as an attempt to be the 100th entry for the MALTMILL.

OK, OK, so it is. just send the MALTMILL over to me now.

From: "Franklin R. Jones" <FRANK@VA5549.Colorado.EDU>  
Subject: RE:\$40 Frige Controller

the Hunter Energy Monitor: Called an Air Stat on the packaging,  
Model 42205(there is a 42206 for 220, but you have to order it)  
built by:  
Hunter Fan Company  
2500 Frisco Ave.  
Memphis, TN 38114

P# 901-745-9222 CT 8AM-5PM

You can buy these at Builder's Square for \$28. The operation is simple:  
Plug  
the frige/freezer into the monitor, plug the monitor in the wall, put the  
probe  
(has four feet of wire) in the frige/freezer, set the monitor to the  
desired  
temp, and your off. The monitor will handle 15 Amps, and has programming  
modes  
for running a Air Conditioner, but aren't really needed. (just override  
for the  
temp you want and put it in bypass) temp range is from 40 to 90 degrees,  
and  
will keep temp -1...+2 degrees from that. WOrks by cycling the power to  
the  
Frige, will stay off for min of 4 mins, to save ware & tear on the  
compressor.  
Very good unit, simple to install.

One Weak Point: it runs off of a AA battery, if the battery runs down the  
unit  
will not work! e.g. the frige will be \*off\*! So one needs to figure out a  
way to  
remind oneself to change it.

<Cynic mode on>

Let's see ... I weigh approximately 240 lbs. That's ~108.86 kg. So at 1.95 g per kg I can ingest 212.277 grams or 7.48 oz. At 75% safrole I would need 9.97 oz of sassafras. Rootbeer extracts that I have seen come in 2 oz bottles which makes 5 gallons of rootbeer. Assuming (1) that it is consumed in a short period of time and (2) the extract is pure sassafras I would need to drink 24.925 gallons of rootbeer to reach the oral toxicity. While there is a 50-50 chance that I will develop cancer there is a 90% plus chance that I will create a very large brown flume orally. Which means I am now below the 50% lethality rate.

<Cynic mode off>

All I am trying to say is when something has been proven dangerous to labrats, quite often the dosage is something normal humans may never approach in their life times. Russell, I am not picking on you, it's just that you provided enough numbers for me to write this little diatribe. I am sure I will get a few responses correcting my math/spelling/use-of-HBD.  
(-: at least 'til article 100 :-)

Subject: Re: Homebrew Digest #920 (July 09, 1992)

A word of warning to anyone thinking of ordering Dave Miller's new book sight unseen. "Brewing the World's Great Beers" should really be called, "An Introductory Guide to Brewing the World's Great Beer STYLES". The book does NOT replace Line's book. It does not give recipes attempting to replicate any particular brand of beer, but gives extract, partial, and full-grain recipes for most of the styles of beer. Anyone reading Zymurgy or the Cats Meow would have seen similar recipes before. The one interesting thing is seeing the supposedly same recipe presented in each of the techniques of brewing. Miller gives the simple steps of each technique without much explanation and even advocates sucking on the siphon hose!

Subject: Re: modified malts and British beers (fwd)

Hi again! Offline, Cush Hamlen indicated that he was interested in differences in flavor and character.

To be clear, many U.S. malts are highly modified.

As for character or flavor, try chewing on some grain! Maris Otter malt, used at Young's, is often described as having a "nutty" character.

British

crystal malts also have a very distinctive flavor. Maris Otter crystal malt, available from Liberty Malting in Seattle, has an 80 Lovibond color and a very sweet, caramel-like aroma. Likewise, something I bought from the local shop labeled British Cara-Pils had a nice caramel or toffee-ish aroma. All barleys are not alike. Objectively, they differ in measures that homebrewers are usually not concerned with, such as protein and nitrogen content, diastatic power, and the like.

Coors uses a Moravian strain that is one of the most prized, but has a different character than pale ale malts.

From: ALTENBACH@CHERRY.llnl.gov  
Subject: SMOKED BEER

FRANK IN HBD 919 ASKED ABOUT MAKING EXTRACT BASED SMOKED BEER.  
IF LIQUID SMOKE IS NOT USED, THEN YOU NEED TO SMOKE AS MUCH SPECIALTY  
GRAIN  
AS POSSIBLE TO GET A NICE SMOKEY BREW. OTHERWISE PROCESS THE BEER  
NORMALLY,  
MOST RECIPE SUGGESTIONS MENTIONED WILL WORK OUT OK. I'VE BEEN SUCCESSFUL  
MAKING ALL GRAIN SMOKED BEER, BY SMOKING A SUBSTANTIAL FRACTION OF THE  
MALT  
, BOTH PALE AND MUNICH, ON MY TRUSTY WEBER. THE TRICK IS TO USE A LOW WOOD  
FIRE WITH HICKORY OR OTHER FLAVORFUL WOOD. MAXIMIZE THE SMOKE AND  
MINIMIZE  
THE HEAT BECAUSE YOU DON'T WANT TO ROAST THE GRAIN. I IMAGINE A SMOKER  
WOULD BE EVEN BETTER FOR THIS, BUT I HAVEN'T TRIED ONE YET. FROM THE  
COMPETITONS I'VE ENTERED, THE JUDGES PREFER THAT THICK TONGUE-COATING  
SMOKE THE GERMAN IMPORTS HAVE. YOU CAN'T HAVE TOO MUCH SMOKE FOR THEM.  
BUT YOUR TASTES MAY VARY. MY BBQ SMOKE PROCEDURE PRODUCES A MORE MILDLY  
SMOKED FLAVOR IN BEER THAT GOES GREAT WITH BBQ STEAK OR SAUSAGE. I THINK  
A FULLY BODIED MALTY BEER BETTER SUPPORTS THE SMOKE FLAVOR, SO MY  
FAVORITE  
IS RAUCHBOCK.

From: tdlong@ucdavis.edu (Tony Long)  
Subject: Al's jockeybox

In reply to Russell Owen who referred to Al's jockeybox:

"I suspect you will have trouble ... since the solubility of CO2 varies greatly with temperature," saying that he had trouble keeping the cold beer carbonated.

I don't believe Russell understands the problem. The idea of the jockeybox is that the keg is kept at room temperature and beer is cooled while being dispensed. I have found the cooling works great, but the dispensed beer loses much of its carbonation! I have found that if there is enough pressure in the keg for dispensed beer to remain at "acceptable"

levels of carbonation, then the beer is jettied out. As I live in the central valley with day temperatures well over 90 this problem has become especially acute of late. If your keg is at cellar temperature and you only want to boost the cooling this sort of set-up seems to work OK.

This brings up a second point. As I live in an apartment and have no room for a second fridge ... does anyone have any alternate ideas that would allow the cooling of kegged beer. Once one has grown accustomed to kegging it is difficult to return to washing bottles. Perhaps J.S. in his

great supportiveness of clever inventions will offer a suitable prize to the individual who can design a suitable beastie : )

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: Bottling my cyser

Howdy,

I've been meaning to ask a question for a while now, and JS's raffle finally motivated me to ask. ;-)

My cyser (fermented apple juice and honey) has been sitting in a secondary for almost 7 months (!), and I think it should be ready for bottling now. A couple weeks ago, I took a teensie weensie taste (I hate to risk contamination and all, but I was dying for a taste). Going down, this stuff feels like Southern Comfort, it's got so much alcohol!. Now I realize that it's not more than 12 - 14 % alcohol, but WHAT A KICK! I've read that frequently, spices can be added to a mead at bottling time, so my question to all the experienced mead makers is this: Is there something I can add that might reduce the burning quality? (Or will it go away by itself?) Is this a common characteristic of a mead? I'm almost ashamed to admit it, but the first mead I've ever tasted was this one, so I don't know what to compare it with.

Thanks,  
Chuck

From: Joe Rolfe <jdr@wang.com>  
Subject: CLEAR BEER

i could not resist a chance to post - for a free grain mill i'll do almost anything - well maybe not .....

but on a recent thread about clear beer from extracts, i too have had some problems with clear extract beers.

these batches are not the normal homebrew size - you could consider me to be the WORLDS LARGEST HOMEBREWER or one of them - jack s. don't take offense

- i don't mean or intend to flame you with this.  
my brewlength has typically been 1bbl plus. i ferment in a stainless unitank and also put wort into carboys for tests (fruit dry hop ...)

i was looking for comment on the following:  
several items i have done and will attempt to do in the future are:

- 1) isinglass - appears to help some, not as much as i would like
  - i have tried the liquid isinglass and will try the A.Gusmer dry isinglass called cryofine in the next batch.
  - added to 5 gallons and bottling leave to much "junk" on the bottom of the bottles and does not appear to compact very well. anyone else used it in bottles?
  - have not tapped the keg version of the same batch yet.
  - have heard that isinglass in the presents of too much yeast causes isinglass to become less effective
- 2) irish moss
  - i let the amount to be used sit in warm (100F) water for hours until it is used, when dumped into kettle it has cooled to ambient
  - have been adding at whirlpool (after heat off) - approx 1 hr before the wort is in the fermenter (maybe to long of contact?)
  - have seemed to notice more haze (permenant and chill when too much moss is used. (added 1.5 oz to 1bb - really hazy, .75oz 1bb appeared less hazy (but also used MF DME instead of MF Cedarex (liquid).
  - will try adding at earlier time (10 min before heat off)
  - never had much in the way of chill haze during my 5 gallon brewlength days.
- 3) water composition
  - my water is soften with a salt based softner, my raw well water had large amounts (1.5ppm) iron, now the water may be too soft(??) i have only used the soft water for brewing of the larger batches. the smaller 5 gallon batches i did use well water and never had chill hazes
  - will get a detailed water test soon
  - will try to add more calcium in the boil to adjust PH, and will try to remember to check the PH (i hate PH papers, got to get one of those temp and ph sensors.
- 4) hops
  - had really lousy hops the first two batches (whole cones of Cascade and Williamette, got better hops (less oxidized and much fresher)
  - have added hops very soon after boil, will try waiting until the hot break is secured.

5) boil

- i have always boiled for a full 90 min
- in larger batchs (1bb +) i boil the full volume
- in smaller batchs (5 gal and less) i could not boil the full volume
- the boil has been less than vigorous (judging from what my 5 gallon batchs have been). have adjusted the propane burner level. will be adding a 4500 watt element for next batch.

6) chilling

- i use dual 25 foot counter flow chiller, the water temp going in is usually around 60-70F, i adjust the flow of water with a ball valve to attain the temp needed for the fermenter, (another use for temp sensor). i usually keep 110 gal of water on hand to chill the wort to 60 - 70 F. the wort is pumped at 4-5 gal per min.

If any of you have comments (constructive or otherwise) i would like to hear from you (email or post).

Do the items appear to be sound brewing principal or excessive worry.... (i can relax later, but worry whilst i am still relativly young:-]

What items are the most important (if any)??

Subject: Re: malts...

Franklin R. Jones in HBD 919 asks about roasting malts:

I scanned Cat's Meow II for some roasted malts and found a few.

>From Perle Pale:

...1/2 pound Klages malt was toasted in a 350 degree oven for 10 minutes.

>From Crying Goat Ale:

Toast 1-1/2 pounds of 2 row Klages malt in oven at 350 degrees for 40 minutes.

>From BrewHaus I.P.A:

Spread (1/2 pound) 2-row Klages on cookie sheet and toast at 350 degrees until reddish brown in color.

>From Helles Belles Maibock:

...toasted (1 pound) malt was done 5 minutes in a 350 degree oven.

>Ole Bottle Rocket (Steam):

Toast (1/2 pound) grains on cookie sheet in 350 degree oven for about 10 minutes.

Glad to hear you got a brewery room setup. I'm still working on mine.

Hope this helps,  
rick

PS. Frank, I tried to mail this directly to you but it bounced (yea, I wont win the MALTMILL with direct posts).

Subject: Re: malts...

Regarding Rauchbier:

I made up a batch of rauchbier to be ready for the July 4th barbeque and it came out pretty well. The smoky-sweet flavor is more subtle than something like Kaiserdom Rauchbier, but is still present and the beer seems more balanced between malt, smoke and hops. The recipe is based on the all-grain one given in Charlie II:

6# light malt syrup  
1# smoked pale malt (hickory - 30 minutes)  
1# smoked crystal "  
0.5# wheat malt  
0.5# pale malt

The 2 lbs of grain were soaked and then smoked over hickory for about 30 minutes. I used the Wyeast Pilsen Lager yeast (2007?) and fermented at 60 degrees. When I bottled I tasted the SG sample and whew boy was it smoky. The smoke has subsided a bit in the bottle enough so that next time I might consider smoking the grains longer or adding another pound. Give it a go and good luck

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: Low alcohol beer (oh no, not again!)

Durn it, I forgot to ask one other question:

Some time ago, we had a rather heated discussion about making low alcohol beers. Other than antagonizing everyone, we concluded that JS's method of heating a fermented beer might/might not work. My question is not related to the heat treatment- we've been through that a little too much. I just want to know, out of curiosity (I am a chemical engineer, after all) what is the process that Anheuser, Miller, Coors, etc. use to make Cutter et al.?

Do they use a "genetically altered" yeast, which is able to eat maltose and produce CO<sub>2</sub> without producing EtOH? (I really have a hard time believing this one.) Do they use vacuum distillation? The only other possibility that I see is separating EtOH from the beer by using osmotic pressure through a semipermeable membrane. To me, the first seems impossible, and the last two seem rather expensive.

Thanks for satisfying my curiosity,

Subject: I'll play

Here goes my attempt at the Malt Mill.

While I'm here, I have 4 hop plants of unknown origins. I just planted them this year and they seem to be doing very well. I made a brew from the parent plant hops last year and my guess is they are Cascades. The problem is there is something eating the leaves. I don't think its aphids since I can't see anything except holes. Are there any other common hop pests that fit the bill?

Also a great pepper beer is any beer with a drop of Tabasco sauce. It kills the head but for most typical commercial beers this is not a problem. I recall many American beers of my youth spiced up this way.

Full-Name: "John Cotterill"

Hey Gang! A couple of quick questions for you all.

1) Does anyone have a good recipe for Blueberry beer? There is a local contest coming up that features fruit beers, and I would like to brew one up. An all grain recipe is preferable, but a good extract recipe would be ok.

2) I keg my beer using soda kegs, and I also ferment in soda kegs. I recently finished a ferment and discovered that I could not clean all of the crud (left behind) off of the keg using a 24hour soak in TSP followed by a sponge bath. The sponge that I was using had one of those green abrasive pads on it so I used it. It cleaned the stuff off without any troubles at all. However, after examining the inside of the keg, I could see patchy sections of small scratches where I used the pad. The scratches are definitely small (I can't feel them with my finger, or finger nail). But, I was concerned that these may be a place that little nasties may take up residence and trash the next brew I ferment in this keg. Does anyone have any idea if I really need to be concerned about this? If it is a problem, can I fix the keg (steel wool - very fine grade maybe)? Hopefully the scratches simply indicate an area where the surface 'polish' is different....

Date: Thu, 9 Jul 92 13:55 EDT  
From: smc@hotsc.att.com  
Subject: Success Re-using yeast cake - WOW!

I just started a batch last night using the "pour the wort on the cake of yeast from the previous batch" method.

First batch:

2 cans (3.3 lbs each) Munton & Fison Light Extract  
2 oz Fuggles pellets (boil)  
2 oz Cascades whole hops (dry)  
Wyeast London Ale (#1028, I think...)  
5.5 gal. batch

Second batch:

1 can (3.3 lbs) M+F Amber Hopped Extract  
1 can (3.3 lbs) M+F Dark Hopped Extract  
1 oz Northern Brewer whole hops (dry)  
Poured on cake from batch above  
5.5 gal. batch

The second batch took off like nothing I've ever seen before. Overnight, the lock was going like crazy - about 5 glugs/second. At this rate, it should ferment in about 2 days!

I went from a lighter beer to darker in this case; I would guess this would be better than trying to go the other way (to avoid any flavors from the stronger beer being left for the lighter beer).

Anyway, thanks to the HBD for this great suggestion. It's easy to bottle while boiling one batch, and you get to re-use the Wyeast for a small savings.

From: johnf@persoft.com (John Freeborg)  
Subject: Wheat Beers

With summer in full swing I plan to do a wheat beer. I picked up the special Wyeast wheat beer yeast, but have yet to get the wheat malt. From reading in Miller's book it says for a wheat beer that you must use 6-row malt in the mash with the wheat. The reasoning is that the wheat has no enzymes to break down the sugars, and 6-row has a ton of enzymes (compared to 2-row anyways).

What is the hbd consensus? Any great wheat recipes people swear by?

What do other people think of the Wyeast wheat beer yeast?

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: Belgian ale

In HBD917 Phillip Seitz gave us an excellent review of  
Belgian\_Ale\_. He notes:

> ... More than hops or  
> even malt, the secret to Belgian beer flavors appears to be  
> the yeast,

Some weeks ago, I posted on my experience with Wyeast Belgian. I recall making the same point: I used essentially the same ingredients as for English Pale Ale (and so, in retrospect, too hoppy for the Belgian style) and got a totally different beer, thanks to having the right yeast. That point seemed to get lost in the polemic which ensued concerning the purity of Wyeast and my sanitary procedures. Perhaps I shouldn't have made an oblique reference to A\_Chorus\_Line\_ ("Dance: 10, Looks: 2") without explaining myself.

One thing that came up in that discussion was the suggestion that I brewed at too high a temp (70F). Phillip sez:

> Belgian-style brewing will come as quite a shock to many:  
> these include obligatory use of large quantities of sugar,  
> high-temperature fermentations (up to and over 85 degrees  
-----  
> fahrenheit), microscopic hopping rates (take \*that\*,  
> hopheads!), and deliberate production of sour and high-ester  
> beers.

Prospective users of Wyeast Belgian should still be aware of one point: the yeast is slow. I'm not talking about a lag in getting started, rather that the yeast seems to take forever in finishing. On the other hand, I received e-mail from Larry Barello who tells me that his techniques of yeast washing (described in the HBD more than a month ago) might cure this problem. I intend to try it when the the weather cools off (come to think of it, maybe I don't need to wait!).

For the record: the beer is now over two months old, more than a month in the bottle. It has mellowed substantially and the bananas have almost disappeared. The beer is still very estery, but that appears to be true to style.

Do I win the MALTMILL? :-)

Cheers,

Rob

From: lee\_menegoni@ptltd.com  
Subject: Inexpensive Temp Control

The Hunter Air Stat is a good choice for inexpensive temp control. It retails for about \$30, I bought mine on sale last year for \$19.99. It plugs into a wall outlet, the refridgerator is plugged into a receptacle in the Air Stat. This receptacle's line current is controlled via a thermo couple on a 36" wire. This receptacle is rated for the current load of a home AC unit so a refridgerator is not an overload on it. It maintains the temp programmed into the digital display +1 / -2, given the thermal mass of 5 gallons of liquid the beer temp shouldn't vary much. The only negative feature I can think of is the units minimum temperature setting is 40F which is still cold enough for lagering.

From: chad@mpl.UCSD.EDU (Chad Epifanio)  
Subject: English vs. American malt

Hi,

This is in regard to someones query about the difference between English and American malts. I may not have had huge experience in this area, but I have made about 15 all-grain batches for each of American and English malt.

I get my malt in 50lb sacks from William's Brewing here in California. The American kind is called Klagges and the English kind is called English Pale

Ale. Both are fully modified, and I believe both are from 2-row malt. This

information is for Williams only, since I have no experience with others.

The add in the catalogue stated that for the "authentic" English taste, you

needed English Pale Ale malt. Beliveing this, I bought a 50lb sack of Klagges, and a 55lb sack of English Pale Ale. I brewed a pale batch out of each, using cultured English Ale yeast, also originally form Williams. The recipes were not exact, but they were close in style. They were made about a month apart. Oh, and both were made using single step infusion process as recommended by some for British beers.

I liked them both, but to be honest, I could not tell if one malt was obviously superior to the other. I cannot comment on the "authenticity" of the English flavor since I have never been across the Atlantic. All in all, I couldn't tell much of a difference between the two. Discalimer: These are my own views of similar beers in an uncontrolled experiment.

Subject: Re: Homebrew Digest #920 (July 09, 1992)

"Mike Daly asks about where to purchase bottled California beers ..."

"Liquor Barn  
201 Bayshore Blvd.  
OK selection of local beers. Poorly handled."

True.

"Almost all Safeways have some local stuff these days."

True.

There are a few good stores in the Haight ... one liquor store I can think of that has a nice variety, maybe two. Some exotics can also be found at a liquor store on Cole Street, right between Carl and Parnassus.

Down around the intersection of Haight and Fillmore is a bar called the Toronado, which has a nice selection of beers on tap. Perhaps the widest selection in the city. You'd find a wealth of suggestions here, since a goodly percentage of the clientele are home brewers. ( Seems that brewing and indoor home gardening go hand in hand. :-) Alas, it's a somewhat rowdy crowd, so I advise that you dress 'comfortably' ... levis, leather, avoid allowing yourself to be stereotyped as a 'suit'.

Enjoy the City !!

Date: Thu, 9 Jul 92 13:56:17 MDT  
From: Rick Myers <rcm@hpctdpe.col.hp.com>  
**Subject: Colorado Brewers Festival**  
Full-Name: Rick Myers

Subject: Colorado Brewers Festival - Review

Well, nobody's mentioned anything about the Colorado Brewers Festival held in Fort Collins, CO held this past June 27, so here's a review (it's also an entry in the WORLD'S GREATEST GIVEAWAY!).

Setup:

This was the third annual festival, held in Old Town Square. The organizers are finally figuring out how to do it right. Last year, it was crammed into a small area and was a madhouse. This year, they closed off a section of the street downtown and put the serving lines there. Much better. You could actually get a beer in under 5 minutes, compared to 20-30 last year. The food vendors were in a separate area from the beer serving lines.

Beers:

The beer selection, well, how should I put it, SUCKED. Each brewery was limited to 1 beer, and most of them were lighter beers (last year they could bring whatever they wanted to). I'm a stout/porter drinker, and I was hard pressed to find anything close to the style I like. The darkest I could find was "Black Bear Porter" from the San Juan Brewing Company. I could see daylight through it, so my craving for diluted malt syrup was not satisfied! I was happy to see the serving lines for Anheuser-Busch and Coors were the shortest, people were going for the beers with more flavor (America is being educated?).

Entertainment:

Several live bands performed. The more I drank, the better they sounded.

Cost:

You bought a mug for \$1.00. Tokens for 6-ounce servings were \$1.00 each.

Overall, the quality of beers was quite high, some had minor problems, but

I still had a great time. A list of breweries and beers follows:

Anheuser-Busch Bud Dry  
H.C. Berger Brewing Indigo Ale  
Boulder Beer/Wilderness PubBoulder Amber  
Breckenridge Brewpub Avalanche  
Carver's Bakery/Cafe Brewery Raspberry Wheat  
Champion Brewing Irish Red Ale  
CooperSmith's Pub & BrewingDunkelweizen  
Coors Coors Dry  
Durango Brewing Co. Durango Dark Lager  
Flying Dog Brewpub Doggie Style

Hubcap Brewery Summer Celebration  
Idle Spur Crested Butte Red Lady  
Judge Baldwin's/Kelley Brewing Amber  
New Belgium Brewing Co. Fat Tire Ale  
Oasis Brewery Capstone ESB  
Odell Brewing Co. Fest Ale  
Rock Bottom Brewery Red Rocks  
San Juan Brewing Black Bear Porter  
The Walnut Brewery Jazzberry  
Wynkoop Brewing Co. Elvis Brau

Date: Thu, 9 Jul 92 16:03 EDT  
From: man@kato.att.com  
Subject: 1993 Conference, maltmill

1993 Conference:

I read in the last Zymurgy that the 1993 conference will be moved into August so as to be around the same time as the Oregon Brewer's Festival. Recently, I read here that the Festival is in July this year. So, does anyone have the real poop on this coordination effort ? Are both events going to be held within the same week or what ?

Maltmill:

I purchased a maltmill a few months ago and have used it in about 10 batches of all grain. I think these 3 statements sum up the pros of the product:

1. My extract efficiency went up around 4 points per pound.
2. I had an astringency problem with most of my previous batches. I attributed this to a poor crush with too much powder. Alas, I could never rid myself of the powder without leaving 1/2 of the grain untouched. So far, all 5 batches tasted have lacked this bitterness.
3. I can crush my grain bill 75 % faster than with a Corona (I sold it to a friend).

The cons ?

1. I have a hard time catching the crushed grain as it leaves the mill. I have to wrap the entire unit inside a plastic bag. I need to fabricate some kind of chute to direct the grain to a receptacle.
2. Sometimes, a piece of grain goes in funny and pushes the 2 rollers apart to the point where they stop making contact. I have to reverse direction for 1/2 a turn and then continue.

All in all, I think the mill is great. I bought the roller spacing option which allows you to vary the space between the rollers for tweaking. I recommend against it. I suspect the problem I have with intermittent slipping is somehow related. In the right hands, I imagine you could do wonders with the option, but I think it works fine without it. I've crushed Briess Wheat, Briess Klages, Briess Crystal, Munton & Fison ale lager and specialty malts without moving the rollers and gotten terrific results. The couple of times I attempted adjustment were disasters (for me, anyway).

Congratulations on a great product, Jack.

From: KENYON%LARRY%erevax.BITNET@pucc.Princeton.EDU  
Subject: FWD: A Couple of Recipes ...

Folks,

Here are two recipes that have worked out really well for me in the past. The first is a simple "kit" beer, the second an all-grain.

1) Porter? Porter? - Recipe for 5 gallons.

6.6# Telford's Porter (2 cans)  
1 oz. Styrian Goldings Plugs (alpha 5.3)  
Bittering (1hr)  
1 oz. Hallertau Plugs (alpha 2.9)  
Flavoring (10 min)  
Wyeast #1056  
  
O.G. = 1.048  
F.G. = 1.020

Add the 2 cans of malt extract to 3 gallons boiling water, bring the mix back to a boil, then add Bittering Hops. I used a hop bag, so the utilization probably wasn't that terrific, but then again the malts are pre-hopped some, so I wasn't too concerned about that. Add finishing hops with 10 min left in the boil. Add tap water to 5 gallons, cool to 75F and pitch yeast starter (~12oz). Lag time is about 12 hours.

This produces a well-balanced (there's that word again!) porter, neither too dry nor too sweet. I currently have a batch of this fermenting with Wyeast Irish Stout Yeast to see if that will make it a wee bit drier.

2) ChuckWeiser - Recipe for 5 gallons.

5.0# Lager Malt  
1.0# Flaked Maize  
0.5# Rice Syrup/Solids  
1 oz. Hallertau Leaf (alpha 4.0)  
Bittering (1 hr)  
1 oz. Saaz Leaf (alpha 3.0)  
Bittering (1 hr)  
1/4oz.Tettnang Leaf (alpha 4.0)  
Finishing (Boil 5 min, steep 10 min)  
Wyeast #2124  
  
O.G. = 1.038  
F.G. = 1.008

Mash Schedule:

30 min - Protein Rest @132F  
90 min - Slowly raise temp to 155F  
15 min - @155F  
15 min - Mash-out @170

Bring mash liquid to a boil, add bittering hops (no hop bag for this one), boil 1hr. Add finishing hops, boil 5 minutes, steep 10 minutes, pour into primary, cool to 75F, and pitch yeast starter ...

This recipe produces a light - but not thin tasting - North American style lager (steam?). The Tett nang Finishing hops gave a really nice fresh aroma to the beer.

Good luck,

-Chuck-

Subject: On Tap (World Beer Review)

Randy J. Smith writes:

>I got a flyer in the mail today for a book on brewpubs across the US  
called  
>"On Tap". I'd like to hear opinions on this book before I get it. It's  
only  
>\$15 or so, but that could be spent on something better, like brew  
supplies!

"On Tap" is put out by the World Beer Review people (Steve Johnson, I  
believe).  
It details brewpubs and micros in the U.S. with a page showing locations,  
directions, beers available, and info about the type of place (fern bar,  
yuppie  
hangout, sleazepit or whatever). It was put out in 1991 (I think) and  
there is  
already a supplement out. It costs about \$15 and the supplement costs  
about  
\$10. WBR has ads in Zymurgy, and is located in Clemson, SC. If anybody is  
really interested, and can't find them in Zymurgy, I will post the  
address (I  
don't have it with me now).

I don't have the supplement yet, but I do have "On Tap" and I would  
recommmend  
it to anybody that does a lot of traveling to different cities and wants  
to  
check out the local beer.

And, no, I have no connection to WBR.

From: adiron!Email@uunet.UU.NET, Harlequin@uunet.UU.NET  
Subject: Keg priming questions

Now I've done it! It seems I've slightly over-primed my first (Cornelius) keg of beer. I went and used 2/3 C dextrose before bothering to read the TCJOHB appendix on kegging. What's my best bet for reducing the resulting carbonation level in the keg? Should I bother?

The beer, a coriander/orange brew, has been under 10 psi of CO2 at about 60-65F for a week now. Should I bleed off some of the CO2 in the headspace to allow more of the dissolved CO2 to come out of solution? Should I chill the keg down first? Should I forget it and simply serve it good and cold to keep the CO2 in solution?

The recent posts regarding kegging have been most helpful. Any further tips would also be greatly appreciated. Sure beats the heck out of bottling!

On a related question, how does one use the CO2 table (plotting volumes of CO2 in beer as a function of PSI and temperature) found in the LISTSERV archive?

Yours in brewing,  
Scott Barrett

Subject: Temperature Control

In a recent posting:

>I think the unit Brian is describing is the Hunter Air-Stat (or something  
>very close to that name). I have one that I use to control my 'fridge.  
>It works perfectly well, controlling the temperature within +-2 degrees F  
>of the set-point. I believe the lower limit on the temperature is 35  
>degrees and the upper limit is 99 (but don't quote me on it :-). I'm sure  
>it would work as well with a freezer. It works just like Brian describes  
>it. This unit has been discussed many times in this digest. I found mine  
>at a semi-local hardware store called Home Depot. I think these are in  
>several regions around the country. It cost about \$25. You may be able  
>to find it in many do-it-yourself stores.

I recently bought one from American Brewmaster mail-order after seeing their ad in the latest Zymurgy. If you can find it in the air-conditioning section of a hardware store like Keith did, you'll save a couple of bucks by eliminating the middle-man. Williams charged me \$29. Works great.

Anyway, here's a related story. Now that it's a little too warm to ferment for us basement-deprived brewers, I decided to make use of that little refrigerator I had in my college dorm way back when. It's much too small for a 5 gallon carboy, so I removed the door, made a wood-frame box, lined it with 2-inch styrofoam, weather-stripped its face, and butted it up against the little fridge. The top is removable, and I secured it to the little fridge with bungee cords. I plugged the fridge into the temperature controller last night. I easily maintained a temperature of 50 F for its first test.

I'm curious to see how cold I can make it. The entire unit sits on a shelf in my garage. When comparing it to a full-sized fridge, it's a great space and money saver.

Subject: Wyeast descriptions

Tom Kaltenbach asks:

> Does anybody have a copy of the description of the different  
strains of  
> the Wyeast liquid yeast cultures? The "brewing in the information  
age"  
> issue of ZYMURGY (couple of issues ago now) mentions that this file is  
> available on COMPUSERVE (I think it's called WYEAST.TXT).  
Unfortunately, I  
> don't have any way to access COMPUSERVE. Could some kind soul please  
send  
> me a copy? Thanks.

I'm fairly new to the Homebrew Digest (a month or so) and am not familiar with such etiquette as repeating past postings. In the short time I've been reading the HBD, I've seen enough messages that begin "I'm new..." that it's probably safe to assume that quite a few readers haven't seen the Wyeast posting mentioned above, so I will include it here. (I've waited one issue to see if anyone else was going to post this.)

But first, I must point out that the Zymurgy special issue from 1989 was on yeast, and had a good article by Byron Burch entitled "Of Yeasts and Beer Styles" that gives addition (subjective) information. I'd type in the descriptions of my favorites, but I'm pressed for time today, and don't know about copyright problems.

Now, here is the relevant information from CompuServe's WYEAST.TXT (which as you can see, originated on the Homebrew Digest!):

FROM INTERNET HOMEBREW DIGEST NO. 742, OCT. 17, 1991:

Date: Mon, 7 Oct 1991 22:58:02 -0400 (EDT)  
From: D\_KRUS@UNHH.UNH.EDU (Daniel L. Krus)  
Subject: Yeast and Spec. Grav's.

There's been a few questions lately about yeast and characteristics associated with them. Here is a retype of some information I received from Wyeast relative to their yeast. This information was obtained a while ago and supposedly this was to be updated and expanded. If anyone has the latest update I would appreciate a copy of it from you since Wyeast wasn't too tickled that I contacted them directly. Sorry if there are any typos.

(Information about NEW strains Belgian Ale [#1214] and California Lager [#2112] contributed Jan. 23, 1992, by Beer Forum member Bill McKinless, of The Home Brewery in Teaneck, N.J.)

#### YEAST CHARACTERISTICS

Some yeast strains are more active and vigorous than others. Lager strains in particular do not show as much activity on the surface as many of the Ale strains. We provide an adequate quantity of yeast to complete fermentation with varying amounts of lag time depending on strain, freshness, handling, and temperature. If you find it too slow, make a starter as recommended on the package. In any event, a closed fermenter with an airlock is recommended.

#### TEMPERATURE

The slow onset of visible signs of fermentation can be improved by starting fermentation at 75 deg. F (24 deg. C) until activity is evident, then moving to your desired fermentation temperature. A few degrees does make a significant difference without adversely affecting flavor.

The normal temperature for Ale yeast range from 60-75 deg. F (16-24 deg. C) A few strains ferment well down to 55 deg. F (13 deg. C). 68 deg. F (20 deg. C) is a good average. Lager strains normally ferment from 32-75 deg. F (0-24 deg. C). 50-55 deg. F (10-12 deg. C) is customary for primary fermentation. A slow steady reduction to 32 deg. F (0 deg. C) during secondary fermentation typically works well.

The fermentation rate is directly related to temperature. The lower the temperature, the slower fermentation commences. Fluctuations in temperature such as cooling and warming from night to day can adversely affect yeast performance.

#### ATTENUATION

Apparent attenuation of yeast normally ranges from 67-77%. The attenuation is determined by the composition of the wort or juice and the yeast strain used. Each yeast strain ferments different sugars to varying degrees, resulting in higher or lower final gravities. This will affect the resid-

ual sweetness and body.

#### FLOCCULATION

All brewing yeast flocculate. The degree and type of flocculation varies for different yeast. Some strains clump into very lary flocculate. Some floc very little into a more granular consistency. Most yeast strains clump and flocculate to a moderate degree.

#### pH RANGES

Typical pH range for yeast fermentations begins at about 5.1 and optimally 4.8. During the course of fermentation the pH reduces to typically 3.9-4.1 and as low as 3.1 in some wines.

#### ALCOHOL TOLERANCES

The alcohol tolerance for most brewing yeast is as least to 8%. Barley wines to 12% can be produced by most Ale strains. Pitching rates need to be increased proportionally to higher gravities. Alternately, Champagne and Wine yeast can be used for high gravities sometimes reaching alcohols to 18%.

#### YEAST PROFILES

Ales (*Saccharomyces cerevisiae*)

1007. Our original Ale Yeast of German origin. Ferments dry and crisp leaving a complex yet mild flavor. Produces an extremely rocky head and ferments well down to 55 deg. F (12 deg. C). Flocculation is high and apparent attenuation is 73-77%. Optimum fermentation temperature: 62 deg. F (17 deg. C).

1028. British #2 (London Ale previously British Ale). Rich minerally profile, bold woody slight diacetyl production. Medium flocculation. Apparent attenuation 73-77%. Optimum fermentation temperature: 68 deg. F (20 deg. C).

1056. American Ale Yeast. Ferments dry, finishes soft, smooth and clean, and is very well balanced. Flocculation is low to medium. Apparent attenuation 73-77%. Optimum fermentation temperature: 68 deg. F (20 deg. C).

1084. First considered just British, but now more specifically Irish. Slight residual diacetyl is great for stouts. It is clean smooth, soft and full bodied. Medium flocculation and apparent attenuation of 71-75%. Optimum fermentation temperature: 68 deg. F (20 deg. C).

1098. British Ale Yeast from Whitbread. Ferments dry and crisp, slightly tart and well balanced. Ferments well down to 55 deg. F (12 deg. C). Medium flocculation, apparent attenuation 73-75%. Optimum

fermentation temperature: 70 deg. F (21 deg. C).

1214. Belgian Ale. (NEW) Abbey-style top fermenting yeast suitable for high gravity beers, doubles, triples, and barley wines. High flocculant strain which clears well. Apparent attenuation 71-75%

1338. European yeast from Wissenschaftliche in Munich. A full bodied complex strain finishes very malty. Produces a dense rocky head during fermentation. High flocculation, apparent attenuation 67-71%.  
Optimum fermentation temperature: 70 deg. F (21 deg. C).

Lager (*Saccharomyces uvarum*)

2007. Our original Lager Yeast Strain. Specific for pilsner style beers. Known as many things, we call it Pilsen. Ferments dry, crisp, clean and light. Medium flocculation. Apparent attenuation from 71-75%. Optimum fermentation temperature: 52 deg. F (11 deg. C).

2035. American Lager Yeast. Unlike American pilsner styles. It is bold, complex and woody. Produces slight diacetyl. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 50 deg. F (10 deg. C).

2042. Danish Yeast Strain. Rich, yet crisp and dry. Soft, light profile which accentuates hop characteristics. Flocculation is low, apparent attenuation is 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

2112. California Lager Yeast. (NEW) Warm fermenting bottom cropping strain, ferments well to 62 F while keeping lager characteristics. Malty profile, highly flocculant, clears brilliantly. Apparent attenuation 72-76%.

2124. Bohemian Lager Yeast. The traditional sazz yeast from Czechoslovakia. Ferments clean and malty, rich residual maltiness in high gravity pilsners, medium flocculation, apparent attenuation 69-73%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

2206. Bavarian Yeast Strain used by many German breweries. Rich flavor, full bodied, malty and clean. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

2308. Munich Yeast from Wissenschaftliche in Munich #308. One of the first pure yeast available to American homebrewers. Sometimes unstable, but smooth soft well rounded and full bodied. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 50 deg. F (10 deg. C).

*Saccharomyces delbrueckii*, *S. cerevisiae*

3056. Bavarian Weissen. A 50/50 blend of *S. cerevisiae* and

Delbrueckii to produce a south German style wheat beer with cloying sweetness when the beer is fresh. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 56 deg. F (13 deg. C).

#### Wine Yeast

3021. Prise de mousse, Institute Pasteur champagne yeast race bayanus.

Crisp and dry, ideal for sparkling and still red, white and fruit wines.

Also can be used for Barley wines. Optimum fermentation temperature: 58 deg. F (14 deg. C).

3028. French wine yeast ideally suited for red and white wines which mature rapidly. Enhances the fruity characteristics of most wines. Optimum fermentation temperature: 72 deg. F (22 deg. C).

#### Malo-lactic Bacteria

##### Leuconostoc oenos

4007. Malo-lactic culture blend isolated from western Oregon wineries. Includes strains Ey2d and Erla. Excellent for high acid wines and low pH.

Softens wines by converting harsh malic acid to milder lactic acid. Can be added to juice any time after the onset of yeast fermentation when sulfur dioxide is less than 15 ppm.

Subject: Boston Brewing Co. Tour

Boston Brewing Co. Tour

I was recently in Boston for a conference, so I decided to check out the Boston Brewing Company (Samuel Adams beers). I took the "T" (subway) down south of town to Jamaica Plain, and walked through a pretty bad neighborhood to get to the brewery. They only conduct tours twice a week (Saturdays and Thursdays), so I planned ahead. There is a nice area with lots of old Boston beer memorabilia to look at while waiting for the tour to start. There is also a display (\*inside\* an old conditioning tank) which takes you through the process of making beer and gets you to answer some trick questions about beer.

Soon the tour gets started, and a young fellow takes you around and shows you their brewing set-up. His knowledge is somewhat lacking (couldn't even \*name\* another type of hops besides Hallertauer when queried), but probably adequate for the general public. The brewery is rather small; it only brews beer for the Boston area. Another brewery in Utica, NY brews for the east coast, and west coast Samuel Adams is brewed in Portland, OR.

Boston Brewing Co. is definitely a brewery with an attitude. They are decidedly snooty about beer, and about their beer in particular. They make a big deal out of a number of things:

1. Their beer follows Reinheitsgebot (the German beer purity law) and is the only American beer sold in Germany.

2. European beer is not fresh and is adulterated with corn for the American market (of course they are mainly referring to Heineken and Becks, but they don't make a distinction).

3. The big American brewers are great brewers, but don't brew good beers.

4. Beers bottled in green or clear bottles are skunky. They talk about the bottle color being determined by the marketing department when the bottles are green. They use Miller as an example of a beer that gets skunky because it is in a clear bottle, but we homebrewers know that Miller can get away with a clear bottle only because it chemically treats its beers to prevent skunkiness.

5. They won the Great American Beer Festival three years running. The story I've heard on the net is that Sam Adams won the consumer preference poll because they hired a fetching young lass in a revealing outfit to serve their beer and ask for votes. I've also heard that this kind of unfair campaigning was the main reason that the consumer preference poll was discontinued, leaving only the blind panel judging.

After the tour, you are escorted into a tasting room where you can sample their wares. We tried Samuel Adams Lager, Samuel Adams Ale, and Samuel Adams Wheat. I must admit that, even though I was a bit put off by their cockiness, I really like their beers. I would describe them as assertively hopped, but not as strongly hopped as an Anchor or a Sierra Nevada beer. They also have a nice maltiness, and the wheat beer had a hint of a clove taste, as well as good wheat character. They also make seasonal beers, including an Oktoberfest, a Winter Ale, a Double Bock,

the famous Cranberry Wheat beer (made with a touch of maple syrup for New England flavor), and possibly a Cream Stout (they had just made a small batch when I was there). Alas, they had no samples of their other brews for sale (believe me, I searched).

All in all, it was an enjoyable tour, with the tasting being the high point. One note for future tour-takers: the tour guide doesn't keep a good watch on the tap while he's tending the souvenir store, and a quick refill of your pitcher is easily accomplished :-).

Subject: rosemary ale and porter

I made a rosemary ale last month. My basil beer came out well, so I thought rosemary was worth a try (that is, my girlfriend thought it was worth a try). It came out okay, pretty dry (low mash temps)and clean. I will offer this advice: 1/2 oz of fresh rosemary in three gallons of beer is too much. It will be good for cooking though.

Also, does anyone have a good Anchor Porter recipe? How is Charlie's Silver Dollar Porter? Should I use California Lager yeast or Irish Ale?

From: tpm%wdl158@wdl1.wdl.loral.com (Tim P McNerney)  
Subject: 98, 99, Why Wait for the Boil?

100?

Anyway, I've been meaning to ask this for a while, but now seems like an oportune moment.

Why do most sources suggest adding the malt extract once the water has started boiling? Is there any advantage to adding it then? I did so last time, but was a bit slow with the stirring and ended up with quite a mess from burnt extract and would much rather add the extract when the water is warm. I suppose that if I am #100, this may be a moot point as I will start up all grain, but on the off chance that I am not, any reason not to add the extract at lower temps.

From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)  
Subject: Guinness Story

My wife was in DC recently, and when she called back to ask if there was anything there that I wanted her to bring back, my mind immediately turned to beer (at least metaphorically).

I remembered reading in a recent HBD that DC was one of the test markets for Pub Draught Guinness in a can (I had tried one earlier that I managed to snag in San Francisco), so I remarked that a can or two of that delicious stuff (see note at end) might be nice, if she could swing it. New Mexico is not a thriving distribution center for odd beers.

Well, I didn't think much more of it until she got home and I found out that she had brought me --- not a can --- not two cans --- but a CASE of Pub Draught Guinness!! I was ecstatic!

It turns out that she had done it the easiest way possible: she just checked the whole case as luggage. She figured that, since it was in cans, it would probably be okay. Anyway, if a few cans did break, the majority would be okay and the hassle factor would be minimized.

Well, the whole case made it to our house okay, and I am now (figuratively) sitting on what is in all probability the only case of Pub Draught Guinness in New Mexico. They taste excellent, with no signs of travel fatigue. What a wonderful wife I have! And she doesn't even like stout! (You all have permission to show this to your wives for inspiration :-)

Mike Hall

Note: For those of you that don't know, the Guinness people have been working on a way to distribute their draught version (which is significantly different from their bottled version) easily. Their draught version is "carbonated" with nitrogen, giving it extremely small bubbles and a very creamy head that lasts until the end of the beer. They finally came up with a way that uses a little plastic insert filled with nitrogen inside a can of beer, with a little hole to let the nitrogen squirt out when the can is opened. It tastes very similar to the draught version. I love it --- it's almost like chocolate milk with a kick. There was a long article in the HBD on it around the time it first came out; check your archives if you want further info.

thin.  
> How can one add "body" to a quick mead? Add a little DME? More fruit?

My guess is that the key problem here is the \*quick\* part. Honey is a  
notoriously slow fermenter, and even after fermentation tends to improve  
with age. Part of that improvement is a perceived thickness. My first  
batch  
of mead was made with only 5 lbs honey, and even after severe aging (I'll  
be celebrating the remaining 4 bottles 3rd birthday soon - by drinking  
one!)  
they are still thin compared to my batch made with 7.5 lbs of honey.

> Is this a fruitless quest? \*ducks\* Note that I don't give a FFAARD  
about  
> standard styles, I just want a nice summer beverage that doesn't take  
> more than a month to complete. 1 1/2 gallons of frozen blackberries,  
> a jug of honey, several million yeasties and I await your suggestions.  
...

Try this recipe:  
1 qt boiling water  
4 tea bags

lots of ice  
sugar to taste

This is a real quick recipe that is very satisfying on a hot day. I guess you could substitute honey for the sugar to get that \*mead\* taste >:-) But seriously, as far as I know, there is no one month recipe for mead if you plan on using honey (is there any other way?), but if anyone else knows of one I'd be very interested to hear it.

Do they make steroids for yeast?

Subject: San Francisco KQED Beerfest

Howdy gang,

This Saturday (7/11) is the annual KQED Beerfest in San Francisco. For those within range that are unaware of it, I highly recommend this event.

There are representatives from breweries all over the world, and of course

samples of all their brews, as well as many different types of grub. \$30 gets you in, buys you a glass and a map, and the rest is up to you.

You

get 3 hours to taste/chug this wide variety of beer and food, and its an excellent oppurtunity to try all those styles and brands that you never have got around to. The hardest part is trying to remember which brews you

liked the best after the 103rd sample, but I like a challenge! Finding the

exit afterwards can be quite thrilling as well.

For those that can make it, its well worth the time and money.

Unfortunately

I don't remember the address, but its somewhere around 4th and Townsend.

I'm

sure you can find out more in the newspaper, or even by calling KQED.

Hope to see you all there,  
Mark

Subject: AHA e-mail addresses

While perusing the last few months of digests, I noticed e-mail addresses for two of the AHA/Association of Brewers staff members:

Charlie Papazian 72210.2754@compuserve.com  
James Spence70740.1107@compuserve.com

Does anyone know of a general e-mail address for the AHA/Zymurgy/Association of Brewers/The New Brewer/Institute of Brewing Studies offices in Boulder, CO? It would be great to zip off questions, comments, and requests to them by e-mail rather than to use the telephone: handy, more efficient, and less expensive. A thought.

Ed

P.S. Of course, I also e-mailed this question directly to the above addresses but I thought I'd share this information and besides, #100 is getting very close...

Subject: Re: Storage of kegged beer

John wonders why kegged beer won't store for a year at room temp.

I have never wondered about it. I assumed that kegged beer, under pressure, would last at room temp just as long as bottled beer. Although I have not stored beer in kegs at room temp (68f) for long periods, I have had some beers in the keg at 48f for nearly a year with no undesirable results. I have pulled kegs from the refer for months at a time (partial kegs) without any ill effects.

If anything is different about kegs, at least for me, it is that my keg tends to be the secondary so I have a fair amount of yeast in the bottom (say, 1/8 cup or so). It is possible with large amounts of yeast that autolysis could set in over a long period of time.

Bottom line for me is that I ain't gonna worry about it.

Cheers!

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: Re: oats and other adjuncts

Technically, steel cut oats are RAW and need to be cooked to liberate the starch. Probably what happens is that they are chopped up so fine and the enzymes floating around in a 2 hour mash (:-) have an opportunity to liquify the starch and conversion happens.

All other forms of oats (flat ones, that is) have been pre-cooked in the squishing process. This also holds true for barley, wheat, tritical, etc. They don't need to be cooked.

Also, regarding mashing of specialty grains. From a technical point of view all crystal malts (down to cara-pils) have already been "mashed" in the husk. Toasted malts (vienna->black patent) have not. Those that have not may dump starch into your brew which might cause a warm haze (worse when cold).

As a point of reference: I have easily mashed 7lb of pale malt (us 2-row) and 1lb each of rolled oats and roast barley to make a fine stout that has no haze whatsoever. Granted, you need a strong light to tell! Oh, to complete the recipe: 1.25oz of chinooks for 60min. Yum, yum.

Cheers!

What temperature did you ferment at? I have heard that keeping the temp @ 70-75 F favours the *S. Delbruckii* more than lower temps, which favour *S. Cerevisiae* (Ale yeast, however you spell it). My last wheat beer used Wyeast Bavarian Wheat yeast in the new packaging, and it's plenty "clovey". The temp in the basement was around 70F during the major portion of the fermentation.

Subject: Re: highly modified malts

Cush Hamlin writes:

>Now the question: has anyone out there experimented with USA versus  
>English malt, and if so can you describe the difference in character  
>they give to a brew?

>

>The Brewmaster at Sherlock's said forcefully "you CANNOT make english-  
style

>brews using USA malt." Is it the highly modified malt that gives their  
>brews their smooth character, or is it brewing skill, etc. etc....?

Case in point: the IPA recipe I presented in the HBD yesterday: I made  
it first with Marris Otter malt from Liberty and a second time with  
Great Western Malting Pale Malt (some mix of klages and harrington).  
Although the first rendition seemed a bit maltier, in fact most people  
couldn't really notice the difference. I think that the high hopping  
level of the IPA + the dry hopping might have masked some subtle malt  
characteristic.

Oh, the GWM versions did better in club tasting than the English malt  
versions.

One thing about true englishmalts, they are kilned higher than US malts  
and thus are a bit darker. I think that compensating with 10-15% low  
Lovibond crystal (say 16L) would largely mask the difference both  
in color, body and malt character.

Cheers.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: Re: Do specialty grains need to be mashed?

> As I understand it, specialty grains do not need to be mashed.

Personally, I think all grains need to be mashed. For a partial mash, If you're just using .5-1 lb of crystal malt or other specialty grain, you can just add an oz. or two of amylaze enzyme and leave the wort at 150F for 20 minutes (based on experience this seems to work). Otherwise, you need to have 50% lager malt (or more pale ale than that) to provide the appropriate enzymes for starch conversion. (as per TCHOHB, aka. Miller).

Make quite certain that you get as much grain as possible out before boosting the temp above 170F, or you will be rewarded with an astringent taste that takes a long time at cold temps to mellow.

Many people think that It's alright just to steep the grain, and you're more than welcome to disagree with me. It certainly doesn't ruin the beer if you do (steep the grain).

>It's sittin' on the counter now, having fermented at about 70f for a week,  
>and is finally ready to bottle. Glad I took a "final" gravity after I  
>took it out of the fridge.

It depends upon the yeast. I successfully fermented my first all-grain batch at 33F in my fridge, using Wyeast Munich Lager yeast. I took it out after 3 months, and the SG had fropped from 1.077 to 1.027. I let sit at room temp another week, and it dropped to 1.020.

BTW, the sparge got stuck, I broke my putter trying to get it unstuck, a lot of husk material made it through the grain bed, and I only wound up with 3 gal of 1.077 wort from 15 lbs of grain. I added polyclar towards the end of the primary (in the fridge) to help settle out the tannins, and it probably was one of the best beers I've ever made :-)

Other lager yeasts don't like it that cold, I guess...

Date: Thu, 9 Jul 92 20:57 CDT  
From: fjdobner@ihlpb.att.com  
Subject: Ale Yeast

In the last week I have brewed a Cherry-Honey-Weiss beer from grain.  
My recipe looks like this:

6# 2 Row English Pale Malt  
4# Malted Wheat  
Gypsum (for adjusting PH)  
Irish Moss (Clarity)  
10.5# Cherries  
1# Honey  
1 oz Saaz Hops - Boiling  
1/4 oz Saaz Hops - Finishing

I mashed using 10 qts at 140 F strike heat for a protein rest at 130 F. Then added an additional 5 qts at 200 F to bring to a starch conversion at 150 F raised to 158 F, with a mash-out at 168 F. Sparged with 5 gallons of water at 168 F recovering over 6.5 - 7 gallons. Boiled for two hours. Chilled down to about 70 F, pitched yeast. OG=1.040 at 70F. After two days FG=1.060 and still bubbling. I racked off the trub (a little late granted) onto 10.5# of frozen/macerated cherries. In addition, I added 1# of honey (boiled with about 1 pint of water). After this point, I saw no more activity w.r.t. fermentation. I tried adding some yeast energizer and extra packet of dried yeast with no success. I believe at least two things could have happened:

1. The frozen cherries chilled the fermenting liquid down to a temperature level below that where ale is productive or active.
2. The freezing of cherries does not thoroughly eliminate the bacteria and wild yeasts that I had tried to freeze out.

I had sampled some opinion from several people on the digest and many said that freezing the fruit is an effective means of killing the un-wanted. Has anybody else got any experience or advice? The batch does not taste bad although the cherry taste is none to prominent.

Frank Dobner

PS; I must say that these whole grain batches sure make me enjoy extract brewing since I finished this one at 3:15 am. I slept happily though.

Date: Thu, 9 Jul 92 08:58:49 PDT  
From: hartman@varian.varian.com (John Hartman)  
Subject: re: Oats

In digest #919, Russ talks about brewing with Oats and Flaked Barey and Wheat. Russ, I'd like a slight clarification regarding your treatment of oats. Are you saying that oats, such as Old-Fashioned Quaker Oats, should be boiled prior to mashing?

My understanding was that flaked grains were pressed between hot rollers which ends up cooking the grain. As a result, flaked barley does not need special treatment prior to the mash. I.e., just add it along with the rest of the dried grains.

I'm not a true stout drinker but my girlfriend is. So I've been trying to make a good oatmeal stout. I used 1 lb. uncooked Quaker Quick Oats last time. It imparted little (no?) flavor or character to the beer. This time I used 1 lb. Quaker Old-Fashioned Oats which had been cooked to a nice gelatinous goo. Am I on the right track or would you suggest I do it differently? Also is this the right choice for oats, i.e., Old-Fashioned Oats?

Thanks in advance,  
John hartman@varian.varian.com

Subject: kegging

Kegged beer will of course keep just as long if not longer at room temperature as bottled beer. Crown caps leak; a well-sealed keg does not and this is why the kegged beer may keep longer.

The notion that o-rings from a used soda keg must be replaced because the soda syrup has impregnated the rubber is a myth for the most part. Sugars and flavor components will come out or off of the o-rings simply by soaking in water. The only way in which these things would be permanently impregnated is if there were some actual chemical bonding between the rubber and the stuff. this seems most unlikely.

Additionally, since the o-rings are not in contact with the beer then the idea that even some minute residual odor will destroy the flavor profile of a malty beer seems very unlikely.

From: gelly@persoft.com (Mitch Gelly)  
Subject: raspberry beer

Greetings,

The raspberries here (WI) are near ripe, and the time has come to formulate a recipe to utilize them. I'm not looking to make a framboise lambic, just a good raspberry beer. I've seen a few good recipes in CM2 and pretty much know whats going into it, but my concern is when to add the fresh fruit? There seem to be a few schools of thought here:

- 1) add the fruit (pureed, whatever) at the end of the boil, steep 'em for x minutes, dump everything in the primary.
- 2) add the fruit to the secondary.
- 3) both, ~75% primary, ~25% secondary.

If you add the fruit to the end of the boil, won't you lose a lot of the aromatics, and won't most of its sweetness ferment out in the primary? And if you add to the secondary, how do you "sanitize" fresh fruit? Is "sanitized" fruit even a concern in the secondary, since the yeast already has a strong foothold and alcohol is present?

And last of all, am I the 100th posting? ;-> :-D d8=

If any of you (and I'm sure there are) have made fruit beers, clue me in. I have fantasized about raspberry beer all year. If I can get enough berries, I also plan on also doing a mead (melomel) using them. Post here or reply personal, your choice. Thanks much.

I'll let you all know how it turns out.

Date: Fri, 10 Jul 92 10:04:09 CDT  
From: tony@spss.com (Tony Babinec)  
Subject: adjunct grains & mashing

The purpose of mashing in all-grain brewing is starch conversion. That is, the starches and other large molecules in the barley malt are converted by enzymes in the barley malt to fermentable and unfermentable sugars.

Most (unmalted) adjunct grains must first be simmered or cooked until they are "gelatinized." If you can find adjunct grains in flaked form, they are already gelatinized. I've found flaked wheat, flaked barley, and flaked maize at either homebrew shops or health food sections of grocery stores.

The gelatinized cereal or the flaked grain is added to the mash. You're relying on the "enzyme power" in the barley malt to convert not only the barley malt's starches but also the adjunct's starches. Thus, someone on HBD advised a "mini-mash." Some brewers first perform a protein rest at 122 to 131 degrees F for 30 to 45 minutes with the adjunct grains added at mash-in before boosting to starch conversion temperature in the low 150s.

"Specialty grains" include crystal malt, chocolate malt, black patent malt, and (unmalted) roasted barley. Crystal malt is already converted. The dark malts are used for their flavor, aroma, and color properties. Thus, some brewers add specialty grains at mash out. Because they don't need to be converted, extract brewers can crack and steep the specialty grains in water, strain the grains from the water, and proceed with their brew.

Date: Fri, 10 Jul 92 09:04:30 MDT  
From: resch@craycos.com (David Resch)  
Subject: Campden Tablets

I recently made a mead in which I wanted to keep as much of the honey aroma as possible. I therefore used sulfite (campden tablets) rather than boiling to keep the nice honey aroma. Unfortunately, I looked at a wine book that suggested 2 tablets per gallon for the initialial sulfiting of the "must".

Well, this was too much for the mead, as it killed several pitchings of yeast. Finally, I ended up boiling the mead anyway to try to drive off some of the SO<sub>2</sub>. After 2 more yeast pitchings, it took off and has been fermenting just fine for several weeks now. If anyone else wants too use sulfite to keep the volatiles in the mead, I STRONGLY suggest no more than one tablet per gallon.

Now my question: In the Lambic book by Guinard, he talks about certain sulfite concentrations for sanitizing barrels, etc. Since I don't have an accurate scale available to me, I was wondering if anyone knew the approximate sulfite concentration when one Campden tablet is dissolved in 1 gallon of liquid?

OK, I admit it, I really do want to know the answer to my question, but the timing of the request is a blatent attempt at winning a malt mill, since I'm thinking about buying one anyway...

From: scott@gordian.com (Scott Murphy)  
Subject: kegging question

I have kegged three of my batches to date. I don't add priming sugar. Instead, I siphon the beer into the keg, seal it and add CO2. I crank the pressure up to 25psi or so, invert the keg, and occasionally give it a good shake. I reach drinkable carbonation levels within a day.

Does anybody think that priming (natural carbonation) is a better way to go than forced carbonation?

>Pour it into a bowl and weigh it on a kitchen scale? Sticky, I would  
>think, but not impossible. Does anybody have an easier way?

I keep a plastic canister of dried malt extract around for many of  
reasons,  
such as for adding a little to a recipe to boost the OG, but I mainly  
keep  
it for the the purposes of making a starter solution for a yeast culture.  
The DME is much more easy to deal with than liquid and keeps a  
loooonnnnggg  
time if it is sealed. Tupperware (TM) works well for the purpose. You  
can  
measure with a measuring cup, estimating the weight or actually weighing  
it  
on a scale. I just "guesstimate" and seem to have good results.

You mighe want to give DME a try.

ITEMS FOR SALE:

If there are any potential microbrewers or large-scale homebrewers out there, I've got some items that you may be interested in:

- Golden Gate beer kegs, with taps and wooden bungs
- Plate heat exchanger, 24 plate
- 140 gallon stainless brew kettle with separate hot-water boiler to fire it up
- 100 gallon stainless fermentor, double-walled
- beer pump with stainless housing
- many other odds and ends to get you started in the microbrewery business, e.g., tri-clover valves and hi-temp beer hose, fittings, taps...

You can have any (or preferably ALL) of these items for a GREAT price!

I used the Elbro Nerkte (Who in the hell is that?) Brown Ale recipe in  
TCJOHB (revised) and it turned out great. I ended up going out of town at  
the end of the primary and decided to rack it into the carboy for a week  
while I was gone. That week ended up as four weeks before I got it  
bottled.

It turned out very smooth with a nice malt body to it.

From: "JOSEPH V. GERMANI" <GERMANI%NSLVAX@Venus.YCC.Yale.Edu>  
Subject: Clove taste and warm kegs.

Greetings,

I have had experience with clove flavors in my beers. Bad experience, actually. I found that using old plastic fermenters (no matter how well sanitized) and long (at least two weeks), high temperature (higher than 70 F)

ferments, I got a clove-like flavor whether I liked it or not. I usually used Edme ale yeast. When I switched to glass and cooler fermenting it went away

(even with the same yeast). Of course, it might be due to the local wild yeast, so it may not happen to everyone.

On to the subject of warm kegs. I don't keg very often, but I have a soda keg of ale in my basement from last fall (I know I should be drinking more--it's a side effect of the late stages of grad school). I did tap it last

fall but just didn't finish it, so it has been kept at 60-70 F since then. I do occasionally tap it and drink some. It still tastes fine to me (and my friends). I do sanitize my kegs very carefully and dispense beer with CO2 (essential if you want it to last more than a day). That's just my data point.

G'day,  
Joe

Subject: Oats, Bitter Dregs, Pins

Subject: Oats, Bitter Dregs, Pins Time:7:48 AMDate:7/10/92  
Steve Kennedy aske why you need other grains when mashing oats.

There are no enzymes in oats. You need the grain to supply these enzymes in order to convert the starch into sugar. The only way to get around this would be to use some enzyme extract, like koji, to convert the oat starch. If you have a local supplier of such an extract, try it. Otherwise just follow the 1 to 1 recipe I stated previously. When I was doing extracts I would mash all my specialty grains with the oats so my mini-mash looked like this:

1lb oats  
.5lb roasted  
.5lb black patent  
2lb 2 or 6 row  
1 to 1.5 gallon water  
bring mash to 155 degrees and hold for 1 hour. Pour grains into colander and rinse with an equal amount of water at 170 degrees. Add extract to this liquid and bring to maximum volume for your kettle for the boil.

I never found the contribution of fermentables from such an oat mash to be significant enough to alter the basic extract recipe. My stouts tend to hang around the 1.055 - 1.060 range so I would target the lower number based on the extract and take the mash sugar as "gravy".

There may be no advantage to "mashing" specialty grains when used with extracts, however I never liked the idea of adding specialty grains to the kettle and then fishing them out prior to adding the extract. I knew I wouldn't be able to remove all the grains and don't like boiling them. I always steeped my specialty grains in 150+ degree water for 30 minutes or so then rinsed them into the kettle. Doing the actual mashing was a painless step to take and just added another 30 minutes to my session.

I have never tried diastatic syrup so I can't speak to its benefits. If "pale malt" (as in British Pale) is to be your adjunct you shouldn't need the DMS as pale malt will supply sufficient enzymes to mash itself.

On another topic:

Douglas DeMers talks about his "bitter dregs" and says:

>Additional 1 gallon of sparge was prepared when gravity of runnings  
>was so high. Even after an addition gallon of sparge, the runnings  
>were high, IMO. The little red worms in the compost heap were happy,  
>though! Next time, I'll use more gypsum to bring the ph down to 5.7!

Your recipe calls for 1 lb of Black Patent in a 5 gallon batch. I'd  
expect your  
pH to be too low as a result of the black malt, not too high. You quote a  
reading of 5.0 at your initial rest of 135 degrees so it sounds like  
calcium  
carbonate would be the "drug of choice" here rather than gypsum.  
Regardless 5.0  
is certainly an acceptable level. What does the pH have to do with high  
final  
runnings? It sounds like you got ample conversion. Wouldn't high final  
runnings  
be a result of a too quick sparge rather than chemistry?

And, Russ Gelinas (the other Russ) says:

>An easy way to remember which keg fitting (2 pins or 3 pins)  
>goes with which dip tube (co2 or liquid) is to think that the  
>beer tube is "more important", and so has a higher number of pins

The liquid tube is also LONGER and so the association with a LARGER  
number of  
pins works as well. (;-)

From: mcnally@wsl.dec.com  
Subject: mashing oats

Oats have no diastatic capacity; they can't starch-convert themselves. The process of mashing is more than just getting the grain hot and wet. Barley and wheat (and maybe rye) contain lots of amylase enzymes that become active at mash temperatures. The enzymes break the starches down to simpler sugars that are fermentable (and taste sweet).

From: gordon@Stars.Reston.Unisys.COM  
Subject: Bottling Temps and Times for Ales

/-/ello,

A few beginner's questions, please.

Four weeks ago, I put my first batch of "ale" (John Bull Amber extract + Wyeast #2112; yes, a weird combo) into bottles. I put 12 bottles in the refrigerator at 35-40 degrees F and kept the rest in the basement at 65-75 degrees F.

Did I make a mistake by putting the 12 bottles in the fridge? Will any secondary fermentation have taken place in the fridge? In general, does it matter what temperature ales are kept at after being bottled? If I did make a mistake with the 12 bottles, can it be corrected now, 4 weeks later?

How long, in general, must ales stay in the bottles before they become drinkable?

I think I'll try a bottle from the basement first.

Thank you for any information.

The odds get even,

Yes. Using the procedure you describe, they will not contribute any  
significant sugars to the wort, whereas they will if you mash them.  
As for the amount they (ideally) contribute, Miller has a table  
in TCHoHB listing figures for various grains, though most people  
only achieve 80%-90% of the ideal.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: sugar/invert sugar

Last night I was making Black Raspberry Sekanjabin syrup and had in front of me two recipes. One said to bring the water and sugar to a boil, remove from the heat and add the vinegar and flavoring, the other said to bring the water and sugar to a boil, add the vinegar and simmer for 30 minutes, then remove from the heat and add the flavoring.

I know that citric acid is used to make invert sugar, will acetic acid work too? How different does invert sugar taste?

Just put saran wrap over it, and store it in a cool place, or  
seal it in an air-tight container. Mold will probably develop  
on the surface over the period of a few months. Just skim off  
the mold before using it, and/or strain out the chunks that make  
it into the boil.

As for measuring it, I have an old can that had 3.3 lb of extract  
in it, and I just guesstimate.

If you warm the extract, it becomes less viscuous.

> On another note, I was happily washing bottles last Sunday and  
>allowed the dreaded boilover to occur. This one was a beaut (and  
>what a waste of perfectly good wort :-( ). Does anybody have a good  
>way to clean those burner pans and rings? The SOS pad didn't get it

If you add amylase enzyme to the wort and keep it at 150F for  
10-20 minutes, the tendency to boil over is reduced (It's on  
par with all-grain batches).

**Subject: Blueberry Beer, Keg Scratches**  
Full-Name: "John Cotterill"

(this was sent yesterday, but it did not make it into the digest)

Hey Gang! A couple of quick questions for you all.

1) Does anyone have a good recipe for Blueberry beer? There is a local contest coming up that features fruit beers, and I would like to brew one up. An all grain recipe is preferable, but a good extract recipe would be ok.

2) I keg my beer using soda kegs, and I also ferment in soda kegs. I recently finished a ferment and discovered that I could not clean all of the crud (left behind) off of the keg using a 24hour soak in TSP followed by a sponge bath. The sponge that I was using had one of those green abrasive pads on it so I used it. It cleaned the stuff off without any troubles at all. However, after examining the inside of the keg, I could see patchy sections of small scratches where I used the pad. The scratches are definitely small (I can't feel them with my finger, or finger nail). But, I was concerned that these may be a place that little nasties may take up residence and trash the next brew I ferment in this keg. Does anyone have any idea if I really need to be concerned about this? If it is a problem, can I fix the keg (steel wool - very fine grade maybe)? Hopefully the scratches simply indicate an area where the surface 'polish' is different....

Date: Fri, 10 Jul 92 11:59:19 CDT  
From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: Oatmeal (more)

>I had heard/read that you need to mash the (rolled) oats, but never  
heard  
>you needed to mash it with equal amounts of X-row malt -- what are the  
>advantages to doing this over just mashing the oats by itself? is this  
>combination necessary? in trying to determine the amount of other  
>fermentibles to use in the recipe, how much should I expect the mashed  
oats  
>and/or malt to contribute?

Oatmeal and steel-cut oats do not contain amylase enzyme, which is  
necessary to convert the starchy oats into sugars. Lager malt  
is a good source of amylase, or you can add diastatic malt syrup  
or supply the enzyme from a refined source. The advantage of the  
lager malt is that the husk material forms a grain bed which will  
act as a filter when you sparge. Ale malt will work also, but  
is not quite as high in enzyme content.

More On Diastatic Malt Syrup:

>I thought I'd try using this as the basis for a light pale ale and was  
told  
>that because the DMS still contained active enzymes that I should mash  
the  
>adjunct pale malt (I was planning to use in the recipe) in the DMS. I  
guess  
>I'm looking for a confirmation on this and perhaps a little procedural  
>advice.

Pale malt is not an adjunct. (Most) anything that is malted supplies  
amylase  
enzyme, anything that has not been malted doesn't, and is called an  
adjunct.  
Other than the terminology, you're on the right track.

a couple of people brough some goldfinch to our 4th of july picnic.  
it's pretty nice stuff, good balance leaning towards hops. it's an  
amberish color and looked like the stoud's fest ale that we were  
drinking.  
it's contracted out to the lion brewery in wilkes-barre, pa. here's  
what jackson has to say on lion:

Old-established brewery in Wilkes-Barre, Penn. Products  
include \_Stegmaier 1857\_ (\*\*), a super-premium lager with a  
hint of new-mown hay in the nose and a hoppy finish, and  
\_Stegmaier Porter\_ (\*\*->\*\*\*), once said to contain licorice  
which it no longer does, but still tastes of it (a small  
proportion of molasses is used, perhaps that is the tang?).  
The brewery has also produced a cherry beer, an oatbran lager  
(for the health-freak market), and a gin-flavored malt  
liquor, \_Sting Ray\_.

hmm, i don't know about that gin-flavored malt liquor, yuk. i would  
recommend the goldfinch, though, it's pretty good...

Date: Fri, 10 Jul 92 10:25:12 PDT  
From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: egs

As a fairly new keg user I thought I would add my \$0.02 worth about kegs and keggings.

I now have 4 soda kegs and use them for both primary and secondary fermentation. In two of the kegs I have short (~1 in) copper caps on the bottom of the pick-up tubes, the caps keep me from pulling up alot of yeast from the bottom of the keg, these are my primary tanks. After three to five days in the primary I transfer to the secondary and let the beer ferment out. In both the primary and secondary I use blow off hoses. I then prime with corn suger as usual and let it condition as needed. I have let stouts condition up to 6 months without any refrigeration. Kegs should work just like bottles, if properly sealed and unopened they can last for months with no problems. If you want to force carbonation or counter-pressure bottle you must to have a refrigerator, the beer must be cold (30-40 degF) in order the get the co2 into the beer. I just pick-up a good used regfrigerator for \$ 25, it is not pretty but work just fine. Last winter I just kept my drinking kegs in the garage and they stayed about the right temperature for drinking but with the warmer weather this no longer works. I do not filter my beer yet but I would like to add this option, as I understand it is quite simple to construct a filter using a water type filter housing and 0.5 micron filter. There are a number of very good articles in Zymurgy about most of this stuff, if you anyone wants these e-mail me and I'll pass on the info. A last piont about tanks my first tank was a 2.5 lb tank and I got two or three batches out of one fill, this included transferring, drinking and cleaning. I bought this tank used with a current hydro-test ( all co2 tanks must have current hydro-testing to be filled) for \$ 30 for a fire e, I just got a 20 lb tank for \$20 from a scrap guy but it must be hydro-test at a cost of about \$20 before I can fill it.

In short I love my kegs and my total cost so far I only have less than \$ 150 in the whole set-up including the refrigerator.

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: Re: HBD 920

Greetings all,

In #920 Craig Vandeventer asks about the need for adjusting the pH of sparge water.

Craig, this has, as I recall, been previously discussed on the digest, and is also covered in some of the homebrewing books, Miller in particular. The basic reason for adjusting the pH of your sparge water is to avoid extracting tannins from the malt husks, especially as you near the end of the sparge and the pH of the naturally rises. With a significant portion of dark roasted malt in the grist this probably won't be a problem, but is definitely a concern with paler beers. The tannins, if extracted, will impart some rather harsh and astringent notes to your beer.

Also in #920, Phil Calvin DoD #242, asks a load of questions. Among them are: What is a cold break? Hot break?

This is something akin to beating a dead horse, given the extended discussion that went on not too long ago. Be that as it may, the short answers are that hot break is the proteins which become insoluble during the wort boil, the ones which make up the trub in the bottom of your kettle, and cold break is the proteins that become insoluble during wort chilling, the ones which end up in the bottom of your fermenter (assuming that you didn't run the hot break through the chiller). Since this we've been around the block on this one several times recently, if anyone wants to pick nits on my simple descriptions please do so via private e-mail.

And lastly, also in #920, Bryan Gros asks about mashing specialty malts, and about working with the various types of oats out there.

Bryan, I think that if you ask two homebrewers about whether or not you should mash specialty malts you will probably get at least three opinions.

For what its worth, my opinion is that if you are doing at least a partial mash already, you should include the specialty malts in the mash. Some of these malts may still contain some starch, which the mash should convert. Even when that isn't the case, I think that the end result is a better marriage of malt flavors if the whole bill of goods is mashed together. For extract brews, with no mashing involved, you probably should just R,DW, HAH.

As to the oats, Quaker oats (at least their oatmeal) are simply rolled oats

with a brand name. I don't think that steel cut oats have been rolled, and don't know what the hell milled oats are. Any rolled oats, branded or generic, can be added directly to your mash as their starch has already been gelatinized by the rolling process. With the steel cut oats you should probably cook them first to gelatinize the starch and make it amenable to enzymatic conversion in the mash kettle. Since the starch in the rolled oats has already been gelatinized, they would be the best choice, unless for some strange reason you want to extend the amount of time it takes you to accomplish your mash.

Ooogy wawa,  
Dr. John

>I have left it chilling overnight, and periodically made sure that the  
pressure  
>kept at 40lbs (I don't have them actively hooked up to the CO2 tank).  
They  
>should be at temperatures below 50F. I will shake them more at home.  
Lastly,  
>when I serve them, I keep the pressure at 5-7psi, but what should the  
storage  
>pressure be? Still 5-7psi or leave at 40psi?

You will have to figure the storage pressure by trial and error. 40psi  
at 50f will give you 4.5 volumes of CO2 - explosive by any measure!

If you have a british style beer you want ~2 volumes. At 50f  
the equilibrium pressure is 12lb I store and deliver my beers at 48f and  
around 15-18lb. A little fizzy for english, a little flat for german.  
No big, I just pour from a great height to kill the carbonation. It  
mostly works out in the end. For german beers you want around 2.5-3  
volumes which works out to 18-24psi.

The table I am working from comes in the fall 1990 Beverage Peoples News.  
Their info line is 1-707-544-2520 (greater fermentations of Santa Rosa).  
Perhaps they can give you a back copy? It also has a good discussion of  
force carbonating your beer.

Cheers!

Subject: Fridge thermostats

Roger suggests using the Honeywell thermostat for converting a fridge to our temperature range. I put forth that a Hunter AirStat or Hunter Energy Miser (?) window air-conditioner thermostats are much easier to use and are cheaper. I paid \$24.95 for mine at Builder's Square. It plugs into the wall outlet, the fridge (or in my case chest freezer) plugs into the outlet on the front of the unit and a remote sensor is at the end of a ~3 foot plastic covered wire. No cutting of wires needed. A different Builder's Square in my area charges \$29.95 for the same unit -- I was told it was because that store suffers from a lot of shoplifting. If you live in Anchorage, and window air conditioners are foreign to your area, ask your hardware store owner to order it from Hunter (the ceiling fan people) and make sure you get the model that has the outlet on the front (the window air-conditioner model).

Subject: re: seeking Heineken-like beer

Someone asked for a recipe to get a Heineken-like beer.  
A favorite of my friends is recipe based on the Complete Joy of  
Homebrewing's "Dutch Pilsener" recipe in the partial mash  
Section (intermediate section?). Sorry, I don't have the recipe  
in the right form since I am at work but from memory I substitute  
Alexander's Pale extract for his extract and use Wyeast Danish Lager  
or Wyeast European Lager (which I prefer). However, I don't  
make it as real lager since I do it in the dead of winter with  
my 60 degree basement. Finally, I found a hopping pattern of using  
half the suggested bittering hops with 15 minutes to go rather than  
all at the beginning of the boil gives a better flavor.

I made this several times and recommend especially for those wanting  
to go from extract to all-grain but are prefer to play it safe. Partial  
mashing is a good way to make the transition.

Russell writes:

>Gases are \*more\* soluble in water as temperature drops,  
>and I suspect that beer is enough like water for this to hold  
>>true in brew.

Yes, I agree.

>Perhaps the length of the tubing in the "jockeybox" is the problem.  
>The amount of beer sitting in the tubing and the amount of time  
>any sip of beer spend sitting in the tubing increase with tubing  
>length. 10 feet of tubing with a cross-sectional area of 1 cm<sup>2</sup>  
>will easily accommodate an entire glass of beer.

I think the problem I had was that this was industrial beer being dispensed continuously from a rented (grungy lines) jockeybox. I still believe, though, that the pressure would have to be pretty high to get the CO<sub>2</sub> to dissolve into the beer in the keg which is at, say 68F. This would be much too high a pressure for dispensing the beer. Even if the beer got to spend a few hours at 50F, so much of the dissolved CO<sub>2</sub> would stay in solution when the beer finally came out of the faucet, the pressure drop may still cause it to foam a lot. That was my hypothesis regrding the situation presented.

john>Does that mean you advocate not introducing oxygen into the keg?  
john>I know some people say that they flush the air out with CO2  
john>before racking into the keg. If this works, it should answer the  
john>original question.

I do advocate minimizing the introduction of oxygen after fermentation  
is complete. The original question was "does priming eliminate  
oxygen during aging?" The answer to this question is still no.

>You had better find a way to keep it cold. You also had better  
>buy a CO2 tank and regulator (it sounds like you don't have  
>one). Refrigerated (if you have good sanitation) your kegged  
>beer could stay good for a year. Unrefrigerated, well, I  
>wouldn't recommend it.

I have wondered about this myself. Does anyone have an  
explanation for it? Considering that your bottled beer will last  
a year at basement temps just fine, why shouldn't a keg do the  
same? Is it because air gets in when you tap the keg? Or do  
just microorganisms get in? Or what?

Well, if your sanitation is good, it should not \*spoil\* whether in  
bottles or kegs, however, the flavor and primarily the nose suffer  
more at 70F than at 50F.

Subject: Stainless Steel Brew Pots

Greetings Brew Brethren:

At the risk of restarting the which is closer, Iowa or Minnesota debate ] :-), not to mention the commercialism debate ]:-), here goes. This is the best price I've seen on a restaurant grade stainless steel stock pot. The price is about 25% less than Superior Product's, for the same brand and model.

Pots: 40 qrt. 19 gauge Polar SS pot @ \$67 and lid @ \$16 plus shipping as of Spring '92.

Other stuff: A variety of things from the catalog including  
SS pots (from small to gigantic)  
Aluminum pots (heavy, professional quality)  
Glassware by the dozen (mugs, pints, etc. \$8-14/dozen)  
Strainers  
Plastic containers in all sizes  
Bus and commercial dishwasher trays  
Great Rubber Gloves (elbow length)  
Knives

De Luca's is a wholesale place, may not do a lot of hand-holding. Also, all sales are final. They will ship, special order, etc.

Address: DeLuca's Restaurant Supply  
2700 27th Ave. So.  
Minneapolis, MN 55406  
612/721-0230 Normal hours plus Saturday Mornings.

Disclaimer

I am not employed by, related to or receiving any kind of compensation from De Lucia's.

>I am an extract brewer who is looking into doing full mashes... A couple of posts recently have confused me about the whole mashing process. As I understand it, adjusting the ph of mash water.....

I don't doubt that ph can be important. Like to a profit oriented commercial enterprise or if you really have wierd water. But PLEASE do not let this bit of esoterica keep you from making the leap to all grain. It is part of the science but don't let it interfere with the fun. I quit messing with ph after going through the exercise on my first batch.

>P.S. Jack, I just received my KitchenAid grain mill in the mail. If you'll give me the freebie(if I'm not #100) I'll do a side by side comparison and post the results here. If I like the Kitchenaid mill better I'll return yours; otherwise, I'll sell my Kitchenaid mill.

I have a better idea, send me the Kitchenaid and I will do a review. I have been drooling over one (for bread making) for years. I suspect it will make great beer bread. As an alternative, just tell us how long it takes to mill a pound and you might pass along the total cost to those not familiar with that wonderful machine.

As a point of interest, I offered to swap a MALTMILL for one of those Italian jobs but the guy invested \$90 in an electric drill to drive it and was approaching the thruptut of a hand cranked MALTMILL and declined my offer.

Of course the same offer applies to your Kitchenaide :)

>From: klm@mscg.com (Kevin L. McBride)

> Considering that your bottled beer will last a year at basement temps just

fine, why shouldn't a keg do the same? Is it because air gets in when you tap the keg? Or do just microorganisms get in? Or what?

I think it is, "Or what?" Which of course translates to MOMILY.

There clearly is no difference other than scale.

However, the recurrent use of the terms "air" and "oxygen" could be clues.

Neither can get into a properly sealed and stored keg.

It may not be obvious to the casual reader but the use of hand pumps on party

kegs is one reason kegs, so abused, go bad. The hand pump obviously pumps

air into the keg which guarantees oxidation and limits the drinkable life to weeks if not days.

>From: Jeff Benjamin <benji@hpfcbg.fc.hp.com>

From: korz@iepubj.att.com  
Subject: Re: adjusting pH of sparge

Craig asks "why adjust the pH of the sparge water?"

The reason for this is that high pH water tends to extract more astringent flavors from the husks of the grains. Lowering the pH (making the sparge water more acidic) will extract less of these undesirable flavors.

Subject: Frank Jones, then and now

Hi all,

This past weekend, while brewing up a festbier, my brewing partner and I conducted a side-by-side comparison of the older, contract-brewed by Catamount version of Frank Jones, and the new, brewed in Portsmouth version.

It seemed to both of us that the older version had both slightly more hop bitterness, and slightly more hop flavor. It (the older version) also seemed just a bit lighter in color. Does anyone know if Frank Jones changed the recipe? Has anyone else noticed the difference??

BTW, this change will not dissuade me from drinking and enjoying Frank Jones. IMHO, still a fine beer, even if it is \*shudder\* storebought.

p.s. I also posted this article to New England Brewing forum. Normally, I am loathe to cross-post (shameful waste of bandwidth), but I had to get my raffle ticket for the maltmill. How many we up to now, Jack??

**Subject: RE: Strawberries, Pectic Enzyme**

I have brewed 3 or 4 batches of strawberry ale, and have had pretty good results of the last two. I would recommend adding the strawberries around the same time you would dry hop, after most fermentation has subsided, to reduce "scrubbing" of the volatile strawberry essence. The little sugar that is present in the fruit may be enough to affect carbonation, so I would let the fermentation go at least a few more days. You can add the berries to the primary, but definitely rack after a few days. I wouldn't recommend adding the fruit just before bottling. Pectic enzyme works very well to reduce the pectin haze caused by heat pasteurization, which I would strongly recommend you do. I use 1/2 Tablespoon per gallon, and it worked so well and so quickly that you could probably cut back to half that. The stuff works in less than 24 hours.

I forgot one other thing: I use about 1.5 lbs./gallon of beer, and end up with an awesome pink-amber color, strong strawberry nose and finish, and a mild strawberry flavor. Tastes best after it is allowed to warm up a bit out of the fridge. Good luck with it!

From: whg@tellabs.com  
Subject: partial mash questions...

Query for the collective conscieincousness of the HBD. I have been doing partial mashes for the last 6 or so batches (2-4 lbs of grain in a gallon or so of water). One of these days I'll have the money to take it full scale, but until such a time I have a question about my sparge method.

My current method is to mash the grains in my 5 gallon brew pot for about one hour at 150-155 degrees. Meanwhile I bring another gallon or so of water to about 185 degrees in the 3gal pot and then put this into the bottling bucket. Next I pour the wort through my spagettii strainer, which is covered with cheese cloth and supended above the 3 gal pot. After pouring throuth the strainer, I move it (now full of grains) to the 5 gallon pot and pour the wort through the grain bed again, in the hopes that a nice filter bed has been set. Next I pour the water from the bottling bucket (while has by now drop to about 170) slowly through the grains. Sometimes I place a small dish in the center of the grains so the water does not disturb the grain bed.

What concerns me is that the wort drips down from the strainer to the kettle bottom. Will this do anything other than possibly darken the wort? Can anyone suggest improvements to my methods? If I decided to try an all grain bach could I split my boil between the 5 and 3 gallon kettles?

I figure to do 5 gallons all grain I need a better sparge system, a 7-10gallon kettle ( owch! \$\$\$), and of course (let this be #100) a MALTMILL or the likes. Does anyone out there have an opinion on the Phil's Sparge sysstem, or any other ready made spargers? Are you just plain better off making your own?

I've rambled enough,  
Walter

Subject: Mendicino Brewing Company's 4th of July Picnic

Phoebe Couch's post about the 4th of July festivities reminds me of my trip up there. I got married last year on the 6th of July in Santa Rosa. I didn't really want to have a traditional get-wasted-and-watch-women-take-off-their-cloths batchelor party so a bunch of friends and i rented a van and a driver and headed up there.

We missed most of the festivities during the day but were there for the end of the BBQ and for the band in the evening. I hadn't seen most of my California friends for a while so we spent most of the evening sampling various pitchers and yacking it up. As the evening got cooler everyone moved inside except us and one other couple who ended up having sex on the picnic table next to us. So my question is: was that just a special floor show the brewery put on for us that night or is that typical of the Mendicino Brewing Company?

Sure brings back memories - but only up to an uncertain point in the evening!

See Ya

Subject: Friday afternoon ramblings

Daniel asks:

> - Can someone suggest any mail order or sources of used tanks,  
> especially if someplace has experience with homebrewers and their  
> particular needs.

You might try Keg Systems Plus, 2802 E. Madison St. #165, Seattle, WA 98112 (206) 322-2037. He advertises in Zymurgy regularly. I've bought several items from him, and my wife bought a nifty jockeybox for me for Christmas. (Double Tap Stainless Steel Cold \$229. A little pricey, but it's pretty efficient. Doesn't require nearly the ice as a coil system.) Used 20 lb tanks go for \$67. Unfortunately, he doesn't sell used 5 lb. You might also try welding supply houses, and even the classifieds under building equipment.

A used tank is the only way to go. The welding supply store where I get my gas doesn't refill your tank when you take it in. They just exchange it for another tank that is full. It saves them a lot of time doing it that way. 5 lbs will probably be fine with only two kegs. I've got 3 five gallons and 5 three gallons, and I have been able to survive with just 5 lbs, but I am seriously considering adding a 20 lb tank. It seems like I always run out of gas just before a party or brew-club meeting.

Kevin asks:

> Can anyone add to Al's observations on this topic. I plan to start kegging  
> with my next batch of beer. I don't have a place to keep kegs cold. .  
..  
> The kegs will be kept in my cellar at around 65 deg f.

I don't have any long term experience, but I've kept kegs in my garage (which probably ranges from 60-80 degrees) for a couple of months with no noticeable degradation in quality. (I bought another refer at a garage sale to take care of the problem, but the damn thing won't work. Anyone want to recharge my refrigerator in exchange for some beer or cider?)

These have been mostly ales, but several of them have been filtered (no yeast to protect them), and still have survived a month or so at room temperature. (It probably helps that they're under pressure.)

Charlie (me) asks:

If I can talk my wife into a road trip, does anybody have any suggestions on where to stay in Portland this coming Friday and Saturday? Something close to the festival, clean, and if possible a pool (can be VERY small, but my 2-1/2 year old twins won't be very happy after the 3 hour drive, so I will need something to get them to lighten up).

Thanks in advance for any suggestions.

Charles Castellow

Subject: Adding Body to Mead

>> How can one add "body" to a quick mead?

> In my experience, adding more honey (two to four pounds per gallon)  
> helps make the flavor more "real". In addition, remember to skim off  
> the white and brown foam when it is heating/boiling - that helps keep  
> the taste clean.

Adding more honey won't necessarily work. Honey is very fermentable. That means that you end up with very few unfermentable sugars left when it is done. Doubling the amount of honey used will double the unfermentable sugars but will that really make a difference? To get more body you really have to add enough honey that the alcohol level gets high enough that the yeast stops working and you have unfermented honey left over. Using a low-attenuating yeast will help but you'll never get a 'quick' mead that way. Be careful with sanitizing bottles too. Any unfermented sugar means danger of bottle bombs!

>  
> 2. Counterflow -- tube-in-hose chiller. Hot wort is siphoned or  
> pumped through a tube which is surrounded by a hose carrying cool  
> water (usually tapwater)....  
>

I think some of the confusion here is because people forget (3).

3. Immersion -- run hot wort through a coil of tubing which is immersed in a bath of cold water.

I started out using (3) but found that I had some problems with blockage of the tubing by hops - especially hop pellets. Other than that the technique works great. You get most of the advantages of a counter-flow chiller without all the plumbing and yet you don't have to use as much water as you do with (1).

All that notwithstanding a blocked chiller is a really difficult thing to unclog so I converted my (#3) to a (#1) by attaching fittings to connect it to a garden hose. (This also went along with my move from the kitchen to the garage for brewing.)

I don't have any suggestions on how to clear up the ambiguity of what gets immersed in what but let's not jump on someone for being stupid (as some - not the above poster) have done.

See ya  
Geoff Reeves

P.S. I was wrong about HBD #921. It only had 25 messages which brings the total to 95. It will be #922 for sure :-). Also I'm relieved that I can post stuff without looking like I'm out for a grain mill. I'm sure I won't be in the first 5 tomorrow. It just happens to be Friday afternoon on a slow day and I happened to have 7 digests backed up in my mail directory.

**Subject: Hops question**

I ordered some Willamette Hops from a brand-new homebrew supply shop that opened in Manhattan [Yea!!! Now Manhattan has TWO (yes, 2) shops! ]. I used the hops today when making Rocky Raccoon's Honey Lager (more or less, from TCJOHB). The hops were from a distributor called Wines, Inc. The hops appeared to be in deteriorated condition (leaves not attached to cones, lots of loose yellow powder I'm interpreting as lupulin) and there was foreign material present (darker green leaves and stems). The foreign material appeared homogeneous as I watched it toil and boil in my wort.

My question is:

Is this foreign material hops vine and leaf as I suspect, was it harmful to my beer and has anyone had this experience?

Thanks,  
Dan Strahs

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: Belgian caramel malts

The latest installment to the Association of Brewer's Classic Beer Styles Series, Belgian Ale by Pierre Rajotte, makes a brief yet informative reference to a few of the new Belgian malts that are now available to homebrewers in the US:

". . . Carapils (10 to 20 EBC, 4 to 8 L) gives added body to light colored beers and is used mainly in Pilsener brewing. Caravienne (30 to 60 EBC, 12 to 23 L) is used in the brewing of lighter colored Specials and Abbey type beers. Caramunich or crystal malt (140 to 160 EBC, 53 to 60 L) has a definite coloring effect. Finally, Special B is a highly colored caramel malt of 300 to 500 EBC (113 to 188 L) and gives a rich caramel-malt taste. It is used in Scotch ales and stouts brewed under license in Belgium. Darker Specials and Abbey beers at times use this type of caramel malt. Its effect is noticeable in beers, giving lots of additional body and coloring. Beers using Special B have more well-rounded malt character than beers colored with only "candi" sugar. . . ."

Those of you who have obtained some of this new and wonderful malt and don't quite know what to do with it (like me) now have some direction towards its use.

Subject: SF Brewpubs & Maltmill

Thanks to Nick Cuccia's terrific list of beer establishments in the SF Bay area, I had a terrific visit there last week.

Got to Pacific Coast Brewing Co. in Oakland (marvelous atmosphere, good food, only average house beers but a fabulous selection on tap); Buffalo Bill's in Hayward (what can I say -- a classic and good, well-balanced beers with character); Gordon Biersch in Palo Alto (nice place, a bit pricey, and good average beers); Twenty Tank Brewery in San Francisco (a real dive, but again good food and pretty good beer. Also a very friendly and informative assistant brewmaster on hand). Tried the Marin Brewing Co. in Larkspur, but got there while they were closed for the holiday. Looked like a fern bar from the window, but I hear their beer is good. What a trip!

It got me thinking about how far we've come in just the last five years. With this kind of variety (and even the beers I rated as average were "head" and shoulders above their big commercial cousins) our standards are getting higher, too. Maybe we'll get to be a real beer country yet. Does anyone know where the big three candidates stand on microbreweries and brewpubs?

Also, I would guess that I might have been that 100th buyer of the maltmill who gave Jack the idea for the lottery. I have to admit I was skeptical, but after seeing one at the AHA conference last month and rereading George Fix's favorable review, I took the plunge. After one trial, I'm glad I did -- got an almost perfect crush and improved my extraction rate. Usual disclaimers, but thought in fairness I should let people have another unbiased opinion.

From: S94WELKER@usuhs  
Subject: FL, OH brewpubs; fruit sanitizing suggestion; maltmill

I will be doing some traveling soon; and was hoping to find some brewpubs in the Fl panhandle or southern AL (is that redundant?). If anyone knows some good spots, send me a message (and I'll post a summary) or post it, what the heck. "S94WELKER@USUHSB.BITNET" is my short address. Second, I have a suggestion for those who hope to sanitize apples for cider... or any other fruit for brewing. Blanch them. This means "dunk in boiling H2O" for a while. I think killing off some of the bugs on the surface would give the yeasties an advantage (and with the other methods suggested, increase the odds of a large yeast population). I have used this method for strawberries which were added to my secondary, and I had no infections. For apples, blanching would have the added advantage of removing wax (added by distributors) and some of the chemicals (although those are a trivial consideration-- cirrhosis and DUIs are our primary threats).

Finally, I am posting this message at this time because of the maltmill shenanigans js is pulling. I am hoping I will be the big winner so I can refuse the prize (being a satisfied extract brewer with no plans to change). Do you watch ESPN, Jack? Well, now you won't need to.

While the DC area is devoid of brewpubs, we have a number of bars well-stocked with microbeers (tops is the Brickskeller; 500+ varieties). Travelers to our city (fair it ain't) should definitely see the place and have one of the 7 SN products, or Dolle Brewers' Bos Keun.

From: megatek!slover@suntan.West (Steven Slover)  
Subject: Source for Stainless Brewpot

Greetings,

I am looking for a source for a large, stainless brewpot to use for a full boil. What size do most people use, 8-10 gallon? I know I could find something at a restaurant supply store but it would probably cost over \$100.

I think I have read here that some people have used old kegs with the top cut off. Is this true? What kind of kegs are they? Anybody have any other ideas for brewpots? It doesn't have to be pretty but cheap would be nice.

Thanks for any info.

Steve

Subject: re: unrefridgerated kegs

In digest #921 Kevin asks about keeping beer in unrefridgerated kegs. I've been doing this for about a year now. The beer keeps well at 65F but its character will continue to change. Keeping the beer at 50-55F slows down the maturation process. Also if you bottle from the keg and then chill the bottled beer it tends to be flat, since the carbonation level in the warm keg will be much lower than that of the chilled bottle temp. Apart from these minor problems you shouldn't have any problems. The Hunter Air Stat is definitely the way to go. I've bought the Air Stat I just haven't gotten 'round to finding a refridgerator. I just can't wait to carry it up the stairs:-)

Cheers,  
John

> 3> Has anyone out there tried making malts? Any publications on this?

At the risk of being commercial, I demonstrate how to make a small batch of malt in my video. It's great fun but just for the exercise. It's cheaper to buy than make. Perhaps one of the nice people out there who received free review copies would like to pass it along to you.

>Lastly: to Jack Schmidling: re: maltmill giveaway... All the systems network managers want to thank you for stress testing their mailers.

I am sure the surge of articles lately is only coincidental.

We are at 69 (as of HBD #920) and counting.

>A few words of "comfort"? My father, when he retired, found that he had to retire about four more times over the next few years from the full time "amusements" he built for himself. Best of luck.

Thanks. There is nothing that boggles me more than to hear retired folk whining about being bored and pining for their job back.

BTW, I retired at 43 and I have never wanted my job back for a nanosecond.

Is taken to mean... adding 5 gals to a ten gallon batch or adding 10 gallons to a 10 gal batch?

>From: ukcy@sunyit.edu (Kevin Yager)  
>Subject: Unrefrigerated kegs of HB

] A used chest freezer with a Hunter Airstat thermostat is the best way to go.

No doubt but.....

] I suspect you will have trouble with carbonation since the solubility of  
] CO2 varies greatly with temperature. I've tried dispensing cool beer  
] through  
] a jockeybox (what you described) and had a heck of a time getting the  
] CO2  
] to stay in the beer.  
] Al.  
]-- End of excerpt from korz@iepubj.att.com

>Can anyone add to Al's observations on this topic. I plan to start  
kegging  
with my next batch of beer. I don't have a place to keep kegs cold. I  
do have a small dorm sized refrigerator which I plan to run some tubing  
through. Effectively the same as a "jockeybox".

I can only add by disagreeing totally. I have no fridge in my basement  
and  
have never refrigerated kegs. I do not know about your jockey box but I  
use  
a "cold plate" which is a stainless tube serpentine imbeded in a cast  
aluminum plate. It is about 8 X 12 X 1 and cools beer as fast you I can  
draw  
it. It holds less than two oz of beer and two cups of cubes will chill  
a  
couple of glasses. It sits in the bottom of a plastic dish pan with  
the tap  
on top of that. I brought it to Milwaukee with a keg of you know what.

In my experience, "after chilling" gives the ultimate control in  
carbonation.  
No matter what level the carbonation is in the keg, chilling on the way  
out  
will force the carbonation to stay in the beer. It also allows you to  
maintain a higher CO2 pressure in the keg than could normally be used  
for  
dispensing because of the restriction in the plate.

It also makes bottling a snap. Release the pressure in the keg to just  
enough to move the beer and foamless, chilled beer runs into the bottle.

The plate is available from any bar supply house.

>From: Jay Hersh <herhsh@expo.lcs.mit.edu>  
>Subject: ale yeast ferments to freezing (NOT!)

>What ale yeast is this?? Did you mean lager yeast. All the Ale yeasts I  
have  
ever used tend to flocculate out and go dormant when I drop them to cold  
temperatures (like say below 45F), in fact I, and many many brewers  
commerical and home, rely on this behavior to stop fermentation and  
clarify the beer, it even has a technical name for it, called cold  
conditioning.

>Care to enlighten us???

Sure. Most readers didn't need enlightening. They recognized the error  
and  
answered the question. But some folks just can not ever let an  
opportunity  
to be nasty pass.

Obviously, I was talking about lager yeast and the problem I anticipated by storing culture slants.

To try again..... in light of the fact that lager yeast ferments down to freezing, how is it possible to store culture slants in a refrigerator for months without depleting the media. I am in the habit of tightening the caps on ale yeast culture tubes but this seems like a prescription for disaster with lager yeast.

Now, would you like to try again?

93 and counting as #921. Looks like Monday is the big day. Sure hope I win one of those beauties.

From: yoost@judy.indstate.edu  
Subject: CO2 tanks

I have found that Beer Distributors have CO2 tanks taps etc. and are usually very helpful.

I bought a refrigerator conversion kit for \$130.00 consisting of:

5# CO2 tank w/reg  
tap to fit through door  
all hoses & connectors

I have both types of keg hookups Genny type (12 horse Ale) or Coors type (George Killian's Irish Red) I have a hose clamp that I can use to change and when I start kegging in Pepsico Kegs I will just change to that.

I may put a short length of hose and 'Quick disconnects' on all of them.

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>  
Subject: Counterflow chiller plans, killer sparge gadget

I realize this has been asked before, but, like everyone, I didn't save the discussion because I didn't need it at the time.

Does anyone have plans they can [e]mail me for a counterflow wort chiller? The concept is pretty straightforward, but it isn't obvious how to build some of the fittings.

Thanks in advance. As payment, here's a handy tip for you all-grain brewers out there.

Tonight we just tried out some new lautering hardware that beats the Zapap lauter tun hands down (Charlie, how could you have lead us astray? :-). Build a sparge "manifold" out of 1/2" copper tubing with slits in it that goes in the bottom of the mash tun. When you're done mashing, simply siphon off the sweet wort and pour the sparge water over the top of the grain. No need to transfer the mash to another container or drill holes in you mash pot.

The manifold is made with about 5 feet of tubing, 4 tees, 5 endcaps, one elbow, and one step-down for matching the size of the plastic hose. We mash in a round pot, so it looks something like (attempted silly ASCII graphics follow):

```
|  -  
+-----]  
  [-----+  
+-----]  
[-----+  
|  
90 deg up /=====----->to hose
```

The horizontal arms have 4-6 slots cut in them, 3/4" apart, facing downward, and sit in the bottom of the tun. Then the elbow turns up the side of the tun and connects to the siphoning hose. Standard copper fittings are tight enough you don't even have to solder. Just cut the pieces of tubing so that the manifold fits snugly in the bottom of your tun.

It sparges just as well as the Zapap unit, and is easier to use, and cost only \$5 to make. Oh, make sure you put the manifold into the tun \*before\* you add the grain, not after.

Subject: Trub

I just made a batch of beer, and this is the first time I have worried (yes, I worried!) about letting the trub settle out. Only problem is that it took overnight for it to all fall out, even after the wort is completely cooled. My question is how much damage can be done by letting the stuff sit overnight to let the trub settle out, then rack to another carboy and pitch the yeast. I know there is a significant risk of infection, but I think I can control for that. What risks of oxidation or other things exist, and how much should worry about them? Does anyone know a better way than I propose?

Thanks in advance for any information!

From: bickham@msc2.msc.cornell.edu (Scott Bickham)  
Subject: Volume Brewers: Any wheat beer recipes?

A couple of brewers in our homebrew club asked for some help in formulating a recipe for a Weizen or Dunkelweizen. They will be making a 50 gallon batch, so any tips on doing a sparge with approximately 50 lbs. of wheat will be very useful.

Since I am on the subject of Weizens, this style, as well as Alt and Koelsch beers benefit from a cold lagering during the secondary stage. Since most ale yeasts are almost dormant at 45 F, would it be beneficial to inoculate the beer with a lager yeast before the lagering period? If anyone has ever tried this, I would be interested in finding out the results.

Happy Brewing,  
Scott (bickham@msc.cornell.edu)

From: Murray Robinson <robinm@mrd.dsto.gov.au>  
Subject: Novice brewer needs help

As a novice brewer I have a few questions about home brewing.

1. What are the best sterilsing agents and procedures to use in order to prevent the little airborne nasties infecting my brew.
2. If one brews from commercially available kits and then adds additional driedmalt to the brew (instead of sugar) can you experience problems with the yeast not being capable of fully fermenting the liquor due to high malt content? (if yes - how do you overcome it? )
3. What's with this racking the beer after primary fermentation? In Australia, no one mucks around with this step. I know it is supposed to allow for a much clearer beer but aren't you increasing the chance of infection? If anyone does use this method with success can you please let me know exactly what steps you go through in terms of sterilisation, when to rack, how long , etc.
- 4.Does anyone out there have a list of the various hops varieties available and whether their use is suitable for enhancing aroma or bitterness or both?
5. Can anyone give me the address and fax number of zymurgy so that I may subscribe?

From: oehler@smpvax.dnet.ge.com  
Subject: Silicones and You

Good Morning all,

Just a bit more about silicone caulking. As I understand it, there are silicone grades available that are FDA approved for food use. They should handle both the temperature and the pH of the mash. They will corrode a copper pipe, however. The acetic acid released as they cure is responsible. Also, when trying to seal a thermoplastic cooler, they may require a primer to adhere properly. The primer may not be FDA approved.

Therefore, it is suggested that a mechanical solution be found instead.

From: ssi!mtd@uunet.UU.NET (Michael T. Daly)  
Subject: Bay Area Bottled Beers

Thanks to Nick for the further info. Also, thanks Russ for the list of places to shop (and not shop). Now for the tough problem. Suppose I walk into one of these places and there in front of me is a set of shelves with 50 (ok, I'm dreaming, maybe 20) different local beers. Which are worth packing up and bringing back to Wisconsin on the airplane?

I have had some of the Anchor and SN products, and I plan on looking for additional varieties which they don't ship (I found the SN Mai Bock in Ft. Collins CO. Very nice. Almost convinced me to start lagering.).

I have had mixed impressions of the San Andreas Brewing Co's Richter Scale Ale -- the first year was very good, the last one I had tasted like orange juice....I think I'll skip them. I seem to remember that Devil's Mt. is out of business....too bad, I liked their porter. I'll get some of the Dead Cat Alley (or what ever they call themselves) products, but I still have a half of a suitcase left....suggestions?

I am especially interested in varieties which I can buy in less than 6packs -- 10 different 6packs leads to either lots of fat about the nether regions (and problems walking) or leaving something behind (not to mention the serious sudden dent in the wallet).

(Russ mentioned Anderson Valley, Winchester, Rogue and Mendocino. Who else?)

It sounds to me like the odor was derived from the stocking, but not necessarily the nylon itself. The obvious explanation would be your girlfriend's feet. But since we treat brewing as a science, I feel that you are now responsible for proving this theory. At your soonest convenience, please stick her feet in a pot of water and gradually raise the temperature.

Take careful notes as to which temperatures produce the aforementioned odor.

If the odor begins to dissapate as you approach 170'F, then we can safely say that we have identified the cause. Try not to confuse the smell of the boiling flesh with the unidentified odor.

Sorry for any offense, but I couldn't pass this one up >:-)

From: ncrcae!brew@devine.ColumbiaSC.NCR.COM (Jim Griggers)  
Subject: Beating a dead silicone, sanitizers

My silicone sealant that is manufactured by Dow Corning and marketed by DAP

has this on its label:

SAFE FOR FOOD CONTACT: When cured and washed, ingredients which remain or which could migrate to food are listed in FDA Regulation No. 21 CFR 177.2600.

There is also nothing in the Material Safety Data Sheet that would indicate food contact should be avoided. I don't have a copy of the FDA regulation, so I don't know what chemicals are available for migration. I personally would not worry about the short term exposure of wort leaching something poisonous from cured RTV.

Chris Lyons asked about an alternative to chlorine in sanitizers. I have just switched to Iodophor because of a recommendation by George Fix. In the recommended concentrations, rinsing is not needed. I have only used this for my last batch which is still in the primary, so I can't confirm its efficacy. Price wise, it is fairly expensive. I bought a case of 6, 1/2 liter bottles for about \$30, which I figure is a lifetime supply. One quarter fluid ounce of Iodophor makes 2 1/2 gallons of solution with 12.5 ppm titratable iodine.

I was going to post on my home-made temperature controller for a refrigerator that used a Hunter programmable thermostat. The nice thing about it over the Air-Stat is that the set point can be set lower than 40F. However, it is no longer available and the new Hunter thermostats have a "feature" in which the a/c control is turned off below 45F.

Date:Tue, 14 Jul 92 11:05:33 EDT  
From: William Boyle (CCAC-LAD) <wboyle@PICA.ARMY.MIL>  
Subject: calculating yield

I have noticed a few questions about converting from dry extract to syrup or from all grain to extract. The easiest way to convert SG's is to know what the yield of each item is and convert. If a recipe calls for a SG of 1.050 and one pound of dry malt yields 45 pts/gal = 9 pts/5 gal, you would need  $50/9 = 5.55$  lbs of dry malt. Also if a recipe calls for 7 lbs of grains which yields about 35 pts/gal (I know this is ideal, but you get the idea)  $7 * 35 = 245$ pts total,  $245/45$ (pts for dry) = 5.44 lbs of dry malt. I know this may be confusing, not the math but the way I have explained it.

Here are two lists of yields which were posted previously (sorry for stealing your work, but I hate typing and I did not want to make my own list, so if there is any error don't blame me :-)).

I treat my entire supply water with gypsum (about 1gm/gal). That seems  
to acidify the mash and the sparge quite well. I get excellent extract  
yields, but I wouldn't draw the conclusion that my yields are a result  
of my sparge water acidification.

Subject: Jockey Box

I,ve been using a jockey box that I bought from Foxx for several years now. The trick to pouring beer with a nice creamy head and retaining a nice level of carbonation is to run the CO2 pressure at 21 lbs. You need this high level of pressure because your draft lines are very long. If the pressure is not sufficient, the CO2 escapes from the beer because there is not enough pressure to keep it in suspension. The CO2 pressure actually drops over the distance that the beer has to travel and by the time it reaches your tap it's at the proper pressure. A lot of people mistakenly think that when they have their first tapping system that if they're getting a lot of foam when pouring a beer that the pressure is too high - it's just the opposite, it's too low. There is a formula, which eludes just now, for calculating line pressure but the standard pressure for 20 to 30 feet of draft line is 21 lbs, start at this pressure first and then adjust - if still a little too foamy then raise it a few pounds.

I keg my beer in Cornelious kegs and bottles but the kegged beer tastes much fresher and the head is always creamier. I have also setup a refrigerator system. If anyone has any questions about any of these systems, I would be happy to answer your questions. I,ve been using these kegging systems now for almost ten years.

May your beer give you good head!!!

Subject: Wyeast wheat

John asks about Wyeast wheat yeast.

I've used this once, fermented at 69F and got no clove character. I've since spoken to several others who have used it, as well as a few posts in HBD awhile ago, and the consensus is that you need to ferment at a higher temperature, say, 75F or 80F to get the clove character. Wyeast wheat yeast (#3056, I believe) is a mixture of *S. cerevisiae* and *S. Delbrueckii*. It's the *Delbrueckii* that gives the beer that clove character so necessary for the Bavarian Weizen style. It appears, from what I've read and heard, that higher temps favor the *Delbrueckii*.

Subject: Belgian ale

I recently made a batch of Belgian ale using some Belgian malt I ordered from Liberty. The malt is distinctly different.

I haven't found Chimay yeast to be slow at all. In fact, since I started using better aeration techniques, I've found it to be pretty snappy.

I am not fond of banana odors in my beer, so I try to keep the fermentation temperature below 70 degrees. I still get a great deal of that "Belgian" character to the beer.

Date: Tue, 14 Jul 92 13:00:36 CDT  
From: tony@spss.com (Tony Babinec)  
Subject: brewing your own sierra nevada pale ale

This recipe ought to get you close. Try it, see how the beer turns out, and then make changes.

Sierra Nevada Pale Ale, the bottle product, has a starting gravity of 1.052, while Sierra Nevada Draught Ale, the draft product, has an SG of 1.048. The draft product tastes a bit sweeter, too. Malts in the grain bill include pale malt, crystal malt, and dextrine malt (aka cara-pils). Hops used are Perle and Cascade. The yeast is their own, which you can culture from the bottle or obtain as Wyeast "American" ale.

So, for a 5-gallon batch, assuming 75% extraction efficiency, try this:

9 pounds U.S. 2-row pale malt  
0.5 pounds crystal malt (60L)  
0.25-0.5 pounds cara-pils malt

1 ounce Perle (alpha=6.5), 60 minutes until end of boil  
0.5 ounce Cascade (alpha=6.3), 15 minutes until end of boil  
0.5 ounce Cascade (alpha=6.3), end of boil

Wyeast "American" ale

Mash at starch conversion temperature of 153/5 degrees F.

Comments: the crystal malt is fairly dark for some color, the cara-pils is there for added body and sweetness. But, don't overdo it with the specialty grains. The relatively high starch conversion temperature will promote body and sweetness. Perles are the signature bittering hop, while Cascades are for flavor and aroma. If I remember, SNPA comes in at about 32-35 IBUs, and the above hop schedule should get you in the ballpark. I don't believe Chico dry-hops SNPA, but go ahead if you so desire.

From: "Steve, dtn 226-2718" <kennedy@ranger.enet.dec.com>  
Subject: Source for reconditioned CO2 tanks

In HBD #921 Dan Roman asked about a source for a source for used CO2 tanks.

There's a company called Bev-Con International (BCI) which lists reconditioned CO2 cylinders (2.5, 5, 10, 15, 20, 50 pound sizes) in their catalog. I acquired their catalog/price list through the N.H. based Brew Free or Die homebrew club. As an example of their prices, the price list I have lists a 5# reconditioned cylinder for \$32.50 (I don't know if this includes the cap/valve). I haven't looked extensively at a lot of catalogs/brochures that carry kegs and CO2 cylinders, but in all that I have seen, this is the first place that I noticed that sells reconditioned CO2 cylinders.

Anyway, the contact information:

Bev-Con International  
6400 Highway 51 South  
P.O. Box 396  
Brighton, TN 38011

Phone: (901) 476-8000  
WATS: (800) 284-9410  
FAX: (901) 476-4811

In addition to CO2 cylinders, their price list includes various makes of beverage tanks (ex. Cornelius) in various sizes, as well as many different types of standard 1/4 & 1/2 size barrels.

Disclaimer: I have no affiliation with BCI and in fact I haven't bought anything from BCI (yet), so this is not even a recommendation. I was recently helping someone else look for a source for reconditioned CO2 cylinders so that's why I noticed BCI sells them and why I have the information.

happy kegging!

Subject: wheat & Belgian yeast

John Freeborg asks:

>With summer in full swing I plan to do a wheat beer. I picked  
>up the special Wyeast wheat beer yeast, but have yet to get  
>the wheat malt. From reading in Miller's book it says for a  
>wheat beer that you must use 6-row malt in the mash with the  
>wheat. The reasoning is that the wheat has no enzymes to break  
>down the sugars, and 6-row has a ton of enzymes (compared to  
>2-row anyways).

>What is the hbd consensus? Any great wheat recipes people swear by?

>From my own experience, I have to save Dave Miller is way off on  
this. I have brewed with a ratio as high as 65/35 wheat/2-row  
barley without any problems. It's possible that the difference  
has to do with the sort of 2-row Dave has access to; he comes from  
the midwest and here in the Northwest we use Great Western's 2-row  
(which seems to be a blend of Klages and Harrington these days).

It may also have something to do with the quality of the wheat  
malt. I wouldn't be surprised to hear that he uses the stuff from  
Briess, which I wouldn't feed to the ducks. I've used either the  
British or the German wheat malts to excellent effect; both are big  
fat grains (with no barley mixed in as has been the case in the past  
with Briess).

Rob Bradley says:

>Prospective users of Wyeast Belgian should still be aware of  
>one point: the yeast is slow. I'm not talking about a lag in  
>getting started, rather that the yeast seems to take forever  
>in finishing. On the other hand, I received e-mail from  
>Larry Barello who tells me that his techniques of yeast  
>washing (described in the HBD more than a month ago) might  
>cure this problem. I intend to try it when the the weather  
>cools off (come to think of it, maybe I don't need to wait!).

Once again, my own experience has been completely the opposite,  
and I've heard the same here in the HBD. I brewed with this  
yeast strain last fall, and the beer went from 1.072 to 1.012 in  
five days. This is not what I'd call a slow yeast!

It's entirely possible that the problem is a lack of oxygen in  
the wort. A shortage of O2 will not necessarily be reflected in  
a long lag time, but will definitely cause an almost-endless  
fermentation. It's also possible that you under-pitched; I  
definitely worked my up from the original bag through starters  
before pitching the yeast into such a high-gravity wort.

If the yeast is not working well for you from the original  
Wyeast supply, then washing it isn't likely to help. Washing  
the yeast pack from the fermenter before storing it in the  
refrigerator is another story.

Brewers! I have noticed the topic of reusing yeast has come up again, and would like to comment, as I have had some success with this technique. When bottling, I dump the yeast from the bottom of the carboy into sterile bottles, cap, and keep refrigerated. A few days ahead of brewing, I pitch into some sanitary wort (Premade, bottled, and refrigerated) to make a starter. When this topic last came up, people said to use the yeast within 3 weeks of refrigerating, but I have had no trouble resuscitating a 3 mo. old culture. Also, someone (Al, I think) mentioned washing the yeast with sanitary water. I have tried this, but found no great advantage. Any junk in the yeast settles out (just be careful when pitching into starter), will settle out of the starter (also pour carefully), not to mention diluted into 5 gal. of wort. Reusing in this way has produced much shorter lag times than when I used to keep agar plates (although single colony starters can't be beat for strain purity). I have kept a Chimay culture, a Chico (WYeast), and German lager (WYeast) going serially for several batches, and only keep a library of stock plates as backup. By the way, I have detected no contamination by colony morphology and microscopy. The one caveat I must add is to practice better than average sanitation. Anyways, IMHO maintaining yeast strains is better than buying new because with time, the yeast become well adapted to you, your setup, and your beer. It truly makes a yeast your own. -Brett

Subject: Great Taste of Midwest

Somebody asked about the Great Taste of the Midwest that Madison, Wisconsin's homebrew club puts on every year. Here is the press release I'm sending out. It is a fabulous time with a ton of breweries. I can post a list of confirmed breweries if anybody wants it. If you are near the area please drop by!

- John

For Immediate Release  
Great Taste of the Midwest  
News Release

On Saturday, August 22nd, the Madison Homebrewers & Tasters Guild will be sponsoring the 6th annual Great Taste of the Midwest Beer Festival. This year's festival will continue a tradition of bringing to Madison the midwest's finest small breweries. Last year, over twenty breweries were represented, serving their hand-crafted beers to over 1000 beer lovers under festival tents. A wide variety of beer styles were served including pilsners, ales, stouts, porters, cherry and wheat beers.

This year's Great Taste will again be held at Olin Terrace Park in downtown Madison overlooking Lake Monona. Gates will be open from noon until 6:00pm. Festival admission of \$12 includes a Great Taste commemorative glass, unlimited tasting of a wide variety of beer styles and flavors, and a chance to meet the brewers. Food will be available, with music throughout the day.

Advance tickets are available at the Wine & Hop Shop on State Street, Star Liquor on Williamson Street, and Steve's Liquor on University Avenue and Mineral Point Road, all located in Madison. For more information on this year's Great Taste of the Midwest, contact Steven Klafka at 608-255-5030.

The Madison Homebrewers & Tasters Guild is a nonprofit club devoted to the history, brewing and appreciation of well-crafted beers.

Subject: Smart Caps

I recently purchased some Smart Caps. If you are not familiar with the brand name, these caps are lined with a material that is supposed to reduce the chances of finding your beer all oxidized when you open the bottle. Enough of the lead in, I have a question about their use. I normally sanitize caps by boiling them for 15 minutes before use. Will this reduce the effectiveness of the anti-oxidants? If yes, how should I sanitize them? Thanks in advance.

Subject: Sparge pH

Subject: Sparge pH Time:7:43 AM Date:7/14/92  
John Freeborg asks about acidifying sparge water.

According to Dr. Lewis at UC Davis, water is not a good buffer, ie. water's ability to alter pH is very weak. In a contest between a mash of 5.0 - 5.5 and sufficient sparge water at 6.5 - 7.5 the mash will win. Only if your local water is on the alkaline side should you worry about modifying the pH prior to sparge. Lewis says that there is no harm in adding lactic acid to sparge water, especially if it makes you feel better about your beer, however the benefit is psychological only.

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>  
Subject: Re: Blueberry Beer

John Cotterill asks:

> 1) Does anyone have a good recipe for Blueberry beer? There is a  
local  
> contest coming up that features fruit beers, and I would like to brew  
one  
> up. An all grain recipe is preferable, but a good extract recipe would  
be ok.

Here's a blueberry beer I made recently. The blueberry character isn't  
as pronounced as I'd like; I think it's partly because the berries  
weren't particularly ripe. The fruit is very subtle, and imparts a  
pleasing wine-like characteristic and acidity. I thought a brown ale  
would lend itself well to the blueberries, and I must say I'm happy  
with the combination.

#### Brown and Blue Ale

6.5 lbs pale malt  
.5 lbs wheat malt  
.75 lbs 80L crystal malt  
4 oz black patent malt (uncracked)  
2 oz roasted barley (uncracked)  
1 oz Goldings (4.9% alpha)  
.5 oz Fuggles (4.5% alpha)  
5 lbs fresh blueberries  
WYeast #1084 (Irish ale)

Procedure: mash in 2 gal. at 130F, protein rest 30 min at 125F, add  
1.25 gal, mash 30 min at 150F, raise temp to 158F until converted (15  
min), mash out 10 min at 170F.  
Sparge with 4 gallons to yield 5.5 gal at 1.046. Add Fuggles and .75  
oz of Goldings after 20 minutes of boil, boil 60 min, add last .25 oz of  
Goldings and boil 15 min more.  
Rinse blueberries in a dilute sulfite solution (after weeding out the  
fuzzy ones), puree, and add to primary along with yeast.

This gave me 5.5 gal of beer with OG 1.046 not counting the blueberries  
(how the heck do you measure gravity with all those solids in there?).  
There was lots of blueberry aroma coming from the fermenter the first  
couple of days, but not very much when I racked after 4 days. I bottled  
after 4 more days in the secondary, at a FG of 1.010.

I think lots of aroma volatiles got lost with all the outgassing in the  
primary; I think next time I may wait to add the berries to the  
secondary. I may also skip the roasted barley, and use only .5 lb of  
40L crystal so the blue from the berries is more obvious.

The next batch is going to be a cherry wheat, with lots of tart  
baking cherries in the secondary and a loong maceration. Yum!

Wheat malt has plenty of enzymes. The potential problem is that wheat is more glutanous, and has less husk material, so may end up sticking up your sparge. Using 6-row might help alleviate this because the larger amount of husks would break up the grain bed.

>What is the hbd consensus? Any great wheat recipes people swear by?

I've never had any trouble with stuck sparges, or with extract efficiency, and I don't use 6-row. I've used 5:5 wheat:British 2-row, and 6:4 wheat:Munich malt, and both methods ran smooth as silk. I should point out that I use a picnic cooler lauter tun. The design of this helps to avoid stuck sparges, in that the liquor flows up through the bottom of the copper tubing- the grain bed is not sitting right on the drainage holes. A standard lauter tun might be more of a problem with wheat malt.

One tip- whatever malt you decide to use, do a protein rest!

>What do other people think of the Wyeast wheat beer yeast?

I think it's great.

From: cmilono@netcom.com (Carlo Milono)  
Subject: Sparge & Decoction

Dear Netland!

I have about fifty batches under my belt, and the last twenty or so have been all-grain. I have four decoction/all-grain batches that have been exquisite! I am curious about something though, that has just now crossed my mind: in decoction, you literally BOIL your grains, and in doing a 'tasteless' American Lager knock-off, I used half 6row and half 2row pale lager malt; it has been said that the 6row has thicker husks and will provide better filtering at the grain-bed, but that the tannins can be bothersome. Also mentioned, is that your sparge water should not be too hot or else you will extract tannins, yes?

Well, the recipe calls for 6row (high tannin) grain, and decoction which boils the grain - sounds like I'll be chewing on a tea-bag, eh? In actuality, all the decoction recipes have been marvelous - a Bohemian Pilsner (Urquell Clone), a Michelob/Weinharts clone, a Maerzen, and a Bock - no bitterness associated with tannins, no chill haze...please explain! I use a triple decoction - classic Noonan - with Dough-in, Acid Rest, Protein Rest, Starch Conversion, and the final mash-out.

Subject: Vinegar making

Has anybody out there made vinegar? My bottle of mother of vinegar seems to indicate that this bacteria is aerobic, and should be fermented with a cotton gauze "lock" which will allow O2 to diffuse. Is this a good idea?

Also... I have some X-mas ale around... and I bet that it would make EXCELLENT vinegar. Only one problem... lots O hops. Will the hops kill the acetobacter? (they are a preservative ya know)

How much alchahol can acetobacter tolerate? The bottle says to dilute wine 2:1.... but what strength wine??? I have pitched some into 2 meads, one of about 6% alchahol (vol) and the other at about 8% ish... but its hard to tell since i fermented fruit pulp, and couled not get an O.G. Will the vinegar be strong enough with 4% alchahol? If you figure most wine is about 12%, dilute 2:1 you get 4%.

thanks for any pointers (or maltmills) you can give me,

aaron

Date: Wed, 15 Jul 92 9:11:33 CDT  
From: tony@spss.com (Tony Babinec)  
Subject: brewing bavarian wheat beer

Wheat malt has a higher protein content than does barley malt. You might employ wheat malt and barley malt in roughly equal amounts. You are looking for the enzymes in the barley malt to help degrade the proteins in the wheat malt. For this reason, when mashing, an initial protein rest is advised. If the usual protein rest is roughly 30 minutes, you might conduct a protein rest for 45 minutes at 122 degrees F before boosting the mash to a starch conversion temperature of 153/5 degrees F.

Wheat malt is also huskless, while barley malt has husks. When properly cracked, the barley malt husks form the grain bed for lautering.

Recipes advise using 6-row U.S. barley because of its higher enzymatic content, but I'd bet 2-row would do fine.

The Wyeast "Bavarian wheat" is--to my knowledge--the only commercial source for *Saccharomyces delbrueckii*, the signature yeast for bavarian wheat beers, and even then, it is blended with an ale yeast. This yeast works fine, so use it. Some homebrewers use dry ale yeasts that are known to be phenolic, but why risk your batch of beer? The Bavarian wheat yeast produces the wheat beer flavor. There have been threads on HBD talking about the presence or absence of a phenolic/clove flavor in the beer when this yeast is used. Byron Burch's article in the Yeast Zymurgy said that the clove character might emerge with age, say, 4 months in the bottle. As a homebrewer, one other way you might influence the flavor character of the beer is by manipulating the fermentation temperature, so instead of fermenting at cellar temperature, you might ferment in the low 70s. This should promote esters, which will give certain "fruit" flavors to the beer, such as banana.

As for a recipe, try this:

4.5 pounds pale barley malt  
4.5 pounds wheat malt  
0.5 pounds cara-pils malt

4 AAUs Hallertauer or other German hop for bittering  
optionally, lightly hop with finishing hop, such as 1/4-1/2 ounce  
Cascades in last 10 minutes of boil

Wyeast Bavarian Wheat yeast

Target starting gravity is in the range of 1.050-1.055, so adjust the above grain bill. For a dunkelweizen, substitute a couple pounds of Munich malt for some of the pale malt, and substitute crystal malt for the cara-pils.

Cracking the wheat malt correctly takes some practice. I set the Corona mill more finely than for barley malt. The idea is not to pulverize the

wheat malt, but to crack it well.

Date: Wed, 15 Jul 92 10:06:03 MDT  
From: scojam@scojam.Auto-trol.COM (Scott James.)  
Subject: Yeast culture idea & Mailing club

I've got two ideas to run past HBD'ers:

1) Anybody ever hear of or tried to culture yeast in Tofu as a growing medium?

Tofu is basically compressed soy bean curds and is high in protein (My Dad used to use it all the time in gourmet cooking, and pizza...) You can get it at most grocery stores, usually a pound for a couple dollars. A lot cheaper than agar, maybe it would work?

2) I think this was discussed before, if so please forgive...

Does anyone know what the legal ramifications/contraints are for mailing bottles of brew through US snail mail? This could be a wonderful opportunity for people to share not only ideas and techniques, but also the brew itself.

I would think it also "sticks in peoples' minds" when they have a taste to match with what they're reading...

Just thinking...

Subject: Watermelon brew...

It's getting close! 100? ;-)

Anyway, about watermelon brew that someone asked about...

A guy in our local brewclub made one. I'm not sure about the exact details but he basically made a very pale ale and added a 20 lb (I think I remember that right) water melon to the secondary. He used rind and all. The beer is great! He thinks that the next time around he will not use the rind as he thinks it gives a slightly bitter flavor, and more melon. He used very little by way of hops if any. If I see him soon I'll ask for the recipe.

This same fellow likes to experiment with odd brews. HE has a friend who works in a candy factory who get industrial strength flavorings. A couple of these are oil based but the others are not. They work well in flavoring brews.

Subject: Sam Adams' attitude

Michael writes:

>Boston Brewing Co. is definitely a brewery with an attitude. They are  
>decidedly snooty about beer, and about their beer in particular.

And then later goes on to say:

>I must admit that, even though I was a bit put off  
>by their cockiness, I really like their beers.

Generally, I don't like anyone (or any company) that has an attitude, but given that Boston Brewing Co. is up against zillions of dollars in advertising from the bland, industrial brewers, I would do the same in their place. It takes a lot to change the tastes of Americans and luckily some inroads have been made, Sam Adams brews included. The left coast seems to have gotten it together already. The Boulder area (in my understanding) is not too far behind. The right coast also has made some progress. Alas, we here at the land-locked middle coast have a long way to go yet. Samuel Adams brews are available in relatively few places -- Baderbrau in relatively few also -- only a handful of beer retail stores carry anything but industrial beers.

Although I wish BBC's tactics were not necessary, I must reluctantly approve, for the good of beer in America. Just think, if a beer like Samuel Adams Boston Lager became as commonplace as Budweiser is now, good beer in America would be the rule rather than the exception.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Michigan State Fair Homebrew Competition

Michigan amateur brewers are encouraged to enter the Michigan State Fair Homebrew competition. Categories are Pale Ale, IPA, Brown Ale, Porter, Stout, Wheat Beer, Bock, Common Beer (Steam), Lager, Pilsner, Continental Dark, Strong Ale/Barleywine, Specialty. Awards will be given to the first 4 places in each class and to Best of Show.

For more information, contact  
Dan McConnell, Competition Director (313)663-4845  
Ken Schramm, Judge Director (313)291-6694  
Mike O'Brien, Competition Registrar (313)482-8565  
FAX (313)485-BREW

Brewers from other states are welcome to enter, and will be judged, but are ineligible for awards. An eight dollar entry fee is due on July 24, but beers must be delivered between July 27 and August 8 (don't ask me, this must be a state fair rule). As far as I can tell, the \$8 covers up to 10 separate entries. Each exhibitor gets a complimentary one day gate pass to the fair (8/28-9/7).

The competition is AHA sanctioned, and is sponsored by the Ann Arbor Brewers Guild, Cass River Homebrew Club, Detroit & Mackinac Brewery, Frankenmuth Brewing Co, Franklin St. Brewing Co, Kalamazoo Brewing Co, Premier Malt Products, and the Stroh Brewery Co.

You will need to get the entry forms from Dan (above); they are NOT the standard AHA forms.

Subject: "Canada Dry" ginger ale

There has been several postings on ginger beer and ginger ales lately. I recently came across a method for preparing the flavouring mixture similar to Canada Dry in a food flavourings text I got several years ago (Food Flavorings: Composition, Manufacture and Use (2nd Ed.) by Joseph Merory (AVI Publishers)). This recipe is not immediately useful as it is compounded of essential oils but should point any inquisitive brewmeister in the right direction.

Grams of essential oil to prepare Ginger Ale Pale Dry

0.5 oil of rose  
0.5 phenylethyl alcohol( a pronounced rosey scent)  
9.5 methyl nonyl acetylaldehyde 50%  
22.0 oleoresin of ginger (responsible for the bite of ginger)  
22.5 oil of ginger (volatile fragrance with no sharpness)  
27.0 oil of bergamotte orange (the orangey scent and flavour present in Earl Grey Tea)  
246.0 oil of orange, Valencia  
300.0 oil of lemon  
372.0 oil of lime

The oils are then dissolved in 95% food grade ethyl alcohol and water with the insoluble fraction which separates being discarded. The 2nd and 3rd ingredients are used to reinforce the rose flavour & reduce the high cost of rose oil. The gingery flavour with little bite which characterizes Canada Dry is due to the large amount of ginger oil present. Due to the great interest in aromatherapy these days oil of bergamotte has become available and is probably available at your local "new age" or natural foods store.

A second formula for a less complex ginger ale contained oleoresin of ginger reinforced with capsicum essence ( derived from hot chili peppers), oils of orange, lime and minor amounts of mace and coriander "with a few drops of oil of rose being optional if a more distinctive character was desired".

He also stated that the active principle responsible for the sharp bite of ginger is only sparingly soluble in water but very highly soluble in ethyl alcohol. The extraction of the compound can be increased without using alcohol if the ground fresh ginger is repeatedly extracted with fresh boiling water. Commercially, this is accomplished with an alcohol/water mixture over several days.

I hope this will be of help or at least interesting. I will post a method for "real" root beer when I find one but am very busy for the near future.

Have fun and happy brewing.

Michael L. Hall Writes:

> and possibly a Cream Stout (they had just made a  
>small batch when I was there). Alas, they had no samples of their other  
>brews for sale (believe me, I searched).

I ALWAYS make a trip to Doyle's Pub (about two blocks from the brewery, get walking directions while you're there) when I take the tour. They have excellent food and ALL of the Sam Adams products available (Where do you think those batches of experimental cream stout go?) I've been able to get the Cream stout there every time I've been and they usually have the Cranberry beer on tap at least 2 months after it sells out in the stores. I don't know why they don't go ahead and release the Cream stout - I like it better than Watney's Cream. The tour guide also usually mentions that the Sunsett Grill has a complete set of Sam Products on tap as well.

I have found that the tour guides tend to vary greatly in their expertise. I've been 3 times and twice had a similar experience as Michael. Once I was treated to a truly knowledgeable guide - answered every question I could ask. Tour all you want - they'll give more. It's the most beer you can get for a buck!

Subject: Some AHA News

In reference to a couple of AHA-related questions in a recent Digest (who knows when this will actually get posted, thanks to maltmill mania - --and a rooty toot to you, Jack):

Next year's AHA Conference will, indeed, be held in beautiful downtown Portland, Oregon. There was a delay in confirmation as the Park Bureau was jerking the Brewers Festival around about dates when they could use the park area alongside the Willamette. The 1993 Festival will be held July 30, 31 and August 1. The conference will be held during the week leading up to the Festival. Be prepared for a LOT of beer, folks.

Good beer, too, I might add; after all this is Portland. :-)

The AHA does not have a generic e-mail address, although the two CompuServe accounts given here are reachable. We have been encouraging the AHA to add a few accounts and it would be nice if they got a net connection. They are actively involved with the CompuServe Beer Forum, and have a special section in the file library there. Sysop Robin Garr also subscribes to the Digest and would love to give you information about accessing any of that information, I'm sure. Wouldn't you, Robin?

From: Mark N. Davis <mindavis@pbhya.PacBell.COM>  
Subject: Re: Acidified Sparge H2O

John Freeborg asks:

> How many all-grain people adjust their sparge water pH? I've been  
reading  
> about putting lactic acid in the sparge water to achieve the proper pH  
which  
> helps improve extraction numbers.  
>  
> Should I worry about this? Do other people? Have you noticed a  
dramatic  
> difference once you started doing this?

Before going any further I should warn you that I'm not an avid pH  
watcher.  
Now that the disclaimer is handled...  
I know from obtaining the official propaganda pamphlet from my local  
water  
co. that my tap water is at a pH of 9.0. On my first two all-grain  
batches  
my extraction rates were anything but good. I then began adding 1/4 to 1/  
2  
teaspoon of citric acid to my 5 gallons of sparge water. Since then, my  
extraction rates have improved. Whether this is caused by the lowered pH  
of the sparge water, or an improvement in my handling of the sparges  
overall  
(probably a combination) I'm not sure. In fact, as I previously mentioned,  
I  
don't even check the pH of anything, so I don't know just how much effect  
the citric acid has. So when I stop and think about it, this post is not  
all  
that helpfull is it? And its probably too late even to win the MALTMILL.  
Oh well, let's just say that a little acidification of the sparge water  
most  
definitely appears to help, so its not a bad idea. How about one of you  
chemistry kind of guys giving us a little more info on the details - but  
please phrase it in a language even us programmers understand >:-)

From: lgold@Cadence.COM (Lynn Gold)  
Subject: Beer yeast and dogs

I changed the subject to "beer yeast" because "brewer's yeast" is a VERY different product from the yeast we brew with.

I discovered the benefits to letting my dog (a 10lb Bichon Frise) tipple a little when I was bottling one of my brews.

I was doing this on my porch, spilling (as we often do) some of the wort as I was siphoning it into the bottles. Fuzzball came by and started licking up the spillage.

Before this, Fuzzball was VERY tasty to fleas. After this, her flea problem magically disappeared. Since this was the only change to her diet, I knew I'd come on to something. Now whenever I open a bottle, I let Fuzzball have the sediment. She enjoys it, and as long as I drink enough :-), she doesn't have fleas.

From: bronson@ecn.purdue.edu (Edward C. Bronson)  
Subject: The MALTMILL Winner and Digest Contents

Congratulations Sheridan!

According to my analysis, Sheridan J. Adams (sja@snoid.cray.com) wins the MALTMILL by submitting a cynical discussion about sassafras and laboratory rats on July 9, 1992 at 10:33 AM.

I am certain that many, many Digesters were counting along with me. When counting, it is important to note that the Contents listed at the top of each Digest does not always tell an accurate story. The Contents

is only a list of all Subject lines that appear anywhere within any submission. If a submission does not include a Subject line, it is not

listed in the Contents. If a submission contains multiple Subject lines,

the submission is listed multiple times in the Contents. Both of these

inaccuracies occurred within the Digests leading up to Number 100.

Here's the counts that I got:

#918:	15 submissions,	15
#919:	23 submissions,	38
#920:	27 submissions,	65
#921:	25 submissions,	90
#922:	42 submissions	

Sheridan's winning entry was the 10th submission in Digest #922.

I mention all of this for two reasons:

- 1) A submission in #923 mentions counts that are wrong.
- 2) Most importantly, to keep the Digest Contents accurate and useful, each submission should contain one and only one line starting with the word "Subject". This line should be chosen by the author to accurately inform digesters of the submissions's contents.

Subject: Re: mashing oats (HBD 924)

Mike McNally writes:  
> Oats have no diastatic capacity.....

Not true! Steel-cut, rolled or flaked oats have no amylase because they haven't been malted, ie. the grain hasn't been germinated and allowed to produce the enzymes - also the heat generated during rolling would destroy the enzyme anyway. Oats are quite competent at producing amylase when germinated - otherwise the seeds would be incapable of mobilising the stored starch reserves in the endosperm. Granted, the amount of amylase produced may be less in barley, but I think I'm right in saying that some (wonderful) German oat beers are made from a high proportion of malted oat, with maybe some barley.

My partner has been working on alpha amylase gene expression in cultivated oat (*Avena sativa* cv. Rhiannon) for the past seven years, so she should know! As in all cereals, the enzyme is produced by the aleurone cells (a thin layer of living tissue just inside the seed coat, surrounding the endosperm) in response to a hormone (gibberellin) which is produced by the embryo on hydration. The gibberellin is probably perceived by a receptor in the aleurone cell membrane, which conveys the signal (via an unknown pathway, the subject of her research) to factors in the nucleus which activate transcription of the alpha-amylase genes (and proteases etc). The mRNA is then translated in the cytoplasm and the enzyme transported out of the cell, where it diffuses into the endosperm and hydrolyses the starch.

From: "Dennis R. Sherman" <sherman@trln.lib.unc.edu>  
Subject: book review - Norwegian brewing

A brief book review:

Odd Nordland. Brewing and Beer Traditions in Norway.  
Oslo-Bergen-Tromso: Universitetsforlaget, 1969.

This book is a fascinating account of the social anthropology of homebrewing in Norway, with some reference to neighboring countries. The data come primarily from several surveys dating from 1925 to 1957. These surveys amassed a huge collection of folk wisdom and practice in home brewing, and are supplemented by a large number of interviews by the author with elderly men and women who brewed at home and/or remember their parents and grandparents brewing at home. I think it fair to say the book gives a very good overview of the state of homebrewing in Norway in the late 19th and early 20th centuries. Many of the practices of the Norwegian homebrewers are documentable to much earlier in history, and Nordland does spend some time dealing with historical changes in brewing, particularly the change from ale made with gruit to ale made with hops.

The brewing practices examined are, for the most part, clearly those of people brewing not as a hobby, but to provide themselves with a staple beverage. Nordland goes into some depth about the various special brews that might be made specifically for weddings or funerals or holidays, although anyone looking for recipes must be prepared to formulate their own after careful reading.

I recommend this book as interesting reading for anyone interested in the history of brewing, or in the interactions of people in a society for whom home brewed beverages were a normal way of life, rather than a hobby.

From: wslack.UUCP!wrs@mv.MV.COM (Bill Slack)  
Subject: Brew a Belgian Ale This Summer

Looking for a cool and refreshing brew for the summer? Tired of the same old flavor profiles? Have you ever had a Hoegarden Gran Cru or similar Belgian Ale? Try your hand at the Belgian wit (white) style of ale; a pale, light bodied well spiced beer made from wheat (and other grains) as well as the traditional barley. The following recipe calls for a two step mash, barley, rye and wheat malts, honey, and some interesting hops and spices.

Rye Wit

The name is courtesy of Dan Hall. This is a variant of Chuck Cox's Nit Wit and my Corey Ander's RN Screw (see below).

Mash:

3 lb. 6 row  
1 1/2 lb. rye malt  
1 1/2 lb. wheat malt

Protein rest 120+F for 30 min.  
Mash 150+F for 90 min.

Boil:

60 min.

The mash liquor  
~3 lb. honey | Use enough honey and dried malt extract  
~2 lb. light DME | to raise OG to 1.050  
1 oz. Hallertau

15 min.

1/2 oz. whole cardamom  
1/2 oz. coriander seed  
1/2 oz. Hallertau

5 min.

1/2 oz. cardamom  
1/2 oz. coriander  
1/2 oz. orange peel

2 min.

1/2 oz. Hallertau

OG about 1.050. Pitch a Belgian ale yeast, such as the one newly offered by Wyeast, or culture some yeast from a fresh bottle of Chimay. Expect an FG of 1.008 or so. Prime and condition as usual.

Note: Crack the cardamom shell and lightly crush the coriander seed. Strain them out before moving wort to the fermenter. The cardamom is not a traditional spice for this beer, so leave it out if you prefer.

Don't want the fuss of mashing? For an extract version, try:

Corey Ander's RN Screw

A version of the gran cru extract recipe in Charlie Papazian's new book.

5 # light DME  
2.75 # clover honey  
1 oz. Hallertauer  
Boil 45 minutes and add:  
1/2 oz. or so of freshly ground coriander  
1/3-1/2 oz. Hallertauer  
Boil 10 minutes and add:  
Another 1/2 oz. or so of coriander  
1/2 oz. or so of ground dried orange peel (zest)  
Boil 3 minutes and add:  
1/2 oz. Hallertauer  
Boil 2 minutes.

Rehydrated Red Star ale yeast (all those ester work well here), or a Belgian yeast as above.  
Ferment and prime as usual.

Expect an OG of 1.047 and an FG of 1.010.

Subject: Re: Homebrew Digest #923 (July 15, 1992)

> From: Mark N. Davis <mndavis@pbhya.PacBell.COM>  
> But seriously, as far as I know, there is no one month recipe for mead  
if  
> you plan on using honey (is there any other way?), but if anyone else  
knows  
> of one I'd be very interested to here it.

My standard recipe for mead takes one month to six weeks. It can be  
adjusted  
to take six months for those who choose to wait.

To 5-gallons of cold water, add 12 pounds of honey. Heat till boiling,  
remembering to skim off the "skum" while it heats. Once it is boiling,  
add about a table-spoon of gresh ginger, sliced thin, and add the peel  
of a lemon (or orange). Boil for about 15-20 minutes. Let cool slowly,  
preferably in your primary fermentation vat. When cool add yeast.  
I prefer mead yeast, but champagne yeast or a general purpose wine yeast  
such as a monrchet yeast works fine. It won't start fermenting for at  
least a day or three. Once it gets started, it goes slowly. At the  
three  
week (or one month) point, bottle, even though its still fermenting.  
Keep the bottles for a week (or three), then refrigerate them (otherwise  
you get glass grenades). To quote Sir Kenelhme Digbie (who's recipe this  
is) "It will be very quick and sweet" (meaning bubbly/frothy and like a  
sweeter beer).

Finess points: the quality and flavor of the honey are important, the  
skimming process can't be overdone, and you can vary the spices to your  
heart's content! Always refrigerate the bottles for 24 hours before  
drinking to get the yeast to settle out (of course). The six-month  
version is to leave the primary fermentation till it mostly completes  
(usually 2-3 months) then bottle and wait another three-four months -  
you usually get a champagne-style drink, dry and bubbly.

Good luck.

Subject:

In HBD #924, Drew Scott writes:

>Does anyone have any experience with adding coffee to stouts?  
>How much should be added so that there isn't an overpowering  
>coffee flavor (assuming a 5 gallon batch) - just an ounce or two?  
>And is it best to leave the beans whole?

I made a coffee stout a couple of years ago and it came out fine. I added 1/4 lb of whole beans to the primary and left them in until I transferred to secondary (3-4 days). I used a robust bean (french roast, I think. Sorry, I don't have the brew sheet here). The flavor of the coffee was wonderful against the roasted flavor of the brew. The oil on the beans did not affect head retention at all. Oddly, under the flavor of coffee and stout, there was a definite chocolate flavor. Mmmmm... maybe I should make it again!

RDWHAHB,

From: Jeff Benjamin <benji@hpfclub.fc.hp.com>  
Subject: Re: Wyeast Bavarian & raspberry beer

Regarding Wyeast Bavarian Wheat, Brian Bliss asks:

> What temperature did you ferment at? I have heard that keeping the  
> temp @ 70-75 F favours the S. Delbruckii more than lower temps, which  
> favour S. Cerevisiae (Ale yeast, however you spell it).

I usually ferment in the basement, about 67F. Maybe next time I'll try moving the fermenter to a warmer place. I'll also check the Wyeast "guide" to see what it says about optimum temp for the yeast.

gelly@persoft.com (Mitch Gelly) asks about raspberry beer. My brewing partner recently made a \*wonderful\* raspberry beer: light, sparkly, pink (head too), and an incredible fresh raspberry aroma. He used 1 lb per gallon of half fresh and half frozen berries, rinsed in a light sulfite solution, pureed, and added right to the primary. No steeping or anything.

I made a blueberry brown ale recently following the same procedure (I posted the recipe a couple of days ago, but I don't know what digest it will show up in-- see the subject "Re: Blueberry Beer"). Most of the blueberry aroma seemed to vanish after a couple of days in the primary, so I may try putting them into the secondary next time.

Neither batch showed any signs of infection, so the sulfite rinse seemed to be sufficient to eliminate any unwanted microbeasts. Your mileage may vary, as usual.

For the raspberry beer, try a light wheat beer, about 50% wheat and OG between 1.040 and 1.045, and use a "neutral" yeast. It really lets the berries show off, and the fruitiness of the wheat is complementary. Much of the sweetness will ferment out, especially in the primary, but we like tart beers (a side effect of having tasted lambics in Belgium :-).

From: ma848295@longs.lance.colostate.edu  
Subject: Colorado Brewer's Festival/dog yeast

In response to Rick Meyers' review: Sounded more negative than my experience. This year's festival drew an estimated 20,000 brew fans and wanna be's: almost twice the crowd of last year. The organizer's definitely got the system down this year. Rick also mentioned his dissatisfaction with the beer selection. This point and his earlier statement about lines being reduced from 20-30 min last year to 5 min this year are directly related. Imagine, if you will, 10,000 people approaching one of 20 brew stands, all having a choice of three or more brews. "I'll have your porter. Or wait...how bitter is your pale ale? Is your stout sweet or dry? Can I have a sip first?....." What happens is you get a beer and go to the end of the next line and sip while you wait. This year each brewer offered only one of their brews. The result: one line per beer. Enough said.

My impression of the festival was that 22 beer selections and 20,000 people with three live bands can only lead to a GREAT time. Perhaps as the festival grows in popularity, the planners will have the facilities to again allow each brewer to offer a selection of brews. If you have a chance to go next year, do it.

Regarding wether or not trub needs to be treated before given to fido. I have been giving the warm, spent grain, as well as the yeast trub at the bottom of my fermenter to my dogs since I started brewing. They love it!! (Major roughage!)

Greetings fellow homebrewers...

Does anyone have some practical advice for drying homegrown hops. I have Beach's book and he has rigged up a contraption with an old hair dryer. I don't have an old hair dryer and am looking for other low-cost alternatives.

BTW, I planted Centennial and Mt. Hood roots this April (Massachusetts) and now have two 16 ft strong vines. The Centennial is covered with cones while the Mt. Hood is just starting to sprout burrs.

Please reply in HBD or to [chuckm@csg3.prime.com](mailto:chuckm@csg3.prime.com)

Thanks in advance.....

From: tony@spss.com (Tony Babinec)  
Subject: belgian malts

De Wolf-Cosyns Maltings is one of Belgium's oldest and largest floor malting plants. They supply many of Belgium's lambic brewers along with more conventional breweries in Northern Europe. Only the finest European barley and wheat are used. The barley (all two-row) and wheat berries are larger than domestic malts. The dark grains are flavorful and not in the least harsh or astringent.

Here is a listing of the available malts along with color ratings:

Base Malts

pale ale	3.5	-	4.5L
pilsen	1.5	-	2
wheat	1.4	-	1.8

Color Malts

Munich	7	-	8
Aromatic23		-	28

Caramel Malts

Caramel-Pils	5	-	10
Caravienne	15	-	30
CaraMunich	70	-	80
Special B	150	-	250

Roasted Malts

Biscuit	23	-	33
Chocolate	450	-	550
Black Malt	700	-	800
Roasted Barley	700	-	800

Here are some comments on the malts. Note that Pierre Rajotte's Belgian Ale book mentions some of these. The color ratings given above differ a bit from those in Rajotte's book, but the ones listed above are from the supplier.

The pilsner malt rivals the finest pilsner malt available. It should be used instead of U.S 2-row or 6-row for such styles as Trippels, wit beers, and various Specials. Note that George Fix's Vienna book also argued that Pilsner malt should be the base malt for the Vienna-Marzen-Fest style. You might also use it in your best Pilsner.

The Munich and Aromatic malts provide malt aroma, body, and color. The Aromatic is slightly darker than a dark Munich, and its name says it all so far as aroma and taste are concerned.

The CaraPils (not to be confused with American Cara-Pils!), CaraVienne, and CaraMunich are basically very fine crystal malts comparable to 10L, 30L, and 80L crystal malts you might use. The Special B is a highly colored caramel malt that, in Rajotte's words, "...Gives a rich caramel-malt taste. It is used in Scotch ales and stouts brewed under license in Belgium. Darker Specials and Abbey beers at times use this type of caramel malt. Its effect is noticeable in beers, giving lots of additional body and coloring. Beers using Special B have more well-rounded malt character than beers colored with only candi sugar." Again, George Fix in his Vienna book argues for using the finest crystal malts to

avoid astringency in the beer, especially for that style.

At homebrew club meetings, those of us in the Chicago Beer Society have been able to sample these malts, as the local Siebel Institute's retail branch had them. NOTE, however, that Siebel Institute is not a supplier of these malts. Moreover, the Siebel Institute exists to serve commercial brewing and not the homebrewing community. I know of a number of suppliers of the grains. Standard disclaimer here: I have no commercial interest, but figured that those whose appetites are whetted would want to know where to get the grains! I don't know prices, so call the establishment.

- Tim Norris, Chicago, IL 312-545-4004--Tim runs a basement homebrew shop. He suggests that homebrew clubs get a collective order together, but is willing to ship small orders.

- North Brewery Supplies, Franklin, WI 414-761-1018--Brian North runs a basement homebrew shop located between Milwaukee and Kenosha. For those of you thinking of getting into kegging, Brian has all sorts of stuff, and can service and refurbish equipment. Call from 6-9 pm his time.

- Alternative Beverage, Streamwood, IL--Don't have their phone number, but their ad is in Zymurgy. Owner Dave Itel (Ittel?) runs a very complete homebrew and gardening shop. As of this writing, they either have the grains or will be getting them shortly.

- Great Fermentations of Santa Rosa: I don't have their catalog with me, but I recall seeing some of the Belgian malts mentioned.

From: localhost!davevi@uunet.UU.NET (David Van Iderstine)  
Subject: Re: Yellowing Hops

Hops are subject to "wilt", a disease that spreads from the ground up. I ordered and planted Cascades from Freshops in Oregon, and they recommended training the hops straight up for at least 6' before going horizontal, and then (when the vines are leafy enough) removing all the leaves between 6' and ground. This will prevent the wilt from spreading upward. For the first year, though, the plants are not really energetic enough to grow that fast or large quickly enough, so I've been plucking the leaves as they show symptoms. Next year, the plants will have a more extensive root system, and will grow quickly enough to "escape" the wilt.

Oh, they also recommended, after the first year, to prune the first growth off, in favor of "more hardy" second growth.

Subject: Hop vine pruning and lagering refrigerator

Congratulations, Jack. You certainly stirred up interest in HBD during the summer doldrums.

A few weeks ago I was complaining here that my hop rhizomes weren't growing, so naturally they are now growing all too well. I have assiduously pruned back new shoots after letting 2 or 3 climb on twine, and now there are 3-5 ft vines from each rhizome. At the junction of each leaf pair with vine, however, there are new shoots orthogonal to the leaves. Since these shoots develop leaves, etc., and appeared to be new vines I have been nipping them in the bud, so to speak. It just dawned on me that these might be the beginnings of flower cones, so I'm "shooting" myself in the foot. In pictures that I've seen of flowering hops, though, I've never seen leaves on the "burrs" that go from the vine to flowers. Any thoughts from experienced hop growers? Anyone with a climate similar to Cleveland getting flowers already?

I have been contemplating getting a cheap fridge and a Hunter Airstat for both lagering and an eventual keggng setup. I recently saw someone suggest a chest type freezer instead of an upright fridge. I am concerned, however, that getting 5 gal of beer in and out or an chest type unit will be difficult, and that the height of the chest will not be sufficient. Any experience?

Thanks in advance.

From: Glenn Anderson <glenn.anderson@canrem.com>  
Subject: wort chillers

I've recently manufactured a counterflow wort chiller out of garden hose and copper tube. It works great, with one exception. After it has sat between batches it seems to develop a sort of light blue flakey substance inside the copper tubing, requiring quite a bit of flushing before all is removed. Does anyone have any idea what this is or if it is harmful to me or the beer. It would seem to me that there must still be microscopic quantities of the material entering the wort and ultimately my belly.

Date: Fri, 17 Jul 92 01:14 GMT  
From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Belle Vue Kriek LA

I live in the Washington, D.C. area, where the weather is beastly hot at the moment, and often sickeningly humid. I'm also a passionate Belgian beer fan, but even a dose of air conditioning is not enough to get me in the right frame of mind to tackle one of the beers in the fridge, most of which weigh in at at least 8% alchohol.

Recently a group of Belgian friends blew through town, and brought me a CARE package of beers and chocolate. Among these was a Belle Vue Kriek LA. Kriek means cherry beer, and LA means low alchohol. The beer is 1.5% by volume, ranking it in the Belgian category III, for table beers.

At first look it seemed to me that this was just the kind of beers that would be dreamed up by the boys down the hall in marketing--the next great thing after dry beer! (More filling, less taste!) This doubt was not assuaged by the fact that Belle Vue is owned by that slimy Belgian octopus, Interbrew.

In fact, it was surprising how not bad it was. Rich red cherry color, but not fluorescent. Excellent head. A slightly sweet taste (a Belle Vue trademark). Not terribly complex, but very pleasant. What was lacking was a bit of tartness, which I overcame by the oral application

of some dark chocolate esters (and a very good match it was).

So, the boys in marketing win one. The stuff was pleasant to drink, left no fog on the brain, and--HOLY COW--had taste! What a concept!

This has been the universal problem with all the low-alchohol beers I've ever run into, and has indirectly sharpened my interest in gin (why drink beer when all that's available is Sharps and Coors?).

In fact, I'd even be willing to buy the stuff again, if it didn't come from t/ose Interbrew slime-balls. But the issue is this--why not add some flavor? Why not have low alchohol beer, when it can be satisfying?

As advocates of responsible drinking, I think this is the sort of thing we could definitely use more of.

On a vaguely related topic, I mentioned to our Belgian visitors my interest

in Pierre Rajotte's new book on Belgian brewing, and the difficulty of getting candy sugar for brewing. Rajotte states that it's available from brewery suppliers in 50 pound bags. I mean, I'm ambitious enough, but that's

a lot of sugar to schlep around. Anyway, our guests said that the stuff is

available almost everywhere--supermarkets, etc.--in both the light and dark varieties. I'm trying to get some via our next courier (end of Aug.

),  
and will post any news on this front.

Subject: Re: Why Wait for the Boil?

>From: tpm%wdl58@wdl1.wdl.loral.com (Tim P McNerney)

>Why do most sources suggest adding the malt extract once the  
>water has started boiling? Is there any advantage to adding it  
>then? I did so last time, but was a bit slow with the stirring  
>and ended up with quite a mess from burnt extract and would much  
>rather add the extract when the water is warm.

OK, here is my understanding--others will correct me where I am  
wrong <g>.

- 1) The warmer the water, the easier it is to dissolve the  
extract.
- 2) The extract will burn if it sits on the bottom of the pot  
while there is high heat being applied.

Therefore, you want to stir the extract into very warm water not  
on the heat. That is why the advice is to get the water boiling  
(it won't get any hotter than that), take it off the heat, stir  
in the extract (previously warmed up), put it back on the heat  
when it is all stirred up (no more sitting on the bottom of the  
pot).

With a flame, just turn off the flame. With an electric heating  
element, you have to lift the pot off the hot element until no  
more extract is on the bottom of the pot.

From: "Stephen J. Vogelsang" <sv0k+@andrew.cmu.edu>  
Subject: Where to get started?

Hi all,

I am new to this beer brewing stuff, and would like some tips on how to get started. Any info would be helpful. What equipment I need, where to get grains and other ingredients, how to store the beer, etc. If you can direct me to a good publication on the subject that would be great. If you happen to be in the Pittsburgh area and can lead me to sources for ingredients and equipment, that would be most appreciated. I don't know whether it matters, but I would like to brew some stouts and porters (just because I seem to like these type of beer in general).

I know absolutely nothing about the process of brewing beer other than the fact that you have some grains and some yeast, so keep any info on a beginners level.

Thanks,  
Steve

From: gummitch@techbook.com (Jeff Frane)  
Subject: Please No More Offers!

Jack et al:

Please, Jack, I'm sure your heart was in the right place, but... the key to a good, interesting Digest is not quantity, but quality. The reason that certain issues of the Digest are interesting is because the people who are contributing are involved in the discussion. This may keep the volume down (which, admit it, makes it easier to read through the Digest in a reasonable period), but it also keeps the discussion lively and current. Right now, I've been waiting for three days for my response to someone to be posted -- and the Digest has been filled with people who are posting comments purely to enter the maltmill lottery.

I can't see what good this is doing, particularly if these people -- who have previously been silent here -- go back to reading and never contributing.

So, Jack, please if you want to give away malt mills, do so, but don't tell anyone that's what you're planning. Let people contribute to the Digest because they have something to say, and allow the normal day-to-day fluctuations in volume to continue. That way people can get back to asking questions and getting responses in a day or two, rather than in a week. And I, for one, can stop reading endless postings of "Did I win?"

Date: Fri, 17 Jul 92 12:00:23 PDT  
From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: All Grain is Expensive (NOT)

I hear this sentiment about all grain brewing often--it's expensive. I will summarize what I spent and let you judge for yourself. I used Dave Miller's book for a reference. Here goes.

Boiling kettle: 33 qt enamelware \$30  
Mash tun: 20 qt enamel ware \$15  
Lauter tun: 2-5 gal plastic buckets \$ 3 each  
plastic spigot \$ 4  
"ensolite" pad (insulation) \$ 5  
Box for mash tun: 4' x 4' x 1/4" plywood \$ 7  
spray-in insulation \$ 4  
Corona mill \$13 (Goodwill)  
Pulleys and motor for corona (I'm lazy) \$10 (ditto)  
-----  
\$91

I save between \$5 and \$15 on each 5 gal batch(I buy grain in bulk). I have made 30 batches with this equipment and couldn't be happier. I use a 60 qt camp cooler for holding my hot sparge water and do a gravity feed with the cooler up high, the lauter tun in the middle and boiler down low. BTW the way, beers made with this equip \*have\* done well in competitions. The only reason I'll change is to get bigger, i.e. 1/2 barrel size.

Cheers,

Glenn Tinseth  
tinsethg@ucs.orst.edu

Date: Fri, 17 Jul 92 16:05:41 EDT  
From: Jay Hersh <herhsh@expo.lcs.mit.edu>  
Subject: Cider and it's yeast

Sorry for the delayed reply...  
In HBD #921 Andy Phillips commented:

>The traditional way of making  
farmhouse (ie. homebrew) cider is simply to crush apples, press out  
the juice and allow it to ferment without any additions, even yeast.  
Fermentation relies on infection by wild yeasts from the air. You  
could try this, but I wouldn't recommend it - there is no guarantee  
that a suitable wild yeast will fall from the heavens, and there will  
be plenty of other bugs waiting their chance to turn your apple juice  
into cider vinegar.

Well this is slightly misleading Andy. The source of the  
wild yeasts is not waiting to drop from the heavens. It is  
already right there on the apples at crushing time. Right  
around the stem on almost all apples is a yellowish, powdery  
substance, referred to by growers as the "bloom". This is  
wild yeasts which collect on the apples, from the air, and  
from insects (i.e. bees) which are responsible for the flowers  
pollination to begin with.

They are not just random yeasts. They live in orchards because  
they ferment fruit sugars well and are able to propagate there.  
I too was skeptical at first, but Paul Correnty (Resident NE  
Cider guru) convinced me to try a ferment with only the yeasts  
present in the pressed cider itself. It is truly wonderful!!  
(and it just got edged out for 3rd place in the AHA National  
by my buddy Bob Gorman.... :-( ).

So while exposing your cider to air is not recommended, it  
is quite possible to make very good cider with the wild yeasts  
that occur naturally on the apples, and thus in the pressed cider.  
One does however have to have a little more patience perhaps,  
as these yeasts are slower to start, and like a long fermentation  
and aging period. Also fortification prior to fermentation is  
recommended as they are very voracious fermenters....

>this one.) Do they use vacuum distillation?

According to an article I read recently (in the Food section of the  
San Jose Mercury News, but it may have been reprinted from somewhere  
else), there are two methods used commercially. One of them was a  
vacuum distillation process. The other did involve a special strain  
of yeast -- not one that didn't produce alcohol, but one that basically  
didn't ferment very much at all. The article didn't go into much more  
detail -- presumably this would mean that they start with an extremely  
low initial gravity, and perhaps add carbonation? I'm not sure.

Well, I've been challenged to brew a decent batch of Sake' and have to admit I know nothing about it. Some time ago someone mentioned that a fungus is responsible for converting the starch in the rice?

Would any and all sake' brewing experts, novices, or wannabe's point me in the right direction?

Mike

Subject: adding body to mead

>>> How can one add "body" to a quick mead?

>> In my experience, adding more honey ... helps make the flavor more "real".

> Adding more honey won't necessarily work. Honey is very fermentable.  
> That means that you end up with very few unfermentable sugars left  
> when it is done. Doubling the amount of honey used will double the  
> unfermentable sugars but will that really make a difference?

I think that my answer of adding more honey was not targetted at the actual question asked by the original poster. In my experience, adding more honey can help make the mead "better". If one makes a quick-mead, where one bottles before the primary fermentation finishes (my usual practice), one gets significant unfermented sugar left, and this adds significant flavor and "richness" to the mead. As commented above, this does lead to glass grenades if the bottles are not refrigerated relatively quickly. I have heard one tale (on this forum, I think) of a recipe for mead that has you open a bottle a week until the pressure in each succeeding bottle "scares you". Then, hold a party immediately and drink off the entire batch.

In my experience, the choice of honey adds richness to the taste and experience, because of the source of the sugars (nectar). Molasses honey, buckwheat honey, orange blossom honey, "raw wildflower honey", all add unique flavors and texture to the taste of the drink, as does the choice of spices. One friend of mine added a pound of crushed ginger to every gallon of his batch of "quick mead" (two pounds of honey per gallon) and ginger lovers in our group thought it was wonderful! They called it "death by ginger".

Now, if you mean "thickness" when you say "body" (i.e., the way that a liqueur has a very viscous flow), then you really would have to add a lot of honey to exceed the capabilities of the yeast to consume it and make alcohol. I've seen mead like this only once, a long time ago, and I thought it was wonderful! It was over two years in the making, and the amount of it was very limited. Someday I'll have the patience to try that recipe!

May your bottles never burst!

other  
> ideas for brewpots? It doesn't have to be pretty but cheap would be  
nice.

I have heard of an interesting solution. Find an old water heater and  
make sure  
that it is stainless steel lined, which is supposedly fairly common. Then  
you  
simply saw it off at what ever level you prefer, giving you a boiling pot  
up  
to maybe 40 gallon capacity. The beauty of this is that the unit comes  
complete  
with a nice stand and best yet - a built in burner! Just hook this puppy  
up  
to a gas line (refrain from ingesting home brews previous to this part)  
and  
fire it up. One other addition that you might need is to add a drain  
spigot  
if the model that you have doesn't already have one. Overall, this is a  
rather  
inexpensive (assuming you find a junker water heater that will work), and  
not  
overly difficult project to create for yourself.  
Disclaimer: I've never actually seen one of these in use...

Subject: Dishwashers

Several issues back (sorry, I lost my files), reference was made to the similarity between dry dishwasher detergent and B-Brite, the difference being that dishwasher detergent has additional chlorine.

At the moment I use heat to sanitize my bottles (actually, I bake them), and have avoided using the dishwasher for this purpose because the water does not reach the required temperature of 170 F. Given the above information about the detergent, does this mean that using the dishwasher is an effective way to sanitize bottles?

Also: am I being unreasonably touchy if I say that I am sick to death of messages about maltmills? I am assuming this giveaway is responsible for the current glut of submissions (which delayed delivery of HBD on several occasions, thereby bringing me to the brink of suicide. . .)

>Subject: CLEAR BEER

>1) isinglass.....

You seem to have left out of your experiments, the simplest, cheapest and most reliable clearing agent... gelatine. 1/2 tsp per 5 gal will clear the muckiest beer in a couple of days.

I don't use it very often but I did use it on the Generic Ale I took to Milwaukee so the World's Greatest Beer would at least be clear.

>Thanks to Russell for his explanation of the dangers of root beer. I will certainly be careful IF I EVER FIND A RECIPE!!!. I'm so surprised by the silence over getting a recipe. Besides Russell's message I have only received responses along this line:

Can't help you on the rootbeer. I suggest you give up because the process to "clean up" natural root is beyond the home brewers' bag of tricks. Certainly testing it to prove it is "safe" is.

I switched to ginger ale and convinced my self I like it as well. We show how to make it from scratch in our video but it is really quite simple.

Slice up and boil one oz ginger root for 20 min. Whiz in blender and pour through strainer into gallon of boiling water with one cup of sugar. Add one tsp vanilla and 1/8 tsp of dry yeast after cool. Put in 4 plastic liter bottles and refrigerate when hard.

>Subject: Low alcohol beer (oh no, not again!)

>Other than antagonizing everyone, we concluded that JS's method of heating a fermented beer might/might not work.

Just for the record, according to Jean Hunter's gas chromatograph, the sample I sent was 1.36% alcohol. Increasing the holding time or temp could no doubt get the number lower but this seems low enough that it does not trigger my urge to drink till the keg is empty and the flavor is only marginally changed.

>Do they use a "genetically altered" yeast, which is able to eat maltose and produce CO2 without producing EtOH? (I really have a hard time believing this one.)

Don't know that it is genetically altered but they definitely use yeast that produces less alcohol but that is about the extent of my knowledge.

I would think that a simple expedient would be simply to use less sugar/malt in the brew to begin with. Judging by what that rubbish tastes like, they do not need any magic yeast.

>From: HAPANOWICZ@bigvax.alfred.edu

I like port wine a lot.

Would you settle for a bottle of this year's dandelion wine? It tastes a lot like dandelion wine, aka Nail Soup, aka raisin/sugar/lemon wine with dandelions in it.

>From: "B\_HADLEY" <BHADLEY@atlas.nafb.trw.com>  
>Subject: What is maltmill?

>Can some describe a maltmill? Is it a mashing machine?

I suppose I am getting suckered again but I will assume this is a sincere question.

Malted barley must be crushed before it can be properly mashed. There are many ways of doing this including, rolling pins, kitchen blenders, grain grinders and roller mills. Only the latter is designed for the task and does the proper job.

Although the efficiency of sugar extraction improves as the particle size decreases, the major flaw that grinders, cutters and blenders have is that they also pulverize the husk of the grain. The mashing process, depends on the intact husks to provide the needed filter bed when sparging the mashed grain. If the husks are pulverized, there is no filtering and impossibly turbid wort results in addition to the fact that the husks will end up in the boil.

Roller mills, squeeze the grain between sets of rollers and only crush the grain enough to release the malt so that it can be reached by the mashing water. The husk is left intact.

Until very recently, there was no ROLLER mill available to the home brewer.

>necessary to convert the starchy oats into sugars. Lager malt  
>is a good source of amylase, or you can add diastatic malt syrup

>...

It is interesting the notion of a "lager" malt. Now I have no doubt that there is such a grain out there, but I believe that the realities of modern brewing make lager malt archaic. Let me explain.

I have heard, and claimed that most US lager malts are in fact fully modified and can be mashed with a single step infusion. I have also hear that most German brewers are now using single step infusion mashing.

Last weekend, at the Oregon Brewers Festival, I had a long discussion with some maltsters from Great Western Malting (GWM) regarding their Pale Malt. This stuff is a 2-Row blend of fully modified malt. The reason it is fully modified is to MAXIMIZE the enzyme content - needed for the high adjunct ratios in Bud, etc. beers. It is blended to produce a highly consistent product. The big boys simply demand that. This is the same base malt used by many west coast microbrewers. It is also the same malt that many, erroneously, call Klages. yes, there is klages in it, but ther eis also Harrington, Crystal and some other names I now forget. If your malt supplier has Huge Baird malts, their "klages" malt is most likely the GWM pale malt as GWM distributes HB specialties.

The bottom line is that step mashing is probably a quaint practice that is a hangover from big commercial breweries that use lots of rice and corn (where step mashing is still needed). For most practical purposes, using all malt recipes with US and european malts single step infusion mashing is adequate and sufficient and won't produce chill haze. I forgot to ask them about their 6-row stuff, but I believe the same story holds as members of the Brews Brothers of Seattle have reported single step infusion mashing of 6-Row working out just fine.

So, anyone else out there given up step mashing when doing all malt recipes and been satisfied with the results? Anyone else have any evidence to support or debunk my claims, above?

I look forward to hearing from Y'all.

Cheers!

- Larry Barello

I think the consensus was that while the dishwasher may not  
effectively \*clean\* your bottles, it can do a good job of  
\*sanitizing\* them if it has a "heated dry" type cycle. The steam  
from that cycle should sanitize quite nicely.

Date: Monday, 20 Jul 1992 09:41:38 EDT  
From: ml4051@mwvm.mitre.org (John DeCarlo)  
Subject: Mead Yeast Nutrients

I have since misplaced my copy, but one of Byron Burch's advertisements (in the form of a newspaper, with articles and such), mentioned a special Mead Yeast that they carry.

The gist of the article was that without proper nutrients, it takes a long time for mead to ferment. And that if you used a beer yeast nutrient set, it would give a harsh taste that would take a lot of aging to remove. Therefore, using a special mead yeast would get you that wonderfully-aged mead taste in much less than a year.

Before I embark on such a proposition, has anyone tested this new yeast nutrient formulation and found it significantly better for their meads?

From: "Rick Ringel - HNS/DCN project" <rringel@hns.com>  
Subject: Trub, Windsor English Ale Yeast

Hello brewers,

I have a data point and a question.

> ALBERT W. TAYLOR writes:

> I just made a batch of beer, and this is the first time I have worried  
(yes,  
> I worried!) about letting the trub settle out.  
> [stuff deleted]  
> Does anyone know a better way than I propose?

I simply pitch as soon as my wort is cool enough, then rack the wort off the trub a few hours later. When the house is cooler, the yeast are slower to get started, so I can leave it overnight. I should add that I only brew ales, so I don't worry about the yeasties hiding in the trub. As long as I rack before the respiration stage is over, I don't worry about the risk of oxidation.

Does anyone have any comments on Windsor English Ale Yeast from Canada? Due to poor planning on my part, I couldn't get liquid yeast for my last batch, and was unable to get Whitbread Ale. :^( Windsor fermented out 7 pounds of malt extract in about 36 hours (at 78 degrees). It only took about 4 hours to finish up the respiration stage. Are the yeasties hyper because of the temp, or is it a characteristic of this strain? What sort of off-flavors are caused by high-temp fermentations?

Thanks in advance.

-Rick Ringel

>I'll get some of the Dead Cat Alley (or what ever they call themselves)  
>products, but I still have a half of a suitcase left....suggestions?

> (Russ mentioned Anderson Valley, Winchester, Rogue and Mendocino. Who  
else?)

IMHO - Leave the Dead Cat (Piss) beer alone. They have had a serious  
infection  
problem for a long time. Devil Mountain can't be out of business as I had  
their  
Railroad Ale yesterday at the California Small Brewers Festival in Mt.  
View, Ca.  
and it was very tasty. I would also skip the bottled versions of anything  
from Winchester. Although this is one of the first brew-pubs that got me  
hooked, I find the bottled versions boring and the pubs beers are not  
always  
consistant.

Unfortunately, many of the beers served yesterday left something to be  
desired.  
Many seemed to be quite young and a few were completely off - Monterey  
(as usual) and Boulder Creek Stout come to mind...

The Anderson Porter was delicious and a big hit, Mendocino Blue Heron Ale  
was very disappointing yesterday, although I have had very good bottles  
in  
the past. Anchor was there and thier products were great. They even had  
Old Foghorn (Which used up about a third of my tokens!) Can you fit a keg  
in your case? One from So. Ca. that I had never heard of "Rhino Chasers"  
had a very nice ale. Can't think of any other great beers that are also  
available in bottles represented yesterday, but one other mention is a  
hefeweizen from Gordon Birsch (of which I got the last glass!) which was  
very tasty. I don't believe they sell in bottles though.

Greg

From: Jeff Benjamin <benji@hpfclub.fc.hp.com>  
Subject: Re: Lager vs Ale malts?

I posted this to rec.crafts.brewing recently, but since the lager vs ale malt discussion is continuing, I thought I'd repost it here for the benefit of those who don't read r.c.b. I also added few more comments.

Re: highly modified malts

According to a local (Ft. Collins, CO) maltster/seed-lab technician Jim Bruce, there is actually little difference in modification between various malts. He says that all malts these days (US ale, UK ale, continental lager) are all highly modified; the differences are in the kilning technique and in the barley itself.

Jim specializes in continental-style lager malts, which he says differ from ale malts in protein content due to a longer, more gradual increase in kilning temperature. Ale malts have a shorter kilning time with a sharper upwards temperature curve. The end result is that lager malts retain more proteins which are necessary to sustain the yeast over long lagering periods. Therefore, he says, you can use a lager malt to make an ale, but not the other way around. He also stresses that lager malts will benefit from a multi-step mash to extract these proteins, whereas ale malt can be used for a one-step infusion and achieve the same protein extraction.

Larry Barello posts that "The bottom line is that step mashing is probably a quaint practice that is a hangover from big commercial breweries that use lots of rice and corn (where step mashing is still needed)." According to Jim, this isn't the case. A step mash is useful for ensuring a high-protein wort, not for converting adjuncts (though it may be helpful there as well). We all agree, however, that in terms of enzymatic power and sugar extraction, lager and ale malts are comparable.

Jim also maintains that the difference between US and UK pale malts is that UK barley is grown in soils that are less heavily fertilized with artificial fertilizers and therefore have a lower nitrogen content.

BTW, for those of you here in the central/south west region (CO, ID, AZ, NM, UT, MT, WY, TX), there's an article on Jim in last month's Rocky Mountain Brews.

For the record, I typically use a 3-step mash (122F for 30min, 150-155F for about an hour, and 170F for 10 min). It doesn't seem that much more difficult than straight infusion. I've done infusion mashes, but I've never done a direct comparison.

>  
> - Jane

'Fraid so, Jane. All thanks to Texas State government and Anheiser-Busch  
(disclaimer: so the story goes). The law says something along the lines  
of  
"alcoholic beverages may not be sold on the same premises as they are  
brewed."  
The result is that all the breweries must have hospitality rooms or  
give the stuff away, etc. but that brewpubs are forbidden.

However, I was talking with some friends about this the other  
day, and one of them said that they knew of a place which made you  
purchase coupons which could be then exchanged for beer. I don't know  
if it would be possible to get round the law that way - maybe the ACLU  
would be prepared to sponsor a test case ?

On the bright side, there are a number of micro breweries in  
Texas whose products can be purchase in draught here in Dallas. So  
it's not all woe. Just make sure you visit the Gingerman, at the  
corner of the Quadrangle (everyone knows where that is).

Roddy McColl.

Yes, it was slightly negative, but only due to the beer selection (which is the main reason I went!) Reducing the waiting time is no excuse for serving mainstream-style beer. If they continue to limit selection and only serve the styles they did this year, I WON'T be attending next year.

By all means, if you've never been, try to make it next year!

**Subject: lactobacillus culture**

I have a friend that would like to obtain a culture of Lactobacillus. Could anyone provide me with a starter or point me in a direction where I can get a starter for him? Many thanks!

The Oregon Brewers Festival was wonderful! There were lots of interesting brews, including a Green Chile Ale. Instead of extinguishing the fire from spicy foods, this one flamed them!

From: Tom Bower <bower@hprnlme1.rose.hp.com>  
Subject: Yeast for a barleywine (recommendations please)?

I've got barleywine on the brain, and am looking forward to making one now for this winter's consumption. It'll be my first attempt, and I have a question: I haven't seen much consensus on what yeast to use...

There seem to be several schools of thought:

- Use a wine yeast (exclusively)
- Use an ale yeast (exclusively)
- Use an ale yeast to start, then add a wine yeast later to finish

At the moment, I'm leaning toward using a hardy ale yeast; the triple-strain Whitbread comes to mind, as (from what I read here on the HBD) it contains one strain which will survive the higher alcohol levels. Also, I imagine the SNPA American Ale yeast may do, since SN uses it for the Bigfoot. I'm trying to look at this barleywine as a strong beer rather than as a wine, and hope-fully de-emphasize the wineyness. All you barleywiners, what say ye??

Is the Whitbread 3-strain ale yeast available in liquid form? (like Wyeast?)

Any recommendations for a first-time BarleyWhiner?

Tom Bower.

In HBD #924, Drew Scott writes:

>Does anyone have any experience with adding coffee to stouts?  
>How much should be added so that there isn't an overpowering  
>coffee flavor (assuming a 5 gallon batch) - just an ounce or two?  
>And is it best to leave the beans whole?

For each of my two Coffee Stouts, I brewed a strong pot (8-10 cups) of either Zimbabwe or Moroccan coffee from Peet's Coffees in Berkeley. The flavor and aroma of good strong coffee was unmistakable, but not overwhelming. I rated the first batch as one of my top three ever. I botched the third batch (didn't boil off nearly enough volume, so the beer turned out Way Too Light) but the flavor was still quite good.

Both of these recipes are based on the one in Cat's Meow 2...sorry, I don't have it here, so I can't give you the exact name or page number.

Subject: Mailing beer (humor)

Let me start off by saying this is a true story.

A couple of years ago, a buddy of mine (Tim) returned to St. Louis from LA.

While living in California, he and another friend had an uncontrollable urge for Busch beer. Not Bud, not but Bussssch!, which I understand is not

marketed much out of the Midwest. (At the risk of detroying all crediability

on this forum, I can attest to the ingrained desire of all St. Louisians for Busch.) As a gesture of friendship, Tim decided to pack up a case of Busch and send it to his wayward friend in LA. He packed up a case and walking into the post office and plunked it down on the counter. The clerk hefted it onto the scale and noting the weight asked if he wanted the package sent "book" rate. Tim mis-understood and thought she was asking if he wanted it sent "Busch" rate. "You've got a special rate for that?" he asked. So the next time your sending beer through the mail, ask for the "Busch" rate.

Does anybody out there have a good oatmeal stout recipe? I am a relatively inexperienced home brewer (so the simpler the better) but am willing to tread new ground (ie full mash brews) in anticipation of an oatmeal stout to warm me on those winter days.

Here's an update on a message I sent in over a year ago. The recipe is one of my all time favorites, and my beer guzzling friends thought it was my best ever, also.

I wash shooting for something somewhere between Sam Smiths Oatmeal Stout and Watneys Cream stout -- two of my faves. A totally biased review follows the recipe.

If you don't want the Cream Stout characteristic, omit the lactose.

I'm not sure how it would work if you don't do a mash, but Wegeng.Henr@Xerox.COM mailed me this comment:

A mini-mash of the oatmeal will work as long as you also mash some malted barley with it, so that there will be enough enzymes to convert the starch in the oatmeal into sugar (oatmeal lacks the necessary enzymes). I've done this a couple times with good results.

You might talk with Jay Hersh -- he once sent me a digest of his extract-based oatmeal stout recipes.

Here's the recipe for my Oatmeal Cream Stout. It was pieced together by comparing a number of Oatmeal and Cream Stout recipes posted to the HBD, as well as information in Eckert's book: Essentials of Beer Style.

10# pale ale malt  
1# roasted barley (500L)  
0.5# flaked barley (1.5L)  
0.5# crystal malt (60L)  
0.5# chocolate malt (400L)  
1.3# steel cut oats (from a health food store)  
0.5# lactose  
9 aau bullions pellets (9% alpha), boil 60 minutes  
0.5 oz fuggles pellets (3.4% alpha), boil 15 minutes  
0.5 oz fuggles pellets (3.4% alpha), steep  
0.7 stick brewers licorice (boil)  
starter culture of Wyeast Irish Ale #1084

Mash with 5 gallons 18 oz (48 oz/#) at 155-150F for 90 minutes.  
Sparge with 3 gallons water at 165F, collecting 6.5 gallons for boil.  
Boil 75 minutes, then force chill.  
Save 1.5 liters boiled wort for priming, ferment the rest.

OG: 1.062  
FG: 1.021 (high due to unfermentable lactose)

COMMENTS

We did a taste test against Youngs Oatmeal Stout, Sam Smiths Oatmeal Stout, and Watneys Cream Stout. It came out tasting **\*\*very\*\*** similar to Youngs: same hop character, a little heavier, sweeter, and slightly less roasty; a bit lighter in color (brown/red vs. brown/black). It was not as rich tasting and full-bodied as the Sam Smiths. It was not as roasty/burnt as Watneys, or as jet-black.

Next time, I would reduce the OG to about 1.050 to reduce alcohol a bit, but add some dextrin malt for improved body. I'd aim a little more toward the Watneys, as it's one of my all-time faves: slightly less lactose, but more roasted malt.

As popular as this was, it didn't last very long. Next time, I'll definitely do a double batch!

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: mashing wheat malt

Hi all,

This past weekend I brewed an all grain dunkelweizen. This was my first experience with wheat malt, I changed my procedure somewhat, and something unusual occurred.

Having read that wheat malt is high in protien, I did an extended protien rest, holding the mash at 118F-122F for one hour. I then raised the temperature of the mash to 155F for one hour, checking temperature and stirring at 10-15 minute intervals. This mash took just over two hours to convert, as verified by several iodine tests. Using the same equipment and procedures(except for the longer protien rest), I have never had a mash take longer than 1 to 1 1/2 hours, using English pale, German 2 row pilsner, Munich, etc.

So, my questions to those who have mashed wheat malt:

Is it normal that conversion took so long? I had read that wheat malt is very high in amalyse enzyme, I expected a somewhat shorter mash than normal.

Is an extended protien rest desirable? Could this have affected the starch conversion?

Some specifics:

5 lbs. wheat malt  
3 lbs. munich malt  
2 lbs. 2 row lager malt  
1/2 lb. black malt - did'nt mash this, just crushed and added to lauter tun.

1.25 qt/lb, water to grist ratio

Initial SG 1.055 after boiling down to 5.25 gallons, so my extraction was reasonable. In fact, everything about the brew seems normal, except for the longer mash.

P.S. There has been a fair amount of discussion on the net lately regarding the clove character (or lack thereof) imparted by Wyeast 3056. Some have posted that higher fermentation temperatures seem to help provide more clove flavor. The above batch is now fermenting away in my 72F-75F basement, so in two-three weeks I'll have some data on this point.

Cheers,  
Jim

You seem to forget that a lot of people don't find it obvious. Many people read this forum to learn new things, and to them it's not obvious.

Additionally you are constantly in the habit of contradicting people, and "debunking" even the most benign and commonly accepted of homebrewing practices. How was I to know that you had made a simple mistake (in your original text you mentioned Ale yeast twice in two places, seemingly quite consistent. I'd perhaps had thought it simply a mistake if in one case you had had it right and the other wrong, the contradiction indicating a typo, but your post seemed to imply that once again you were challenging something) rather than being engaged in propagating some new found wisdom.

Sorry Jack, but for one who is constantly passing himself off as an expert on things, continually contradicting folks, pushing his products and opinions as the one "true religion", you're gonna have to do a little better. If you can't make a short simple posting and not get something as basic as lager and ale yeasts confused why should anyone believe your opinions about any other issue. Your credibility problem is your own, and not of my making....

On the subject of Jockey Box's, John Francisco was on the right track. According to Dave Miller, the pressure needed is related to tubing material and length. He gave quite an in-depth talk on this at the AHA Conference this year. I believe that notes from the conference are available through the AHA (and there is some discount prrio to October I seem to recall), which would include the necessary info to calculate the proper pressure for your line lengths (this seems to be very system specific). Sorry I didn't take notes, so I only have my recollections of the general content of the talk to guide you to those notes.

Dave Ballard asks about metallic tastes in an IPA. I had often noticed

many otherwise fine beers entered in contests having this flavor. The initial assumption was the kind of pot used, but talking with George Fix and reading his fine book now leads me to think otherwise. George indicates that in beers with high hopping levels and low water hardness apparent metallic flavors arise. While I have not done independent testing to verify this I would suggest your consulting George's Principles of Brewing Science. Do you know the hardness of your water?? Do you add anything to harden the water?? My suggestion would be to start looking there.

There are no brewpubs in Texas. In Dallas the place to go is apparently the Gingerman (sorry don't know the address) if you're looking for beer selection.

In the past I have had great success in drying my hops in the oven. I turn it on to the lowest heat setting, approximately 125F, set them on foil or cookie sheets and leave them overnight. My understanding is that hop growers use a similar temperature but do this in a ventilated room rather than an oven, but this technique has worked OK for me the 2 years I have used it.

Subject: Re: dryhopping

Keith asks about how long to dryhop. I used to dryhop in the primary as soon as the krauesen falls so the high-power fermentation does not lift the hops into the blowoff tube and clog it AND because the large volume of CO2 would scrub a lot of the bouquet out of the brew. Then, the beer would sit for two or three weeks in the primary until I was ready to bottle (we're talking ales here, of course). I noticed that if I waited longer before bottling, I got less bouquet, so I decided to try a new approach. What I now do, is dryhop 7 days before bottling. I wait for the fermentation to complete, dryhop, wait 7 days and then bottle/keg.

From: lgold@Cadence.COM (Lynn Gold)  
Subject: Beer yeast and dogs

I changed the subject to "beer yeast" because "brewer's yeast" is a VERY different product from the yeast we brew with.

I discovered the benefits to letting my dog (a 10lb Bichon Frise) tipple a little when I was bottling one of my brews.

I was doing this on my porch, spilling (as we often do) some of the wort as I was siphoning it into the bottles. Fuzzball came by and started licking up the spillage.

Before this, Fuzzball was VERY tasty to fleas. After this, her flea problem magically disappeared. Since this was the only change to her diet, I knew I'd come on to something. Now whenever I open a bottle, I let Fuzzball have the sediment. She enjoys it, and as long as I drink enough :-), she doesn't have fleas.

>From: oconnor@ccwf.cc.utexas.edu (donald oconnor)

>The notion that o-rings from a used soda keg must be replaced because the soda syrup has impregnated the rubber is a myth for the most part. Sugars and flavor components will come out or off of the o-rings simply by soaking in water.

I would be interested to know how long you soaked them. I never bought new ones but I have soaked them overnight in: bleach, 100% alcohol, vinegar, baking soda, lie water and several other things which now escape me. I can still smell coke on all four of the ones I have. One of them that was only casually soaked in bleach and carefully flushed with water, all but destroyed a batch of beer. The taste of coke was so strong, the beer was barely drinkable.

>Additionally, since the o-rings are not in contact with the beer then the idea that even some minute residual odor will destroy the flavor profile of a malty beer seems very unlikely.

I would be interested to know how you think the o-ring seals without contacting the beer. My guess is that at least 30% of the large one sealing the lid is exposed to beer on the inside.

>From: scott@gordian.com (Scott Murphy)  
>Subject: kegging question

>I have kegged three of my batches to date. I don't add priming sugar. Instead, I siphon the beer into the keg, seal it and add CO2. I crank the pressure up to 25psi or so, invert the keg, and occasionally give it a good shake. I reach drinkable carbonation levels within a day.

Welcome to the club. I used to let it sit for a week to carbonate before I learned that shaking the hell out of it would do the job in 15 minutes. However, I am curious to know why you invert the keg. It seems like an unnecessary exercise.

>Does anybody think that priming (natural carbonation) is a better way to go than forced carbonation?

I kinda do but the lack of sediment and turn-around time are tough to fight.

>From: korz@ihlpl.att.com  
>Subject: Fridge thermostats

>Roger suggests using the Honeywell thermostat for converting a fridge

to our temperature range.

Just, pray tell, what is "our temperature range"? I am having a hard time not being bored with all this talk of fridge temp controllers.

Baderbrau ferments, ages and bottles/kegs their beer at 50F. This is a high quality pilsner lager and any fridge I have ever seen can maintain 50F with no outside help.

What am I missing?

>From: korz@iepubj.att.com  
>Subject: Re: My jockeybox

>Russell writes:

>Perhaps the length of the tubing in the "jockeybox" is the problem.  
>The amount of beer sitting in the tubing and the amount of time any sip of beer spend sitting in the tubing increase with tubing length. 10 feet of tubing with a cross-sectional area of 1 cm<sup>2</sup> will easily accommodate an entire glass of beer.

>I think the problem I had was that this was industrial beer being dispensed continuously from a rented (grungy lines) jockeybox. I still believe, though, that the pressure would have to be pretty high to get the CO<sub>2</sub> to dissolve into the beer in the keg which is at, say 68F. This would be much too high a pressure for dispensing the beer. Even if the beer got to spend a few hours at 50F, so much of the dissolved CO<sub>2</sub> would stay in solution when the beer finally came out of the faucet, the pressure drop may still cause it to foam a lot.

I think I see the light. Your jokey box is a big coil of copper tubing with all the potential problems outlined above.

Whereas, the cold plate is a very short run of very small gage tubing in a killer heat sink. This seems to have enough advantages to make it worth starting over:

1. Holds only 2 oz of beer.
2. One cup of cubes will chill a glass or two.
3. Narrow tubing simulates long run without holding a lot of beer.

The point of (3) is that you can boost the keg pressure to properly carbonate beer at room temperature and still dispense it properly.

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: Oatmeal Stout recipe

Al Korz chastised me for including a partial recipe for Oatmeal Stout in HBD #924 (an article about mashing oats and other specialty grains). To set the record straight here is the entire recipe:

7lb Great Western MAlting (GWM) Pale Malt. (e.g. 2-row pale/lager/ale malt)  
1lb Huge Baird (HB) Roast Barley (also supplied by GWM)  
1lb Rolled Oats from my co-op.  
8oz HB light caristan (e.g. 15-20L crystal)

Entire brewing water supply (7gal) treated with 5gm gypsum and 1 gm chalk (calcium carbonate).

Mash in with 8qt @ 137f, target temp 123f.  
After 30 minutes, step with 5qt boiling water, target temp 154f  
Conversion done in 20 minutes or so. Mash out at 168.  
Sparge with remaining supply water to collect 6 gal  
boil 60 minutes with 35gm chinook pellets (13% alpha) Est. IBU 67  
OG with 5.5 gal of wort is 1.054  
Chill, pitch 12gm dry whitbread ale yeast.  
TG after 6 days @ 68f was 1.020, 3.73 %w/w, 183 cal/12oz  
Fine with 1/2tsp gelatine dissolved in water when kegging.

I kegged with 1qt of wort recovered from the kettle after chilling. I strain out the hops/trub with a fine hop bag and can the wort to preserve it until kegging time. It would work just as well to force carbonate or use priming sugar. Don't over do it. Stouts are not supposed to be fizzy. Still, with all that Oatmeal, the head is tremendous! Get out a fork and knife when drinking :=)

This stout has a smokey aroma - probably due to the large amount of roast barley. Even though it has a lot of hops, it seems balanced. I think that Oatmeal makes teh resulting beer quite sweet. If served too cold (say 45f or below) it will be quite bitter. At 50-55 it is like nectar. Sip, sip - writing this article gave me a thirst so I opened up a bottle. Mmm, good stuff. I bottled the last gal or so from my keg to make room for another beer...

Cheers!

- Larry Barello

From: ml4051@mwvm.mitre.org (John DeCarlo)  
Subject: Why Control a Refrigerator?

Jack S asks [and I paraphrased]:

[why use an external thermostat with a refrigerator?]

I don't know what Baderbrau does, but here are the general reasons for using a thermostat with a refrigerator or freezer.

- 1) Most refrigerators are not designed to maintain a specific temperature.  
The temperature may vary by 5 to 10 degrees at a particular setting in many commercial fridges.
- 2) Calibrating a refrigerator (which setting keeps it closest to 48 F?) is a difficult process, particularly because of 1) above. If you always wanted to ferment and lager at the same temperature, it might not be so bad.
- 3) [This doesn't yet apply to you and may never, Jack.] The temperature you choose to ferment at and to lager at depends on the particular yeast strain you use and the style of beer you are trying to achieve. If you vary these (and most homebrewers do), you may rarely ferment and lager at the same temperature twice in a row.

A typical three-batch use may have a lager fermenting at 45F and then lagering at 38F. Next week the brewer makes an ale and ferments it at 65 F. Two weeks later another lager, this recipe calling for fermenting at 42F and lagering at 35F.

You can easily see how an external thermostat will greatly ease the job of this homebrewer.

From: tony@spss.com (Tony Babinec)  
Subject: barley wines--yeast & technique

Tom Bower asks about barley wines and the yeast to use. I don't have a lot of barley wine brewing under my belt, but here's my experience.

I think the two yeasts mentioned are the obvious place to start. One very good homebrewer uses Wyeast "American" ale almost exclusively for his beers, including barley wines, and has gotten excellent results. He says that he might try another yeast for barley wine. His sensory perception is very acute, at least compared to mine, and he smells stuff that I don't; I thought his beer was just fine. And Bigfoot Ale turns out very nicely, especially for that gravity.

The Whitbread ale yeast is Wyeast "British." I would use that in preference to the dry whitbread ale yeast. George Fix has commented on the three strains in the yeast, one of which is a high-alcohol performer.

I see no reason to go to a second yeast, such as a champagne yeast. The best commercial barley wines are made with house yeasts, and we should be able to match that. However, getting a properly attenuated beer from the yeast is not necessarily straightforward.

I made a barley wine in March, and decided to use Whitbread. The beer came out at about 1.086 starting gravity. I left it in primary fermentation

for most of March, racked it to another carboy at the beginning of April, racked it again at the beginning of May, and bottled in early June.

One reason to give it such a long time is that you could see fermentation activity in the carboy. To keep the yeast going, I'd occasionally rouse the yeast by swirling the carboy for a minute or so to stir things up. Also, for reasons I'm not entirely clear on, it seems that dry hopping will

sometimes get a slowed fermentation going. Either the hops (pellets are easier to use here) provide a nucleus for suspended yeast, or there is something in the hops that gets the yeast going. Or, maybe it was the racking that did it. In any event, in my experience, it needed a long secondary fermentation. Also, dry hopping makes sense for this beer. Sorry, I don't have the brewing notes with me, so I don't have the final gravity, but I'm pretty sure it was in the 1.020s.

You should add hops as much as you like. For one thing, the large starting gravity in the boil pot means that proportionately more hops are needed to attain bitterness. The huge, heavy maltiness of the beer needs hop bitterness to offset it. Add hops at different times in the boil, and dry hop. The long aging, both in secondary and in the bottle, means that hop character will change and fade over time. These beers can be stored for a long time, and you'll want to have one in a year or two or more.

How did my barley wine turn out? I haven't tasted it since bottling, and should taste it one of these days to see how it's progressing. With bottling in June, I'm thinking that it might be drinkable towards year-end. It tasted good at bottling time.

One other thing: how much priming sugar should you use at bottling? I normally use 3/4 cup for 5 gallons, and I more or less halved that

amount. You don't want a fizzy barley wine, and with all that malt and sugar and a strong performing yeast, you don't want a gusher down the line.

Have fun!

Subject: Re: high-temp ferment

Rick asks:

>What sort of off-flavors are caused by high-temp fermentations?

High-temperature fermentations cause an increase in the production of esters, a slight increase in the risk of bacteria reaching levels of significance, an increase in the production of diacetyl and an increase in the production of fusel (higher) alcohols. The esters, diacetyl and fusel alcohols, are not necessarily off-flavors unless they are produced in such large quantities that they are distracting or inappropriate for style (such as low-to-mid gravity lagers). Note that "high-temperature" is relative -- for an ale, temperatures over 75F are usually considered "high" whereas for lagers, temps over 50F are usually considered "high." Also, nothing starts suddenly at a particular temperature, it's all a continuum.

On a related note: if your yeast has a tendency to create phenolics (like Munton & Fison's Muntona yeast), it will create a more the higher the fermentation temperature.

One factor that should also be addressed is that our brewing environment may be different during warmer months: doors opening more often, open windows, higher humidity (great for mold production), higher concentrations of wild yeasts as well as bacteria in the air, and warmer tapwater (resulting in slower chilling if you use a tapwater-powered chiller). Therefore, sanitation during warmer periods is much more important and off-flavors can often be traced to problems in the environment.

>retain more proteins which are necessary to sustain the yeast over long  
>lagering periods.

Just one minor addition: yeast can't use the proteins directly, they do  
however, require the amino acids which make up these proteins. The  
protein rest that generally has been accepted as "required" for lager  
malts

is for the purpose of giving the proteolytic enzymes an opportunity to  
break the proteins into amino acids. According to Charlie's TCJoHB (and  
probably TNCJoHB -- I've read both, but I'm sure it's in the original),  
highly-modified malts have lower protein levels and higher levels of  
these  
required amino acids. Given that recent posts (Jeff's included) have  
indicated that "all malts these days... are highly modified" I don't know  
how much of the protein/amino acid issue (and subsequent importance of  
the  
protein rest) is still true. Comments?

From: korz@ihpubj.att.com  
Subject: Wyeast Whitbread / Barleywine yeasts

Wyeast #1098 is (allegedly) the Whitbread 3-strain.

I would use Wyeast #1056, "American Ale" which is (allegedly) the Sierra Nevada yeast. Whereas the Whitbread is a fine yeast, I, personally, feel that Whitbread beer has too "breadlike" a flavor, so I've avoided Whitbread yeast. If you like the flavor of Whitbread beer, then you've got a choice. I'd skip the wine yeast.

While I'm at it, someone (sorry) asked if Bell's beers have culturable yeast in them. They certainly do have yeast in the bottom of the bottle, but I don't know if it's culturable -- try it.

From: gummitch@techbook.com (Jeff Frane)  
Subject: Green flakes, etc.

First of all, a hearty THANK YOU to Tony Babinec for all the information on Belgian malts. I'd heard these were available, and had asked George Fix a couple of questions about them, but this information is all I needed and enough incentive to urge Steinbart's to start carrying them. Is the Belgian Ale book referred to part of the AHA series? I haven't seen it, although I've been looking for it eagerly.

From: Glenn Anderson <glenn.anderson@canrem.com>

Glenn asks about little blue flakes coming out of his wort chiller. Sounds to me like verdigris--and it sounds like time to bring in the chemists. According to the dictionary, verdigris formed by the action of acetic acid on copper is poisonous, while a deposit of copper carbonates is not.

What I don't understand is why they're appearing. I've been using the same counterflow wort chiller for about seven years and I've never seen anything like that.

>dry hop in the secondary?

It's long enough, but ... Having dry-hopped 20+ batches, I've learned there is a significant change over a longer period of time as the beer slowly gathers hop character from the infusion. My own experience has been that the beer only really develops that incredible hop essence after about 4 weeks. (I'm able to determine this by the simple scientific method: I drink the beer from the keg which is dry-hopped. It usually reaches its peak about the time it runs out!)

I don't know at what angle you're storing your kegs -- I keep mine upright and the only time the large o-ring touches the beer is during the carbonation agitation. My guess (I bought my kegs new) is that the o-rings \*inside\* as well as outside the the disconnects (I'm only familiar with ball-lock) are to blame for the cola/rootbeer/etc. flavors. Foxx sells the little o-rings for probably a dollar per dozen. At that price, why bother keeping the old ones?

Our temperature range is 32F-75F or so. The original thermostats on all my fridges (and especially my chest freezer) won't do any better than 40F. You need to consider the apartment dwellers who simply don't have a 65F basement or anyone who wants to brew lagers.

> Baderbrau ferments, ages and bottles/kegs their beer at 50F. This is a high  
> quality pilsner lager and any fridge I have ever seen can maintain 50F

> What am I missing?

Maybe the insulation on your fridge is bad. Under nomal circumstances (now I'm lagering a bock in one fridge and trying to keep 40 pounds of fruit frozen till I get a chance to brew with it in another), my two "ale fridges" are set to 54F and my "lager fridge" (a little one, on which I use the original thermostat) is about 37F. On the issue of Baderbrau, it's a \*great\* lager, but not a pilsner -- 50F is much too warm for

lagering a pilsner which (like Pilsner Urquell) are lagered at 33F. 50F is really at the warm end of lager fermentation.

As you will recall when you first posted your window screen lautering system, I said that it would probably give you lower extraction efficiencies. A short while ago, you posted a recipe and your extract efficiency was pretty low, which could be due in part to other factors, but I'm sure that the fact that your lautering system only draws runoff from the center is most of your efficiency problem. I checked my files and could not find your recipe, but to the best of my recollection, it was 9 lbs of grain yielding 5 gallons of 1045 wort. This is 25 points per pound/gallon ( $45 * 5 / 9$ ). Many HBD posters have reported 33 points and some even higher. 33 points would give you 1059 from 9 lbs of grain. Looks to me as if you're throwing away (or composting or making bread from) 25% of your grain's sugars.

Larry writes:

>Al Korz chastised me for including a partial recipe for Oatmeal Stout  
>in HBD #924 (an article about mashing oats and other specialty grains).

Gee... I hope my email to you didn't sound too harsh. All I meant to say was that you gave the grains and hops for a recipe, yet you didn't originally include the yeast (and in retrospect, the fermentation temperature).

I've found that the yeast makes the biggest contribution to the flavor of a beer -- more so than ratios of grains or type of hops. If one was to try to duplicate your beer without knowing the yeast or fermentation temp, their version would probably taste significantly different.

In general, when posting recipes, we all need to remember that thanks to Mark Stevens and Karl Lutzen, our recipes have a much longer half-life. Virtually any recipe that is posted will, eventually, end up in The Cat's Meow.

A1.

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Root Beer

There have been a number of posts asking about Root Beer recipes, well I came across this,

#### OLD FASHIONED ROOT BEER

"Use strong bottles with patent stoppers or tie corks in securely. Use a stone crock or granite vessell in which to let drinks stand while 'working.' Fresh roots from the woods are always preferable to dried herbs. Select a cool place in which to store the drinks; the longer they stand in a warm place after bottling, the more effervescent they will become! When filling bottles, fill to within an inch of the top.

1 cake compressed yeast 5 pounds sugar  
2 ounces Sassafras root 1 ounce Hops or Ginger Root  
2 ounces Juniper Berries 4 gallons water  
1 ounce Dandelion root 2 ounces Wintergreen

Wash roots well in cold water. Add juniper berries (crushed) and hops. Pour 8 quarts boiling water over root mixture and boil slowly 20 minutes. Strain through flannel bag. Add sugar and remaining 8 quarts water. Allow to stand until lukewarm. Dissolve yeast in a little cool water. Add to root liquid. Stir will. Let settle then strain again and bottle. Cork tightly. Keep in a warm room 5 to 6 hours, then store in a cool place. Put on ice as required for use.  
"

The Fleishman Company, Excellent Recipes for Baking Raised Bread, 1912

I have never tried this recipes, always used extract for local homebrew store, but I thought someone might find it useful.

I suffered with this also. After spending portions of days messing  
around  
with the old rubber on cornelius  
kegs (and still smelling the soda-pop  
stench), I paid a very modest fee (the dollar  
amount is lost to my aging brain cells)  
for a complete set of new rubber parts.  
I would have done it sooner if I knew how cheap it  
was. The stainless steel cleans well with one of the hydroxide cleaners,  
but that rubber seems to be a tough nut to crack.

> quality pilsner lager and any fridge I have ever seen can maintain 50F  
with  
> no outside help.

I have a refrigerator you haven't seen, and it would never go above 45F.  
Moreover (due to some phenomenon I don't understand) when there was  
a primary fermentation in it, it would actually chill down to the high  
30s. My only attempt at a lager fermentation in this environment  
produced  
a very sluggish primary ferment.

I now have a Honeywell controller attached and am quite happy with the  
results: I have successfully done refrigerated  
ale primaries of 65F in the summer  
(when my house was in the high 80s).  
If I ever try a pilsner, I'll go for the highest primary temp  
I can get away with, which many people think is 50F.

>ale malt can be used for a one-step infusion and achieve the same  
>protein extraction.

Although I don't doubt the accuracy of your buddies statements, classical literature on brewing/mashing (e.g. The Practical Brewer) make it pretty clear that the lower temperature protein rests are to provide short amino acid chains that the yeast can use for a nitrogen source. Intermediate length chains contribute mouthfeel and body. Longer chains cause chill haze. Over cleaved protein (e.g. too long a protein rest) can cause head retention problems as well as insipid mouth feel.

>From your description, Ale malts should have more longer chains - due to the shorter time that they are kilned at temperature that favor protolytic enzymes (pardon my spelling). In fact (from memory, no reference at hand)

the longer germination time (aka over modification) is what is responsible

for the availability of free amino nitrogen (FAN) without the protein step in mashing. Lager malts (classic undermodified) presumably have more

of the starch locked up in the steely endosperm with long interlocking protein chains. The protein rest is needed here to generate FAN, reduce long chains (chill haze) and liberate the starch for sugar conversion.

>

>Larry Barello posts that "The bottom line is that step mashing is probably a quaint practice that is a hangover from big commercial breweries that use lots of rice and corn (where step mashing is still needed)." According to Jim, this isn't the case. A step mash is useful for ensuring a high-protein wort, not for converting adjuncts (though it may be helpful there as well). We all agree, however, that in terms of enzymatic power and sugar extraction, lager and ale malts are comparable.

I was not being clear: The step mash is to generate more FAN since the corn and rice has such low quantities to begin with. Steeping has nothing

to do with starch conversion, per se. The fully modified grains available today don't have a problem with long proteins or insufficient FAN for yeast growth. With undermodified malts (which we agree are probably unavailable today) the step mash is needed for chill haze and starch release as well as FAN.

>

>Jim also maintains that the difference between US and UK pale malts is that UK barley is grown in soils that are less heavily fertilized with artificial fertilizers and therefore have a lower nitrogen content.

Please get some references from you buddy. The above statement sounds like cow doodoo to me. Also, run my statements, above, by your friend. I don't mind being corrected if the state of the art has changed recently.

I hope folks don't find this article too long. This is an interesting subject that has pretty broad implications on how much work we homebrewers do to get award winning beers. One reason I got started on this is that I observed many commercial micro-brewers using single step infusion mashing using various "lager" malts (e.g. GWM Pale Malt) and wondered why they were getting excellent results with so little work. Another tidbit to chew on. Many use relatively high temperatures too, like around 160f for the single step. Perhaps that is to compensate for the minimal use of expensive specialty malts?

Cheers!

From: cestes@argos5.DNET.NASA.GOV (Chris Estes)  
Subject: Culturing Yeast

I was wondering if anyone out there could give me some pointers on the best methods of culturing yeasts from beer (SNPA in particular). I know that its available from Wyeast, but lets hypothesize...

If I were cheap and lazy (which of course I am not!) would the following scenario be possible and if not, why not? : During the course of brewing my next batch of beer, I (perhaps with some help) drink a six pack of SNPA, leaving 1cm or so of beer (and yeast sediment) in the bottle (beer is to be drank from a glass - no lips on bottle). When my brew is done, I swish the yeast sediment up and dump the bottles into my primary.

Will this work? Must I do more to use Sierra Nevada's yeast?

Just wondering...

Date: Tue, 21 Jul 92 09:45:07 CDT  
From: whg@tellabs.com  
Subject: The St. Louis Brewing Company (ala Dave Miller)

I recently visisted Dave Miller's Brewpub/Micro-Brewery. It's in a pretty strange part of town in St. Louis (21st and Locust). The brewery is called the St. Louis Brewing Co. (or something very close to that) and the attached bar/restaurant is called the Tap Room. The atmosphere is quite nice. It's the old factory/warehouse motif, with lots of bare wood and duct work. The brewery is in plain view behind a big glass wall so you can gaze enviously at the equipment as your wine and dine (beer and dine?). The food was quite good by the way.

And now what you've all been waiting for da' beersss. They had six beers on tap and the bartender was perfectly willing to give you an ounce or so of each for a grand total of \$0.00. Let's see they had:

Pilsner - Didn't try it but probably should have as it's Miller's fav style.  
Weizen - very sour, definatly in the Berliner Wiess arena  
American Wheat Ale - Boring, definatly for the adventureless yuppsters.  
ESB - Very clean bitter much like a fresh Fuller's.  
Irish Stout - Black and creamy as you'd expect.

There may have been one more but my memory is foggy. My overall impression is that all the beers were technically excellent. Not a flaw could be found. But honestly, they all seemed to be so good as to be almost sterile and adventureless. All of these beers would do very well in competitions as they are faultless and perfectly examplify the style, but somehow they lack depth in their character. These are of course my admittedly non-expert opinion.

The best brew in the house was the guest beer Bully Porter form the \*\*\*\*  
\*  
brewery in Colorodo (does anyone know who brews this?). I only got half a glass sinse the keg was running out, but it was chewy and chocolately and just all around yummy.

I've only made two batches which could be considered barleywines -  
I usually chicken out and go for something slightly lighter (but not  
much)

batch 25:

20 lb lager malt  
1/2 lb crystal malt  
5 lb munich malt  
1 lb roasted lager malt  
2 tsp gypsum  
1 hr 15 min protein rest 132 - 115 F  
mash 152 F w .5 oz amylase enzyme for 2.5 hrs  
mash out 165-172F  
sparge with 168F H2O to make 11 gal  
siphoned off to make 9 gal sweet wort at 1.064 (i.e. the sparge stuck,  
so I stirred it up, letting husk material into the sweet wort.  
I then let it settle, and siphoned off the husks -  
note the substandard extraction rate)  
26.5 g 5.6% AA Goldings leaf 1:40  
25 g hallertau leaf 1:40  
26.5 g 5.6% AA Goldings leaf :50  
25 g hallertau leaf :50  
7-14 g hallertau leaf :40 (scales became unbalanced)  
7-14 g hallertau leaf 10:30  
.75 tsp irish miss :10  
cooled to 88 F, pitched WHITBREAD ALE yeast  
OG 1.090, racked after 1 week G 1.034, bottled 1 week later  
w 4 oz (by weight) corn sugar, FG 1.034

I wrapped it in a cold towel, but there was so much heat  
released from the fermentation that it became quite warm.  
After 36 hrs I put it in a bucket of 70F water.

I submitted it to the AHA's homebrew contest this year. Both judges said "not enough alcoholic punch" and "not enough hops" for a barleywine, and both gave it a 27, though from the breakdown of the scores, I got the impression that they agreed on the 27 beforehand, and then somehow tried to justify it (since 27 corresponds to "not true to style"). Both agreed that it was well-brewed, malty, estery. 1 judge said slight chill haze and the other said somewhat astringent.

Maybe it made a better scotch ale,  
But I loved her, and she's gone, captain.

then there's batch 29:

10 lbs schreirer 2-row  
5 lbs munich  
1 lb wheat  
323 g crystal malt  
1/5 tsp salt  
1/2 tsp epsom salt  
1 tbsps gypsum  
4.5 gal 145 F water to make mash ph 5.3  
protein rest 126-120 30 min  
mash 153F for 2:50  
mash out 165-170  
sparge water ph 5.8 to make 8.5-9 gal wort  
1-3lb 5oz can glenbrew hopped scotch bitter 1:25  
1/2 oz 4.2% AA fuggle plug 1:14  
1/2 oz 4.1% AA hallertau leaf 1:14  
1/2 oz 4.2% AA fuggle plug :40  
1/2 oz 4.5% AA fuggle pellet :40  
1/2 oz 4.1% AA hallertau leaf :40  
1/2 oz 4.2% AA fuggle plug :13  
1/2 oz 4.5% AA fuggle pellet :13  
made 4 gal, sG 1.099 wort  
pitched Wyeast Belgian Ale starter - ferment at 65-70 F  
for 6 weeks. FG 1.031 bottled w 100 g corn sugar.

After 3 months in the bottle, there is still very little carbonation. I definitely should have added more yeast at bottling time. The beer tastes more like a port than a barleywine. Very little hop character. It's a belgian strong ale like I wanted, but not quite what I was aiming for. I'll see what time does to her.

anyway, I've used up my bandwidth to this congested digest today, My vote: go for the whitbread ale, keep the temp high for the early fermentation if you want an estery product.

Oh, and on the subject of oatmeal stouts - Does anybody else think that Sam Smith's has a bacon flavor? How does a Bacon stout sound?

From: johnf@persoft.com (John Freeborg)  
Subject: Keg connects

I just ordered the keggng equipment today so of course now I have a question! I have (3) pin lock soda kegs which used to contain diet coke and sprite. Somebody posted a message about how to disassemble the in/out connectors so they can be cleaned. I tried to do this on one of my kegs and came to the conclusion that I was probably going to rip the valve

off before it ever came apart. Am I doing this wrong? Do they come out (easily)? Are the small o-rings everybody talks about the ones I see on the outside of the valve housing? I have the large 3-4" diameter o-rings for the main opening, but I ordered some replacement o-rings for the valves. Are there more o-rings inside the valves I should be concerned about? Is there any way to clean the downtube easily?

Are there \*bad\* consequences that can happen if your CO2 tank tips over on its side (other than trashing the gauges)? Does the liquid CO2 enter the keg - or freeze the line so bad it snaps apart? Or am I worrying too much.....

I'm also in the new apartment hunting mode at the moment and am wondering how other people use their propane cookers. I've got a King Kooker propane burner which works great. However, I may have to brew on my patio in the new apartment. Not a problem for most of the year, but this is Wisconsin so doing it during Nov, Dec, Jan, Feb is probably not feasible. Do other people use these things inside? I've heard of using them in basements, but what about well ventilated kitchens (sounds like inviting disaster to me...). I can just see the fire investigator asking me how the fire started - "Well, you see I was in the middle of brewing this awesome stout when a boil over occurred and all hell broke loose...".

Subject: WINNER, Hops, Yeast, Mashout, Trub

To: Homebrew Digest  
Fm: Jack Schmidling

We seem to have a concensus on the 100th article.

Congratulations Mr Adams, you will soon be the owner of your very own MALTMILL. As you article had little to do with brewing and I do not recognize your name, I suspect others share my interest in knowing what you plan to do with it. Are you a brewer? Will this make an all-grainer out of you?

Now, to claim your MALTMILL, all you have to do is post a 1000 word essay on why my beer is the World's Greatest. Then I will pop a contract into the mail that will only commit you to ten years of promotional tours, at your expense of course. Upon receiving your signed and notorized copy I will start scrounging up reject parts and probably get one to you in time for Homebrew Expo 2001.

Seriously, congratulations and welcome to a very elite club. Most of us had to work a little harder for ours, but that's life.

If you send me your shipping address, I will get it out to you.

>From: sxs32@po.CWRU.Edu (Subbakrishna Shankar)  
>Subject: Hop vine pruning and lagering refrigerator

>Congratulations, Jack. You certainly stirred up interest in HBD during the summer doldrums.

There seems to be a range of views on this subject.

> A few weeks ago I was complaining here that my hop rhizomes weren't growing, so naturally they are now growing all too well. I have assiduously pruned back new shoots.....

I sugest you stop pruning your several vines that you have allowed to grow. Just let them grow and prune only the new shoots at the base.

> Anyone with a climate similar to Cleveland getting flowers already?

I have pea sized flowers one one vine in Chicago.

Interestingly, they are only on the vine that I forced to grow horizontally when it reached the top of my six foot fence. The growing tip has dried up and all growth is now in the flowers.

Two other vines from the same plant were allowed to grow vertically up strings and they are three times as long and no sign of flowers. It appears that they will yield many time more hops than the one forced to grow horizontally but will flower later in the season.

Needless to say, I gave on on the fence idea for the rest of my plants and they are all climbing up string.

They are Chinook, BTW.

>From: gummitch@techbook.com (Jeff Frane)  
>Subject: Please No More Offers!

>Please, Jack.....I can't see what good this is doing....

Tell that to Mr Adams!

>From: Jay Hersh <herhsh@expo.lcs.mit.edu>  
>Subject: Cider and it's yeast

> Well this is slightly misleading Andy. The source of the wild yeasts is not waiting to drop from the heavens. It is already right there on the apples at crushing time.

Good discussion on "wild" yeast.

For those not aware of it, virtually al varietal wines depend on the indigenous "wild" yeast found on the grape in the field.

Champaign yeast is scraped off of grapes growing in the Champaign region, Burgundy yeast comes from grapes growing there, etc.... Each type is supposed to impart a unique character to the wine and is one of the reasons Europeans have gone to such great lengths to protect the names of their wines.

There is nothing evil about "wild" yeast, after all, that is how wine and beer were discovered/invented. It is just that we have become technosnobs.

We know how to scrape off a little of that special yeast and pure culture it to avoid contamination by any other undesired organisms. We know how to sterilize our must/wort and be absolutely certain that it will be true to type.

This brings up an interesting project, and fits right into the plans for my anticipated bumper crop of apples and limited crop of grapes and elderberries.

I am going to try to pure culture the apple yeast if I can find the bloom that Jay is talking about. All I have ever noticed on apples is the common rust which is also a fungus but not nearly as welcome.

>From: polstra!larryba@uunet.UU.NET (Larry Barello)  
>Subject: Re: Lager vs Ale malts?

>The bottom line is that step mashing is probably a quaint practice that is a hangover from.....So, anyone else out there given up step mashing when doing all malt recipes and been satisfied with the results? Anyone else have any evidence to support or debunk my claims, above?

I would like to expand the poll to find out something I have been alleging from limited anecdotal experience.

First of all, I think you are right about step mashing being a waste of time with the malts we use as far as extract efficiency is concerned.

I however, believe that a mashout at 170F+ is the best insurance there is to avoid a set mash and would like to hear from people who can support or disprove the hypothesis. I have never had a set mash so I do not need to hear from others who have not. I just want to hear from those who have and whether or not they use a mashout.

TRUB.....

One additional comment on trub.... I have been dumping the trub from the brew kettle into a gallon jug and letting it settle in the fridge over night and get a quart or more of wort that I can either sterilize and dump in the ferment or use for starting the yeast for the next batch.

That's a quart of beer I used to throw away. Put another way, it's a simple and freebe, 5% increase in yield.

From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: Re: mashing oats

Jeff Mizener sent me a direct mailing asking about German oat beers. My reply bounced back, so I've posted it here:

Jeff,  
Sorry, my information was second-hand. A beer-loving colleague of mine went to a scientific conference in Bavaria (on cereal storage products - proteins & starch) and at the main conference dinner beer was served instead of wine. He showed me the menu - there were several Weizens, 3-4 rye (roggen?) beers (there is at least one rye beer available here in England) and 2 oat beers. He was very enthusaistic about the oat beers, but his judgement may have been impaired by that stage....

From: KENYON%LARRY%erevax.BITNET@pucc.Princeton.EDU  
Subject: Plating out WYEAST #3056

I just brewed a Weizen (recipe to follow) which is now fermenting with Wyeast #3056. I streaked a wort/agar petri dish with a sample from the Wyeast pouch. Since 3056 reportedly contains a 50/50 mix of *s. cerevisiae* and *s. delbrueckii*, do I need to maintain a slant of each of each of these strains and build each up prior to starting, or can I maintain both on the same slant?

The latter sounds unlikely, so here's my question (?)... How will I be able to distinguish between the two strains on the plate? Is 50/50 the best ratio to use for pitching subsequent batches?

I would like to hear any and all experience on this subject as soon as possible since my plate already had visible growth as of this morning, so please email to me and I'll summarize to the digest ...

Now for the recipe:

Weizen Schmeizen, 10 gallons

6.6# can IREKS Wheat Malt Extract (100% Malted Wheat)  
6.6# can IREKS Light Malt Extract  
2 oz Hallertau Leaf, Bittering, 60 min. (alpha=4.4)  
1.5 oz. Cascade Leaf, Bittering, 30 min. (alpha=5.7)  
.5 oz Hallertau Plug, Aromatic, 15 min (alpha=2.9)  
Wyeast #3056 from a 1qt starter. Lag time 6-8 hrs.

Bring 3 gallons water to boil, remove from heat and add malt extract syrup (yes, all of it). Bring mixture to boil, add Hallertau bittering hops. After 30 minutes add Cascade bittering hops, 15 minutes later add Hallertau plug (I used hop bags for all 3 additions).

Cool wort (about 3.5 gallons) to about 100F, siphon onto another 3.5 gallons of cold tap water, aerating vigorously. This produced 7 gallons of wort with a S.G.=1.065 (I get great extract efficiency from my extracts!).

I intend to rack (dilute) this into two secondaries each containing 1.5 gallons of water. Since there won't be any new sugars for the yeast to contend with I don't plan on aerating the additional water. I figure this should get me to 10 gallons of what would have been S.G.=1.045 beer, if I had the capacity (or desire) to brew/primary the entire volume.

Pitched yeast starter @75-80F.

I'll post the results when I know them ...

Thanks, -Chuck-

Date: Wed, 22 Jul 92 11:57 CDT  
From: korz@ihpubj.att.com  
Subject: ESP/culturing/malehops

First, I'd like to point out that there were \*two\* instances of ESP (no, not ESB) in the last HBD. First, I asked about the importance of protein rests with fully-modified malts, which was telepathically relayed to Larry Barello, who answered my question, and then there was the request for brewpubs in St. Louis followed by Walter Gude's review of Dave Miller's brewpub (I'm sure glad I didn't post right away).

Secondly, I'd like to answer Chris' question about culturing from commercial beers such as Sierra Nevada. I've had great success with SNPA yeast, both from Wyeast and from the bottles. I have heard a rumour that SN has begun filtering their beers (I hope someone can dispel this rumour) -- I'm quite sure that their Pale Bock has no yeast in the bottom. The SNPA I have is a few months old and still has yeast in the bottom. I recommend you use a starter, Chris. All you have to do is put two tablespoons of malt in a cup of water and boil it for ten minutes. Cool that with the cover on the pot. When the mini-wort is at 70F, pour (from a foot or so above the sanitized funnel -- for aeration) the wort into a bottle in which you've left (as you had mentioned) the last 1cm of beer. Flame the lips of the bottles before every pour for added sanitation. I usually use three bottles of SNPA poured together into a single bottle and 8 ounces of wort. Attach and airlock. If the beer was around 60F or so, there is less shock to the yeast and it seems to start faster -- sometimes in as little as 12 hours. I suggest you wait 24-35 hours. At high-krausen, a 3-piece airlock will bubble about once every 1-2 minutes (equivalent to 40-80 bubbles/minute in a 5 gallon batch).

Finally, a question:

What do male hops look like? I think my Nugget may be a male. The "cones" look really tiny with 20-30 3/8" to 1/2" spikes sticking out of them. I'd be pretty upset if I raised this plant from a pup and then find out I have to rip it out. (Just for completeness, males are unwelcome in hopfields -- they fertilize the females causing them to make seeds instead of concentrating their efforts on lupulin.)

Al.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: yeast/O-rings/Bully Porter

>I see no reason to go to a second yeast, such as a champagne yeast.

If you do, make sure that you use a large starter, and pitch at high krausen. There isn't enough O2 left in the wort for the yeast to undergo multiply (and/or the high alcohol kills much of the active yeast), so it's even more important to get the yeast going before adding it to the already-fermented wort.

From: Chris McDermott <mcdermott@draper.com>  
Subject: Cream Stouts and Lactose

Cream Stouts and Lactose

As I understand it, lactose is often added to cream stouts. Since the lactose is unfermentable by normal "beer" yeasts, it remains in the final product to give it a sweet, "creamy" flavor. Unfortunately, lactose is not only unfermentable by the yeasty-boys, it is also undigestable by many humans. Does anyone have a reasonable suggestions for a lactose substitute in these recipies. Perhaps there is a "natural" procedure for doing this, like using more specialty malts, or higher mash temps, but my inexperience has left me in the dark. Anyone got a light?

From: ISENHOUR@LAMBIC.FNAL.GOV (John L. Isenhour)  
Subject: yeast cultivation from bottles, barley wine

Chris Estes writes:

>I was wondering if anyone out there could give me some pointers on the  
>best methods of culturing yeasts from beer (SNPA in particular).

The Yeast issue of Zymurgy has some good info. What I have been doing lately is to create a sterile starter (I use a pressure cooked - yeast flask or large flask or quart mason jar) 1-2 Tablespoons dry malt per 500 ml of good water. I let the beer bottles settle for a coupla days after purchase. Then I pour the bottles into a pitcher immediatly putting the yeast dregs into the sterile media, then shake the container, then store in a warm (75 deg f) place. It usually starts right up with little pinpoints of 'head', and is ready to go in a coupla days. I then pitch that into a gallon glass starter of 2 liters and taste it for infection. When the 2 liters of starter is ready to go I brew. I've gotten great results this way, and you can inoculate a quart mason jar and refriderate it it in a plastic bag, and it keeps for several months. I would advise making a starter rather than adding right to the carboy to decrease the lag time.

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Root Beer Repair

OK so I should have know better than use tabs in my email. Let try again.

#### OLD FASHIONED ROOT BEER

"Use strong bottles with patent stoppers or tie corks in securely. Use a stone crock or granite vessell in which to let drinks stand while 'working.' Fresh roots from the woods are always preferable to dried herbs. Select a cool place in which to store the drinks; the longer they stand in a warm place after bottling, the more effervescent they will become! When filling bottles, fill to within an inch of the top.

1 cake compressed yeast  
5 pounds sugar  
2 ounces Sassafras root  
2 ounces Juniper Berries  
1 ounce Hops or Ginger Root  
1 ounce Dandelion root  
2 ounces Wintergreen  
4 gallons water

Wash roots well in cold water. Add juniper berries (crushed) and hops. Pour 8 quarts boiling water over root mixture and boil slowly 20 minutes. Strain through flannel bag. Add sugar and remaining 8 quarts water. Allow to stand until lukewarm. Dissolve yeast in a little cool water. Add to root liquid. Stir will. Let settle then strain again and bottle. Cork tightly. Keep in a warm room 5 to 6 hours, then store in a cool place. Put on ice as required for use.  
"

The Fleishman Company, Excellent Recipes for Baking Raised Bread, 1912

A couple of notes from the Oregon Brewer Fest

A great time! Lots of great beers

I worked next to Devils Mt. Brewery on Friday night. They were pouring Railroad Ale, I saw no one from the brewery but they seem to still be in business

I had a long talk with someone who works at Widmer... they only use one yeast and the repitch from batch to batch. The Hefe-Wisen is kegged young (4-5 days?) and before kegging the recirculate the beer to reach the desired cloudy state.

From: avalon!jm@siemens.siemens.com (Jeff Mizener)  
Subject: PET bottles & missing digests 928 & 929

Well, I won't win a maltmill but the mailtool in Openwindows 2 has a bug that causes it to disobey the command to save a message to a new file sometimes.

Could someone send me digests 928 & 929? Please drop me a note first and then send as I don't want to get 30 of each. Thanks.

I recently went on a camping/rafting trip with number of beer brewers and drinkers (mostly drinkers). A friend from Canada brought 24 one liter PET (green plastic soft drink) bottles full of homebrew. Needless to say he was pretty well accepted into the group.

But the PET bottles caused a stir. The assembled group oohh'd and aahhhh'd over the bottles (& the beer) but generally admitted that this was an unfamiliar but desirable method of storing beer.

He buys them at one of the (at least 3) homebrew supply shops in Kingston, Ontario for \$cdn9 per dozen. He says they're cheaper mailorder.

Well, not one to be the last to try something new, I went to Canada and bought 12 liters & 24 half liters, with caps (good sealing caps). They don't break, they're easy to clean, they're light and my next batch of bitter will go in them. When they get old, you can recycle them (at least in Raleigh...).

Any comments??? My local BrewStoreMeister said that they were available but rather expensive. He said that Coors had floated some trial marketing balloons but the reception had not been real good. In Britian you can buy lots of different beers in 2 litre pet bottles. Granted, there's a certain visceral satisfaction to opening a crown-capped bottle and hearing the `pffffssstt', but is there any reason why we shouldn't use these bottles?  
?

Raft trip attendee and digest subscriber Bob Safranek tells me he found the bottles at a HB store in Milwaukee @ \$13.00 for 24 - 16 oz. More expensive than Canada but not bad...

Cheers,

Jeff

From: KIERAN O'CONNOR <OCONNOR%SNYCORVA.bitnet@CUNYVM.CUNY.EDU>  
Subject: Fridges, yet again.

Sorry, but one more note on fridges.

Refrigerator thermostats have upper and lower bounds so that they can be used for food, not lagering. If you have one and want to test it to see how low a temp it will achieve, remove the thermostat.

Connect the two thermostat wires (the green one is a ground) and let it run for about 30 minutes. Make sure you have a thermometer in there, or preferably, an inside/outside thermometer (the kind with a probe). Then you can see what type of thermostat to buy. The key here is that you can't let this fridge run forever w/o some type of thermostat, the compressor will run out.

If you are interested, I wrote an article for our club newsletter (Ithaca Brewers' Union) and I will forward it to you if you wish a copy. Just put in the message "Brew News Request".

Subject: lallemand and its yeasts

In a recent HBD, someone asked about Windsor dry yeast from Lallemand. I haven't yet used it, but I picked up some information from the G.W. Kent table at AHA National. As many homebrewers use dry yeasts, and as rumor has it dry Whitbread ale yeast is disappearing, I thought I'd post some information on Lallemand. This comes straight from their company literature. If anyone has experience using any of their yeasts, please post to HBD. If anyone is interested in Lallemand products or information, you should obtain them from G.W. Kent via your homebrew shop.

The following is reprinted from Lallemand literature...

Lallemand, Inc. was founded in Montreal by a young immigrant who left his native Alsace after the Franco-Prussian War of 1870-1. Today, Lallemand has state of the art facilities in France, Denmark, Canada, and the United States. Lallemand is the largest producer in the world of Yeast Nutrition products to aid in fermentation. Many of the largest breweries around the world use Lallemand's Fermaid nutrient. In addition to brewing yeasts, Lallemand is a major producer of bakery products, distillery yeasts, bacteria for the food, pharmaceuticals and agricultural fields, and the world's largest producer of wine yeast. More than 75% of France's champagne producers use Lallemand's Lalvin EC-1118 strain of yeast. Lallemand also produces the popular strains Lalvin K1V-1116 and Lalvin 71B-1122.

Windsor English Ale Yeast is a powdery yeast that gives a drier beer which is clean and well-balanced. This yeast produces an ale which is estery to both palate and nose with a slight fresh yeast flavor. This yeast completely ferments wort within 4 days. Windsor Ale is a classic top fermenting yeast with some flocculating characteristics. It is best used at traditional ale temperatures after rehydration.

Nottingham Beer Yeast (ale yeast?) is remarkable for its high degree of flocculation. This yeast settles out very quickly and firmly. Many brewers have commented that Nottingham Beer Yeast appears to glue itself to the bottom of fermenters and bottles. The obvious benefit is the reduction of filter usage and a clearer beer.

German Konig Lager Yeast produces a very clean beer with a fresh yeasty character. This yeast completely ferments wort within 5 days at 77 degrees F and it is not flocculent. It settles slowly to the bottom of the tank after fermentation is finished. It can be used to ferment worts between 45F and 86F. However, it should be noted that the flavor characteristics of the yeast change between these two extremes of temperature.

Subject: mashout,hops,cooler

Not in that order, actually. First, those small spikey growths on your hops may very well be the beginnings of the cones; they start out looking like burrs, then eventually turn into cones. I'd say give it a couple of weeks. If they don't change, or if you notice definite pollen falling from the spikey growths and you have female plants nearby, you might well have to pull it up.

On the subject of hops, I just brewed a wheat beer finished with my own Hallertauer hops. In contrast, the Cascade plant (1 year younger, actually I got it from Dave Wills of Freshops for the Manchester conference!) is just now producing the "burrs". I think the H may be done for the season; Japanese Beetles really damaged it. Strangely, they haven't touched the Cascade.

Re. mashout: I always mashout at 170+ degF. I've gotten one stuck sparge out of 10 or so batches. The grain was crushed pretty finely, too much powder, so I think that was the cause. Mashing out should help \*avoid\* stuck sparges, but it won't eliminate them. It also helps extraction efficiency. I sparge in a \*10\* gallon cylindrical cooler from Wal-Mart. Service Merchandise has them too. That size cooler is seasonal stock, so don't wait.

**Subject: re Single Step Infusions and American Malts, Blue Flakes**

Recently Larry Barello asks about experiences with single stepping vs. using a protein rest when mashing. When I switched to grain brewing, I assiduously followed everything Dave Miller told me to do. It paid off, as the first batch was quite an improvement over my extract brews. One regret I had was that there was so much more to do than when extract brewing.

Well I set out then to streamline the process of mashing. One of the first things I did was to try the same recipe/procedure sans the protein rest. The elimination of the protein rest made no difference. That was many batches ago and have not used a protein rest since. I assume that the protein rest is obviated by the use of modern, fully modified malts.

Glenn asks about blue flakes coming from his counter-flow chiller. I suspect you use some chlorinated solution to store your chiller. I used to do that with mine and found that the chlorine slowly corrodes the copper.

Don't do that if you are. When I'm done brewing I just run 140F hot water through both the inner and outer flow paths of the chiller for about five minutes, then store it dry. This works fine and I haven't had any infections in say 30 batches. Hope this helps.

Cheers,

Subject: SN Pale Bock yeast

Al (korz@ihpubj.att.com) mentionned in hbd 931 that he thought that Sierra Nevada's Pale Bock did not contain yeast. That is not the case in the bottles we get in New York. I recently cultivated the yeast from one bottle, and have it now on slants and in the freezer. I have not used it yet, so I have no idea how it behaves during brewing, but it appears to be extremely flocculent.

From: Bob\_Konigsberg@3mail.3com.com  
Subject: Setting up starter wort

On the advice of a friend, I got a case of quart mason jars, boiled up 3 gallons (in the end) of generic wort (3# liquid malt extract), and then canned them in a pressure cooker. voila - several months (depending on usage) pre-supply of sterile wort.

Just sterilize a gallon jug, start the wyeast packet a day in advance of adding to the starter wort (or use dry yeast), pour the yeast in, and fit with a fermentation lock about two or three days before you brew. Use a sterilized funnel to keep the wort and yeast away from the mouth of the bottle.

By way of example, the overflow bucket for the last batch was full of foam the following morning; this was about 9 hours after pitching.

I avoided this for a while as being too much work, but now that I've made three batches each with virtually no lag time (<12hours), and my beers no longer have infection problems, I'd recommend this to everyone. It's made a tremendous improvement in the quality of my beer. After the first batch this way, I threw all previous batches down the drain. Credit would also have to go to the counterflow (got it right this time) wort chiller for keeping the wort sterile during cooling, but I think the vigorous (otherwise sterile) yeast culture probably deserves most of the credit for clean beer.

The Pale Bock is the only filtered Sierra Nevada beer.

(Thank goodness for that!)

Another data point: the fastest, cleanest fermentation I've had to  
date was with yeast I took from a couple of SN Porter bottles.

Subject: Champaign & sparging

rf@ddsw1.mcs.com (Jack Schmidling) writes:  
> Champaign yeast is scraped off of grapes growing in the Champaign  
region,

That's funny, I've never seen many grapes aound here...  
Champaign is in Illinois, Champagne is in France.  
I guess we could start making a sparkling wine here,  
and legitamitely call it "Champaign", though.  
(btw, Is that the correct spelling of "legitamitely"?)

>I however, believe that a mashout at 170F+ is the best insurance there  
is to  
>avoid a set mash and would like to hear from people who can support or  
>disprove the hypothesis. I have never had a set mash so I do not need  
to  
>hear from others who have not. I just want to hear from those who have  
and  
>whether or not they use a mashout.

I have had quite a few set mashes. Most of them involved wheat malt,  
and in those that didn't, I ground the grain finer than I usually do.  
Only once did I omit the mashout. The sparge ran noticeably slower  
at first, but wheat malt and fineness of grind seemed to be much  
bigger factors.

I don't know how to define "set", though, so put it this way:  
A normal sparge for me takes 2 hours. Multiply by 1.5 if wheat malt  
was used, or 2.5 if it made up 50% of the grist. Multiply by .6 when  
using < 7 lbs of grain (this is rare for me).

I suspect that your use of the Maltmill has quite a bit to do avoiding  
set mashes. I see now that the Malt Shop in WI is offering a "Maltmill"  
for \$99. Is this the one and only?

Maybe this fall I'll get one, but for now, I'm trying to figure out  
how to produce enough beer for my own consumption with the least  
amount of effort possible. This means using extracts only, making the  
least amount of mess possible, and I'm trying to get a Firestone keg  
system together. I'm sick of putting in a 12-hr brew day, followed  
by an hour or two extra cleanup of the kithen the next day, followed  
by a 2-hr bottling session (includes cleanup time). Heck, I could  
drink half the previous batch in that 16 hrs! (Last time I tried,  
I passed out halfway through the boil, though.)

Finally, a question:

What do male hops look like? I think my Nugget may be a male. The "cones" look really tiny with 20-30 3/8" to 1/2" spikes sticking out of them. I'd be pretty upset if I raised this plant from a pup and then find out I have to rip it out.

Al.

Don't rip them out. Those sound like immature flowers to me. Just wait and watch them get bigger. The little "spikes" will drop off shortly.

(reprinted without permission from Air & Space- Aug./Sept. 1993)

#### Strange Brew

When the shuttle Discovery lifted off last January, it had, officially, 42 experiments to conduct. But thanks to a Canadian pub and avid homebrewer-astronaut Bill Readdy, a 43rd experiment was added at the last minute: a study of the effect of zero gravity on hops.

Readdy smuggled aboard about nine ounces of hops, bought at a Houston homebrew store, and slipped them into the fresh food locker. They were almost eaten during the flight by a fellow astronaut who, apparently bored with his own rations, wanted to sample the "green leafy stuff" in the plastic bag.

After the shuttle landed at Edwards Air Force Base in California, the hops were sped by courier to Spinnakers Brew Pub on Vancouver Island, British Columbia, where Brewmaster Jake Thomas was waiting to include them in "Discovery Ale: A Taste Worthy of Those Who Dare to Explore." Weeks later, Readdy and the rest of the crew showed up for a taste. Aside from an entourage of 30 or so from NASA and the Canadian Space Agency, only a select handful of beer connoisseurs from Campaign for Real Ale, Victoria chapter, and a few bewildered tourists witnessed the event.

Stepping behind the bar, Readdy drew the first glass of Discovery Ale, rapidly quaffed a few mouthfulls, caught the drips on his NASA rugby shirt, and proclaimed, "I declare this ale fit for human consumption!"

It certainly was. The full-flavored amber ale drew both scientific and spiritual acclaim as the cask was drained in the time it takes to climb out of a spacesuit.

Discovery Ale certificates, signed by the brewmaster and the Spinnakers proprietor, were handed out to the astronauts and the rest of the samplers.

In exchange, the pub received a large color photo of the Kamchatka peninsula taken during Discovery's flight.

**Subject: King Cooker Modification**  
Full-Name: "John Cotterill"

I use a propane powered King Kooker for my boils. The unit is great at getting the water to the boiling point (10-15 min for 10 gallons). The problem that I have, however, is once boiling, the heat needs to be reduced to prevent an extremely vigorous boil. At low settings, the flame burns too rich and produces lots of carbon on my boiler which is a pain to clean and very messy. I would like to add a small burner ring to the cooker for low settings. Does anyone know where I could locate a small ring (without buying a stove attached to it)? Any other suggestions?  
Thanks, JC

Fm: Jack Schmidling

>From: korz@ihpubj.att.com

> I would be interested to know how you think the o-ring seals without contacting the beer. My guess is that at least 30% of the large one sealing the lid is exposed to beer on the inside.

<I don't know at what angle you're storing your kegs -- I keep mine upright and the only time the large o-ring touches the beer is during the carbonation agitation.

First of all I suspect the contact during agitation is not trivial because this is when the beer does most of its absorbing. Furthermore, even when not directly in contact with beer, the rubber outgasses to the atmosphere in the keg and this is absorbed directly into the beer. Whatever the mechanism of transfer is/was, it was sufficient to strongly flavor the beer.

> Foxx sells the little o-rings for probably a dollar per dozen. At that price, why bother keeping the old ones?

The usual reason... sloth.

>As you will recall when you first posted your window screen lautering system, I said that it would probably give you lower extraction efficiencies. A short while ago, you posted a recipe and your extract efficiency was pretty low, which could be due in part to other factors, but I'm sure that the fact that your lautering system only draws runoff from the center is most of your efficiency problem. I checked my files and could not find your recipe, but to the best of my recollection, it was 9 lbs of grain yielding 5 gallons of 1045 wort. This is 25 points per pound/gallon ( $45 * 5 / 9$ ). Many HBD posters have reported 33 points and some even higher. 33 points would give you 1059 from 9 lbs of grain. Looks to me as if you're throwing away (or composting or making bread from) 25% of your grain's sugars.

Two points here. You have all the numbers right except the volume. I have never made a 5 gallon batch, they range from 6 to 7+ and that may sound trivial but if you do the math, you will find the extra gallons put it pretty

close to nominal.

Having said that, I did get a little depressed over the yields Larry B was getting by comparison and found the culprit to be..... would you believe... the MALTMILL. It turns out I have been using a reject from the early days when I was unable to control the spacing very well. The spacing was about .080 at one end and some grain was getting through barely touched and lots not properly crushed. I declared myself the winner of an impromptu lottery and took one out of the "shipping department" with the proper spacing. I used this on the last batch and the yield improved substantially.

In defense of the EASYMASHER, it is very easy to check the thoroughness of extraction by stirring and resparging the spent grains and checking the gravity of the runoff for lost sugar. I do this routinely and there is none.

I hate to seem so hide bound but that 4 inch tube of window screen works as well if not better than the most sophisticated lautering system. It further has the distinct advantage of running clear after less than one cup is drawn off.

It works so well, as a matter of fact, that it will be introduced as a new product in the next issue of Zymurgy.

Bet y'all can't wait till I sell 100 of them. :)

According to Noonan's "Brewing Lager Beers," this is correct. I was  
attempting to condense, from memory, an entire evening's conversation  
on a topic I really don't know much about. Always a dangerous thing  
to attempt :-).

Out of curiosity last night, I carefully de-husked small samples of both  
Hugh Baird pale malt and Jim Bruce's pale malt and compared the length  
of the acrospires (i.e., the modification). The Baird was "fully"  
modified; the acrospires were usually 3/4 to the entire length of the  
kernel. Jim's malt, on the other hand, was what Noonan would describe  
as an undermodified "American" malt, with the acrospire usually one-half  
to three-fourths the length of the kernel.

Perhaps that's why Jim advocated the use of a full step mash when he gave  
us a sample of his malt. The batch we made with it is in its final  
ferment  
right now, so I don't yet know how it will do with respect to head  
retention, chill haze, etc. (I also haven't had a chance to discuss  
the subject with Jim yet, either. I'll post more when I do.)

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Belgian Impressions - Brugge

For most visitors to Belgium, the Flemish city of Brugge (Bruges in French) is on the list of "must see" places - and for good reason. The city's well preserved architecture and network of canals give it a unique ambiance and charm. A brief synopsis of Brugge's history will shed some light on how this came to be.

A few hundred years ago, a relatively large, navigable river ran through Brugge and to the Belgian coast. There was quite a bit of trade along this river, from which Brugge derived considerable wealth. As a result, the town was built with some of the finest architecture of the day. It seemed as though Brugge would continue to grow and prosper, until Mother Nature intervened. The river changed its course.

This left Brugge without its lifeline. Its commerce withered, and it became much poorer. While wealthier communities were able to continue building and "improving", Brugge was not. Furthermore, Brugge was spared in two world wars, but many other parts of Belgium weren't so fortunate. Consequently, Brugge is not filled with modern ugliness, but instead has retained its old world character. As irony would have it, Brugge is again one of Belgium's wealthier cities. Its architectural treasures attract the dollars of tourists from around the world.

Prior to WWI, Brugge had 31 breweries. Today there are two : Straffe Hendrik (translatable as Strong Henry), and De Gouden Boom (The Golden Tree). Time did not permit a visit to Straffe Hendrik, but I did get to spend a wonderful afternoon at De Gouden Boom. I was met at the brewery gates by Louis Van Reeth, De Gouden Boom's commercial director. He proved to be a very gracious host.

De Gouden Boom traces its roots back to 1872, when it was founded by Jules Vanneste, and was originally called 't Hammerke (The Hammer). It has been passed down from father to son, and is now run by Paul Vanneste, the fourth generation brewmaster. In an age of rampant brewery closures and takeovers, De Gouden Boom survives as an independent operation. Fortunately, the Vanneste's have a 12 year old son, and it is hoped that the tradition will continue.

Today they produce four different beers. Brugs Tarwebier is their Wit beer. It is pale yellow and cloudy, with a soft yeasty and refreshing palate. It has been a very successful product for them, as Wit beers have grown in popularity in recent years. At 5%v, the Wit beer is their lightest entry. They also make two Abbey style beers, a Dubbel and a Tripel, under the name Abdij Steenbrugge. The Dubbel is a deep brown color, with rummy flavors from the addition of dark candy sugar, and yeasty estery notes from the fermentation. The Tripel is appropriately pale in color, and is somewhat drier than the Dubbel. It has the same estery fermentation byproducts, but its flavors are more in balance. Their heavy weight beer is called Brugse Tripel. It weighs in at 9.5%v, and is my personal favorite. It's a big, rich, complex brew which is amazingly smooth given its potency. This brew spends a full four hours in the mash tun to extract every last bit of sugar from the grains. It's packaged in a variety of sizes, including 1.5 liter magnums, which add alot of weight to your luggage, but are worth every ounce.

The beautiful copper brewhouse looks traditional enough, yet is controlled remotely from a not so traditional electronic panel. To keep all of the modern technology in line, a larger than life image of St. Arnouldus watches over the control room. St. Arnoldus, the patron saint of brewers, is said to have invoked a miracle by producing beer after an abbey brewery collapsed in the 11th century. His popularity in Belgium persists to this day.

The brews all go through about one week of primary fermentation, and are then moved to aging/maturation tanks for secondary. The CO2 given off during primary is collected by an elaborate system of airlocks and pipes, and is used to carbonate kegged beer. The beers are all filtered and centrifuged with the exception of the Wit, which retains its yeasty character. The other bottled beers are then inoculated with a different culture for conditioning. The rather large bottling line can crank out 14,000 bottles per hour. After filling, the bottles move on to a warm room, where they are stored at 25 degrees C (77F) to encourage another fermentation. Both warm conditioning and centrifuging are rare practices in the US, and may seem unusual to readers in the states. They are, however, fairly common in Belgian breweries.

De Gouden Boom produces 30,000 hecto liters annually (about 26,000 barrels), and of course generates quite a bit of spent grain. They dispose of this by-product by feeding it to cattle on nearby farms. Making light of this, Mr. Van Reeth commented, "In Brugge, the cows don't give milk, they give beer!"

After touring the brewery itself, visitors can get a glimpse of Brugge's brewing history. De Gouden Boom is devoted to preserving this history, and maintains a brewery museum on the premises. A large part of the museum is devoted to the old malthouse, which was built in 1902 and remained in operation

until 1976. All of the original machinery is still in place. The rest of the museum focuses on the many breweries that formerly existed in Brugge, displaying old pictures, documents, barrels, maltmills, and breweriana from days gone by. Of special interest is a map, complete with photographs, indicating the locations of the defunct breweries. Since almost all of the buildings are still intact, the truly obsessed can wander around the city and find several of the old breweries.

Like all good brewery tours, this one culminated in a trip to the bar to sample the wares. The hospitality room at De Gouden Boom is much like a Belgian cafe. A large group had started their tour ahead of us, and they were in full swing by the time we made it to the bar. Their presence added a festive air to the simple elegance of tasting room. All four beers are available, both for consumption on premises or carry out. In addition, glassware, gift packs, and the usual souvenirs can be purchased.

As the brewery was closing, Mr. Van Reeth made a final gesture of good will. He presented us each with a magnum bottle of Brugse Tripel, corked and wrapped in foil. Definitely a beer to be saved for a special occasion, and one that will encourage several toasts to St. Arnoldus, to Brouwerij De Gouden Boom, and to Louis Van Reeth.

De Gouden Boom is open for public tours. Call ahead for hours.

From: eurquhar@sfu.ca  
Subject: Re: KENYON yeast culturing

In a word YES. If a yeast culture has more than one yeast species/strain present in the mixture both must be maintained separately and grown up separately for the balance to be maintained. If not then one species will become dominant over time as it is very unlikely that growth rates are exactly matched.

As to how you tell the difference that is a much more difficult problem. Since both strains are *Saccharomyces* they will appear to be very similar to the naked eye and likely also under the microscope. If you simply streaked out from the undiluted wort mixture then chances are very good that none of the colonies which have appeared are composed of only 1 species.

The easiest way would be to dilute a sample of the inoculated wort by 1000 to 10,000 times and streak out this mixture over several plates. However, doing dilutions like this should be done aseptically with sterile water or wort.

Since, you are at Princeton I would suggest going over to the biomedical library and taking a look at "Yeasts" either the edition by Lodder(1980?) or Kreger VanRij(1984). This is the standard reference work on yeast taxonomy full of great pictures and detailed descriptions. Everything including all methods you would need are included. If you need any more help you know where to find me.

Welcome to the wonderful world  
of yeast culturing

From: bob@rsi.com (Bob Gorman)  
Subject: Flame

In HBD #926 Jack Schmidling writes about his cold plate and adds:

"I brought it to Milwaukee with a keg of you know what."

This remark I can not leave untouched. I tasted some of that beer. It was a terrible brew, infected, astringent and unbalanced. As one conference goer stated: "How fitting it's served in urine sample cups."

Although this a direct flame against Jack, it is also the truth.

From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: Re: Cider yeasts

My statement about yeast "falling from the heavens" in cider making was, of course, complete nonsense, as Jay Hersh pointed out. The unreliable source was a book about the history of Somerset cider. I've now gone and read the scientific reports of the old Microbiology Department here at Long Ashton Research Station, which state that cider yeasts came originally from the surface of the fruit, but are now usually introduced from culture. The reports do point out, however, that in a cider factory with a continuous brewing process (and the customary poor sanitation), the local flora in the factory is at least as a source of yeasts as the apples themselves, particularly as the factory yeasts have been acclimatized to the conditions.

Continuing on this theme, Jack S. says he plans to culture yeast from the apples for making cider. This is probably not a simple task, since there will be many different yeast species on the surface of the fruit, some of which may produce a very unpalatable drink if used to ferment the juice. The Long Ashton Report of 1971 describes eight different yeasts isolated from apples, including varieties of *S. cerevisiae*, *S. uvarum* and members of other genera (ie. not *Saccharomyces*). The standard yeast used in the cider brewery here is an isolate of *S. uvarum*. The authors also tested the effects of inoculating apple juice with a mixture of *S. uvarum* or *S. cerevisiae* with one of the other 'wild' yeasts (e.g *Candida pulcherrima*\*). They concluded that the resulting cider had in many cases a 'more full flavour' than with the single *Saccharomyces* yeast alone (which explains why cider produced using a single cultured yeast is inferior to that produced from yeasts present naturally on the apples), but that some combinations were unpleasant, with acetic or sulphurous tastes. If you culture from apples without a knowledge of yeast identification, chances are you'll get a very different drink from that made with a commercial yeast, or with the natural mix of yeasts on the apples.

Incidentally, you can probably buy cultures of all these wild and cultivated yeasts, at a price, from your national yeast collection. Over here, a single dried ampoule costs 19 pounds from the National Collection of Yeast Cultures in Norwich.

\* N.B. These scientific names may have changed since 1971: taxonomists like to change the names every few years to convince themselves that they're at the cutting edge of science and to confuse the rest of us.

Andy

Date: 24 Jul 92 08:45:00 EDT  
From: Joel (J.N.) Avery <JAVERY@BNR.CA>  
Subject: Priming with honey, growing hops, beer on draft

I prime exclusively with honey, mostly because I have it in the house, and corn sugar is forbidden to go near my beer. I add about 3.5 ounces for a slightly less than 20 litre batch (my carboys are 19.8 litres, which is 5 US gallons I believe). Never having primed with corn sugar, I can't give any advice about what the equivalent amount of sugar would be. A recent mead thread indicated that honey was very fermentable (so is corn sugar), so amounts might be very close.

As for technique, I boil the honey up with some water, to sanitize the honey. That started a discussion about whether or not the boiling was required, and the digest turned really scientific about whether any nasties could live in honey. And, as Bones might say, "Dammit Jim, I'm a computer scientist, not a biologist". I still boil it, but just to be anal. I can't remember the final verdict.

I'm not sure if it matters, but I am a cake mix brewer.

While I have your attention, I planted hops this year. One vine I fed the the local bunny rabbit, and the other is about 6 or 7 feet, and seems to be growing about one inch a day. I'm in Ottawa, Canada, and I am wondering if this is typical, slow, or what. No signs of flowers.

Maybe you can help me with my house renovations as well. I am currently in the later stages of planning my new kitchen, and I figure to incorporate beer into the plan. I want to build a cold room in the basement under part of the kitchen to store beer and wine, and maybe some food, but the food isn't important here, just the beer. I plan to convert to kegging, and keep the kegs in here, and run lines up to the kitchen so that I can have two kinds of beer on draft by the kitchen sink. I brew mostly bitters, and brown ales, and figure that this room will be about 12 degrees Celcius in the summer - perfect for my beer style.

Has anyone tackled this in the past? I figure that the beer lines once they leave the cold room should be of narrow diameter to minimize the amount of beer that could get warm. Should I leave the kegs under constant CO2 pressure, or should I control the CO2 from the kitchen? What other design considerations should I consider?

Subject: S. Delbrueckii

Thanks for the quick responses wrt my #3056 culturing question.

To Eric Urquhart - I'm not at Princeton, that's just the Internet router that our system uses to connect to the rest of the world. I can check the local library, but am a bit skeptical that I'd find the reference you posted.

You were absolutely right about not being able to detect the difference with the naked eye. Several HBD posts had mentioned that two types of colonies would be present, and that the larger would be S. Delbrueckii. Well, I've got some large and some small, but it seems that the sizes could be related to the either of the following phenomena:

1. The proximity of the colonies to one another on the plate, i.e. - ALL the colonies from the initial streak are smaller than those from subsequent streaks (2-4). If there is less food per colony, the colonies will be smaller, no?
2. Two different strains of different sizes (or replication rates) which show up as differently sized colonies on the plates.

I believe Option 2 is the more commonly held opinion by Digesters. In its defense, there do seem to be a number of colonies which appear to have come from a single cell (They look round from the top, and like little yeast mountains from the side), I just wish I could tell the difference by some means other than diameter and height of mountain. I do have an old toy microscope which can enlarge to 600x. Will this help? I don't think its got any slides or covers, does anyone know where I can pick some up?

As always, thanks for any and all help.

-Chuck-

Date: Fri, 24 Jul 92 9:33:31 EDT  
From: ncrcae!brew@devine.ColumbiaSC.NCR.COM (Jim Griggers)  
Subject: Good and bad malt, fittings

In HBD 926 gummitch@techbook.com (Jeff Frane) writes:

->It may also have something to do with the quality of the wheat  
->malt. I wouldn't be surprised to hear that he uses the stuff from  
->Briess, which I wouldn't feed to the ducks. I've used either the  
->British or the German wheat malts to excellent effect; both are big  
->fat grains (with no barley mixed in as has been the case in the past  
->with Briess).

Which brings me to a question about malt quality in general and Briess  
malt in particular. How good or bad is Briess barley malt compared to  
other brands of malt? How many brands of domestic malts are available?  
I am aware of Great Western Malting and Briess; how many others?

Alternative Beverage in Charlotte, NC only carries Briess, and I doubt it  
is worth the expense of having 50# of malt shipped clear across the  
country  
just to have a slightly better quality malt.

Another topic: Not only is South Carolina a beer wasteland, but a  
hardware  
wasteland as well. After searching most of the hardware stores and home  
improvement warehouses, I am still looking for a fitting that will  
connect  
a 3/4" FPT to a 1/4" vinyl hose. This is for connecting my 1/4" beer  
lines  
to a filter housing that has 3/4" connections. I was hoping to save some  
money over the filter kit offered by The Filter Store Plus, and besides,  
the  
fitting shown in their ad looks larger than 1/4". My Supervinyl hose  
from  
Superior won't stretch much bigger than 1/4".

Subject: Advanced brewing advantages?

Subject: Advanced brewing (NON-EXTRACT) worth it?  
Sender: joed@mozart.cbs.umn.edu  
Organization: U of MN Herbarium

Here's the scoop. I've been brewing now with extracts for about a year and a half. I've made a dozen or so batches of many tasty styles of brew. I've recently been thinking of getting more involved and move on to all grain brewing but I'm not really sure if it's worth the effort. I'll need lots of new equipment, more time dedication, etc. Those may even be advantages as I like the process and care of brewing but how much can I expect the quality of the beer to increase assuming it's properly done?

Also, what are some good sources (books) to get started. I have been brewing exclusively from Papazian and a little self experimentation.

Thanks in advanced for all opinions, experiences, flames, biases, misinformation and advice.

From: mpl@pegasus.attmail.com  
Subject: Japanese Beetles

My grapes used to suffer terribly from Japanese Beetles feasting on them. I bought one of those traps, and it stopped most of the problem, but I hated changing the bags full of dead beetles (which I had to do almost every day). I eventually wound up putting down a japanese beetle killing bacteria (made by Ringer, I think, although there are several brands available). It's non-toxic (only kill the japanese beetles), and, since it's a living organism, you only have to put it down ONCE (unless you put down something that kills it).

I sprinkled it on the lawn around the grape vine and watered it in. In the 2 years since, I've seen maybe 2 or 3 japanese beetles on my grape vine. I have no messy bags to change, and I'm putting no chemicals on the grapes (or into the environment). This was one of the best \$10 I ever spent. If you have japanese beetles bothering your hops, I highly recommend this stuff (I guess the downside is you have to put it down a year before it becomes effective - it kills the grubs over the winter, not the beetles in the summer).

>it)? Any other suggestions?

I don't know anything about smaller burner rings, but here's a suggestion  
from  
my days as a Boy Scout:

Coat the bottom of the brewpot with liquid soap (dishwashing liquid)  
before  
you brew. It will dry on the surface, and not cause any problems during  
cooking.  
The black soot will still accumulate on the pot, but the clean-up  
afterwards  
will be trivial. Water will dissolve the soap and the black soot will  
come off  
easily. Bar soap works okay, too, if you make sure that you rub a good  
coating  
over the whole bottom.

From: tom@kalten.bach1.sai.com (Tom Kaltenbach)  
Subject: FREE! software for searching Homebrew Digest

Over the past couple of weeks, I've written a PC program that might be of interest to homebrewers. The program is called THREAD, and its purpose is to search the back issues of the Homebrew Digest and extract those messages that follow a certain "thread" of conversation. THREAD attempts to do this by extracting all messages that contain specified key words; as a consequence, the program also functions as a general subject-searching program. For example, if you wanted to search for all messages related to kegging, you might use "kegging" as a key word (as I recently did). Logical combinations are also possible; for example, if you wanted all of the recent references to Jack Schmidling's MALT MILL, you could search for "malt" AND "mill" NOT "miller" (the NOT "miller" excludes the many references to Dave Miller's books). The key words are not limited to a single word, for example, you can search for messages mentioning "dave miller" OR "dave line". Up to 10 key word specifiers are allowed.

THREAD operates on IBM PC or compatible 8088/80286/80386/80486 microcomputers running MS-DOS, so it does require that the digests are stored as ASCII text files in a directory on the PC hard disk. The program has been uploaded to the archives at sierra.stanford.edu, where it can be found in the /pub/homebrew directory. The files are listed below. Note that all the files are in ASCII format except for the binary executable, so you must set the file type appropriately in when transferring with ftp.

thread.exe	binary file, MS-DOS program executable
thread.pas	source code, written in Turbo Pascal 5.5/6.0
thread.uue	uuencoded version of thread.exe, for those without ftp
thread.doc	documentation and program description

Any comments, questions, or suggestions can be sent to me at the address below. If there is enough interest in a VAX/VMS version of the program, I may try to convert the source code into a VMS PASCAL version.

Subject: re: PET bottles

I used both 500mL and 1L PET bottles a few years ago with very good results. Although they may not be as appealing as a tall, proud beer bottle, they have a number of unique advantages. When you use a bottling wand to fill a PET bottle, the tip of the wand sits nicely in the dimples at the bottom. The flowing beer quickly fills the dimple and covers the tip of the wand, thereby helping to reduce aeration. Capping is a breeze; just twist them on snugly. Just before capping, I'd squeeze the bottle until the level of the beer was at the top of the bottle, then secure the cap. This left the bottle initially dimpled, but the headspace was purged of air. Checking the level of carbonation later on was as simple as squeezing the bottle. The dimples also served to hold the yeast sediment when the beer is decanted. Furthermore, plastic is safer than glass.

My only concern with these bottles is that they are green, and if green plastic equates with green glass, this may result in light-struck (skunky) beer. I've also heard that oxygen can penetrate the plastic, but I don't buy it because of the pressure inside.

Give them a try; they worked great for me.

Subject: Buffalo Confusion

From: gak@wrs.com (Richard Stueven)

>Mike McNally said:

>> All I can say is that the Hefeweizen from Twenty Tank was  
>> even worse.

>Everything that Twenty Tank makes is even worse.

>Bill Owens may deserve credit for getting the California microbrewing  
>industry off the ground, but his brewpubs make uniformly bad beer.

Well, I hope that I'm not the 20th person to point this out, but.....

There seems to be some confusion here. Bill Owens is not connected to  
20 Tank. He has founded 3 brewpubs.

1. Buffalo Bill's in Hayward. The second brewpub in CA, third in the  
US since prohibition. Bert Grant in Yakima was first, and Mendocino  
in Hopland was second. Buffalo Bill's is still under Bill's control.
2. Brewpub on the Green in Fremont. Co-founded by Bill and John  
Rennels. Problems developed between Bill and John, and Bill left.  
John went thru several brewers, and the pub had its ups & downs.  
The investors flip flopped, and John is out and Bill is back.  
BP on the G is now under Bill's control again.
3. Bison Brewing in Berkeley. Bill ran Bison very poorly, things  
were in a dismal state. The brewery was on the verge of closing  
in April 1990, when Bill was ousted. Eric Frietag and Scott De Oca  
took over. Their beers are unusual, but the business is doing quite  
well now.

Two brothers named John and Reid Martin have also founded three brewpubs.

1. Triple Rock in Berkeley. One of the first, very popular with  
the UC Crowd. A success from day one.
2. Big Time in Seattle. Spurred by the success of Triple Rock, one  
of the brothers founded a sister pub to the north. The two pubs  
are nearly identical in decor. Similarly, Big Time is popular with  
UW students.
3. Twenty Tank in San Francisco. Quite different from the other two.  
Urban industrial warehouse atmosphere, South of Market nightclubby  
crowd. Wear black.

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: Re: Priming with honey

I have heard a lot of people say they would like to use honey as a priming agent. I really don't see the advantage in this, for two reasons:

- 1) Honey takes an very long time to complete fermentation.
- 2) The amount of honey that you will need for priming will not significantly affect the flavor of the finished beer, unless you are making a very light beer.

The object of priming, is to get a consistent carbonation level. And, in my case, I want this phase to complete as quickly as possible! If you prime with honey, you're carbonation level will change very slowly with time. If you correct for what you think is a low carbonation level (say after a week or so in the bottle) by adding more honey next time, you will have overcarbonated bottles if you wait several weeks to drink the beer.

My suggestion is to just prime with glucose (the REAL name for corn sugar--Dextrose is a trade name). You will not negatively affect the flavor of the beer by using sugar in such small quantities. I'm risking getting flamed here, but I would also say that using gyle (wort) instead of sugar for priming is a waste of time--for purists only. You won't be able to taste the difference. (If you've done a subjective, side-by-side comparison on the same batch of beer and and found out otherwise, please post your results--I'd be very interested.)

If you want a honey/mead-like flavor in your beer, then add a significant amount to the primary. (That "significant" amount will vary greatly depending upon the recipe and who you talk to.) Expect it to take several weeks to complete fermentation.

These are, of course, just my humble opinions.  
By all means, experiment; and have fun.

-Alan

From: ZLPAJGN%LUCCPUA.bitnet@UICVM.UIC.EDU  
Subject: gorman's lack of tact

Dear Brewers

While I'm not usually given to jumping on someone for stating their opinions, I must STRONGLY OBJECT to the type of attack levied by Bob Gorman against Jack in the last HBD. Aside from the fact that Mr. Gorman has exposed himself as a pompas ass, he has also unwittingly joined the ranks of the very brewers he criticizes by assuming that his taste buds are the final athority on the issue of what qualifies someone else's homebrew as good or bad. Worse, his level of attack (note that I did not use the word, "criticism," Bob) is at best sophomoric.

Much can be said about Jack - indeed, much has!! But with responses like Gorman's, I as a novice homebrewer, will remain reluctant to share my products with fellow brewers for their "criticism" for fear that my efforts too will be deemed equivalent to excrement.

No one, Bob, NO ONE! deserves that sort of comment, regardless of the quality of their efforts. Who deid and left you Brew Master?

Sincerely,

John G. Norton

Fm: Jack Schmidling

Subj: MICROMASHING

In my tireless crusade to convert extract brewers to all grain "real brewers", I have developed a "Mr Wizard" type approach that not only teaches the fundamentals in a way a child can handle but provides a simple and easy way for "master brewers" to test new ideas and disprove old "momilies".

MICROMASHING scales down a batch of beer to a size that can be handled in sauce pans, measuring cups and the kitchen stove.

I have used the system to optimize the spacing between the rollers of the MALTMILL. I have used it to convince myself that decoction contributes to extraction yield and to experiment with different infusion temperatures and adjunct contributions. As it only takes about an hour to do a "batch", several experiments can be conducted in single afternoon.

Equipment required"

small saucepan (500 ml beaker)  
funnel  
two inch diameter piece of window screen  
graduated measuring cup  
thermometer (100-200 F range)  
hydrometer (optional)  
balance (optional)

The piece of window screen is pressed into the bottom of the funnel to create our lauter tun.

The batch size is a scaled down from 10 lbs grain to produce 6 gallons of wort at a gravity of about 1.050. This comes to 60 gr. (2 oz) of malt and 300 ml of wort. If you don't have a balance, 60 gr of uncrushed pale malt is about 1/2 cup.

We start by crushing the malt. You can use a blender, rolling pin, hammer, maltmill or do nothing at all as I did in one experiment. The yield from uncrushed malt was 1.005. I just had to do it.

Pour the crushed malt in the saucepan or beaker and add 200 ml (1/2 cup) warm

water. Stir this gently till thoroughly mixed. This is know as "doughing in". Heat this slowly to 155F, stirring constantly. The smaller the pan, the easier it is to control the temperature. Maintain this temperature for 15 minutes and stir frequently to distribute the heat. I use a beaker and drop it into a styrofoam block with a hole in it but only because I am trying to control it precisely. This step is know as "saccharification" and is the period during which enzymes are converting starch into sugar.

If you want to add a touch of science here, put a drop of wort in a spoon and add a drop of iodine. After doughin, it turns black. After saccharification, it remains the same color as the iodine. This indicates that the starch has been converted.

The next step is called "mashout". After 15 min at 155F, raise the temperature to 175F. Place the funnel in a tumbler or graduated cylinder. Stir the mash and dump it into the funnel.

In your saucepan, bring 2 cups of water to a boil and add this to the mash in funnel as the level drops. Keep the water level above the grain level. This

step is know as "sparging". You can stir gently to speed things up. When you have collected exactly 400 ml (1 1/2 cup) of wort, stop sparging. (When

I say "exactly" I am referring to controlled experiments but if you are just trying to learn the process, nothing is critical.) If you simply want to

know what you have done, cool the wort to room temp and measure the gravity.

It should be around 1.040. If you don't have a hydrometer, a taste will leave no doubt about what you have done.

You have just made your own malt extract. You are now an all grain brewer.

To complete the task, the 400 ml should be boiled down to 300 ml to get the proper proportion. You can add a few hops pellets to get the full ambience if you like and there is nothing to keep you from adding yeast and fermenting it out.

From a practical standpoint, you can save the wort and use it as starter for yeast or add to your next extract batch. You can also mix it back up with the spent grain, add some flour and yeast and bake a few loaves of beer bread.

Have fun,

js

Steve Boege asks:

> I am intersted in using honey as priming sugar. It seems to me that  
> this was discussed here recently. How much honey should be used to  
prime a  
> five gallon batch of beer? How should it be prepared?

>From what I understand, honey is considered virtually 100% fermentable  
sugar.  
Given that fact, I assume that you would use equal quantities as you  
would  
corn sugar. As for preparation, same story as corn sugar. Just boil it up  
in  
a quart or so of water to sterilize it and dump it in. If for some  
reason, you  
don't feel that there are enough yeast nutrients left in your beer, then  
you  
might want to add a bit to supplement at this point, but its probaly not  
necessary for this small quantity of honey.

Good luck and good drinking,  
Mark

Subject: Re: Sterile yeast starters

Bob was discussing the creation of sterile wort for use as a yeast starter:

> On the advice of a friend, I got a case of quart mason jars, boiled up  
3  
> gallons (in the end) of generic wort (3# liquid malt extract), and then  
> canned them in a pressure cooker. voila - several months (depending on  
> usage) pre-supply of sterile wort.

What I've used as a standard yeast starter for the past 10 or so batches is much simpler, and apparently equally efficient.

I just boil up 1 quart of water with 3 tablespoons corn sugar and 1/4 teaspoon of yeast nutrient, cool to 80°F, and pitch my dried yeast in a 1 gallon apple cider bottle. My airlock is nothing more than the metal bottle cap with a hole poked in it and some tin foil wrapped around it. My assumption is that there will be enough CO2 output from the start to ensure a one way airflow out of the bottle. The tinfoil just keeps airborne particles from falling through the hole, but is loose enough to allow CO2 to escape. Anyway, the results have been excellent. All of my brews are actively bubbling away by the morning after I pitch the yeast (which inevitably always occurs sometime past midnight, occasionally I miss extract brewing >:-), and I've never had an infection problem. It just seems to me that its not worth the hassle or expense of making sterile wort when I spend 10 minutes the day previous to brewing to make my quick starter. What I'm wondering is does anyone see a problem with my methodology? Am I just consistently lucky when it comes to lack of infection? Is my beer karma running short?

Mark

From: Neal.Raisman@UC.Edu (Neal A Raisman)  
Subject: scrumpy

This is a recipe for a strong British cider called scrumpy. It is really strong. One glass and the world begins to glow. A second glass, makes it all go.

12# of mixed apples. Be sure they are clean and with no belmishes  
1/2# raisins  
1/2# raw meat  
1 gal. water at 70 degrees  
tradition calls for bakers yeast but I recommend a champagne yeast

Chop all ingredients. Then grind the apples and raisins. A food processor is helpful. Toss the ingredients into the water and stir. Add the yeast and seal the brew bucket with an airlock. Each day, stir the ingredients by swirling the ingredients in the closed bucket. After the first fermentation slows, about 8-10 days, move to a secondary fermenter. If you like a dry cider, add a second dose of yeast to the secondary fermenter. Seal with an airlock. Let sit until it the fermentation slows to a very slow, almost imperceptable bubble. Move to a carboy to get out more of the particulates. Let it sit for about a week and bottle.

The scrumpy will need to mature for about four months before you will want to even try it since it will give off a strong unpleasant smell and almost vinegary taste. The longer it is allowed to mature, the better, smoother and drier it will get.

It is wonderful served cold when mature. I have let it sit for a year and it is quqite fine.

No fancy sign off here. Neal Raisman raismana@ucunix.san.uc.edu  
D and unpleasant smell and have an almost vinegary staste

Subject: On Bob's Comments

In HBD 932, Bob Gorman said:

> This remark I can not leave untouched. I tasted some of that beer.  
> It was a terrible brew, infected, astringent and unbalanced. As one  
> conference goer stated: "How fitting it's served in urine sample cups."  
>  
> Although this a direct flame against Jack, it is also the truth.

Which provoked, in HBD 933, this outburst from John G. Norton:

> ... I must STRONGLY OBJECT to the type of attack levied by Bob  
> Gorman against Jack in the last HBD. Aside from the fact that Mr.  
> Gorman has exposed himself as a pompas [sic] ass, he has also  
unwittingly  
> joined the ranks of the very brewers he criticizes by assuming that  
> his taste buds are the final authority [sic] on the issue of what  
qualifies  
> someone else's homebrew as good or bad. Worse, his level of attack  
> (note that I did not use the word, "criticism," Bob) is at best  
> sophomoric.  
>  
> Much can be said about Jack - indeed, much has!! But with responses  
> like Gorman's, I as a novice homebrewer, will remain reluctant to  
> share my products with fellow brewers for their "criticism" for fear  
> that my efforts too will be deemed equivalent to excrement.

... and so forth.

John, let me explain a few things to you. First, and this has been the sticking point in many of the discussions involving Jack, there is a world of difference between deliberately introduced flavor effects outside the "main stream", and flaws due to poor technique. Bob's comment referred ENTIRELY to the latter. I tasted the same beer on the same evening Bob did, and agree with Chris Campanelli:

> Funny, I tried some of the WORLD'S GREATEST GENERIC ALE. Granted,  
> it was somewhat astringent/unbalanced due to a heavy-handed hop  
addition,  
> but I detected no infection. Bitter? Yes. Infected? No.

John, it was technically bad beer. This is not based on personal taste. It was simply poorly made. We've all made beer like that, but I've read HBD since before the issues were numbered, and to date Jack is the only contributor who has trumpeted his beer and his techniques so noisily and tirelessly. When Jack first began posting I reacted to the questionable information he was placing before HBD's readers, but I have neither the time nor the energy for the pointless, endless battles that "discussions" with Jack quickly become. I no longer even read his postings, and strongly urge that you approach his advice with caution. It has frequently not been good. Much more reliable information is available in a number of very good books; my favorite remains Dave Miller's "Complete Handbook of Homebrewing".

You really have little to worry about in having others taste

your beer, unless you're brewing for ego gratification rather than excellence. If I (or, for that matter, Bob) were to taste your beer knowing you to be a new brewer, we would tailor our comments with a goal of giving you encouragement and information you could use. If Jack's beer had been presented to me as the product of a first-year brewer, I would have called it an excellent effort, and suggested he pay attention to temperature control, water chemistry, and recipe formulation, first. The position Jack has chosen to occupy, though, calls for an altogether different standard. If you are to set yourself up as the definitive source of brewing information, you'd better be prepared to deliver. Clearly, Jack is not, and Bob's comment must be taken as the natural operation of the "self-cleansing" process as it applies in homebrewing; it was the closure of the feedback loop as a means of correcting distortion, and it is new brewers, without the experience to sort the good information from the bad, that benefit most from this process.

From: Jacob Galley <gal2@midway.uchicago.edu>  
Subject: Gorman, PET bottles, Fermenting Meat??

First, there is absolutely no reason for Gorman to humiliate Schmidling like that in public. I don't really care how much you hate him, and I bet 99.44% of the readers don't either. Please try to act like adults, people, (this from one who is not yet Of Age) or at least take it outside and let the rest of us try to learn something.

Next, what's the difference between PET bottles and the run-of-the-mill plastic soda bottles we find in the States? A couple brewers I know use these regularly, because they're easier than smaller glass bottles, and you don't even need a capper. They don't seem to affect the beer in any way. However, they're ugly. Personally, I'd like to rid myself of plastic entirely, for aesthetic reasons (hard to say with a straight face while typing). But I'm still curious how PET bottles are superior to the ones I've seen. Why not use glass gallon jugs, like from cranberry juice, etc? There's actually a local brewer (or at least he's a bottler) a few blocks away from me who uses gallon jugs. Motto: "Won't go flat" <-- Not true. I'd expect it to keep until opening, however.

Finally, what purpose does MEAT serve in fermenting?? Yesterday's scrumpy recipe is not the first I've seen which includes meat. There's Charlie's for-your-amusement Cock Ale from the Eighteenth Century, and I believe Sir Kenelm Digby, Kt., (1669) had an ale recipe with some kind of meat, too. What gives?

PS - If anyone's asking, I like receiving the Digest on weekends, though I can see how it could get overwhelming for the Monday --> Friday crowd.

Jake.

Subject: Sour brown ale recipe sought

Hey there,

Found a bottle of Goudenband and before I drink it I was wondering if anyone had a recipe for this or other Flanders Sour Brown Ales? There is yeast in the bottom; what if I just add this to sterile wort and let it build up for a few days (as opposed to plating it out, which I could also do, but is not recommended in some cases of yeast blends, such as Chimay).

Any advice welcome. Thanks muchos.

Subject: software review: THREAD

Hey, now. I just downloaded Tom Kaltenbach's THREAD program today, which he announced in the HomeBrew Digest yesterday. The program's a jewel. It allows you to search back issues of the HomeBrew Digest for any given string(s) using the logical operators AND, NOT, and OR. Any article meeting the string criterion is displayed to the screen, and you can either write it to disk or not. You can also run the program in automatic mode, writing all valid articles to disk for later perusal. It's also pretty speedy. Even on my ancient 8086, I could get through 750k of HBD's in a minute or two, automatic mode-wise. To give you a point of comparison, I recently used Magellan to search through my 500 or so back digests for information on kegging. Searching, choosing, and printing took the better part of a day. But with Tom's program, I'm sure I could finish in about an hour, tops. Say 15 minutes to search all the back digests, maybe another 15 minutes to peruse the output file for which articles I in fact did want to keep, editing as needed, and then maybe 10 minutes of printing. What's more, the search and the printing don't need to be babysitted, so my actual realtime involvement is just perusing the output file, whereas with Magellan, I couldn't leave the terminal. Great program, Tom. You've given me more time to brew now.

Content-Type: text  
Content-Length: 1794

In HBD933 Joe Dalsin (joed@mozart.cbs.umn.edu) writes:

->I've recently been thinking of getting more involved and move on to  
->all grain brewing but I'm not really sure if it's worth the effort.  
I'll  
->need lots of new equipment, more time dedication, etc. Those may even  
be  
->advantages as I like the process and care of brewing but how much can  
I  
->expect the quality of the beer to increase assuming it's properly  
done?

I am not going to address the question of beer quality. There are people  
on the Digest far more qualified than I that can answer that question.  
However, I was just reading some back issues of Zymurgy, and Joe's  
statement reminded me of an editorial in the winter 1991 issue by Charlie  
Papazian titled "Turtles and Zymurgy".

..... "Beermaking, beer drinking; isn't this what a lot of  
this zymurgy stuff is all about? Enjoying the process.  
Often never minding how great the beer tastes or  
doesn't taste. Totally involved with the process of learning.  
Making mistakes. Not getting it just right. All the while  
loving the journey; savoring the long journey and appreciat-  
ing the process. There's so much more to enjoy there than  
the quick swallow at the end of the process--the goal." .....

I know I enjoy the creation of a beer just about as much as I enjoy  
drinking it. The brewing process certainly has enough technical aspects  
to keep a tinkering engineer like myself happy tweaking equipment and  
processes. I enjoy brewing as a \*hobby\*, so switching to all grain was  
just one more process to play with.

From: PGRAHAME%**BENTLEY**.BITNET@mitvma.mit.edu  
Subject: **PET Bottles**

I was intrigued by comments from the subscriber who spoke of PET bottles available for homebrewing from Canada. In Ontario, more than one micro-brewery set up using PET bottles for economic reasons: far cheaper than purchasing a conventional bottling line. They have been fairly well-received by the public, and one Toronto homebrew friend recycles these as part of his bottle ensemble. He also uses sturdy glass soda bottle (quart size) which take metal caps. When I began brewing here, I used US soda bottles, 1 & 2 quart size, because I had nothing else and didn't want to buy a capper. I also used the odd commercial quart beer bottle (Bud, Coors, etc.), and a few Canadian 750 ml glass bottles I had. ALL of these take the same plastic twist-on caps. Now here's the interesting part. My main concern was breakage; from that perspective I expected the plastic bottles to be the best. My next concern was sealing; I expected the plastic bottles to seal better (plastic against plastic). To my surprise, I have never broken a bottle, even with very lively brews. I did not really trust the US beer bottles, since they are for single use & artificial carbonation. With short storage (3 - 4 weeks), I notice no difference. With longer storage (2 months) the result was surprising. The beer stored in glass was much better, with no off-tastes. The beer stored in plastic had a taste with I attribute to oxidation. Since the seals and conditioning were fine in all cases, I assume the plastic is "breathing" to some extent. This result has been repeated over several batches. Accordingly, my aim is to go all glass. The Canadian bottles are great, made for multiple use & very strong. Obviously, trips across the border are in order. I still don't trust the US beer bottles re ability to take pressure, and besides you have to deal with the lifeless beer that comes in them! I still see no reason, apart from esthetics or perhaps judging rules, for using metal caps though. The plastic caps hold up over many uses & thus create less waste, in a way. I have never had one fail. A last comment on PET: the Canadian plastic beer bottles are much thicker than our plastic soda bottles, so should store a bit longer; still I would expect oxidation to be a problem to some extent. Are there any cheaply available glass bottles similar to the Canadian 750 ml soda bottles? And are there any real reasons not to use twist-on caps?

Cheers, Peter

From: Brett Shorten <s05bas@cc.uow.edu.au>  
Subject: Question on racking after chilling

I think this question may have been addressed recently, but I have forgotten the answer and am anxious to know!

I recently made an immersion chiller, and used it for the first time 2 days ago. It worked brilliantly, cooling my brew from boiling to cold in about 15-20 mins. However, when I then immediately racked to primary, I was stunned by the prodigious amount of break material, at least 5-6 litres (what we measure in in Australia). As a result, from 21+lt of wort, I only successfully got 18lt to primary, and even then I transferred a small amount of break material with it.

So how can I enjoy the benefits of chilling without sacrificing a large percentage of wort in the process? The only thing I can think of that I might have done to contribute to the problem was to pour the boiled wort into another container before chilling, in order to strain out the leaf hops in the boil.

One other question that occurs to me. What is the recommended procedure for dry-hopping in the secondary with pellet hops?. Are they added as is, or 'dissolved' first?

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: hops,beetles,comments

A friend of has a Cascade (we think) hops plant with what we guessed to be 6+ oz. of cones on it. My Cascade has maybe 1 oz. We live about 2 miles apart. He allowed the plant to have some 12 shoots; I only let mine have 4, as states common wisdom. Now I wonder about that wisdom. There are other factors which effected our yields (different age plants, different soils and sun exposure), but I'm wondering just why it's supposedly best to allow only 3-4 shoots. Any hops experts have the answer?

Thanks for the info on Japanese-Beetle-killing bacteria; I'll look into that. My lawn also happens to have grubs.....wonder if there's a connection.

That's lots of wondering, also about this Bob/Jack/et.al. discussion. I thought it was already common knowledge on the HBD that's Jack's "world's greatest beer" was really not; that Jack himself admitted it was overhopped and was just "the beer that was ready" for the conference. So when Jack talks of his WGB I always take it to be tongue-in-cheek and self-deprecating. If I've read Jack correctly over the past few months, I don't doubt he enjoys jabbing with his WGB comments because he knows how much it aggravates some of you! My final comment on this, and it applies to many other things on this list as well, is to lighten up. We all want to make the best beverages possible, and making beer can and does involve complicated scientific issues, but, hey, we're making \*Beer\*, not looking for an AIDS vaccine. So, relax.....

From: "Deborah Poirier" <POIRIER@INRS-ENER.UQuebec.CA>  
Subject: PET bottles, dishwashers, overnight brewing

from: poirier@inrs-ener.quebec.ca

Hello fellow fizicists!

Well today's posting on 1 liter plastic soda bottles was quite a surprise to me, since I assumed EVERYBODY used them! I guess it's a Canadian thing, but worth trying, IMHO, since they come in good sizes (1 and .5 liter) and you don't have to wash labels off. BUT the best reason to use at least a few of them per batch is that you can squeeze them to see how your carbonation is coming along. For impatient types like myself, they're great. To quote a brewing buddy, when it's hard, it's ready. :)

Now I have two questions:

1. do many of you use your dishwashers to sanitize bottles and hoses? I do, with extra hot water and I slosh in a few glugs of bleach midway along. No problems so far, but is this the safest way to go? Would "sparkleen" or just regular dishwashing detergent work better?

2. the other night, late into the sparge, I decided to abandon ship and go to bed, leaving 6 gallons of wort in pots on the stove (no heat), which I boiled and hopped the next morning when I was feeling perkier. So far it has fermented uneventfully, and I found it quite pleasant to split the brewtime into parts.  
AM I IN TROUBLE NOW???

Thanks for any advice.  
Deb

From: Joe Rolfe <jdr@wang.com>  
Subject: Bacteria Problem??

hi all,

whilst labeling my last batches, one of which has been in the bottle over a month ( can drink that fast :) i saw a strange "growth" and film on some but not all bottles. from picking thru the brew book i have it appears to be Acetobacter (milky film on the surface). the bottles in question also have "white spots around the surface of the beer (sorta like ring around the collar). on all bottles of all batches that i have done in the past i remember a slite film on the surface (holding up to a lite and looking from below the surface) but none as obvious as this particular batch.

It does not appear like strands or rope (although there seems to be some specs floating around in the volume of the bottle). Seems like i can rule out Lactobacillus.

taste seems fair - it was a very bitter batch to begin with and the quality of the hops used was marginal. it does taste a little sour - could not tell if vinegar was the flavor/sourness or not - all i had was cider vinegar not the white (does it matter???)

i am going to save one (at least) bottle to look at under a scope, and find some willing soul to look/taste the stuff (any takers??? eastern mass).

the batch previous did not show the same problem, and some of the bottles in the same batch are still (looking) ok. the batch after has been in the bottles for only 2 weeks. i do remember a couple of the dreaded fruit flies seem to be hanging around at the time (practical brewer indicates they can cause the problem)

for sanitation i have been using B-Brite - but may change. i have now gotten ahold of an idophor concentrate that i will start using and save the b-brite for the cleaner portion of the fermenter and hoses. bottles usually go into clorox (heavy doses) for a primary scrub/soak then rinse. on bottling day another soak in clorox and jet spray rinse with hot water. the bottling is done by a wand with spring loaded tip, i have noticed in the past quite a bit of splashing in the bottom of the bottle until the tip is covered. i tip the bottle to limit the splashing as much as possible.

some questions:

How long does the B-Brite remain active as a sanitizer once added to warm-hot waters?

how long does it usually take for the various bugs to show up?  
bug releated to wort, fermentation and packaging

where do these bacteria ususally come from?

any one looked at the surface and seen this film? could it be from having  
a fermentation going (ale) and this film be the so called skin that  
appears  
during primary after the rocky foam head falls??

any one out there with some inputs??

thanks in advance

joe rolfe

Richard; Just what does Mr. Owens have to do with 20 Tank? He has no affiliation with the Martin brothers that I am aware of. While the beer at 20 Tank is generally on the sweet side and hopped less than I prefer, I have never had one there which I would have called infected or seriously flawed. They currently have an IPA running which is very pleasant. I must admit that I gave the hefe-weizen a miss based on the comments here in the Digest.

Subject: S delbrukii identification

In response to Chuck about how to identify *S. delbrukii*, I summarize below an experiment I wrote up here a few months ago:

I bought a pack of wyeast 3056 bavarian wheat (about 1 month outdated when I finally opened it) and streaked the contents on malt agar plates. there were numerous colonies that largely looked the same... Chuck is right that both spacing of the colonies and their genetic identity will determine their size on the first plate. Most of the colonies were pale cream white; about 1% or less was more grayish and smaller.

I picked a dozen to a fresh plate, making 3mm streaks with a sterile toothpick for each. The color difference was retained, but the size difference was not impressive. After a month on the plate, though, one of the colony types was more "wrinkled"-- I think it was the creamy one, but I can't recall now and my notes are at home.

Then I made up a dozen "starters" with DME in water... no hops, and sterilized them. After inoculation with the individual colonies, they all fermented vigorously. I tasted each at 2 weeks, and the taste was consistent with the colony type:

The abundant creamy colonies made an estery somewhat sweet product that was "weissbier-like" I concluded that these were *S. delbrukii*.

The rare gray-ish colonies made a very dry product with no discernable ester flavor. I think these were the *S. cerevisciae*.

By this analysis the packet of wyeast was 99% *delbrukii*, and less than 1% *cerevisciae*, but note that my packet was outdated. I think your chances of picking a *delbrukii* at random is pretty good, if you taste a test culture.

After I posted this, a couple of folks wrote that they use pure *delbrukii* cultures in their weissbiers, and this is what I've done in the last couple of batches. I'm very satisfied with this approach.

good luck...

Subject: Water

There was so much activity recently that I avoided sending anything to HBD, but it seems to have gone quieter. I have no objections to free offers, but could I request that future ones chose a small integer such as 10 or 15 rather than 100. It might reduce the sudden overload of information that is too much for my limited brain.

But in passing I noticed a few items that were worth a comment, some of which I make now. Apologies if these have been dealt with already.

Joe Rolfe HBD 922:

> - my water is soften with a salt based softner...  
If this is a standard domestic water softener that needs 'recharging' by the addition of common salt, then don't use it for brewing liquor. I am not a chemist, but I am told that these softeners do not reduce the amount of salts in solution, but change them. For example Calcium Carbonate is converted to Sodium Carbonate (or should they be bicarbonate?). The sodium salts are 'soft' to the extent that they don't form a scum when used with soaps/detergents, don't precipitate when heated and don't form (chalk) deposits on heating elements etc. That is they are 'soft' as far as the washing machine and dish washer are concerned. They are not soft in the way the brewer needs their liquor. In fact you now have a liquor still having carbonate ions (high pH) that are not as easily removed, and you have increased the sodium content (not good if you have a dicky ticker).

John Freeborg also HB 922:

>How many all-grain people adjust their sparge water pH? I've been reading about putting lactic acid in the sparge water to achieve the proper pH which helps improve extraction numbers.

There have been a number of replies to this one, so I shall just add that if you are making pale ales, bitters etc then dilute (food grade) sulfuric acid might be preferable to lactic acid (if you are using acids rather gypsum). There are times when I might even consider using dilute HCl.

Subject: Priming with honey

As another data point, I have primed a few batches with honey and I have been very pleased with the results. Contrary to what someone (sorry, can't remember who) posted recently, and to what I myself thought, it does \*not\* take longer to carbonate your beer than corn sugar. I find that it takes just about the same amount of time. I have also primed with saved gyle, my favorite method, and it does seem to take a little longer to carbonate. I very rarely use corn sugar to prime with any more.

Subject: What I've Learned...

Dear Fellow Brewers;

I just read my latest HBD (the # escapes me now), and decided to put in my two cents' worth.

I have been brewing off-and-on for about 6 years now, and looking back, the most important thing that I've learned is that we should ALWAYS be having fun doing whatever we do, brewing, loving, and living!! I've learned this after much labor in my various occupations, one of which was as an assistant brewer at a well-known microbrewery (now I think it's almost a regional) in Oregon.

During my brief tenure there, one of the things that struck me is that, the process is the same, the ingredients are the same, the work a little more hectic, and as always, the possibility for worry the same. The interesting thing though, is that we were usually too busy to worry about things because of the amount of work to be done. And not that it would help any either! Granted, the water we were using was as pure as the driven snow (as a matter-of-fact, it did come from a glacier), the yeast we were using came from WYEAST, hops from the best hop yards around, and malt from Great Western just down the river a bit. This isn't to say that no other brewery didn't use the same stuff, but you get the idea: Use the best ingredients you can---if your water is drinkable, then it should be okay; try to use liquid yeast if possible (it makes a BIG difference); hops are hops, but make sure they're fresh. Regarding malts, a lot of HBDers use extracts, so I think I won't say any more 'bout that.

As you can see, I have a tendency to get long-winded. I guess what I really want to say is use the HBD to exchange ideas and opinions, but keeping comments constructive. The recent string of disparaging remarks made me wince and hope that I would have a little more cooth (sp?), lest one of my beers not be to someone's liking.

Well, I suppose I better get back to my insects. Maybe next time my brain won't be so fried (thesis time) and I'll be more organized. Thanks,

Mr. Pete

P.S. If you're ever in Hood River, ask for a Full Sail.

>I don't know how to define "set", though, so put it this way:  
A normal sparge for me takes 2 hours. Multiply by 1.5 if wheat malt  
was used, or 2.5 if it made up 50% of the grist. Multiply by .6 when  
using < 7 lbs of grain (this is rare for me).

Never having had one, I can only guess. I presume it means that the  
wort  
stops flowing. If one thinks of the mash as starchy, sugary glue,  
reinforced  
with husks, the importance of maintaining as high a temperature as  
possible,  
consistant with not ruining the beer, becomes obvious. When you let  
glue  
cool, it sets.

>I suspect that your use of the Maltmill has quite a bit to do avoiding  
set mash.

I would love to agree with you but I still think it is temp. But that  
is  
what this poll is all about. Let's hear from more people with set  
mashes.

> I see now that the Malt Shop in WI is offering a "Maltmill"  
for \$99. Is this the one and only?

Shonuff.

>Maybe this fall I'll get one, but for now, I'm trying to figure out  
how to produce enough beer for my own consumption with the least  
amount of effort possible. This means using extracts only, making the  
least amount of mess possible, and I'm trying to get a Firestone keg  
system together. I'm sick of putting in a 12-hr brew day, followed  
by an hour or two extra cleanup of the kitchen the next day, followed  
by.....

People love poking fun of my "window screen mash tun" aka Easymash but I  
have  
it down to about 5 or 6 hours now and there is only one kettle to clean  
up.

>From: bob@rsi.com (Bob Gorman)

>This remark I can not leave untouched. I tasted some of that beer.  
It was a terrible brew, infected, astringent and unbalanced.

I wouldn't be so crude as to post the comments of George Fix here but I  
think

most of us who have read them probably give his a little more credibility.

> As one conference goer stated: "How fitting it's served in urine sample cups.".

For those not familiar with the rules, the contract for exhibit space specifies that beer samples be served in glasses with a capacity of three ounces or less. I was simply following the rules.

Date: Mon, 27 Jul 1992 18:45:51 +0100  
From: G.A.Cooper@qmw.ac.uk  
Subject: Oatmeal Stout

There have been requests for oatmeal stout recipes. Try this one from the second edition of the Durden Park 'Old British Beers' book by John Harrison. It is based upon Maclay's 63/- Oatmeal Stout brewed in 1909 (Maclay's was a Scottish brewery, and 63/- means 63 shillings). The OG should be around 46. "A chewy, satisfying stout"

Ingredients per imperial gallon (\*see footnote):

1.25 lb Pale Malt  
2 oz Amber Malt  
4 oz Black Malt  
0.75 lb Breakfast Oats  
1 oz Goldings

The oats should be good old-fashioned (Quaker) breakfast oats. Amber malt in this recipe means a 'speciality' grain roasted to a colour of around 70 EBC (somebody out there can convert that to lovibond) - should be a roasted grain not a pale crystal malt.

You can work out your own preferred method if you wish, but how about: Mix the oats with 2 (imperial) pints boiling water and stand for 10 mins before mixing with the malts. Stiff mash at 155 F for 3 hours then mash out for 30 mins at 170 F. Boil for 1.5 hours (all the hops). Dry hop if you wish.

(c) copyright reserved - so don't go putting this into other books without asking permission!

\* the footnote:

Q. If US pint is 16 fl oz, and imperial pint is 20 fl oz, why is it that 1 US gallon is not 4/5 of imperial gallon?

A. We cannot agree what volume 1 oz water occupies. 1 US fl oz = 29.574ml

1 imperial fl oz = 28.41ml. Therefore 1 US gallon = 5/6 imperial gallon  
(approx)

I suppose you all knew that already.

harvesting hops

Hello,

I am reposting this simple question since it got lost in the "Digest Marathon" earlier this month. My question concerns harvesting hops. Is it standard practice to wash the cone after harvesting and drying or will rinsing wash away the good stuff? The reason I ask is that after drying and freezing my first harvest I noticed some small bugs or spiders in the bag. I'll probably rinse them before I use the hops or else I'll end up making "Spider Ale".

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Mashing and Lauter Tun

First an opinion to go with all the others,

I also think that Bob Gorman attack was too much for the HBD, I just don't like to read this stuff. I am not a big fan of Jack, I think a lot of his info is bunk but his also has his good points too. As far as the HBD goes lets just talk about things related to brewing and leave the personal stuff some where else.

Now for a real question,

I am now building a cooler lauter tun and need some help. I bought a 5 gal. round cooler which I think should be large enough for up to 8 lbs of grain. I am going to use a single step mash at 150-155F and sparge out at 170-175F.

So,

1. To make my filter I am going to use copper pipe with hole or slit cut into to the bottom, which is better? How about Jacks EASYMASH (yes I would love to hear from Jack about this) what kind of screen does it use. Al. or Plastic?  
Should I solder the conections?

2. How do I connect the copper pipe filter network to my valve? Should I use the spring loaded valve that comes with the cooler or would it be better to use some other type of valve?

Please reply to me directly and I'll let everyone know what works for me,

Tom Feller

Date: Mon, 27 Jul 92 12:11:31 EDT  
From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: hops problem & hops question

Ok, so the vine got tall, and the top half is covered with cones that will be ready soon.

The Problem:

Some of the cones have grown so large and close together that something has taken up residence between them. I know this because there's some spiderwebby-looking stuff in there. Maybe it's bugs, maybe it's fungus. I figure if it's a fungus those cones are trash, but if it's bugs I may be able to clean off the outside, do a little `internal inspection' and maybe keep them if they look OK on the inside. Good idea? Bad idea?

I'm gonna need to dry these hops, I don't have enough to make it worth building a dryer (maybe next year :) so I figure on just spreading 'em out on some screens and waiting a few days.

The Question:

Sunlight will skunk beer. The compound that gets skunked is from the hops. How come the hops don't get skunked on the vine? I assume that skunking only happens when the hop compounds are mixed with other beer compounds and then struck by the appropriate color of light. I expect no problem with sun-drying my hops, am I wrong?

From: gkushmer@Jade.Tufts.EDU  
Subject: S..l..o...w ferment - in need of advice

About a week ago I went out and made up a batch of wort for Pale Ale. For yeast I used 1056 American Ale Yeast (liquid). This was the first time I had used their new packaging since the eruption days of past, and when the package hadn't visibly swelled after two days of culturing, I thought it might be more from the packaging than the contents within.

Come pitching time, I snipped open the package, hearing a little CO2 release, and then threw it in the wort - shaking the carboy vigorously.

After a few days of nothingness, I called the shop and got a replacement yeast package (same brand). This time, the culture turned the package into a pregnant cow and I pitched, aerated, and hoped.

The next morning, there was some activity, but not an awful lot. 24 hours later, there was nothing much going on. This wort has never seen high krausen and I was very careful in all of my procedures.

What I need to know is: would yeast nutrient help at this stage? What should I do if the yeast doesn't take off? Should I re-pitch again? Is there a chance that there was something toxic in the original package that might be killing off the yeast?

This is becoming a bit troublesome! Any help or advice would be appreciated. BTW, I forgot to take an OG reading, so I can't really compare the rate of progress (readings have never phased me much anyway.)

Cheers,

- --gk

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Arnoldus and Gambrinus

From: Jay Hersh <hersh@expo.lcs.mit.edu>

>Ahem, not to refute your thoroughly interesting article on the breweries  
>of Bruges, C.R., but the Czech name Gambrinus as the patron saint of  
brewers.

>Anyone got the low down, will the REAL patron saint of brewers please  
>stand up???

Glad you found the story interesting.  
The confusion here seems to be coming from your assumption that there is  
a single, bona fide, universally accepted patron saint of brewers, and  
that  
all others are apocryphal. This is simply not the case.

In Belgium, the patron saint of brewers is Saint Arnoldus, Arnold the  
Strong  
of Oudenaarde. He invoked god to create more beer after an Abbey in  
Flanders  
collapsed in the 11th century. Images of Saint Arnoldus can be found  
watching  
over breweries throughout Belgium today. If he isn't REALLY the patron  
saint  
of brewers, no one bothered to tell the Belgians, and they don't seem to  
care.

Gambrinus is a legendary figure in many European brewing nations. One  
version  
of his story depicts him as Czech. (Maybe you could tell us this version,  
Jay) The Belgians have their own Gambrinus as well. He is considered the  
original "King of Beer", this of course being prior to the wonderful  
products  
of mass media and Anheuser Busch. The name "Gambrinus" is thought to  
derive  
from Jan Primus. Jan I was duke of Antwerp, Brabant, and Louvain in the  
13th  
century. Among other things, he is credited with having introduced the  
toast  
as social custom. In reference to Gambrinus, Jackson claims, "The King of  
Beer  
was most probably a Belgian, though he can be spotted all over Europe."

Beer and brewing are integrally intertwined with the history, religion,  
social customs, etc. of many European nations. Therefore, it should come  
as  
no surprise that there are many tales of saints and kings of various  
lands  
performing beery miracles, introducing social customs, or simply drinking  
alot!  
Moreover, this richness makes the history of brewing far more  
interesting,  
even if exact historical accuracy is blurred.

A toast to Gambrinus and Saint Arnoldus,  
CR

From: michael@wuppsych.wustl.edu (Michael Biondo)  
Subject: re. isolating S. delbrueckii

Fellow homebrewer and HBD-er, Tim Fahrner (MILBRANDT\_J@wums.wustl.edu) recently isolated S. delbrueckii from Wyeast 3056 with great results. Basically, he plated out the 3056 and inoculated small starters, each with an isolated colony from the plate. The starters were incubated and final identification was done by smell and taste. All the delbrueckii starters all had that distinctive cloviness in the taste and smell. One of the delbrueckii starters was then streaked to a new plate.

I received a slant from that plate and subsequently brewed a weizen patterned loosely after Dave Miller's recipe. I followed his mashing schedule and also took his suggestion to use a yeast energizer.

Well, the effort turned out a final product that was exactly what I was looking for - a lot of, almost mouth-puckering, cloviness.  
OG: 1.044 FG: 1.012

I have subsequently streaked a second plate using the yeast from the secondary of the above batch. My plan is take an isolated colony from that plate to brew the next batch. I thought it might be interesting to see if an isolated colony from a yeast of a prior batch would yield any difference in flavor ie. more cloviness.

Opps, sorry for getting off on a tangent - just wanted really to pass along another possible method of isolation and identification of S. delbrueckii.

Good Luck...  
Mike

Subject: Follow-up on my comments re: Gorman

Dear brewers,

To all who responded both privately and in the HBD, I wish to thank you for both the support for my position, and for some points well taken about contributing to / participating in issues which are essentially periferal to the jist of this forum in the first place. (How's that for an opening sentence?!)

To start, judging from the responses I received, there was nearly unanimous agreement that criticisms such as Gorman's do little to promote and further our mutual interest in homebrewing. But then again, judging from those same responses, Jack's comments don't help much either... I have been reading this forum sinse the first part of this year, and have been aware of the various controversies that seem to follow Jack around. (Indeed, when I had only just subscribed to this SIG, I thought that Jack was running for some public office, or something!) I remember the Schmidling-Frane flame sessions over dry vs. liquid yeast - an all together healthy debate, until it occasionally stooped into ad hominum attacks. I also remember that many on the forum grew tired of the bickering, and either cancelled their subscriptions, or pleaded for it to be carried on via e-mail and leave the net to discussion and constructive criticism. So, I was not unaware of "arf," nor unwittingly defending his ego. I was, rather, calling for such attacks like Gorman's - and like those Jack has made in the past (and will undoubtedly make again) - to more tasteful, and less tackless.

However, in posting my own criticism, I was engaging in the very thing I was attacking, as some of the other responses pointed out. With respect to those brewers, may I say that that was a point well taken. Perhaps the best way to aviod more flame sessions surrounding the postings from those who don't know jack schmidling about brewing is to either ignore their pomposity (?) or to take it off the net.

So, while I continue to feel that Gorman's tact was an insult to the idea of constructive criticism - even in Jack's case - I must agree that my own objections probably helped to fuel the "flames" rather than quell them. For this alone I express my regrets to those on the net who would rather not deal with such drivol.

Cheers (isn't this what it's all about anyway!!?):

John

Subject: Mead from Micah Millspaw

This article has been posted before but there have recently been a lot of mead questions on the HBD and some of the info here may be of use. What ever other mead type questions are left post them and I take a shot at em.

PS I've made a lot of mead.  
WASSAIL Micah Millspaw 7/22/92

The oldest of beverages, the newest of techniques. High tech has come to mead making.

Because of the commitment of time involved, many people are quite hesitant about getting into mead making. Generally it takes less equipment and the ingredients are cheaper than those needed for brewing. Someone who is extract brewing is already covered (equipment wise) to be a mead maker.

To the veteran mead makers out there, you know the time and effort (mostly time) spent on a mead can be exceptionally rewarding. On the other hand something could go wrong and unnoticed for a year or more and that can be very disappointing. The amount of time we put into a mead can make the loss seem much worse than the loss of a batch of beer. It is also possible to radically reduce the length of time it takes to produce a consumable mead/ melomel/ methiglin.

Let us consider some ways of reducing or eliminating the chance of disaster striking your mead. These efforts should also shorten the fermentation time.

Meads are known to have long, slow fermentation times (1-4 months is common). This long term ferment tends to tie up a carboy that might be used more productively (for beer maybe?). The reason that mead takes a long time to ferment out is that honey is woefully lacking in the nutrients that yeast needs to effectively metabolize the mead wort.

The cure is to add yeast nutrients. Yeasts like ammonium salts, these are those little white crystals available at most homebrew shops. These will do the job of sustaining the yeast, but there are some nasty side effects. If too much of the ammonia salt crystals are used, their taste and aroma will remain in your mead(yuk). The only way to get rid of the ammonia taste/smell is to age it out, this often takes years. Fortunately there are better yeast nutrients. The best that I have used so far is bacto nitrogen base yeast nutrient from DIFCO. This nutrient is available from pharmaceutical and laboratory supply houses. The difco has no flavour/ aroma side effects but is rather expensive, the plus is, a small amount will do lot. Detailed information for amounts to use should be provided when you purchase the nutrient. Recently a yeast nutrient for meads became available from Great Fermentations of Santa Rosa which they claim will ferment out a mead in three weeks at 70 degrees F. I have used this nutrient several times and have found that if the temperature is maintained it is possible to ferment out in three to four weeks. This nutrient is reasonably priced and is easy to get.

Having addressed the need for yeast nutrients, it is a good idea to have some yeast to go with them. Liquid culture wine and champagne yeasts of high quality are easily obtainable. Many dried yeasts are also of interest to the mead maker. One for the most important features of a yeast to the mead maker is alcohol survivability. Meads in general and especially high gravity meads have alcohol levels far exceeding that of most beers.

Prise de mousse (*S. bayanus*) and Pasteur champagne(*S. cerevisiae*)

are excellent for traditional and high original gravity meads. Epernay, a wine yeast is very complimentary to melomels (fruit meads). Most wine yeasts are entirely adequate for mead making. Try a few different ones if your looking for something unique in flavour. It is possible to use ale or lager yeasts (I've tried both) to ferment mead, but I've been less satisfied with the results (flavour) when compared to meads made with wine or champagne yeasts.

Some mead makers like to use "killer yeasts", these are identified by the letter K preceding a name or number. The killer yeasts work well in conjunction with other saccromyces yeasts. The "killers" function is to eliminate competing wild yeasts. It is not normally necessary to use this type of yeast unless you choose not to boil your mead wort. (the not boiling is part of an ancient process and will not be discussed here)

It is important to prepare a yeast starter so as to have enough yeast ferment your mead. As there is a great deal of information available about making yeast starters, I'll not go over it much. The only suggestion that I will give is to use confectioners sugar instead of dry malt extract in your starter, this removes the chance of strange flavours in traditional meads. I use 1/4 cup sugar to one quart water and 1/4 tsp of yeast nutrient in my starters.

The properly prepared yeast in conjunction with the essential yeast nutrients should result in a vigorous 3-4 week ferment. It is important to allow adequate headspace in the fermenter and the blow off method is recommended.

After your mead has reached the desired specific gravity, it should be racked into a soda keg. Kegging the mead gives you control over carbonation levels and oxygen exposure problems. It is also possible to arrest the fermentation at a desired point by kegging and sub-micron filtration. I have had good luck adding fruit concentrates and essences to filtered meads. They are very stable in comparison with bottle conditioned fruit meads.

A clean soda keg should be blanketed with CO2 prior to racking in order limit oxygen exposure. Fermented meads are very susceptible to oxidation. Oxidation will result in some very unsatisfactory flavours in the finished product.

Decide if your mead is to be sparkling or still (flat). If the mead is to be still, rack into the keg, put on the lid and seal it with as low a pressure as possible (I recommend filtration). If the mead is to be sparkling I strongly recommend force carbonation. I've found that using "methode champenoise" with mead to be unpredictable and usually unsatisfactory. Rack into the soda keg, seal it then pressure up to 30-40 psi and set it aside for a while. Mead seems to be slow to absorb carbonation (compared to beer) and since mead should improve with reasonable aging this will all work out nicely.

What to do with a 5 gallon keg of mead? It is possible to put it on draft in your home. The drawback is that the mead, when present in large amounts could overwhelm you. The option is to counter-pressure bottle from the keg. Counter-pressure fillers should allow you to purge the bottle with CO2 prior to filling. Removing the normal atmosphere from the bottle is absolutely necessary limit oxygen exposure. The mead that you're putting into the bottle should be a finished and stable product and you don't want the oxygen to ruin your efforts.

Before bottling, sample the kegged mead to ascertain its conditioning; age, carbonation level, etc...Cool the keg of mead down to 35-40 degrees F. so as to improve its ability to hold CO2 in solution. Clean your bottles and fill them up. Enjoy.

Subject: Mashing adjuncts from Micah Millspaw

On to the topic of using adjuncts. A lot of bandwidth has been devoted to mashing oats. While at the AHA conference in Milwaukee I had the opportunity to talk to one of Millers brewmasters. We were discussing the use of adjuncts in Millers brewing process. Miller uses corn as their main brewing adjunct. I mentioned that I had had some trouble when trying to gelatinize corn and I was told that what Miller does is to cook the grain with 10% malted barley until it gells and then add it into the mash. Their mash is conducted with one step. This should work equally well with oats. I plan try it soon myself.

Subject: Competition announcement from Micah Millsapw

Attention everyone

I would like to inform you all of a homebrewing competition that is coming up soon. The SAAZ homebrew club and St. Stans brewery are jointly hosting the first annual fest beer competition. The judging will be at St. Stans on Sept. 27 and is open to the public. It takes 3 bottles and 5 dollar per entry. The prizes are good ; best of show gets a 50 lb sack of pale malt and St. Stans will brew the winning beer and serve it at their brewpub, all first place winners will get a one pound bag of hops plus a ribbon, seconds and thirds will receive hats , t-shirts and pins with the St. Stans logo plus ribbons.

the catagories are:

LIGHT LAGER  
WHEAT  
OKTOBERFEST/MARZEN  
GERMAN ALT  
FEST BEER OPEN

ENTRY DEADLINE IS SEPT 18 BEFORE 5:00 PM  
fees are 5 dollars per entry make checks to STANISLAUS AREA ASSOCIATED  
ZYMURGISTS.

SHIP MAIL OR DELIVER TO : ST. STANS BREWING CO.  
ATTN: BILL COFFEE  
821 "L" STREET  
MODESTO, CA. 95354

For more info contact Ray Call at 209 478 6170

Subject: Info on East Anglia / Bottling with Yeast

Item 1:

In early October my wife and I will be traveling in East Anglia (England) while she does research for an upcoming book. My only assignment is to provide company and have fun, and one sure way to do this is to scout the local beers and breweries.

My question: are there any HBD readers in East Anglia that would be willing to consult with me on pubs and breweries? I do have a copy of the Good Beer Guide, but would appreciate local advice. I'd particularly like to visit any breweries that accept visitors, and would be willing to consider an international homebrew exchange if anybody over there wants to meet. We'll primarily be in Bury St. Edmunds, Ipswich, Norwich, and Cambridge, from approximately October 2 to October 11.

Item 2:

With great anticipation I am planning to make the extract-based triple recipe in Pierre Rajotte's new book, Belgian Ale. Due to the gravity of the beer (1.081) Rajotte recommends adding fresh yeast to the brew at time of bottling, along with the usual corn sugar. Does anyone out there have experience with this? I'm planning to use the Wyeast Belgian yeast, and would normally make a starter. For bottling, however, I wonder whether I should simply mix the yeast with the boiled sugar solution and bottle.

If anybody has comments on either of the above you're welcome to send them to me directly; I'll post a summary if enough info comes through.

P.S. Rob Gardner, I don't know who you are, or even if you really exist. However, I think it's time we nominate you for homebrew sainthood for the service you provide to the community. Thanks!

**Subject: Highgate Dark Mild**

My wife's all-time favorite brew is Highgate Dark Mild [Bass Highgate], which is described as "(1036) - dark and fruity" in the 1989 Good Beer Guide.

I've tried several recipes from the CJHB and from Dave Line's books.

She's

liked most of them, but doesn't think they're exactly what she's looking for.

Does anybody have an accurate recipe for Highgate Dark Mild? Has anyone tasted it? If so, can you describe it a little better?

Thanks in advance for any help.

From: fjdobner@ihlpb.att.com  
Subject: Wheat/Barley Malt Extract

Bavarian Weiss/Wheat Beer Brewers,

I began grain brewing 1 1/2 years ago simple to attempt to perfect the Bavarian Weiss Beer style as far as my palate can tell. I learned quite a few things along the way (with about 12 batches behind me for this style). I must say though, all grain brewing is a lengthy labor of love. Therefore, earlier this year I decided to make the brewing session a bit shorter by buying a couple of cans of Munton and Fison Wheat malt extract (which is 45% barlet malt and 55% wheat malt) and proceed with the following recipe:

2-3.3# Cans of M&F Wheat Malt Extract  
1 1/2 oz Hallertauer Hops (boiling)  
1/2 oz Hallertauer Hops (Finishing)  
1/4 Tsp Irish Moss  
3/4 Cup DME for Bottling (Turned out to be too little)  
WYEAST Bavarian Wheat Liquid Yeast

I brewed according to the standard procedures one finds in TCJoHB for an extract brew adding the Irish Moss in the last 10 minutes of boil. What I found was a much fuller bodied beer than would be called for in this style beer. Also the color and the way light passes through the liquid is really far than I expect from my ideal of shining golden Bavarian Weiss. Has anyone else had this experience with this brand of malt extract or others? I have more experience with grain than I do with extracts so I would value the opinions of extract brewers with Wheat experience.

Subject: Re: Sour brown ale/starters

Steve writes:

>in some cases of yeast blends, such as Chimay).

Chimay is fermented with a single strain culture and (to the best of my memory) bottled with a single culture too. I think that the bottling culture \*may\* be the same culture.

I've successfully brewed an Orval clone by culturing from the bottom of Orval bottles. It is reported that Orval uses a mixed culture of 5 strains at bottling, with which I can concur. Of the three bottles in which the yeast did start, all three starters tasted and smelled differently. I simply used the one that smelled and tasted like Orval. The resulting brew also did.

I suggest you go ahead and culture the bottle dregs, then taste the starter and decide whether to use it or not.

Sorry I can't help you with your Flander's Brown recipe, but I'd like to comment on starters in general. Someone (sorry) said they use corn sugar + yeast nutrient for their starters. I propose that 1 oz (by weight) of light dried malt extract in 8 fl. oz. of water boiled 10 min (or, even better, pressure cooked) then cooled to 80F would be much easier. I've used this type of light wort (1.020) for starters for two years and have had very good luck with it.

Subject: Re: Question on racking after chilling

Brett writes:

> I recently made an immersion chiller, and used it for the first time 2  
>days ago. It worked brilliantly, cooling my brew from boiling to cold in  
>about 15-20 mins. However, when I then immediately racked to primary, I  
was  
>stunned by the prodigious amount of break material, at least 5-6 litres  
>(what we measure in in Australia). As a result, from 21+lt of wort, I  
only  
>successfully got 18lt to primary, and even then I transferred a small  
amount  
>of break material with it.  
> So how can I enjoy the benefits of chilling without sacrificing a  
large  
>percentage of wort in the process? The only thing I can think of that I  
>might have done to contribute to the problem was to pour the boiled wort  
>into another container before chilling, in order to strain out the leaf  
hops  
>in the boil.

After chilling, I let the wort sit for 1/2 hour to an hour (depending on  
how tired I am) and the hot and cold break mostly sink to the bottom. I  
then pour the wort through a funnel which has a strainer in the bottom.  
Sometimes the strainer clogs near the middle of the pour (drat!) in which  
case I must either stir with something sanitized or dump the funnel,  
clear  
the strainer, resanitize and begin again. If it keeps clogging, I just  
remove the strainer and let the break go into the fermenter. Usually,  
the strainer clogs only at the very end and thus I get all but about one  
quart (~liter) of wort into the fermenter. If a little break gets into  
the fermenter, no problem -- it's not worth worrying about.

I suggest you let your kettle sit (covered) for a 1/2 hour or so before  
transfer to the fermenter and you'll probably get 20 of 21 liters into  
the fermenter. Minimizing trub during the primary fermentation will  
minimize higher alcohol production (which we would prefer to avoid).  
Incidentally, trub during respiration is good. I'm thinking about pitching  
the yeast right into the chilled wort in the kettle and let the yeast  
munch on the trub during the 1/2 hour to 1 hour "break settling rest."

> One other question that occurs to me. What is the recommended  
procedure  
>for dry-hopping in the secondary with pellet hops?. Are they added as  
is, or  
>'dissolved' first?

If you can get fresh leaf hops, use them. Leaf hops will float a lot  
longer  
than pelletized hops and then allow you to siphon out from under them. In  
either case, just toss the hops into the secondary (I just toss them into  
the primary seven days or so before bottling for single-stage ferments).

Thanks, Frank, for the nice review of THREAD. I'm glad other homebrewers are finding the program to be useful.

I've had a couple of inquiries about how to gain access to the archives at sierra.stanford.edu via ftp. By convention, anonymous ftp sites have guest accounts with the account name "anonymous" and usually your e-mail address as the password. Before transferring a given file, make sure the file type is set to binary/ASCII as appropriate.

> 'dissolved' first?

Have you ever seen the Alka-Seltzer commercials? You know, "Plop plop,  
fizz  
fizz". That about sums it up. I've tried several methods of dry hopping  
in  
the secondary, and each has its own advantages/disadvantages. At first I  
just  
dumped some pellets into the carboy (ala Alka-Seltzer) and let it do its  
stuff.  
Very easy, and when the hops sink it done. Cleanup on the other hand was  
very  
tedious. Next I tried whole hops. Same general results, but a little  
harder to  
add through the carboy neck, and higher possibility of infection I assume.  
After being sick of cleaning hop scum from my carboys, I tried using a  
hop bag  
inside. After what seemed hours of wrestling I managed to beat the carboy  
two  
falls out of three, and got a full hop bag through the narrow neck. A  
similar  
battle ensued upon removal, and I ended up with a face full of wet hop  
goo  
(but I was particularly proud of an escape I performed from a near pin >  
:-)  
Finally, I tried a hop bag with pellets. Don't bother! The pellets are  
ground  
fine enough to float right out of the hop bag and the results are simila  
to  
pellets by themselves, except you get to go on a fishing expedition for  
the  
empty hop bag.  
You asked for the recommended method...I doubt you'll find one specific  
choice  
(which is typical of the HBD - and why I find it so informative).  
Personally,  
I'm sticking with the Alka-Seltzer.

Lager Daze,

From: whg@tellabs.com

Subject: Re: Advanced Brewing (NON-EXTRACT) worth it?

It has always seemed to me that, yes you can make better beer in an all grain process, but I'd say you can also likely make much worse beer. Given the same process from the point of the boil on, I've always felt there are a lot of things you can screw up in the mash/sparge process (bad crush, poor temp control, oversparging) that could potentially give you a sorry wort. It seems to me that while you can maybe only climb so far up the quality scale with extracts, short of an infection you can only be soo bad as well. As of yet I'm still doing partial (1/3 of sugars) mashes. I wouldn't be at all surprised if when I take the final plunge (next fall?) that initially the quality of my brews goes down. Especially when entered in a compitition and they need to exemplify a partiular style. There's a lot of variable to get right.

Subject: washing hops

My question concerns harvesting hops. Is it standard practice to wash the cone after harvesting and drying or will rinsing wash away the good stuff? The reason I ask is that after drying and freezing my first harvest I noticed some small bugs or spiders in the bag. I'll probably rinse them before I use the hops or else I'll end up making "Spider Ale".

I havent the faintest idea. I do know that back in the old days farmers used burning sulphur to fumigate their hops once they had been dried. Perhaps spiders etc are responsible for those unique flavours that are always so hard to duplicate.

From: djt2@po.CWRU.Edu (Dennis J. Templeton)  
Subject: Connecting copper filter pipe to cooler-mashtun

Tom asks about how to best connect the slotted copper tubing to the opening of his cooler tun. I thought I'd share what I did since it avoided all the fuss with the "food grade (ha)" silicone sealant.

I used the 5 gallon Rubbermaid/Gott water cooler (orange) and unscrewed the spigot... I saved it in case the cooler is ever reincarnated as a cooler.

For a filter, I spiralled about 3 feet of flexible 3/8 inch copper tubing to fit the bottom, and cut 1/4 in slits in the bottom spaced about 1 inch apart, as has been suggested here before.

To connect the two, I used a polypropylene (working temp to 250 degrees) 3/8 inch tube-to-tube bulkhead union that fit precisely in the cooler hole.

Once the bulkhead is tightened, the gasket that comes with the cooler seals well. If you take the bulkhead out you can still use the cooler.

This part comes from US Plastics Corp (800)537-9724 (part number 61123, \$1.20)  
It's worth getting their catalog, as they have a full line of valves, vinyl tubing, and tanks too. Minimum order is \$10 I think.

I then connected some 3/8 vinyl tubing to the outlet with a valve clamp. I run this about 5 feet over directly into the kettle on a cajun cooker.

It works for me.

From: tony@spss.com (Tony Babinec)  
Subject: overnight brewing

Deborah Poirier says she accumulated 6 gallons of wort and let it sit overnight intending to add hops and to boil in the morning. Is there a problem with that? I would be concerned that as the temperature of the wort fell, bacteria and wild yeast might establish themselves. On the other hand, upon boiling the wort in the morning, anything that started in the wort should be killed. Is this true? You hear scare stories about commercial breweries that get certain infections that are difficult to eradicate. The question is whether there was enough time for anything to get started in earnest. Certain resultant flavors, such as souring, should they become established, would be permanent and irremovable in that batch of beer.

Sour mashing is easily accomplished as an overnight brew. For the allgrain brewer, conduct the mash as usual. At the end of starch conversion, let the temperature of the mash fall to roughly 130-135 degrees F, add a half-pound of cracked malt, cover the mash, and insulate it. Let it sit from 15 to 24 hours and resume brewing. That is, sparge and collect the wort. If you leave the mash in the brewpot, you might set your oven to 135 and place the mash pot in the oven overnight. Charlie Papazian's new edition describes sour mashing in an appendix, and even suggests a method for the extract brewer. In any case, you are relying on the fact that the malts you use are figuratively crawling with bacteria. The resultant soured beer might be called a Kentucky Common Beer. Or, you might use the beer as a base for a fruit beer.

In "Belgian Ales," Pierre Rajotte describes the "Oud Broun" style typified by Rodenbach and Goudenband. He gives a few recipes. The grain bill for these produces a fairly pale beer. Rajotte suggests using a longer boil, say 2 hours. He also says he has left the wort on the stove overnight at a low simmer. The idea is to achieve a reddening or browning through long simmer and resultant caramelization of sugars in the wort. In the morning, add the finishing hops, end boil, and do the usual wort chill and racking. With appropriate yeast, you'll emulate an Old Brown. Or, again, this beer becomes a nice base beer for fruit, notably raspberries.

From: homebrew@tso.uc.EDU (Ed Westemeier)  
Subject: Lauter tuns & hop drying

Tom Feller asks about building a cooler lauter tun using a round picnic cooler and copper pipe filter network.

For the past year, I've been using a variation of the Phil's Sparging System, by Listermann Mfg. Co. They advertise in \_Zymurgy\_ and the products (like Phil's Philler) are available in many homebrew retail outlets.

Besides the basic system using two plastic buckets, assorted tubing and fittings, sparging sprinkler and perforated plastic plate, they also make the plate in sizes to fit 5 & 10 gal. round coolers (the "Gott" model (Rubbermaid brand) orange drinking water coolers that you often see used by highway construction crews.

Using this system with a Gott cooler, I have been enjoying easy mashing/laughtering and relaxing a whole lot more than I used to. The Gott cooler holds the temperature of contents to within a few degrees for 2 hours or more, and the perforated plastic screen element is easy to clean. In short, it's both simple and effective.

Usual disclaimers, but ask your retailer to order the sparge system sized for one of these coolers. As I recall, it was well under 20 bucks, and the cooler was available in my local K-mart for about 12 bucks.

Also, Carl West asked about sun-drying hops.

Not a good idea, IMHO. That's why hop growers build oast houses. Direct sunlight has a deleterious effect on hops AFTER they have been harvested. Dry them in the shade and you'll be a lot better off.

From: Glenn Anderson <glenn.anderson@canrem.com>  
Subject: blue stuff, pets, space

On July 21, Jeff Frane sez:  
>Glenn asks about little blue flakes coming out of his wort chiller.  
Sounds to me like verdigris --

On July 22, John Hartman sez:  
>I suspect you used some chlorinated solution to store your chiller. I  
used to do that with mine and found that the chlorine slowly corrodes the  
copper.

Thanks for the comments guys. I did in fact use a chlorine solution to  
sanitize the chiller after the first couple of uses and perhaps I was  
less than thorough in rinsing as it was going to storage. Since the  
blue flake problem occurred I have stopped doing the final rinse with  
sanitizing solution, I simply do a 5 minute "power" rinse with hot-hot  
water, then put it away for next time - no more flakes.  
The moral of the story, for those interested, don't leave chlorine  
sanitizing solution in contact with brewing copper for any extended  
period  
of time, you may end up with verdigris, which you should definatly worry  
about.

On July 23 Dave Ballard sez:  
>When the shuttle Discovery lifted off last January, it had, officially,  
42 experiments to conduct. But thanks to a Canadian pub and avid  
homebrewer-astronaut Bill Readdy, a 43rd experiment was added at the  
last minute: a study of the effect of zero gravity on hops.

.  
.  
.

Stepping behind the bar, Readdy drew the first glass of Discovery Ale,  
rapidly quaffed a few mouthfulls, caught the drips on his NASA rugby  
shirt, and proclaimed, "I declare this ale fit for human consumption!"

Hey now Dave, what was omitted was just before Bill Readdy made that  
declaration he states "Beauty, eh. Bob and Doug MacKenzie would be  
proud. It just goes to show theres more to Canadians than snowshoes and  
ice fishing."

On July 23 Jeff Mizner sez:  
>Well, not one to be the last to try something new, I went to Canada and  
bought 12 liters & 24 half liters, with caps (good sealing caps).  
They don't break, they're easy to clean, they're light and my next batch  
of bitter will go in them. When they get old, you can recycle them (at  
least in Raleigh...).

Any comments??? My local BrewStoreMeister said that they were available  
but rather expensive. He said that Coors had floated some trial  
marketing

Jeff, I used to use the 500ml PET bottles prior to moving to kegs. They  
cost me about 35 cents a piece with the cap (which is re-useable). I now  
have about 200 bottles and caps which I have no use for. I would be glad  
trade them for a Cornelius keg if anyone is interested. (sure)

The PET bottles are excellent, you simply fill them, squeeze the air out and cap. The bottles then "pop" out once the priming has taken effect. I found it to be a good barometer of when the beer had finished priming as bottles became hard with the pressure. They're easy to clean, re-useable and recycleable.

The only problem I had was that I found they tipped over easily, which stirred up sediment which made the beer chewy.

...GA

Subject: CONSOLATION PRIZE

To: Homebrew Digest  
Fm: Jack Schmidling

I am pleased to announce that a MALTMILL is speeding on its way to Sheridan Adams as winner of the recent giveaway. He has informed me that he is indeed a homebrewer and has been through the baptism of the rolling pin. Hopefully, he will now be able to crush enough grain to do a whole batch with grain.

Congratulations again, Sheridan.

Now, it should be obvious to most that there is one very disappointed reader out there who, like many of us, thought he was the winner based on counting articles in the indices. To allay any feelings of unfairness, I have decided to award Dan Keever, a consolation prize.

I was hoping to send him a (not yet released) MALTMILL jr., but I am not happy with the overall operation of this scaled down version and I am not yet ready to put one into the field, even a free one.

Therefore, I am sending to him a (soon to be announced) EASYMASHER KIT. This is a spigot, strainer and all the fittings needed to convert any large kettle into a mash tun or killer brew kettle for extract or grain. It's all brass and copper, no window screen:)

Congratulations, Dan Keever. Send me your address and it will be on its way.

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: Packaging Hops

Hello Fellow Relaxers,

I would like to share with you my method of packaging homegrown hops.  
Three words: baby food jars.

I was at home worrying one day (shame on me) about how to package the fruits of my new hobby when I came up with this idea. I was mainly worried about using plastic ziplocks to keep hops in my freezer. My freezer gives this unpleasant "freezer" odor to food and ice cubes. This is a taste I definitely did not want in my homebrew. I was considering asking my local brewstore entrepreneur to package the hops for me in exchange for some of my hops, or money. He has one of those vacuum sealing machines that seals food in thick plastic bags. I was also considering getting one of those sealing machines myself, but they are a little expensive.

So I said, "why not glass". Baby food jars are the perfect size. I can cram about half an ounce of dried hops into the really small jars (2oz, I think). Extrapolating, with the help of many college courses in mathematics, the larger 4oz jars will hold about one ounce of dried hops. I have to extrapolate because the harvests from this first year of growth on the first three hop varieties to mature were less than an ounce each. (I expect to get around two or three ounces from the next two varieties to become ready--Chinook and Cascade.)

What I do is weigh the flowers, then put them in a large mixing bowl. I then stick the jar the into the pile of flowers and start shoving the hops in with my hands. Then, I make sure to label the jars with the variety and weight, using masking tape. It works for me. The jars seal pretty well. This would be a space-saver over just cramming flowers into a plastic bag; but I'll bet that those sealing machines would pack them tighter. Maybe I'd get one if I had the money and was sure that the plastic was not permeable to freezer odors. (There's another gadget to put on the list.)

If you don't have a toddler yourself, maybe you know a friend who does.

Happy Hopping,  
-Alan

From: Stephen Brent Peters <sp2q+@andrew.cmu.edu>  
Subject: priming sugar & rice solids

Hi Gang,  
I just want to take some of your time to relate my meager experiences with priming with malt and brewing with rice solids.

My latest batch, turned out like a cream ale:

- 3 lbs dried light malt extract
- 1 lb dried rice solids
- 1 package wyeast american ale yeast
- 1 oz haullertaur hops boiling
- 1/2 oz H hops put in 10 minutes before the end of the boil
- 1/2 oz H hops finishing
- 1/2 cup roasted barley

Don't be anal-retentive about the hop amounts. I winged it on the fly, approximating from a Papazian recipe. The significant technical improvements in this batch were the liquid yeast and using malt instead of corn sugar for priming. If anyone out there is thinking of moving up to liquid yeast, do it. The taste of the yeast itself is much improved - it still tastes like yeast, but it doesn't taste bad, and leaves much subtler favors. I read in Papazian's book that using malt for priming makes for different bubbles that have a creamier texture. Sure enough, it does. The result was a light, refreshing brew with a delicate delicious flavor that leaves your tongue floating on a cloud.

About the rice solids: last year I bought something I think was called "sweet rice" at an Asian grocery store. When cooked this stuff produced a mush rather than your typical rice kernels. It was mildly sweet too if I remember correctly. Is this a way of making my own rice solids? Anyone have a clue what would happen if I dumped a pound or two in the brewkettle?

next week I'll be driving all the way across the USA and stopping at every brewery I can find! See you in SanFrancisco!

From: oconnor@ccwf.cc.utexas.edu (donald oconnor)  
Subject: o-rings

There seems to be some disagreement with my earlier statement regarding the 'dirty o-ring infecting your beer' myth so i went ahead and did a little experiment.

i took 10 dirty large o-rings from used soda kegs. some had dr. pepper, sprite, big red, mountain dew and i don't know what else. i rinsed them off under the faucet for a few seconds, then soaked them in a pail of water overnight, then hung them up in the garage for 2 days. I then heat sealed them in a polyethylene bag with plain water for a day. when i opened the bag i could not smell any soda pop whatsoever. also, the water tasted just like water.

let me explain why this business of dirty o-rings ruining the flavor profile of homebrew has never made any sense. Beer is essentially water with a little alcohol. If you soak o-rings in water and/or alcohol and the stuff won't come out, then why in the hell would it ever come out in your beer which, i'll repeat myself, is water and alcohol? Secondly, if you can smell the pop on the o-ring, then it is coming out. that's why you can smell it. Third, o-rings are not very large. Unless you believe there are little elves making soda pop in there, it's hard to imagine getting enough of anything out of them to ruin 5 or as some claim, 20 gallons of flavorful, malty brew.

finally, o-rings are cheap and since my wife sells them i guess this makes me the world's worst salesman. on the other hand, hard hats are cheap but we're not all wearing them because Chicken Little says the sky is falling.

From: homebrew@tso.uc.EDU (Ed Westemeier)  
Subject: Sun drying hops (correction)

I responded to a question about drying hops in the sun by saying that direct sunlight had a deleterious effect on hops after harvesting. This was based on some traditional wisdom (or "momily") that had been rattling around in my skull, not from any actual scientific information. I felt a bit guilty about my hasty answer, and herewith retract it.

There is no reason why you can not use the sun to dry your hops.

The harmful effect of sunlight that produces skunky or light-struck beer is based on the fact that the iso-alpha acids that are produced during the boil are inherently unstable. The light produces a reaction between the iso-alpha acids and some sulfur compounds found in the proteins, and the result is that skunky note we universally abhor.

The alpha acids in the hop flowers are much more stable, and should not be adversely affected by the sunlight. RDWHAHB.

Subject: Sanitizing Beer Bottles in Dishwasher

IN REPLY TO:

poirier@inrs-ener.quebec.ca

>>Hello fellow fizzicists!

>>Now I have two questions:

>>1. do many of you use your dishwashers to sanitize bottles and hoses?  
I do,  
>>with extra hot water and I slosh in a few glugs of bleach midway along.  
No  
>>problems so far, but is this the safest way to go? Would "sparkleen" or  
just  
>>regular dishwashing detergent work better?

>>Thanks for any advice.  
>>Deb

I have used the same bottle sanitizing technique since brewing my first  
batch  
in 1980 and have never had problems, assuming you're not getting bottles  
out  
of a trash can. After consuming a beer (homebrew or import or non-  
twistoff  
longneck), I rinse it out thoroughly with tap water and allow to dry  
upside  
down in the sink. After drying, I place all "clean" bottles upside down  
in  
it's case until bottling time. Then I run the bottles through the  
dishwasher  
WITH NO SOAP! I visually inspect each bottle prior to filling- if there  
appears to be a problem, set that bottle aside for a future batch and use  
a  
chlorine solution to really clean it. It's easy and it works!

> . . .  
> . . .  
> . . .  
> /Chris  
>

I'm a firm believer in useful, general utility programs. In fact, I've used a similar program to the one Chris mentioned for the last couple of years for searching the back issues of the digest. However, using such a utility is a very time-consuming task for an extensive search. The reason is that general file searching utilities have no knowledge about the individual messages that comprise the Homebrew digest, and this is the reason that I wrote THREAD. Time to toot my own horn. 8-)

THREAD is a message-based search program. That means that it reads each message from a given digest issue, and searches just the message for all the key words. In contrast, a general file search utility searches the entire file for the key words. For example, let's say we wanted to extract all the advice on growing your own hops, and let's say the general utility program can handle logical operators (i.e. AND, OR, NOT). Then a search for "grow" AND "hops" with THREAD will pull up only those MESSAGES with the key words, whereas the general utility will pull up every DIGEST with the key words. The result is that you have to sift through a huge amount of unrelated text to extract the messages related to growing hops. Believe me, even with THREAD, you get plenty of messages that are not of interest -- in the search example above, you'll also get messages related to "the growth of the hops

industry", etc. In short, a message-based search program will save a huge amount of time and effort for the homebrewer.

Maybe someone in the Mac world that has the Turbo Pascal compiler for the Mac could compile THREAD and upload it somewhere for other Mac users? I've provided the source code with the THREAD program files...

Just as an aside, I've released the THREAD program as public domain. I don't ask for any donations or registration fees. I started writing THREAD to save time for myself, and quickly realized that others might benefit from it too. Therefore, I put more effort into making the program fast on PCs with a variety of processors/clock speeds, documenting the program and source code, and debugging it before it was released.

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: Packing Hops: Addendum

Hi Brewpeoples,

I made a mistake in my last post about using baby food jars for storing hops. I wrote:

```
| I can cram about half an ounce of dried hops into the really small jars  
| (2oz, I think)....the larger 4oz jars will hold about one ounce of  
| dried hops.
```

Well, I just got home and packed the first pickings from my Chinook plant and realized that the small jars are 4 fluid ounces and the large ones are 6 ounces. With a little effort I was able to cram one ounce of fully dried hops into the 6oz jar. (I got 0.6 ounces into the 4oz jar.) One other thing I remembered: your hands smell absolutely wonderful after packing the hops! A small amount of lupulin sticks to your hands. Not much sticks to the glass bowl though. Use glass; lupulin seems to stick more to plastic.

Happy Hopping,  
-Alan

>From: Mark N. Davis <mindavis@pbhya.PacBell.COM>

>Finally, I tried a hop bag with pellets. Don't bother! The pellets are  
>ground  
>fine enough to float right out of the hop bag and the results are simila  
>to  
>pellets by themselves, except you get to go on a fishing expedition for  
>the  
>empty hop bag.

Using this method, I've dry hopped a few times and haven't really had  
this trouble of which you speak. Some of the ground hops might have  
gotten out of the bag, but the majority of them were definitely in  
there when I took out the bag.

As for getting out the bag, I took the string part and jammed it between  
the rubber stopper and the carboy lip. This made two things easy - to  
remove the bag I just pull, and to remove the stopper I just pull. I  
used to worry about possible infection from this, but when you figure  
that there is a good deal of alcohol plus the level of hops in all this,  
the  
risk seems rather nominal. After all, I was more worried about the risk  
of infection from the hop pellets, unsterilized, being thrown in the  
wort.

But through all of this, I've never seen my siphon clogged with hops  
from dry hopping. Maybe I'm lucky, or maybe I'm too relaxed to notice  
:-)

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Sanitizing & wort priming from Micah Millspaw

I've recently come across some cleaning solutions for my stainless equipment. The first is K O dyne it is an iodaphor type sanitizer and will work on all homebrewing type equipment, it kills just about everything that could screw up beer with a two minute contact time at 12 1/2 ppm and is FDA approved. The best part is that it is cheap, about \$14 per gallon. The other cleaner is an MSR this is strictly for cleaning the stainless it contains phosphoric acid and is great for removing beer stone from your fermenters it sells for about \$10 per gallon. I got this info and the stuff from a local dairy supply place, since the dairy people face similar problems as do brewers they are very knowledgeable about SS equipment. So find a dairy supplier and pick their brains it may be worth the effort.

=====  
Wort priming, I have been freezing in a plastic jug some of the sweet wort from my mash to use for priming and or making up for fermentation losses. When I use the wort I thaw it out, boil it then add it into the secondary fermenter, seal the fermenter and let it carbonate. Its cheap easy and doesn't effect the flavour profile of the beer.

From: gak@wrs.com (Richard Stueven)  
Subject: Re: Advanced Brewing (NON-EXTRACT) worth it?

In HBD #937, Walter Gude (whg@tellabs.com) speculates:

> As of yet I'm still doing partial (1/3 of  
> sugars) mashes. I wouldn't be at all surprised if when I take the final  
> plunge (next fall?) that initially the quality of my brews goes down.

Here's a data point: I brewed my first all-grain batch after brewing  
21 extract batches. It was the best beer I had brewed up to that  
point, and they keep getting better (IMHO).

> Given the same process from the point of the boil on, I've always felt  
> there are a lot of things you can screw up in the mash/sparge process  
> (bad crush, poor temp control, oversparging) that could potentially  
give  
> you a sorry wort. [...]  
> There's a lot of variable to get right.

No arguing that. On the other hand, look at the amount of control you  
gain when you mash. You don't know what's in the extracts...corn  
sugar, cane sugar, hop varieties and amounts...who knows. With a full  
mash, you know exactly what's in your beer because it's all right in  
front of you.

You and many others refer to the mashing process as "Advanced  
Brewing". In my opinion, that perpetuates the myth that mashing is an  
arcane and difficult process that novice brewers can't possibly do  
right. That's simply not true...ANYBODY can do it! All you need are a  
couple of extra plastic buckets\* and maybe another 1.5 to 2 hours of  
brewing time, and you're set. (Oops...bad choice of words...you know  
what I mean. :-)

Take the plunge!

have fun

In  
>either case, just toss the hops into the secondary (I just toss them  
into  
>the primary seven days or so before bottling for single-stage ferments)  
.

Siphoning under the floating leaf hops sounds like a drag to me. I use  
pellets with great success. I know when fermentation is \*complete\* when  
the pellet crud sinks to the bottom. Occasional agitation of the carboy  
(about once a day) will encourage the stuff to sink. Then I just rack  
in the normal way. Also, pellets are much easier to get into and out of  
the secondary.

Cheers!

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Siphoning and Wort Chillers

Thanks to everyone how sent me mail about my Cooler Lauter Tun. Once I get the thing built I will post what I learned.

Now for my on the the subject,

Due to water restriction here in Portland I decided to change the way I used my Wort chiller. Instead of putting the copper coils in the hot wort and passing cold water inside the chiller I put the chiller in a bucket of ice water and run the hot wort inside the chiller. I made a siphon rod out of 3/8 copper pipe with a cap in the end and a hole drilled about 3/4 in above the end so I would not pick up too much stuff off the bottom of the pot. Here the problem I got the siphon started OK but it never had a good flow. Yes I did pick up some hops but I stoped and cleaned everything out and still had bad flow. It took almost a hour to siphon about 4 gal.(I pour the rest in through a funnel and screen).

Does anyone use this method? Does anyone have any ideas on how to make it flow better? Any better ideas on how the cool wort with the least amount of wasted water?

Thanks

Tom Feller

From: Raymond Taylor <NU028463@VM1.NoDak.EDU>  
Subject: Wyeast strains

I've been using Wyeast liquid yeast cultures for a number of years and my brews have really improved as a result. They're great!

I was wondering if anyone could give me an answer to a question that has been on my mind ever since I started brewing with Wyeast strains.

Williams Brewing sells liquid yeast cultures that are produced by Wyeast but these are not identified by the standard Wyeast name or code number. What exactly is Williams Burton Ale Yeast? Is it Wyeast British Ale #1098? Is it Wyeast London Ale #1028? Could Burton Ale Yeast actually be a different "proprietary strain" produced by Wyeast exclusively for Williams Brewing?  
.

I think Williams also sells a Wyeast produced English Ale... I have the same questions as above for this one.

I have used the Burton Ale many times and really like this strain.

THANKS IN ADVANCE!!

Ray "Liberty" Taylor

Subject: Re: Bottling with yeast

Two batches I've done recently, have been quite high in gravity and I've had no problem with carbonation *\*without\** adding yeast at bottling. One was an Imperial Stout with a measured OG of 1090 made with the yeast cultured from the dregs of Sierra Nevada Pale Ale and the other was a Chimay clone with an OG of 1087 made with Wyeast Belgian Ale yeast.

Other yeasts, however, may not do as well. I've read about adding yeast at pitching when brewing lagers that were bulk lagered at 33F for 3 months, but did not add yeast at bottling time to my 1074 OG Bock, but I only lagered that for 1 month at 45F before bottling. No problems with carbonation. This bock was made with Wyeast #2308 (Munich Lager) yeast.

One *\*important\** word of advice: I fermented the Chimay clone at 68F and it came out with a very pronounced banana aroma -- I strongly suggest fermenting at a lower temperature, say, 60F. Also, this yeast at 68F fermented very quickly for two days and then took a long time (two weeks) to finish. It's behavior may be similar at 60F.

From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
Subject: Cooler Lauter Tuns

I have been using the 5 gallon cylindrical Gott/Rubbermaid orange cooler as a lautertun with apparent good results. Rather than use the slotted copper tubing or window screen over a pipe to filter the wort from the grain, I have been setting a stainless steel steamer (one of those odd kitchen items that looks like a flower with petals that unfold to double the diameter and that has little 1/2" legs). It is just the right size to fit in the bottom of the cooler and when the grain is in a mesh nylon grain bag sitting on top of the steamer I suspect that I get a better filtering action than with the slotted tubes and with much less work/expense.

Has anyone else tried this, and with what effect?

Chris Karras (RKarras@PennSAS.UPenn.edu)

From: ithaca!amber!phoebe@uunet.UU.NET (P. Couch)  
Subject: Re: Connecting copper filter pipe to cooler-mashtun

I use faucet compression fittings on my cooler.  
I removed the original faucet and left a 1/2' hole.  
The false bottom was about 10 ft of slotted copper pipes and  
it goes to a 3/8' to 1/2' brass (pipe joint? I forgot the name) inside  
the cooler and on the outside, a 1/2' to 3/4' (pipe joint?) with a couple  
washers in between(to cover the hole), on the outside a plastic  
faucet (3/4') I got from Brewmasters (San Leandro),  
I didn't use a metal faucet because I didn't want to  
burn my hand at 170 while sparging. And Teflon tape in between  
All the pipes and joins and washers are from the hardware store under  
plumbing and are for standard kitchen faucets.  
I have used the mashtun a couple times and it doesn't leak.

As for Extract versus All-Grain, I find that my All-grain brews are  
definitely cleaner, smoother with more complex characteristics. But  
the procedures are also different. I think that the basic All-Grain  
process (mash/sparge then hop at different time) makes better beer than  
the basic extract process (throw everything into the boil  
at different times), but with a little work, extract brewing can make  
beer just as good.IMHO.

By the way, My Cascade(planted April 92) is full of giant cones and they  
are  
starting to smell good. The Nugget and the Mt Hood are coming along with  
a few burrs, but the Willamette is doing nothing.  
Thanks for all the replies/help.  
P.

From: PGRAHAME%**BENTLEY**.BITNET@mitvma.mit.edu  
Subject: sparging and time

Brian Bliss, several digests back, writes that a normal sparge takes him two hours. My question for sparge adepts out there is this: Two hours! ?

It takes me no longer than 20 to 30 minutes to sparge 7 gallons of water at 170 F through 7 lbs of grain. I have followed Dave Line's instructions closely, and have done this a half a dozen times with consistent results and without any stuck or "set" sparges. This time frame allows for a very gentle and leisurely sprinkle, just enough to keep the water level a tad above the grain bed. So how can this process possibly take two hours?

I note there is a shared interest out there in improving the overall time spent on all-grain brewing. Currently my best time from starting the mash

to pitching the yeast is about ten hours.  
Sage comments on sparge time, refinements, invited.

From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: Re: cleaning bruheat boiler

I've had a Bruheat boiler for about ten years, and it's been getting darker each time I use it. The malt (especially darker ones) seems to colour the plastic, and won't come out however hard I try to clean it. I just relax, don't worry and have a homebrew.

The element is different. Burnt malt on the surface will probably shorten its life as it will retard heat transfer to the mash. The answer is to use a grain bag to contain the mash: this suspends the grains above the heater and you don't get the burnt bits stuck to it. Cordon Brew sell a bag designed specifically for the Bruheat. One disadvantage is that there is a "dead space" of about 3 litres below the bag, which means that you need more liquor to get a reasonably stirrable mash, and consequently have to mash slightly longer - the thicker the mash, the higher the enzyme concentrations (??). You also have to make sure that the bag doesn't touch the element, otherwise you'll be cleaning bits of molten plastic off it and you need a new grain bag (as I did first time).

With the grain bag, the element does get a bit of dried scum on it, but I can get mine reasonably clean with an old toothbrush.

Cheers,  
Andy

Subject: Micro Brewery Sampler, Boston, 5 Aug

Hi!

For those of you who are in the Boston/New England area:

A local public radio station, WBUR (90.9), is sponsoring  
"A Brewers' Offering"

Details:

Date: 20 August 1992, 6-10 pm

Location: 808 Commonwealth Ave, Boston, MA  
Directions: Near Boston University (BU) Bridge;  
T: Green line, BU-Central or BU-West stop.

Brewers: approx. 24 microbreweries, approx. 70 beers,  
quantity limited by MA state laws. You will  
get 20 "tickets" for redemption at each brewer's  
booth for a 2-3 oz. sample (total: approx. 4-5  
standard bottles). Additional tickets  
may be purchased for 5 cents each.

Snacks: approx. 21 food vendors, unlimited

Music: Live Jazz!

Gift: 10 oz. Pilsner glass with event logo

Legalities: ABSOLUTELY NO ONE UNDER 21 ADMITTED (no kids!!!)

Cost: \$30.00, to benefit WBUR

Payment: Mastercard, Visa, or Check

A confirmation letter will be sent out, you pick  
up the tickets at the door)

TICKETS WILL NOT BE ON SALE AT THE DOOR!!!

WBUR  
630 Commonwealth Avenue  
Boston, MA 02215

(617) 353-3800

Hope to see you all there!

Tom

- > There's a lot of variable to get right.

While there's a great deal of truth to that, no one who is considering moving to all-grain brewing should be intimidated by it. There is some additional knowledge involved in all-grain brewing, some new techniques to be mastered. However, it is not all that difficult, especially if a brewer is already doing partial mashes with significant amounts of grain. In your case Walter, where you are mashing grain for 1/3 of the fermentables in your brew, you are already closer to all-grain brewing than you believe.

Before I "took the plunge", I took advantage of the tremendous wealth of information on mashing and sparging provided by our fellow HBDers. Another good source of information is Greg Noonan's book "Brewing Lager Beer", which contains detailed, easily understandable descriptions of the mashing and sparging processes (usual disclaimer regarding lack of commercial interest applies). I would encourage any brewer considering moving to all grain brewing to \*educate\* themselves first, poke through the HBD archives, read some of the literature. All-grain brewing is MUCH EASIER than many people believe.

In my own case, I brewed my first all grain batch several months ago after 60-70 extract and partial mash batches. It was, IMHO, the best beer I ever made. Each of the subsequent six batches has been an improvement over the last.

There's no turning back now,  
Jim

**Subject: Re: sparging and time**  
Full-Name: Michael J. Gerard

The last time I sparged it took around 1.5-2 hours...

I think a lot of it has to do with how dense your filter bed is.  
I have played with the idea of moving the grain bag slightly.  
This would speed up the flow; I'm not sure what it would do to the  
sparge.  
I think it would speed things up. I used to sparge without a lauder tun  
(just a bag and a collector). I got good extracts percentage wise in 15-  
20  
minutes but being scaled by 170 F water wasn't worth it. It's easier to  
sit and have a homebrew and watch the future homebrew trickle away.

I plan to try moving the sparge bag SLIGHTLY next time. I'll use an old  
recipe and see if I can speed up the flow but still get a high extract  
percentage.

Then consider me lame. When I first started mashing, before I got some of the right equipment and technique, my beer was not an improvement over extract brewing. I had problems crushing malt, problems mashing, problems with sparging, problems with balancing hops, problems with yeast. It's a wonder I kept at it.

Now, mashing seems easy. I've got better equipment - a Corona mill, a five gallon stainless steel pot, a wort chiller, a large burner, nested plastic sparge buckets (I call the Tower of Power). And I've done it off and on for nine years so I know which parts to worry about and which not to. I do a single temp infusion mash in a styrofoam cooler, I don't mashout, I don't recirculate sparge, I don't siphon off cold break. It takes me about four hours to make beer. As blasphemous as it sounds, there is more to life than making beer, and if it took me all day like some, I wouldn't do it.

So, if someone is happy making extract beers, I don't see any problem with that. I'm not going to insist they make the investment in time and equipment to do full mash beers.

I use this very same apparatus (the steamer) in a large bucket as my  
lauter  
tun. (high quality ascii graphics below) It expands to exactly the  
right  
diameter. I haven't used it in conjunction with the grain bag yet (I  
just  
bought my grain bag), but it seems to do the trick quite nicely as far as  
holding the grain above the bottom. The filtering action is fine. The  
only  
problem I've had is pouring ten pounds of grain from my mash tun  
(Bruheat)  
into this contraption without knocking the steamer crooked. This has  
resulted in a few pieces of grain coming through my outlet hose but never  
anything worse.

This is not earth shattering, but it does show that you don't have to go  
nuts  
buying expensive equipment to do full mashes.

Now that I have a grain bag, I'd like to hear from others who've used it  
to

mash and sparge straight out of a Bruheat or similar gadget. Problems?  
What  
grain/water ratios do you use (this seems to be a bone of contention  
between  
Bruheat and Dave Line)? The reason I'd like to do this is to avoid  
having to  
dump all that hot grain into a separate lauter tun. Comments and ideas  
to  
streamline the process are welcome.

Norm

From: mcnally@wsl.dec.com  
Subject: re: chillers

I may be strange, but I really enjoy the wort chiller debate.

I need to understand how the "immersion chiller as makeshift flow-through chiller" actually works. I like to get my beer down to about 50 degrees (F) as quickly as possible. To do this, my calculations show that do drop my just-after-boiling five gallons of wort down to fifty degrees, I need to "mix" it with at least 42 gallons of ice water:

$$V_c = (V_b T_b - V_b T_t) / (T_t - T_c)$$

where  $V_c$  = chilled water volume,  $V_b$  is wort volume,  $T_c$  is chilled water temperature,  $T_b$  is wort temperature, and  $T_t$  is target temperature. Now, I don't have a 42 gallon bucket, and I don't know many people who do, so I just don't see how I could possibly use this setup to chill my wort. Now, if you're happy with chilling down to 80 degrees, you can do that with much less chilled water (about 12 gallons at 32 degrees). I don't have a refrigerator, so all my chilling has to be done with the chiller.

For some time I've been using a sump pump to circulate water from a bucket of ice water through the chiller. I don't use much water this way, and I get the wort cold in about 45 minutes. Of course, I have to keep refreshing the ice in the bucket, and I find that about 4 7 pound bags from 7-11 do the trick. (When I'm not lazy I freeze the ice myself, but I'm usually lazy.)

What temperatures do people normally shoot for when chilling?

> My question for sparge adepts out there is this: Two hours!?  
> It takes me no longer than 20 to 30 minutes to sparge 7 gallons of  
water  
> at 170 F through 7 lbs of grain.

My question is this: 7 gallons!? That seems like an awful lot of water to sparge with for 7 gallons (on the order of 2x what it should be). My usual ration is one-half the number of gallons as you had pounds of grain (e.g., 4.5 gallons for 9 lbs of malt). What kind of gravity do you get out of the tap by the end? If the outflow isn't sweet any more, I stop sparging.

But I agree, two hours is an awful long time to sparge. You can extend your sparge time significantly by doing a lot of recycling, but I've found the biggest factor to be the grind of the grain. My sparges were always sticking when I used the old coffee grinder at the local brew shop. Now that I have my Marcato mill, the sparge water drains through as fast as I can pour it. Sparge times are now down to 15-20 minutes.

> Currently my best time from starting the mash to pitching the yeast is  
> about ten hours.

Now that seems a little long. I have certainly done batches that took that long, but my basic procedure is now to about 6 hours (I can \*almost\* do one in the evening after work :-). Let's look at an idealized schedule:

```
hours step
-----
(opt) .75 grind grain (can be done day before)
1.5 mash (step: 30m @ 122F, 50m @ 150F, 10m @ 170F)
.5 sparge
.5 wait for wort to come to boil :-
1.5 boil & hopping
.5 cooling (immersion or counterflow chiller)
(opt) 1.0 aquarium-pump aeration
-----
6.25 total time
```

Even if you add "slop" time beyond the ideal schedule, it's still well below 10 hours. Eliminate grain-grinding and use splash aeration, and you're down below 5 hours!

The key is to use "dead" time during the mash, boil, and cooling stages to clean up, heat your sparge water, etc. About halfway through the mash, I start my sparge water heating and sanitize sparging implements so that as soon as the mash is done I'm ready to go. During the boil, I sanitize my fermenter, clean up my mash and sparge stuff, prepare the chiller and such. Heck, I sometimes even vacuum the living room or mow the lawn during a brew session. And there's certainly time in there to drink a homebrew or two.

From: ALTENBACH@CHERRY.llnl.gov  
Subject: Wort Chilling Water Wastage

In HBD938 Tom Feller was concerned about wasting water during wort chilling.  
There is no need to waste any water while chilling your wort if you save the cooling water and recycle it for other uses. I use a counterflow chiller and collect 30 gallons of cooling water from a 10-gal batch, saving it in 5-gallon plastic water carboys. Then I use that water during the week for soaking fermenters, landscape watering, spa makeup, and other household chores. None is wasted. I also keep some filled carboys around as an earthquake emergency supply (recommended for CA brewers) in case my homebrew bottles are broken and I run out of beer. So chill out your wort with all the water you want, then recycle and relax.  
Tom Altenbach

Subject: Brewing time (was Re: Advanced Brewing (NON-EXTRACT) worth it?)

In HBD #938, gak@wrs.com (Richard Stueven) writes:  
[...]

>You and many others refer to the mashing process as "Advanced  
>Brewing". In my opinion, that perpetuates the myth that mashing is an  
>arcane and difficult process that novice brewers can't possibly do  
>right. That's simply not true...ANYBODY can do it! All you need are a  
>couple of extra plastic buckets\* and maybe another 1.5 to 2 hours of  
>brewing time, and you're set.

Having recently started all-grain mashing, thanks to the encouragement and help of members of this esteemed forum (special thanks to Martin Lodahl!) and The Draught Board (brewclub), I agree with all of what you say except the time involved for all-grain. There are many, many factors which will affect the amount of additional time for all-grain brewing, so to state categorically that "only" another 2 hours time is required is unfair. A more accurate statement (IMO) would be that at least 1.5 hours more of brewing time is required. Typical all-grain brewing from start to pitch for me has averaged around 6-7 hours.

True, experience shows certain shortcuts and the things which can be done in parallel once the methodology and the process are understood. I'm still learning, too, with many great beers yet to be brewed and for me they'll be all-grain. To me, all-grain brewing is worth the additional time and trouble, but I'm always looking for ways to decrease the time involved while increasing the quality of my beers.

The additional time required for all-grain brewing can be greatly affected by the mashing technique (is it infusion? step? or decoction mash?), the beer style (for example, a wheat beer will require a protein rest which is additional time), and the equipment the brewer has at his/her disposal. (For example, my "cajun cooker" can bring 5 gallons of sparge water to temperature in under five minutes!) A discussion concerning sparge time is already in progress elsewhere in this forum, and it certainly appears that sparge time varies wildly from brewer to brewer. As a personal aside, my time is more valuable than obtaining the maximum theoretical extract percentage, so I'd opt for using more malt rather than a 2 hour sparge! However, at the suggestion of Russ Wigglesworth (thanks, Russ!) I increased my sparge time from 20 to 40 minutes and was pleased with the results.

Folks considering all-grain should definitely read The Complete Handbook of Homebrewing (David Miller, 1988, Garden Way Publishing, Pownall Vermont, 248 pages) or The Complete Joy of Home Brewing, (Second Edition) by Charlie Papazian.

Also, one of the zymurgy special issues (probably the All-Grain Issue) has a "staggered brewing" article which I recall has some other time-saving hints.

Here's my thumbnail time budget at the front-end of all-grain brewing, with things which can be done in parallel indented. Note also that in all-grain brewing, the boil time is often 90 or even 120 minutes. A maximum of 60 minute boil is highly recommended for extract brews, to keep caramelization to a minimum.

crack grain 10-20 minutes (0 - buy pre-cracked)  
heat mash-in water 1-20 minutes (depends on equipment!)

mash-in 3+ minutes (check/adjust Ph, etc.)  
protein rest 45 min. (depends on brew, most not needed.)  
raise to conversion temp. 5-15 minutes  
starch conversion 20-120 minutes.  
heat sparge water 5-30 minutes.  
mash-out 5-15 minutes  
sparge 20-120 minutes (sparge into the boiler)  
begin boil [... here we join the extract-only brewers ...]

Quickest time would be to use pre-cracked grains in a single temperature infusion mash with a quick (20 minute) sparge. With my equipment, that would probably be around 1.5 hours additional.

I'd recommend an all-grain-wannabe brewer get Miller's book (above) and try a partial mash or two, just to get the feel for the process. Then, if it feel right, jump right in! If not, don't feel bad. Remember that award-winning beers are brewed from all-grain, partial-mash, and extract recipes. The important thing is to just brew it!

Subject: Re: Advanced Brewing (NON-EXTRACT) worth it?

I post the other day about my concerns in switching to all grain process. As I stated then, I've no doubt that I will eventually make much better beer doing a full mash then using strait extracts. However recieving replies like:

> If your beer quality goes down when switching to full mash beers, then you  
> are lame.

cause a f\*\*k you kneejerk reaction. Somehow I thought this was a forum for discussion and exchange of ideas. I guess I was wrong.

The point of my post was that I have been steadily progressing from all extract, to extract+specialty, to partial mash, and will probably "cross the line" soon.

Each step (18 batches) I changed one thing at a time and have been able to keep a handle on what was good and what was not. All I'm trying to say is that maybe there is something to be said for getting the "boil forward" part of the process down before jumping in all the way. That my learning to crawl before you run might end of benefitting you in the long run. But then maybe I'm just lame :-).

Subject: Re: Saving water with wort chiller

...deleted talk about wort chillers wasting water  
>  
> Does anyone use this method? Does anyone have any ideas on how to make  
it flow  
> better? Any better ideas on how the cool wort with the least amount of  
wasted  
> water?  
>

I too use an immersion chiller, running cold tap water through copper  
coils  
immersed inside a bucket of hot wort. In addition, I live in the SF bay  
area,  
where water rationing has become a way of life (you easterners don't know  
how much you can take tap water for granted). To do my part, I no longer  
wash my car, I take shorter showers, and I've trained my bladder to hold  
its  
contents longer, for fewer flushings - except during homebrew quaffing >  
:-).  
But I'm talking brewing here. My solution for conserving water, while  
also  
cooling my wort rapidly, is to do the whole cooling process on the front  
lawn/desert. This is the only time that it gets watered at all (besides  
the  
semi-annual rainfall) so I don't at all feel guilty about letting the  
water  
run for 15-20 minutes. Look at it this way:

If you don't force cool the wort and get an infected batch, then it  
goes  
down the drain anyhow, and you've wasted at least 5-7 gallons right  
there!

In case anyone was wondering, aren't you afraid of having hot wort  
sitting  
out there in the great outdoors, with all those wild and crazy yeasties  
dancing in the air? My solution is to dump my brew kettle's contents into  
a 6 gallon plastic fermenter bucket, drop in the immersion chiller, and  
then  
to seal the lid on over the top, leaving only tiny cracks where the  
chiller's  
I/O tubes stick through. The plastic tops for these buckets are rather  
flexible  
making this an easy task. I also leave my wooden spoon and thermometer  
sealed  
inside, so that I don't have to sanitize them each time I want to stir  
and  
check the temp.

What, there's no water for the Californian's to drink? Let them drink  
homebrew!

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Dry hoping, sparging and all grain brewing

That I'd add another data point of a few recent topics. I tried dry hoping once with a couple of PVC pipes that had a lot of small holes drilled in them and plugs on each end. I filled the pipes with fresh flower hops and placed them in the carboy, hanging on a string. The pipes didn't sink well so next time I added a brass ball at the bottom of the tube to help it sink. Easy in, easy out. The results were less than perfect. My conclusion was that the hops really need to be LOOSE in the wort for best results. The operation was a success, the patient died. On the subject of sparging, I usually try to push my sparge time to 20-30 min. I have a pump on the output of the mash tun and I have to valve it down to restrict the flow. I don't personally believe that long sparges vs short sparges really makes a lot of difference in the resultant gravity or quality of the runoff. I believe there is a big difference in the grains we all get and the gravity per pound per gallon varies all over the map. I recently tried an experiment to prove this, but it didn't work so well. My start to finish times for grain brewing 10 gallon batches is typically 4 1/2 hours. That includes setup, brewing and cleanup. I can't believe someone would spent 10-12 hours brewing and continue to brew for very long. You marathon brewers out there need to do a little time and motion study and invest in some hardware to shorten your brew day.

I accept, just keep that gain turned up.

>From: homebrew@tso.uc.EDU (Ed Westemeier)  
>Subject: Lauter tuns & hop drying

>For the past year, I've been using a variation of the Phil's Sparging  
System, by Listermann Mfg. Co. They advertise in \_Zymurgy\_ and the  
products (like Phil's Philler) are available in many homebrew retail  
outlets.

>Besides the basic system using two plastic buckets, assorted  
tubing and fittings, sparging sprinkler and perforated plastic plate,

As a reluctant critic of someone else's pride and joy, I refrained from  
asking Phill an obvious question when he demonstrated his Sparging  
System to  
me in Milwaukee. However, I am less reluctant about posing the question  
to  
the readers of the Digest.

It is generally agreed that the most efficient method of sparging is to  
maintain a cover of water over the grain on the order of a half inch or  
more.

For those not familiar with Phil's system, it has a rotating sprinkler  
gadget  
that causes the wort to fall on the mash in a circular pattern. If a  
layer  
of water is maintained above the grain, this whole contraption serves no  
purpose whatsoever. Pouring the water into a shallow bowl nestled in  
the  
grain and just below the water level, is just as effective in  
distributing  
the water in addition to being free.

What am I missing?

Subject: PET Bottles

>From what I understand, the "run-of-the-mill" plastic soda bottles ARE made of PET. These bottles can be reused without incident, speaking from experience. I even used the old caps. One distinct advantage I can see it that the plastic doesn't seem to absorb odors much. Another is that you can continually monitor carbonation levels, just by giving the bottles a squeeze. No problem with the reused caps withstanding the pressure, I have found. The bottles themselves can withstand pressures in excess of 120 PSI.

To collect the bottles, I posted a contest on my system's bulletin board offering full bottle of homebrew from the current batch to the person donating the most bottles. Such an approach also serves to get people to pay attention to recycling the bottles. That's what I did with the leftovers.  
Give it a try!

Subject: Mouth Feel

Beer Evaluators,

I read the article from the Summer issue of Zymurgy by Michael Tierney on carbonation in beer titled "From Carboy to Beer Glass: A Note on Froth." A very interesting article that I am sure to read many more times. One fact he mentions in his article is that mouth feel is the word that professionals give to a properly carbontated beer that tingles on the tongue a little. My interpretation of mouth feel up to this point was more a measure of body. My question is: does mouth feel refer only to carbonation and its sensation?

Subject: Re: Bruheat Cleaning & other

Brett asked how to clean a Bruheat heating element. First off, its a lot easier to clean if you remove the element from the "kettle". Brillo does a fair job, but the best thing I've found is the copper pot scrubbers available at most supermarkets. If you clean it up after every use with the pot scrubber, it shouldn't take more than 30 seconds or so (brillo used to take me 5-10 minutes!).

Be careful when you remove the heating element not to damage the rubber (?) washer. You'll have to remove the washer to clean the element, but I've had a good deal of trouble with that. Experience has shown my washers only have a lifetime of 10 batches or so. Of course the local homebrew store doesn't carry spares (even though they sell the bruheat), and plumbing places have not been helpful. You don't really need the washer to create a good seal. It IS important as an insulator for the thermostat. When I tried not using a washer, I couldn't get the darn thing to boil! (Now I'm using a homemade cardboard washer and am having no problems at all!)

Someone wrote an article in Zymurgy a few years back about the care and feeding of the Bruheat. He always started each batch by boiling a bleach solution, then running that through his wort chiller. I never saw the need to be overly concerned about sanitizing something I'm going to be boiling in, so I don't boil bleach in the kettle. (Of course the wort chiller should be sanitized as best as possible.)

Ken Johnson writes:

> If your beer quality goes down when switching to full mash beers, then  
you  
> are lame.

I think that might be a little harsh. There are several variables to be concerned with when you make the step to all-grain brewing that aren't a concern to extract (and partial mash) brewers.

First, your equipment. If you're brewing on the stove, and you have an electric stove, its a lot of work to keep the proper temperatures. (See the Zymurgy special issue on all-grain brewing. Ekhart shows a log where he's having to change his settings every minute or so. Hardly my idea of relaxing and having a homebrew.)

Another important consideration is your water. Sure, there is information available on how to properly prepare your mash water, but it is something an extract brewer hasn't been concerned about.

Then, of course, there's the time element. When doing an extract brew (or all-grain when you get to the boil), you can pretty much ignore what's going on and attend to other pressing needs (having a homebrew, changing diapers, or whatever). When making an all-grain batch, you're committed to a longer time period, and since temperature is pretty critical, it demands more of your attention. That's fine if you have the time.

Unless you've read a bunch about all-grain brewing, or helped somebody else do it, I think it is very possible that you might have a slight degradation in quality for your first few batches as you come up the learning curve. For a professional brewer to

experience these problems, I think maybe the term "lame" applies, but for the casual homebrewer, I don't think I'd consider someone "lame" just for experiencing a learning curve.

(There seems to be a presumption that there are no beer styles that are adequately represented by extracts. Granted, you can produce an infinite variety of styles if you use all-grain, but I dare say there are some styles that can be done quite well using extracts, possibly with specialty grains or partial mashes. If this were not the case, there would be NO medal winners using extracts. Probably the majority of the medals are won by all-grain, but the fact that some folks are still placing with extracts would lead me to believe that you can still brew some fine beers from cans/powders.)

From: John Robinson <UDAA002@OAK.CC.KCL.AC.UK>  
Subject: Re: cleaning bruheat boiler

I've mashed and boiled in an Electrim bin (similar to the Bruheat boiler I think) for several years, and kept the element clean by switching it OFF during the mash, with a couple of heavy blankets wrapped round the bin to conserve the heat. I preheat the liquor to about 71F before pitching the malt (8 lbs in 3.75 UK gallons) and the temp. falls to around 66F. After 3 hours it's usually around 61F. I don't do any starch tests, but the wort comes out nicely balanced for a dry-ish bitter - 5 gals at OG 1042.

I tried using a grain bag, but gave it up in favour of a perforated round splashguard of the kind used to cover frying pans. I found one which was just the right size to sit above the heating element and tap, supported by 2 upturned glass dishes!

One other hint - after running off the boiled wort, cover the element with fresh hot water before it's had a chance to dry. You can then rub off most of the crud very easily. Afterwards I run the heater for a minute or two in the fresh water.

Cheers,  
John

From: pmiller@mmm.com  
Subject: Malto dextrine, wort chiller filter

Greetings all!

Does anybody know how much malto dextrin to use in a 5 gallon batch of beer?

I remember seeing this question raised in the HBD before, but I don't remember if it's ever been answered.

I used some in a brown ale recipe to add a little sweetness. The guy at the homebrew store didn't have much experience with malto dextrine and told me to add the whole 8 oz bag. I chickened out and only added 4 oz, but the beer was still a little sweeter than what I was looking for. (Of course, I also added 6 oz of crystal malt to the same batch which probably added to the overall sweetness... Why only change one variable when you can mess around with 6 or 7?  
;-)

So, what's the scoop? Anybody else out there ever use this stuff?  
Charlie says that malto dextrine will also add body to the beer, but Miller basically pooh-poohs that idea and claims that it will add sweetness only. From the limited conversation I've seen about malto dextrin here on the net, I get the impression that most homebrewers look down their noses at the stuff and would be less likely to add it to their brew than stink-bait (or even silicone caulking ;-).

.....

The other day, Tom Feller asked:

> .....Instead of putting the copper coils in the hot wort and passing  
> cold water inside the chiller I put the chiller in a bucket of ice water  
and  
> run the hot wort inside the chiller....[T]he siphon started OK but it

> Does anyone use this method? Does anyone have any ideas on how to make  
it flow  
> better? Any better ideas on how the cool wort with the least amount of  
wasted  
> water?

I've used the copper-coil-in-a-bucket-of-ice-water method to cool my wort a few times. I use a technique gleaned from this very digest to strain the hop

leaves: jam the end of your racking wand into a copper choreboy scrubbing pad. I take the added precaution of threading some wire through the choreboy and twisting it around the racking wand so the darned thing doesn't fall off in the middle of the transfer. (Anybody ever had a choreboy slip off or am I just making extra work for myself?)

This method has worked pretty well for me so far. The choreboy has only gotten completely blocked with hop leaves once and that was near the end of the transfer anyway. FWIW, I'm probably going to switch over to hop pellets exclusively next fall; I found out that one of my favorite beers (Summit Extra Pale Ale) is made with hop pellets and having used both, I find hop pellets easier to use than flowers/plugs. The upshot being that I won't need to use the choreboy anymore.

BTW, if you use one of those plastic racking canes like I \*used\* to, you'll find that the nearly boiling hot wort will soften the plastic and make it curl slightly. Then if you try to heat it back up to straighten it out, it will snap in two. (Gee Rocky, I guess I don't know my own strength...)

Subject: 10gal. H2O coolers

10gal. H2O coolers  
For those of you who have tried to find these and failed, here's what worked for me. I called Rubbermaid and they gave me the number of their regional distributor, who in turn gave me the number of their local sales rep., who told me not a single retailer in the area bought the product. So, what I did, was I marched down to my neighborhood hardware store (True Value) and had them special order one for me. Once they located the micro-fiche that had the Rubbermaid cooler products on it, there was no muss or fuss. I expect to have it in my hot little hands in a week. The only drawback is that, they insisted on charging me FULL retail on it because they had to special order it. Wholesale, they go for about \$32, but I ended up paying about \$65 including tax. So, if you go this route, try to negotiate the price down a bit.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

Subject: extract vs. all-grain

To add in a data point, my last 20 or so batches have been all-grain. As a test, my most recent was from from extract only, 3.3 lbs. BME wheat (which is 1/2 wheat and 1/2 barley) and 3 lbs. dried malt, with 4th generation liquid yeast. It's not bad, but it doesn't nearly compare to the fullness and richness of the all-grain batches. It also has that stereotypical homebrew tang. I'm afraid there really may be no going back.

Fwiw, the batch will sit untouched for a week. I'm on a prescription drug that has an effect similar to Antabuse, the drug given to alcoholics that makes them very ill if they have alcohol. Hopefully that extra week of cold conditioning will make the batch more palatable. Certainly, a week of homebrew "cold turkey" should work in its favor...

Subject: Chiller and Sparging

>From the replies to my question about saving water it seem to me that some sort of recirculation is the best idea. I also think my flow problems will be helped by some more height from the brew pot to my primary. I have had a number of replies about holding 30 to 50 gal. of water and using it later but I just don't have that kind of room or that many buckets.

A question here,

Why does Mike McNally want go to 50 deg.F this seem to be overkill to me unless he is making lagers. I cool to about 70-75 deg.F and then ferment in by basement which in the summer stays at 70-75 even on the hottest days. With my last brew, running hot wort through the chiller in bucket of ice water, I used three bags of ice. The resulting wort was at 70 deg.F. I have had some replies on counter-flow chillers and for the same final temp we are looking at about 40 gal. of tap water.

Now on to the sparging question,

What is the difference between mash-out and sparging. I understood that if you mash out at 170 deg.F you raised the temp of the mash to 170 deg.F and then keep it at this temp for some time. With sparging you let the mash water drain out as you add sparge water, trying to keep the water level above the grain bed. How could it take 2 hr to run water sparge water through your grain bed unless the sparge was stuck(set mash?).

My plan is:

- -- Fill my cooler with grain add hot water for a final temp of 155 deg. F
- -- Let this sit until conversion about 1-2 hrs. I'll use the iodone test
- -- Recirculate until the run-off is not cloudy.
- -- Run 170-175 deg.F water(sparging?) throught the grain bed keep the water level about 1/2-1 in about the grain bed untill the run-off is not longer sweet or I reach my 7 gal. volume.
- -- Then proceed as usual

I believe I am using a single step mash at 150 deg.F with a 170 deg.F  
sparge  
I won't be using a protein rest or a mash-out. Did I discribe this right?

The reason I want a little discussion about this is that lately I have  
become  
confused about what people are doing and I need some help. It seems that  
sometimes people say mash-out when they are really sparging and the other  
way  
around.

As usual I would like to thank everyone for there help, I have learn more  
here than with all the books I own.

From: "CMD 2NDLT ALBERT W. TAYLOR " <S94TAYLOR@usuhsb.ucc.usuhs.nnmc.navy.mil>  
Subject: Wort Chilling, Some chilling thoughts...

Before making my immersion chiller, I advocated using a 2.5 gallon jug of bottled water at near freezing temp to cool the wort down to pitching temp.

This worked very well for about 10 batches. I now use my new toy, which will cool 3 gallons of boiling wort to 80 degrees F in about 15 minutes while using only 15 gallons of tap water (at ~65 deg F). BTW the whole thing only cost me \$25 to build. I then add the same bottled water, but at room temp. to bring to 5 gallons. I seems to me that combining the two techniques would easily allow for cooling to a reasonable lager pitching temp.

Another idea, though much more elaborate, is to send the cooling water through a copper coil submerged in an ice bath before it gets to the wort. This would cool the water down to around 40 deg, based on my crude measurements of the heat exchange of my chiller. This idea may best be described as a flight of fancy, but I always did like the t.v. show "MacGyver".

I'm interested to hear comments on my ideas, in public or private :-)

From: jeg@sangabriel.desktalk.com (John E. Greene)  
Subject: All Grain Brewing.

A few years back I splurged and bought myself the AutoMash(tm). I set everything up the night before, program the timer and set the delay and go to bed. When I wake up in the morning the AutoMash is purring away stirring the grain with "Ready to Sparge!" on its display. I can do up to a 6 step mash if I so desire. I really like it because it does everything for you. No stirring, no monitoring the temperature. The kettle has a water jacket in which the heating element is contained. This in combination with the propellers really keep the temperature consistent, eliminating hot spots.

It wasn't cheap but there are a lot of fellow brewers that are more than willing to donate a few dollars to use it for the weekend. It didn't take long to make up for the initial investment.

If I have any complaint about the device it would be the difficulty in getting the grain out after it is done. With the water jacket and the grain combined, the thing is very heavy. I usually have to scoop the grain out using a pan and dump it into the sparging vessel. A minor annoyance compared to fully automatic mashing.

In HBD #939, Greg writes:

>

>I will be brewing an ordinary Bitter and have read that you should  
>aim for about 300 ppm sulfate to be true to style (according to  
>Zymurgy special issue). Assuming I have 0 ppm sulfate in my water,  
>how much Burton water salts should I add to obtain 300 ppm sulfate in  
>5 gallons? Are there formulal to obtain the info? Thanks.

>

I use the following chart that I calculated out. I don't  
use burton salts since I have not a clue as to what proportions of  
gypsum, salt and epsom salt are in it.

Gypsum (calcium sulphate dihydrate):

62ppm/gm/gal Ca++  
147ppm/gm/gal SO4-

Calcium Chloride dihydrate:

73ppm/gm/gal Ca++  
127ppm/gm/gal CL-

Calcium Carbonate (precipitated chalk):

107ppm/gm/gal Ca++  
157ppm/gm/gal CO3--

For making IPA I use 14gm gypsum and 1.5gm chalk in seven gallons  
of supply liquor, of which 6 gals gets into the beer (5.5 gal after boil)  
- that works out to something near 300ppm of sulphate.

Sorry I don't have volume conversions handy. I have heard that  
one tsp is about 5 grams. The best thing to do is get a cheap  
loading scale from a gun shop. Or, if you have \$50 to blow,  
there is a place in Vancouver BC that sells an electronic  
scale. I got one and checked it out; it is pretty accurate  
compared to my triple beam. I measured 5, 75 anmd  
300 gram objects and it was within 2gm @300 and within a gm (  
the resolution limit) in the lower ranges.

The place is NamTai and they can be reached at 1-800-661-8831.  
It costs US \$49 and that includes shipping. I saw the ad for  
this scale in the Wall Street Journal several months ago.

Cheers!

Ah, that famous protein rest... I have made a half dozen wheat  
beers with 50:50 wheat to barley malt. the last two I made I  
dispensed with the protein rest and saw no evidence of protein  
induced chill haze. Maybe I didn't chill it enough (48f). But,  
given what I know about US, in particular Great Western Malting, malts  
I would say that protein rests for even wheat beers is a waste of  
time.

Going out on a limb: the *\*only\** time you need a protein rest is when  
using unmalted adjuncts, in particular oats, wheat or barley. And then  
only if the adjunct is more than an ounce /gal of brew. I.e. don't  
worry if you are just adding 4oz as a heading agent.

Cheers!

Subject: chilling temperatures

From: Deborah Poirier

Mike McNally asked:

>What temperatures do people normally shoot for when chilling?

It depends on the yeast I'm using, but I usually gun for 18-20 C. That was with a flow-through chiller. (Beer in coils, coils in partially plugged kitchen sink with cold water running). The output temperature depended on how quickly I let the wort drain through the tubing: faster=hotter output. But tonight I'm debuting a new counterflow chiller that I made yesterday. Can't wait!!! I'll still adjust flow rates to get about 20C, though.

OK, I'll bite: why use the stainer gizmo if you're gonna put your  
grain in a porous grain-bag anyway?

I use a set up similar to you two, but I have a large, round plastic  
collander which fits snugly and seals tightly around the edges when  
pushed to the bottom of the cooler. I wanted to avoid the grain bag  
because when I first started mashing (with the Zapap lauter tun), much  
of the sparge/wort ran down between the bag and the walls of the tun  
-- path of least resistance and capillary action I imagine; it avoided  
the grain and gave a low extraction rate. Also, the collander fits  
tightly enough that it doesn't budge when you dump all the grain or  
mash onto it. (Remember to run some string through it so you can pull  
it out, though!)

Your milage may vary, blah, blah, blah. :-)

Subject: Re: Dry Hopping with Hop Plugs

From: Patrick\_Waara.WBST129@xerox.com

I have a question regarding dry hopping with hop plugs. It seems the hop plugs are just a little too large to easily fit through the mouth of the carboy. In the past I have attempted to break the plug in two by working it back and forth in my hands, which is no easy task (and probably an infection risk). A knife did not seem to work too well either. Does anyone have any suggestions as to how to get the hop plug easily into the carboy? Thanks.

Sounds like you can just crush the plugs in the bag that it came in (with a roller or a hammer) or put it in a (coffee) grinder. I usually use a funnel and the handle of a spoon to push the hops thru.

>water temperature,  $T_b$  is wort temperature, and  $T_t$  is target  
>temperature.

You're close, but you're missing one very important thing. Your solution  
would  
be right \*if\* you were mixing zero degree water with your wort. However,  
you're  
not just mixing zero degree water (and getting the cooling power of the  
water),  
you're also mixing ice, which has additional cooling power. [Note 1] The  
cooling  
power of water is referred to as the specific heat,  $C_p$ , which is

$C_p = 1 \text{ cal} / \text{g C}$   
p

In other words, it takes one calorie to raise the temperature of one gram  
of  
water one degree Celsius. [Note 2] The cooling power of ice (at 0 C) is  
referred  
to as the heat of fusion,  $H_{ls}$ , which is

$H_{ls} = 80 \text{ cal} / \text{g}$   
ls

In other words, it takes 80 calories to melt one gram of ice at 0 C into  
one  
gram of water at 0 C. In addition, ice can exist at different  
temperatures, and  
supercooled ice has a cooling power of roughly

$C_p = .5 \text{ cal} / \text{g C}$   
p

How about an example for clarity. First of all, let's assume that the  
specific  
gravity of water, wort and ice is roughly constant. That lets us work in  
terms  
of volume instead of weight and doesn't add significant error. Then,  
assume  
that we have five gallons of hot (100 C) wort and a tub full of 3 gallons  
of  
ice at -10 C and 2 gallons of water at 0 C. Further assume that the  
specific

heat of the wort is the same as water, and calculate the final temperature of the collection after it has come to a thermal equilibrium. First let's do an energy balance:

Wort Water

$$(1 \text{ cal/g C}) (100 - T) 5 \text{ gal} + (1 \text{ cal/g C}) (0 - T) 2 \text{ gal} +$$

Subcooled ice ice

$$(.5 \text{ cal/g C}) (-10 - 0) 3 \text{ gal} + -(80 \text{ cal/g}) 3 \text{ gal} +$$

Melted ice water

$$(1 \text{ cal/g C}) (0 - T) 3 \text{ gal} = 0$$

Multiplying out gives:

Wort Water Subcooled ice ice Melted ice water

$$500 - 5T - 2T - 15 - 240 - 3T = 0$$

and...

$$245 = 10 T$$

$$T = 24.5 \text{ C}$$

Since we dropped some units along the way, we don't know what the number of calories each contributed is, but we can determine the relative amounts of heat transferred:

Wort Water Subcooled ice ice Melted ice water

$$377.5 - 49 - 15 - 240 - 73.5 = 0$$

You can see that the water helped, and the melted ice water and the subcooled ice helped some too, but the majority of the cooling was done by the melting of the ice itself. In fact, let's calculate just how much ice melting (not considering the melted ice) it would take to cool 5 gallons of wort to room temperature (about 20 C):

$$5 (100 - 20) + X (-80) = 0$$

$$X = 5 \text{ gallons of ice.}$$

In fact, that's a good and easy thing to remember: you need as many gallons of ice as you have wort in order to cool your wort 80 degrees C (and have 0 C ice water left over). If your final water temperature is higher, or your ice was colder than 0 C, then you need less, of course.

Therefore, I think that the answer to all the water shortage problems is to trade

water for energy. Namely, freeze your water to increase its cooling power. Here's a tip: Use old milk/OJ/whatever cartons to freeze blocks of ice for cooling. Then rip off the cardboard for a good chunk of ice. It's not sterile, but if it doesn't touch your wort, who cares?

Michael L. Hall  
Thermohydraulic nut :^)

[1] - It's not strictly correct to refer to the "cooling power" of something. There's no such thing as cold, only lack of heat. Heat moves from hotter spots to cooler spots. I just use the term "cooling power" as an aid to understanding.

[2] - A Calorie (capitalized, used in dietary stuff) is equal to one kilocalorie.

From: Pat Lasswell <patl@microsoft.com>  
Subject: All-grain mashing time

Here's my \$0.02:

My brewing day is about 12-hours long, but in that time, my brewing-partner and I eat, drink and talk, with copious amounts of each. Since I spend most of my time (like right now) sitting in front of a CRT, 12 hours of human contact is refreshing. Were he unable to make it to a particular session, I do not think that I would do a three-decoction mash like I usually do; I would probably do something that takes only six hours or so. My point is simple: brewing with someone else is more fun than doing it alone; it's also a little easier, as every now and then you need 4 hands. Lastly, you may find it difficult to get someone to brew with; however, I dare say that most of us know at least one person who is "kind of interested". Invite them over and/or offer to teach them how. The world needs more brewers. .. :)

From: Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU>  
Subject: Blue stuff, pick-up tubes, o-rings, etc.

Some of this is dated. Sorry. The posting glut of a couple of weeks ago knocked me out of synch.

As for the thread on the blue-stuff in copper wort chillers:

Mike sez:

>Based on my world-class understanding of chemistry, I'd guess that the  
>blue stuff that forms on your copper wort chiller is copper sulfate.  
>If I'm right, then you definitely want to get rid of it; it's toxic.  
>You might try rinsing with a little vinegar and salt in boiling water.

Hate to butt heads with your world-class understanding of chemistry, Mike, :-)) but the blue stuff ain't copper sulfate. Copper sulfate is formed from trying to sterilize the copper with sodium metabisulphite and that's why treating copper with sodium met is generally discouraged. And you're right. You would definitely want to get rid of that stuff.

In another post, Jeff speculates:

>Glenn asks about little blue flakes coming out of his wort chiller.  
>Sounds to me like verdigris--and it sounds like time to bring in  
>the chemists. According to the dictionary, verdigris formed by the  
>action of acetic acid on copper is poisonous, while a deposit of  
>copper carbonates is not.

Well, since clorox doesn't contain acetic acid, I would doubt it's verdigris. This does raise the question of whether cleaning copper with vinegar is a good idea since it IS acetic acid.

I've noticed it in my chillers down through the years and have never worried about it. I figured that since it was particulate matter that it settled out with the yeast and never made into a bottle of beer anyway.

Still I guess it is time to call out the chemists. What is that stuff? Could it be the cause of my curly hair? :-))

Dennis writes in response to the best way to connect slotted copper tubing to the opening of a cooler tun:

>To connect the two, I used a polypropylene (working temp to 250 degrees)  
>3/8 inch tube-to-tube bulkhead union that fit precisely in the cooler hole.  
>Once the bulkhead is tightened, the gasket that comes with the cooler seals  
>well. If you take the bulkhead out you can still use the cooler.

>This part comes from US Plastics Corp (800)537-9724 (part number 61123, \$1.20)  
>It's worth getting their catalog, as they have a full line of valves, vinyl  
>tubing, and tanks too. Minimum order is \$10 I think.

I use this same part in the construction of the BrewChiller. I'll go out on a limb and sell these to anyone who wants them if you'll send

send me a dollar bill, a 29 cent stamp and a self-addressed stamped envelope. That'll save some of you from having to buy \$10 worth of parts to get one.

Donald Oconnor writes concerning the o-rings on kegs:

>let me explain why this business of dirty o-rings ruining the flavor  
>profile of homebrew has never made any sense. Beer is essentially  
>water with a little alcohol. If you soak o-rings in water and/or  
>alcohol and the stuff won't come out, then why in the hell would  
>it ever come out in your beer which, i'll repeat myself, is  
>water and alcohol? Secondly, if you can smell the pop on the  
>o-ring, then it is coming out. that's why you can smell it. Third,  
>o-rings are not very large. Unless you believe there are little  
>elves making soda pop in there, it's hard to imagine getting enough  
>of anything out of them to ruin 5 or as some claim, 20 gallons of  
>flavorful, malty brew.

That may be all well and good, Donald, and it makes a nice intellectual argument but all I can say is that you should have tasted that nice Coca-cola lager I made about 8 years ago when I switched over to kegs. Buy new O-rings. And don't think twice about it. It is definitely NOT a myth. You can go ahead and put your next batch of all-grain into a keg with old o-rings. But don't say that I and several others of us haven't warned you. (I'm not trying to be a smart a\*\*. But you seem adamant about this and I don't want you to ruin a batch of beer.)

Tom Feller asks:

>I made a siphon rod out of 3/8 copper pipe  
>with a cap in the end and a hole drilled about 3/4 in above the end so I  
would  
>not pick up too much stuff off the bottom of the pot. Here the problem I  
got the  
>siphon started OK but it never had a good flow. Yes I did pick up some  
hops but  
>I stopped and cleaned everything out and still had bad flow. It took  
almost a  
>hour to siphon about 4 gal. (I pour the rest in through a funnel and  
screen).

>Does anyone use this method? Does anyone have any ideas on how to make  
it flow  
>better?

Don't solder the end of the tube closed. Cut the end cap off and solder an inverted 3/4" copper cap on the end of the tube. In effect, it does the same thing the little orange caps do on the plastic siphon canes. It causes the wort to be sucked from above instead of from below. Tie a copper wound, Chore-Boy pot scrubber to the bottom of the tube to filter out the hops. In addition you can tie some mosquito netting or a fine-mesh hop bag around that to further improve the filter action.

And finally, Mike asks:

>What temperatures do people normally shoot for when chilling?

Though I'm sure some would disagree, I shoot for 70 degrees when chilling. According to Dave Logsdon at Wyeast, this is a very comfortable temperature for yeast and they show a dramatic increase in growth compared to even 60 or 65 degrees. Then I take the fermenter to the basement (55 degrees). By the time the wort reaches ambient

basement temperatures the yeast have had a chance to bask for a while in 70 degree wort and are up and running. To me, it seems to be the best of both worlds.

Cheers!

From: Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU>  
Subject: Answers to Bruheat questions

Brett Shorten asks about cleaning the Bruheat:

I've been using a Bruheat for 11 years and distributing them for 6. By far, the best way to clean the element is to use B-Brite. After a round of making beer, rinse the bucket, fill it with enough water to cover the element, add a tablespoon or two of B-Brite and boil. The white coating of sugar that is always on the element will float off in a minute or two. If the element is already blackened, you may need to add more B-Brite and boil for a longer period of time, interspersed with some soaking.

I just discovered this last year and am amazed at how good a job B-Brite does. It's non-abrasive and keeps the element shiny clean. BTW, it cleans the plastic bucket extraordinarily well, too.

On the same subject, sherpa2 (no sig) sez:

Subject: Re: Bruheat Cleaning & other

>...its a lot easier to clean if you remove the element from the  
>"kettle". Brillo does a fair job, but the best thing I've found is the  
>copper pot scrubbers available at most supermarkets. If you clean it  
>up after every use with the pot scrubber, it shouldn't take more than  
>30 seconds or so (brillo used to take me 5-10 minutes!).

Use Brillo pads or copper scrubbers only as a last resort. They will scratch off the plating. I find that this is only necessary when cleaning an element that hasn't been cleaned since God knows how long. Routine boiling with B-Brite should eliminate the need to ever use an abrasive pad.

>Be careful when you remove the heating element not to damage the  
>rubber (?) washer. You'll have to remove the washer to clean the  
>element, but I've had a good deal of trouble with that. Experience  
>has shown my washers only have a lifetime of 10 batches or so. Of  
>course the local homebrew store doesn't carry spares (even though they  
>sell the bruheat), and plumbing places have not been helpful.

The rubber washers were a big problem in one of the shipments I received a year or so ago. They improved the quality in the last few shipments but even those aren't as good as the old black washers they used to use. Those suckers lasted for years.

Anyway, I've got spares. Again, send me a self-addressed stamped envelope and I'll send you 3 or 4 for free.

While we're on the subject, I rewrote the instructions for the Bruheat in the spring. They're much improved over the old instructions. The B-Brite routine is covered and, among other things, a trouble-shooting guide is included. I know there are a lot of Bruheat users on the net so if you want a copy of the new instructions, email me and I'll send them to you.

Whew! Lots of talk about the Bruheat lately. Norm writes:

>I recently purchased a Cordon Brew brand Bruheat Boiler for mashing and

>Now that I have a grain bag, I'd like to hear from others who've used it to  
>mash and sparge straight out of a Bruheat or similar gadget. Problems? What  
>grain/water ratios do you use (this seems to be a bone of contention between  
>Bruheat and Dave Line)? The reason I'd like to do this is to avoid having to  
>dump all that hot grain into a separate lauter tun. Comments and ideas to  
>streamline the process are welcome.

I always advise transferring the goods to a separate lauter tun and sparging back into the Bruheat. By doing this, you can be bringing the wort to a boil as you sparge. This is a big time-saver.

Use a quart pot to ladle several quarts of the mash over to the lauter tun to take some of the weight from the Bruheat. You can then pour the last bit of the mash over, give a quick rinse to the Bruheat, and start sparging back into it. Fairly simple process, actually.

Cheers!

I've been using a Thorne-Electrim Bruheat clone for a while now, with no real problems. I don't use a grain bag as such, but rather a square metre of terylene netting which I knot under the handle. This functions reasonably well, as it hangs down into the bin most of the way to the element when full of grain. I drain and sparge directly from the bin as well, which has the disadvantage of not freeing the bin to heat sparge water but is otherwise convenient.

The one observation I have made is that I need to use a lot of mashing water. When I went according to the book (Wheeler) I got a miserable efficiency, under 70%. This is presumably because of the free volume under the grain. However, this week I brewed and used the ridiculously high ratio of 4 galls (imperial, about 18 litres) to 7.5 pounds of grain. This, and a careful sparge, resulted in my highest extraction yet, about 89%. Wheeler suggests a thin mash results in a sweeter beer; I'm waiting to see. (\*\*Comments welcome\*\*)

It's great for single-step mashing (I don't make lagers, but I imagine a multi-step mash would be quite convenient). I heat the water to c. 72C, stir in the grain (tired arms!) and generally find the temp to have dropped to c. 67C. I wrap a few old sweaters around the bin, and that keeps the temp very solid, dropping no more than 2 deg. in 45 mins. It thus generally needs no more than one heating boost in a 1h30 mash (stir vigorously while heating!).

Tip: when you're interested in raising the temperature, rather than maintaining a boil or mash, bypass the simmerstat. This cycles on and off even when below the desired temp, and really slows things down when you're trying to get the boil started. I have an old kettle with similar connections, so I use the lead from that: it'll bring the spargings to a boil in little over half an hour.

>From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
>Subject: Cooler Lauter Tuns

>I have been using the 5 gallon cylindrical Gott/Rubbermaid orange cooler as a lautertun with apparent good results. Rather than use the slotted copper tubing or window screen over a pipe to filter the wort from the grain, I have been setting a stainless steel steamer (one of those odd kitchen items that looks like a flower with petals that unfold to double the diameter and that has little 1/2" legs). It is just the right size to fit in the bottom of the cooler and when the grain is in a mesh nylon grain bag sitting on top of the steamer I suspect that I get a better filtering action than with the slotted tubes and with much less work/expense.

I can't help but wonder how messing (literally) around with a grain bag fits into your "less work" equation.

It seems to me that filling, installing, emptying and cleaning a grain bag is far more work than hosing out a bucket or kettle with a built in strainer.

Of course you can reduce the work by using a new one each time but then the cost goes up.

Am I missing something?

Subject: Extract/Extract Kit Reviews

Fellow Brewers,

Personally, I enjoy the discussion w.r.t. grain v. extract brewing since I am at a point where I have done both and enjoy both. Specifically regarding extract brewing, I would like to know if any large or small evaluation of extracts or extract kits has been undertaken? I am sure that I can go through the Cat's Meow and come up with a top five extracts by looking through the recipes but I sure would like to survey people's opinions on:

1. Top ten extract kits (kind with yeast, already hopped, add sugar etc. )
2. Top ten extracts (hopped or unhopped versions)
3. Comments

I will be glad to post the results if brewers would send me e-mail privately. Use the e-mail address in the header. I think that this would be a nice compilation in order to help out new brewers in the choice of extract with which to start.

From: des@pandora.swindon.ingr.com (Desmond Mottram)  
Subject: Re: cleaning bruheat element

I apologise for not giving credits but I'm having a few problems with hanging on to HBDs once read. One person mentioned problems cleaning his Bruheat boiler and someone else recommended a grain bag but said take care not to melt it on the element.

A grain bag certainly works for me, I never have to give the element more than a good scrub with a pot scourer to bring it up bright and shiny.

I've

never had to dismantle the element either, though I've only done 10 or so batches with it so far. Furthermore the grain bag I bought specifically said that the bag was constructed of heat resistant materials which would not melt on contact with the element, provided it was covered with water or

wort. I'd suggest looking out for one of these.

Someone else mentioned having to transfer the grains to sparge them, again

not necessary if your mash tun (lauter tun? I'm British) has a tap at the bottom. When the mash has finished just crack open the tap and run sparge water in at the top as the wort runs out.

Lastly, anyone going to the Great British Beer Festival at Olympia, London, this week? 300 British beers, ciders, perrys, excellent imports, plus music, food and creche. Does anyone disagree that this IS the world's greatest beer event, Oktoberfest notwithstanding :-)?

Subject: Splitting Hops plugs for Dry Hopping

In HBD 939, Pat sez:

>I have a question regarding dry hopping with hop plugs. It seems the hop plugs are just a little too large to easily fit through the mouth of the carboy. In the past I have attempted to break the plug in two by working it back and forth in my hands, which is no easy task (and probably an infection risk). A knife did not seem to work too well either. Does anyone have any suggestions as to how to get the hop plug easily into the carboy? Thanks.

You're right, trying to "cut" the plug with a knife doesn't work very well. The

way I do it, is to put the plug (flat side down) on a cutting board, take a shar

p  
STURDY knife and pierce the tip into the center of the plug. I then bear down a

nd  
work the knife back and forth. After you work the tip through the plug, about h

alf  
of the plug will have been severed. It is then much easier to rip the plug in t

wo  
pieces with your hands. I repeat, tho, use a sturdy knife since it can take a considerable amount of leverage to work the knife through the plug.

From: Joe Rolfe <jdr@wang.com>  
Subject: Counter Flow Chillers

hi all,

i have a problem with the volume of water required for utilizing counter flow - i know of no other way around using one, so i need to try and minimize the amount of water used.

what i have is 2 25 foot (1/2" copper inside 1" plastic hose)

to cool the batch to 80 F - i have been typically using 1.5 times the wort in water. the water is at approx 65-70 F. the hot water coming out is at approx 120 - 130 F. Wort in at 200 - 210 F. i would like to use less water and get the temp of the wort lower. i have seen other posts regarding water usage in the 3 times range.

what i would like to know

- 1) would adding another 50 feet of chiller help get temp down to 65-70 F range (water in) and also would it cut down the water usage?? i am assuming with the current set up the performance is a little low - hot water out is perhaps to cold??
- 2) does anyone have the "rocket science" part - formula for modeling the flows(wort and water), lengths, temps.... etc??

thanx in advance

>  
> where Vc = chilled water volume, Vb is wort volume, Tc is chilled  
> water temperature, Tb is wort temperature, and Tt is target  
> temperature. Now, I don't have a 42 gallon bucket, .....

On this issue I have good and bad news to Mike, but good news to everyone else using the "immersion in ice" type chiller where the wort is siphoned into a copper coil which is immersed in ice water. The bad news is that when phase changes occur (solid ice to liquid water) the formula that Mike used, which he derived from the averaging formula

$$Vc * Tc + Vb * Tb = (Vc + Vb) * Tt(1)$$

is no longer valid.

The good news is: the actual target temperature will be much lower than predicted by (1) due to the latent heat required to change (melt) 32 degree F ice into 32 degree water. For example, if you "mix" equal amounts (by weight) of boiling water at 212 degrees (F) and ice at 10 degrees (F) (a typical temperature inside a freezer) you get water in equilibrium at about 52 degrees (F). The formula for computing the equilibrium temperature (assuming the equilibrium state is liquid and the wort has the same thermal properties as water) is

$$Tt = (Tb * Vb + (0.453 * Ti - 73) * Vi) / (Vi + Vb)(2)$$

where Vi and Ti are the volume and temperature of the ice. In this formula, 0.453 is the ratio of heat capacities of ice to water, and 73 is the value for the latent heat required to change ice to water divided by the heat capacity of water. Of course, for equation (2) to have some validity, the ice will have to be constantly stirred so that the equilibrium temperature approximates what is actually occurring in the wort chiller. Also, if you initially add water to the ice in your bucket, you can approximate the effects by first modifying the volume and temperature of the "boil" (as if the water was added to it) using (1), and then apply (2) with the modified values for Vb and Tb. The bottom line is that you need only about 6 gallons of ice to reduce the temperature of boiling wort to 50 degrees F.

From: sami@scic.intel.com (Sam Israelit)  
Subject: A question, a warning, and ...

My new apartment only has an electric stove so I find myself in the market for a "cajun cooker". Can anyone with experience with these devices make a recommendation on performance, cost, availability, etc...?

I was at a garden party last weekend and got into a discussion on the golden hops (not a brewing variety) that the owner was raising. He made a comment that I thought might be of interest to all of the hop growers on the net. It appears that when some varieties of hop vines are cut open, the "sap" (for lack of a better word) can react with the sun. If the grower brushes the hop vine with bare skin (ie, an arm) and doesn't wash off the "sap", it can react with the sun light to cause a rather severe burn on the skin (Maybe "photocautic" is the right word, but I don't know for sure)

These burns can be very painful and can cause scars. It's not the kind of thing that is going to happen immediately, though I have been told that with some plants it can occur very quickly. It's probably early still to start thinking about cutting down your hop vines, but I thought it would be worth passing on the info. This isn't something to be paranoid about, just be careful if you are like me and you don't wear a shirt when you spend the day "cutting back" the garden during the final sunny days of the season. To be on the safe side, though, I'll wear a long-sleeved shirt and gloves when cutting down my hops in the future . . .

And, finally, in a recent HBD issue, Ken Johnson wrote:

> If your beer quality goes down when switching to full mash beers, then  
> you are lame.

Whoa Ken! Reach down deep and grab the reins! You seem to be a little bit harsh in that statement and my first reaction was to tell you to go to hell. Hopefully this comment just came across wrong because the written word can't easily convey tone and inflection. Before you send mail, re-read it to make sure that what you wrote actually says what you mean.

From: mcnally@wsl.dec.com  
Subject: mill experiences

I brewed with grain crushed in my own mill yesterday for the first time, and I'm pleased. It may seem amazing, but I've brewed lots of all-grain batches (maybe 30) and I've never had a mill. On my last two brews I crushed with a marble rolling pin (laugh away).

I have a Marga Molino, fitted with an extended hopper and an output chute fashioned from some plastic scraps picked up at a local plastic store. It's fitted to a board with a hole cut through to match the geometry of the chute. The collection bucket is positioned on a shelf below the hole. I drove the mill with a 3/8" boring bit fitted to a variable-speed power drill.

The crush took a little longer than I thought, but overall I did a little over 10 pounds of grain in just under an hour. For a significant portion of the time I had the mill adjusted a little too tight, so next time I'll probably finish a lot faster.

Even when the mill was too tight, the crush seemed very complete, much more so than that achieved by my former source of crushed grain, the Fermentation Settlement in San Jose (which is not to bad-mouth them). The husks came through very nicely, most completely intact. I did get a lot of flower, but since the husks were there I didn't worry. When I loosened up the mill I noticed that I still got flour, but less.

At mash-in, several big starch clumps formed. These I broke up with a wire whisk with little effort. The mash went fine and I had complete conversion in a little over an hour. Sparge was not unusual, perhaps a little on the quick side. When it ran clear, it ran *\*real\** clear.

The best part was that my extract efficiency was *\*way\** better than before. The OG of the five gallons was about 64, giving a utilization of about 31. Previously, I had never gotten better than maybe 27.

Thus, if you don't have a mill, get one. The Marga is OK, and I'm sure the MALTMILL is too.

Subject: Mouthfeel

>I read the article from the Summer issue of Zymurgy by Michael Tierney on carbonation in beer titled "From Carboy to Beer Glass: A Note on Froth." A very interesting article that I am sure to read many more times. One fact he mentions in his article is that mouth feel is the word that professionals give to a properly carbontated beer that tingles on the tongue a little. My interpretation of mouth feel up to this point was more a measure of body. My question is: does mouth feel refer only to carbonation and its sensation?

Hmm, for myself and other judges I know of these are both correct, i.e. mouthfeel is a measure of smoothness and fullness of the beer, and how well blended the carbonation is. In other words how the beer feels in your mouth. This is a complex sensation, and comprises an interplay of the factors of body and carbonation (poor carbonation feels prickly or sharp and "bites" at your tongue).

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Dry hoping & All grain brewing from Micah Millspaw

Dry hopping, a different approach. I have recently begun dry hopping my beer after fermentation and after kegging. I take my beer filter canister and a cheap (\$2) 5 micron filter put the filter in the canister and shove 1/2oz of aroma hops into the canister around the filter. I then use CO2 to push the beer thru the hop filled filter into another keg. IMHO this gives a very noticable hop bouquet and adds no bitterness, it also eliminates some of the messy problems that occur with normal dry hopping methods.

=====  
All grain brewing. I do it because its way way cheaper than using extracts. Malt extracts at retail prices are about \$3 per pound in my area, I pay about 21 cents per pound for barley malt. As for the time it takes, my brewing equipment is semi-automated, but even with that I see about 4-4 1/2 hours for a 16 gallon batch. Most of that time does not require my presence, I pop into the brew house for the mash in, go eat breakfast, come back for the mash out and sparge ( the sweet wort is being pumped into the kettle as comes out of the mash tun) as soon as a boil is achieved I leave again come back in an hour make hop additions, for the rest of the boil the only times that I go near the kettle is to add hops. I do clean up the mash tun and prep the primary fermenter during the boil time but doesn't take much. I usualy get a lot of yard work done while brewing.

Date: Mon, 3 Aug 92 12:48 CDT  
From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: N-A, The Secret

To: Homebrew Digest  
Fm: Jack Schmidling

Cynic that I am, while pondering the discussions about low alcohol yeast and exotic processes used by the majors to produce low alcohol beer, I took the insipid taste and total lack of beer character this stuff has as a major clue to the secret.

Having two gallons left after keggling a batch of stout, I added one "exotic" step to my N-A process.

As a review, I heat the ready-for-bottling beer to 170F (uncovered) and hold it there for 30 minutes. I then let it cool (uncovered) to 150F at which point it is below the Pasteurization temp and must be covered and cooled for bottling or keggling. I then tap this into a keg and cool it in a bucket of running water. When room temp I force carbonate it.

According to Jeane Hunter's gas chromatograph tests on samples I sent to her, this results in about 1.3% alcohol.

The "exotic" step I added to this batch was to add a gallon of WATER prior to keggling.

We had it last night with pizza (on beer bread crust, of course) and Marilyn and I agreed that it was the best N-A we have made to date. It has a nice creamy head, tastes like stout with just a hint of coffee from the roasted barley. The N-A usually takes about a week to lose the cooked taste for the heating but this stuff tasted great after 24 hours.

I have little doubt that another gallon or two of water would still leave us with more flavor and beer character than the stuff from the majors and reduce the alcohol well below the .5% level required of N-A.

I also have little doubt that this is the expedient the majors use to achieve the low alcohol level.

The addition of water not only reduces the alcohol level but obviously also

the calories. It reduces the body and total character but the basic "taste" is not lost and off flavors are of course, reduced as well.

From: gkushmer@Jade.Tufts.EDU  
Subject: One gallon mead?

I have been thinking of making a one-gallon mead from a Leatherwood honey (made in Tasmania) that my housemate brought home. I have a package of Red Star Pasteur Champagne yeast that consistently yields me good results in larger batches - but I'm questioning the wisdom of dumping that entire package into one gallon of water/honey.

Meanwhile, I have in a secondary in my basement five or so gallons of mead that has been inactive for at least three weeks. It's looking very clear, yet I was thinking that maybe I could take some of the mead from that carboy and dump it in the one galloner. Would the inactive yeast from that mead work in this new environment? Or is this a bad idea?

Maybe I should re-hydrate the Red Star package and dump some of it in the one-gallon carboy? I could get a mason jar, sterilize it, and put the majority of the yeast in that in my fridge.

While I'm at it - does anyone have a yeast strain they like that they could recommend? And I don't mean something that one of you chemistry goons made up on your research grant :-). I'm looking for some commercial alternatives that I can get.

Cheers,

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: Diacetyl Rest question

Does anyone have any parametric experience with diacetyl rests and has a good handle on what limits should be respected?  
I seem to recall from the Practical Brewer, that temperatures in the range of 60-65f reduce diacetyl quickly to very low values.

I have a lager that has mostly fermented out at 48f. I have moved it to my Ale fermentation box (e.g. the laundry room) and it is around 62f. Since it is mostly fermented out I am not too worried about excess ester production while the yeast completes the fermentation. After it completes fermentation I plan on kegging, carbonating and lagering at 40f for a month or until it clears.

Oh, I am using a Pilsner Urquell D yeast. I don't know anything more about it than that.

Thanks!

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Querying the experts

Hate to do it folks, but its amateur chemistry time again. First, the reasons behind head retention. Miller states that proteins reduce surface tension of CO2 bubbles, thus facilitating retention. This piece of reasoning was also repeated in a recent Zymurgy article. This doesn't sound altogether intuitive to me. Also, I distinctly remember a physics class in which we added detergent to water in order to reduce its surface tension; yet detergent is the nemesis of head retention. So what gives?

Secondly, Rajotte (in "Belgian Ale") and formation of higher alcohols. He makes a rather vague claim that yeast activity increases said alcohols, therefore oxygenation of the wort prior to pitching reduces same. From my reading of Fix, I understood the opposite to be true. I presume there are complex interactions between a variety of factors such as yeast strain and health, free nitrogen, temperature, specific gravity, fructose content, fat content and dissolved oxygen, so is it possible to state a general rule? I seem to remember one of the Beer Hunter episodes in which a brewery used a technique to promote the formation of fusel oil late in the fermentation, whereas Rajotte seems to be more concerned with what happens during respiration.

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: sparging questions

Hi All,

In HBD# 940, Tom Feller asks:

>What is the difference between mash-out and sparging. I understood  
>that if you mash out at 170 deg.F you raised the temp of the mash  
>to 170 deg.F and then keep it at this temp for some time.

That's a pretty accurate description of mash out. It's done to stop enzyme activity and to help avoid a set mash.

>How could it take 2 hr to run water sparge water through your  
>grain bed unless the sparge was stuck(set mash?).

Two hours seems a little lengthy to me as well, but it is certainly possible. My first all grain batch, I set the tap on the lauter tun for the merest trickle, i.e., if I just nudged it the runoff would stop entirely. Two hours of sparging later, the runoff still measured around 1.053. Anxious to get on with it, I opened the tap, and ran the remainder of the sparge water through quickly.

I've done a half dozen batches since then, each time increasing the runoff rate and carefully recording the SG and final volume. At the moment, I'm averaging 5 gallons sparge water through 9-10 pounds of grain in just under one hour, and still getting 30-32 points/pound/gallon. The plan is to keep increasing the runoff rate until I see a significant dropoff in extraction, in an attempt to achieve a good time/quality tradeoff.

I mention this because of the recent thread regarding sparge times. I think it's interesting that the times reported by other net.brewers vary so much. Anyone else out there drawn this sort of correlation between sparge time and extraction?

>My plan is:

>Fill my cooler with grain add hot water for a final temp of 155 deg.F

This is single step infusion mashing, works well with highly modified malts.

>Let this sit until conversion about 1-2 hrs. I'll use the iodone test

Using iodine is a good practice, you want to be sure conversion is complete. I suspect it won't take 2 hours for conversion though, especially with highly modified malt. I'd start iodine testing at 45 minutes to 1 hour.

>Recirculate until the run-off is not cloudy.

>Run 170-175 deg.F water(sparging?) through the grain bed keep the water level about 1/2-1 in about the grain bed until the run-off is not longer sweet or I reach my 7 gal. volume.

I use both the hydrometer and the taste test to determine when to quit sparging, and have found that the taste of tannin first becomes

noticeable around 1.020. At about 1.015 - 1.010, there is no longer any detectable sweetness, this is when I stop. Surprisingly, these three events (no sweetness in runoff, 1.010 on the hydrometer, and full pre-boil volume achieved) all seem to occur at just about the same time.

>Did I discribe this right?

You did, and you're on the right track, your plan looks good to me, should work just fine.

Happy Brewing,  
Jim DiPalma

From: emeeks@unity.ncsu.edu  
Subject: breaking up hop plugs

Hi everyone,

I just started using plugged hops on my last few batches, and in my enthusiasm I just have to add my \$.02.

I break up the plugs quite easily with a pair of sharp kitchen shears. Rather than slicing it into pie-like wedges, I take advantage of the "cleavage planes" within the compressed plug. I have found you can start a notch in the side of the plug, then peel it apart into two thinner plugs (of course, the same can be accomplished by inserting a thin, sharp knife into the side and twisting a little). Once it is in thinner sections, you can easily fold (tear if you prefer) the layers and stuff them in the carboy. Other than fresh hops, nothing beats the smell of those inner plug layers.

I just get the sections small enough to fit in (with a little force) the carboy. After just a few days in the secondary, the hop plug separates the rest of the way by itself.

Gee, and I couldn't understand why all the "dull" postings on breaking the inner seal of a Wyeast package! Just goes to show you: Given the proper context, any tidbit of info can be significant.

Subject: Tun in Again

I can see the advantage of a lauter tun separate from my Bruheat mash tun / boiler (starting the boil in parallel with the sparge). My question is this:

If I use a grain bag in my Bruheat will it support the entire weight of, say, 10lbs of wet grain (how much would this weigh)? I'd like to pick up the entire mass of wet grain and place it into the lauter tun in one easy step.

What I don't want to do is rip open my grain bag and drop (pour?) the goods onto my kitchen floor (likely resulting in happy dogs and an unhappy wife).

I suppose I'm just being lazy, but then "laziness is the father of invention".

From: mcnally@wsl.dec.com  
Subject: chilling to 50 degrees

I've gotten several pieces of mail about chilling to 50 degrees. Most think I'm nuts.

I chill to a low temperature because I want a good break and I want to let the break settle for several hours (overnight). The low temperature improves the cold break \*and\* reduces the probability of contamination. I don't have any means of refrigeration other than the chiller which will drop the temperature so effectively.

I like to ferment at 60-65 degrees anyway. I've had mixed results with the beers I've fermented warmer than that.

In his talk on wort chillers at the Conference, Jeff Frane said the most  
enlightening (to me) fact of the whole conference: that cold break begins  
at 65F. Wow! Since then, I've been chilling down to 60F with my  
immersion

chiller, waiting a half hour or an hour for the cold break to form and  
then

running very warm water through the chiller to bring the wort back to  
pitching temperature. Note that this is also possible with a counterflow  
chiller and the coil-in-bucket chiller, but you must siphon twice. I  
need

to use only very warm water because although my chiller outlet hose is  
PE and can withstand a lot of heat, the inlet hose is only PVC and melted  
once when I ran 140F water through it (it buldged out and then burst like  
a bad radiator hose).

>bed. How could it take 2 hr to run water sparge water through your grain  
>bed  
>unless the sparge was stuck(set mash?).

Simply put, mash-out is the final act of mashing. By boosting the heat  
of  
your mash to 170-175F and holding for about five minutes, you effectively  
end  
starch conversion. After mash-out you can begin the recirculation  
process  
and then move on to sparging. Some eschew the mash-out, just as others  
prefer  
not to use a protein rest. If you're happy with your results, that's  
cool, but  
I recommend both steps. But the fact of the matter is, there should be  
no  
confusing mash-out and sparging -- they are definitely NOT the same  
thing.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Malto-dextrine

I am certainly not the final authority on brewing, and most of my knowledge is still based on reading rather than experience. This disclaimer aside:

I did an experiment at home to see what the results of using malto-dextrine and lactose would be in terms of flavor, mouthfeel, and added gravity. Two one-gallon batches of water were prepared, one with a cup of MD, the other with a cup of lactose. Both were boiled and cooled.

Both added substantially to mouthfeel. The malto-dextrine added nothing at all in terms of flavor, while the lactose added a very slightly sweet taste--really rather mild, but noticeable. Each raised the gravity of one gallon of water from 1.000 to 1.014. If I'm not mistaken, this rise in gravity consists entirely of unfermentable sugars, and would therefore remain after fermentation is complete.

As for use of these, I'm still experimenting. My philosophy at the moment is that both serve as extract-brew equivalents of dextrine malt. Armed with the gravity results above, I therefore use the malto-dextrine to supply the same number of gravity points as the desired amount of dextrine malt (1/2 pound of dextrine malt is pretty common, with a whole pound for fuller, more substantial beers). I don't have my notes here, but this comes out to about 1/2 or 1 cup of the above. I've seen recipes here on HBD that use as much as 14 ounces of lactose.

If I'm doing something wrong here I'll be glad to be corrected-- I hate wasting beer!

From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
Subject: lauter/mash tuns

Chris Shelton asks why use a strainer/steamer if a grain bag is also being used. Although I have not experimented without both the steamer and bag, the theory is this: the steamer raises the level of the grain above the drain (which is set into the side of the tun) so that as the grain is sparged the sparge water drips from the grain bed with a horizontal cross-section equivalent to the diameter of the tun and then collects beneath the steamer and flows to the drain; the grain bag provides a finer filter for the bottom of the grain and generally keeps the grain bed together to make clean up easier. Not using the steamer may lead to plugging the drain and not using the grain bag might lead to grain falling through the steamer and flowing through the drain.

A collander filter in the bottom of the tun probably does much the same thing as I have described, but I would guess clean up is tougher than with a grain bag. With the bag, I just lift out the grain, set in in the sink to finish dripping and carry it out to the garden. Since I am keeping the sparge water to within a half inch of the top of the grain bed to keep it afloat, I have not had a problem with sparge water running down the side of the tun and not sparging the grain. At least I think I do not have that problem.

Another reader asks whether a grain bag really makes it easier to clean up, since the bag has to be emptied and washed and what not. Putting the grain bag in the tun takes about 15 seconds and removing the grain in the bag less time. Rinsing out the tun after removal of the bag is quicker than it would be if the bag were not used, I think, since there is less grain to rinse out and cleaning the bag consists of dumping the grain in the garden, turning the bag inside out and rinsing it for a minute or so in the sink. I have not been sanitizing the bag as it is nylon and the wort does get boiled. I do not think this is a big deal, and makes it easier to move the grain out--but the \$7 for the bag might not be worth it to everyone.

>to 5 gallons. I seems to me that combining the two techniques would easily

>allow for cooling to a reasonable lager pitching temp.

>

So, what is an appropriate pitching temperature for Lagers? I have seen brewers go through extreme lengths to make sure both the pitching yeast and the wort are at fermentation temps (e.g. 48f) and I have seen others (yours truly) just chuck the yeast (room temp or refer temp) into the wort that comes out of the chiller (~65-75f). Both work fine. In fact it would appear that my RDWHAHB method works better since the yeast goes through the lag time faster due to the higher temperatures. Of course, by the time the yeast gets really going, my beers are at 48f (~6-24hr depending upon the quality of the starter).

>From club tasting results I can't see any reason to worry about pitching lager yeasts at fermentation temperatures. Does anyone else have a different opinion (hah!) that they would share with the net?

>unless the sparge was stuck(set mash?).

You're right about the difference between mash-out and sparging. There  
are  
two reasons for mash-out that I can think of: 1) stopping conversion (in  
some cases, as when making a highly dextrinous wort, you may want to stop  
conversion before all the dextrans are converted to fermentables) and  
2) raising the temperature of the \*grain\* to 170F so the sugar flows more  
easily away from the husk material (this way, you don't use sparge water  
to  
warm the grain and the grist stays at 170F (or as close to it as your  
insulation allows) for the entire duration of the sparge).

A 2-hour sparge does sound excessive, but too fast a sparge will also  
lower your extraction efficiency.

strainer.  
> Of course you can reduce the work by using a new one each time but then  
the  
> cost goes up.  
>

I use a Gott cooler with a copper tube with slots in the bottom.  
The grain bag gets set into it when dry, and tied down around the cooler  
top.  
Then I add water and grain, alternating and stirring. The grain bag  
really  
is no problem. In fact I think it makes cleaning a little easier.

When I'm done I can carry the cooler out to the compost pile, lift  
the grain bag out, and invert it to dump out the grain. Then I simply  
rinse  
it and let it dry.

I certainly wouldn't say it makes things any harder, and perhaps makes  
cleanup a little easier. While I know plenty of folks who use a collander  
or vegetable steamer false bottom and no grain bag approach with good  
results,  
using the grain bag what and slotted pipe combination as I have also  
works fine.

From: oconnor@ccwf.cc.utexas.edu (donald oconnor)  
Subject: blue stuff, proper credit, oring finale

This blue stuff on the copper tubing is interesting. I apologize for not having followed the thread until reading Kinney's post. I'm a very discriminating reader; I only read posts that have my name associated with them.

Since Kinney makes and sells copper wort chillers, it seems a bit convenient for him to have dismissed the blue stuff for years. I also make wort chillers and Lynne sells them. I have not seen these blue flakes but I'm a chemist so lets see if we can figure this stuff out. As best as I can tell, it's blue and insoluble in water. There are many copper salts that fit this description. Copper sulfate is green and soluble, so we can rule it out. Verdigris can mean either an acetate salt or a hydroxide salt of copper. The latter is both blue and insoluble. There are also copper salts of phosphate, nitrate, carbonate, and arsenate that are both blue and insoluble. It should be fairly easy to determine if one of these is the culprit. We could use a little chalk (carbonate), tsp (phosphate), distilled water and a few other simple chemicals to ferret out most of these possibilities. If someone would like to email me more of the particulars of how this blue stuff appeared, I'd be glad to have a go at it.

There's often a good deal of discussion on the digest about picnic cooler lautertuns, slotted tubing, pot scrubbers, kegging and converting old water heaters into burners. I would just like to mention that Al Andrews of Riverside California (whom I've never met in spite of living there during graduate school) published a great deal of useful detailed information about these things a decade or so ago. For example, I think it was Kinney who a few months ago took credit for the pot scrubber on the bottom of the pickup tube idea, even though I first saw that idea in an Al Andrews publication, The Tapper, of 1981. Now Kinney, I realize that 2 people can independently come up with the same good idea, but it's a scientific fact that excessive self-backslapping can knock a few memory chips off line. Al Andrews may still sell back copies of his Tapper so people might try getting in touch with him. Al Andrews used to make and sell really beautiful wort chillers not like the cheap ones Kinney and I make. See the picture on page 293 of the Papazian's new edition to see what I mean.

NOW! Who wants to challenge me about those orings? You boneheads are wearing me down. One heretic (I'm sorry I forgot who) actually offered to send me an oring that still smells like root beer. I, of course, ignored it because like Kinney I'm not interested in any facts that contradict my truth. Glenn Tinseth had the brass to discuss the chemistry of this business (he's a chemist too). I'm sorry Glenn but I feel much more macho taking on these "IS TOO!" types like Kinney and Jack.

By the way Kinney, the next meeting in Austin for the support group for humans who have been abducted by aliens is September 13. (I'm not making this up.) Bring your o-rings.

>always be dried before using.

I have been wondering about this too, and polling every local  
brewer I know who grows hops. As far as I can tell, it depends  
on how relaxed you are <g>.

If you \*don't\* dry your hops, you have to either not care about  
how much bitterness they add or use some rough rule-of-thumb,  
such as 6 oz. of fresh hops = 1 oz. of dried hops. (Of course,  
you still don't know what alpha acid rating the hops have  
anyway.) I suppose if a cup of dried hops is about an ounce,  
then the same would be true for fresh hops.

In conclusion, I have no hard data, and people do all kinds of  
things from careful drying, air removal, and freezing to dumping  
them in fresh from the vine, without problems.

>Maybe I should re-hydrate the Red Star package and dump some of  
>it in the one-gallon carboy? I could get a mason jar, sterilize  
>it, and put the majority of the yeast in that in my fridge.

I hear this from new brewers all the time. As far as I know,  
even for mead, the more yeast you pitch the better off you are,  
since it reduces the lag time during yeast reproduction.

Can anyone point me to a reference that describes the typical  
yeast reproduction activity for homebrewers? (Something like:  
1) Throwing in one packet of yeast scenario--fifteen minutes for  
yeast cells to rehydrate and acclimate, twenty minutes for yeast  
population to double once, doubles twenty times before  
fermentation begins, lag time of 7 hours.) You see, I have no  
idea how long it takes the yeast to double in population, how  
much yeast you have in 5 gallons before fermentation begins, or  
how much yeast you might expect in a dry yeast packet (which  
itself might have only 30% viability), a Wyeast packet, a pint  
starter at kraeusen, etc.

Thanks.

From: Dances with Workstations <buchman@marval.ENABLE.com>

Subject: Why cut the plug?

Several missives have discussed how best to cut a hops plug in order to get it into the carboy for dry hopping. Far easier than cutting, though, is to moisten the plug with an ounce or two of preboiled water. Or you can use an ounce of vodka, and perhaps get some extra protection from infection. The moistened hop plug will be supple enough to push through the neck of the carboy.

Enjoy,  
Jim Buchman

>majority of the yeast in that in my fridge.

It isn't a good idea to use the slurry from higher-alcohol brews,  
mead included. The alcohol can kill or stunt most of the yeast,  
leaving only foreign or mutant alcohol-tolerant strains active.  
The last little bit of fermentation they do won't affect the  
flavor too much, but you can get some foul stuff if they do the  
majority of the fermentation. Of course you can try (in order  
to get a more alcohol-tolerant strain of yeast), but make sure  
to make a starter first, and see what it tastes like.

I wouldn't think one package (7g) would be too much yeast for  
a 1-gal batch. I've done it before (red star champagne, to make  
a \*very\* dry cider) with no adverse effects (other than the dryness).

From: sami@scic.intel.com (Sam Israelit)  
Subject: Beer Head and Priming

I just opened the first bottle of my version of the TCJoHB Maerzen and it has almost no head!!! I get about an 1/8 of an inch, but this rapidly disappears. Bummer . . . I believe the culprit is the way I primed. In the past I have used corn sugar. Armed with my new HBD knowledge, I decided to prime with dry malt extract. I used 1.25 cups of boiled in about 2 cups of water. I think the problem is that I didn't pack the DME into the measuring cup. I treated it kindof like flour when I am making bread (which also occasionally doesn't work!) so don't thin that I got enough DME for a proper prime. My question is, does anyone know the weight of DME that they use for priming? Is this a completely wrong idea? Is there something else I am doing wrong (related to this topic since there are probably numerous things that would cause a purist to cringe)? The maerzen tastes great, but there just isn't much head to it at all. Any comments would be appreciated

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Your hops are ready to pick when...

Your hops are ready to pick when:

- They feel papery and dry when you squeeze them
- The lupulin glands at the bases of the petals of the cones are a dark yellow, like the yellow of the lines on the highway.

If the tips of the petals are turning brown, PICK NOW! they're getting too old.

Hint for picking:

I've found that the stems of the cones are too tough to pinch through with my thumbnail, and simply pulling tends to rip the plant apart. What worked on my Bullion and Hallertaur was to grip the cone by the petals right next to the stem and bend the cone 90 degrees and pull. This allowed me to pick with one hand and hold the container with the other.

I grew mine on poles that were strapped to 4' iron stakes driven into the ground. When it came time to harvest, I just unstrapped the pole, laid it down, picked the hops that were ready (all of them), then strapped the pole back up. This was very convenient because the pole holds everything very still while the picking is going on. I'm leaving the vines up instead of cutting them down in hopes that the rhizomes will continue to grow and be that much bigger and healthier next year.

The hops are now in jars in the freezer, I'll dry them when I get home from Pensic. Any body see a problem with that?

Carl

Al Korzonas writes (in HBD #941):  
| In his talk on wort chillers at the Conference, Jeff Frane said the  
most  
| enlightening (to me) fact of the whole conference: that cold break  
begins  
| at 65F. Wow!

Has anyone heard this statement made anywhere else? Anyone's experience  
bear this one out? I have a VERY hard time believing that you need to  
cool below 65F before you start getting cold break.

Before I started using an immersion chiller, I had maybe half an inch of  
break material in my primary fermenter. Now that I chill the wort down  
to about 70F, I get at least three inches of cold break (after it settles  
for a few hours).

Subject: Why Mash Out?

Steve Hamburg writes (in HBD #941):

| Simply put, mash-out is the final act of mashing. By boosting the heat  
of  
| your mash to 170-175F and holding for about five minutes, you  
effectively end  
| starch conversion.

NOVICE ALERT!

I have a question. If the goal of mashing is to convert all starch into  
sugar, then why do you need to halt this process? If mashing is  
complete,  
and there is no starch left, aren't the enzymes just sitting there doing  
nothing anyway? Is there something else going on?

Subject: Beer foam secret revealed

Conn Copas writes, in HBD #941:

>Hate to do it folks, but its amateur chemistry time again. First, the  
>reasons behind head retention. Miller states that proteins reduce  
>surface tension of CO2 bubbles, thus facilitating retention. This  
>piece of reasoning was also repeated in a recent Zymurgy article. This  
>doesn't sound altogether intuitive to me. Also, I distinctly remember  
>a physics class in which we added detergent to water in order to  
>reduce its surface tension; yet detergent is the nemesis of head  
>retention. So what gives?

There is a nice letter in the July 92 Physics Today, pg. 91, about beer  
foam and (the lack of) champagne foam. ("I Get No Thick from Champagne")  
It is from a Gianni Astarita of the Univ. of Naples Federico II in  
Italy. He says that film stability is influenced by the "Marangoni  
effect" and that

... When mass transfer is taking place (in this case, when CO2  
is being desorbed in the gas phase), the thin films are or are  
not stable depending on the \*sign\* of the derivative of the  
surface tension with respect to concentration.

He goes on to note that the sign of the derivative is influenced by the  
presence of proteins from malted barley.

Subject: Carbonation

Jay writes:

    Hmm, for myself and other judges I know of these are both correct, i.e. mouthfeel is a measure of smootheness and fullness of the beer, and how well blended the carbonation is. In other words how the beer feels in your mouth. This is a complex sensation, and comprises an interplay of the factors of body and carbonation (poor carbonation feels prickly or sharp and "bites" at your tongue).

This sounds a bit confusing. I'm not sure what you mean, especially regarding "poor." As we all know, each style has its appropriate level of carbonation, e.g cask conditioned bitter is virtually flat whereas some Belgian Ales really sparkle (what I would call prickly or sharp). So, do you mean that *over*carbonation feels prickly, etc.? If this is the case, then I agree, otherwise, I'm confused by the part of your statement which is in parentheses.

I just thought of another situation: the size of the bubbles, however I haven't quite figured out how to control bubble size. Some have said (here in the HBD) that priming with malt extract in stead of corn sugar gives finer carbonation (smaller bubbles), but I can't see how this could be (does someone have an explanation?). I suspect that the bubble size has to do with surface tension and the body of the beer (this may be where the mouthfeel brings it all together). Comments?

From: Michael Howe <howe@gp\_sparc45.gwl.com>  
Subject: Re: Brewpubs in Denver

Gary Franko asks:

- > I am looking for brewpubs in Denver, Boulder, Golden area. Any
- > suggestions or recommendations would be greatly appreciated.

Gary,

There are quite a few brewpubs in the area. Some of the more popular are as follows:

Rock Bottom - 16th St. Mall (Downtown Denver)  
Wynkoop Brewery - (about)18th & Wynkoop (Downtown Denver)  
Champions Brewery - 15th and Larimer(Downtown Denver)  
Walnut Brewery - Walnut St. - (Boulder)  
Oasis Brewery - Canyon St. - (Boulder)

Those are the main ones in the area. There are still a number more around the area, including some in Ft. Collins, as well as the mountains(i.e. Vail). If you would like to find out more, just mail me at:

howe@gp\_sparc45.gwl.com

Michael Howe

P.S. - If you want my opinion, go to the Wynkoop Brewery if you're in Denver

or the Walnut Brewery if you are in Boulder. The Walnut Brewery and Rock Bottom are owned by the same guy, so the atmosphere and beer at each place is pretty similar. The beers at Champions and Oasis aren't quite as good. Each of the places usually has at least one special, seasonal beer available. You might call ahead when you are here to see if something interests you.

P.P.S - Keep in touch - let me know what you think of everything when you go.

Hi, Jay.

No nasty flavors I'm aware of. I finally retired my first styrofoam cooler after eight years of service. A new one set me back \$1.79. I'm not a chemist, but I don't think styrofoam reacts with water in any way. After all, it makes great coffee cups (I can see the environmentally sensitve reeling at that).

> miller)

The keg I use is SS (from Swiller).

Before scrapping your keg, though, I would check to see if it has a polypropylene coating inside. If it does, go ahead and use it anyway, because your brew will never touch the aluminum. My keg has this plastic coating inside, and as long as you don't heat up the keg dry, it will survive the heat of a boil. I use a 160K BTU propane cooker on mine and the coating is still fine after many boils. If I'm not mistaken, this is the same plastic used for the bucket of the BruHeat boiler.

Pat

FWIW, I would go ahead and use it whether it had the coating or not. I think the dangers of aluminum are highly overrated.

>

>Can anyone give me a source for the grain bags ??

>

1. Leave the personal jabs out of postings. It doesn't reflect well on the poster (e.g. you).
2. I have a spare grain bag that I will be willing to sell you cheap. I use a close fitting false bottom that I fabricated out of a sheet of polycarbonate plastic (HDPE or polypropylene should work as well). I think grain bags are a compromise - they don't sparge fast, they are not too efficient, they are a hassle to clean and they are expensive (mine cost ~\$12)
3. Although I am not an EasyMasher user, it sounds inexpensive, easy to use and clean and probably not too bad for efficiency if your pot is fairly tall and narrow. In addition it doubles as a nice boiler complete with straining drain.

Email me for an address if you are serious about buying a sparge bag. Mine was used only twice.

Subject: WYEAST Etymology (HBD

Fellow Hop-Heads:

In HBD #941, the question came up as to the origin of WYEAST. JAO was on the right track about the reference to a mountain nearby, although it is not Mt. Adams or St. Helens.

The name Wy'east is the name the local Native Americans gave to what is also known as Mt. Hood. Note that the spelling is different than that of the yeast company, but this is to reflect the nature of the buisness, and a bit of the local history. WYEAST (the yeast-maker) is located in the foothills of WY'EAST (the mountain), unless of course, they've moved.

Well, that's all for now. Don't forget:  
ATTITUDE IS EVERYTHING!!!!!!

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Cooler Lauter Tun

I also use a lauter tun made from a Gott/Rubbermaid 5-gal drink cooler. My grain bag was obtained at the local homebrew/wine shop, sold as a "press bag" for a winepress. Many of the mailorder beer/wine-making catalogs carry these. I think mine was made by Wine-Art. It is very strong and I have no difficulty carrying up to 12 pounds of wet soggy spent grain over to the neighbor's cows. The upper lip of the cooler has a flexible lip that forms a seal when the lid is screwed down. This lip is handy for tying the bag in place with string. If you aren't using a bag yet, I highly recommend it.

The stainless steel vegetable steamer under the bag is necessary part. If you just use the bag alone, it will not leave a liquid space at the bottom. This will force the wort to channel through the grain and leave a "dead space" on the bottom opposite the outlet. The liquid space under the steamer allows the flow to be evenly distributed over the entire horizontal cross section of the grain bed.

I put a small stainless collander on top of the grain. This protects the top of the grain bed from being stirred up by the sparge water. It also holds the small submersible pump that recirculates the wort to clarify it.

My pump is made for aquarium use. It is rated at 16 Gal/Hr. In twenty minutes the wort is crystal clear. I'm very pleased with how it works, and

my arm no longer gets tired from pouring the recycled wort back in the top of the lauter tun. The collander is handy during sparging, in case my attention wanders and the liquid level drops below the grain.

Sparging takes about 40 minutes. I will run much faster than this, but I find I get a better yeild with pauses. The next time you are sparging, and it is starting to lighten up, take a sample and stop draining for 5 minutes. After the pause, take another sample. It will be richer.

I suspect that this is far more elaborate than is necessary to brew good beer. Yeild isn't all that important: Stronger beer takes more grain. If it tastes good, you did it right.

>127ppm/gm/gal CL-

Larry, I would like to know of a supplier for Calcium Chloride dihydrate. I remember reading a post from you about a year ago and how CCd was helpful for sparge efficiency. Also, my water supply is rather high in sulfate concentration so adding gypsum can be deleterious (at least for lager brewing). The CCd would be perfect. So I called many chemical suppliers (>5) and none would do business with individual buyers, only company's and such. So I gave up and forgot about it. Now I read your post and I am once again pissed off that this chemical is unavailabe to me. So please, tell me where I can purchase this stuff. By the way, I tried to email Larry directly on this but my mailer bounced it back to me.

Jim DiPalma wrote:

> I use both the hydrometer and the taste test to determine when to

>three events (no sweetness in runoff, 1.010 on the hydrometer, and  
>full pre-boil volume achieved) all seem to occur at just about the  
>same time.

I have read this from several different sources, that of terminating sparging at ~1.015, and was wondering if people were allowing the sparge runnings to cool to room temp or were adjusting to compensate for the heat of the sparge as the flow exits the sparger when checking for ~1.015. The temp of the sparge is quite hot compared to room temp and it seem some correction would have to be made if the reading was taken from the hot liquor.

Thanks,

From: michael@frank.polymer.uakron.edu (Micheal Yandrasits)  
Subject: verdigris

There has been a recent discussion about verdigris on the digest and a call for clarification. Here goes. Verdigris is "truely" copper acetate (sometimes called crystals of Venus\*) and forms on copper in the presents of acetic acid. Verdigris is soluble in water, alcohol and ether. It is also "moderately toxic". I suspect this is not what is on everyone's cooling coils. "The green rust with which uncleaned copper vessels become coated and which is commonly termed verdigris is a copper carbonate and must not be confused with true verdigris"\*. It looks to me like the green flakes are really copper carbonate. Copper carbonate,  $\text{Cu}_2(\text{OH})_2\text{CO}_3$ , is insoluble in water and "toxic by ingestion". The other popular possibilities, copper sulfate and copper chloride (green or blue) are soluble in water and thus unlikely (these two are "toxic"). My only problem with the copper carbonate hypothesis is that I think  $\text{CO}_2$  must be dissolved in the water to react with the copper. Presumably wort boiling for an hour or more would be completely free of  $\text{CO}_2$ . Anyone else have a sugestion? Could it form while cleaning with tap water? Should copper be cleaned with boiled water? My info says copper carbonate is soluble in acids, perhaps cleaning with an acid may work. How hard is it to dry the inside of a cooling coil? It might be a good idea to make sure there is no standing water left to react with the copper. Just a few thoughts.

\*Most of the above was taken from "The Condensed Chemical Dictionary" 3rd Edition Revised by Gessner G. Hawley, New York, Van Nostrand Reinhold Co. 1981

Subject: Infections from tap water?

Greetings all!

I've got a question that was prompted by something that was originally posted on rec.crafts.brewing...

In response to a question whether or not to boil all tap water that contacts your brew slk6p@cc.usu.edu wrote:

> Tap water (at least most taps) contain VERY few bacteria or fungi. You  
> could hardly even find one at high magnification.

Is the above statement true? and here's why I ask:

I'm a novice brewer with about 7 extract batches under my belt (or 'down the hatch', I should say :-). I didn't really know what I was doing at first (like I'm an expert now...), and so some flaws in my first beers escaped me in the beginning. Having had the summer to sit back and think about things, I realize that all my beers had the same funny, barely noticeable after-taste (astringent and bitter, but not like hop bitterness).

All my batches were cloudy and one batch that I liked so much that I set some aside to savor over the summer developed into The Gusher Bottles From Hell\*.  
It doesn't take a rocket scientist to figure out that I had an infection problem.

I changed a lot of things going from batch 1 to 7 including: switching from a plastic fermenter to a glass primary and secondary, started using a bottling wand, going to the blow off method, the addition of a wort chiller, switching from b-brite to bleach, switching from dry to liquid yeast, dry hopping. ..  
Well, you get the picture. Basically, if I saw it discussed on this digest twice, then I tried it at home ;-)

The things that I kept the same were 1) I rinsed all my equipment with tap water after sanitizing and 2) I added 2 gallons of grocery store fill-it-yourself distilled water to my 3 gallons of wort after the boil. I figured that it's one or both of these things that's causing the infection.

This fall I plan to buy a cajun cooker and nuke all 5 gallons of the wort. I was also planning to switch to iodophor and nix the tap water rinse.

So the question is: Has anybody else ever experienced infection problems due to a tap water rinse or am I barking up the wrong tree and should I concentrate on other infection sources?

Phil Miller (pmiller@3m.com)

\* Lest you think I have a cast-iron tongue, the after-taste was subtle and well hidden in 'heavier' beers like my brown ale and raspberry stout.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: MASHOUT v.s. SPARGING

To: Homebrew Digest  
Fm: Jack Schmidling

>From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
>Subject: Chiller and Sparging

>What is the difference between mash-out and sparging. I understood that if you mash out at 170 deg.F you raised the temp of the mash to 170 deg.F and then keep it at this temp for some time. With sparging you let the mash water drain out as you add sparge water, trying to keep the water level above the grain bed.

I think the confusion here results from the fact that there are two basic mashing techniques used by homebrewers.

In my opinion, the preferred method is "kettle mashing". In this process, the water is mixed with the grain and brought up to various temperatures through the application of heat from the stove. This allows not only control of the temperature profile but also provides the ability to experiment with different profiles and "steps". One such step is the "mashout", wherein the temperature is raised to 175F and held for some period of time. The usefulness of mashout is subject to debate and I leave that for the chemists. It is my opinion, however, that one major advantage is that it greatly reduces the risk of "set-mash" and provides a natural transition to sparge temp with minimal heat loss.

None of this has anything to do with sparging, yet. If the kettle is equipped with a spigot and some sort of strainer or false bottom, sparging is only a matter of opening the spigot and adding hot water as the level drops.

The other, and probably more popular method among homebrewers, is the (for lack of a better term) plastic bucket system. I really don't know what this is called but have seen numerous references to zapp and would like someone else to help here. I have never used this system but understand it to be adding hot water to grain in a bucket and after a prescribed period of time, it is transferred to another bucket with a false bottom or grain bag and hot

water is run through this for sparging. Some calculation and planning must be done to assure that the mash arrives at the right temperature when the water and grain are mixed and substantial insulation is required to maintain the temperature through the process. Little can be done to adjust it once underway.

>I believe I am using a single step mash at 150 deg.F with a 170 deg.F sparge I won't be using a protein rest or a mash-out. Did I describe this right?

Pretty much but you can now see the problem. As you add 170F water to a large volume of mash at 150F, the actual temp will be closer to the latter. One can argue about the significance of this but again, the colder the mash, the more likely is a "set mash".

>How could it take 2 hr to run water sparge water through your grain bed unless the sparge was stuck (set mash?).

In most cases, it is by choice. The gurus claim that the longer it takes, the better the extract efficiency. This is another debatable point but I suspect that in some systems, such as the grain bag approach, there is no way to rush the job. In the kettle, it will run off as fast as it can get through the spigot. I have to adjust the spigot to get the appropriate flow rate. I also sparge with boiling water to assure that the temperature remains in an acceptable range.

Other than the publicity from a very popular book for the bucket approach, it is hard to understand why so many brewers have opted away from kettle mashing. You need a kettle anyway and in this simple and (in my opinion) superior approach, the transition from extract to all-grain becomes learning the process instead of collecting a bunch of equipment.

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: Re: Sparging

In HBD #941 Al writes

>...

>You're right about the difference between mash-out and sparging. There are

>two reasons for mash-out that I can think of: 1) stopping conversion ..

.

This is the conventional wisdom. There is no way a 10 min mash out at 170f is gonna stop conversion. I can name at least two local breweries that MASH at 160-162f! (Thomas Kemper and Hales) and I suspect a lot more around the PNW do as well. Another 8-10f isn't going to magically kill the enzymes.

>2) raising the temperature of the \*grain\* to 170F so the sugar flows more easily away from the husk material...

Yeah, that is the real reason! Plus I am willing to bet that any residual

starch is converted \*real fast\* at this temperature...

>

>A 2-hour sparge does sound excessive, but too fast a sparge will also >lower your extraction efficiency.

Just feeling contrary: I have noticed no correlation between fast sparge and poor extract efficiency. There is a definite correlation between crummy crush and poor efficiency. I use a false bottom and sparge as fast as I can (my record is 15 min/6.5 gal) and I routinely get .034/lb/gal (after the boil) for a typical pale ale. The sparge rate really depends upon how much flour I get in my crush; the grain crushed with a corona takes 30-50min to sparge, the grain crushed with a proper roller mill takes 15-30 min to sparge.

Cheers!

From: Brett Shorten <s05bas@cc.uow.edu.au>  
Subject: British v Other pale malted grains

I was interested in a recent thread which never quite seemed to get off the ground. It concerned differences in colour between beers made with British and US malts. Being an Australian, I am assuming that our pale malts would be very similar to those in the US, given the similarity of mainstream beer styles.

At any rate, I recently made a batch of "Fullers London Pride", following Dave Line's recipe. Although the beer is still very young, I have tried one bottle and found it to be disappointing colourwise, being significantly lighter than the real thing (I was in London recently, and saw many pints of the real thing!). I am convinced that poor extraction is not the reason, as my OG was spot on. So, whilst communicating with an English HBD aficionado (Hi Andy!), I asked him about this. It turned out that he has used the same recipe and got a beer just as dark, or a little darker, than the real thing. This suggests to me that differences in the colour of the malts is the most likely explanation. I wondered if bumping up the amount of crystal used would help to achieve the desired result, but Andy felt that this may adversely (in terms of replicating the type of beer targeted) affect the flavour. He was kind enough to send me a section from a British book of recipes for traditional high gravity ales dealing with home roasting of pale malts to achieve darker colourings etc.

So what does the HBD think? My contention is that Australian (and US, as far as I can tell) pale malted grains are not suitable for making authentic British ales, unless they can be slightly darkened somehow. I worry, though, what this may do to their ability to supply fermentable sugars. Alternatively, I wonder whether some judicious blend of, for example, pale and Munich malts may achieve the desired result.

Looking forward to some interesting discussions

> British ales, unless they can be slightly darkened somehow. I worry,  
though,  
> what this may do to their ability to supply fermentable sugars.

Last time I was brewing in Australia (about 2 1/2 years ago), I had the  
opposite experience. The malt available from homebrew shops was of  
anonymous  
origin and not even labelled as 'pale' or 'lager'. It's extract value was  
standard, around 30/gall, but it seemed to me to be more kilned than  
British  
pale malt. On both taste and colour grounds, I used to limit the  
contribution  
of the malt to an SG of around 40 when attempting to replicate (in my  
misguided  
fashion) the local brew. Using higher proportions of malt used to result  
in  
something resembling a Scotch heavy, which I find hard to replicate here.  
I  
suspect this accounts for the frequent classifying of Australian  
commercial  
brews as 'sweet lagers' (these have no resemblance to the products brewed  
under  
licence in Britain). I found the malt to be temperamental regarding chill  
haze  
and astringency, so it probably resembles US 6 row in that respect.

Couldn't agree more that the facility for step mashing is useful if one  
wishes  
to make a wide variety of brews and/or wishes to mash out. However, I  
have  
reservations about systems in which heat is applied directly to the mash,  
and  
that includes stove-top mashing and buckets with heating elements. My  
experience is that these systems give some of the character of a  
decoction  
mash and thus result in a relatively dextrinous wort, presumably because  
beta amylase doesn't survive the direct heating very well. Most of the  
time I  
brew bitters and stouts and so this situation is fine, but there are  
exceptions. Eg, when brewing barley wine or belgian ale I usually want  
the  
terminal gravity to be less than 1/4 of the original. I also make an old  
ale  
which consists of about 1/3 crystal malt, which once again requires  
special  
treatment. IMHO, the ultimate in versatility is the "mash tun in a hot  
water  
bath" system. My tun consists of a stainless steel milk urn, sitting on  
blocks  
in a plastic bin fixed with a heating element. Oddly enough, I'd gladly  
swap  
the tun for something made of a lighter weight, more conductive metal.

Subject: FLAVOUR/ODOR IN ORINGS

hi all,

all this talk about orings is making me hungry :]

seriously thou, i have a bunch of kegs, bought used. the rings are not new (but i bought new one anyway). i scrubbed the hell out of the kegs with an acid (Diversey - Attitude - standard disclaimer) which usually takes everything off stainless.

replaced one oring and left a coke oring on another, sealed added CO2 (mainly for pressure check) and left them for weeks side by side. when i went to filling them up the coke can had a distinct odor the other can did not. tried this experiment again with other cans that seemingly smelled different (different soda in'em). the ones i did not change the orings on had a sweet odor others were generally odor free.

for what it is worth - i have a friend who has probably 30 times the amount of kegs i have, he never did any changing, but after one use the oring has a beer smell to it. he turns his kegs over fairly regular.

so to make a point - if the orings smell, i feel it will get into the beer. if this bothers you - try soaking the orings in cheap beer (BUD) for a couple of weeks or more. i had tried boiling, B\_BRITE, other Diversey products, bleach, tsp, iodine, nothing seems to remove the odor.

just a couple of cents worth - no flaming directed at anyone :]

Comments?

>  
> Al.

There was some interesting traffic on this issue in RCB prior to and on 21  
Feb  
92. Here's an extract :

>From "The Winemaker's Dictionary":

"Ethyl Pyrocarbonate is an unstable compound formed when bottle  
fermentation

^^^^^^ ^^^^^^^^^^^^^^^  
occures. It is formed by the joining of alcohol and carbon dioxide. On  
opening the bottle the rate of loss of carbon dioxide (or the rate of  
bubble  
formation) is inversely proportional to the concentration of ethyl  
pyrocarbonate. Thus a good sparkling wine retains its 'fizz' for a long  
time  
because the bubbles can only form as the decomposition of ethyl  
pyrocarbonate  
> takes place."  
>

This was basically an argument for natural conditioning over forced  
conditioning. FWIW, I can't detect any differences between priming with  
sucrose, extract or wort, at least with ales matured at cellar  
temperature. I  
can detect large differences between bottle conditioned beers and those  
draught  
brews which have been dispensed through an agitator. The latter are  
typically  
milky at first and take around 1 minute to clear, and have a  
characteristic  
creamy mouthfeel which bites much less on the tongue. This can also be  
simulated successfully using nitrogen as an artificial conditioning gas.  
I  
arrived in the home town of Bellhaven beers, in Scotland, recently, and  
was  
disappointed that there wasn't a handpump in sight. I was about ready to  
inform  
the local publicans that I had ideological objections to keg beer, but it  
turns  
out that Bellhaven have gone down the Guinness route and are  
experimenting with  
nitrogen. These brews were vastly superior to their keg beers in terms of  
head  
retention, mouthfeel, and general freshness. Whether they were  
pasteurised or  
filtered, I couldn't determine.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: lots of things

For Alan E: I understand there to be \*2\* temps of major cold break production.  
The one at 65 degF produces more than the one at the higher temp (not sure just what that temp is.). The two temps are not magic numbers though, they are just the approximate temps of maximum break production along a range of temps at which break production occurs.

Re. mash-out: mashing is a continuum, with the mash reacting differently at the various temps. Starches/sugars will be converted at a range of temps, from the 140's (or lower?) right up to the temp at which the conversion enzymes are denatured, that is, until they are chemically (physically?) changed so that they cannot do the conversion anymore. A rest of 10-15 minutes at 170+ degF is usually considered sufficient to denature the majority of the enzymes and "stop the conversion". I'll leave it to the chemists to tell us just what happens at that temp., but suffice it to say that a few degrees \*can\* make a difference with what's happening with the mash. Depending on your mashing temp. and time schedule, not mashing-out can result in a dry (as in not sweet) beer. I'd suggest reading Papazian/Miller/Noonan/Fix for a full description of the chemistry, but basically, mashing involves not only starch->sugar, but also big sugars->smaller sugars. Mashing-out can help retain some of the larger sugars, usually to the benefit of the final beer(drinker). Another (the main?) benefit of mashing out is to help the sarge run smoothly.

Phil: Contrary to what your friend might have said, there is quite a bit of possibly beer-spoiling life in tap water. My wife is an aquatic biologist; I've seen the numbers. It varies considerably, depending on source, season, time of day,..... If you are on a reasonably good city water supply and are pitching a good supply of yeast, I doubt your infection problems are coming from the tap water rinse, but it is possible. A way to check, I suppose, is to pour boiling tap water into a clean bucket and use that for rinsing. You said you added distilled water. Are you sure that it's \*distilled\*? Plain \*bottled\* water can still contain bacteria. Truly distilled should be ok. If you're filling your own bottle, the water may get infected at that time. Other places to check are your bottles, and any tubing.

Jack: the Zapap (from Papazian, backwards) is a bucket with a zillion holes inside another bucket with just one outflow hole. The mash goes into the

holey bucket, as does the sparge water, and the wort flows into the second bucket underneath, and out the outflow hole. It works, but it's tedious. I'm pretty pleased with my cooler/sparge setup.

Finally, D oringC, if you've got a beef with Kinney, take it off the list.

From: mcnally@wsl.dec.com

Subject: cold break temperature

In Dave Miller's book, it is pointed out that break material forms as you chill the beer all the way down to freezing. Indeed, "chill haze" is cold break. Thus, if you chill the beer as much as possible before fermentation, you cause the break proteins to coagulate and drop out before the beer gets to the bottle.

If I had a good refrigerator for brewing, I'd rack into a carboy after as good a chill as I could get with my immersion chiller, then stick it in the fridge and drop the temperature as much as possible overnight. After pitching, I'd of course let it warm up; the yeast will get going before any undesirable organisms.

From: homebrew@tso.uc.EDU (Ed Westemeier)  
Subject: Harvesting hops

In response to recent questions, here are my thoughts on harvesting hops (I live in Cincinnati, about 39 degrees latitude):  
I started harvesting my Cascade about ten days ago, and will continue harvesting for another month at least. I started harvesting Hallertauer just a few days ago, and will continue for another month. Nothing to harvest yet on the Northern Brewer or Saaz vines (they don't get as much sun as the others).

I judge readiness to pick by the feel of the cones. When they begin to feel papery and springy, they are ready to pick. Before that, they feel moister and compress more readily. Whatever you do, don't wait for them to turn brown. If you're still not sure after feeling them, grab one and manipulate the leaves to look inside. If you see an abundance of yellow lupulin glands, it's ready to pick.

Size is really variable. The first clue to readiness is probably the elongation of cones. I have found that even when adjacent cones are very different (one long and pointed, the next small and rounded), they can both be ready. If one or two cones is ready, you can safely assume that all the cones on that lateral and the opposing lateral are also ready.

After harvesting, I spread the cones out on a piece of nylon screening (the kind you use to repair window screens) in the basement. After a week or two, they are fully dried. Then I weigh them and put them in plastic sandwich bags, half an ounce to the bag. These bags are then put in on-gallon size ziplock bags. I fill the big bags with CO2, close them tightly and store them in the freezer.

The main advantage of drying hops before using them is to standardize the alpha acid content in a given quantity. Some major brewers claim that storage improves hops (especially the noble ones), but I doubt if the homebrewer would find it worthwhile unless you're brewing lambics.

>

I think what Steve meant to say was, "you effectively end enzyme activity."

Presumably, starch conversion is already done at this point. Enzymes are still converting non-fermentable sugars (dextrins) into fermentable sugars

(maltose), though. Both types of sugar are desirable in the wort, the relative amounts depending on the desired style. Mash-out stops this enzyme

activity at the (presumably) desired point in time.

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Blue copper flakes in California homes

I live close to a community of new homes that has mysteriously had problems with blue water. All these homes have copper pipes. The builder, water supply company and MANY experts have been stumped on what causes this problem. They all agree that these people should not drink their water. Now these people gave approx. \$350-\$400k for these homes (it is Calif). They are VERY upset! The builder has been supplying them with bootled water for drinking and cooking for at least 2 years now. All sorts of explanations have been proposed. Some say the water is TOO pure, not having enough calcium to coat the copper. Some say its a reaction with the residue of the flux used to solder the pipes together. Some say its electric currents flowing in improperly grounding mains causing electrolysis. At any rate, the blue water causes the people to feel very ill if they drink the water. I would suggest brewers with blue flakes in their coolers should take steps to prevent them. The discussions on the WHYS can continue.

>there just isn't much head to it at all. Any comments would be appreciated

Sounds to me like you used enough DME for priming a 5 gallon batch. My experience is that the size of the bubbles and head retention in general are greatly influenced by the degree of maturity of the beer. Since this beer is a Maerzen, I assume it's been lagered for some period of time. The relevant questions are 1) Did you leave it at room temp for a week after priming to let the yeast go to it before they go dormant during lagering? and 2) How long has it been aged? Ales primed with DME may take 4-5 weeks to develop proper carbonation at room temp. Having no experience with making lagers I can't say whether this extended room temp "rest" is also required before cold-aging a lager primed with DME. Anyone else know?

On the general question of DME vs. corn sugar, Dave Miller says corn sugar ferments quickly, so that the CO2 first goes into the head space in the bottle, then is forced into the beer by pressure. With DME or wort priming, the fermentation is much slower, and the CO2 stays in solution as it is produced.

However, once the CO2 is in solution (say 2 weeks for corn sugar, 4 weeks for DME) it knows not from whence it came. The size of the bubbles and the head retention from properly aged batches differing only in their priming should be the same. For better head retention try the famous "heading agent" or 1/4 cup flaked barley.

Subject: comments on the maltmill

Greetings,

True to his word, Jack sent the MALTMILL. I received it this past Friday and was able to try it out Sunday. As I told Jack, I was an extract brewer exclusively until this spring when I started using specialty grains. The only comment I will make to the digest is that it beats the pants off of a rolling pin. If anyone wants other comments send me email.

About a year ago there was some talk about using a pressure cooker to brew beer in. I asked if the higher temperature could hurt the beer and not hearing any answer either way I tried it. I have not seen any problems that I can pin on the temperature. It does have a couple of advantages, for one I don't get any boilovers. Also I am able to cool it off by putting the kettle in a sink of cold water and since it is still relatively well sealed I needn't worry about an airborne infection invading it. There is the problem of adding ingredients once the pressure is on. One can find a way around that if they really want to.

Date: Thu, 6 Aug 92 11:45:16 CDT  
From: tony@spss.com (Tony Babinec)  
Subject: vienna and munich (towns, not malts!)

I tried sending this to doug and it bounced, so here it is.

Douglas: I had the good fortune to visit Vienna & Munich in 1984. While my "beer consciousness" then was not what it is now, I did try the beer. Aside from beer, you and your wife are visiting two great cities and a beautiful part of Europe.

Central Vienna is ringed by the RingStrasse. You'll find all sorts of museums and municipal buildings along that street, and I highly recommend walking. The central landmark in Vienna is St. Stephan's. Near the church is the intersection of Kartnerstrasse and Graben. Karntnerstrasse is one of the great commercial streets in the world, so be sure to do some window-shopping as well as stops for coffee and pastry. You might see whether there will be any musical performances at the Staatsoper or Volksoper, although depending on the timing, the musical action might be at Salzburg. Armed with a few guidebooks, you should be able to find dwellings where Mozart, Haydn, Brahms, Schubert, etc., lived.

So far as beer goes, seek out the Reichenberger Griechenbeisl at Fleischmarkt 11. This is a very old house with bay windows, several storeys, many small vaulted rooms, and "the well-known famous pilsner beer" (meaning Pilsner Urquell). Aside from that, you'll spot many restaurants and "cellars" at which you can eat and drink.

Also, look for this season's newly released young wine, termed "sturm." You might see signs in the windows of restaurants and bars announcing "Sturm ist das!" A trip by car or tram to the nearby Vienna Woods and hills will lead you to the wine country. You'll find restaurants where you can sit, eat, and have the wine. You'll also find walking trails if you are so inclined. The wine village of Heiligenstadt (sp?) has the home at which Beethoven stayed when he began his great creative period in the early 1800s.

Munich, of course, is home to a half-dozen brewers, and you'll also spot other beers in the town. Each brewery runs a beer hall and a separate restaurant at which their beer is served. Central Munich is closed to car traffic and is a large pedestrian mall. It's easy to find the Hofbrauhaus in one of the plazas. I also recall a bar call the Bier Museum that had a good selection of beers. As reported in HBD, you'll see the way the Germans serve pilsner, namely, squirt some in the glass, let it sit, squirt some more, etc. Evidently, the pilsner pour gives the beer the desired mouthfeel. Also, you must have Weisswurst, mustard, pretzel, and beer before Noon.

The Munich beers are: Augustiner, Hacker-Pschorr, Hofbrau, Lowenbrau, Paulaner, and Spaten. You might also spot Ayinger. I don't have it with me, but Michael Jackson's Pocket Guide to Beers is a good reference to Munich, and you really ought to carry it on your trip.

Aside from beer, Munich has fine churches and museums, and an outdoor market in the town center.

Lastly, take notes and tell us about the trip when you return!

>and there is no starch left, aren't the enzymes just sitting there doing >nothing anyway? Is there something else going on?

I'm pretty sure that Steve meant "conversion" in general. Hopefully, when

you begin the mash-out, all your starch has been converted at least to dextrines. If you want a dextrinous wort, you want to stop the conversion

of dextrines to simple sugars. You're right about the starch, though, you

really do want to convert all the starch, but not always do you want all your wort's sugars to be glucose (that, by the way would be a wort destined

to be dry beer).

Then js writes:

>The other, and probably more popular method among homebrewers, is the (for

>lack of a better term) plastic bucket system. I really don't know what this

>is called but have seen numerous references to zapp and would like someone

>else to help here. I have never used this system but understand it to be

>adding hot water to grain in a bucket and after a prescribed period of time,

>it is transferred to another bucket with a false bottom or grain bag and hot

>water is run through this for sparging. Some calculation and planning must

>be done to assure that the mash arrives at the right temperature when the

>water and grain are mixed and substantial insulation is required to maintain

>the temperature through the process. Little can be done to adjust it once

>underway.

The Zapap Lauter Tun is just that, a lauter tun and has no ties to whatever

method of mashing you use. The Zapap tun is from Charlie's book (those familiar with Harry Caray will realize the source of the name sooner) in which

Charlie describes several mashing methods. I've built a Zapap and have

purchased a sparging bag, but have not done a direct comparison yet. I plan to first build a slotted-tube-in-cooler lauter tun and then compare all three.

>>How could it take 2 hr to run water sparge water through your grain bed >>unless the sparge was stuck (set mash?).

>In most cases, it is by choice. The ghurus claim that the longer it takes, >the better the extract efficiency. This is another debatable point but I >suspect that in some systems, such as the grain bag approach, there is no way >to rush the job. In the kettle, it will run off as fast as it can get >through the spigot. I have to adjust the spigot to get the appropriate flow >rate. I also sparge with boiling water to assure that the temperature >remains in an acceptable range.

I believe that noone has said that "the longer [the sparge] takes, the better the extract efficiency." Rather, all experts agree that \*TOO FAST\* a sparge will lower efficiency. There is a happy medium, which can be reduced by keeping the grain as close to 170F as possible, throughout the sparge.

>Other than the publicity from a very popular book for the bucket approach, it >is hard to understand why so many brewers have opted away from kettle >mashing. You need a kettle anyway and in this simple and (in my opinion) >superior approach, the transition from extract to all-grain becomes learning >the process instead of collecting a bunch of equipment.

As I've noted earlier, Charlie's book, "The New Complete Joy of Home Brewing," describes both single-step infusion and step ("temperature-controlled" or "upward-infusion") mashing. He also very-basically describes decoction mashing and refers the reader to Greg Noonan's book, "Brewing Lager Beer."

You can build a Zapap Lauter tun for under a dollar, so your argument about "collecting a bunch of equipment" is full of holes (pun intended). You can get two 5 or 10 gallon HDPE buckets free from a local bakery or restaurant and rather than using a valve (which would be better) you can use a length of hose and a plastic, adjustable hose (pincher) clamp.

If you bought Charlie's book, Jack, I'll bet you could learn a lot.

Back to kettle mashing for a second. If you've got a non-removable false bottom, you cannot stir the liquid that is closest to the heat and it would seem to me that Jack's pipe-and-window-screen kettle would also make stirring at the very bottom of the kettle inconvenient, at the least. Both these cases are invitations for scorching both the mash and the wort.

Al.

From: tony@spss.com (Tony Babinec)  
Subject: london-area pubs

A bit of background which you might already know: English pubs are either "tied" (attached) to one of the brewers or "free." You want to find a "free house" that features different beers from different brewers. On the other hand, a tied house is fun when you can sample two or more beers from the same brewer and the brewer is one of the independents such as Fuller's or Young's.

Speaking of which, the Young's brewery is in Wandsworth and the Fuller's brewery is in Chiswick, both on the west side of town. I visited Wandsworth, which I recall being within walking distance of the Clapham Junction rail station. You'll find several Young's pubs there. I didn't tour the brewery, but those who have say it's a terrific tour. At a Young's pub, sample the Ordinary and the Special bitters. At a Fuller's pub, go for the Chiswick Bitter and the ESB! Above all, look for cask-conditioned real ale served from the hand pull tap.

Most pubs have a last call about 10:45 and close at 11. So, in order to use your time wisely, you might either try to have a bit of food at a pub, or quaff ales all evening and then look for a place to eat around closing time. You can find ales at the restaurants, and there are also some all-night dance clubs that serve ale.

Michael Jackson's Pocket Guide recommends:

The Lamb at 94 Lamb's Conduit St, Bloomsbury--Young's pub

Star Tavern at 6 Belgrave Mews West, Belgravia--Fuller's pub

The Sun on Lamb's Conduit St.--wide range of out-of-town ales

any of the Firkin chain, for example, Frog and Firkin,  
41 Tavistock Crescent--their own beers, including Dogbolter

The Orange, 37 Pimlico Rd--try the Porter!

The Greyhound, 151 Greyhound Lane, Streatham Common

I had the good fortune to go to London for business a couple of years ago. My colleagues put together a pub crawl that starts at the Thames near the center of London and visits pubs in Chelsea and Belgravia. You'll notice a number of the above pubs listed below. You might not want to do the whole thing in one crawl!

Ferret & Firkin, Lotts Road, Chelsea--own beer

Cross Keys, Lawrence Street, Chelsea--Courage (try Director's)

Orange Brewery, 37 Pimlico St, Pimlico--own beer

Antelope, Eaton Terrace, Belgravia--Benskins

Star, Belgrave Mews, Belgravia--Fullers

Nags Head, 53 Kinnerton Street, Belgravia--Benskins

Grenadier, Wilton Row, Belgravia--Watneys

Final advice--Get a map of London, and get the CAMRA Good Pub Guide, which you should find at better bookstores.

>From all the mail I have been receiving about the AutoMash, I thought it would be worth-while posting the information about it here.

Specifications:

Grain Capacity: 5 - 11 lbs.  
Liquid Capacity: 18 qts. max.  
Mash Steps: 1 - 5 plus delay.  
Maximum Step Duration: 2hrs, 5 minute intervals.  
Maximum Delay: 12 hours, 15 minute intervals.  
Temperature Range: 40 - 180 F, accuracy +/- 2 degrees F.  
Power Requirements: 120 VAC, 60 Hz, 1500 Watts.  
Safety: over/under temp., over current, low water, all grounded construction.

Made by:  
Scientific Brewing Systems  
1125-B Arnold Drive, Suite 256  
Martinez, CA 94553

(415) 376-6000

List price: \$599.00

I am in no way connect to SBS other than a satisfied customer. When I first received the unit I had a few questions/concerns about it and called them. I had to leave a message but they called back shortly and were very friendly and helpful.

From: Bob\_Konigsberg@3mail.3com.com  
Subject: Yeast growth rates

In hbd #942, John DeCarlo asks about yeast reproduction rates.

According to Dr. Lewis of UC Davis, the reproduction cycle of yeast is about 120 minutes. In addition, the reproduction cycle of wort spoiling bacteria (he didn't specify particular ones) is about 20 minutes under similar conditions. This means that the wort spoilers can, in 24 hours (enough to let you not relax and worry), overwhelm the yeast and do their damage. The yeast do eventually finish up the job, but the beer is already trash at that point (Unless you LIKE lactic acid).

All the more reason for a good starter. I recommend a 1 quart starter with a 2 to 3 day lead time on pitching. My friends and I then see lag times measured in single digit hours or less. Since I usually brew in the evening, I don't stay up to watch, but it's always busy in the morning.

>This is the conventional wisdom. There is no way a 10 min mash out at >170f is gonna stop conversion. I can name at least two local breweries >that MASH at 160-162f! (Thomas Kemper and Hales) and I suspect a lot >more around the PNW do as well. Another 8-10f isn't going to magically >kill the enzymes.

Enzymes are the closest things to magic on earth, really, and they are proteins, so it's not surprising that 8 or 10F \*could\* denature them in a very short time. I'm only going by data from Fix, Papazian and Miller, but all three mention deactivating enzymes in the mash-out.

Unfortunately,

George and Charlie are a bit sketchy on the temperature at which Alpha-amylase (a-amylase) and Beta-amylase (b-amylase) really, denature, but Dave says that 5 minutes at 168F will "stop all enzyme activity positively." Now, I don't exactly agree with this, but we must consider the actions of these two most important enzymes. A-amylase breaks long chains of glucose molecules (starches) into dextrans (liquification or dextrinization). B-amylase produces glucose, maltose (two glucose molecules) and maltotriose (three glucose molecules) from the starch molecules (saccharification) but is limited when it hits a 1-6 link in the

starch chain. A-amylase works best at warmer mash temperatures (149-153F)

whereas b-amylase prefers lower temps (126-144) and according to Charlie, b-amylase will "become deactivated within 40-60 minutes at a temperature of 149F." Therefore, temperatures favoring b-amylase produce worts that are more fermentable and temps favoring a-amylase produce worts that are less fermentable (so, since I love beers that tempt you to spread them on toast, I can't wait to try Thomas Kemper and Hales beers during next years conference! -- BTW, the Winekeller Breweries here in metro Chicago, mash at 153F and their beers are like having sex in a canoe).

What I was talking about in my post, was primarily referring to stopping conversion in the context of making highly-dextrinous worts, although I probably did not mention it (oops). From what I've read and experienced, 170F may not stop a-amylase from cutting a few more large dextrans (let's hope there's no starch left) into smaller ones, but will effectively stop the b-amylase from creating more fermentables from the remaining dextrans.

How long has it been in the bottle? Beer carbonated with DME or gyle  
takes longer to develop carbonation. It is well worth the wait though. I  
usually find that about an extra week over what I was used to with corn  
sugar  
does the trick. This is, of course, only one brewer's opinion but I'm

I'm sorry, I missed the posting in 941 (I was on vacation--yipee!), and have to note that I was misquoted by Al Korzonas. I just happen to have a copy of my presentation here; anyone who attended will tell you that I read certain parts verbatim and this is one: "The cold break--which consists of similar organic compounds--begins after the wort has been cooled below 60 degrees C (140 degrees F)."

The problem is that Al heard "fahrenheit" when I said centigrade. Hence Alan's rightful confusion.

experience with extract beers. According to this fellow, even the most thorough of water purification cannot guarantee a 100% kill of bacteria. This isn't a problem for drinking water, as there's no real opportunity for the bacteria population to increase -- in your glass or in your body. However, if you then introduce a few cells into an environment like fresh wort -- wonderful temperatures, lots of sugars -- then you can get plenty of bacteria.

Nowadays, when I teach beginners I always urge them to boil EVERYTHING (and in fact, a full wort boil is even better, for other reasons) that is going into the fermenter. The system I use calls for boiling 2-1/2 gallons or so a the day before brewing, cooling it down and adding it to the sterile carboy. The boiled, concentrated wort is added to that.

> I'm a novice brewer with about 7 extract batches under my belt (or 'down the hatch', I should say :-)) I didn't really know what I was doing at first (like I'm an expert now...), and so some flaws in my first beers escaped me in the beginning. Having had the summer to sit back and think about things, I realize that all my beers had the same funny, barely noticeable after-taste (astringent and bitter, but not like hop bitterness).

> All my batches were cloudy and one batch that I liked so much that I set some aside to savor over the summer developed into The Gusher Bottles From Hell\*.

> It doesn't take a rocket scientist to figure out that I had an infection problem.

> Good catch, really. You'd be surprised how many people continue to drink beer like this without understanding they have a problem!

> I changed a lot of things going from batch 1 to 7 including: switching from a plastic fermenter to a glass primary and secondary, started using a bottling wand, going to the blow off method, the addition of a wort chiller, switching from b-brite to bleach, switching from dry to liquid yeast, dry hopping...

> Well, you get the picture. Basically, if I saw it discussed on this digest twice, then I tried it at home ;-)

> The things that I kept the same were 1) I rinsed all my equipment with tap water after sanitizing and 2) I added 2 gallons of grocery store fill-it-yourself distilled water to my 3 gallons of wort after the boil.

> I figured that it's one or both of these things that's causing the infection.

> Change them both, why don't you. If you're sanitizing with the right concentration of chlorine you shouldn't have to rinse at all, and you're pretty much defeating the purpose by throwing that water onto your sanitized surfaces -- try using boiled water if you feel a need to rinse.

From: "CMD 2NDLT ALBERT W. TAYLOR " <S94TAYLOR@usuhsb.ucc.usuhs.nnmc.navy.mil>  
Subject: Yeast Reproduction

The question was asked how long does it take "before fermentation begins?" I think a point is being missed here. Fermentation begins as soon as the first yeast cell is capable of metabolizing sugar. That is as soon as it hits the wort (assuming rehydration). More accurately, it will begin when the yeast must shift to anaerobic metabolism, as soon as all the O2 is consumed. You won't see the results of fermentation until the wort has become saturated with CO2. I have seen CO2 evolving as soon as 4 hours after pitching, after a very large pitching rate.

Is it just me, or did everyone get a truncated HBD on 6 August? Will someone please send me the complete issue? Thanks!  
Al Taylor

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Re: Counter Flow Chillers <rocket science>

In HBD #941, on 3 Aug 92, Joe Rolfe asked about cutting down on water usage and getting a lower output temperature from his counterflow chiller.

Here is the Rocket Science part.

My source is 'Cryogenic Engineering' by Russel B. Scott, D. Van Nostrand Co. Inc. 1959. Heat exchangers are important to cryogenics because they form a very important part of the refrigerators used to liquify gases. It really is "rocket science", since you need lots of LOX and other gasses to "make der rockets go up." Other engineering books on steam power, oil refining and thermo-hydrodynamics will provide similar information.

I'm not going to go into the mathematics, but try to explain everything as empirically as possible. Heat transfer equations are very heavy on differential equations. This stuff is not only hard to type without a mathematical typesetting system, but it isn't very accessible to most people.

Joe's questions get right to the nub of the tradeoffs involved in heat exchangers. In the best of all worlds, you would use as little water as possible, get the biggest temperature drop, and do it as quickly as possible. Unfortunately, all three of these factors work against at least one of the others. All of these factors are expressed in the heat-transfer coefficient.

This coefficient is expressed as:

watts / [(cm\*\*2)(deg K) in CGS    Watts per square centimeter-degree Kelvin

That's how much heat flows into the wall of the heat exchanger tube from the liquid in contact with the tube wall. The formulas assume that the tube is straight, cylindrical, and smooth, and that the flow of the liquid inside of it is turbulent (i.e. the tube is small enough that the flow doesn't channel in the center.) The factors that determine the heat transfer coefficient are:

The specific heat of the fluid - This is a measure of heat (as opposed to temperature) and empirically is measured by how much ice is melted by a given mass at a given temperature. Beer wort has a higher specific heat than water. The concept of specific heat supposedly came from Count Rumford burning his mouth on some apple sauce. The apple sauce was at the same temperature as his tea which didn't burn. He had just got his first thermometer and was measuring everything in sight.

The mass velocity of the liquid: g / sec cm\*\*2    How much mass is passing through a given cross section each second. For a given tubing size, this is strictly determined by the available pressure and flow. For your water supply this is effectively limited by the maximum pressure available.

The thermal conductivity of the liquid. Surprisingly, this is quite low

for most liquids. Water is nearly an insulator, if all convection is suppressed. I assume that wort has a low conductivity as well. Things like mercury and sodium metal have high conductivity.

The diameter of the tube. For tubes that don't have a circular cross section, this is replaced by the "hydraulic radius" which is defined as the cross-sectional area divided by the wetted perimeter.

In designing a heat exchanger, there are only a few of these things that we can influence. We can alter the mass velocity by turning up or down the flow on the faucet or altering the siphoning height. We can pick the diameter of the tube that we use.

Remember that we are looking at maximizing the heat-transfer coefficient at one point of the tube in one direction (wort to tube or tube to water)

We are only dealing with a slice, so that if the transfer coefficient is maximized, then we will get the most heat transfer out of a given length of tubing. The transfer coefficient will also set an upper limit on the in/out temperature differential for a particular length. If the tube was infinitely long then the water out temp and the wort in temp would be equal, and the wort out temp would be the same as the water in. The drawback with an infinitely long tube is that you would collapse both your lungs before you could get the siphon started. Also for an immersion type cooler, it would not be possible to fit an infinite amount of tubing in your brew pot, no matter how tightly you coiled it.

At any rate, you want the coefficient as high as you can get it. It is maximized when the tube is small (or the hydraulic radius is small) and the mass velocity is big. This has several implications:

- 1) better heat transfer means using more water (faster flow).
- 2) Smaller tubes are better than bigger ones. This makes sense, since there is more surface area for the same amount of copper. It is limited by the ratio of cross sectional area to wall thickness. The very small tubes have a problem with this, in that their inside area is small compared to the relative thickness of the wall. Heat transfer is inversely proportional to wall thickness, so there is a limit to how small is small enough.

Well, we don't want to use more water, so that's out. Joe is already using 1/2" tubing in his cooler, so it would be rude to tell him to get smaller tubing. Wasteful too. What we can do is decrease the hydraulic radius of his tube. A circular cross-section has the lowest possible ratio of area to perimeter. This is why bubbles are round. So how about making the copper tubing not round. There are some very high efficiency fluorescent light tubes that have a rippled surface to increase the surface to volume ratio. The tubes look pinched, the pinches alternating 90 degrees from each other. Maybe this could be done with a pair of vice-grip pliers so the tube doesn't get pinched too much.

This high ratio of surface area to volume is why the breweries use flat plate coolers, the transfer coefficient is quite high if you get away from using tubes. Multiple small tubes in parallel are also used for high efficiency heat exchangers.

If you are building a cooler, here are some things to consider:

\* for the same price, more feet of small tube are better than fewer feet of big tube.

\* The coefficients in a counterflow exchanger need to match. The water side will have to have a larger flow to match the lower specific heat of water compared to wort.

\* If you have a choice, thinner copper tube is better since heat flow is equal to conductivity / thickness.

\* When using an immersion chiller, stir the wort. This will raise the mass velocity on the wort side and improve the heat transfer. Remember: water and wort are poor conductors, heat transfer takes place by convection.

To get into the true "rocket science" of counterflow wort chiller design, the specific heat, conductivity and viscosity of hot beer wort need to be known. Can anybody help?

Date: Thu, 6 Aug 1992 13:19:52 -0700 (PDT)  
From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: History of Sparging and Mashout

Sparging is a fairly recent technique. In Andrew Ure's 'Dictionary of the Practical and Useful Arts', 184?, sparging is described as a process only used in Scotland for producing high gravity ales. Traditional English ale brewing used multiple mashes to get all the extract. Usually there were three mashes: Strong Beer, Middle or Ordinary, and Small Beer. The respective gravities were 1.060+, 1.030+ and 1.020-. Small beer was sometimes called Table beer. It is also the source of the saying, "That's small beer [compared to...]" Each of the three mashes was brewed and fermented separately. Porter was the first English Ale that combined the mashes. [See Terry Foster's 'Porter']

Ure's article on beer is very complete. The process of sparging is well described. Ure even compared the yields of sparging vs triple mashing, noting that sparging gave a better yield. He encouraged the adoption of sparging as an improvement to the brewing process, and lamented that more brewers didn't avail themselves of this technique.

The reason for sprinkling the sparge water over the top of the grain bed is that the mash tun was not kept full of liquid during the sparge. About half the wort was run out before the sparging was started. The sprinkling was necessary to prevent channeling in the grain bed. No mention of why this was done. The modern method of keeping the liquid level above the grain only requires that the added water not disturb the grain bed.

Why let the liquid level drop? My guess is that brewers were just continuing to hold on to the old practices learned from the triple mash method. If more than half of the liquid was drained the "goods" might get too compact and stick. The liquid was needed to float the grains so they didn't get too tight.

My next reference to sparging comes from the 1895 Encyclopedia Britannica (article on Brewing.) Now everybody is sparging and the description is the same as Ure's. Ure is even cited as the source for improved yield for sparging. No mention is made of the triple mashing method.

So in 50 years, sparging went from a curious custom of the savage Picts (just kidding) to the standard brewing practice in England. Neither of these two sources say anything at all about lager brewing. All references are only to England. The inference is that lager brewing was a rarity in England at the turn of the century.

So sparging is a recent practice, less than 150 years in widespread usage.

Here's a puzzle: Neither of these two sources say anything about mashing out. The descriptions are quite detailed as to temperatures and so forth, so it's not an oversight.

Who can find an early reference to mashing out? What is the origin of

this curious custom?

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Mashers & Coolers from Micah Millspaw

Wort chillers and igloo coolers.  
Unless I misunderstood, several HBers are using the round vertical type ice chests as lauter vessels, that is something to sparge in. Since these industrious brewers have gone to the trouble of putting a false bottom in the cooler why not use it as you mash tun as well, these things are certainly well insulated.  
Also I have seen 10 gallon metal coolers of this type at hardware stores for around \$50 they are galvanized on the outside and have a food grade coating on the inside. A fellow in my homebrew club made a mash/lauter tun from one of these coolers and is very happy with it.

On to wort chillers, I am planning to build a newer, and I hope better immersion chiller. The basis of my idea is that with a 1/2 inch copper line with tap water running thru it picks up from the wort about as much heat as is possible in the first nine feet. And so I intend to build a chiller that uses 4 circuits each 12 ft long in parallel made of 1/2 inch copper. I will have to use a manifold on both the inlet and outlet and will probably add some temperature sensors and water pressure gauges, in hope that these may give some way to optimize the delta T by varying the flow rate. Anybody try anything similar? If so please post the pluses and minuses. Thanks

From: camartens@ucdavis.edu  
Subject: SmartCaps Info

TO: BEER NET MEMBERS

FROM: BRUCE ZENNER,  
VICE PRESIDENT, RESEARCH AND DEVELOPMENT  
AQUANAUTICS CORPORATION

CONCERNING: USE OF SMARTCAPS\*

Some friends and fellow brewers who are on BeerNet told me that there had been some discussion of SmartCaps and how to use them effectively. Aquanautics developed these crowns in collaboration with a closure manufacturer, Zapata Industries. I headed the development project.

These crowns have a liner material containing an oxygen scavenging formulation, and can remove headspace oxygen and control oxygen permeation through the gasket material for up to six months. The chemistry is a catalyzed oxygen reduction system, and is generally regarded as safe (GRAS) by U.S. FDA criteria.

SmartCaps\* are activated by exposure to high humidity, thus they are stable under normal storage conditions, and activated by the moisture content in beer. However, they should NOT be boiled to sterilize, since this will activate the oxygen reduction system prior to use, and decrease the effectiveness of the SmartCaps following bottling.

If you sterilize your SmartCap crowns, do so by hypochlorite (bleach) or metabisulfite treatment instead of boiling; you'll increase the effectiveness of the SmartCaps.

If you have any questions, or comments, I can be reached by calling Aquanautics at (510) 521-4331, or by writing to me:  
Bruce Zenner  
Aquanautics Corporation  
980 Atlantic Ave., Suite 101  
Alameda, CA 94501

Our technical services representative, Charles Benedict, can also answer questions if I am not available.

Good luck and remember, there are no bad beers....some are just better than others!

Hi everyone. My name is Craig Martens. I am relatively new to brewing and beernet. In response to Michael Lewandowski's inquiry about SmartCaps on July 14, I asked Bruce if he would write a little blurb about their use being

that he is their inventor and also a homebrewer. I would just like to add that  
I receive nothing for doing this etc. You can also reach Bruce through me if you have any questions at [camartens@ucdavis.edu](mailto:camartens@ucdavis.edu). Brew long and prosper.

Date: Thu, 6 Aug 92 17:22:08 EDT  
From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re Wort cooling (added salt)

Adding salt to the ice blocks used in chilling isn't going to help much (if at all). What the salt does in icecream making is allow the water to stay liquid (thus contacting more of the surface of the inner canister and cooling it more effectively than straight ice) at temperatures below its normal freezing point; you can produce horrid icecream by putting too much salt in the freezer, which gets the mix too cold too quickly and produces ice crystals instead of smooth-frozen cream.

Somebody who has a better grasp of munging specific heats might be able to say whether having the ice become water at a lower temperature represents an improvement in cooling; in a previous round I was told that the specific heat of ice is much lower than that of water. But this isn't likely to be a large effect, since the freezing point won't be depressed very much---I think the limit for salty water is ~5 centigrade degrees based on the freezing-point depression of water and the maximum solubility of salt in water.

From: BELLAGIO\_DAVID@Tandem.COM  
Subject: RE: Infections with Tap Water Rinse

In reply to Phil Miller's query about infections from tap water, I will have to start by saying that I am also a NOVICE with only 2.5 batches under my belt.

I have an R/O system for my water supply that I use for my brew water. It makes a world of difference. I still boil all of my water, but I still rinse with tap water. What I do is turn up my hot water heater the night before to its hottest position. Then I rinse with this HOT water. I measured the temp and it was between 160 and 170 degrees. You actually develop a tolerance to hot water after numerous sprays on your body and hands. I figure that anything in there was killed by the overnight increase in temp.

> Tap water (at least most taps) contain VERY few bacteria or fungi. You  
> could hardly even find one at high magnification.

I think the idea of adding chlorine to the water is in order to kill bacteria.  
I don't know if all bacteria is killed however.

> The things that I kept the same were 1) I rinsed all my equipment with tap  
> water after sanitizing and 2) I added 2 gallons of grocery store  
> fill-it-yourself distilled water to my 3 gallons of wort after the  
boil.  
> I figured that it's one or both of these things that's causing the  
infection.

I think the tap water rinse is probably OK, but would suggest at least doing a hot water rinse. I think your problem is adding the unboiled grocery store water. Even though it is distilled, the container you used may not have been sanitized and/or the water coming out is not actually what you think. You should simply boil it separately and let it cool covered, then add it in. This is only my novice opinion.

Now a question for the more experienced. It seems that I have ran into my first screw up as a brewer. I recently made a Christmas Ale which ended up with a OG of 1.063. I racked the cooled wort into my primary 6.5 gallon plastic fermenter and topped up with sanitized cool water to what I thought was the 5 gallon mark, but then I worried I put too much in. I pitched the yeast and figured Not to Worry. Well that was 8/2 and now on 8/6 the kraeusen has gone into the airlock and clogged it. I assume this led to the

lid popping off the fermenter. I ferment under my house as it stays at 70 degrees during the summer and also has lots of bacteria present. My question is what to do now? I think I have a few options:

- 1) Get pissed off more than I am now and chuck the whole thing and brew a new batch and don't worry.
- 2) Rack some beer out and put the lid on and clean the airlock and then worry about whether it is infected or not.

I used Wyeast 1007 and noticed that the description that someone posted before stated that it has high flocculation compared to medium for all the other Wyeast ale yeasts. Does this mean it will produce more kraeusen? The problem also is I probably will take action before I get to hear any of your responses, but will welcome them to help determine what to do if this happens again.

Super Dave

Subject: The Alien Retorts

Re: Donald O'Connor's diatribe of yesterday

Gee, Don, my post evidently got under your skin. Sorry, Pal. I ruined several batches of beer because I didn't change the o-rings and was simply trying to keep a fellow brewer from making the same mistake. It appeared to me that you were talking from a theoretical point of view. I enjoy theoretical discussions as much as anyone but experience is the final arbiter. I was just passing along my experience.

So. While we're on the subject. Just what have you been doing? Have you been kegging your beers using old o-rings? Have they been turning out OK? For the record, the stouts I made suffered no discernible Coke flavors. It wasn't until I made a lager that I realized something was amiss.

As for the pot scrubber idea, I got it from my late brewing partner, Mike Morrissey, the guy responsible for both bringing the Bruheat into the U.S. and for helping me refine the bottomless fermenter which eventually turned into the BrewCap. He said he didn't know where he saw the idea first but he thought it was a good one. It could have been Al Andrews. If you say it was, I have no reason to dispute it. It is a good idea and kudos to Al. All I know is I've been using the scrubber for years. The flourish I added was to wrap it in a fine mesh hop bag which, for me, greatly increased the filtering action. In the spirit of the digest, I passed it along. I sure wasn't trying to slap myself on the back. That always throws my elbow out of joint and I hate it when that happens!

Frankly, I'm irked by your claim that I'm not interested in any "facts that contradict my truth". While you might truthfully say that of yourself, I called on the chemists to settle the dispute on the blue stuff on copper. I AM interested in knowing what the stuff is. I HAVE seen it in my wort chillers and I DON't want to contaminate anyone's beer. Jeez!

Aw. What the Hell. I can't resist...

>By the way Kinney, the next meeting in Austin for the support group >for humans who have been abducted by aliens is September 13. (I'm >not making this up.) Bring your o-rings.

That's OK, Don. You take my ticket. Texas is a long drive from here.

Just another cheap, boneheaded, heretical post from the Southland.

Sigh. It's times like these that make me wish for the good ol' days in the HBD when the members of this forum were only interested in open minded, friendly discussions of the issues; when we were all genuinely

concerned about helping each other in their quest for the world's perfect beer. Remember when people used to commend us for being the best-behaved bunch on the net? Remember when?

From: Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU>  
Subject: Yeast reproduction and cold break formation figures

Now let's see if I can get in a post without being flamed...

HBD regular and Fidonet Zymurgy leader, John de Carlo asks:

>Can anyone point me to a reference that describes the typical  
>yeast reproduction activity for homebrewers?

This may not be exactly what you want, John, but I finally found this table when cleaning off my miserable excuse for a desk this past weekend. Dave Logsdon gave it to me about 6 years ago as he was getting Wyeast off the ground.

#### Yeast Reproduction Time

TEMPERATURE    ALE    LAGER

104 degrees F.	4.0 hr.	no growth
95    "	2.0	4.8 hr.
91	1.4	1.8
82	1.6	2.0
68	3.2	3.7
50	11.0	9.0
45	42.0	24.0

As I understand this table, it effectively gives us a report on lag time. The smaller the hour figure, the shorter the lag time. Clearly both lager and ale yeast reproduce at faster rates at temperatures of between 82 and 91 degrees. The reproduction rate is still vigorous but starts falling off at temperatures between 68 and 82 degrees.

These are not recommended fermenting temperatures. I assume they speak to the respiration phase when the yeast is/are reproducing and have yet to start fermenting the wort. At least that's my recollection of the conversation I had with Dave. (Yo, Jeff. If you're listening, correct me if I'm wrong.)

It's as a result of this table that I've advocated pitching yeast at around 70 degrees then moving the fermenter to the basement/refrigerator. The yeast reproduces at a comfortable temperature and should be hitting a reasonable population figure by the time the wort cools to the ambient temperature of the fermentation room/chamber and starts fermenting. Of course if you're pitching with an up and running yeast starter with a sufficient yeast count, the pitching temperature of the wort is not as critical.

Alan Edwards notes:

>Al Korzonas writes (in HBD #941):  
>| In his talk on wort chillers at the Conference, Jeff Frane said the most  
>| enlightening (to me) fact of the whole conference: that cold break begins  
>| at 65F. Wow!

>Has anyone heard this statement made anywhere else? Anyone's experience  
>bear this one out? I have a VERY hard time believing that you need to

>cool below 65F before you start getting cold break.

>Before I started using an immersion chiller, I had maybe half an inch of  
>break material in my primary fermenter. Now that I chill the wort down  
>to about 70F, I get at least three inches of cold break (after it  
settles  
>for a few hours).

I decided to check my copy of Malting and Brewing Science on this one since I have the highest degree of respect for the opinions of both Jeff and Al. There I found the following chart that may shed light on this discussion.

Cold break (I added in the Fahrenheit temperatures -krb)  
(mg/ml)

If I may interpolate, trub formation is relatively light, albeit measurable, at temperatures above 100 degrees F. At temperatures below 100 degrees the curve begins to steepen significantly. I also think one could read the chart as saying that trub formation is minimal until it reaches the 64 degrees *Centigrade* rather than Fahrenheit, at which point it begins increasing until it reaches 40 degrees C. where it begins increasing at a moderately faster rate.

Yet again, if you look at the curve at around 64 degree F., it really starts taking off. So perhaps that's what Jeff was trying to say. I didn't hear Jeff's talk so I'm not sure what he said or what his sources are. Still, if this chart is to be believed trub formation begins, although slightly, once the wort begins cooling, though significant trub formation doesn't occur until wort temperatures drop to around 100 degrees F., with exceptionally fast cold break formation kicking in at 64 degrees F.

The text goes on to say,

"During the cooling of wort, cold trub progressively precipitates. It is impossible to remove all the potential precipitate because the trub continues to form during fermentation and subsequent beer cooling. However, many breweries, especially those concerned with lager

fermentation, remove much of the cold trub...

A recent survey has shown that in Swiss breweries, the cold break content of beers varied over a wide range...The effects on fermentation, maturation and beer clarification were not significant. During the course of successive fermentations, the preference of tasting panels shifted from beers where cold trub had not been removed to beers where partial removal had been practiced. The overall impression from other studies is that the presence of cold trub may stimulate the rate of fermentation, possibly by providing nuclei for carbon dioxide release; on the other hand, with more delicate beers there seems to be more possibility of having unacceptable sulphury aroma and taste.

.....

The production of cold trub has received little biochemical study. Many years ago, it was claimed that to get maximum trub production it was necessary to cool slowly over the range 120-80 degrees F., at least 30 seconds being required, and mechanical agitation being desirable. Later results described worts where the best cold trub formation occurred when cooling from 140-70 degrees F. took place in 3 seconds or less." (pp. 523-524)

So there you have it according to Hough, Briggs, Stevens and Young. Some cold trub is formed as soon as the beer begins cooling, with significant trub production beginning around 64 degrees F. Not only temperature but also the speed at which the wort cools appears to be a factor according to some. Its removal seems to be more important when brewing delicately flavored beers than with heavily flavored ones. At least that's the way I read it.

Troubles on my mind,

Kinney Baughman

From: klm@mscg.com (Kevin L. McBride)  
Subject: Ken Johnson, the lamest

Warning: This article contains a mild flame. I tried to resolve this matter by e-mail, but Ken seems to be either incapable or unwilling to engage in a conversation where he might have to admit that he may have stepped a little bit out of bounds.

I've kept it reasonably mild, but if you want to know what I really think about this subject, ask me by e-mail.

I apologize in advance for the waste of bandwidth, but I needed to say this. I'm pissed and I think that at least some of you are too. To make up for this, I will post a recipe next.

On Thursday, July 30th, I sent the following letter to Ken Johnson in response to his unnecessarily harsh statement:

> You write:  
>  
> > If your beer quality goes down when switching to full mash beers,  
> then you  
> > are lame.  
>  
> and you make yourself look like a jerk for posting such crap. One  
> Jack Schmidling is enough, we don't need you posting flame bait too.  
>  
> Please consider posting an apology for this rash, completely  
> unnecessary statement.  
>  
> The purpose of the Homebrew Digest is to share knowledge and  
> experience. My first couple of mash experiences were miserable.  
> People on the HBD helped me fix my problems and now my beers are fine.  
> We don't want novices being scared off by self-proclaimed wizards who  
> say that you are lame if you can't figure it out by yourself.  
>  
> You probably just encouraged several beginning all-grain brewers to  
> switch back to extract brewing with your stupid comment.

I finally received a reply from Ken today, August 6th. His reply consisted of a single word:

"bullshit"

Ken, I attempted to be reasonable about this. I contacted you by e-mail and told you, without resorting to outright flaming, that I thought you were out of line and that the Homebrew Digest deserved an apology for your rash statement.

I now see that attempting to reason with you is like having an argument with a tree stump. You have shown yourself to be an asshole and I sincerely hope that you lose whatever credibility you may have had in this forum.

F.O.A.D.

From: klm@mscg.com (Kevin L. McBride)  
Subject: All-grain Smoked Porter recipe

The smoked porter served at Greg Noonan's Vermont Pub & Brewery inspired me to brew this. I love Greg's version and tried to come up with something similar.

The smoke flavor is a little bit more assertive than in Greg's brew, but is not so overpowering as to be unpleasant. The sweetness of the crystal and cara-pils balance the bite of the dark malt so that the beer is pleasantly bittersweet, as a porter should be, and the smoke flavor just floats over your tongue. The finishing hops are barely noticeable. The smoke masks most of the hop flavor.

The beer is 3 weeks old now. In a few more weeks it should be really wonderful.

The name was supplied by Dan Hall. Don't ask. We were indulging in a few bottles of really good Belgian beer at the time and I think we were slightly buzzed.

"Clubhouse Poked Smorter"  
=====

#### The Grist:

8 lbs. M&F 2-row lager malt  
2 lbs. hickory smoked M&F 2-row pale malt \*  
1 lb. Munich malt  
1 lb. Crystal malt  
1/2 lb. Choc. Malt  
1/2 lb. Black malt  
1/2 lb. Cara-pils

\* (I had 2 lbs. of pale just lying around, so I used that as the smoked grain for no particular reason other than to get rid of it.)

The smoked grain was done on a charcoal fired smoker with wet hickory chips. Total smoking time was close to 45 minutes. I would have cut the smoking time down, but I wet the grain first and it took that long for it to dry on the smoker.

#### The Mash:

Struck mash at ~120F for protein rest. Pulled a single decoction, brought to a boil, held for about 10 minutes, and re-infused to raise temp. to about 155F which was held in a 5 gallon Igloo cooler until conversion was complete.

Sparged with 4.5 gallons of 170F water. Yielded ~7 gallons of wort.

#### The Boil:

Total boil time about 70 minutes.

1 oz. (~30 IBU) Northern Brewer plug hops (boiling 60+ minutes)  
1 oz. Cascade leaf hops (finishing ~5 minutes)

Chilled with Dan Hall's Immersion Chiller from Hell.

Original Gravity: 1.052 (Actual yield to the fermenter was about 5.5 gallons and this was after a good boilover where I lost at least a quart)

Pitched a 16oz. starter of Wyeast 1028 London Ale made from a culture that lives in my fridge and has served me faithfully for a number of brews.

After 5 days in primary, I racked to a keg and refrigerated. I am slowly artificially carbonating it and letting it settle and mature. It won't be formally served until the September BFD meeting, but it is already shaping up to be a fine brew. (I sneak a taste now and then.) This beer should go great with sausage and other hearty foods.

Final Gravity: 1.016

that would be a good way to get the juice from the apples but where do  
you go  
from there.

>  
>If anyone has some recipes or suggestions please help and THANKS.

<don't use red star champagne yeast (ale yeast will  
make a sweeter product).

That advice depends on a few variables not the least of which is the  
sugar  
content of the juice. Most juice needs to have sugar added just to get  
enough alcohol to preserve it and the high tolerance of champagne yeast  
would  
not even enter the equation of most straight juice. It would run out of  
sugar before even ale yeast got tired.

Secondly, one can always add sugar to adjust the sweetness after  
fermenting.

Thirdly, one usually will add lots of sugar to make a higher alcohol  
apple  
wine and ale yeast would produce an undrinkably sweet wine.

>From: BOB JONES <BJONES@NOVAX.llnl.gov>

>Subject: Wort cooling

>I use a immersion chiller placed in my kettle to cool the wort. During  
the  
summer months the tap water is warmer and I will use another immersion  
chiller to pre-cool the water by placing this cooler in a 5 gal bucket  
of  
cracked ice... I have wondered if it would help to add salt to the water  
before it freezes. This works to lower the temperature when  
freezing ice cream, so why not in cooling wort?

It will just make your freezer work harder freezing it. You should put  
the  
salt in the chiller with the ice to lower the temp of the water but the  
ice  
will melt faster so you will need more. You just can't get nothing fer  
nothing no mo.

>correction would have to be made if the reading was taken from  
>the hot liquor.

Whenever specific gravity is measured with a hydrometer, the reading must be corrected if the temperature of the solution is other than 60F.

I sparge with water at 170F, the temperature of the runoff is ~140F-150. (I really have to do something to insulate my lauter tun a little better). According to the references I have, this temperature requires a correction of, if memory serves, 15-16 points. So, when I say I stop sparging at ~1.010 - 1.015, the hydrometer is actually reading 0.995 - 1.000.

> In HBD#942, Larry Barello wrote:

<portions of thread regarding reasons for mashout deleted>

>This is the conventional wisdom. There is no way a 10 min mash

>local breweries that MASH at 160-162f! (Thomas Kemper and Hales)  
>and I suspect a lot more around the PNW do as well. Another  
>8-10f isn't going to magically kill the enzymes.

A couple of months ago, I had an experience that would seem to substantiate that statement. I arrived at my brew partner's house a little late, as he had just started heating the mash up to the sugar rest range. We started socializing, neither of us was paying any attention to the mash. About 20 minutes later, we finally got around to checking the temperature, and it was at 175F. I'm not sure how much time it spent at that temp, probably 10-15 minutes. We quickly added some cold water to get the mash temp down below 160F, we were both concerned that what we had made was a very expensive batch of porridge. However, an iodine test done about one hour later showed conversion was complete. The beer came out fine. I had one other batch since then where the mash temp got

to 165F briefly, and that mash converted just fine as well.

The moral here is that the amalyse enzyme seems to be a little tougher than we give it credit for. I still mashout every batch, but I do it to get the grain to the same temperature as the sparge water, and thus prevent too much heat loss in my not-very-well insulated (for now) lauter tun.

Cheers,  
Jim

Subject: Soft water (how to get it?)

Ladies and Gentlemen of the Jury:

Next weekend I plan to try the extract triple recipe in Pierre Rajotte's Belgian Ale. In his listing Rajotte specifies that this should be brewed with soft water.

Several weeks ago I did what everybody always says to do, and contacted my local water board (in this case the Washington Aquaduct, serving Washington D.C. and Arlington, VA) for information on my water. I got back three massive charts listing everything anybody could conceivably want to know. Amidst this small print was the hardness table, stating that on average our hardness was 110 (was this for calcium carbonate?).

According to Charlie, soft water is rated at 0-50. I've read that water softeners don't actually remove the minerals but convert them, and I don't have a water softener anyway. Would it make sense to use enough distilled water to cut the value down to size (say, 3 gallons to two of tap water)? Or am I missing something?

I'm also perfectly willing to use 100% tap water if the alternatives are too complex.

Anyway, I am specifically appealing for help from any of our HBD chemists or experienced brewers. Having seen some of the more technical posts recently, I will ask that any explanations be kept to words of one syllable or less for us members of the chemistry-impaired. Thanks!

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Re: Counter Flow Chillers <rocket science>

In HBD #941, on 3 Aug 92, Joe Rolfe asked about cutting down on water usage and getting a lower output temperature from his counterflow chiller.

Here is the Rocket Science part.

My source is 'Cryogenic Engineering' by Russel B. Scott, D. Van Nostrand Co. Inc. 1959. Heat exchangers are important to cryogenics because they form a very important part of the refrigerators used to liquify gases. It really is "rocket science", since you need lots of LOX and other gasses to "make der rockets go up." Other engineering books on steam power, oil refining and thermo-hydrodynamics will provide similar information.

I'm not going to go into the mathematics, but try to explain everything as empirically as possible. Heat transfer equations are very heavy on differential equations. This stuff is not only hard to type without a mathematical typesetting system, but it isn't very accessible to most people.

Joe's questions get right to the nub of the tradeoffs involved in heat exchangers. In the best of all worlds, you would use as little water as possible, get the biggest temperature drop, and do it as quickly as possible. Unfortunately, all three of these factors work against at least one of the others. All of these factors are expressed in the heat-transfer coefficient.

This coefficient is expressed as:

watts / [(cm\*\*2)(deg K) in CGS    Watts per square centimeter-degree Kelvin

That's how much heat flows into the wall of the heat exchanger tube from the liquid in contact with the tube wall. The formulas assume that the tube is straight, cylindrical, and smooth, and that the flow of the liquid inside of it is turbulent (i.e. the tube is small enough that the flow doesn't channel in the center.) The factors that determine the heat transfer coefficient are:

The specific heat of the fluid - This is a measure of heat (as opposed to temperature) and empirically is measured by how much ice is melted by a given mass at a given temperature. Beer wort has a higher specific heat than water. The concept of specific heat supposedly came from Count Rumford burning his mouth on some apple sauce. The apple sauce was at the same temperature as his tea which didn't burn. He had just got his first thermometer and was measuring everything in sight.

The mass velocity of the liquid: g / sec cm\*\*2    How much mass is passing through a given cross section each second. For a given tubing size, this is strictly determined by the available pressure and flow. For your water supply this is effectively limited by the maximum pressure available.

The thermal conductivity of the liquid. Surprisingly, this is quite low

for most liquids. Water is nearly an insulator, if all convection is suppressed. I assume that wort has a low conductivity as well. Things like mercury and sodium metal have high conductivity.

The diameter of the tube. For tubes that don't have a circular cross section, this is replaced by the "hydraulic radius" which is defined as the cross-sectional area divided by the wetted perimeter.

In designing a heat exchanger, there are only a few of these things that we can influence. We can alter the mass velocity by turning up or down the flow on the faucet or altering the siphoning height. We can pick the diameter of the tube that we use.

Remember that we are looking at maximizing the heat-transfer coefficient at one point of the tube in one direction (wort to tube or tube to water)

We are only dealing with a slice, so that if the transfer coefficient is maximized, then we will get the most heat transfer out of a given length of tubing. The transfer coefficient will also set an upper limit on the in/out temperature differential for a particular length. If the tube was infinitely long then the water out temp and the wort in temp would be equal, and the wort out temp would be the same as the water in. The drawback with an infinitely long tube is that you would collapse both your lungs before you could get the siphon started. Also for an immersion type cooler, it would not be possible to fit an infinite amount of tubing in your brew pot, no matter how tightly you coiled it.

At any rate, you want the coefficient as high as you can get it. It is maximized when the tube is small (or the hydraulic radius is small) and the mass velocity is big. This has several implications:

- 1) better heat transfer means using more water (faster flow).
- 2) Smaller tubes are better than bigger ones. This makes sense, since there is more surface area for the same amount of copper. It is limited by the ratio of cross sectional area to wall thickness. The very small tubes have a problem with this, in that their inside area is small compared to the relative thickness of the wall. Heat transfer is inversely proportional to wall thickness, so there is a limit to how small is small enough.

Well, we don't want to use more water, so that's out. Joe is already using 1/2" tubing in his cooler, so it would be rude to tell him to get smaller tubing. Wasteful too. What we can do is decrease the hydraulic radius of his tube. A circular cross-section has the lowest possible ratio of area to perimeter. This is why bubbles are round. So how about making the copper tubing not round. There are some very high efficiency fluorescent light tubes that have a rippled surface to increase the surface to volume ratio. The tubes look pinched, the pinches alternating 90 degrees from each other. Maybe this could be done with a pair of vice-grip pliers so the tube doesn't get pinched too much.

This high ratio of surface area to volume is why the breweries use flat plate coolers, the transfer coefficient is quite high if you get away from using tubes. Multiple small tubes in parallel are also used for high efficiency heat exchangers.

If you are building a cooler, here are some things to consider:

\* for the same price, more feet of small tube are better than fewer feet of big tube.

\* The coefficients in a counterflow exchanger need to match. The water side will have to have a larger flow to match the lower specific heat of water compared to wort.

\* If you have a choice, thinner copper tube is better since heat flow is equal to conductivity / thickness.

\* When using an immersion chiller, stir the wort. This will raise the mass velocity on the wort side and improve the heat transfer. Remember: water and wort are poor conductors, heat transfer takes place by convection.

To get into the true "rocket science" of counterflow wort chiller design, the specific heat, conductivity and viscosity of hot beer wort need to be known. Can anybody help?

Subject: Milwaukee homebrew supply shops

Howdy folks

I have a buddy who'll be in Milwaukee at the end of the month. He'd like to know if there are any good homebrew supply shops. I'd appreciate any references, since I can get him to pick me up some cara-pils while there. (Rare as hen's teeth here in Montreal).

Thank you in advance, kind souls who send me info!

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: History of Sparging and Mashout

Sparging is a fairly recent technique. In Andrew Ure's 'Dictionary of the Practical and Useful Arts', 184?, sparging is described as a process only used in Scotland for producing high gravity ales. Traditional English ale brewing used multiple mashes to get all the extract. Usually there were three mashes: Strong Beer, Middle or Ordinary, and Small Beer. The respective gravities were 1.060+, 1.030+ and 1.020-. Small beer was sometimes called Table beer. It is also the source of the saying, "That's small beer [compared to...]" Each of the three mashes was brewed and fermented separately. Porter was the first English Ale that combined the mashes. [See Terry Foster's 'Porter']

Ure's article on beer is very complete. The process of sparging is well described. Ure even compared the yields of sparging vs triple mashing, noting that sparging gave a better yield. He encouraged the adoption of sparging as an improvement to the brewing process, and lamented that more brewers didn't avail themselves of this technique.

The reason for sprinkling the sparge water over the top of the grain bed is that the mash tun was not kept full of liquid during the sparge. About half the wort was run out before the sparging was started. The sprinkling was necessary to prevent channeling in the grain bed. No mention of why this was done. The modern method of keeping the liquid level above the grain only requires that the added water not disturb the grain bed.

Why let the liquid level drop? My guess is that brewers were just continuing to hold on to the old practices learned from the triple mash method. If more than half of the liquid was drained the "goods" might get too compact and stick. The liquid was needed to float the grains so they didn't get too tight.

My next reference to sparging comes from the 1895 Encyclopedia Britannica (article on Brewing.) Now everybody is sparging and the description is the same as Ure's. Ure is even cited as the source for improved yield for sparging. No mention is made of the triple mashing method.

So in 50 years, sparging went from a curious custom of the savage Picts (just kidding) to the standard brewing practice in England. Neither of these two sources say anything at all about lager brewing. All references are only to England. The inference is that lager brewing was a rarity in England at the turn of the century.

So sparging is a recent practice, less than 150 years in widespread usage.

Here's a puzzle: Neither of these two sources say anything about mashing out. The descriptions are quite detailed as to temperatures and so forth, so it's not an oversight.

Who can find an early reference to mashing out? What is the origin of

this curious custom?

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Mashers & Coolers from Micah Millspaw

Wort chillers and igloo coolers.  
Unless I misunderstood, several HBers are using the round vertical type ice chests as lauter vessels, that is something to sparge in. Since these industrious brewers have gone to the trouble of putting a false bottom in the cooler why not use it as you mash tun as well, these things are certainly well insulated.  
Also I have seen 10 gallon metal coolers of this type at hardware stores for around \$50 they are galvanized on the outside and have a food grade coating on the inside. A fellow in my homebrew club made a mash/lauter tun from one of these coolers and is very happy with it.

On to wort chillers, I am planning to build a newer, and I hope better immersion chiller. The basis of my idea is that with a 1/2 inch copper line with tap water running thru it picks up from the wort about as much heat as is possible in the first nine feet. And so I intend to build a chiller that uses 4 circuits each 12 ft long in parallel made of 1/2 inch copper. I will have to use a manifold on both the inlet and outlet and will probably add some temperature sensors and water pressure gauges, in hope that these may give some way to optimize the delta T by varying the flow rate. Anybody try anything similar? If so please post the pluses and minuses. Thanks

From: camartens@ucdavis.edu  
Subject: SmartCaps Info

TO: BEER NET MEMBERS

FROM: BRUCE ZENNER,  
VICE PRESIDENT, RESEARCH AND DEVELOPMENT  
AQUANAUTICS CORPORATION

CONCERNING: USE OF SMARTCAPS\*

Some friends and fellow brewers who are on BeerNet told me that there had been some discussion of SmartCaps and how to use them effectively. Aquanautics developed these crowns in collaboration with a closure manufacturer, Zapata Industries. I headed the development project.

These crowns have a liner material containing an oxygen scavenging formulation, and can remove headspace oxygen and control oxygen permeation through the gasket material for up to six months. The chemistry is a catalyzed oxygen reduction system, and is generally regarded as safe (GRAS) by U.S. FDA criteria.

SmartCaps\* are activated by exposure to high humidity, thus they are stable under normal storage conditions, and activated by the moisture content in beer. However, they should NOT be boiled to sterilize, since this will activate the oxygen reduction system prior to use, and decrease the effectiveness of the SmartCaps following bottling.

If you sterilize your SmartCap crowns, do so by hypochlorite (bleach) or metabisulfite treatment instead of boiling; you'll increase the effectiveness of the SmartCaps.

If you have any questions, or comments, I can be reached by calling Aquanautics at (510) 521-4331, or by writing to me:  
Bruce Zenner  
Aquanautics Corporation  
980 Atlantic Ave., Suite 101  
Alameda, CA 94501

Our technical services representative, Charles Benedict, can also answer questions if I am not available.

Good luck and remember, there are no bad beers....some are just better than others!

Hi everyone. My name is Craig Martens. I am relatively new to brewing and beernet. In response to Michael Lewandowski's inquiry about SmartCaps on July 14, I asked Bruce if he would write a little blurb about their use being

that he is their inventor and also a homebrewer. I would just like to add that  
I receive nothing for doing this etc. You can also reach Bruce through me if you have any questions at [camartens@ucdavis.edu](mailto:camartens@ucdavis.edu). Brew long and prosper.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re Wort cooling (added salt)

Adding salt to the ice blocks used in chilling isn't going to help much (if at all). What the salt does in icecream making is allow the water to stay liquid (thus contacting more of the surface of the inner canister and cooling it more effectively than straight ice) at temperatures below its normal freezing point; you can produce horrid icecream by putting too much salt in the freezer, which gets the mix too cold too quickly and produces ice crystals instead of smooth-frozen cream.

Somebody who has a better grasp of munging specific heats might be able to say whether having the ice become water at a lower temperature represents an improvement in cooling; in a previous round I was told that the specific heat of ice is much lower than that of water. But this isn't likely to be a large effect, since the freezing point won't be depressed very much---I think the limit for salty water is ~5 centigrade degrees based on the freezing-point depression of water and the maximum solubility of salt in water.

From: BELLAGIO\_DAVID@Tandem.COM  
Subject: RE: Infections with Tap Water Rinse

In reply to Phil Miller's query about infections from tap water, I will have to start by saying that I am also a NOVICE with only 2.5 batches under my belt.

I have an R/O system for my water supply that I use for my brew water. It makes a world of difference. I still boil all of my water, but I still rinse with tap water. What I do is turn up my hot water heater the night before to its hottest position. Then I rinse with this HOT water. I measured the temp and it was between 160 and 170 degrees. You actually develop a tolerance to hot water after numerous sprays on your body and hands. I figure that anything in there was killed by the overnight increase in temp.

> Tap water (at least most taps) contain VERY few bacteria or fungi. You  
> could hardly even find one at high magnification.

I think the idea of adding chlorine to the water is in order to kill bacteria.  
I don't know if all bacteria is killed however.

> The things that I kept the same were 1) I rinsed all my equipment with tap  
> water after sanitizing and 2) I added 2 gallons of grocery store  
> fill-it-yourself distilled water to my 3 gallons of wort after the  
boil.  
> I figured that it's one or both of these things that's causing the  
infection.

I think the tap water rinse is probably OK, but would suggest at least doing a hot water rinse. I think your problem is adding the unboiled grocery store water. Even though it is distilled, the container you used may not have been sanitized and/or the water coming out is not actually what you think. You should simply boil it separately and let it cool covered, then add it in. This is only my novice opinion.

Now a question for the more experienced. It seems that I have ran into my first screw up as a brewer. I recently made a Christmas Ale which ended up with a OG of 1.063. I racked the cooled wort into my primary 6.5 gallon plastic fermenter and topped up with sanitized cool water to what I thought was the 5 gallon mark, but then I worried I put too much in. I pitched the yeast and figured Not to Worry. Well that was 8/2 and now on 8/6 the kraeusen has gone into the airlock and clogged it. I assume this led to the

lid popping off the fermenter. I ferment under my house as it stays at 70 degrees during the summer and also has lots of bacteria present. My question is what to do now? I think I have a few options:

- 1) Get pissed off more than I am now and chuck the whole thing and brew a new batch and don't worry.
- 2) Rack some beer out and put the lid on and clean the airlock and then worry about whether it is infected or not.

I used Wyeast 1007 and noticed that the description that someone posted before stated that it has high flocculation compared to medium for all the other Wyeast ale yeasts. Does this mean it will produce more kraeusen? The problem also is I probably will take action before I get to hear any of your responses, but will welcome them to help determine what to do if this happens again.

Super Dave

Subject: The Alien Retorts

Re: Donald O'Connor's diatribe of yesterday

Gee, Don, my post evidently got under your skin. Sorry, Pal. I ruined several batches of beer because I didn't change the o-rings and was simply trying to keep a fellow brewer from making the same mistake. It appeared to me that you were talking from a theoretical point of view. I enjoy theoretical discussions as much as anyone but experience is the final arbiter. I was just passing along my experience.

So. While we're on the subject. Just what have you been doing? Have you been kegging your beers using old o-rings? Have they been turning out OK? For the record, the stouts I made suffered no discernible Coke flavors. It wasn't until I made a lager that I realized something was amiss.

As for the pot scrubber idea, I got it from my late brewing partner, Mike Morrissey, the guy responsible for both bringing the Bruheat into the U.S. and for helping me refine the bottomless fermenter which eventually turned into the BrewCap. He said he didn't know where he saw the idea first but he thought it was a good one. It could have been Al Andrews. If you say it was, I have no reason to dispute it. It is a good idea and kudos to Al. All I know is I've been using the scrubber for years. The flourish I added was to wrap it in a fine mesh hop bag which, for me, greatly increased the filtering action. In the spirit of the digest, I passed it along. I sure wasn't trying to slap myself on the back. That always throws my elbow out of joint and I hate it when that happens!

Frankly, I'm irked by your claim that I'm not interested in any "facts that contradict my truth". While you might truthfully say that of yourself, I called on the chemists to settle the dispute on the blue stuff on copper. I AM interested in knowing what the stuff is. I HAVE seen it in my wort chillers and I DON't want to contaminate anyone's beer. Jeez!

Aw. What the Hell. I can't resist...

>By the way Kinney, the next meeting in Austin for the support group >for humans who have been abducted by aliens is September 13. (I'm >not making this up.) Bring your o-rings.

That's OK, Don. You take my ticket. Texas is a long drive from here.

Just another cheap, boneheaded, heretical post from the Southland.

From: Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU>  
Subject: Yeast reproduction and cold break formation figures

Now let's see if I can get in a post without being flamed...

HBD regular and Fidonet Zymurgy leader, John de Carlo asks:

>Can anyone point me to a reference that describes the typical  
>yeast reproduction activity for homebrewers?

This may not be exactly what you want, John, but I finally found this table when cleaning off my miserable excuse for a desk this past weekend. Dave Logsdon gave it to me about 6 years ago as he was getting Wyeast off the ground.

#### Yeast Reproduction Time

TEMPERATURE    ALE    LAGER

104 degrees F.	4.0 hr.	no growth
95    "	2.0	4.8 hr.
91	1.4	1.8
82	1.6	2.0
68	3.2	3.7
50	11.0	9.0
45	42.0	24.0

As I understand this table, it effectively gives us a report on lag time. The smaller the hour figure, the shorter the lag time. Clearly both lager and ale yeast reproduce at faster rates at temperatures of between 82 and 91 degrees. The reproduction rate is still vigorous but starts falling off at temperatures between 68 and 82 degrees.

These are not recommended fermenting temperatures. I assume they speak to the respiration phase when the yeast is/are reproducing and have yet to start fermenting the wort. At least that's my recollection of the conversation I had with Dave. (Yo, Jeff. If you're listening, correct me if I'm wrong.)

It's as a result of this table that I've advocated pitching yeast at around 70 degrees then moving the fermenter to the basement/refrigerator. The yeast reproduces at a comfortable temperature and should be hitting a reasonable population figure by the time the wort cools to the ambient temperature of the fermentation room/chamber and starts fermenting. Of course if you're pitching with an up and running yeast starter with a sufficient yeast count, the pitching temperature of the wort is not as critical.

Alan Edwards notes:

>Al Korzonas writes (in HBD #941):  
>| In his talk on wort chillers at the Conference, Jeff Frane said the most  
>| enlightening (to me) fact of the whole conference: that cold break begins  
>| at 65F. Wow!

>Has anyone heard this statement made anywhere else? Anyone's experience  
>bear this one out? I have a VERY hard time believing that you need to

>cool below 65F before you start getting cold break.

>Before I started using an immersion chiller, I had maybe half an inch of  
>break material in my primary fermenter. Now that I chill the wort down  
>to about 70F, I get at least three inches of cold break (after it  
settles  
>for a few hours).

I decided to check my copy of Malting and Brewing Science on this one since I have the highest degree of respect for the opinions of both Jeff and Al. There I found the following chart that may shed light on this discussion.

Cold break (I added in the Fahrenheit temperatures -krb)  
(mg/ml)

If I may interpolate, trub formation is relatively light, albeit measurable, at temperatures above 100 degrees F. At temperatures below 100 degrees the curve begins to steepen significantly. I also think one could read the chart as saying that trub formation is minimal until it reaches the 64 degrees *Centigrade* rather than Fahrenheit, at which point it begins increasing until it reaches 40 degrees C. where it begins increasing at a moderately faster rate.

Yet again, if you look at the curve at around 64 degree F., it really starts taking off. So perhaps that's what Jeff was trying to say. I didn't hear Jeff's talk so I'm not sure what he said or what his sources are. Still, if this chart is to be believed trub formation begins, although slightly, once the wort begins cooling, though significant trub formation doesn't occur until wort temperatures drop to around 100 degrees F., with exceptionally fast cold break formation kicking in at 64 degrees F.

The text goes on to say,

"During the cooling of wort, cold trub progressively precipitates. It is impossible to remove all the potential precipitate because the trub continues to form during fermentation and subsequent beer cooling. However, many breweries, especially those concerned with lager

fermentation, remove much of the cold trub...

A recent survey has shown that in Swiss breweries, the cold break content of beers varied over a wide range...The effects on fermentation, maturation and beer clarification were not significant. During the course of successive fermentations, the preference of tasting panels shifted from beers where cold trub had not been removed to beers where partial removal had been practiced. The overall impression from other studies is that the presence of cold trub may stimulate the rate of fermentation, possibly by providing nuclei for carbon dioxide release; on the other hand, with more delicate beers there seems to be more possibility of having unacceptable sulphury aroma and taste.

.....

The production of cold trub has received little biochemical study. Many years ago, it was claimed that to get maximum trub production it was necessary to cool slowly over the range 120-80 degrees F., at least 30 seconds being required, and mechanical agitation being desirable. Later results described worts where the best cold trub formation occurred when cooling from 140-70 degrees F. took place in 3 seconds or less." (pp. 523-524)

So there you have it according to Hough, Briggs, Stevens and Young. Some cold trub is formed as soon as the beer begins cooling, with significant trub production beginning around 64 degrees F. Not only temperature but also the speed at which the wort cools appears to be a factor according to some. Its removal seems to be more important when brewing delicately flavored beers than with heavily flavored ones. At least that's the way I read it.

Troubles on my mind,

Kinney Baughman

From: klm@mscg.com (Kevin L. McBride)  
Subject: Ken Johnson, the lamest

Warning: This article contains a mild flame. I tried to resolve this matter by e-mail, but Ken seems to be either incapable or unwilling to engage in a conversation where he might have to admit that he may have stepped a little bit out of bounds.

I've kept it reasonably mild, but if you want to know what I really think about this subject, ask me by e-mail.

I apologize in advance for the waste of bandwidth, but I needed to say this. I'm pissed and I think that at least some of you are too. To make up for this, I will post a recipe next.

On Thursday, July 30th, I sent the following letter to Ken Johnson in response to his unnecessarily harsh statement:

> You write:  
>  
> > If your beer quality goes down when switching to full mash beers,  
> then you  
> > are lame.  
>  
> and you make yourself look like a jerk for posting such crap. One  
> Jack Schmidling is enough, we don't need you posting flame bait too.  
>  
> Please consider posting an apology for this rash, completely  
> unnecessary statement.  
>  
> The purpose of the Homebrew Digest is to share knowledge and  
> experience. My first couple of mash experiences were miserable.  
> People on the HBD helped me fix my problems and now my beers are fine.  
> We don't want novices being scared off by self-proclaimed wizards who  
> say that you are lame if you can't figure it out by yourself.  
>  
> You probably just encouraged several beginning all-grain brewers to  
> switch back to extract brewing with your stupid comment.

I finally received a reply from Ken today, August 6th. His reply consisted of a single word:

"bullshit"

Ken, I attempted to be reasonable about this. I contacted you by e-mail and told you, without resorting to outright flaming, that I thought you were out of line and that the Homebrew Digest deserved an apology for your rash statement.

I now see that attempting to reason with you is like having an argument with a tree stump. You have shown yourself to be an asshole and I sincerely hope that you lose whatever credibility you may have had in this forum.

F.O.A.D.

From: klm@mscg.com (Kevin L. McBride)  
Subject: All-grain Smoked Porter recipe

The smoked porter served at Greg Noonan's Vermont Pub & Brewery inspired me to brew this. I love Greg's version and tried to come up with something similar.

The smoke flavor is a little bit more assertive than in Greg's brew, but is not so overpowering as to be unpleasant. The sweetness of the crystal and cara-pils balance the bite of the dark malt so that the beer is pleasantly bittersweet, as a porter should be, and the smoke flavor just floats over your tongue. The finishing hops are barely noticeable. The smoke masks most of the hop flavor.

The beer is 3 weeks old now. In a few more weeks it should be really wonderful.

The name was supplied by Dan Hall. Don't ask. We were indulging in a few bottles of really good Belgian beer at the time and I think we were slightly buzzed.

"Clubhouse Poked Smorter"  
=====

#### The Grist:

8 lbs. M&F 2-row lager malt  
2 lbs. hickory smoked M&F 2-row pale malt \*  
1 lb. Munich malt  
1 lb. Crystal malt  
1/2 lb. Choc. Malt  
1/2 lb. Black malt  
1/2 lb. Cara-pils

\* (I had 2 lbs. of pale just lying around, so I used that as the smoked grain for no particular reason other than to get rid of it.)

The smoked grain was done on a charcoal fired smoker with wet hickory chips. Total smoking time was close to 45 minutes. I would have cut the smoking time down, but I wet the grain first and it took that long for it to dry on the smoker.

#### The Mash:

Struck mash at ~120F for protein rest. Pulled a single decoction, brought to a boil, held for about 10 minutes, and re-infused to raise temp. to about 155F which was held in a 5 gallon Igloo cooler until conversion was complete.

Sparged with 4.5 gallons of 170F water. Yielded ~7 gallons of wort.

#### The Boil:

Total boil time about 70 minutes.

1 oz. (~30 IBU) Northern Brewer plug hops (boiling 60+ minutes)  
1 oz. Cascade leaf hops (finishing ~5 minutes)

Chilled with Dan Hall's Immersion Chiller from Hell.

Original Gravity: 1.052 (Actual yield to the fermenter was about 5.5 gallons and this was after a good boilover where I lost at least a quart)

Pitched a 16oz. starter of Wyeast 1028 London Ale made from a culture that lives in my fridge and has served me faithfully for a number of brews.

After 5 days in primary, I racked to a keg and refrigerated. I am slowly artificially carbonating it and letting it settle and mature. It won't be formally served until the September BFD meeting, but it is already shaping up to be a fine brew. (I sneak a taste now and then.) This beer should go great with sausage and other hearty foods.

Final Gravity: 1.016

>I have an apple tree outside my apartment and I was wondering how to  
make a  
hard cider. A friend has one of those juicer machines and I was  
thinking  
that would be a good way to get the juice from the apples but where do  
you go  
from there.

>  
>If anyone has some recipes or suggestions please help and THANKS.

<don't use red star champagne yeast (ale yeast will  
make a sweeter product).

That advice depends on a few variables not the least of which is the  
sugar  
content of the juice. Most juice needs to have sugar added just to get  
enough alcohol to preserve it and the high tolerance of champagne yeast  
would  
not even enter the equation of most straight juice. It would run out of  
sugar before even ale yeast got tired.

Secondly, one can always add sugar to adjust the sweetness after  
fermenting.

Thirdly, one usually will add lots of sugar to make a higher alcohol  
apple  
wine and ale yeast would produce an undrinkably sweet wine.

>From: BOB JONES <BJONES@NOVAX.llnl.gov>

>Subject: Wort cooling

>I use a immersion chiller placed in my kettle to cool the wort. During  
the  
summer months the tap water is warmer and I will use another immersion  
chiller to pre-cool the water by placing this cooler in a 5 gal bucket  
of  
cracked ice... I have wondered if it would help to add salt to the water  
before it freezes. This works to lower the temperature when  
freezing ice cream, so why not in cooling wort?

It will just make your freezer work harder freezing it. You should put  
the  
salt in the chiller with the ice to lower the temp of the water but the  
ice  
will melt faster so you will need more. You just can't get nothing fer  
nothing no mo.

Subject: Runoff temp, mashout

Hi All,

In HBD#941, I wrote:

I use both the hydrometer and the taste test to determine when to quit sparging, and have found that the taste of tannin first becomes noticeable around 1.020. At about 1.015 - 1.010, there is no longer any detectable sweetness, this is when I stop. Surprisingly, these three events (no sweetness in runoff, 1.010 on the hydrometer, and full pre-boil volume achieved) all seem to occur at just about the same time.

>In HBD#942, Gerald Winters wrote:

>correction would have to be made if the reading was taken from  
>the hot liquor.

Whenever specific gravity is measured with a hydrometer, the reading must be corrected if the temperature of the solution is other than 60F.

I sparge with water at 170F, the temperature of the runoff is ~140F-150. (I really have to do something to insulate my lauter tun a little better). According to the references I have, this temperature requires a correction of, if memory serves, 15-16 points. So, when I say I stop sparging at ~1.010 - 1.015, the hydrometer is actually reading 0.995 - 1.000.

>and I suspect a lot more around the PNW do as well. Another  
>8-10f isn't going to magically kill the enzymes.

A couple of months ago, I had an experience that would seem to substantiate that statement. I arrived at my brew partner's house a little late, as he had just started heating the mash up to the sugar rest range. We started socializing, neither of us was paying any attention to the mash. About 20 minutes later, we finally got around to checking the temperature, and it was at 175F. I'm not sure how much time it spent at that temp, probably 10-15 minutes. We quickly added some cold water to get the mash temp down below 160F, we were both concerned that what we had made was a very expensive batch of porridge. However, an iodine test done about one hour later showed conversion was complete. The beer came out fine. I had one other batch since then where the mash temp got

to 165F briefly, and that mash converted just fine as well.

The moral here is that the amalyse enzyme seems to be a little tougher than we give it credit for. I still mashout every batch, but I do it to get the grain to the same temperature as the sparge water, and thus prevent too much heat loss in my not-very-well insulated (for now) lauter tun.

Cheers,  
Jim

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Soft water (how to get it?)

Ladies and Gentlemen of the Jury:

Next weekend I plan to try the extract triple recipe in Pierre Rajotte's Belgian Ale. In his listing Rajotte specifies that this should be brewed with soft water.

Several weeks ago I did what everybody always says to do, and contacted my local water board (in this case the Washington Aquaduct, serving Washington D.C. and Arlington, VA) for information on my water. I got back three massive charts listing everything anybody could conceivably want to know. Amidst this small print was the hardness table, stating that on average our hardness was 110 (was this for calcium carbonate?).

According to Charlie, soft water is rated at 0-50. I've read that water softeners don't actually remove the minerals but convert them, and I don't have a water softener anyway. Would it make sense to use enough distilled water to cut the value down to size (say, 3 gallons to two of tap water)? Or am I missing something?

I'm also perfectly willing to use 100% tap water if the alternatives are too complex.

Anyway, I am specifically appealing for help from any of our HBD chemists or experienced brewers. Having seen some of the more technical posts recently, I will ask that any explanations be kept to words of one syllable or less for us members of the chemistry-impaired. Thanks!

Date:Thu, 29 Jun 89 21:17 EDT

**Subject: Hop aromatics and aging**

hoppiness when brewed) not on the effects of its aging after turning into beer

(I think thats why the authors called it 'potential hoppiness'. After 11 years

of brewing, I use only hop flowers, and avoid pellets when I can. (...)

- ----

I was reading an article from THE AMERICAN SOCIETY OF BREWING CHEMISTS "Changes in Hop Oil Content and Hoppiness Potential During Hop Aging" Foster and Nickerson 1985, when I ran into the following...

Four catagoies of hop types became apparent...

1. High hoppiness potential when fresh and retains it after aging  
Kirin II, Wye Challenger, Wye Target

2. High potential when fresh, lost after aging  
Cascade, Galena, Brewers Gold

^^^^^^

3. These show an increase of hoppiness with aging (!!!)  
Hersbrucker, Tettnang, Record, Fuggle, Blisk, Eroica, Hallertau, M.F.,  
Willamette, and Styrian. ^^^^^^ ^^^^^^^^

^^^^^^^^

4. Low hoppiness when fresh, low when aged  
(these were discribed as 'good keepers' but not good aromatic hops)  
Negget, Cluster, Perle, Columbia, and Olympic

The Kirin II hop had and an aged 'aromatic' compound level of 9.68 micro-  
L  
per gram, with a 'citrus' value of 24.56. Most of the other hops had  
values  
in the 3.0 to 5.0 range! Does anybody on the net know where I can get  
some

of this variety of hop? It looks like a really good aromatic.

Date: Fri, 7 Aug 92 11:32 EDT

From: hjl@gummo.att.com

Subject: Dry malt extract priming and fermenting mead

Sam Isrealit asked about the amount of dry malt extract to use in priming. He quoted 1.25 cups as producing too little head. Volume of the batch was omitted. My experience when shifting from corn sugar to dry malt extract was that a 25% increase in sugar volume produced about the same level of carbonation. For a 5 gallon batch, I am currently using one cup of dry malt extract for the prime and get consistently good carbonation and head volume and retention.

Regarding fermentation of honey to make mead: About eleven years ago I bought five gallons of wild-flower honey, diluted it to a specific gravity of 1.1 (wine strength), added acid blend (tartaric, citric, malic) to .9% and sprinkled in five sachets (5g ea) of dry Montrachet wine yeast. This produced about 25 gallons of liquid. It was January and both the water and the fermentarium (New Jersey cellar) were cold. I waited. Nothing happened. After three weeks I took a gallon of the solution upstairs to the kitchen (75 degrees F), confidently fitted a fermentation lock and waited. Nothing happened. After another three weeks I got a book and read about "Making Mead" (name of book). Book said that honey has an enzyme which inhibits the growth of yeast (clever bees) and to destroy the enzyme, you boil the honey solution (as in mead kitchen). Not wanting to risk changing the flavor of the honey, I tried another approach.

I got about one pound of grapes (Thompson seedless - no flavor), crushed them, strained the juice, and added one sachet of yeast. Fermentation was active the next day. I added half as much honey solution as grape juice. Fermentation continued unabated. I repeated the 50% addition every day until I had 15 gallons of actively fermenting mead at which point I pitched it into the remaining (and still quiet) solution. Subsequent fermentation proceeded normally and the mead was (and still is) good.

In retrospect, I probably could have achieved the same result by boiling a pint of the honey solution.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re bubble size

wrt korz's query about differing bubble sizes (and hence differing tastes)  
with various methods of priming:

Miller reports the same allegation (size related to malt/cornsugar) and dismisses it as being untrue if beers are compared /after/ carbonation of the malt-primed is complete---corn sugar ferments quicklyt enough that the CO2 takes a while to properly dissolve (he says), while malt ferments much more slowly and is finely divided from the start.

I can't argue this from personal experience; I don't have any good simple comparisons. Miller appears to have some prejudices (strong preference for lagers, pushing people into mashing too soon) but this seems plausible.

Date: Fri, 7 Aug 92 9:32 GMT  
From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: Re: Mash out at 170F

There's been a bit of correspondence on the HBD recently about the stability of enzymes at different temperatures (eg. on whether mash-out at 170F kills amylases), and the effect of mash thickness on the wort. I have access to a literature database that I periodically search for brewing references. One paper I pulled out and subsequently sent off a reprint request for was by Robert Muller (Brewing Research Foundation, Redhill, Surrey, England), entitled "The effects of mashing temperature and mash thickness on wort carbohydrate composition" (Journal of the Institute of Brewing (1991) Vol 97, pp85-92). The author is interested in producing normal gravity, but low fermentability worts for low alcohol beers. His results can be summarized as follows (I won't attempt to reproduce his graphs in ASCII).

At 65C [149F in old money], the half life of alpha amylase is 42 minutes; that of beta amylase is 15 minutes. Thus, after 30 min at 65C, there remains 62% of the alpha amylase activity and 25% of the beta amylase. At 80C [176F], both enzymes are less stable: the half life of alpha amylase is about 13 minutes, that of beta amylase about 6 minutes. The loss of beta amylase at both temperatures is exaggerated by the observation that there is much more alpha-amylase activity present to start with: the total potential activity of alpha amylase at 65C is 88g of starch hydrolysed per gram of [pale] malt; in contrast, the total potential activity of beta amylase is 3.5g of maltose produced per gram of malt. The loss of beta amylase due to temperature denaturation will therefore be more significant than loss of alpha amylase.

This loss of beta amylase results in a higher proportion of malto-dextrins, which are non-fermentable (at least with ale yeasts: modern super-attenuating strains, such as used for diet beers, are less choosy). A mash carried out at 80C thus produces a wort which is only 20-30% fermentable, compared with the 65C wort which is about 80% fermentable.

Using this data, it's possible to draw the following conclusions about the consequences of a "mash-out" at 170F [77C]:

- 1) Beta amylase will be almost completely destroyed, but 25% of the alpha amylase activity will survive (and will be more active at the higher temperature).
- 2) This alpha-amylase may break down any starch remaining in the mash, preventing starch haze in the final product (but increasing the malto-dextrin content).
- 3) The main purpose of mash-out is probably a combination of (2) and to aid in the flow of the sugar solution from the husks (as suggested previously), due to the decreased viscosity of the wort at the higher temperature.

Sorry this went on so long.

Andy

From: megatest!jao@Sun.COM (John Oswalt)  
Subject: Sassafras; low cal ginger beer

Fellow homebrewers,

I've made several batches of "root beer" from root beer concentrates, which contain the same sort of artificial colors and flavors as commercial root beers. I would like to make real root beer, from recipies posted here and on the net. However, I have never seen the essential ingrediant, sassafras root, for sale anywhere in this country (USA).

The Bread of Life, a Bay Area health food store I frequent, has sassafras bark, but no sassafras root.

So my questions: Can sassafras root be obtained in the United States? Is it even legal in the USA? Can root beer be made from sassafras bark?

On another, related subject: I made ginger beer using the recipe Jack Schmidling gave in HBD 928, and it turned out well. Based on my experience in "extract" root beers, I made a low cal version by substituting an appropriate amount of sweet-and-low for half the sugar. I think you can get away with using even more artificial sweetener than this, though of course you can't eliminate all the sugar: yeast can't live on sweet-and-low. I'll try 25% sugar 75% sweet-and-low and report on the results.

I don't know about you all, but I have to watch calories, and if I drink sugary soft drinks, I can't drink homebrew.

From: "John Cotterill" <johnc@hprpcd.rose.hp.com>  
**Subject: AutoMash(tm)**  
Full-Name: "John Cotterill"

About a year ago, I was interested in buying the AutoMash(tm) as I have heard many good things about it. When I contacted Scientific Brewing Systems, I was informed that the small unit (described in the last HBD) at \$599 was no longer available. They have replaced it with a unit that is quite a bit larger (18lbs of grain max - I think). This unit came at the price of about \$1200. Too much for my budget. The folks at SBS stated that there were lots of requests for larger systems. Lots of their sales were to clubs or groups of homebrewers who were buying a unit to share. Since the costs were also being shared, and to make the unit as versatile as possible, they designed the larger unit. I think it is called the MightyMash(tm). Things could have changed in the last year, so beware....

Subject: Back issues

Folks-

If you need a back copy of the HBD, there are a couple of ways of getting one:

- 1) FTP directly to sierra.stanford.edu, and then change directories to pub/homebrew/incoming. Then get the issue by number.
- 2) Send mail to listserv@sierra.stanford.edu and send a message with one word: "help". Listserv will help you do the rest.
- 3) Use bitftp. A pretty handy server at princeton, it will ftp for you (I use it sometimes, even tho' I \*can\* ftp. Send to bitftp@pucc and send this message

```
FTP sierra.stanford.edu binary
USER anonymous
cd pub/homebrew/incoming
get 943
QUIT
```

At the get line, substitute the issue number for the one you want. If you want more than one, put another get line in. Up to ten requests can be made.

This little script can be edited to deal with any ftp site, just change the address. BTW, some folks only on the internet may get a note from BITFTP saying that it wont do it for you. Sorry about that.

Any further questions, e-mail me.

From: bickham@msc2.msc.cornell.edu (Scott Bickham)  
Subject: Wheat allergies

Recently my sister found out that she suffers from an allergy to wheat. That means that she should stay away from any type of food made from wheat grain or flour. So what does this have to do with beer? Well, beer is listed as one of the substances to avoid, except for "some beers that are made without wheat."

This sounds ridiculous, since most beers are not made from wheat, and there would not be any problems. If the doctor included wheat and barley in the same class, then by definition this would include all beers.

The biggest problem I have with his prognosis is that the contribution of wheat to beer is completely different from making products with wheat flour. The husks are filtered out in the sparge and are not present in the beer, while the proteins and starches are broken down and mostly metabolized by the yeast. My belief is that unless my sister is allergic to a specific protein in wheat that survives malting, mashing, boiling with hops and fermentation, then there is no foundation for the doctor to advise her to stop drinking "most" beers. Does this sound plausible, or is there any other information we should be aware of?

Happy Brewing,  
Scott

Subject: Styrofoam Cooler Death Toxins in Your Beer?

(Sorry about the first botched posting...)

Greetings All!

>From a recent thread on styrofoam:

>> I'm not a chemist, but I don't think styrofoam reacts with water  
>> in any way.

> Me either, but I thought it was pretty certain that when a styrofoam  
> container contained hot liquid, it releases some carcinogen into the  
> liquid. (Disclaimer: this is hearsay.)

Just for the record, polystyrene (the thermoplastic used to make styrofoam) is very inert and I wouldn't worry about dying bizarre, agonizing deaths from ingesting it in its pure form. The problem, if there is one, will be from any unreacted styrene monomer remaining in the polystyrene. (I think this is what Jake was referring to with his comment.)

Your nose is a pretty sensitive detector, so if you can't smell any styrene in your styrofoam, I wouldn't worry about it. And believe me, you'll know styrene if you smell it -- it stinks to high heaven. (There's a lot of styrene in polyester casting resins used to make fiberglass auto bodies, canoes, and such. If you've ever worked with that stuff you know the industrial strength wooden-stake-between-the-eyes-headache-causing chemical odor that I'm talking about.)

According to the Merck Index, styrene is 'sparingly' soluble in water so your sweet wort shouldn't leech much of it out assuming that there is some there. (Styrene is soluble in alcohol so I suppose you could always 'clean' the surface of your cooler by rinsing it with a hot water/alcohol mixture, but I think this is overkill.)

The LD50 for styrene is 660 mg/kg in mice (ingested). Roughly, that means that if you fed one thousand mice who weighed 180 pounds 2 oz of styrene, five hundred of them would die. (The other five hundred would probably be on their knees retching and looking at you with malice in their beady little eyes...)

Styrene is not listed as a carcinogen in the Merck Index (11th ed., 1989).

Finally, according to the Encyclopedia of Polymer Science and Engineering, the recent trend in the production of food grade polystyrene is focusing on reducing the levels of residual styrene to improve odor and taste characteristics (from 800 ppm to 200 ppm). Reading between the lines, the taste and odor of styrene must be pretty noticeable, and if you're not experiencing odor and taste problems with your picnic cooler and coffee cups, I'd guess you don't have anything to worry about.

The bottom line: Mashing in styrofoam picnic coolers should be no problem.

Phil Miller (pmiller@mmm.com)

PS. Just out of curiosity, everybody is using food grade PVC tubing for siphoning, right? (-: Just kidding, just KIDDING!! :-)

Disclaimer: Like most scientists speaking on topics not directly in their field, I know just enough to get into trouble.

From: scojam@scojam.Auto-trol.COM (Scott James.)  
Subject: Mashing Idea...

The other day I saw a hot water heater sitting on a curb...I wondered how this might work for mashing. My tap water is 140F, maybe a hot water heater could be modified (top cut off? and connected to accurate thermostat...) to mash homebrew?

I think this would be ideal if brewing large quantities..15 gal. or filling several carboys (yeast comparison experiments in common wort, etc.)

Also, I never heard any response about culturing yeast on Tofu (soy bean curd, very high protein). Does anyone think this would work as a poor man's substitute for agar? Maybe this could be a cheap way to streak yeast and separate mixed cultures?

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: Thanks & Hop Packaging

THANKS

Thanks to all those who answered my mash out question. Thanks to Jeff Frane (a.k.a. The Horses Mouth) for clearing up that cold break question. Cold break is apparantly a continuous process that starts at 60 centigrade (140F). I plan on trying a full mash next time.

I keep learning more and more from this group of people. I'd like to take the time to thank everyone who contributes to the HBD. How do other homebrewers get along without this forum?

Now, back to our regularly scheduled program.

HOME GROWN HOPS

Carl West (in HBD #942) gave us some very good hints for how and when to pick hops. He also writes:

| The hops are now in jars in the freezer, I'll dry them when I get home  
| from Pensic. Any body see a problem with that?

I'm far from an expert, but I remember reading in my handy-dandy hop growing book (you know, the small paperback with hops all over the cover--sorry, it's at home right now) That you shouldn't put hops in the freezer before drying. They will turn to mush over time, like cooked spinach, or lettuce that you leave in the fridge too long. (I don't know how long you will be gone, Carl.)

It doesn't take me any effort for to dry hops. I spread mine out in the bottom of an open cardboard box, one layer thick, and let them sit in the garage for two days. They are out of the sun and warm. (My garage gets up to 100F these days.) The guy who wrote the hop homegrowing book says that he has a friend who lays them out in his attic. There might be something to drying them quickly, but I can't see how two days of sitting out would hurt--they've been outside for several months already.

John The Hopdevil writes (in HBD #943):

| Whats the best way to store homegrown hops? Should I press them into  
| a brick? For storage of freshhops I have been using the thick shiny  
| (mylar?) plastic bags that had laser cartridges in them, I air them  
| out for a few days and wire tie the regular gallon ziplock bag inside  
| it.

Yikes! I cringed when I read that. Where I work, toner cartridges are classified as hazardous waste--seriously! I wouldn't want those bags anywhere near anything that even comes close to my mouth. I hope you are at least cleaning them very well. I pack my hops into glass jars. Baby food jars are a good size for me. (Refer to my posts in HBD #937)

Date: Fri, 7 Aug 1992 14:48 PDT  
From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: NA beers from Micah Millspaw

Help for jack; I most likely posted something about this before but I'm not sure. Jack has been playing with his NA's again and found that by adding water to them after alcohol removal they do taste better. The important thing is to add the right amount of water to restore the beer to its pre-alcohol reduced state. Too much and it will taste thick and slimey like some of the commercials IMHO, too thin and there won't be any taste. So what to do, first take the specific gravity of the beer before you evaporate off the ethanol, then take the specific gravity after your evaporation procedure. The difference is the amount of water that you need to add. There is however a problem, water and ethanol have different densities, so you must allow for this. So you need to add more water to lower the specific gravity than the amount of alcohol that you removed. I have a crude formula, but it is very volume related, and the results are subjective. After all you have to drink it to verify. This should be valid for 5 gallon batches and ignores some factors that I decided were not pertinent to homebrewing NAs.

( delta G \* 8.339 )128 = H2O oz

delta G is the difference in specific gravities before and after ethanol evaporation. Readings must be taken at, or adjusted to 60 degrees F to be valid.  
specific gravity expressed as .010 or .013 for example

have fun with this

I got it from All World Scientific, Lynnwood, WA. 1-800-28WORLD

500gm, USP of the dihydrate cost \$15 - a rip off since 55gal drums go for \$.75/lb! But, then, at 5gm/batch it will last a long time.

There will be an additional charge to have it shipped to your address. I suspect it is minimal.

Cheers!

-- additional commentary deleted ----

Well, I did call my congressman (Matt McHugh, who is not running  
for re-election :-( ) and he responded:

Dear Mr Dimock:

My Ithaca office told me that you called regarding the so-called  
"Crazy Horse" language in the Treasury Department appropriations  
bill that the House considered last month. I appreciated hearing  
from you, and wanted to take this opportunity to discuss this with  
you.

The language was removed from the bill on a point of order.  
House rules do not allow legislation to be attached to an apporpriatons  
bill - - that is, they require that only rules directly affecting how  
government funds are spent be addressed in those bills. The senate  
has no similar prohibition, and so it may attach similar language to  
its version of this bill.

I understand that when you called, you said you had heard that the  
amendment would prohibit the use of the names of historical personages  
on alcoholic beverages. That is not true. The amendment would have  
given the Treasury Department authority to prohibit use of a name if  
it could damage or alter that person's reputation.

The language was drafted specifically to allow the Department to  
prohibit use of the name of the Indian chief Crazy Horse. When he was  
alive, Crazy Horse campaigned against alcohol use among Indians. His

tribe and his descendants oppose the use of his name to sell alcohol. Moreover, the company planning to use his name plans to target Indian markets for the product. Although it may be legal, the plan to use his name to promote the very thing he opposed is clearly reprehensible.

Thanks once again for contacting me about this. Your concerns are always welcome.

Best regards.  
Sincerely,  
Matthew F. McHugh

Sounds like another case of irresponsible action on the part of one money-grubbing brewer having to be restrained by laws which will probably cause headaches for years to come in totally unrelated situations. What ever happened to voluntary ethical behavior???

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: ANOTHER MOMILY? and sundry other stuff

To: Homebrew Digest  
Fm: Jack Schmidling

ANOTHER MOMILY BITES THE DUST!

Well, sort of.

The counter-intuitive warnings of using bleach to sanitize stainless got to be more than my skeptical mind could handle so I decided to do some simple experiments.

Exactly one week ago, I made a solution of 1 part bleach to 1 part water and did the following with it:

Poured several ounces into the depression near the handle of the lid of my 10 gallon Polar kettle.

Placed a strip of 5 mil SS sheet metal in the solution along with a lab type wafer forceps, a kitchen spoon and some sheet metal screws. Unfortunately, all my kegs are full so I could not include them in the experiment.

Not surprisingly, one week later, there is not the slightest clue of any reaction on the kettle, forceps or SS strip. However, very strange things happened to the spoon and screws. The spoon has a tiny pit that develops a "rust flower" within hours but after a week, nowhere else but that single spot.

The screw heads remained bright and shiny with not the slightest hint of corrosion even under high magnification with a metalurgical microscope. However, the threads looked like they were boiled in acid. Large pits and holes all over the place.

After writing the above, I did find some inconspicuous signs of incipient corrosive action in one spot on the lid.

This one is tough to summarize but it would seem that even in very strong concentrations, there is normally little risk of damaging most stainless vessels that we deal with if bleach is used as the sanitizing solution for the short period of contact time typical of cleaning our equipment.

I would further add that, in the concentrations most OTHER people use, i.e. one ounce of bleach per gallon of water, the risk is probably zero.

I can not begin to explain what happened to the spoon or screws but I guess I would not leave bleach in a keg to keep clean till next use without a few test runs first. However, to slosh a little bleach around in it and then to thoroughly rinse it seems a totally safe way to sanitize it.

I sanitize my fermenter by boiling a bit of water in it just prior to filling so I don't need to deal with the bleach.

>Al Korzonas writes (in HBD #941):  
| In his talk on wort chillers at the Conference, Jeff Frane said the most enlightening (to me) fact of the whole conference: that cold break begins at 65F. Wow!

>I have neither heard it before nor does it match experience nor do I believe a word of it. I think it can safely be identified as a MOMILY until further evidence is offered.

FRANE says Centigrade. Good example of the virtue of counting to ten (24 hrs in this case). MOMILY dismissed.

>From: Conn Copas <C.V.Copas@lut.ac.uk>  
>Subject: Re : MASHOUT v.s. SPARGING

>However, I have reservations about systems in which heat is applied directly to the mash, and that includes stove-top mashing and buckets with heating elements. My experience is that these systems give some of the character of a decoction mash and thus result in a relatively dextrinous wort, presumably because beta amylase doesn't survive the direct heating very well....

Good example of why brewing is so much fun. Noonan wrote an entire book on the virtues, merits and wonders of decoction mashing and you say it ruins the beer.

>From: korz@ihpubj.att.com  
>Subject: Re: Why mash out?/Zapap lauter tun

>Back to kettle mashing for a second. If you've got a non-removable bottom, you cannot stir the liquid that is closest to the heat and it would seem to me that Jack's pipe-and-window-screen kettle would also make stirring at the very bottom of the kettle inconvenient, at the least. Both these cases are invitations for scorching both the mash and the wort.

Thanks for the segue.

My first attempt at a single kettle mash/lauder tun had the traditional false bottom. This was a SS plate with a zillion holes, laboriously drilled/punched in that sat on three SS posts over the pipe/screen/spigot gizmo. It had all the problems you suggest. The mash scorched, big bunches got under the plate and on the second try, it got so bad that I had to remove it, to finish the batch.

Well, that was lucky part of invention. As it is impossible to get the plate back in under 10 pounds of grain, I had to sparge without it and I anticipated disaster. Well, the wort ran clear after about 3 ounces and I completed the sparge without a hitch and you know the rest of the story.

I have made exactly 20 batches using this method and the only change I have made was to switch to copper and brass from galvanized pipe and window screen.

The size and form of the strainer are such that nothing gets stuck under it and one quickly develops a slight hump up over the pipe in the stirring routine.

I know it's tough to believe something so simple can work so well, but so it goes.....

Finally, the following was posted to usenet in response to a discussion on extract efficiency and I might as well insert it here.

#### EXTRACT EFFICIENCY

I computed the extract ratio of my last ten batches and got the following numbers:

27, 27, 26, 30, 28, 27, 25, 28, 29, 28

So that we are all using the same prayerbook, I calculated the ratio as follows: gals/lbs X gravity. The gravity being the first two digits following the zero after the decimal point.

i.e. 1.050 = 50

e.g. 7 gal/10 lbs = .7 X 50 = 35

All of these (as have all my all grain batches) have been made by kettle mashing as described in my article called "Easymash".

There is one very significant point to consider before one abandons one's current system in despair of achieving widely publicized ratios.

It is easy to come up with the wrong numbers if the volume is not accurately known. For example, if in the above, a gallon of wort was left behind in the

trub and not included in the calculation, the actual yield would have been 40.

This may seem like it is cheating but just because you throw it away, does not mean it is not part of the net sweet wort.

The early design of EASYMASH left about an inch of wort on the bottom of the kettle and it took me awhile to figure out that this was part of the equation. The new design leaves less than a quart behind.

In any case, one can and should recover this (lost wort). You can pour it into a gallon jug and refrigerate it overnight. It will settle out nicely and you can pour off the clear wort into the fermenter or save it for starting the yeast for the next batch.

Subject: Wort chillers revisited

Fellow Brewers-----

Just a quick note on chillers. If you're interested in being very efficient (thermodynamically speaking), and want to save water, what about making the best of both worlds?

Here's what I'm thinking: Instead of connecting your counter-flow chiller to your faucet, why not invest a few bucks in an inexpensive submersible (sump) pump and a big bucket. Use the bucket to serve as a reservoir of ice water (use the milk carton trick) in which the pump is placed. Circulate the chilling water for a few minutes to cool the tubing before starting the wort through. It is probably a good idea to have a pinch-clamp on the wort outlet and plenty of extra ice handy to get the wort cooled to the desired temp (20-25 deg C).

So anyway, that's my contribution to the continued progress of happy home brewers all over, for whatever it's worth (my contribution, that is)

And don't forget, A.I.E.

Mr. Pete

Date: Sun, 9 Aug 92 22:14 GMT  
From: Phillip Seitz <0004531571@mcimail.com>  
Subject: It's not too late for summer beers

Summer here in Washington, D.C. is usually an exercise in survival, with extremely hot days and high levels of humidity. What's needed is a tasty low-gravity summer beer that you can drink a lot of.

We're having some Belgian guests later this month, and to keep them well watered I whipped up the following recipe. The idea was to combine the gravity and carbonation of an English mild with the color and flavor of a Pacific Northwest amber (Hale's Moss Bay Extra is my favorite). The hop bitterness and flavor is quite citrus-like, and dominates the flavor profile. This is rather standard for West Coast beers but pretty explosive in comparison to ordinary commercial brews. It turned out quite nicely, and amazingly fast: from kettle to beer glass in 15 days (see disclaimer below). Cheap, too.

#### Citadel Summer Amber

3.3 lbs. American Classic light liquid extract  
1 lbs. Laaglander light DME  
0.5 lbs. crystal malt (40L)  
1 tsp. irish moss flakes (10 mins)

0.5 oz. Cascade pellets (60 mins.)  
1.5 oz. Cascade pellets (20 mins.)  
1 oz. Cascade pellets (0 mins.)  
1 oz. Cascade pellets (in secondary)  
(all hops 5.1% alpha)

2 packages Munton & Fison ale yeast, rehydrated  
80 grams corn sugar for priming (about 1/2 cup)

Batch size: 5 gallons  
Original gravity: 1.033  
Final gravity:1.010  
Primary: about 18 hours  
Secondary: 11 days

#### Disclaimer and Notes:

As a member of the basement-impaired I brew in my house, where the temperature is 80F during the summer. The temperature undoubtedly helps with the short brew time--but if it works, why not? I did use a wort chiller (immersion type) to protect against infection.

I used dry yeast because I was too impatient to start a liquid yeast, and M&F was what I could get at the local brewing store.

The third hop addition went in right after the end of the boil, just before hooking up the wort chiller.

Next time I'll probably use 60L crystal to increase the color a bit, and skip the first hop addition altogether. The beer is plenty bitter already, and the hop flavor is the most important element.

(line above should read: "(immersion type) to prevent infection."

Subject: Ascorbic acid

Howdy!

I can vaguely remember, way back when, a discussion in this forum regarding the addition of ascorbic acid (also known as vitamin C) to a brew for the purpose of preventing oxidation. Is this done at bottling time? In what quantities? I s'pose one could add food grade vitamin C available at any pharmacy or grocery store, right?

The reason that I'm interested is that I have a batch of mead that's ready for bottling. Actually, it's an apple mead (cyser), and it was probably ready 4 months ago! I'm really getting paranoid about oxidation; I understand that meads are more susceptible to oxidation than beers. I have no experience with meads; this is my first. I'd really be interested to hear from anyone who's added a.a. to a mead before, and especially about deleterious flavor effects.

Cheers,  
Chuck

Date: Mon, 10 Aug 92 11:41 GMT  
From: Andy Phillips <PHILLIPS@LARS.AFRC.AC.UK>  
Subject: Re: Why mash-out?

There's been a lot of correspondence on the HBD recently about the stability of enzymes at different temperatures (eg. on whether mash-out at 170F kills amylases), and the effect of mash thickness on the wort. I have access to a literature database that I periodically search for brewing references. One paper I pulled out and subsequently sent off a reprint request for was by Robert Muller (Brewing Research Foundation, Redhill, Surrey, England), entitled "The effects of mashing temperature and mash thickness on wort carbohydrate composition" (Journal of the Institute of Brewing (1991) Vol 97, pp85-92). The author is interested in producing normal gravity, but low fermentability worts for low alcohol beers. His results can be summarized as follows (I won't attempt to reproduce his graphs in ASCII).

At 65C [149F in old money], the half life of alpha amylase is 42 minutes; that of beta amylase is 15 minutes. Thus, after 30 min at 65C, there remains 62% of the alpha amylase activity and 25% of the beta amylase. At 80C [176F], both enzymes are less stable: the half life of alpha amylase is about 13 minutes, that of beta amylase about 6 minutes. The loss of beta amylase at both temperatures is exaggerated by the fact that there is much more alpha-amylase activity present to start with: the total potential activity of alpha amylase at 65C is 88g of starch hydrolysed per gram of [pale] malt; in contrast, the total potential activity of beta amylase is about 3.5g of maltose produced per gram of malt. The loss of beta amylase due to temperature denaturation will therefore be more significant than loss of alpha amylase.

This loss of beta amylase results in a higher proportion of malto-dextrins, which are non-fermentable (at least with ale yeasts: modern super-attenuating strains, such as used for diet beers, are less choosy). A mash carried out continuously at 80C thus produces a wort which is only 20-30% fermentable, compared with the 65C wort which is about 80% fermentable.

Using this data, it's possible to draw the following conclusions about the consequences of a 30min "mash-out" at 170F [77C]:

- 1) Beta amylase may be almost completely destroyed, but 25% of the alpha amylase activity will survive (and will be more active at the higher temperature).
- 2) This alpha-amylase may break down any starch remaining in the mash, preventing starch haze in the final product (but increasing the malto-dextrin content, and so increasing the sweetness and body).
- 3) The main purpose of mash-out is probably to aid in the flow of the sugar solution from the husks (as suggested previously), due to the decreased viscosity of the wort at the higher temperature.

And now I have a question: why do unmalted grains such as wheat and rye have to be gelatinized (cooked) before mashing? I just made a batch of bitter with 2 lbs of flaked rye, forgot to gelatinize it, but got a sensible yield: about 85% of the maximum possible. Any have a hard, scientific explanation for this?

Sorry this went on so long.

Andy

From: smith%8616.span@Fedex.Msfc.Nasa.Gov (Vote Libertarian in '92!)  
Subject: heat transfer properties of wort

hey--

After checking my fluid-mechanics textbook (Intro. to Fluid Mechanics, Janna, 2nd ed.), it appears that beer wort's viscosity is going to be within 1% of that of water at a given temperature. A good initial value to use is that of water at 100 degF, which is approximately  $1.4 \times 10^{-5}$  lbf\*s/ft<sup>2</sup>. Density is within 1% as well, but you can be exact with that since you have a hydrometer. I would expect specific heat to be about 1-5% higher than that of water, which is 1 Btu/lbm/degF.

Since few heat transfer correlations are accurate to within 20%, I would not worry too much about the exactness of wort measurements.

One thing to remember in wort-through-a-tube chillers is that the viscosity is going to increase as cold break forms, causing a reduction in flow rate. By how much? Good question. If people send me accurate measurements of flowrate, temperatures, tubing sizes/configurations etc.

I will make a stab at producing an empirical calculation of The Wort Chiller, but no promises....

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: softer gentler water

In HBD 944, Phillip Seitz asks how to get soft water. About 6 months ago, I picked up a great little book called, "The Pocket Guide to Bottled Water."

It's written by Arthur von Wiesenberger, and published by Contemporary Books (Chicago, 1991, ISBN 0-8092-4056-4). I think the book is aimed at yuppies, but brewers can profit from it too. When I wanted soft water, I used Great Bear Natural Spring Water, which was the softest I could get locally. The book gives these numbers for Great Bear:

Ca0.53  
Bicarb 18.3  
Sulphates 2.41  
Mg0.7  
Na2.85  
Chlorides 0.93

The figures are ppm. The beer turned out fine.

I concur that, within reason, there is no such thing as pitching too much yeast. They Zymurgy Special Issue on Yeast is an excellent reference for the things you are wondering about. I don't have it here so I can't answer these questions directly. I seem to recall that it was considered ideal to pitch about 2 million active yeast cells per milliliter of wort! and that with this pitching rate the yeast population would double an average of 2.5 times.

Another interesting yeast "fact" was that the yeast became active most quickly if pitched into 90!F wort (or hydrated in 90!F water). This makes me wonder about chilling the wort down to <65!F for a cold break. I typically cool to 70!-85!F. In my recent Pale Ale experiments I've been pitching 12g packets of Whitbread Ale Yeast which have given me starts in less than 2 hours which I suspect may be due to these warmer temperatures.

Subject: 2 hour sparging

In HBD# 940, Tom Feller asks:

>How could it take 2 hr to run water sparge water through your  
>grain bed unless the sparge was stuck(set mash?).

James Dipalma answers:

> Two hours seems a little lengthy to me as well, but it is  
>certainly possible.

Terry Foster suggests in his book (either "Pale Ale" or "Porter"  
I forget) that 2 hours is the appropriate time for a sparge and  
that the flow should be adjusted to achieve this elapsed time.  
However he also mentions that this is not necessarily practical for  
home brewers. Jim, let us know how your experiment goes though!

Subject: Hop Plugs and Pellets, What's the difference

> From: beb@pt.com (Bruce Buck)  
>  
> I've been brewing for several years and have always used hop pellets.  
> Now there seems to be a lot of discussion about hop plugs. What  
exactly  
> is the difference between the two? What are the advantages and  
disadvantages?  
>

Hop pellets are ground up compressed hops. Hop plugs are unground  
compressed  
hops. Both can usually be found in vacuum bags or nitrogen filled bags  
so they stay fresher longer than loose hops. Hop pellets are easy to  
work with but can be difficult to remove because they are ground so fine.  
I prefer hop plugs because they are easy to remove and, I admit it,  
simply because they look like hops once they have soaked in the  
wort for a while and loosened up. It really would be a great innovation  
though if they made the plugs small enough in diameter to fit through the  
neck of a carboy. That problem is leading me to dry hop in my keg for the  
first time this batch. This may turn out to be a good technique anyway -  
as others have pointed out.

Subject: Re: all malt vs. extracts

There are many styles of beer for which excellent brew can be made with extracts and some for which at least partial-mashing is almost necessary to make a true-to-style batch. The lighter-colored and lighter-bodied styles that \*require\* a malt nose, IMHO, are the ones hardest to make excellent without mashing at least part of your grains. I've made several stouts that were excellent without mashing, I just used extract and steeped the roasted barley and black patent malts in the water as I brought it to a boil. On the other hand, when I judged bocks in the first round of the National Competition, very few of the beers in my flight had the requisite malt nose. Although I did not check the recipes of the malt-nose-deficient brews, I think it's a fair assumption that the ones that had no malt nose were extract brews. Now I really wish that I would have checked. Its one of the added benefits of judging.

One argument for going all-grain instead of extract is the additional control that you get when you mash the grain yourself. I contend that there is an equal if not greater variability available to the brewer by using various brands of malt extract. Each extract maker uses different mash temepartures and profiles and if you experiment enough, you can learn which are the more-fermentable brands and which are the more dextrinous and which are poorly made (and create 6 inches of trub in your fermenter). Another thing to consider is that the technology available to the extract makers is well advanced of that which we have in our kitchens. Among the brands to which I have narrowed my usage, I've found great consistency.

Therefore, my position on this topic is that you can make very good beer in all styles without mashing and you can even make excellent beer in some styles without mashing, but for some styles, mashing the grain yourself is virtually necessary to achieve excellence.

Subject: yeast culturing

Hi All,

As part of the never-ending quest for improvement of my beer, I've decided to try my hand at yeast culturing. I have read Roger Leigstad's book, "Yeast Culturing for the Homebrewer", and believe I have the basic idea. I have seen several posts over the past few months from people who have grown pure cultures from single yeast cells, isolated the *S. delbrukii* strain from Wyeast 3056, etc. It is these net.brewers that I ask the benefit of thier experience.

I have located a source for glass petri dishes, pipettes, slides, etc. What other equipment will I need? If a micro\$cope is needed, what power of magnification?

I have access to the libraries of some local colleges. Which texts are recommended?

Procedural info on identification and isolation of different strains, propagation techniques, etc., would be appreciated.

Peering over the edge of a deep, dark abyss,  
Jim

>from there.

><don't use red star champagne yeast (ale yeast will make a sweeter product).

>That advice depends on a few variables not the least of which is the sugar  
>content of the juice. Most juice needs to have sugar added just to get  
>enough alcohol to preserve it and the high tolerance of champagne yeast would  
>not even enter the equation of most straight juice. It would run out of  
>sugar before even ale yeast got tired.

Not all sugars are fermentable by every yeast. Lactose is not fermentable by any of the Saccharomyces yeasts and thus can be used to sweeten cider (or beer or mead, for that matter) without having to kill the yeast with alcohol content.

>Secondly, one can always add sugar to adjust the sweetness after fermenting.

If mean adding sugar at bottling, this implies that you've somehow killed or filtered out the yeast or else the yeast will go at the new sugar. Adding sugar at serving time seems heretical, but it *is* the traditional way of serving Faro (a Belgian Lambic style which is incredibly sour from welcomed lactic acid bacterial activity).

From: bryan@tekgen.bv.tek.com  
Subject: Flurry of "break" material.

All this talk about cold break material got me to thinking about something.  
I do (90%) full wort boils in a 10 gallon brewpot and use a counterflow chiller. Usually 8 to 9 gallon batches, all grain. After I am finished boiling,  
I put the finishing hops in the brewpot and put the lid on for 30 minutes.  
Then I siphon through the counterflow chiller. The wort coming out of the chiller is a murky brown color, (for a pale ale). Between the time I pitch  
and the time the yeast takes off, 3 to 4 inches of "fluffy break" material  
will settle into the bottom of the carboy, then when the yeast takes off, it all gets mixed back up together again. It usually take a week or so before the fermentation has settled down to the point that the wort clears  
again. At this point, the material is more compact and is only 1 to 2 inches  
in the bottom of the carboy. I rack into the secondary at this time. It is  
usually within 10 S.G. points of being finished.

I figure this is probably hot and cold break material, though I do get around a quart of hot break in the bottom of the brewpot. Any comments about  
this "fluffy break" that gets stirred up during primary fermentation?

Also, thanks to those who posted the good technical articles in Mondays digest, you know who you are and you know which parts were the good ones.

Some do, however, this system lends itself only to single-step infusion mashes or decoction mashing, unless you've got an immersable heating element. Upward-infusion (i.e. temperature-controlled) mashing is usually done in a Bruheat-type masher or stovetop and then transferred to the lautertun. Note also, that "round" is not a pre-requisite. I've seen many square ice chest lauter tuns.

>the pluses and minuses. Thanks

I think the idea is sound, except I would offer that you should use a smaller diameter tubing (I used 3/8" OD) and see how many feet have efficient heat transfer. Apparently, you have the math or patience to determine this and I would like to know what the efficient part of the length is on a 3/8" OD tube. However, I think Paul's post earlier in HBD944 supports your multiple tube theory.

Since I've got your attention, Micah, could you post some references for your early June post regarding lipids in beer. I was fascinated and want to read more about them. Thanks.

From: Glenn Anderson <glenn.anderson@canrem.com>  
Subject: 2 pot boils

I'm wondering what adjustment would be required to my hop rate, if any, when using two pots to boil 5 gallons instead of one.

Assuming that I boil 2.5 gallons in each pot and hop only one of the pots.

I'm using the AAU system described by Miller in TCHoHB, would the utilization be the same as if I boiled and hopped the entire volume?

I'm guessing not, simply because of the volume of wort present to dissolve hop resins into.

I would appreciate any comments/calculations anyone could share.

From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Brewpub plans for Ann Arbor, MI

This article appeared in the Ann Arbor News (10 August 1992, Monday), page C1 . I've condensed it greatly, mostly removing information not immediately relevant to the subject and general info about brewpubs which i suspect the average homebrewer knows about. A fuller version is on alt.beer and rec.crafts.brewing... Sorry, but i cannot provide the article number.

-----  
Couple plans pub that offers home brew

By Dave Wilkins (News staff writer)

Barry Seifer and Jennifer Kirscht want to brew and serve specialty beers in downtown Ann Arbor.

If their well-researched business plan can overcome a string of obstacles, Grizzly Peak Brewing Co. could, by next spring, be Michigan's first brewpub.

They also plan to stock a full bar, offer both burger-and-ribs fare and upscale dining, have an 80-seat banquet room, add a rooftop beer garden, and sell contemporary home furnishings in a third-floor loft.

Brewpubs, however, are prohibited in Michigan. That's one of the more daunting obstacles facing Seifer and Kirscht.

On Jan. 1, they formed a corporation: Seifer & Kirscht Inc.

Last month, they bought the Cracked Crab building.

They have hired an architect and a lobbyist, who is pushing a bill that would allow brewpubs to operate in Michigan.

Still on the list of things to do:

- + Find investors for the venture, which may cost up to \$1.3 million.

- + Hire a properly schooled brewmaster

Another hurdle: neither Seifer or Kirscht have restaurant or bar experience. They will hire experienced people, they say.

Michigan's liquor laws specifically separate the manufacturing, wholesaling, and retailing of alcoholic beverages -- and, therefore, prohibit brewpubs.

Seifer and Kirscht are counting on House Bill 5407, which would allow brewpubs to operate in the state under strict limits.

The bill has passed the House and is now in the Senate's State Affairs, Tourism and Transportation committee.

There is no formal opposition to the bill, McKinney says. It's supported by the state Commerce Department and the Michigan Restaurant Association. The powerful Michigan Beer and Wine Wholesalers Association is neutral.

If the bill doesn't pass, Seifer and Kirscht say they will move ahead with their restaurant and bar, and perhaps brew their beer at another site or contract with another brewer.

[Any typos are mine -- AjD]

> wine and ale yeast would produce an undrinkably sweet wine.

I'm not sure what you're saying here. I have used Red Star Champagne, Red Star Epernay, and Whitbread Ale yeasts in Ciders. I have always had to fortify them somewhat so that they did not ferment out too completely, as the apple sugars are highly fermentable, though the Ale yeast will tend to quit earlier than the Champagne yeast.

I personally do not like sweetening after fermentation, and would rather choose the right yeast and level of fortification so that the final product ends at a desirable gravity.

My personal favorite ciders were produced with the Ale yeast, or the Epernay. I thin keither of these are easier to work with than the Champagne yeast in terms of acheiving a desirable final gravity

From: Pierre.Jelenc@cunixf.cc.columbia.edu  
Subject: parallel chiller

In HBD #944, Micah Millspaw mentions planning to build a parallel immersion chiller with four 12ft lengths of 1/2 inch tubing, and asks for comments.

I made something similar, with two 20ft pieces of 3/8 inch copper tubing. The tubing was first held together with string and tape, so as to be coiled side-by-side, then it was shaped so as to bring both inlets and outlets to two T compression fittings, the inlet one going to a quick-disconnect fitting to the tap, and the outlet to a similar quick-disconnect to the sink. The advantage is that the construction is all metal up to the joints, and thus can be boiled thoroughly for sanitizing. The in and outflow plastic tubings are then connected and the water started in seconds, without heat damage to them.

This construction allows me to cool 5 full gallons to water-temperature plus 5 degrees F in a bit less than 15 minutes. The wort must be stirred slowly to optimize heat transfer.

From: oconnor@ccwf.cc.utexas.edu (donald oconnor)  
Subject: oring challenge

okay guys. rather than continue on along this "is too, is not" discussion about orings and soda let's have a little experiment to put a little substance behind the opinions.

here's the experiment. i have what i think most would call a light lager (9 lbs vienna malt and some saaz hops) that's been sitting in a used keg for about 5 weeks now. it was the first time i had used the keg and i did nothing special at all to clean either the keg or orings. i.e., i simply rinsed the soda out with warm water and cleaned the oring and lid with warm water, then soaked the keg in a weak bleach solution before filling with the beer. i am willing to ship a bottle of this beer to several people who have been claiming that old orings will ruin the beer. all they have to do is taste and smell the beer and tell me what kind of soda pop was in the keg before the beer. i will even tell them that it was either coke, root beer, or dr. pepper. i personally doubt that anyone will be able to detect any hint of any soda pop whatsoever let alone claim that it has 'ruined' the beer, but we shall see.

Now who should be the judges. I must insist that kinney baugham and al korz be 2 of them since they seem the most insistent. others i would like on the panel are al richter, john rose, glenn tinseth and the person who wanted to send me an old root beer oring whose name i can't seem remember. there was another gentleman who posted to the digest last friday expressing his experience who would be a good choice as well. It will cost about 3 bucks each to ship these out so i'm not inclined to send one to everyone reading the digest but i think i have room for a couple of more. So these people should simply email me their postal address and i will send off a bottle in the next day or two. I don't use a counterpressure bottle filler but i've had good success filling bottles with a piece of vinyl tubing attached to the end of the picnic faucet as someone suggested on the digest some time ago. when you get your bottle do whatever you like to determine which soda pop (root beer, coke, or dr. pepper) was previously in the keg and just email me the answer. i will post the results to the digest after receiving all of the replies.

So there's the challenge. let's see if kinney b and al k are really so sure of their previous statements that an old oring will 'ruin' a light lager.

by the way, if al korz' address contains words with more than 4 letters someone may wish to help him out. based on his personal email to me i can assure you he needs no help with the 4 letter words. he's mastered them all.

Subject: truncated digests

In HBD 945, Dave Bircreports receiving a truncated digest on August 6. The same thing happened to me, too. Dave, the digest is not really truncated, which is evident from the fact that your directory will show that it's a long file. The cause of the problem will not show up in Wordperfect, nor--I suspect--would it in other wordprocessing formats. The problem is simple: a control-Z code was entered in the text at line 200. The software interprets this as "end of the file" thus creating the appearance of truncation. I could not discover this bug with "Reveal Codes" presumably because it lies "outside" the file as read by the software. However, the solution is simple. Just go into the file with DOS EDLIN or a similar editor, and DELETE line 200 (there is nothing on it but Control-Z). Then SAVE the file. Magically, the whole file will now be readable.

From: andy@tonga.wustl.edu (Andy Leith)  
Subject: Bleach and SS, holes, Minneapolis

Jack posts details (#945) of an experiment that he did to determine whether or not bleach will corrode stainless steel. He didn't have an empty keg to use in the experiment. Some time back I got lazy and left a cornelius keg of mine sitting with the bleach sanitizing solution in it. The following week I kegged an IPA and when I pressured up with CO2, a thin stream of pale ale spurted across the kitchen from a tiny pin hole in the side of the tank.

So if you leave bleach solution in your keg for a long enough time (> 1 week) it probably WILL corrode the keg regardless of what intuition may say to the contrary.

If anyone has any safe ideas on how to repair a pin hole in my keg I would be most grateful.

I would also like to know of any brew shops, brew pubs, clubs, or homebrewers in the Minneapolis area, as I am moving there from St. Louis in a couple of weeks

Thanks

Andy Leith      andy@wups.wustl.edu

[goes on to mention trying several other things, finally adding  
some grapes and being successful.]

The thing that you were missing in the first trial was yeast  
nutrient. Normally, brewers don't have to worry about this,  
because it is contained in the ingredients (malt or fruit).  
However, if you are making a straight mead (no fruit, only  
honey), then you need to add yeast nutrient yourself. Yeast  
nutrient can be as simple as ammonium chloride, but there are  
also various brand names available on the market that different  
people swear by. Any good book on making mead should have a  
discussion of this.

From: Bob\_Konigsberg@3mail.3com.com  
Subject: Stainless Steel corrosion

In HBD # 945 Jack Schmidling writes about his chlorine/stainless steel experiment.

I've had corrosion problems with stainless especially where it is of cheap(er) quality. The first stock pot I had was ok, but I left the lid on, with liquid (no chlorine) overnight, and the next morning, the lid was covered with rust flowers and pitting. In two cases our stainless tableware (an inexpensive set) has developed similar marks.

FWIW, it seems that the mixing of ingredients in the stainless alloy is not always as good as it should be, and lumps (crystals??) of straight steel/iron are left in the material so that the chromium oxide (whatever form) does not form a complete seal on the material, hence the rusting.

None of the high quality stainless stuff I've bought has ever shown any of these problems, so it goes back to "you get what you pay for" or if not, then take it back to the store.

any  
Jane> chlorine left on the equipment kill all the good stuff? (I'm  
currently  
Jane> using 1-2 Tbl. of chlorine bleach per 1 gal water.)

This was covered a while ago on the HBD, I think Bob Jones and George Fix went back and forth on it a bit. I seem to remember the final outcome being that 1/2 c. of grocery store bleach per 5 gallons of water was sufficient to get the chlorine level to the 200 ppm or whatever concentration it was that will sanitize. I've been using this concentration with 30 minute contact times and no rinsing for about 4 or 5 batches now, and haven't noticed any problems -- my yeast takes off ok, and I don't notice any off-flavors from the bleach treatment. I am very careful to pour out every bit of chlorine/water that I can, which usually requires tipping the carboy upside down several times with several minute "rest" periods in between, to allow the drops to run down the side and pool in the bottom of the carboy. The pools pour out easier than trying to shake the drops out.

If you want to convince yourself that the beer flavor isn't being affected, take it to your local homebrew club and have some guinea pigs taste test it for you (Hi Dave!). Or enter it in a competition that will provide feedback and check what the judges say. Or drink it yourself, and if you're happy then it works.

A quick run of "units" shows 16 tablespoons per cup, so I'm using 8 tablespoons per 5 gallons. Your 1-2 Tbl. per gallon (5-10 Tbl. per 5 gallons) is right in the ballpark.

Subject: truncated digests

About these truncated digests. I think what happens is sometimes a stray end-of-file marker gets put in. For example, I use WordPerfect to write my posts, which I then save as ASCII and upload to the Vax for mailing. The problem is that WordPerfect puts an EOF at the end of the file, which I then strip out using my Vax editor. Sometimes I forget, though, and then depending on the software you use to read the digest, you may or may not get truncated at the EOF I left in. My software (Browse) ignores the end-of-file, so the digest looks ok to me, but other software respects the EOF, hence truncation. Even if you get someone to email you another copy, until the EOF is stripped, you'll still get truncated.

Now let's just hope I remember to take the end-of-file out of THIS post.

From: scojam@scojam.Auto-trol.COM (Scott James.)  
Subject: Mash - Hot Water Heater

Last time I suggested the idea of mashing with a modified hot water heater.

After some investigation, here is what I've discovered...

1. Hot water heaters are insulated with 1~3" glass. This would be a real pain to cut through.
2. They heat upto 180F, but with a variance of +/- 20F. The stability comes from the thermal isolation of that thick glass barrier.

After talking with this owner/operator of a local heating business, we started talking about possibilities. They ranged from using a kiln(!!) with a temp. controller to keep a steel vessel at a constant mash temperature to using a pot wrapped with nichrome wire as the heating element, all encased in some kind of insulation.

To me, this almost sounds like building a nuclear powered baby-bottle warmer.  
It could be done, but why so expensive?

I'm currently using a 50 qt. coleman cooler with added hot water... draining through a copper tube with slits cut into it with a hack saw. I keep getting stuck sparges, but I think it's because the brew shop I use to grind my malt uses an old coffee mill--I get lots of flour.

Oh well, I just wanted to keep you posted about ideas and progress (or lack of)

Subject: Re: Sassafras; low cal ginger beer

megatest!jao@Sun.COM (John Oswalt) writes:

>So my questions: Can sassafras root be obtained in the United States? Is  
it  
>even legal in the USA? Can root beer be made from sassafras bark?

Here in Pennsylvania the best place to get sassafras root is in the woods. The trees are not extremely hard to find. The leaves look something like this:  
(excuse crude ascii drawing)

```
      0000
     0  0
    0 0
   0000 0 0 0000
  0  00 00  0
 00  0  0  00
   00 0  0  00
    000000
     0  0
00
 0 0
  0 0
 0 0
00
```

All of the edges are smooth, and not all of the leaves will be properly formed. You should be able to find some trees that are small enough to dig up or pull out of the ground. I would suggest doing this on private land (yours or a friends) as it's probably not legal to dig up trees in a park.

>Sigh. It's times like these that make me wish for the good ol' days in the HBD when the members of this forum were only interested in open minded, friendly discussions of the issues; when we were all genuinely concerned about helping each other in their quest for the world's perfect beer. Remember when people used to commend us for being the best-behaved bunch on the net? Remember when?

Sounds like a real bore. I think the "problem" is that people are starting to think for themselves instead of simply repeating the same tired old lines from popular books.

>From: dipalma@banshee.sw.stratus.com (James Dipalma)  
>Subject: Runoff temp, mashout

>Whenever specific gravity is measured with a hydrometer, the reading must be corrected if the temperature of the solution is other than 60F.

This may seem like a trivial point but that is only important when comparing measurements with someone else who is going through the same ritual. One could be a happy brewer and make terrific beer taking all measurements at 100F as long as he didn't get upset about not reaching other's standards. I take all gravity measurements at tap water temp and never bother correcting it. This is also one of the reason my yields never seem quite up to snuff. However, the difference over 10-20 degrees is within the measurement error of just trying to read a hydrometer.

>ingredient, sassafras root, for sale anywhere in this country (USA).

>The Bread of Life, a Bay Area health food store I frequent, has  
sassafras  
>bark, but no sassafras root.

>So my questions: Can sassafras root be obtained in the United States? Is  
it  
>even legal in the USA? Can root beer be made from sassafras bark?

The same thing happened to me. The bark is everywhere, but the root  
is not to be found. One guy even tried to sell me finely chopped  
bark, and claimed that it was root. I may be stupid, but . . .

I ended up trying the bark. It smells great, but is unable  
to impart much taste to the tea. The result is a nice soft drink, but  
not what one expects from root beer. You might try to substitute, say,  
8 or 10 ounces of bark for 2 ounces of root in 4 gallons.

You might also consider harvesting wild sassafras for the roots. I  
don't know about California, but in New York it can be located rather  
easily along any major highway. (I am at the moment too lazy to  
harvest, but I plan to do so in the near future.)

flight of  
> fancy, but I always did like the t.v. show "MacGyver".

I have devised just such a device. I got it in my head that I wanted to  
bend  
some copper tubing one night, so I went out the local hardware store.  
They  
were having a sale (\$21us) on pre-packaged 50' coils of 3/8" tubing for a  
price  
lower than 25' of the regular bulk tubing. So I got the coil figuring  
I could make two and give one away. Well as I was contemplating said  
copper  
tubing I had a brainstorm (ok maybe a brainshower). Knowing that Texas  
tapwater (or more specifically hosewater) was downright warm in the summer  
I  
pulled my two-liter bottle soda bottle of ice out of the freezer and  
wound  
about seven feet of coil around it. Then I left about two feet straight  
and  
wound the rest (except for a straight bit at the end) into a double coil.

Volia, I had created WortChiller-zilla(tm). The thing is ugly I'll admit,  
but  
it cooled down my last batch (~4 boiling gallons of wort) in a much  
shorter time than my usual ice batch (didn't think to measure said time,  
it being the end of a long home-brew/drink day). I had put a frozen two-  
litre  
soda bottle inside the small coil and put the coil in a small pan with  
ice cubes. Added a water to the pan and had a pre-chiller. I then put  
the  
wort chiller in the pot (I had boiled it a short time in the wort to  
sterilize

it) and turned on the tap water.

On the observation of a brewfriend next time I will omit the seperate pot with icecubes and use my washtub/icebath around the pot as a pre-chiller.

That way I'll get the best of both worlds, ice bath for outside of pot and wortchiller inside the pot.

From: Jim Grady <jimg@hpwalq.wal.hp.com>  
Subject: low-cal ginger ale

There was a post yesterday about making low-cal ginger beer by substituting sweet & low for sugar. The last batch of root beer I made (from extract) I made with just half the sugar (no sweet & low) because commercial soda pops are so sweet. My complaint is only the lack of flavor from the extract I used; I like the reduction in sweetness.

From: ty@sangabriel.desktalk.com (Tyson M. Kostan)  
Subject: Re: CO2 Purity

I too am interested in CO2 purity. There are two potential contaminent types that I wouldn't want in my beer: those that eat wort (such as bacteria) and those that are toxic, or add flavor to the wort (such as oils). Anyone with info on this, please tell.

With SCUBA gear, the main concerns are H2O accumulating in tanks (which isn't by itself too harmful to beer, but causes lung problems in humans). Not a problem by its self, but it can cause the interior of tanks to oxidize (I know aluminium oxide doesn't taste too good, and may have other ill effects).

Receintly, a friend of mine and I had his tank refilled at an industrial CO2 supplier. The guy filling the tank laughed when he saw the size of Ed's tank (a 5 pounder) and filled it at no charge. I'm sure more CO2 ended up in the atmosphere than in Ed's tank. However, Ed has had many a successful batch off that tank.

I still prefer to take the "Relax, don't worry..." approach.

Not since the space shuttle blew up has there been so much attention given to this topic. Can we please DROP this issue? If you guys want to conduct further experiments and talk about this do it directly between each other then post a SINGLE report on your findings.

The same goes for the attacks on other's comments, "lame" or not. Use direct mail to work out your frustrations. Let's get back to the quiet consideration of the finer points of home brewed beer and leave the personality conflicts behind.

Now on to a REAL digest comment...

Beware when you pitch at warmer temps (like 85F) that as the wort cools to the room temp (or below) the pressure in the carboy will drop and may pull in fluid from the airlock or the blow off bucket. Be sure to pitch at sufficient rates to get the yeast producing CO2 fast enough to compensate for the pressure variation and keep the flow of gasses in the right direction.

To which I reply:

I went home and looked this up in several books that I have on mead (and yeast in general) and found that I was a little incomplete and a tad misleading in my post from yesterday. Yeast nutrient is sort of like vitamins for yeast --- it contains a lot of different chemicals. Basically, it has all (or some) of the compounds that yeast need to get started. Apparently, two of the things yeast need most are nitrogen (from ammonium salts) and phosphates (from phosphate salts...duh), so that a good substitute for the "complete" yeast nutrients is just ammonium phosphate, not ammonium chloride, as I said yesterday. The various brand names of yeast nutrient on the market probably have all of the other goodies that yeast need.

The books also said that yeast would actually ferment without yeast nutrients, but it takes a long time (like several months). A slurry of old yeast can be used instead of store-bought nutrient, as it has the proper goodies too.

This makes sense, I have heard of several people who are allergic to  
wheat  
that are allergic to wheat beers also. It may be possible for her to  
ingest  
filtered wheatbeer but not some varieties of turbid hefeweissens, for  
instance.  
If the allergy is a \*mild\* one (class 1 or only a coupla hundred units  
reactivity), you could determine empirically by trying a few of the  
filtered  
ones, have some antihistamines ready. Its really hard to avoid wheat in  
processed foods these days, so total exposure is the way to look at this  
picture.

From: James S Durham <js\_durham@pnl.gov>  
Subject: Sanitizing kegs with bleach

Just to add another data point to the study, I use cornelius kegs from time to time. Since I seem to finish 5 gallons of kegged beer much faster than 5 gallons of bottled beer, I keg my brew infrequently. During the long and frequent off-times, I sometimes leave the keg filled with bleach water to remove any residual beer (or soda) taste and to keep the keg "squeaky-clean." I have never noticed any rust, holes, scale, or discoloration of the stainless steel keg or assorted parts. Neither have I noticed any deterioration of the O-Rings. Note that I usually use a standard solution of 2 T bleach per 5 gallons of water.

I have a possible solution for people who do not want to taste residual soda in their kegged beer. I usually keg a stout that is so full of flavor that I wouldn't be able to taste the difference. If I remember, I'll post the recipe tomorrow.

From: aderr@BBN.COM  
Subject: Homegrown hops....

I've been reading this newsletter for over two years, but this is the first time I've ever posted an article. I'm an extract brewer (so far) with 6 batches brewed. All six batches have turned out great and I believe that this Digest has helped greatly with that. Thanks!

Anyway.... I just harvested my first batch of cones from my first-year hops plants last night. The conventional wisdom seems to be "don't expect to get very much from your plants in the first year". Well, I guess I either got lucky or did something very right, because I picked about 2 gallons (I'll weigh them after they're dry) of ripe cones and left at least twice as many unripe cones on the vines!

I thought I'd let people know what I did, just in case it WAS something I did right. I bought 3 Cascades rhizomes from The Modern Brewer (in Cambridge, MA) somewhere around the first week of May. I dug about a 3' x 2' x about 1.5' deep hole next to the foundation of the sunny side of my house, and filled it with a mixture of topsoil, composted manure and peat moss, and planted the rhizomes about a foot apart and about 2" deep. We had a very strange spring this year, and the final two frosts were several days after I planted.

I watered them every day or two, and about once a week I added a tablespoon of Peters 15-30-15 houseplant fertilizer to the water. It was several weeks before I saw any activity from the plants, but once they started, it was like the best stories I've read here about hop vine growth! I put three heavy cotton twine lines up the side of the house attached to a crossbar held up by another piece of twine through a pulley, so I could let the lines down at harvest time. The pulley was mounted about 15'-18' up the side of the house. The vines grew 2"-3" per day on bad days and over 6" on good days. They hit the top of the trellis and tried to go further, but when they decided that they couldn't, they just started to get bushier and darker green.

By the way, I cut back all but the single best shoot from each root, and the plants got sun from about 10am until sundown.

Next, they got completely covered with "burrs", and within about two weeks the burrs all started turning to cones. When the cones started looking like they might be ready to pick, I re-read Pete Soper's "A Hop Growing Primer" (and several posts in HBD), but I wasn't exactly sure what people meant by a "papery" feel. Well, I guess the only way to describe it is... well... like tissue paper. They also have a papery \*sound\* when you squeeze them. The main thing to keep in mind, if you've never grown hops before, is that the sound and feel are distinctly different from unripe cones.

I started out using scissors to snip the cones off, but after a while I just started pinching or pulling them off with a small bit of stem just below the cone. I have to tell you, it's a wonderful thing to put your face in the middle of a huge bowl of freshly picked hop cones and inhale deeply. In the words of Penn Gillette in Penn and Teller's "The Invisible String":

"It's a pretty thing.... it's a \*very\*... pretty... thing"

Now I can't wait to brew a batch of nice IPA or Steam Beer (oops,

excuse me... "California-Style Ale") with my own, homegrown hops!

Thanks for all the help,  
Alan Derr

From: KLIGERMAN@herlvx.rtpnc.epa.gov  
Subject: STYRENE AND NATURAL ROOT BEER FLAVORS

A recent concern in the HBD was styrene leaching into the wort from plastic equipment. Styrene appears to be a weak carcinogen in laboratory rodents. Styrene oxide, its primary metabolite is a carcinogen in rodents and a fairly potent mutagen. However, it has not been determined if styrene is carcinogenic or mutagenic to man (or woman) at high concentrations, and it is doubtful that the very low levels that could leach from plastic would be dangerous.

Natural root beer flavor comes from sassafras. Sassafras oil contains relatively large amounts of safrole, which is a liver carcinogen for rats and mice. It has been prohibited as a flavoring agent in the U.S. since 1960.

From: rfozard@sword.eng.pyramid.com (Bob Fozard)  
Subject: extract hot-break

I've been doing all-grain for about the last 10-15 batches, and now I wanna do an extract batch and reflect on the differences. The obvious advantage is the amount of time spent in the kitchen, but if I'm going to spend a couple of hours in the kitchen, and invest all that good karma into my fermenting beer, I want something that I truly enjoy drinking.

Since I've changed my brewing technique quite a bit along the way, I expect my planned extract batch to be somewhat better than my previous ones. Contemplating this, I've been thinking of other ways to improve my extract procedure.

I'm not sure where I've seen this (maybe it was here), but is it true that much of the hot-break has already been precipitated out of extract syrup? If this is the case, I would expect that the 60+ minute boils I've done in the past did more damage to the wort (in the way of caramelization) than good. Perhaps this also has the effect of driving off much of the malt aroma that someone recently mentioned seems to be missing from extract brews. If using hopped extract, perhaps just a 10-15 minute "sanitation" boil with perhaps the addition of flavor/aroma hops would be the better way to go. If using un-hopped extract, we have the option of using pellets and doing a slightly longer boil (30-40 minutes for pellets??), or using the liquid hop concentrates that don't require boiling (isomerized??). Comments and/or experiences with this are requested.

I've tasted some pretty darn good extract brews, but none of my previous extract batches were close to what I've been able to produce with all-grain. Probably one of my problems was with oxidation. Typically, an extract brewer will mix the hot wort with some cold water to get it to 5-gallons of pitching temp. wort. I feel that splashing the hot wort into a carboy of cold water might lead to unwanted oxidation. This time I will do a full-volume boil and use my immersion chiller, but I wonder about the boil time and caramelization. Could this be a source (or one of them) of that extract "twang" that is present in some extract batches. It clearly isn't always there, at least not by my tongue, but what causes it when it is?

> much yeast. They Zymurgy Special Issue on Yeast is an excellent  
> reference for the things you are wondering about.

Funny, I was just reading that article this morning... In a 5 gal batch, you want (according to the article) 40 billion ( $4 \times 10^{10}$  for you tech weenies) yeast cells at pitching time. This can be accomplished by (1) pitching 10g of viable, rehydrated dry yeast, or (2) pitching a 2 cup (500 ml if you're metric) active starter.

Dry yeast should be rehydrated at about 100F (38C). You can then cool it to the pitching temperature by slowly blending in 2c (500ml) of wort. Sudden temperature changes of >20F (10C) should be avoided.

The premise of the article is that a sufficiently large population of active yeast will help to prevent nasty organisms from getting a foothold in your yummy wort.

From: Martin Wilde <martin@gamma.intel.com>  
Subject: Mash efficiency comments

With all the traffic on the BS of mash efficiency, I thought I would present the results of an experiment I conducted.

My normal sparge of 45 minutes produces roughly 70% efficiency. This is with my equipment. Your equipment may produce different results. Thus avoid the pitfalls of someone saying you must sparge for 2 hours. My sparges flow rate starts out slowly and then is increased as time goes by.

For an experiment I sparged for 90 minutes and my efficiency was 90%!!. My beer was also slightly more tannic and grainy tasting (from the milking of the grain bed for every drop). Keep in mind, this is on my equipment - yours will be different.

Most people I have talked to say BS to the notion of 2 hour sparges and say grain is cheap. The extra hour of sparging is more expensive to me time-wise than the buck or two for the extra grain.

When you are reading a book on brewing - don't put the author on a pedestal and assume that they are the ultimate god... Just use whatever works for you.

Announcing the demise of Barley's Brew Pub here in Phoenix and the opening of Coyote Springs Brewing Co. Now under new ownership/management, Coyote Springs Brewing Co. will be doing some nice interior remodeling to enhance this wonderful gathering place for you to meet with friends and enjoy the finest beers made in Arizona.

Candy Schermerhorn, noted columnist for Zymurgy magazine, famous for delicious recipes using beer, will be designing a completely new menu with items based on the wonderful beers brewed at Coyote Springs by the original Barley's brewmaster, John Vogt-Nilsen. If you find yourselves in Phoenix, you MUST make it a point to visit.. you'll be glad you did.

From: gelly@persoft.com (Mitch Gelly)  
Subject: Ruby Tuesday

Greetings,

The raspberry beer has been in the bottle a few weeks now and is just unbelievably good. Here is the recipe, although the wild raspberries are probably already history in most places. (Next year!)

#### RUBY TUESDAY

7 lbs. light malt extract syrup  
7 lbs. fresh wild raspberries  
1 lb. english crystal malt (had no lovibond rating on pkg, I'd guess ~40)  
2/3 oz. cascades whole hops (~3.5% alpha)  
1 campden tablet  
1 pkg. Edme ale yeast (11.5g)  
1/2 cup corn sugar to prime

Brought 2.5 gal. water to boil with crystal malt in grain bag (removed grain bag when water was at 170 F). Added extract and brought to boil, boiled for 60 minutes. All of hops for 45 min.

Chilled wort to ~100 F and strained into carboy (prefilled with 2.5 gal cold water). Rehydrated yeast in 90 F water for 15 minutes and pitched, topped off carboy with water, and mounted blowoff tube. O.G. 1.040

After two days of healthy ferment (~75 F) added fruit. Pureed raspberries with campden tablet, added to fresh carboy (better use a 6 or 7 gal carboy if you got it, the fruit takes up space!), purged carboy with CO2, and racked beer into it. Swirled it around a little to mix it up (don't shake it up) and put blowoff tube back on. Let sit another week and bottle. I only used 1/2 cup corn sugar to prime, and it was plenty. Didn't take a final gravity.

Comments: Color was absolutely phenominal!! Ruby red and crystal clear. Not even chill haze. I was amazed at the clarity. Excellent raspberry nose and flavor, sort of like a raspberry wine. As the beer would sit in your glass, the raspberry aromatics would get stronger. Not sweet, kind of tart. Nice. On the down side, it was a little \*too\* raspberry for some, not enough beer character. Next time I will go for 9-10 lbs extract.

Very pleased with the outcome, thanks to all who sent me suggestions. I have a peach beer in the bottle a week now, based on the same recipe except using 12 lbs. of peaches and pale malt instead of crystal. Excellent

summertime beverages, the women (and I) love it.

And now a question: How acidic are raspberries? I have about 5-6 lbs of raspberries left, and 15 lbs. of light clover honey, and they're just waiting to be magically transformed into a melomel. I have not made a mead before, and a lot of the recipes I've seen call for acid blend, or just tartaric acid. Will 6 lbs of raspberries raise the acidity enough in a five gallon batch, with 15 lbs of honey? And will yeast nutrient be necessary (since there's fruit in there)?

Cheers,

Mitch

From: adiron!partech.com!scott@uunet.UU.NET(Scott Barrett)  
Subject: Fresh hops vs. dried hops

In HBD 941, CHUCKM@CSG3.Prime.COM wondered about using fresh hops rather than dried hops. Since harvest time is approaching in central New York, I had been wondering about the same thing. I decided to do a little digging.

In an article describing hop processing in the Hops and Beer special issue of Zymurgy, it is mentioned that hops go from about 80% water to about 8% water when processed into bales. The answer is now within reach.

Assume that we want to determine the amount of fresh hops required to give the bittering value equivalent to 100g of 4.6% alpha dried hops. The dried hops is comprised of the following:

8.0g	H2O	8.0%
4.6g	alpha acids	4.6%
87.4g	other (solids)	87.4%
=====		
100.0g		

Assuming that the weight change during drying was solely from loss of water, the 92g of non-water material in the dried hops must have constituted only 20% of the fresh hops that were dried. So the fresh hops must have broken down thusly:

368.0g	H2O	80.0%
4.6g	alpha acids	1.0%
87.4g	other (solids)	19.0%
=====		
460.0g		

So, the alpha level of the fresh hops was only 1% and 4.6 times the weight of the dried hops is necessary if using fresh instead.

A general formula that can be used for different fresh and dried water percentages is as follows:

$$H_f = H_d [(1-W_d)/(1-W_f)]$$

Where:

H<sub>f</sub> is the weight of fresh hops to be used  
H<sub>d</sub> is the weight of dried hops normally used  
W<sub>d</sub> is the percentage of water in the dried hops (e.g. 0.08)  
W<sub>f</sub> is the percentage of water in the fresh hops (e.g. 0.80)

Another Zymurgy article entitled "Suburban Hop Farming" mentioned that 4 pounds of hops were dried to a weight of 13.25 ounces, a ratio of 4.8. Assuming a final 8% water content, the original hops must have been 81% water. This seems to support the numbers shown above.

In HBD 942, John DeCarlo gave a 6-to-1 rule of thumb for getting an

equivalent bittering value from fresh hops. This would be appropriate if the fresh hops were approximately 85% water. This certainly seems within the realm of possibility.

As always, your mileage may vary.

Yours in brewing,  
Scott Barrett

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: RE: chillers

Michael Hall has written a very good paper on the calculations required for a counter-flow type chiller. I believe that Mike mentioned that he was preparing to submit it to Zymurgy. I searched the last two months of archives for it, but came up dry. John Palkovic kindly sent me a copy. There is a rights reservation at the top, so I'm retroactively asking Mike's permission. My system's mailer keeps bouncing Mike's address. I believe I can reply if he contacts me.

That being said... Mike's calculations suggest that a siphoning counter-flow cooler would need to use a length over 30' if it was made of 1/2" copper tubing, but that 25 - 30' of 1/4" tubing would give a good heat exchange efficiency. The interesting part of Mike's results is that there is a minimum length for any tubing diameter. Using a longer length does no harm, but you are buying more tube than you need.

An immersion cooler will have a higher velocity, since the water is being driven by the mains pressure, rather than a siphon. Since heat transfer is proportional to velocity, the tubing lengths would presumably be shorter. In a parallel tube immersion cooler, smaller would be better. The length of the cooler tubes would be determined by the number of tubes in parallel, the I.D. of the chiller tubes, the water supply pressure and the diameter of the supply line at the tap. Most outdoor hose bibs are 1/2" pipe, while sinks are usually 3/8".

FWIW, my 25' x 3/8" immersion cooler has an outlet temp near the wort temp, but only if I stir pretty fast. Also pipe is measured by I.D, but bendable tube is O.D. This means that tubing sizes are bigger than the fluid cross-section. The difference is considerable for the smaller sizes.

Subject: Flaked grains

Andy Phillips asks:

>And now I have a question: why do unmalted grains such as wheat and  
>rye have to be gelatinized (cooked) before mashing? I just made a  
>batch of bitter with 2 lbs of flaked rye, forgot to gelatinize it,  
>but got a sensible yield: about 85% of the maximum possible. Any  
>have a hard, scientific explanation for this?

Yeas, Andy. Flaked grains are already gelatinized in the "flaking"  
process  
(grains are steamed and then rolled) and do not need to be cooked before  
introducing them into the mash-tun. Raw grains need to be crushed/cracked  
and  
cooked to break up the starch globules to allow the enzymes gain access.

So it sounds like you don't have a problem. More info on the cooking  
process  
can be had in books like M&B Science or the Practical Brewer.

Subject: Headspace

Jack says:

>It seems that there is a very simple solution IF the problem is the O2  
in  
>the headspace. Why not just fill the bottle up and leave NO headspace?

It depends whether you are concerned about thermal expansion/  
contraction.

That is, beer and glass rates being different and glass being breakable.  
But I agree with what Jack implies, which I take to be that O2 in the  
headspace is probably not a problem for bottled conditioned beers. Stay  
relaxed with the hobby. Remember there isn't much O2 up there, yeast is  
a good 'scavenger' of O2 whilst growing and it will probably use it all  
up during the first few days of bottle conditioning anyway.

Unless, of course, someone else knows better :-)

Happy brewing

Subject: RE^2- chillers

RE^2: chillers  
In #947, Mr de Armond says:

> That being said... Mike's calculations suggest that a  
> siphoning counter-flow cooler would need to use a length  
\*\*\*\*\*  
> over 30' [...]  
> An immersion cooler will have a higher velocity, since the  
\*\*\*\*\*  
> water is being driven by the mains pressure, rather than a  
> siphon. Since heat transfer is proportional to velocity,  
> the tubing lengths would presumably be shorter.

First, the siphoning in the counter-flow chiller, under standard operating procedure, refers to the siphoning of the wort through the inner tube of the chiller, not the outer tube through which tap water is driven. So in both cases the coolant is being driven by pressure. Aside, with a long enough siphon you can develop some pretty good pressure. Ever empty a waterbed, on the fourth floor, with a garden hose dropping all the way to the ground? :-)

Second, I beleive that the velocity in question is the velocity of the wort relative to the coolant, or cooling element. This leads me to beleive that the wort being siphoned through the counter-flow would have a greater velocity than the wort in which the immersion chiller is immersed. And since the heat transfer rate is proportional to velocity, the tubing length of the immersion chiller would have to be greater. Of course if you stirred very vigorously, the wort in the pot (immersion) may have a greater velocity.

I am the proud owner of a counter-flow chiller that works extremely well (read fast), though I admit is a water hog. I think that each type of chiller has its own points. I love the fact that mine works so fast, but on the other hand, I don't like that it can't leave all that cold-break in the brew-pot, instead of my primary, like an immersion chiller would.

While beer will give you that magical bliss, the more you drink the more you ...

From: JADAMS@SWS@PSI%HDSRTR@MRGATE@SNMRTR  
To: "homebrew@hpfcmi.fc.hp.com"@M\_INTERNET@MRGATE@SNMRTR@SNMRTR

We may not have brewpubs (it's called the "Budweiser law") - but we do have pubs that engage in "tap wars". Frontrunners in the tap race are the Brewery Tap in the oldest part of downtown historical district and LeVeau's in the museum district. They each have around 40 to 50 brews on tap.

I-10 & Hwy 6 is not exactly happenin' central. The only good place I know of in the vicinity is the Hops House at 2321-A Hwy 6 S., 496-0623. The best places are around Rice University: the Gingerman, Munchies, Churchill's (at the Red Lion Restaurant), McGonigle's Mucky Duck, Crown & Serpent, LeVeau's and several others. All have Sierra Nevada on tap - my minimum requirement.

Beer Central is at DeFalco's Home Wine and Beer Supplies, 5611 Morningside, in the Rice Village, 1 mile south of Hwy 59, Greenbriar exit, 1 block west of Greenbriar near University Blvd. Greenbriar borders the campus. Just walk into DeFalco's and ask where you can get a decent beer in this town, and you'll be deluged with suggestions. Their number is 523-8154. Hours are 10-6 M-F, 'til 8 Thurs, plus 10-4 Saturdays.

The Foam Rangers Homebrew Club meets the third Friday - 8/21 - it gets pretty wild - there are often other club activities. Call DeFalco's for info. Tell 'em I (John Adams) said "Hi!". I live near the Astrodome + that's the week of the Republican Convention = I'm going diving in the Florida Keys.

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Mashing from Micah Millspaw

Adding to the mash discussions. I suggested the use of the insulated cooler type mash tun because it can be used with both single temp. infusion mashes and upward step infusion mashes. It is a simple thing to increase the mash temperature by adding more hot water at the time it is needed for the step increase. The mash out can be conducted the same way. This approach to mashing is a part of the gentle mash that can reduce the effects of hot oxygen reactions. By way of explanation, I start the mash fairly tight 20-24oz per lb. and add sufficiently hot water to make the temperature steps I want without exceeding 32oz per lb grain to water, for a normal mash. For a first run only mash I use up to 48-50oz per lb. Also no stirring as the hot water is either underlet or sprayed or both at the same time. My mash/lauter tun is loaded with temp. probes and it works very well. I have been mashing in this way for the past four years and have many ribbons to show for it. Also it is easy and I'm lazy.

From: "PAUL EDWARDS" <8260PE@INDINPLS.NAVY.MIL>  
Subject: malt prices

In HBD #947, Brian asks about malt prices. \$0.95/lb in 55 lb quantities is high. Try a friendly micro-brewery if one is nearby. One of our locals will sell any of the grains they use to homebrewers in just about any quantity for \$0.50/lb. That's OK if you want to use Briess lager malt and specialty grains, but then sometimes beggars can't be choosers. I know that at that price, the micro is still making money. Their only caveat is that you call ahead and make sure it's not brew day or bottling day when you want to stop by, and I wouldn't go in and ask for only one pound. The folks in our club who take advantage of this deal usually coordinate their purchase and buy in full sack quantities. This place will even run the grain thru their roller mill for a small fee. (a couple of bucks per sack) I've heard that many micro's will do this as long as you don't interrupt them when they're busy. You can still get your specialty grains from your local HB, so as not to p\*ss them off.

One the \*really\* high side, there's a local shop (left over from the Wine-Art days) which gets a lot of first-time homebrewers/winemakers. This shop asks \$3.95 for a one-pound bag of pale malt! They buy it pre-packaged from Wines, Inc. The other shop in town is at least smart enough to buy in bulk (or go in with the micro on pallet loads) and break stuff down into 1, 5, and 10 lb bags, and charges a reasonable price. Guess who gets the repeat business??

From: mcnally@wsl.dec.com  
Subject: wheat allergies

I don't know much about wheat allergies, but I do know about beer. The turbidity in a hefeweizen is from yeast, not wheat; both hefe and klar beers are filtered. I would predict that if one causes an allergic reaction, so will the other (unless the B vitamins in the yeast counteract the allergy).

Most beer doesn't have wheat in it anyway, so a doctor who advises against "most beer" is not beer-aware.

From: blossomf@ttown.apci.com (Karl F. Bloss)  
Subject: Help for a novice

Wow! You guys are really advanced. I've just browsed through two issues of Homebrew and I'm lost. I need some advice for a total novice (don't laugh, you have to start somewhere)?

My roommate and I were given one of these homebrew kits, so we gave it a whirl. Of course, we didn't know the importance of proper sanitation and the first batch was contaminated ("This is the best wine I've had in a long time"). For the next, we properly sanitized a bottled-water carbuoy and made the second kit with the indicated amount of sugar. Sure enough, the beer was good, but had a 'caramelly' flavor. So a friend told us to use no sugar and double malt extract. This gave great results with a rich, lager-style beer. Our friends were baffled by the Old Milwaukee labels and Tab caps ("I got 'em 'cause they were cheap.").

Any suggestions why this works with the double malt? Any other suggestions?

Thanks!

> concentrates that don't require boiling (isomerized??). Comments  
> and/or experiences with this are requested.

A month ago I did my first all-extract/no-mash brew since I switched to all-grain/mostly grain a year ago. (Well, there was the brewferm lambic krieg kit batch, but that doesn't count). Anyway, I boiled the full amount vigorously for an hour before adding any hops, and then added fuggles/goldings over the next hour. I cooled with an immersion wort-chiller, and got a good 1.5" of hot break in the bottom of the carboy, the same I usually get with all-grain.

> I've tasted some pretty darn good extract brews, but none of my

> present in some extract batches. It clearly isn't always there, at  
> least not by my tongue, but what causes it when it is?

I think you've hit the nail on the head with the oxidation comment...

Anyway, the batch had a 4 lb edme strong ale kit, 4 lb of unhopped amber extract, and 2 lbs of lt. brown sugar in it. hops were: 1 oz goldings leaf (old), 1 oz fuggle leaf (old), 1 oz fuggle pellets (fresh), about 1/3 of each at 60, 40, & 20 min. I also added 1/2 tsp of netmeg at the finish, and 1/2 tsp irish moss. Edme ale yeast (weeast belgian ale starter went bad, & I coldn't find the packet of whitbread ale yeast I thought I had). OG 1.071, FG 1.013. I siphoned off the hot break into another carboy like I usually do, then aereated and pitched. I left it in the primary for 3 weeks, at room temp (80F+). I bottled with 140 g corn sugar, and another re-hydrated packet of edme ale yeast, since the alcohol content is pretty high.

I tasted it last night after a week in the bottle, and it seems to have developed a decent amount of carbonation already. It's got an alcohol nose to it, plenty of body, balanced by more than enough fuggly flavor, which blends into the nutmeg/brown sugar (the former is fading rapidly) sweetness, which fades again into hoppiness,

leaving a clean palate. Lets see, that's 5 different sensations, at different times, and I'm quite pleased. Once you taste it, you have to drink more - I only took sips, but I never sat the glass down until it was empty! A (non-homebrewing) friend came over, I poured him a glass, and it too was empty before it touched the table. Anyway, it's better than many (but certainly not all) of my all-grain batches.

I had expected a FG in the 1.025 range, and consequently overhopped. (The year old hops were quite a bit fresher than I thought, since they were vacuum-packed.) Obviously, I didn't caramelize it much in the boil, or the FG would be higher than 1.013. Aging should mellow it, and do it good.

If you do a full boil, you don't have to worry as much about caramelization. I seem to remember from Miller that 2.5 gal of 1.100 wort will caramelize 4X as much as 5 gal 1.050 wort, and will be twice as caramelized when diluted to 5 gal.

Boil the heck out of it...

bb

>> best-behaved bunch on the net? Remember when?

> Sounds like a real bore. I think the "problem" is that people are  
starting  
> to think for themselves instead of simply repeating the same tired old  
lines  
> from popular books.

Actually it wasn't a bore at all and there wasn't much repeating of the  
same  
old tired lines from popular books. This was a great forum for  
discussing  
the various techniques people have discovered that work better or somehow  
disproved what was printed in the books. Everyone would try the changes  
and  
report back what they thought and how it went. It was a very  
constructive  
process. The 'experts' on the list played more of a mentor role offering  
what  
they knew and what they experienced to be taken at face value. It was up  
to the reader to decide if they would like to take the advice or try  
something  
that better fit their way of brewing.

Then there were the many humorous brewing accounts frequently posted by  
people  
such as Florian Bell. Florian has his own way of doing things and it  
works  
for him. Unfortunately Florian doesn't post much any more and much of  
that  
'Entertaining' flavor of the digest has long since disappeared, being  
replaced by the more forceful 'technical' brewers who seemed to have this  
unrelenting drive to \*make\* you understand why they are \*right\* and  
others are  
\*wrong\*.

I think the "problem" is that people think that everyone brews for the  
same  
reason. They can't imagine anyone not having the same motivation for  
brewing. Some people brew to accurately reproduce specific styles, some  
people brew to make a beer they enjoy drinking, some people brew because  
they like the brewing process. Each of these people will have a  
different  
way that is right for them or works for them. Now, it seems, that one has  
to  
risk public ridicule if they post their experiences even though it may  
not  
be 'technically' correct. I, like many, feel it's not worth it. I get  
enough of that crap at work and my brewing is intended to help me relax  
from  
that.

**Subject: Sassafras**

Sassafras can be found growing wild in the woods in N. Ala. I have pulled roots on several occasions. I don't know how many roots you would have to boil

to get enough flavoring for a batch of root beer. Perhaps an old cookbook could tell you, maybe under sassperilla(?).

Look in the Audubon Guide to North American Trees p.451 for a description.

he range is "extreme S. Ontario east to SW Maine, south to central Fl, west to E. Texas, and north to central Michigan; up to 500 in the Southern Appalachians." In other word almost the entire E. U.S.

No, it sounds like the forum for discussion about home brewing topics, that it is supposed to be. People thinking for themselves will only add new or different perspectives to the discussion. They won't add flames. There is no reason to attack someone personally because of their view on a particular topic. After all, this is a home brewing forum, not a presidential election :-).

On to more important topics:

I brewed a wheat beer which should be done aging this weekend. This week, four bottles decided to break. To prime, I used one gallon of sweet wort that I drew off before pitching. The other bottles seem fine so I don't think I overcarbonated (over primed?) and the gravity levels were right on target. I guess its time to be a little more selective about the bottles I use for bottling.  
The ones that broke tended to be a little thinner than most of the others.

Wheat beer tends to have more of a head than most other beers. Whats the cause of this? Do these beers have a higher CO2 content causing the head (and breaking bottles)? Julius Echter bottles are pretty heavy - probably a good reason for that!

Saturday night, Lobster, Steamers, & fresh Wheat beer... can't wait.

>I can vaguely remember, way back when, a discussion in this forum regarding the addition of ascorbic acid (also known as vitamin C) to a brew for the purpose of preventing oxidation. Is this done at bottling time? In what quantities? I s'pose one could add food grade vitamin C available at any pharmacy or grocery store, right?

Unless someone else wants to take credit, I believe I started the discussion when I first announced my video. The guy in the brew shop featured in it claims that a tsp of Vitimin C will cure oxydation problems. He also claims that oxidation causes a cidery taste in the beer which seems an opinion unique to him so that may be a clue to the validity of the Vitimin C cure.

>Subject: yeast culturing

> As part of the never-ending quest for improvement of my beer, I've decided to try my hand at yeast culturing.....I have located a source for glass petri dishes, pipettes, slides, etc. What other equipment will I need? If a micro\$cope is needed, what power of magnification?

I have published (and emailed to you) an article on yeast culturing for beginners. It is a very simple and easy to understand method that requires an absolute minimum amount of equipment and knowledge. There is no EASYEAST here, just trying to pass on what I learned the hard way.

If anyone else would like a copy, email will get you one.

>From: korz@ihpubj.att.com Subject: Re: Cider  
>>Secondly, one can always add sugar to adjust the sweetness after fermenting.

>If mean adding sugar at bottling, this implies that you've somehow killed or filtered out the yeast or else the yeast will go at the new sugar.

I was referring to the standard practice of nursing along a batch of wine to

get the maximum alcohol out of it consistent with the type of yeast used.

The sugar is added during the late stage of fermentation. If all the sugar is added at the beginning, it can OD the yeast and stick or worse yet if you miscalculate, the yeast dies and the wine is too sweet.

The practice is to start with a gravity that you know will ferment out and then add sugar in small increments each time fermentation ceases until the desired degree of dryness is achieved. This can take several months but it is the time tested way of doing it.

>From: bryan@tekgen.bv.tek.com  
>Subject: Flurry of "break" material.

> All this talk about cold break material got me to thinking about something. I do (90%) full wort boils in a 10 gallon brewpot and use a counterflow chiller.

You might explain what that 90% means.

>The wort coming out of the chiller is a murky brown color, (for a pale ale).

I know the pros and cons of immersion vs counterflow have been beaten to death but I can't resist pointing out that the wort coming out of the kettle after immersion chilling is crystal clear. I just do not understand why anyone wants all that yuck in the fermenter or the bother of letting it settle and racking again.

>From: Glenn Anderson <glenn.anderson@canrem.com Subject: 2 pot boils

>I'm wondering what adjustment would be required to my hop rate, if any, when using two pots to boil 5 gallons instead of one. Assuming that I boil 2.5 gallons in each pot and hop only one of the pots.....

I think you are sadly mistaken if you think the beer in the kettle without the hops has been properly boiled. You might as well not boil it at all.

The correct approach is to use equal amounts of hops in each kettle.

>From: Jay Hersh <hersh@expo.lcs.mit.edu>

>> Thirdly, one usually will add lots of sugar to make a higher alcohol apple  
>> wine and ale yeast would produce an undrinkably sweet wine.

>I'm not sure what you're saying here.

If one simply added lots of sugar at the beginning, the ale yeast could quit fermenting long before the sugar was fermented and long before a wine yeast would quit.

> I have used Red Star Champagne, Red Star Epernay, and Whitbread Ale yeasts

in Ciders.

As a point of interest, I pure culture RS Champaign a few weeks ago for my next batch of wine and both petri dishes turned up mould colonies. One dish was never opened after inoculation as a control and the other was the one transferred to the slants. Both had the same species of mould.

My next batch should be interesting. I don't have enough of anything but apples to make 5 gallons so I picked the mullberries and elderberries as they ripened and froze them. Looks like the grapes and apples will be ripe about the same time. I also found out that elderberries need to be dried before use. Fresh, they are tasteless but dried, are very fruity.

> I have always had to fortify them somewhat so that they did not ferment out too completely, as the apple sugars are highly fermentable, though the Ale yeast will tend to quit earlier than the Champagne yeast.

That is one way to do it but adding sugar and letting it ferment seems more natural but that is a moot point.

>I personally do not like sweetening after fermentation, and would rather choose the right yeast and level of fortification so that the final product ends at a desirable gravity.

I don't consider fermentation over till bottling time but more importantly your method sounds too much like Gallo. And unless you get real lucky, you can easily miss the mark.

>From: oconnor@ccwf.cc.utexas.edu (donald oconnor)  
>Subject: oring challenge

>here's the experiment. i have what i think most would call a light lager (9 lbs vienna malt and some saaz hops) that's been sitting in a used keg for about 5 weeks now. it was the first time i had used the keg and i did nothing special at all to clean either the keg or orings. i.e., i simply rinsed the soda out with/ warm water.....

Perhaps the key here is the word "soda". The manufacturers will be the first to tell you that not all sodas are equal. My bad experience was with Coke.

As I said before, the first batch in a keg with casually cleaned oring was undrinkable (but I drank it anyway:). I have not noticed the coke taste since but the orings in all my kegs still smell like Coke not beer.

From: sami@scic.intel.com (Sam Israelit)  
Subject: Head Space, etc . . .

In HBD #947, Jack Schmidling writes that you could bottle leaving no head space. This is 180 degrees out of phase with what more than 20 other people have told me. They said that you have to have a minimum of one half-inch of space at the top or the bottle won't properly carbonate. I've never thought to ignore this advice so I don't know what happens if you fill it to the brim. Considering that the pro breweries do this, I'll run with the pack on this one.

Also Jack, you state that maybe people are starting to think for themselves here and that is what is causing the recent flame-outs. Well thinking for yourself and being an asshole are entirely independent characteristics. And I'm not referring to you with that statement, but with a few of the others recently posted. As a relative novice (I've only been at this for about 25 batches), I have learned a great deal through the more experienced brewers debating the different aspects of brewing. Challenging the techniques of others helps everyone to understand the underlying art. No one is saying that we can't think for ourselves, but rather that we should keep it to a constructive confrontation.

And finally, the peach weissen turned out to be pretty tasty. I used 12 lbs of California white peaches and I should probably have only used 9. It does have that banana flavor to it. What causes that? Is it from fermenting it at too high a temperature? Will it mellow out over time? Anyway, the next attempt is an all-grain stout (my first all-grain). Based on the discussions I expect it too be fun.

I received one reply, from Brian Smithey      smithey@rmtc.Central.Sun.COM

>I have no experience using ascorbic acid to prevent oxidation, but  
>thought I'd pass on my plan. I have a strong mead that's been  
>fermenting for a little over 3 months now (my first mead too), and  
>after that much time I want to be very careful with it. I'm also  
>a bit concerned about oxidation, especially since I expect the mead  
>to take a year or two to develop and mature. I'm planning on using  
>the new oxygen scavenging SmartCaps on my mead, and also on a six-pack  
>or so of each batch of beer that I brew from now on, and keep that  
>six-pack for "competition bottles".

This seems like sound advice to me. Certainly, SmartCaps should be able to prevent, or greatly reduce, absorption into my mead of oxygen in the headspace. But, I am also concerned with oxidation that can occur during racking and bottling. (If I ever get a keggung setup, I won't have this problem anymore ;-)

It's just occurred to me that the kinetics of the oxidation reaction might be slow so that dissolved oxygen could come out of solution as headspace O<sub>2</sub> is absorbed by SmartCaps. Any comments on that?

Assuming that the kinetics are not MUCH slower than the absorption on the caps, I am back to my original question: Has anyone used ascorbic acid in a mead? I am wondering about the effectiveness, procedures, and side effects.

Thanks for any advice, (and thanks to Rob for maintaining this forum)  
Chuck

From: rstya@mowgli.mda.ca (Roy Styan)  
Subject: modified V.S. under modified malts

I've recently started using british two row pale malt grains imported from England, hence have dispensed with the protien rest during the mash (and gosh, life IS alot easier)! The beers have been working out just fine, but I've noticed that the primary fermentation takes about twice as long as it did before. HMMMMM... Could this be because there isn't quite as many protiens in the wort as there would be using an undermodified malt with a protien rest? How will this slower fermentation affect the taste of the beer (my experiments have not been controlled enough for me to derermine this yet)?

Any thoughts y'all have on this subject would be appreciated. Thanks,  
Roy

>I really thought that Home Brewing's most important rule was  
>Relax. Dont Worry.

>(OK, maybe it really is 'Sanitize', but I'm sure Relax is high up  
>in the rules).

Flaming refers to the act of setting fire to somebody's words, and is rather usenet-ese in its usage, although it is reaching wider acceptance ("my supervisor was really annoyed and sent me flame mail"). Yep, I'm finding that certain individuals get really boring when all they do is whine and criticise, unless they somehow manage to impart some useful knowledge in the whining and criticism. Such are the pitfalls of usenet and many e-mail lists. Ignore it; think of 'em as so many wrong numbers, when the misdialing idiot blames you for his/her mistake. :-) It would also be really useful if the flammers took it to e-mail... and maybe we could stand less adjectives like 'stupid', 'lame', and such. A few more fresh lupulins, that's what we could \*all\* use, to put the 'lax' back in relax!

On to the more important (and not stupid!) question of exploding bottles. I have been brewing for about a year, and have never had an explosion (well, except for the bottle that broke when I dropped it - but I think the concrete floor may have helped that along!). Non-impact bottle explosions

seem to have two causes - infected bottlings and overpriming. Infected bottling usually means that the bottles were insufficiently sanitised, or that the beer may have been infected going in. This is not as common a reason as overpriming, as most homebrewers (you included) seem to understand that keeping it reasonably clean is important and fundamental. So let's see if you're overpriming.

What priming method are you using? If you're adding a measured dosage of sugar to each bottle, you're asking for trouble. Much better is to prepare

a priming solution - a cup of dry malt extract dissolved in a pint of boiling water, and added to the 5-gallon batch in a priming bucket, will

produce a slow, but steady and non-exploding carbonisation. Other priming agents - 3/4 cup of corn sugar, or a mixture of 1/4 cup of fruit syrup plus 2/3 cup DME, all dissolved in one pint of water - will work well too, with the fruit syrup contributing something unique to the flavour profile; it sure worked well with a raspberry wheat and a raspberry amber ale!

Relax, don't worry, and make sure you don't get hurt by the exploding bottles! Better luck next time.

End of HOMEBREW Digest #948, 08/14/92  
\*\*\*\*\*

-----

Date: Now  
From: rdg@hpfcmi.fc.hp.com (Rob Gardner)  
Subject: Homebrew Digest Policy Note, PLEASE READ!

#### Homebrew Digest Policy Statement

The purpose of the Homebrew Digest is to discuss the amateur production of beer, and includes all aspects of brewing. Though the main focus is on malt beverages (beer), we welcome discussions on homemade wine, mead, and cider, as well as other fermented (but not distilled) beverages.

The Digest is a grassroots forum, deriving all content (and hence usefulness) from its subscribers. The digest is not moderated, edited or censored in (hardly) any way, and so the overriding guideline for content is *\*constructiveness\**. Simply put, if you have something constructive to say, then it is welcome, otherwise it is not. If you have something to say that you wouldn't feel comfortable saying to somebody's face, then it is probably not going to be welcome in the digest either. And in agreement with standard network policy, crass commercialism is frowned upon.

If a contributor does not adhere to this guideline, I suggest that he be deluged with *\*private\** flames, since, as stated above, I will (hopefully) not censor digest content. In other words, government of the digest will be minimal, and the subscribers have to police themselves in order to maintain the digest's record of lots of signal and little noise.

Requests to me for back issues, archives, cat's meow, instructions for ftp, etc., will be silently discarded. There are simply too many subscribers to provide personal service to each one. Removal requests are handled as time allows and in general, no reply is sent. Remember that there are lots of redistribution points for the digest, so I may not be able to delete your address. And, if you have subscribed to the digest via the BITNET listserver (BEER-L) then you *\*must\** unsubscribe the same way! Remember to include your *\*name\** in all requests so I have a better chance of finding you in the list. This is especially critical for change of address requests! Remember that most correspondence sent to homebrew-request will probably not be answered unless specifically requested.

Requests should be sent to the *\*request\** address (homebrew-request), and articles should only be sent to the digest address (homebrew). Mixups between these addresses will be handled haphazardly at best, but probably will be ignored. If handled at all, they might generate a nasty response, since they add to my workload. Please, please, check your reply address before mailing something here! Please limit the size of articles to less than 8k bytes otherwise they will be rejected. Please limit line lengths to 80 characters, since not everyone has fancy displays. Also please limit the size of your signature to save valuable digest real estate, and try to give your articles useful subjects lines. Thanks for helping to make the digest better for everyone!

Rob

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: RE: ammonia and phosphates for yeast

RESEARCHES ON FERMENTATION

M. Pasteur, of Lille, has recently been awarded a prize by the French Academy for his researches on fermentation which throw much light on this little-understood department of chemistry.

He shows that the germ in which fermentation originates is a living substance,-- organic, not inorganic, as some suppose; and leads to the conclusion that there is a remarkable analogy between fermentation and physiological action. ...Introduce yeast globules into a mixture composed of candied sugar, ammoniacal salt, and a phosphate, and the ammonia will disappear by transformation into the complex albuminous matter of the yeast, while the phosphate gives it left up to form new globules.

...From this [analysis] it is evident that the yeast plant can only grow where it can obtain a due supply of nitrogenous and mineral matter. When, by the presence of a salt of ammonia and phosphates, these conditions were abundantly supplied, M. Pasteur found the development of the yeast plant rapid and the fermentation exceedingly active; but when the growth of the plant could only take place through the assimilation of albuminous substances that were already appropriated, as in grapes, beet-roots, etc. the same processes went on, but with diminished velocity.

-- from the Annual of Scientific Discovery: or, Year-book of Facts in Science and Art for 1861. Edited by David A. Wells, A.M. Author of Principles of Natural Philosophy, Principles of Chemistry, Science of Common Things, etc. Boston: Gould and Lincoln, 1861.

Subject: Cider, water

In reading my post on sassafras, it should read at elevations of up to 5000 ft. If anybody tries to make root beer from real roots , I would like to know how it turns out. I noticed a post a few issues back about using R.B. extract, the resulting brew seemed weak. I read some place to use two bottles of extract (double of what you would usually use). I tried it but half the bottles exploded and I was too scared to try and open the others.

I have read alot about cider making but have I missed the posting of any recipes?

RE: boiled water - usually use tap water to bring my wort up to 5 gal in my fermenter. I haven't had a problem but I never thought about it. I use tap water because it is very cold and shortens the cooling time and, in my mind, lessened the time for airborne bugs to enter. Birmingham has had a micro brewery opened. The beer is good, reminds me of an IPA. First brewery in AL in about 60 years. Made me wonder why UA1VM distributes this letter (Bible belt and all that). Afraid to ask, may cancel if powers that be realize it.

**Subject: Porter recipe**  
Full-Name: Ted Manahan

> Does anyone have a recipe (grain or extract) for a SN porter like brew?  
> Any clues as to how to get that creamy taste?

I came pretty close with the recipe for Silver Dollar Porter from the original TCJOHB. Another similar recipe is "Tina Marie Porter" from the Cat's Meow. Both of these are all grain recipies.

The porter that I made was based on these two recipies. It turned out very smooth and creamy - I attribute this to the high final gravity I got from a long slow mash. My FG was 1.022, which is pretty thick.

Subject: Mashing, Hefe

According to Micah Millspaw:

>I start the mash fairly tight 20-24oz per lb. and add sufficiently  
>hot water to make the temperature steps I want without exceeding  
>32oz per lb grain to water, for a normal mash.

What do you folks think about this... pretty standard, rule of thumb sort of stuff? Seems to measure up pretty closely with Miller, Papaz. etc. recipes. I just never thought along those lines, I guess that's why Micah has the ribbons to show for it....

Secondly, I assume in this "insulated cooler type mash tun" that a grain bag is used?

Another note from yesterday...

>both hefe and klar beers are filtered

I thought hefe was unfiltered. I know that Sprecher's Hefe is unfiltered.

From: Tom Bower <bower@hprnlme1.rose.hp.com>  
Subject: Great Western Malting closes retail outlet in Corning, CA

Just a note to let all you HBDers know: Great Western Malting has closed its one and only retail outlet in Corning, California. They used to sell 5 & 10 lb boxes of specialty malts and 11, 22 and 40-lb boxes of two-row malt direct to homebrewers...but no longer. I called their Vancouver, WA office (which had sent my check and order form back to me when I tried to order grain from Corning) and they now have a 2000-lb. minimum order (I don't think I'd have much luck explaining THAT to my wife).

If you want more info, you can try contacting:

Lee Ann Stewart  
Shipment Coordinator  
Great Western Malting Co.  
P.O. Box 1529  
Vancouver, WA 98668-1529  
(206) 693-3661  
(503) 285-7711  
FAX (206) 699-9381

Now I'm wondering where to get high quality, affordable grain...join a home-brew club and take advantage of co-op buying?

>I put the finishing hops in the brewpot and put the lid on for 30 minutes.  
>Then I siphon through the counterflow chiller. The wort coming out of the chiller is a murky brown color, (for a pale ale). Between the time I pitch and the time the yeast takes off, 3 to 4 inches of "fluffy break" material will settle into the bottom of the carboy, then when the yeast takes off, it all gets mixed back up together again. It usually take a week or so before the fermentation has settled down to the point that the wort clears again. At this point, the material is more compact and is only 1 to 2 inches in the bottom of the carboy. I rack into the secondary at this time. It is usually within 10 S.G. points of being finished.  
>  
>I figure this is probably hot and cold break material, though I do get around a quart of hot break in the bottom of the brewpot. Any comments about this "fluffy break" that gets stirred up during primary fermentation?

By all means siphon the beer off of this break material before fermentation begins. This also gives you another chance to re-aerate the wort to help the yeast reproduce. It is also interesting to note that this break material does not form with the "mix the concentrated wort with cold water method". It is a sign that your boil was sufficiently long and you did everything right - why waste all that effort and let it get mixed back into solution where it can stay and cause haze and/or affect flavor?

- - - - -

>Assuming that I boil 2.5 gallons in each pot and hop only one of the pots.  
>I'm using the AAU system described by Miller in TCHoHB, would the utilization be the same as if I boiled and hopped the entire volume?  
>  
>I'm guessing not, simply because of the volume of wort present to dissolve hop resins into.

why don't you just divide the hops evenly between the two pots, and mix them (carefully, w/o causing oxidation) throughout the boil? (That's what I do...)

From: Chuck Cox <chuck@synchro.com>  
Subject: Coffeemaker Mashtun

I just bought a cafeteria coffeemaker for \$1.

It appears to be a near-perfect mashtun. It has a pair of side-by-side 5 gal tubs, all stainless. It has a swivelling sparge head, temperature control, dual sparge/fill timers, some kind of recirculating pump, and what appears to be an overflow or level sensor.

As far as I can tell, I just need to add false bottoms and a more accurate thermometer to turn this into a semi-automatic recirculating mash/lauter tun.

Has anyone out there already done this? Any advice? After a thorough disassembly & cleaning, the first batch will be a nice big stout (with an involuntary hint of coffee). What is a good cleaner to remove coffee taste/aroma from stainless? I don't have to remove lots of gunk, the system is already very clean, and I know it works, I had coffee out of it last week.

I bought it from Bose Corp (a client), so I'm going to call it the AcoustiMash B-)

Wyeast's European Ale yeast is a good Alt yeast. All imported  
Alts I've seen are pasteurized, as are the few Koelschs that  
make it over. I know of no sources of authentic Koelsch yeast,  
but I'm of the opinion that Wyeast's German Ale yeast, #1007,  
would make a pretty good rendition of a Koelsch.

From: cole%nevis.hepnet@Lbl.Gov  
Subject: Adjuncts, Oatmeal and mashing

Hello all. I found the extensive discussions concerning mashing/non-mashing of adjuncts this summer to be refreshingly restrained, polite, and informative.

So far I have only brewed extract beers and have always steeped my grains rather than mashing them. Early in the summer I posted a comment about problems

I encountered when "steeping" rolled oats. As a result of the discussion I will

probably start doing partial mashes on the way to doing full mashes.

However,

there are some technical aspects concerning the use of adjuncts that I feel

the discussion only danced around which I would like to see addressed.

I'm sure

I could find answers in the Principles of Brewing Science etc... but to be

honest I don't have time right now for such an involved study so I hope the

experts in this forum can enlighten me.

Question 1: What exactly is one trying to extract from adjunct malts ? My impression is that for kilned malts like chocolate or black malts we want the coloring agents and coloring a flavor imparted by the kilning process. What provides these flavors ? Most of the color and some of the flavor seems to be provided by burnt malt (ie. soot) but are there also complex carbohydrates, proteins, oils etc... extracted ? I basically understand (I think) that Crystal malt provides complex sugars, but what else ?

Question 2: Same as 1, but for unmalted barley, wheat, and oats ? I used roasted

barley in my stout and could clearly detect its presence even though I only steeped it. What did I get out ? I find the typical answer of "aromatics" to be very unenlightening. What exactly are these "aromatics" ?

Question 3: For both of the above, how are mashing and steeping different in

what they extract from the malts/grains (aside from the obvious difference that mashing provides converted sugars and steeping does not. As I see it, the point of using of adjuncts is not to provide more sugars, so I'm not sure I really understand the need for mashing. Does the mashing process also facilitate the release of [fill in the blank] ?

I realize that the answers to these questions may be complicated, but I think

they would help me and others better understand the use of adjunct malts and

unmalted grains.

An unrelated question. While travelling in Germany this summer I tried a Weizenbock for the first time. It was made by a brewery called Maisel or something like that -- may have spelling wrong. It was quite good. The

label had a Star-of-David on it with Bayreuth (I think) written under it. I didn't have a chance to check with the locals but I thought Bayreuth might be Beruit in German. Can anyone tell me about this brewery or about Bayreuth ? I am interested in knowing whether this beer really came from Beruit, is brewed under contract in Germany for an outfit in Beruit, or is simply a German beer.

Thanks to both Rob for maintaining this forum and to all those who provide useful information and constructive criticism.

Date: Fri, 14 Aug 1992 12:36:17 EDT  
From: bob@rsi.com (Bob Gorman)  
Subject: Sanitizing Soda Kegs

There have been some recent discussions about the effects of using bleach to sanitize kegs. I just wanted to take this opportunity let people know how I sanitize my kegs. I don't use bleach because I don't like to give my kegs a final rinse with unsanitized water, especially when using them for primary fermentation. My tap water smells, tastes and looks like a pond (think of fish juice). I don't like to get this stuff anywhere near my beer without boiling it first. So I sanitize my kegs with boiling water and here's how.

First I boil up about 2 gallons of water on the stove, for about 20 minutes. This is then dumped into the keg facilitated by a funnel, wear shoes when doing this. The lid is then snapped into place and the keg agitated to raise the internal pressure in the keg and create a positive seal with the lid. After this the keg is laid down on its side and is casually rolled around on the kitchen floor for a while. When it's time to remove the water a hose and liquid disconnect is attached. Some of the water pushes its self out from the existing internal pressure, and the rest is pushed out with CO2. I usually run this water through my tap lines to keep them nice and clean.

After this I pressurize the keg with CO2. As the air in the keg cools down it will create a negative pressure and suck air back in through the lid. The pressureization prior to cooling negates this effect and also adds an additional blanket of CO2 to the keg.

The end result is a sanitary hose, liquid disconnect, and keg which has nice blanket of CO2 in it. And what better to do with it then to fill it with beer.

This may sound like a lot of work, but it's actually pretty easy. Using boiling water helps me relax about sanitation and there's no need to fuss with chemicals.

Cheers!

Date: Fri, 14 Aug 92 10:56 PDT  
From: James S Durham <js\_durham@pnl.gov>  
Subject: Sassafras, Stout Recipe

I have noticed some discussion on sassafras used to make real root beer. I originally came from Illinois, where my wife's family enjoyed finding and making tea out of sassafras root. When we visited the covered bridge festival in Indiana last year, we were told that it is illegal to sell sassafras root in the US because it is very carcinogenic. Compared to sassafras, tobacco is a low risk substance. I do not know if this is factual, since I did not hear about it from an expert, but it may explain the difficulty in obtaining sassafras in commercial stores. Does anyone else have additional information?

I use several "standard" extract recipes when brewing. These recipes have always produced outstanding results, IMHO, and in the HO of most of my friends. Sometimes my friends don't believe that I actually made the stuff. So here is my favorite stout recipe, which I was given by Tom Bellinger, owner of "Jim's Homebrew Supply" in Spokane, WA. No, I don't work there and I infrequently buy supplies there, much to Tom's chagrin. But he does have great recipes!

#### WATSON'S ALEMENTARY STOUT

Ingredients for 5 gallons:

6 lb. Dark DME  
1 lb. Crystal Malt  
3/4 lb. Roasted Barley  
1/4 lb. Black Patent Malt  
2 oz. Galena Hop Pellets (30 + 30 min. boil)  
1 oz. Cluster Hop Flowers (1 minute boil)

Add cracked crystal malt, roasted barley, and black patent malt to 1.5 gallons cold water. Bring slowly to a boil. Remove spent grains and sparge with 2 quarts hottest tap water. Add DME and return to boil. Add 1 oz. Galena hop pellets and boil 30 minutes. Add second ounce Galena hop pellets and boil another 29 minutes. Add cluster hop flowers and boil 1 minute. I cool the wort with an immersion wort chiller, then pour the wort through a wire strainer and sparge with 2 quarts boiling water. Pitch yeast (EDME works very well) when wort is at 75F. Ferment out completely (about 1 week), prime (3/4 c. corn sugar), and bottle. Ready to drink in 1 more week, but improves steadily until it's all gone (usually about 3 months if I ration it).

This recipe produces a full-flavored stout beer that will mask any off-flavors, including infection, O-rings on soda canisters, etc. When kegged and kept at a pressure of 25 psi, it resembles Guinness stout (the Irish version) when poured into a glass. It's taste, however, is somewhat sweeter than Guinness, more reminiscent of Murphy's Stout (another popular stout served in Ireland). This beer is the closest thing to a true Irish stout that I have encountered in this country.

Sometime later I'll post another recipe or two.

Jim Durham

From: 105277@essdp2.lanl.gov (GEOFF REEVES)  
Subject: stack for browsing through digests offered

Greetings fellow brewers,

I have been working on a tool for browsing through the digests and I guess it's time to share it with the rest of you. I find it makes reading this group a lot easier and it also makes it easier to keep articles that I'm interested in for future reference. I know that there are other digest browsers around and one has been offered here before but I decided to write one that fits my needs better and it may fit yours better too.

The "Reeves Digest Browser" is a hypercard stack which makes it easy to navigate through digests. It is for use with Macintosh computers. It is called the "Reeves Digest Browser" to distinguish it from other Digest Browsers which are around. It reads text digests into hypercard putting contents information into a contents window and each message into its own message window. It should work on any digest but has been tested only on the homebrew and grateful dead digests.

You can import single digests or multiple digests. Once that's done, messages can be shown by clicking on the contents window, choosing "read messages", clicking "next" or "previous" message buttons, or choosing the message number. Messages can also be edited and/or exported to their own files. Complete help is available for all buttons and fields by option-clicking on the button or field you want to know about. This stack is offered as shareware.

I'm not worried about the moral implications of commercializing this group because I'm willing to trade the stack for homebrew ;-)

It is available by anonymous ftp from  
sierra.stanford.edu  
/pub/homebrew/incoming  
gdead.src.emu.edu  
/pub/gdead/drop-box  
and I have sent it to sumex.stanford.edu but I don't think it is available just yet. You can also do a decnet copy from  
essdp1.lanl.gov disk0:[105277.tohome]. Finally you can just send me e-mail and I'll mail it to you.

From: William Boyle (CCAC-LAD) <wboyle@PICA.ARMY.MIL>  
Subject: Wort Chilling

This is for people who need or want to save water. You can put your wort chiller in line with your hot water heater. What you will need is three valves, two "T"s, a short length of pipe, and some garden hose. During normal use you open valve 1 and close valves 2 & 3, during chilling you open valves 2 & 3, and close valve 1.

You don't want to put this into your whole house water inlet since you would be heating your cold water also. All you would have to do is plan to do something that needs hot water and while you are doing that your wort is cooling down. You can shower, do dishes, do laundry, or anything else that uses hot water. This system not only saves water but it also recycles the heat.

> for the step increase. The mash out can be conducted the same way. This  
> approach to mashing is a part of the gentle mash that can reduce the  
> effects of hot oxygen reactions.

The statement that oxygen reactions can be bad even in the mash makes me wonder about old-fashioned small brewery mash tuns, the open kind with big rotating paddles that vigorously mix the mash. Are they reducing the quality of their beer without knowing it?

Perhaps, back in the old days, that was the only way they could keep a constant mash temperature with their direct-fired tuns. Lack of high-quality insulating materials and matters of scale may have kept small commercial brewers from using the "add-water-to-an-insulated-tun" scheme that many homebrewers today use.

John Freeborg asks:

> Does anybody know where to  
> get a good culture of authentic Kolsch or Alt yeast? Is there any  
> brands that I might be able to get it from the bottle dregs?

My roommate brews a pretty close Kolsch approximation using the Wyeast European Ale, which is fairly neutral. Actually, we think one of the keys to the Kolsch style is cold-conditioning: doing a tertiary fermentation at about 40F for 10-14 days. That helps give it some of the "cleanness" of a lager even though the primary and secondary are at ale temps (67F in our basement). If you do find a source for Kolsch yeast, though, please post it.

Then Roy Styan brings up the subject of malt modification again:

> I've recently started using british two row pale malt...  
> hence have dispensed with the protein rest during the mash....  
> The beers have been working out just fine, but  
> I've noticed that the primary fermentation takes about twice as long as  
> it did before.

The difference in proteins depends on what kind of malt you used previously. The consensus was that all commercially available malt these days is highly modified, so you'll get the same amount of protein extraction whether or not you do a protein rest (very little of the protein is locked up in the endosperm, as it would be with an under-modified malt). It is possible that the grain has different amounts of other nutrients due to different growing conditions.

I assume everything else, besides the malt, is the same as before, especially the yeast. I've found that different strains of yeast can make a huge difference in fermentation rate of a given wort. I can't think of anything bad a slow fermentation might do, barring a slightly greater risk of infection at the start (not as much alcohol as soon to keep the nasties away).

bottling.  
>The ones that broke tended to be a little thinner than most of  
>the others.

Before questioning the bottles, I'd take a closer look at the amount of  
sweet  
wort (gyle) used to prime. One gallon sounds like an awful lot (I'm  
assuming  
you're making a standard 5 gallon batch).

I've been priming with gyle for over five years because I prefer the  
result  
to that obtained with corn sugar. While the exact amount of gyle required  
varies from batch to batch, for me it usually works out to be somewhere  
between 32 and 48oz for 5 gallons. If you back off on the priming, you'll  
probably be happier with the result.

>Wheat beer tends to have more of a head than most other beers.  
>Whats the cause of this? Do these beers have a higher CO2  
>content causing the head (and breaking bottles)? Julius Echter  
>bottles are pretty heavy - probably a good reason for that!

Wheat beers are generally well carbonated, but I suspect what you're  
referring  
to is not the carbonation level, but the head retention instead. Wheat  
aids  
in head retention, and many brewers add it to the mash for that reason.

Cheers,  
CR

From: bszymcz%ulysses@relay.nswc.navy.mil (Bill Szymczak)  
Subject: Re: Why bother with yuck?

In HBD 948 in response to someone reporting murky brown wort coming out of a chiller (for a pale ale) Jack Schmidling responds:

>I know the pros and cons of immersion vs counterflow have been beaten to  
>death but I can't resist pointing out that the wort coming out of the  
kettle  
>after immersion chilling is crystal clear. I just do not understand why  
>anyone wants all that yuck in the fermenter or the bother of letting it  
>settle and racking again.

One reason is that I've read somewhere that the trub from the cold break can assist the yeast in its aerobic phase, and therefore adding it to the fermenter, and reracking after 6 to 12 hours is actually a good thing to do, (although I agree it may be a bother). Perhaps a better reason (for not using an immersion in kettle chiller) is that in some parts of the country, e.g. in the D.C suburbs of Maryland, the temperature of the tap water is 80 - 82 degrees F in the summer and if you want to chill your wort to 75 degrees F, you would be out of luck. Of course you could first chill the tap water with some pre-chiller, but this is also a bother. For this reason, I used an immersion in ice type chiller for my first attempt at an all-grain brew, and with about 5 or 6 gallons of ice, was able to cool 6 gallons of boiling wort to 72 degrees F in 15 minutes. In the winter, or in colder climates, the immersion in kettle may be more attractive.

Not silly at all. That's what I found in my book-foraging experience of a couple of days ago. Actually, it only makes sense that dead yeast would contain the things that live yeast needs to grow. I believe that the book I read said something about washed yeast hulls being used as a yeast nutrient.

Chuck Coronella writes:

>Has no one used ascorbic acid?

>I can vaguely remember, way back when, a discussion in this forum regarding the addition of ascorbic acid (also known as vitamin C) to a brew for the purpose of preventing oxidation. Is this done at bottling time? In what quantities? I s'pose one could add food grade vitamin C available at any pharmacy or grocery store, right?

I use vitamin C, I just didn't respond because I thought that everyone else would :-). Here's my understanding of it:

1. Add at bottling time, but don't boil it because it destroys the chemical structure.
2. Use about .5 tsp per 5 gallons (if I remember correctly).
3. It reduces oxidation by grabbing up any available oxygen before it can react with the beer.
4. Supposedly it doesn't matter very much, but if it reduces your worry, use it (so I do).

As an interesting side note, I have been recently juicing a bunch of apricots (for a wine or mead, or maybe both :) and putting the resultant slush into a gallon jar for keeping. This stuff starts out a dull orange color, but turns darker brown when exposed to air (oxidation), which happens fairly quickly. I managed to get almost a full gallon with little oxidation, so I decided to sprinkle some vitamin C on top of what was left before I put it in the refrigerator to retard any additional oxidation. It's hard to sprinkle through a small hole,

so what I got looked more like a little pile of vitamin C. The next morning, the little pile and the area around it (within an inch) looked exactly the same as the night before, but the rest of the surface area had turned brown to a depth of about 1/4 inch. That says something to me about the worth of vitamin C!

About wort chillers:

There have been several posts of late about wort chillers, and a little confusion. First of all, there is some confusion about what to call the different types of chillers. I would like to suggest, for the sake of discussion, some standard names to use for the different types:

1. Counterflow chillers - These are the "tube in a tube" chillers, with hot wort in the inner tube and cold water in the outer tube, and the two liquids are flowing in opposite directions.

2. Immersion chillers - These are the kind that have a coil of tubing (with cold water flowing \*inside\* the tubing) that is inserted into a pot of hot wort. The wort is on the outside of the tube, and water is allowed to flow through the tube until the wort is chilled sufficiently.

3. Bath chillers - These are the chillers where the hot wort flows on the inside of a coil of tubing, which is placed in a cold bath of water or ice-water.

and, for completeness,

4. Simple chiller - This is when you set your entire brewpot (containing hot wort) in an ice-bath or water-bath or even in the snow!

Some of you have seen the little write-up that I did on one of these kinds, the bath chiller. It is also roughly applicable to a counterflow chiller, although a better (more specific) analysis of that type may be done. As far as the status of that goes, I am planning on submitting it to Zymurgy eventually, but I want to include analyses of the other types of chillers too and I haven't had much spare time recently.

There have been some statements that the heat transfer rate is proportional to the velocity of something. Well, this is true and it isn't :-). The heat transfer coefficient due to convective heat transfer is

$$Nu = \frac{h D}{k} = 0.023 Re^{.8} Pr^{.4} = 0.023 \left( \frac{\rho V D}{\mu} \right)^{.8} \left( \frac{c_p \rho \mu}{k} \right)^{.4}$$

So that h is proportional to  $V^{.8}$ . This means that a fluid moving past a wall picks up heat faster if it is moving faster. However, since it is moving faster, the fluid doesn't have as much time to pick up heat from the wall. These effects almost completely cancel each other out, so that given a fluid

passing through a tube of constant wall temperature, the outlet temperature of that fluid has only a weak dependence on the velocity of the fluid. This dependence is not linear, but rather about  $\exp(V^{-.2})$ , depending on the correlation you choose.

If you are interested in getting a copy of my write-up, please email me. I am doing it this way so that I can keep track of who has it (just to send out revised versions) and because it is so long that I am afraid of jamming the HBD.

Subject: Allergies

The current discussion of an allergy to wheat reminded me of my wife (no, not in that way!). She suffers from an allergy to some beers, wines, and cheeses. Homebrew affects her the worst (bad for her, good for me). Her throat swells up and becomes painful. Researching this briefly led me to believe that the culprit was tyramine (yeast product). I'd love to hear any thoughts you folks have about alternate explanations. Also, if you've come up with a way to reduce/remove this reaction she'd appreciate it tremendously.

Thanks for your help.

From: klumpp@casbah.acns.nwu.edu (David Klumpp)  
Subject: labels and H2O bottles

In response to two recent posts:

I produce labels by designing them with McDraw and printing on Avery 5455 "Adhesive-Backed Full Sheets." The sheets feed well through our lab's Macintosh Laserwriter II. The 8.5x11 sheets give great flexibility for choosing size and shape. I can usually squeeze 6-10 labels per sheet, again depending on size, shape, and whether or not I make neck labels too.

The labels look great and adhere well, although condensation will cause the label to wrinkle slightly as the paper expands. The labels also easily removed without a need for soaking. At ca. \$11/20 sheets (5-10 cents/label), cheaper alternatives certainly exist.

A friend employs one such economical approach. A sheet of labels is printed on a laser printer, photocopied, and the label back is wiped with diluted Elmer's. Upon drying, the labels adhere well and require only a brief soak to remove the residual glue.

On procuring water bottles for fermentors, we contact local bottled water suppliers. They happily provide empties for \$6-8 and are quite amused when we mention why we want the bottles.

I hope these comments are of use.

Heart quaffing,

Dave

> Umm, this may be a silly half baked idea, but I was under the  
> impression that many commercial yeast nutrients are in fact  
> made from yeast.  
> Can any professional biologist types comment on the accuracy  
> of this idea??

Let me preface by saying that I am certainly not a professional  
biochemist nor do I play one on TV, but, the same reasoning struck  
me about a year ago. After all, if the growth of new yeast buds  
is limited by the available building material, the best source  
for new yeast should be from old yeast, right?

Well the answer is probably true but to get old yeast also means  
that bacteria, mold spores, and who knows what will tag along.

So that's were my thought-experiment ended. I had considered  
buying packages of dry brewing yeast or even baking yeast and  
grinding it up. But fear of contamination has me still buying  
the over-priced packages of commercial yeast nutrients...

From: Glenn Anderson <glenn.anderson@canrem.com>  
Subject: supplies/wyeast 2112

Could anyone give me the name and number of any Brewing Supply shops in Chicago or the Chicago area that I can mail order supplies from. Please e-mail to glenn.anderson@canrem.com

On another note, has anyone had any negative experiences with Wyeast 2112? I recently made a batch of dark steam beer that stuck at 1.030 and then turned into brown infected liquid. The first 2 or 3 days of fermentation looked good, big foamy krausen then all stopped. I was fermenting at around 50 Degrees F. Could this be too cool for the 2112?

I had no fermentation for 3 weeks, then nasty critters started at the wort. The whole batch shot down the drain last night.

I've made alot of beer and this is my first infection. I've used Wyeast products and have never had a problem, other than the seams of the package breaking when I whacked it.

Thanks.....GA

>from that.

Very well put, I only recently started getting the HBD, and when I first read it I was mystified at how some readers would take offense at someone doing something that was not technically motivated. I learned brewing from two old men, namely my grandfathers, they both did things differently and they both produced very good beers. And each had it's own flavor. Most of my equipment is homemade, and the techniques I use are pretty old (and abstract at times) but I wouldn't dare post them here for fear of getting flamed by a "techy" saying my hydrometer reading was all wrong or I used the wrong temp. and therefore my beer could not possibly be worth drinking and I must be an idiot for doing something like that.

If I wanted a scientifically produced beer, using standard equipment and a standard yeast using a precisely determined temperature with a predetermined exact amount and type of sugar...I'd go buy a Bud.

Not sure .55/lb is obscene but that is what I pay for it from Minnesota Malting in 25 bags plus UPS shipping. Contact is Bob Jensen (507) 263 3911.

Someone just recently mentioned something about half that price but I let it pass. I insist on indirectly kilned malt and I doubt that the real cheap stuff is.

>From: Martin Wilde <martin@gamma.intel.com>  
>Subject: Mash efficiency comments

>My sparges flow rate starts out slowly and then is increased as time goes by.

Lots of people say something like this and I do not understand why this happens unless they are all using grain bags. Mine will run out as fast as it can get through the spigot if I keep the level up. I control the rate by throttling it back.

>For an experiment I sparged for 90 minutes and my efficiency was 90%!!

Just when I thought I was on board with the points/lb/gal, we now switch to per cent efficiency. 90% of what? According to many sources, you can not extract more than about 75% of the starch/sugar from malt no matter what you do.

>When you are reading a book on brewing - don't put the author on a pedistal and assume that they are the ultimate god... Just use whatever works for you.

I can't think of any art/science where this has proven to be more true than in homebrewing. My books go back to the 60's and are replete with absurdities. The newer stuff is typically more accurate but about half the info is totally subjective and one books contradicts the next.

That is what is so great about this medium. There is instant feedback and the garbage gets sorted out or at least identified as debatable.

>It depends whether you are concerned about thermal expansion/contraction. That is, beer and glass rates being different and glass being breakable.

It is refreshing to find a good sound reason for doing something, isn't it?

However, I guess the reason THAT reason never occurred to me is that, intuitively, I would guess the expansion and contraction in beer in going from fermentation to refrigeration would be trivial compared to the normal headspace.

However, in answering my own question, I bet it has something to do with accidental freezing of bottled beer. The expansion of ice is NOT trivial.

So, is it possible that homebrewers, who would not think of letting their beer freeze, could reduce the headspace to the point where O2 is simply a non-issue?

>From: jeg@sangabriel.desktalk.com (John E. Greene)  
>Subject: Re: The Good Ol' Days...

>Actually it wasn't a bore at all and there wasn't much repeating of the same old tired lines from popular books. This was a great forum for discussing the various techniques....

The following has be extracted from email and seems appropriate here...

I suspect that the distribution list has grown significantly since the good old days also. Aside from the stuff that makes you feel uncomfortable, I would suggest that, in the final anlaysis, the overall quality has gone up.

In order to attract and keep a large readership and talented contributor list, you must take the good with the bad. I just find it unfortunate that so many people are incapable of just ignoring the bad (mine included) and taking it all for what it is worth.

From: srussell@msc.cornell.edu (Stephen Russell)  
Subject: Database of contacts to homebrew clubs

I maintain a list of e-mail contacts to several homebrew clubs. The dual purpose of keeping such a list is to aid in membership recruitment as well as to promote interclub communication and activities. An ftp site has already been established for the exchange of copies of club newsletters as a result of the creation of this list.

If anyone would like information on one or more of the clubs on this list, just send me some e-mail. The list of clubs with contacts has been appended to the body of this message.

If you are a member of a club and would be willing to be on the list as a contact person for your club, just send me some e-mail. Don't be put off by the fact that someone may already be 'on' for your club -- some clubs have 4 or 5 people listed; the more the merrier.

There are some 80 clubs on the list, but I am always looking for more additions, both in terms of additional clubs and additional 'listees' for clubs already on the list -- please come aboard!

Similarly, if you have any questions about this list...just send me e-mail.

Cheers and beers,

STEVE

Date: 16 Aug 1992 12:55:28 -0400 (EDT)  
From: homebrew@tso.uc.EDU (Ed Westemeier)  
Subject: Sanity, fun, and hops

First, the sanity part.

Please, folks -- if someone's posting bothers you, don't reply with your sarcastic comments, and don't send nasty personal e-mail. JUST IGNORE IT. They're only seeking attention, and the worst punishment for them is to be ignored.

Second, the fun part.

The Fourth Annual BEER & SWEAT was held Saturday at the Oldenberg Brewery/Drawbridge Estate near Cincinnati. This is the largest homebrewers gathering in the Midwest, and maybe the second biggest in the US for all I know. At least six clubs from at least five states were present, and we had (by my count) about 200 attendees and at least 25 kegs of GOOD homebrew. Needless to say, a great time was had by all. Homebrewers and their families always seem to get along well together, and I have found them to be some of the nicest people I've ever known. Try to make it next year if you can!

Third, the hop part.

Steve Casagrande writes:

> Reading about all the lucky homebrewers with their own hop  
> vines has made me curious. What kind of yield do you get  
> from a hop vine, in ounces, once you've dried the hops?  
> E.g., is it 6 oz, or 6 lbs?  
> If I dedicate about 10' of a small garden along the side of a  
> house to hops, what could I expect for a total crop?

Hop varieties are vastly different in their yield per vine, so there really isn't any standard answer. My most prolific producer is the Cascade, which gives me about 4 ounces (dried) per vine.

The main thing you want to be aware of is to keep different varieties 6 to 8 feet apart from each other, or after a few years you won't know which is which when they start coming up in the Spring. You should be able to plant three different varieties in your plot with no problem, though.

Cheers & beers,  
- -- Ed

Date: Sun, 16 Aug 92 10:51 CDT  
From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Yeast Culture

To: Homebrew Digest  
Fm: Jack Schmidling

My mailbox is flooded with requests for the yeast culture article so it seems appropriate to repost it occasionally.....

#### JACK SCHMIDLING ON YEAST CULTURE

##### Objective

The objective of culturing yeast is to isolate a single cell from a beer or culture that has the characteristics desired and encourage this cell to reproduce enough offspring to start a new batch of beer.

This is easier said than done but with reasonable care, luck and modest investment, can be accomplished by the serious home brewer.

##### General Program

The general program is to dilute the original culture and spread it over the surface of a growth medium in a petri dish so that individual cells are far enough apart to allow them to grow into visible colonies without touching each other.

A sample from one of these typical colonies is transferred to a test tube containing a growth medium. When this colony is actively growing, it is considered a pure culture and can be refrigerated for later use or started by covering with beer wort. When this starter is actively fermenting, it is poured into a larger amount of wort which, when active, is pitched into the beer.

##### Basic Assumptions

The procedure makes a number of assumptions which are correct, often enough to allow it to work well enough, to satisfy most requirements.

The first assumption is that one can select the desired strain by looking at colonies on a petri dish. This is more or less true because the overwhelming

majority will be the same, i.e. the dominant strain. Bacteria, molds and many wild yeasts are obvious and recognizable to the naked eye.

The second assumption is that, while still very small, all round colonies are the progeny of single cells.

The third assumption is that all such colonies, at least in the center are mono clonal or at least mono-cultures and otherwise sterile.

To do the job right, one would have to study the original diluted culture under high magnification and do a presort at that level. This is revealing and fun. It also gives an indication of any bacterial contamination in the culture but the rub is marking individual cells and finding them later when they grow into colonies. This is done using a calibrated X-Y stage on the microscope and making careful notes. Fortunately, however, I do not believe that it is really necessary for the home brewer, although a must for the lab selling selected strains.

#### Details

There are many growth media available for the purpose and no doubt someone can recommend a source or recipe for the ideal but for my experiments, I mixed two packets (16 gr) of Knox gelatin with one cup of 1.020 wort. After heating and dissolving, this is poured into petri dishes and test tubes and sterilized in a pressure cooker for 15 min at 15 lb.

The petri dishes are turned upside down after solidifying and cultured this way to prevent water of condensation from falling on the medium. The test tubes are cooled on a slant to allow the water to settle on the bottom when vertical. They are also stuffed with cotton before going into the pc. You can also use tubes with plastic screwcaps and avoid the cotton.

It should be noted that gelatine melts around 75 F so its use in summer is precarious. The better alternative to gelatine is agar agar. This is available at oriental food stores in stick form. Half a stick (about 4 inches) in a cup of wort will get you through the hottest weather.

#### Isolating Cells

The first step is to inoculate the petri dish with as diluted a mixture as possible. The books are full of procedures for doing this but I find the simplest is just as good. Take a copper wire or thin glass rod and heat

several inches in a flame to sterilize. Dip this, when cool, into a working beer or yeast culture. If starting with dry yeast, desolve one granule of yeast in a test tube with about one inch of sterile water. Gently drag this across the gelatin in the petri dish, trying not to break the surface. Next, draw the wire across this line at several points, to further dilute the sample. Turn the dish over onto the cover and "incubate" at room temp for several days. Do this on several dishes just for insurance and as controls.

#### Pure Culture

The next step is to visually inspect the surface of the petri dish under low magnification (hand lens or naked eye will do) to pick out a "typical" colony that appears to have come from a single cell. All colonies should be rejected that are any shape other than perfectly round and differ in any way from the majority.

Flame your wire again and after cooling, remove a small sample from the center of the selected colony and poke this into the surface of the medium in a "slant" test tube. You can do this to several slants, with the same sample, to assure all slants are the same or flame the wire and take a new sample from a different colony. You can make as many slants as you will need for several months and throw away the petri culture.

You now "incubate" the slants until 25% or more of the surface is covered with the pure colony and then refrigerate them till needed.

#### Starting

When needed for use, cover the slant with sterile wort and pitch when ready, i.e fermenting. For best results, this starter should be used to pitch about a pint of wort, a day or so before brew day.

This process can be used on anything from a packet of Red Star to a bottle of your favorite beer and will produce a pure culture. There is no guarantee however, that the strain will remain the same for ever because of natural mutation. As it is my experience that the most common and objectionable contaminants of dry yeast are bacteria and mold, this process will guarantee at least, to eliminate these most serious problems.

I was intrigued by the recent posting on the quality of beer made from Red Star that was re-cultured. I was also "impressed" by the number of contest

winner's who use Wyeast and now rise to the challenge of winning the  
"World's  
Greatest Brewer" trophy using re-cultured Red Star instead of just  
joining  
the Wyeast bandwagon.

From: Stefan Karlsson <stefank@math.chalmers.se>  
Subject: Wort Chiller - help requested

I'm about to make myself a wort chiller.  
I think it will be an immersion type.

I first bought some 3/16" copper tubing, but realised that it was too narrow, so I found some 30-40' of 3/8" in my father's basement. I think it should be better.

Now, what's the best construction?

If you have a single spiral I guess you'd let the water flow from the bottom to the top, because of the wort getting colder at the bottom (right?). What if you use double spirals. Should you start at the bottom of the inner spiral and then from the top go down and let the inner spiral start from the bottom? OK, you who'd been building those before, please give me some advise.

Subject: Recipe for Fullers ESB wanted

Does anyone out there in Netland have a good, preferably grain-based recipe for Fuller's ESB? I've made the version in Dave Line's book "Brewing beers like those you buy", which, although very good, tastes and looks nothing like the real thing. It's also extract based, and I would prefer to try an all-grain recipe - I'm not an all-grain snob, but my brewing did improve when I switched to grain.

Thanks  
Andy

Announcing  
the 9th Annual  
Dixie Cup  
Homebrew Competition

America's second largest homebrew competition  
will be held October 16 and 17, 1992 in Houston, TX.

The Dixie Cup is sponsored by the Houston Foam Rangers  
Homebrew Club and DeFalco's Home Wine and Beer Supplies  
of Houston. It is an AHA and HWBTA sanctioned competition.

Entries will be accepted in basically the same style  
categories as those used for the AHA national competition.  
The final list of styles will be in the entry info.  
The entry fee will be \$6. Brewers are allowed to enter up to two  
beers for each style.

Information on how to enter the Dixie Cup will be snail-mailed the first  
week of September.

Beer entries will be due October 9.

To receive info on the Dixie Cup, drop me a note and I'll  
see that it is sent to you.

My address is : slamb@milp.jsc.nasa.gov

If you wish to go to the source, mail a request for info  
to:

Dixie Cup 1992  
c/o DeFalco's  
5611 Morningside  
Houston, TX 77005  
Tel. (713) 523-8154

Of course, all of the information in this post will be superceeded  
by the official entry stuff.

P.S. I had my brother post this, I haven't been able to get  
anything to go to the HBD by myself. Can anyone offer any assistance?  
I get the HBD everyday, no problems.

Hi All,

I just wanted to express my thanks to all who responded to my post last week regarding yeast culturing. The number of responses and amount of material received was almost overwhelming.

To those who wrote to me asking to pass the information along, I'm working on compiling the information into a comprehensive, organized form. It'll go out today.

Once again, HBD has proven to be a valuable resource.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: making labels stick

My favorite label sticking method uses milk (I didn't make this up, I got it from a friend). I laser-print my labels on plain paper. After cutting the sheets into labels, just dip the back of a label into a saucer of milk, then press it onto the bottle. A quick sponge application gets rid of the excess milk. They stick great, but come off easily when wet (a feature, not a bug).

From: andre vignos <andre@Think.COM>  
Subject: Fast fermentation

This weekend (saturday) I started a batch of nut brown ale and I am a little curious about the way it is fermenting. After adding the yeast to this room tempature batch, I gave the beer a quick swirl. Within an hour I started seeing some action. This is pretty fast by my standards but it didn't bother me. After 24 hrs the blow-off was complete (serious blowoff), again this seemed pretty quick but I had read that this type of ale his a shorter fermentation period then most (5-6 days). I took off the blowoff tube and put on the bubbler (can't remember the name for the silly thing). This morning I timed the delta between bubbles and it is allready over a minute. A rule of thumb I heard was that when it takes more then two minutes between bubbles then it is ready to bottle. It seems to me that this will occur within the next day. Should I be concerned? Do I need more yeast? I did use 7 lbs of extract in addition to a pound of partially mashed grains. I will take a specific gravity reading soon (tomorrow). If it is in the right range (1012-1020) should I just go ahead and bottle it? Will the beer not come down to the right gravity if there is not enough yeast to convert all the sugars?.

Do I worry too much?-Andre

From: paweb@ohpspd.com (Philip A. Webster)  
Subject: Canadian Beers

Someone recently asked a question about Canadian beers, especially those available in the U.S. I haven't seen a response yet, so here is one from me.

As far as I know, the beers exported to the Excited States are the same as those available here in the Great White North. That is, they are the light, pilsener style beers produced by the big brewers, which achieve massive sales by means of extensive advertising aimed at young, blue collar (usually white) males. Of course, with the current trade dispute on this very topic, exports are likely to be at a very low level until the lunacy subsides.

With regard to strength, you should be aware that the reputation of Canadian beers as being stronger than U.S. beers is a fallacy. This arises because we measure alcohol content by volume whereas south of the 49th it is by weight. Since alcohol has a specific gravity of less than one, a beer of, say, 5% by volume would be about 4% by weight. Hence the confusion and the unwarranted reputation.

My first paragraph notwithstanding, we do have some good beers up here, from a burgeoning number of microbreweries and brewpubs. If anyone is planning a trip to Toronto or Southern Ontario (perhaps for the World Series :-] ) , drop me an E-mail and I will put you onto some good places.

Doug Behm writes:

> If anybody tries to make root beer from real roots , I would like  
> to know how it turns out.

I have made root beer from real stuff, approximating from a 100-year old recipe. The recipe included sassafras bark, wild cherry bark, yellow dock, wintergreen bark, molasses, and a few things I can't remember. The only ingredient that I had any trouble finding was the wintergreen bark, and oil of wintergreen from the druggist added after cooling proved a satisfactory substitute.

The result was tasty, highly complex, and not a lot like what we are accustomed to thinking root beer should taste like. To make something like modern root beer, it would probably work best to use wintergreen and little else.

And yes, kids, this is illegal, because sassafras contains a carcinogen.

Subject: Re: Great Western Malting closes retail outlet in Corning, CA

Tom Bower <bower@hprnlme1.rose.hp.com> writes:

> Just a note to let all you HBDers know: Great Western Malting has  
> closed  
> its one and only retail outlet in Corning, California....  
> and they now have a 2000-lb. minimum order

I've noticed an alarming trend recently in that several companies, now including Great Western, have decided that they will no longer sell direct to homebrewers at all, have jacked their formerly wholesale prices up to retail, and/or are imposing outrageous minimum orders.

What a great way for these people to alienate a growing segment of their market. I realize that Great Western probably makes most of their money by selling grain 10,000 lbs. or more at a time to micros. They do seem, however, to have been doing a rather brisk business in the homebrewing market as well.

Foxx Beverage, who got into the homebrew kegging supply business by popular demand and has done us a tremendous service, is now getting out of it.

I can see two possible reasons for this trend:

- 1) The companies in question have decided that it is just too much work to service hundreds or thousands of small orders and they want to stick to wholesale, an all-around much easier job.
- 2) The Home Wine and Beer Trade Association (HWBTA) is putting pressure on suppliers to not compete with retail homebrew supply shops.

If the reason is #1, I can grudgingly accept it, but will try to talk the vendors in question out of this policy. If the reason is #2, I think some not so nice letters to the HWBTA would be in order about their policies.

I support my local homebrew supply shop, and I think that everyone else should too. I do, however, feel that we should also have the option of going directly to the supplier when we want to order in bulk or if we want to special order stuff that our retailer doesn't normally carry. Special orders from retailers tend to be outrageously priced.

Fight for your right to shop around for the best price! Don't let the retail associations bully us! Vote with your wallet!

From: Chris Goedde <goedde@shape.mps.ohio-state.edu>  
Subject: Siphon Woes

The good news is that I brewed my third batch over the weekend. The bad news is that siphoning it into the secondary was a major hassle. The cause of this hassle is CO2 coming out of solution inside the siphon tube, collecting at a bend in the tube and stopping the siphon; as a result, I had to restart the siphon several times. Needless to say, this has me worried^H^H^H^H^H^Hndering.

This particular batch had been in the primary for ~30 hours (although I also had this problem when racking my second batch, which had been in the primary > 2 days). The kraeusen had fallen and the air lock was glubbing about once per minute (it had been streaming pretty continuously about eight hours earlier). I don't have this problem when racking at bottling time, so my preliminary diagnosis is that I'm not waiting long enough before racking to the secondary, but I'm wondering if there's something I can do to prevent this, or if there's something I can do while siphoning when I see the bubbles forming and starting to collect.

Thanks,

chris

Subject: Homebrew Digest #945 (August 11, 1992)

Jack Oswalt writes:

So my questions: Can sassafras root be obtained in the United States?  
Is it even legal in the USA? Can root beer be made from  
sassafras bark?

Where I live, sassafras root can be obtained quite easily -- you go to  
the woods and pull up some sassafras seedlings.

You can recognize sassafras because it's the only common kind of tree  
that has three different shaped leaves -- some are like a mitten with  
a left thumb, some are like a mitten with a right thumb, and some are  
like a mitten for an alien with two thumbs.

Interestingly, sassafras and ginseng are closely related. In the  
nineteenth century, you used to be able to obtain ginseng root the  
same way you can still get sassafras root.

However, the Chinese or Koreans decided that "Real New England Ginseng  
Root" was the best stuff, and it got overharvested and is now rare.  
So the herb companies marketing ginseng to Americans advertise "Real  
Korean Ginseng Root".

From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
Subject: Yeast Questions

This weekend I made what I think might be a sort of Alt-like ale--at least that is what I hope it will be. I used Wyeast 1007 German Ale with 6 lbs. of 6-row, 1 lb. of Munich and 1 lb. of crystal (60 L.). That was pretty much what my local supplier had that was precrushed. In attempting to make up a recipe that I thought would be good, I scanned Cat's Meow II and looked in a number of other books. Wyeast 1007 does not seem very popular. So, what do YOU use 1007 for? (The current HBD has a couple messages sugesting the Wyeast European Ale yeast for Alts.)

I would like to use the 1007 again by pitching from the secondary to a new batch, and with some advance work I think I can get a real recipe to try for a known beer style. Please lend a hand/recipe, if you can.

BTW, I used Chinook and Tetnanger to aim for an IBU of 28. Maybe this will be good. The yeast (dated 8/5) really took off after pitching.

I've seen two of these over the years: Dave Logsdon brews in one that he bought from a government surplus site -- it had never been out of the box. He did some fancy plumbing with it and had the two tubs replaced with a single unit. The way it's set up you can circulate either steam (or very hot water) or cold water through the jacketing, so it can be used for mashing, boiling and fermentation. Pretty spiffy. But there are plans for something that sounds very much like yours in an old issue of Fred Eckhardt's Amateur Brewer. These aren't Fred's plans -- the originator's name escapes me -- but as I remember there were very concise. Sorry, I don't have my issues here with me and may not even have that issue, but you could try contacting Fred directly; he has back issues of most, if not all, the old ABs.

Maisel is in, I believe, the city of Bayreuth. They make an extraordinary beer called Dampfbier, which I haven't been able to find here in Oregon for two many years. Dampfbier was apparently their

attempt to do something "different"-- it's the equivalent of a steam beer, but darker. Incredible. The star you describe can be spotted on a lot of old beer logos -- including the old Weinhard brewery here in Portland. I remember reading about it specifically in connection with Maisel and have been going crazy trying to find where I read it -- the star was, I believe, a craft or guild symbol and used by all German brewers at one time. There is no connection -- other than appearance -- with the Jewish Star of David.

If anyone can point me to a reference on this, I'd really appreciate it, by the way.

From: SLK6P@CC.USU.EDU  
Subject: Yeast: Freezing & Nutrients

A couple of responses to some posts in HBD 949  
I can't remember who wrote them- so here they are up for grabs.

1) Glycerin: It's use in storing yeast.

For bacterial cultures we had used 10% glycerin. I would agree, use your normal culturing medium. You won't be able to pipet pure glycerin (extremely viscous) so make a 50% soln and use that.

If you want to maximize viability, I would recommend a quick freeze (so there is less chance for ice crystals to form inside yeast cells.) Make a dry ice/alcohol bath. (rubbing alcohol is fine- you should be able to get dry ice from the grocery or refrigeration supply) Dip your tubes of cells and medium and glycerin into them until they freeze, then place them in the freezer. ideally -70 deg C- not likely for a home freezer. Alternatively use a ice/rock salt bath for a quick chilling.

In addition- try to use a concentrated culture of yeast from the exponential phase of growth (fastest). They will be more able to withstand the freeze than old bugs. Again- ideally you would want to concentrate the cells (but may not have the equipt) by centrifugation. Alternatively: You could use a solid medium for growth (plates/slants)

, then scrape up a gob of cells and mix into the medium in your tubes (for a thick cell slurry).

Lastly: Be sure to use a good plastic tube for freezing. Preferably one with a tight screw cap. Glass tubes would be likely to dismember themselves upon freezing.

2) Yeast Nutrient: Now I don't know exactly what goes into the YN we buy from homebrew suppliers, but in micro labs for yeast and bacterial cultures Yeast Extract is a very common component of many different types of media. I believe it is essentially pulverized yeast, but may have had some components separated out. (Since it is and "Extract"). This type of stuff is available from DIFCO suppliers and other "biologicals" supply stores.

Regarding "grinding up yeast" yourself (Bob D.) I would not recommend trying it. The cells are microscopic, and to effectively "pop" them open with a coffee grinder or rolling pin is quite unlikely. You could try freezing them with liquid nitrogen and grinding with a mortar a pestle. Sonication is effective. But often enzymes are used to degrade the cell walls of the fungi, then the cells are lysed releasing all the goodies from inside. (At least these are ways to get the cells open to get their DNA). I presume for good yeast extract you MUST open the cells to make the proteins, amino acids, vitamins etc available to the growing yeast. Seems that it is easy enough to buy the stuff. We generally use it in such small quantities that it is not a financial setback, and to make it yourself might require more expense than it's worth (anyone know the going rate on sonicators?)

Well anyway. Hop on ye heathens!  
Brew on Brethren of Barley, Bee, and Vine.

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Bleach in SS kegs from Micah Millspaw

About bleach and SS kegs. I have often heard it said that chlorine bleach would corrode stainless steel. Most of the stainless that homebrewers encounter is either 304 or 316 stainless, the 316 is very corrosion resistant and is the material that most cornelius type kegs are made of. Moderate use of chlorine bleach will not harm the kegs. I have many kegs and have been cleaning them with bleach for several years, I only recently switched to iodophor sanitizers. I did however have one bad experience with the bleach, I loaned a keg to a fellow homebrewer who had all of his kegs full, unfortunately he filled the keg with boiling water and a strong bleach solution, something came up and the keg was left sitting with this solution in it for several hours. I received a horrified phone call telling me the the keg was ruined, when I saw the keg it was infact badly pitted and unsuitable for storing beer. So it may be okay to use bleach on stainless steel but not hot or for a long time.

> the over-priced packages of commercial yeast nutrients...  
>

Dried yeast is sold as a food supplement by many health food stores, at a cheap

rate. It would be interesting to see how it actually ferments. Some commercial

breweries also divert their excess yeast into the manufacture of toast spreads,

as in "Vegemite" in Australia and "Marmite" or "Promite" in GB, all of which

are touted as being high in vitamins, but unfortunately also high in salt. I

presume that some of this interest in organic nutrients arises from health as

well as cost concerns. If so, beer trub is a rich source of protein and therefore nitrogen and is a good nutrient for the more robust wines, meads and

ciders. The sparging leftovers are best, as boiler trub is loaded with hop

bitterness. You could try bottling some trub, then pasteurising it prior to

use. Avoid heating it beyond about 75C, or it will extract too much tannin. It

will inevitably increase both tannin and fusel oil content of anything it is

added to, but that might not necessarily be out of place in a full bodied, high

alcohol brew.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Chillers and Labels

This weekend I measured the flow through my 25' x 3/8" (1/4" ID) immersion chiller. It filled a 5 gallon carboy in 1:43 (avg of two runs, 0:01.5 difference between the two). This is a flow rate of ~2.9 gal/minute. With continuous stirring it takes about 20 minutes to cool 5 gal to 80F. My water temperature at the tap is 58F. So, I'm using about 58 gallons @ 58F.

Mike McNally (HBD 939) gives a formula for minimum water consumption that indicates I cannot use less than 27.5 gallons. I figure that makes my immersion chiller ~50% efficient. I just bought two 20' lengths of 3/8" OD tube at a going out of business sale. Should I hook them in parallel or in series to get the quickest cooling with the least water consumption?

I'm inclined parallel, but I'd be interested to hear comments.

David Clump asks what other people are using for labels. I'm xeroxing three labels per letter-size (8 1/2" x 11") sheet. 8 1/2" will wrap nicely around a long-neck bottle. I've tried all sorts of adhesives: mucilage, Elmer's, rubber cement, and glue sticks. I like the glue sticks best. It is not messy, soaks off easily, and is easy to use. Next best is mucilage, but there is a lot of difference between brands. The cloudy variety that comes from Mexico is best. The very clear mucilages can be very hard to soak off. Try a glue stick...

Is there any sort of a forum, newsletter, APA, pen pals club, etc. for people who like making and collecting homebrew labels?

Paul de Armond --- If it tastes good, you did it right!

> probably be happier with the result.

I checked the recipe, it indeed calls for one gallon of  
gyle. The beer tasted fine, with a slightly larger than average  
head. The carbonation level is a little higher then it probably  
should be. All in all, not a bad brew. It wouldn't win any  
awards, but everyone who tried it liked it and had more than one  
(thats my measure of success!).

The recipe is the (May or June) recipe of the month from the  
Beer and Wine Hobby in Woburn, MA. If anyone else is thinking of  
brewing this, the consensus is to use 1/4 - 1/2 as much gyle as  
the recipe calls for.

From: ALTENBACH@CHERRY.llnl.gov  
Subject: HOP ALLERGIES

Here's another data point for the beer allergy discussion. My wife has many diagnosed allergies, and claims an allergy (tho undiagnosed) to HOPS. Even the slightest contact with my backyard hop vines causes her to break out with hives. Hop aromatics filling the house during wort boiling gives her a stomach ache, as does drinking very bitter beer. Fortunately the balanced and malty styles are ok, so we can drink lots of those.

Subject: Yeast washing

Decided to go over Dave Miller's book Brewing the World's Great Beers, and found a tidbit I'd missed earlier. He goes into washing yeast. If I understand the method it essentially consists of getting yeast from the primary, and storing it in a sterile container for 12 hours. Dump half of the contents of the container, replacing that with chiller, sterile water, and stirring the concoction. This should be done two more times at 8-12 hour intervals, and pitched about 8 hours after the final washing. Has anyone else tried this? Any tips or anecdotes? Thanks in advance.

From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: RE: siphon woes

Chris Goedde reports a problem with CO2 coming out of solution during siphoning into secondary. I've had this problem in the past, and I can think of three ways to reduce it:

- 1) The CO2 comes out at the top of the siphon tube because of the reduced pressure here - you can minimise this by reducing the height difference between the two ends of the siphon tube ie. raise the secondary up somewhat. Unfortunately, this is fine in theory, but I sometimes found that although less gas came out, the bubbles were more likely to stay stuck in the bend because of the slower flow rate.
- 2) Rouse the primary several times before siphoning. If you rock the vessel, you may be able to liberate CO2 without disturbing the sediment too much. Alternately, shake a few hours before racking to allow the crud to drop back to the bottom.
- 3) Siphon a few days later, when the gas production has dropped off - I usually rack about 4-5 days after pitching. I see no reason why later racking should harm the beer (but I would welcome postings from those with different opinions).

From: Steve Anthony <steveo@Think.COM>  
Subject: near bottle failure

I went down to the basement last night to grab a brew, and reached for a bottle. To my surprise, it was stuck fast to the shelf. I mean stuck. Two hands, some pulling, with my face turned away incase it broke, etc. It finally came free, with some paint from the shelf. The bottle was sticky, so that answered why the thing was stuck to the shelf. However, the question remained, how did the bottle get sticky?

Upon opening and pouring the brew, the answer became clear. I found a small lump of crust on the neck of the bottle; just above where the body of the bottle turns into the neck. washing it abit, I noticed a hairline crack in the bottle. What had happened was obvious, the pressure in the bottle was pushing the beer out throught the crack.

Well, at any rate the beer was good, and I promised myself that I'd check my bottles as I empty and wash them, to avoid having one of them turn into a glass grenade. As the guy on TV said, "Let's be careful out there".

BTW, it was a Grolsch bottle, although I don't think that has much to do with it.

Subject: Canadian Beers

>>As far as I know, the beers exported to the U. S. are the same as those  
>>available here in the Great White North. That is, they are the light,  
pilsener  
>>style beers produced by the big brewers, which achieve massive sales by  
means  
>>of extensive advertising aimed at young, blue collar (usually white)  
males. Of  
>>course, with the current trade dispute on this very topic, exports are  
likely  
>to be at a very low level until the lunacy subsides.

>>With regard to strength, you should be aware that the reputation of  
Canadian  
>>beers as being stronger than U.S. beers is a fallacy. This arises  
because we  
>>measure alcohol content by volume whereas south of the 49th it is by  
weight.  
>>Since alcohol has a specific gravity of less than one, a beer of, say,  
5% by  
>>volume would be about 4% by weight. Hence the confusion and the  
unwarranted  
>>reputation.

Most foreign brewers who export to the U.S. use a recipe specifically  
tailored  
for U.S. tastes. Heine-corn is a great example. The Brador malt liquor  
available in Canada is indeed stronger than that available here. The  
latest  
bottle I got of it says 6% alcohol by volume. The U.S. version is 5%.  
There  
indeed are several mass-produced Canadian beers not available here.  
Moosehead  
makes a malt liquor called James Ready which is good and their "Busch" is  
called Alpine, which is a good summertime beer to quench a thirst.

Also, each state has its own laws governing alcohol strength. Here in  
North  
Carolina, the maximum allowed is 6%. Thus, we cannot get ECU 28,  
Samiclaus,  
Bigfoot, Old Foghorn, etc, etc. Mendocino Brewing Company of California  
is  
kind (or smart) enough to brew separate batches of some of their stronger  
beers  
for NC and other states lower in alcohol than the versions available in  
California.

Note that even though most Canadian beers available here are 5% by  
volume,  
these are STILL stronger than Bud and Coors! See Fred Ekhardt's book on  
Beer  
Styles to get the scoop on alcoholic strength of many commercially  
available  
beers.

From: smanastasi@mmm.com

Subject: Proposed process for moving from extract to all grain

I am an extract brewer ready to go all grain. I have diligently read the last 200+ homebrew digest articles and now am ready to come out of the Homebrew Digest closet and begin posting. I have summarized all Homebrew Digest wisdom on going all grain into an easy 10 step process. Please comment. After final review, this could be of value to all us simple extract brewers.

Please - this is only the basics. Let's not argue the merits of immersion  
.vs. counterflow chillers (again). Half the fun of homebrew is discovery.

New equipment:

1. Mash/lauter tun. 5 gallon cooler with a false bottom and improved spigot system, ideally with temp probes added.
2. 10 gallon brew pot - preferably stainless steel.
3. Immersion or counterflow wort chiller.
4. Grain mill (or access to one).

Easy 10 Step Procedure:

0. Crush grains such that each kernel is broken into several parts but not flour-like.
1. Place grain in cooler.
2. Add hot water such that water covers all grains and temp is 135F. Try not to exceed 20 oz.s per 1lb of grain. Let sit for 30 (??) minutes. This is the protein rest period.
3. Raise temp to 168F by adding hot water (how hot, I don't know). Maintain this temp for 45 (??) minutes. Do not exceed 32 oz.s per 1lb of grain (total water). This is the starch conversion period.
4. Begin draining cooler into brew pot. One can recycle the wort by slowly draining the cooler until 7 gallons of wort have been collected. This is the sparge process.
5. Boil and add hops, etc. as if doing an extract brew.
6. After boiling is complete, chill wort to pitching temp via counterflow or immersion chiller.
7. Siphon cooled wort off of cold break into carboy allowing wort to airate.
8. Pitch yeast and dry hop, etc. as if an extract brew.
9. Enjoy a far superior beer due to all sorts of "all grain" advantages well documented in Homebrew Digest.

From: "C. Lyons" <LYONS@adcl.adc.ray.com>  
Subject: Question about adding yeast at bottling time.

I have a question about the addition of yeast at bottling time. Is this recommended, and if so how much yeast should be added for a 5 gallon batch? The reason I ask is that I have repeatedly primed with 3/4 cup of corn sugar and have gotten poor carbonation. I have increased the amount of corn sugar to 1 cup for my last three batches, which has improved the carbonation, but is still far from the carbonation of commercial brews. I typically brew extract pale ales with and let the beer sit in the secondary for 4-to-5 weeks. Could the yeast be settling out and not in sufficient enough quantity for bottling? Any comments would be appreciated.

Subject: Re: Plum Wine

Thomas Kellogg asks about Japanese plum wine. I have many Japanese friends and I believe the beverage you ask about is not made the way you think it is made. They have a drink called "umeshu" (oo-may-shoo) which is made from green plums, sugar, and vodka (or some other high-alcohol distilled liquor). The high alcohol prevents any yeast or bacterial growth. The ingredients are all thrown together, sealed, and left alone for a year. If you want details (like a recipe) contact me and I'll get it to you. If it is a true wine you are looking for (like any of the non-grape-based wines out there) you'll have to ask someone else. Good luck.

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Re : Recipe for Fullers ESB wanted

Whilst Fullers ESB is one of my favourites, I don't believe the formulation is overly elaborate. You need an initial gravity of 55, which can be achieved with 9-10 lbs of (ale) malt. Substituting 0.5-1 lb of that with wheat malt will improve head retention. A protein rest is probably of dubious utility when using ale malt. The brew is reasonably light, so go easy on the specialty grains; say 0.5 lb of crystal malt at most as a substitute for the above. Up to 1 lb of a dark brown sugar could add interest (as a substitute for 1.3 lbs of malt), but in that case make sure you use a clean yeast and a reasonably cool primary ferment. The real signature of ESB is derived from hop aroma, and that requires dry hopping with around 1oz of English Goldings in the secondary. In the boiler, I prefer to avoid Goldings and would use around 2.5oz of seedless Hallertauer, with 0.5oz Goldings for finishing. Aim for a terminal gravity of around 12.

>and, in my mind, lessened the time for airborne bugs to enter.

Doug,

Always boil your water. Tuscaloosa water has the highest chlorine levels in the state. Boil for at least 30 mins then let cool overnight. This will also kill any nasties in the water. I checked Tuscaloosa water and it has > 5 ppm chlorine. I believe swimming pools have less than that. You can smell the chlorine coming out of the tap. Tuscaloosa water very cold? What part of town are you in? You might measure the temp with a thermometer. Where I live, the tap water is > 80F!

>Birmingham has had a micro brewery opened. The beer is good,  
>reminds me of an IPA. First brewery in AL in about 60 years. Made me  
>wonder why UA1VM distributes this letter (Bible belt and all that).  
>Afraid to ask, may cancel if powers that be realize it.

Apparently a law was recently changed to allow brewing. I dont know the exact wording or what it exactly permits. UA1VM distributes this message because the 'powers that be' is me and I brew! :-)  
Dont worry BEER-L isn't going anywhere anytime soon.

Re: Birmingham Brewing Co.

Latest word is Brewmaster Lee Nicholson who was instrumental in restarting the company, was fired last month. This could have some major implications. Such as, if the beer doesnt sell well, the beer ignorant snobs who are probably running it now, will change the recipe...you know, make it lighter?

From: gelly@persoft.com (Mitch Gelly)  
Subject: Getting labels to stick (and come off easily)

Greetings,

I know this isn't highly technical or directly related to the quality of your beverage, but a couple of people have inquired as to a better method for keeping your labels adhered to the bottle. This thread was also in rec.crafts.brewing (don't smack me, I know the HBD is the TRUE source of enlightenment, I just read r.c.b because we have a news feed, and it's there for the reading).

What was passed on to me by a friend (Hi Brian!) was to use rubber cement. A thin (or thick, no matter) coating on your label will keep it on the bottle until you want it off, and then it peels right off, cleanly. I've even put labels on cold bottles in the fridge, with no problem.

Labels are a fun addition to the beverage. For home consumption I generally do not bother, but they're usually a hit at club meetings or at any other gathering where you're rewarding people with the fruits of your labors.

Cheers,

Mitch

From: SLK6P@CC.USU.EDU  
Subject: Re: PlumWine/Siphon/ChicagoBrewSuppliers

In response to a couple of posts in HBD 950:

1) For Thomas Kellogg- here is a plum wine recipe from the Art of Wine Making. If you want more detail e-mail me  
Per gallon:3 lbs Plums

2.5 lb sugar

1/2 level tsp yeast nutrient

1/4 tsp grape tannin

1/2 tsp pectic enzyme

1 campden tablet

1 1/2 level tsps acid blend

Wine yeast

Starting specific gravity should be 1.090-1.095, acid 60%.

Follow normal wine brewing techniques.

2) Chris Goedde has siphon woes: Getting bubbles in the racking tube and siphoning ceases. A hassle I've experienced. A couple options:

a. Increase the height drop between your source and recipient of your siphoning. The greater the height, the faster the flow. This might help keep the bubbles moving.

b. If you have a CO2 tank hanging around, apply a LITTLE positive pressure to your carboy (but leave it UNSEALED- partially, so you don't build up too much pressure and BLOW IT UP!) This will help push the brew through the tube, and also reduces chances for oxidation. The best way might be to stick your racking tube through a stopper with two holes. Then stick the CO2 outlet tube into the stopper too. Don't keep building pressure, just get it flowing, and add a little pressure as required.

3) Glenn Anderson was looking for home brew suppliers in the Chicago area.

My E-mail to him got rejected- so here are a couple.  
Brewin Beer 6148 W. Belmont Ave, Chicago, IL. 60634 (312) 685-2895  
Fred Lane Co 1515 W. Berwyn Ave, Chic.IL. 60640 (312) 275-5600  
PMP fermentations 121 Wayne St. Peoria, IL. 61603 (309) 637-0400  
Mitchels Vineyard and Berry 434 State St. Madison WI. 53703 (608) 257-0099

I'm sure there are more. I haven't tried these, just have the addresses so if anyone know which (if any) of these are good, please lemme know.

Guess that's enuf for know. Brew on ye brethren of Barley, Bee, and Vine.

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: All Grain Help

Well I did it last night, my first all grain brew. It did not go very well!

My round cooler mash/lauter tun work OK, I used a Phill's Phalse bottom and a toilet type water valve to control the flow rate. The problems here were the valve moved thin wall of the cooler and the valve got very hot and was difficult to turn. I had to hold the valve with a wrench in order to adjust it, oh well, live and lrean.

To the point or rather the problem, very very low extraction. I used 3 lbs of 2 row malt and 3.5 american wheat. I decide to do a protien rest because of the wheat, 30 min. at 122-118 deg.F. Then raised to 158 deg.F and placed in my cooler for 1 hr. after the hour the temp was at 153 deg. F I added about 3 qt. to 180 deg.F water to try and raised the grian to mash out temp, this did not really work only raised to about 160 deg.F. I recirculated the run off until clear and the used sparge at about 175 deg.F, the sprage was too fast, about 25 min. I sparged until the run-off not longer tasted sweet, this was about 1.008, I then added water to make my 7 gal. , stirred and took a SG reading, 1.020. The recipe I was using as a general guide was a fruit ale from Dave Miller new book, it called for 4 lbs. of two row and 2.5 lbs. of wheat, I followed the recipe's mashing instructions, the expected SG was 1.045.

Now I am in trouble I could have lived with a SG around 1.032 but 1.020 was not goiog to cut it. So I heated up my 7 gal. of not so sweet wort to 160 deg.F and put it back into my cooler, this raised the mash temp to 153 deg.F. I let this sit for another 45 min. then sparged with the hot wort at 175 deg.F. Well after all this and a boil I ended up with about 5.5 gal. of wort at a SG of 1.028. Anyway this is now in the primary and we will see what happens.

So what is my problems.

Did I need more two row to convert the wheat?

Should I have checked the mash water for ph. level?

Should I have mashed longer at 155-158 deg.F?

Did I sparge way too fast?

Could my Hydrometer be wrong?

Or am I just lame? (Sorry could not resist)

And yes I cooled the wort before taking the SG readings.

Oh, thanks to everyone for the cooler mash/lauter tun ideas and the  
copper  
cleaning pad as a filter idea, They worked great!

I plan on doing another all grain brew on Friday.

And don't forget; the 3rd annual Homebrewer Gran Prix is an official part of the Dixie Cup. This is your chance to challenge me for the title of World's Fastest Homebrewer. Other titles to be defended: World's Fastest Female Homebrewer, Texas' Fastest Homebrewer, Medford's Fastest Homebrewer, etc.

The Dixie Cup is the best homebrew event in the country. It is the most fun you can have without risking arrest (especially in the South). Hell, if the republicrats found out, they'd probably make it illegal, so enjoy it while you can. Just don't go into any enclosed spaces with the boys from the Crescent City Homebrewers.

Subject: mash tun design from Micah Millspaw

Clearing the details;

Just to clear things up. My mash/lauder tun is stainless steel and is not insulated, SS is a poor conductor and the wet grain is a great thermal flywheel. I lose 2 degrees per hour. There is no sparge bag either, the tun has a false bottom made of 10 gauge perforated stainless steel, in fact the whole thing (my brewery) is stainless steel and is quite easy to care for. Also, it is possible that many small breweries did go out of bussiness because of their mash stirring habits, or so claims G.Fix.

Subject: K. Bloss going to Germany

In HOMEBREW Digest #949, Karl Bloss asks:

>I'm heading to Germany in about a month. Is there anything I should  
look  
>for there that is not available here?

Where are you going in Germany?? There are more than 1100 brewers, and they collectively produce over 4500 different beers! There are a \*lot\* of beers that are never seen in the USA - we tend to get the bigger brewers' products, from Munich, Bremen, Frankfurt, and some of the stronger regional brewers, but a lot of the little guys are left behind, not to mention the German brewpubs (Hausbrauereien) and microbrewers. There's lots of Pils, Altbier, Koelsch, Rauchbier, Fraenkische Ungespund'n, and Weissbier that aren't shipped very far from where they are produced, and never mind the international export market!

"I'm heading to Germany", in this context, is about as specific as "I'm visiting [ the USA | Canada | France | Japan | any fairly big country ]."

Tell us \*where\* you plan to visit, and you'll get better info about what to check out - I can promise you that much personally!

Prost!

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: Returning to the Good Ol' Days

Ah, yes, the good ol' days. While that phrase seems a bit trite, it is basically true. The reason that they were good is that the signal-to-noise ratio (another overused phrase) was very high. The main reason for that is that the digest was full of questions and answers--good questions and good answers--and not so much speculation and flamage. It was not a bore, it was a joy to read--a real learning resource. There were not many who just spewed speculation and guesses in order to feel important. It was not that people weren't thinking for themselves; there were those who questioned the established routines. And there were usually constructive replies--or at least good debates (full of information) with very little name calling. The tension was very low. It seems that these days, there are those who are just waiting to pounce. (At least we haven't reverted to spelling flames.)

I'm not saying that the digest sucks right now (I think it's great); it just gets tiring sifting through all the garbage.

Maybe a little selective remembering is at work here, but there IS a difference (otherwise, not so many would agree).

How do we return to those days? RELAX!

If it's a flame, sleep on it (then take it to email).

Remember, everyone has a different method that works for them. There are no RIGHT ways of doing anything.

Forgive others' mistakes.

Remember, there are PEOPLE at the other end. If we were all in one big room, and someone made a "lame" mistake, would everyone jump up and call that person an asshole to his face? I don't think so. They might take him aside (hint: email) and point out his mistake. Don't burn your bridges (before they hatch? :-).

We are all here to help each other and to better ourselves.

-Alan

From: gxd@po.CWRU.Edu (Guy DeRose)  
Subject: Heavyside Ale recipe

Here is a recipe I made last night for a Scotch Heavy Ale. It is my 4th batch to date.

Heavyside Ale  
(Ingredients for 5 US gallons)

3.5# Glenbrew Heavy 80/- Ale Kit  
2.25# Laaglander Dark DME  
0.5# crushed Crystal malt (20L)  
1 oz. Northern Brewer hops (steep last 10 min)  
2 pkg. dry ale yeast from kit

Notes:

Prepare yeast by reconstituting in 16 oz. warm tap water in a jar before brewing begins. Slowly bring 1 Qt. cold tap water with 1/2 lb. crystal malt to a boil, about 30 min. Remove spent grains by pouring the liquid through a strainer into the main brewpot and sparging with 1 Qt. boiling water. Add 3 US pints of water to brewpot and bring to a boil. Add can and DME and boil for 15 min. Steep hop pellets in hop bag for 10 min with heat off, then remove hops and pour concentrated wort into the fermenter. Since I've marked the outside of the (plastic) fermenter in gallon increments, I then added cold water to raise the level to the 5 gal. line. After cooling I pitched the yeast, sealed it up, and attached the fermentation lock. After less than 7 hours, the wort was bubbling like mad. I intend to prime with 1 cup dark DME when finished. It really looks and smells great in the fermenter, and I am looking forward to drinking it.

Subject: headspace

js asks:

> So, is it possible that homebrewers, who would not think of letting  
their  
> beer freeze, could reduce the headspace to the point where O2 is simply  
a  
> non-issue?

You could try it, but store 'em in a bucket. Water is virtually incompressible, when it `decides' to be bigger because of the temperature, it gets bigger. Period. You'd be surprised how small a temperature change it takes to break a sealed glass bottle that is completely full of water. I know, I tried it.

In my (limited) experience there is a direct correlation between the size of headspace and the carbonation of the beer. I don't know if this is a causal relationship or not, or what the mechanism is if it is. Will the yeast shut down if the pressure goes up too far or too fast?

From: arf@ddsw1.mcs.com (Jack Schmidling)  
Subject: Classified Section

To: Homebrew Digest  
Fm: Jack Schmidling

In an effort to remove the friction and flaming caused by the seeming commercial aspects of occasional posts, I have decided to address the issue directly.

It is obvious that a need exists to connect users and sources of homebrewing equipment, ideas and supplies, be they personal or commercial. To exclude the hobby computer network from making this connection, is to fight technology and progress and to cut off our nose to spite our face. The trick is to do it in a way that is not only a useful addition to what we are already doing, but to do it in a way that is not offensive or injurious to the existing networks and fora.

I have presented and discussed my proposed project on usenet and although one can't please everyone, the concensus is that it is a good idea and I am implementing it forthwith.

Until or unless invited to post it to HBD or any other forum, the weekly CLASSIFIED SECTION will be posted only to the rec.crafts.brewing newsgroup on usenet. Anyone may email ads to me and direct responses to any email or US Mail address but the list itself will only appear on usenet for the present.

The restrictions are few, simple and explicit. They are spelled out in this preview posting.....

The following is the weekly edition of the r.c.b CLASSIFIED SECTION

All submissions must be brewing related, 5 lines or less and no item may be posted more then once in a 30 day period. Items may be submitted as WANTED or FOR SALE and may be either personal or commercial. Send submissions to arf@ddsw1.mcs.com with CLASSIFIED as subject.

.....

FORSALE... The World's Greatest Beer, \$99 per bottle, money back guarantee.  
email to arf@wgb.com for details and testimonials from the world's great

brewers.

WANTED.... One bottle of the World's Greatest Beer. Price is no  
object. I  
will even pick it up and shake hands with the brewer. If anyone knows  
where

I can find one, email to [jay@humble.pie.com](mailto:jay@humble.pie.com).

.....

You get the idea. I am open for business. Send me your stuff.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Some old root beer receipts, sassafras

These recipes come from: The Scientific American Cyclopedia of Formulas, edited by Albert A. Hopkins [query editor of the "Scientific American"] New York, Scientific American Publishing Company, 1921

Root Beer--1.--To 5 gal. of boiling water add 1 1/2 gal. of molasses. Allow it to stand for 3 hours, then add bruised sassafras bark, wintergreen bark, sarsaparilla root, of each 1/4 lb., and 1/2 pt. of fresh yeast, water enough to make 15 to 17 gal. After this has fermented for 12 hours it can be drawn off and bottled.

2.--Pour boiling water on 2 1/2 oz. sassafras, 1 1/2 oz. wild cherry bark, 2 1/2 oz. allspice, 2 1/2 oz. wintergreen bark, 1/2 oz. hops, 1/2 oz. coriander seed, 2 gal. molasses. Let the mixture stand 1 day. Strain, add 1 pt. yeast, enough water to make 15 gal. This beer may be bottled the following day.

3.--Sarsaparilla, 1 lb.; spicewood, 1/4 lb.; guaiacum chips, 1/2 lb.; birch bark, 1/8 lb.; ginger, 1/4 oz.; sassafras, 2 oz.; prickly ash bark, 1/4 oz.; hops 1/2 oz. Boil for 12 hours over a moderate fire with sufficient water, so that the remainder shall measure 3 gal., to which add tincture of ginger, 4 oz.; oil of wintergreen, 1/2 oz.; alcohol, 1 pt. This prevents fermentation. To make root beer, take of this decoction, 1 qt.; molasses, 8 oz.; water 2 1/2 gal.; yeast 4 oz. This will soon ferment and produce a good, drinkable beverage. The root beer should be mixed, in warm weather, the evening before it is used, and can be kept for use either bottled or drawn by a common beer pump. Most people prefer a small addition of wild cherry bitters or hot drops to the above beer.

[disclaimer - these recipes are reproduced for historical interest. They may make you swell up and turn purple, loose all your bodily hair, or withdraw from presidential politics. What can I say? Mileage varies... ]

About sassafras... My 1930 Merck's Index, 4th ed., says that sassafras is supplied as either the root or bark of the root. If the current sassafras bark is from the trunk, then it's not the stuff in the old recipes. Sassafras root, oil, etc. is a federally controlled substance because of the presence of safarol and iso-safarol [sp? they may end with an 'e']. As I recall, it was placed on the federal list in 1977-8. It is toxic to the liver as well as carcinogenic. Oil of sassafras smells very much like root beer, but not as strongly as modern root beer extract. My hunch is that the taste and aroma that you want are volatile oils and not the safarol. I wouldn't choose to drink safarol, but others might...

From: Jim Griggers <ncrcae!brew@devine.ColumbiaSC.NCR.COM>  
Subject: CO2 purity

I posted a note on rec.crafts.brewing some time ago in response to someone asking about the purity of CO2. I could not find my original article, so here is the gist of what I said:

>The CO2 that I buy for dispensing beer is not sold as a gas, but rather  
>a liquid. Both places that I have had my tanks filled store the CO2  
>liquid in refrigerated tanks. The filling process is very similar to  
>having a propane tank filled, in that the tank is placed on a scale to  
>determine when the tank is full. Liquid CO2 is mostly what is in the  
tank  
>after filling. As the CO2 gas is removed from the tank, the liquid  
turns  
>into gas to maintain a fairly constant pressure. Gas can be used up for  
>quite some time while the gas pressure stays the same. It is only when  
>the last of the liquid CO2 evaporates that the tank pressure will start  
to  
>fall.  
>  
>Given that the CO2 was put in the tank as a liquid, very little of the  
>atmospheric gases should be in the tank. Nitrogen and oxygen require  
>low temperature and high pressures to liquify them. I think my original  
>article on R.C.B. addressed someone's concern on getting CO2 that was  
>mixed with nitrogen.

After writing the above, I called "Air Products" and asked if they sold different grades of CO2. The response was "yes, we do." They sell standard industrial grade CO2, along with at least 5 others. All range from 99.8% pure for industrial grade to 99.995% pure for research grade. I then said, "What do you sell for dispensing beverages?" Answer: The industrial grade. I just saw that one person on the Digest works for Air Products. Maybe he can shed more light on this subject.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: BEER CONCENTRATE

To: Homebrew Digest  
Fm: Jack Schmidling

A most amazing story appeared in this morning's Chi Trib. It seems that Coors is claiming to use Rocky Mountain Spring Water in the beer that they are "brewing" in Virginia and Busch is pointing out the absurdity of this in an ad. Coors is suing Busch and Busch is countersuing.

Coors defense is absurd and illogical and I only repeat it because I think it brings a new term into the brewing lexicon and an insight into how this rubbish is really "brewed".

They claim that the "beer concentrate is produced in Colorado and we only add water" in Virginia.

It is getting harder and harder to find anything what ever to call big beer other than a colossal hoax, fraud and rip-off, regardless of what people claim about their sophisticated and hitech processes.

It is interesting to speculate just what "beer concentrate" might be. I suspect there is something missing from the process because if one only added water it would be pretty flat.

So the minimum would be beer fortified with alcohol to which water is added and carbonated.

If it is low alcohol, it would not have to be fortified, and this business seems to justify my recent contention that they get rid of the alcohol simply by diluting beer with water.

The other possibility is that the mashing is done in Colorado and the sweet wort or boiled wort is shipped to Virginia to be boiled/fermented and then diluted with enough water to get rid of that beer taste.

I used to look at friendly looking taverns with a wistful eye when walking by but now I sort of wanta go in and chase out the money changers and knock some sense into the idiots drinking that slosh.

From: aew@spitfire.unh.edu  
Subject: getting labels to stick (and come off easilly)

gelly@persoft.com (Mitch Gelly) says:

>What was passed on to me by a friend (Hi Brian!) was to use rubber cement....

This sounds good, I'll have to give it a try - what about all that rubber residue when you peel off the label? Does it come off with the paper?

I've been using the following method: 3 parts water 1 part Elmers white glue. Labels stick great and a quick rinse of hot water while you're rinsing the inside of the bottle and the label and glue slides right off. Of course I use plain paper labels printed on my laser printer - glossy labels might be harder to remove because the water wouldn't soak them as easilly.

Previously I've read here in the HBD to use milk, but I tried that with little success - The labels seem to jump off of the bottles after a week.

Thanks for the tip Mitch,

>>  
>> ... Christopher Lyons  
>> lyons@adcl.adc.ray.com  
>>

I'm certainly happy to put in my 2 cents worth on this issue but as you  
may or  
may not have noticed by reading the HBD, you'll get various opinions on  
any  
question. The HBD is indeed a valuable resource. However, an equally  
good  
source is BOOKS. Charlie Papazian's "The Complete Joy of Homebrewing"  
and Dave  
Miller's "The Complete Handbook of Home Brewing" and, new for beginners,  
Dave  
Miller's "Brewing the Great Beers of The World (?)". Everyone on the  
HBD  
should own or at least have access to one or more of these books.

Priming is one area where most authors agree: do NOT prime each bottle  
individually (read one of the books for the why not to this answer). I  
use 3/4  
cup corn sugar most of the time and have ample carbonation. Some recipes  
require less (stout, if the recipe comes from Miller requires only 1/2  
cup).  
Your problem is probably in leaving it in the secondary for 4-5 weeks.  
Most  
ales should be completely fermented out in 7-14 days (if 65F or warmer).  
Even  
when I brew lagers, I only let it sit in the secondary at 50F for three  
weeks.  
Indeed the yeast WILL settle out. At that point, more sugar isn't the  
answer.  
You may need additional YEAST. But again, the best solution is to bottle  
after  
7-14 days (take a hydrometer reading to know when to bottle).

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinass)  
Subject: all grain stuff

Good list of all-grain equipment/steps. I'd recommend a 10-gallon (or more) cooler though; it allows you to add all the sparge water at once, and then drain it all off without having to babysit it. My last batch had 70% efficiency that way, which is fine with me.

A quick efficiency primer: Points per pound (PPP) only work if you are using a single type of grain; different grains have different maximum PPP's. I figure out efficiency as follows - Multiply the pounds of each grain by it's max. PPP (found in the literature, actually I use the numbers in the Brew Recipe Formulator). Total these up, and you have the maximum possible points from your grist (ie. 100% efficiency). Take the original gravity of your wort, subtract the 1.000. Multiply this by the number of gallons, and you have the number of points of your wort. Divide this by the max. possible points, and there's your efficiency.

Along a similar note, the first-time all-grainer said he had very low efficiency. Actually, you weren't too bad. The formula above gives 60% efficiency, more or less (again from the BRF, I should send Chris some money I guess). Use more pale malt next time; that should help convert more of the wheat. Wheat beer is not very high OG anyway, so relax and enjoy it, it sounds like a fine summertime drink.

Finally, I haven't gotten the answer I'm looking for re. stirring an infusion mash. I infuse the grist to conversion temperature, then put it in an insulated box. It stays well within 2 degrees. My question is, is it better to stir the mash occasionally, or best to just let it sit? It's not a matter of evenly distributing the heat, but rather of mixing up the enzymes/starches/sugars.

Russ

From: Bob Konigsberg <bobk@NSD.3Com.COM>  
Subject: Assorted Comments

First of all, thanks to Steve Anastasi for his summary of full grain. As an extract brewer, I'm always interested in information that will help lead me to the holy grail :-)

Christopher Lyons asked about adding yeast at bottling time. I've had a similar problem with lack of carbonation with 3/4 cup. I've been told that (Haven't verified it yet) that I'm waiting too long (about 3 weeks) after racking to a secondary, and that there isn't enough yeast to do the job within the space of a few weeks. The recommendation here is to rack to the secondary, and bottle within 2 weeks. That's hard in my case with a 1 year old running around, but I'll try next time.

Question: Has anyone make an extract brew with JUST dark malt extract, or maybe with some crystal? How did it taste? What kind of body. I'm looking at trying it just for the heck of it, but was wondering if anyone else has already done this.

Another item of interest (I haven't tried this). I was talking with Brian of Fermentation Frenzy, and he said that when he got a beer that was too sweet at bottling time, he quickly boiled up (in plain water) some northern brewer hops, and added them to correct the sweetness/bitterness ratio. Has anyone else tried this? And if so, with what success?

As another experiment, I'm going to make a batch with 6 lbs. Alexander's light extract, and then go heavy (3 lbs) on the crystal malt to see how much it takes to get that "caramelly" flavor. Again, any others out there who've done something like this? I'm trying to do some experiments to push normal limits of ingredients to see what the effect of extremes are in order to establish some scale for ingredients other than straight malt.

Regarding sensitivity to hops, I've found that a bittering rate much above 11 AAU's gives me instant heartburn. Hop aroma doesn't seem to have anything to do with it. Not much, but it's another data point.

Lee is the one who, along with his lawyer partner (first mistake?),  
got  
the laws changed to allow breweries in Alabama. He used to run a  
homebrew  
supply store in Homewood long ago. He founded a brewpub in Tampa FL. and  
then  
came back to Birmingham to start the Birmingham Brewing Co. I talked  
with Lee  
several weeks ago, very soon after the trouble began at the brewery. I  
posted  
nothing here because he asked that I not discuss the specifics of the  
case due  
to possible legal ramifications. All I will say is that the situation is  
still  
up in the air and don't count Lee out just yet. John Zanteson, the other  
brewer (Head Brewer, Assistant Brewmaster or something like that) who  
came  
from Hopland in Mendicino CA, is still there and is now acting  
brewmaster. I  
also plan to tour the brewery in the near future and post a review. The  
beer  
is now available on tap here in Huntsville and is quite good. There is a  
Red  
Mountain Red Ale and Red Mountain Golden Lager. It is also available in  
Birmingham-area bars (especially the 5-points south area). Not in  
bottles yet.  
Anyway, I'll be talking to both Lee and John again soon and I'll post any  
updates that I can.

Subject: Coffeemaker Mashtun

Chuck Cox <chuck@synchro.com> effuses:

I just bought a cafeteria coffeemaker for \$1. It has a pair of side-by-side 5 gal tubs, all stainless. It has a swivelling sparge head, temperature control, dual sparge/fill timers, some kind of recirculating pump, and what appears to be an overflow or level sensor.

As far as I can tell, I just need to add false bottoms and a more accurate thermometer to turn this into a semi-automatic recirculating mash/lauter tun. Has anyone out there already done this?

In one of the back issues of Zymurgy, there's a picture of a Rodney ``RIMS'' Morris device which I recall was based on a two-urn Coffee Thing. Might want to check the article, or write him.

The setup sounds great -- any suggestions how I can acquire one :-)  
or was this just a random event? :-)

Subject: RE: low extraction

Hi All,

In HBD#951, Tom Feller wrote:

>To the point or rather the problem, very very low extraction.

<description of brewing procedure deleted>

>So what is my problems.

Welcome to the wonderful world of all grain brewing, Tom. I've made only 7 all grain batches myself, so I'm hardly an expert, but I did notice a couple of things in your post.

Two common causes of low extraction are too coarse a grind of the grain, and sparging too fast. Check your grind, ideally each kernel should be broken into 4-6 pieces and the husks nearly intact. There should be no grains left intact. Of course, this is the ideal. If you're using a Corona mill as most of us are, you'll get some flour and a few of the grains do come through intact, but make sure the kernels are well broken up to the extent that this is possible.

There was a repost from HBD#313 in r.c.b the other day which was essentially a treatise on sparging. Among other useful bits of information was that the runoff rate should be around 10-12 minutes per gallon. I run my sparge a little faster than that, usually around an hour for 6.5-7 gallons, and I get around 30 pts/lb/gal. At 25 minutes for 7 gallons, your runoff rate sounds a bit fast.

>Should I have checked the mash water for ph. level?

Yep. I use test papers that are available from most homebrew suppliers. They're cheap, not super accurate, but they don't have to be. Check the mash ph after doughing in the grain, if it's anywhere between 5.0 - 5.5 or thereabouts, it's fine.

>Should I have mashed longer at 155-158 deg.F?

Use an iodine test to determine if conversion is complete. If so, continuing to mash at that temperature will cause long chains of dextrans to become shorter chains of dextrans, but won't improve extraction ratings.

>I then added water to make my 7 gal.,  
>stirred and took a SG reading, 1.020.

Adding water will dilute the solution and lower the SG reading. Run your sparge until the SG is 1.008-1010, corrected for temperature of the runoff, then stop sparging. You'll extract more tannin than sugar if you continue beyond this point, though it sounds like you already knew that. If you end up with less than 7 gallons of wort, take your SG reading \*before\* adding water to get to the proper pre-boil volume, and remember to adjust your extraction calculations for the volume you do have. Then add water to get to 7 gallons, you're going

to boil this down to 5 - 5.5 gallons anyway, and the SG will be higher after the boil.

This leads to another point in your post that was not clear. You mentioned that the expected SG was 1.045, usually this means after the wort has been boiled down to 5 gallons, yet you compared your reading of 1.020 taken when you had 7 gallons. A more valid comparison would have been the 1.028 for 5.5 gallons you ended with after the boil. If you had boiled down to 5 gallons, you would have got something over 1.030.

A personal observation: I own some of Dave Miller's books, they are generally excellent. However, Miller seems to insist that homebrewers should be able to get the theoretical maximums of 35-36 SG pts/lb/gal. If you beat through the math for 6.5 pounds of grain, 1.045 for 5 gallons of wort, it works out to ~35 points. I have never gotten better than 32, I generally get around 30. The point that I think needs to be made here is that if a brewer is getting somewhere in the ballpark of 28-30 points, that's fine. When designing or following recipes, use whatever figure you do get, and adjust accordingly (use a little more grain).

One final word of encouragement to Tom: glad to see you're brewing again this Friday, don't be put off by some of the posts that have appeared in this forum in recent weeks (lame NOT!). NO ONE is born knowing how to make good beer, there is a significant learning curve involved. IMHO, the learning is part of the \*fun\*.

My longest post \*ever\*, hope it helps,  
Jim

 From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
 Subject: sparging manifold design

I finally took the leap (step?) to all-grain this weekend. After reading posts about "slotted pipe" manifolds for sparging, I realized that I had everything I needed to build such a setup (well, I had to get a tee and an elbow). I took some 3/8" tubing from my mega-chiller-from-hell (50' of tubing is \*too much\*), cut slots every 3/4" to 1" with a hacksaw, crimped one end, bent the other, and attached the bent ends to a tee fitting. I cut another length of tubing just tall enough to reach the top of my rectangular cooler and attached it to the center of the tee. An elbow at the top connects to 6' of pvc tubing to make a siphon hose. Total expenditure: <\$5.

Wonderful ASCII graphics drawing:

```

  /-----/
  / | | | | | | | | | /
  | | | | | | | | |
  | | | | | | | | |
  /---/Top view
  | | | | | | | | |
  | | | | | | | | |
  /---/
  | | | | | | | | |
  | | | | | | | | |
  /-----/
  / | | | | | | | | | /
  /-----/

```

<--Tube coming up from tee.  
 Slots are in bottom of tubing, cut about 1/2 way through.

It worked. Sort of. I had to "back flush" it with air (translation: blow into the end of the siphon tube) to clear husks (I assume) out of the slots to really get it started. It took over an hour to drain 4 gallons of first runnings from the cooler (this was a barleywine recipe). Before I use it again, I'm going to widen the slots. Since it siphons 7 gallons of plain water from the cooler in about 20 minutes, I am assuming that the slowness is at least partly due to the slots getting blocked by husks or grain particles. If a few come through at the beginning, it's easy enough to dump that bit of wort back into the cooler until the filter bed gets set.

Any other suggestions or comments (preferably based on experience with a similar setup) would be appreciated. (Jack, I know about your system, but I want to try to collect over the entire bottom of the cooler, especially as it is longer than it is deep.)

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: RE: siphon woes

I too have had the problem with bubbles breaking the siphon. In my case it was because I was using one of those racking `canes'. At the place where the soft tubing is shoved onto the hard `cane' there's a great deal of turbulence in the flow, that's why and where the bubbles come out of solution and cause the problem. My answer was to get rid of the `cane' and just use the soft tubing. Cut the pick-up end of the tubing at a severe angle so that it won't seal against the side of the carboy.

Subject: Re:siphoning

>Chris Goedde writes that CO2 coming out of solution in the siphon tube is stopping the action.

I never liked the idea of siphoning twice. So, as a primary, I use a 7 gal. plastic bucket with a spigot installed about .5-1" from the bottom. I place a board or some magazines under the spout during fermentation so that most of the sediment collects away from the outlet, and then when the kraeusen falls and I'm ready to rack, I tip the bucket forward slowly, attach a hose to the spigot, and open the valve. (Just as a precaution to keep creatures out of the spigot, I cover it with plastic wrap or a sterile plastic baby bottle liner--I have lots of these--until racking.) I'm new to homebrewing myself, but this has worked well for me with my first few batches. If anyone has comments on this approach, I'd like to hear them.

From: richer@desi.HQ.Ileaf.COM (Al Richer)  
Subject: Electric boiler construction

For the edification of the assembled audience, I wish to present this tale of the assembly of a stainless-steel electric boiler from locally

available materials. This is not a project for the faint of heart, nor for those with marginal metalworking and electrical skills.

It involves drilling, filing, sawing, silver-soldering, and wiring for 220volts and heavy ampereages. IF YOU ARE NOT COMFORTABLE IN THESE SKILLS, PLEASE DON'T TRY IT!

Also, I accept no responsibility for you if you get burned, stuck, zapped or otherwise mutilated trying this. You're on your own...

But, as Shakespeare said, the play's the thing. Let us be off...as if we weren't already...

The container of choice here is a standard 1/4 keg, in stainless steel. I obtained mine from a scrap dealer with a hole punched in the top, for \$1/pound, as scrap. Scrap dealers around here are touchy on this, but can usually be persuaded to sell if you're friendly.

Once you have obtained your container, the next task is to remove the top. My weapon-of-choice for this is a jigsaw with a metal-cutting blade attached. It makes fairly handy work of the top, better if you periodically grind off the mount of the blade to expose a new tooth area. After cutting, flat-file the top of the keg to create a smooth, rounded edge. This is important, as the top edges after cutting will be very sharp. WEAR GLOVES WHILE PERFORMING THIS STEP, as it is far too easy to slip and gash yourself while filing.

Now, we need to add the connector for the element, as well as a drain port on the bottom. For the drain port, I drilled a hole to take a length of 3/8" copper tubing. This size is a good fit for a 1/2" drill bit. I then silver-soldered the copper into the hole, and then soldered a tubing to male pipe fitting connector onto the copper tubing. This was then mated to a ball valve. Thus, we can then drain without having to lug and slosh, as the case may be.

A note on silver soldering: I obtained mine from Sears. it comes in a blister pack with flux for about \$10. It was enough to do this job, and leave some for repairs. Also, yes, it is food-safe, being 55/45 tin and silver.

I used an oxy-propane torch rig to do the silver soldering. It took a bit of patience to get the larger bits hot enough without overheating the stainless steel, but it worked fine. Straight propane is not hot enough for the larger fitting (I tried it). Be careful not to overheat the stainless steel, as it will crack and cause you no end of trouble.

The larger connector(to take a water heater element) is nothing more than a 1" NPT female to copper pipe adapter. I drilled and filed an opening in the side of the keg body, just above the rounded bottom. Into this, I inserted the copper fitting, which I then silver-soldered in place. A tight fit is good on this, as silver solder does not bridge gaps terribly well.

At this point, install the heating element and check the boiler for leaks. I used a 3500 watt low density heating element from Grainger. Any low-watt-density element compatible with the materials in the keg can be used. Use the standard ring washer that comes with it, and a little Teflon tape makes installation a bit easier.

The controls for this are fairly simple. I used a 15 amp, 220 volt electric stove control I purchased locally from an appliance repair shop as a "throttle". I found this necessary when the element, connected directly, threw wort out of the pot with the vigor of the boil...

I installed the control in the lid of a deep, waterproof aluminum box I purchased locally. The side of the box was drilled for a watertight grommet for a 12 AWG power cord, and the bottom drilled to take the nut of the element. The box is held to the keg by the element, and the gasket goes to the outside of the box, between it and the keg fitting. The element is wired to the heater control, which is then wired to a cord set for 220 V.

Operation of the device is fairly simple. It controls not unlike a regular electric stove, but works better as the heat is being directly dissipated in the wort. Stirring is definitely required, though, as convection is not enough to prevent hot spots. I have yet to have any problems with hop bags or anything else, though. They seem to work fine.

I'm going to try rigging this with a thermostatic control for temperature as time permits, but it works fine for my all-grain boils now.

From: SSIEGLER@LANDO.HNS.COM  
Subject: Chillers and Bernoulli

I have been reading with interest (and awe) the discussions on chillers, but may have missed the following, if discussed (or dismissed).

It seems that most of the discussion centers on increasing the amount of water thru the wort with larger and larger tubes. This seems in contradiction to Bernoulli's Principle.

As I understand it, as air is forced thru increasing smaller tubes the rate of flow increases, and the temperature drops. This is important for the pilot because as the air is forced thru the carb, the temperature of the air decreases and the carb develops ice (under certian circumstances: humid, cool air) even when the outside air temp is above freezing. You can see this by sucking air into your mouth thru a straw (try different size straws)

I would think that forcing water thru the tube instead of air would yield similar results.

If you were to replace the one large tube, with multiple smaller (ie, capillary (sp?) type) tubes, I would expect a greater cooling rate, even though there was less surface area per tube.

Sorry, I dont have any formulas to back up this hypothesis. If this is wrong (or dumb [how would you bend capillary copper tubing?]), please tell me where I went wrong.

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>  
Subject: Re: All Grain Help

Just a few comments on some folks posting about moving to all-grain brewing.

smanastasi@mmm.com outlines a 10-step procedure for all-grain brewing. It looks right on (at least, it's darn close to what I do :-). My only confusion is on step 4:

> 4. Begin draining cooler into brew pot. One can recycle the wort by  
> slowly draining the cooler until 7 gallons of wort have been  
> collected. This is the sparge process.

It should probably read "Begin draining cooler into brew pot \*while sprinkling 175F water over the mash\*". Pretty important, otherwise you'll never end up with 7 gallons of sweet wort. My rule of thumb is to use about 1/2 gallon of water per pound of grain. Also, I very rarely collect as much as 7 gallons after my sparge; more like 5.5-6 gallons for a 5 gallon batch of beer. You can always add more water during the boil if you need to lower your gravity, without the risk of extracting unwanted flavors from the grain husks by oversparging.

thomasf@deschutes.ico.tek.com (Thomas D. Feller) tried his first all-grain batch the other day, and complained of low extraction. I don't you he really got a low extraction -- you just weren't using enough grain for the amount of beer you were trying to make.

The amount of grain ("3 lbs of 2 row malt and 3.5 american wheat") is low for a 5 gal batch. A pound of grain is \*not\* equal to a pound of malt extract. For a beer with O.G. 1.045, I'd use about 8 pounds of grain. You said you followed a recipe from a fruit beer. Well, a lot of fruit-beer bases are intentionally very light, to let the fruit flavors come through, and because the fruit itself adds lots of fermentable sugars.

Also, a half-gallon of liquid will change your gravity by 3-5 points, depending on what that gravity is (lower-gravity wort won't change as much as higher-gravity wort). So if your gravity comes out too low, boil a little longer and settle for less wort of the correct gravity. If you'd boiled all the way down to 5 gallons, you'd at least have been up over 1.030.

To answer your specific questions: you don't need more two-row, I make 50/50 barley/wheat beers all the time; I've never worried about pH (no flames, please); your mash was plenty long; a longer sparge might help some, but not to the tune of 20 points; an easy way to check your hydrometer -- it should read 1.000 in plain water; and no, you aren't lame.

Good luck on the next batch.

Subject: Finishing Hops

Thanks to everyone for the replies to my all grain problems,

Everyone seems to think Dave Miller numbers of 1.045 for 6.5 lbs of grain are high and my extraction rate of about 23 pts/lb/gal are not to bad for a first all grain brew.

Now to another question about Dave Miller's book, Brewing the Worlds Great Beers. I would say over 70% of his recipe call for no finishing hops. As a NW hophead I have always added finish hops to every brew. Now I am not worrying about it, I like my beers but I bought is book to get some ideas about brewing different styles. So here the question are adding finish hops as unusual as this book implies?

Oh, I am sorry about the "lame" comment, we do need to move on.

Tom Feller

Subject: Re: gyle

>There has been some talk of using gyle to prime. How  
>does one keep gyle until it is needed? Does it need to  
>be boiled before it is used?

Mark,

I use a sanitized one-liter swing-top bottle to store the gyle. I chill all the wort after the boil as usual, then when I rack to the fermenter, I simply divert the first liter or so into the bottle. The bottle goes into the refrigerator until it's needed.

Kraeusened beers take a little longer to develop their carbonation, but I think they taste much better than beers primed with corn sugar or even malt extract. Give it a go!

have fun

From: dougd@uts.amdahl.com (Douglas DeMers)  
Subject: Extraction rate (was Re: All Grain Help)

In HOMEBREW Digest #951 thomasf@deschutes.ico.tek.com (Thomas D. Feller) writes regarding his first all-grain brew (congratulations, BTW):

>To the point or rather the problem, very very low extraction. I used  
>3 lbs of 2 row malt and 3.5 american wheat. [... process elided ...]  
>the sparge was too fast, about 25 min. I sparged until the run-off not  
longer  
>tasted sweet, this was about 1.008, I then added water to make my 7 gal.  
'  
>stirred and took a SG reading, 1.020. [...]

I've never seen it stated for all-grain brewing, but it is my understanding that the gravity readings given in Miller for example, and others are after the boil. And when Miller says something along the lines of expecting 33 points per pound of malt per gallon - I believe that is after the boil and not after the sparge. If this is incorrect, then I've got a real problem with my extraction rate.

On my first couple all-grain sessions I was a little concerned with low extraction rates when checking the gravity after sparge, but the gravity after boil was reasonable and the beers turned out just fine.

A pre-boil starting gravity of 20 does seem a little low, but you are starting with only 6.5# of malt and you diluted it even further by adding water. My last stout had ~10# malt with an after-sparge gravity of in the 25-30's, but an after boil gravity of 48.

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: Re: Chillers and Labels

Paul D'Armond writes about modifying his immersion chiller, Asking whether to make it longer or to parallel the existing coils. He also said he uses ~60gal of water to chill a five gallon batch of beer.

Regarding the modifications: if the outlet water is not boiling hot, then you need to make the chiller longer. Parallel is another way of making it effectively longer: it reduces the flow rate in each tube so there is more (relative to the fluid going through the tubes) heat transfer. Which way you go is probably going to be determined by what is easiest for you to fabricate. From my experiences with immersion chillers, the biggest problem is keeping the hot wort stirred up. I have seen a very effective immersion chiller that is two coils, an inner and an out one. The coils are spaced out about 1" by some cross pieces soldered on. The inner coil is centered in the outer one with other cross pieces. The whole contraption is agitated in the wort continuously until chilling is done.

I use a 25' 3/8"od counterflow chiller, I get various amounts of cold break in my carboy but usually, if I am careful and don't suck over hot break the amount is very small - less than a 1/4" on the bottom of a 5.5 gal batch. The amount is even smaller when you consider that the bottom of a carboy is domed. In anycase, The yeast crop dominates the volume of crud by the end of fermentation. The following are typical numbers from my chiller:

Wort in: 195f  
Wort out: 73f  
Coolent in: 66f  
Coolent out: 90f  
Flow rate: 2 gal/min  
Chill time: 13 minutes (26 gal).

In the winter the coolent is 5-8 deg cooler (tap water, of course) with a corresponding decrease in outlet temp; I usually throttle down the flow rate for an exit temp of 70f (ales) or as low as I can get (lagers). If I slow down the coolent flow rate, the outlet temp goes quite a bit higher. I suspect a 40' chiller would be more efficientd

> nicely around a long-neck bottle. I've tried all sorts of adhesives:  
> mucilage, Elmer's, rubber cement, and glue sticks. I like the glue  
sticks  
> best. It is not messy, soaks off easily, and is easy to use.

Something that works well for home use: label the bottlecaps, not the  
bottles.

We use the little adhesive dots that you put on a diskette to show its  
density; or you can get stars, etc. Our last three batches were Spruce  
Beer (green star on bottlecap), Raspberry Mead (red star), and Luner  
Lager  
(yellow dot with a half moon on it). Or we just use our batch number.  
(my brother frequently requests an old Numba' Seven).

Using this method, you don't have to worry about washing the labels off  
the  
bottle later. Also, it gave my three-year-old niece a way to help out at  
a brew session: she was in charge of putting green dots on the  
bottlecaps.

She took this duty very seriously, and was most thorough; many bottles  
came  
out with four or five green dots, just to insure that you don't forget  
what you're drinking.

Cheers,  
Jim Buchman

From: Pat Lasswell <patl@microsoft.com>  
Subject: Making yeast nutrient

When making soup stock, one boils the stuffing out of scraps and bones to extract proteins, flavor, etc. Shouldn't the same thing be possible with yeast? That is, is it possible to make yeast soup for the yeast to feed one? (Barbaric little cannibals, they are!) Boiling yeast slurry would lyse the cells to be sure. It also occurs to me that yeast contain autolytic enzymes, which leads me to wonder if it is possible to do a "yeast mash" to cause these enzymes to be freed, breaking down the yeast cells. I have tasted yeast bite and know that it is an awful thing, but I assume that actively growing live yeast would slurp this stuff up like a (malted) milk-shake. Lastly, boiling the slurry would sanitize it for the most part, so nobody would have to worry. :-)

[ This idea sounds a lot like all-grain brewing, so maybe I should include a lautering step; maybe .... nyah]

Just a thought -- I haven't tried it myself (yet).

Beer me!

Pat Lasswell

PS. I have noticed (and others have as well) that a disproportionate number of brewers have beards and moustaches; any sociologists out there?

PPS. Thanks Rob...

Subject: Old Time Instructions

Dear brewers,

I'd like to second Neil Mager's motion regarding Walley Blume's sharing his grandfathers' recipies and methods. Though I'm still only a novice at this wonderful craft, I think there's something to be learned from how they brewed before the advent of "Techno-brewing." Plus, I personally find the prospects of brewing an old traditional ale or lager quite nostalgic. (I'd love to host another homebrew party and tell my guests that the beer they're enjoying was from an old Civil War era recipe, or from the foothills of the Smokey Mountains during Prohibition! (Those who know of my present occupation can appreciate the irony in my second example ;-))

However, I hope that my being a novice doesn't hinder my experimenting with these recipies and methods. All of my brewing has been from extracts, adding a few specialty grains here and there. Most have been successful batches, but I've also been cited by the EPA for other batches that have been... Well, lets just say that I named one such batch, "Chicago Tunnel Water"!

So, Walley, please post (maybe via personal email if you want to avoid being flamed by the "techno-brewers" and other beer geeks who take OUR craft too seriously).

Cheers,

John

From: "C. Lyons" <LYONS@adcl.adc.ray.com>  
Subject: Questions on cooling with ice and sparging.

I re-read Charlie's 2nd edition book and have a few questions that I hope the HBD followers could answer.

1) On page 367 of TNCJOHB, one of Charlie's tips includes:  
"Do not add ice to your wort in order to cool it."

In the past I have found the addition of ice quickly brings the temperature of the wort to yeast pitching temperatures. Could someone please explain the concern of using ice?

2) Why is it important to use 170F water for sparging? I am contemplating switching to all-grain, but am confused by the purpose of the sparging step. If the purpose of the sparge is to rinse the grains and remove the remaining "goodness", then why can't cold, or boiling, water be used?

Not worrying, just concerned!

From: melkor!rick@uunet.UU.NET (Rick Larson)  
Subject: FREE! software for searching Homebrew Digests

I translated Tom Kaltenbach's thread program from Pascal to C, replaced all the screen stuff with curses functions, and ported it to various flavors of UNIX (SunOS, HP-UX, Ultrix, XENIX, ...). Stephen Hansen put it in the homebrew archives (sierra.stanford.edu in the /pub/homebrew directory).

The following is Tom's description of thread from Digest 933:

..  
Over the past couple of weeks, I've written a PC program that might be of interest to homebrewers. The program is called THREAD, and its purpose is to search the back issues of the Homebrew Digest and extract those messages that follow a certain "thread" of conversation. THREAD attempts to do this by extracting all messages that contain specified key words; as a consequence, the program also functions as a general subject-searching program. For example, if you wanted to search for all messages related to kegging, you might use "kegging" as a key word (as I recently did). Logical combinations are also possible; for example, if you wanted all of the recent references to Jack Schmidling's MALT MILL, you could search for "malt" AND "mill" NOT "miller" (the NOT "miller" excludes the many references to Dave Miller's books). The key words are not limited to a single word, for example, you can search for messages mentioning "dave miller" OR "dave line". Up to 10 key word specifiers are allowed.

..  
I find it very useful. Maybe you might.  
rick

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: YOU'RE DOING FINE

To: Homebrew Digest  
Fm: Jack Schmidling

>From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)

>To the point or rather the problem, very very low extraction. I used  
3 lbs of 2 row malt and 3.5 american wheat...

>I recirculated the run off until clear and the used sparge at about  
175  
deg.F, the sprage was too fast, about 25 min.

Why was it too fast? It is hard to tell if you mean you blew it or have  
no  
control over the rate.

> I sparged until the run-off not longer tasted sweet, this was about 1.  
008,  
I then added water to make my 7 gal., stirred and took a SG reading, 1.  
020.

It is hard to understand why you would complain about the low gravity  
AFTER  
adding water. If the gravity is too low, you need to evaporate water  
not add  
it.

> The recipe I was using as a general guide was a fruit ale from Dave  
Miller  
new book, it called for 4 lbs. of two row and 2.5 lbs. of wheat, I  
followed  
the recipe's mashing instructions, the expected SG was 1.045.

One can only presume that the expected gravity of 1.045 was for 5  
gallons not  
for seven. To get 7 gals of 1.045 from 6.5 lbs of grain would require an  
extraction rate of 48 pts/lb/gal.... out of sight.

>Now I am in trouble I could have lived with a SG around 1.032 but 1.  
020  
was not going to cut it. So I heated up my 7 gal. of not so sweet wort  
to  
160 deg.F and put it back into my cooler, this raised the mash temp to  
153  
deg.F. I let this sit for another 45 min. then sparged with the hot wort  
at  
175 deg.F. Well after all this and a boil I ended up with about 5.5 gal.  
of wort at a SG of 1.028.

You ended up with an extraction rate of about 24 pts/gal/lb. Nothing to  
crow  
or complain about and possibly what can be expected from the combination  
of  
grain used.

>So what is my problems.

All things considered, I don't think you have any very serious ones.  
Just  
use more grain next time and congratulations on making the plunge.

>I plan on doing another all grain brew on Friday.

I would just double the grain quantity to assure success. You can tweek  
it  
in on later batches.

Instead of running the wort back through the mash, just run more sparge  
water  
through it and boil longer. If you really want 7 gals of beer, you will  
need  
at about 10 gals of sweet wort.

I would never add raw water to a brew. I would always opt for running  
it  
through the mash to get more volume and a bit more beer.

BTW, gravity and extract numbers are based on the boiled wort, ready for  
fermenting. But there are so many alternatives that unless you know  
exactly  
how someone else measured it and the accuracy of his measurements, it is  
pretty much of a myth anyway.

From: SLK6P@CC.USU.EDU  
Subject: Dogs/Brewing- Puppy Porter

Don't slay the dog, breed it! 8/7/92

I just wanted to relay a rather unorthodox and unusual brewing experience.  
A brewer like the "Murph" might want to take this as an example of extreme "NOT WORRYING"

\*\*Mind you- I do not recommend these methods, nor prefer them myself--  
\*\*but hey-- sh#t happens.

Last night I began brewing a darker Porter style beer. I ground my grains for a 12 gallon batch and began a step mash as I usually do.

As always my two dogs were acting feverishly strange since I was brewing. (well the fact that one of them was VERY pregnant and due any day might have explained her strange behavior and heavy panting). Some friends stopped by, so we chowed a pizza, drank and talked about homebrews(-ing)

After our chow session, they departed as I began sparging. I have one 5 gallon bucket with a mesh net and spigot which I strain through into a five gallon pot. The thing that caused me trouble was that I got distracted during the sparge. At a certain point (after the first 5 gallons of wort passes) I have to switch pots and get my 15 gallon pot under the spigot.

The reason I got distracted was that I realized my pregnant dog had dropped two puppies in my bedroom during our dinner. (I'll lock the dogs away from our pizza, but not the beer....) So I stopped to watch the next

one appear in a blitz of slimy goo. What a joyful sight!

So anyway--- then I turned around to realize that at least 1-2 gallon of sweet thick brown wort had just overflowed my 5 gallon pot onto the floor, and was collecting in the downhill corner of my kitchen. I couldn't just mop it up, and throw it away (although proper technique would tell you to!)

So here's where I improvised techniques. A friend had once spilled (well his kid did it) a large glob of grain on the floor during the sparge. So he just scooped it up and figured he was going to boil it all anyway.... So with this vision (and knowing his beer tasted darn good despite the floor

venture) I grabbed some clean towels (mostly clean- at least they weren't dirty socks) and mopped up the wort, squeezing it into the brewpot (hateful thought isn't it- I know at least half of you are groaning painfully at the thought.) I rinsed the towels and used the rinse water in the sparge.

I thought it would be a good idea to boil this one a little more vigorously and longer than usual. So I hopped the hell out of it, and boiled away. It sure smelled good.

I used my (first time) two stage cooling system:

1: Bucket (carboy) of ice water mix runs through 20 ft of 1/4 inch copper tubing immersed in the wort. Ran ~ 8 gallons of cold water through the tube and collected it in a bucket (for water plants, garden etc.) This brought the temp down to about 60 deg C. I figured that the hot wort would sterilize the tubing and the inside didn't touch the beer, so it wasn't sterile.

2: Then I siphon the wort through 10 ft of 3/8 in copper tubing immersed in a bucket of ice water. The tubing had a chlorine solution siphoned through it, then water, then wort. The ice bath brought it out at ~30 deg C. The wort never touched the ice solution directly. So I pitched my starter yeasts and hauled the beer to the basement.

I did see one dog hair in my plastic primary, so I scooped it out. It almost seemed silly to worry about contamination at this point!

Anyway- It was an interesting adventure. I probably wouldn't have been quite so carefree if I hadn't been tapping the keg all afternoon as I ground grains in the basement. But for all you worriers out there, you may not want to go to the extreme of relaxation I enjoyed in this brew adventure, but don't be too paranoid. I feel confident (based on MANY past beers) that I will have a full bodied yummy product in a couple of weeks, despite all the mishaps.

I decided to call this one  
"HAIR OF THE DOG" (any northern exposure fans out there?)  
or "PUPPY PORTER" (by the way it was 3 boys, 3 girls- American Eskimos)

So by the end of this brew night I had 8 dogs in the vicinity. What a night! Brew on, and don't worry ya'll.

---

Hoppy Brewing. J. Wyllie (The Coyote)  
SLK6P@cc.usu.edu  
"You're not my mom. My mommy had 6 nipples and licked my belly" Buck Bundy

---

\*FOLLOWUP: The beer brewed well. It was a good ferment. I've kegged the first half, and it is not yummy and filling our tummies. The second half gained some honey in the secondary and is still fermenting before bottling time arrives.

CONCLUSION: Despite all the mishaps and adventures of the night, I had fun brewing, my dog had pups while I brewed, I goofed majorly, but recovered- w/o worrying to an extreme, yet arrived with a healthy happy brew in the end (and 6 happy sleepy pups).

P.S. I haven't noticed any hairs in any beers yet- so maybe I'll go with PUPPY PORTER for the name, besides it's leaves a more palatable image.

Subject: Re: K. Bloss going to Germany

Date: Tue, 18 Aug 92 9:08:59 PDT  
From: tahoma!dgs1300@bcstec.ca.boeing.com (Don Scheidt)  
Subject: K. Bloss going to Germany

In HOMEBREW Digest #949, Karl Bloss asks:

>I'm heading to Germany in about a month. Is there anything I should  
look  
>for there that is not available here?

Where are you going in Germany?? There are more than 1100 brewers, and  
they collectively produce over 4500 different beers!

The two best beer guides to the breweries in Franconia (a region in  
Bavaria  
bounded by Nuernberg on the south and Kulmbach on the north and [I think]  
Bayreuth  
on the east) are:

Ein Wanderfuehrer fuer Biertrinker  
and  
Suffig Almanach.

They are both in German and of course unavailable in the US. But as Don  
said,  
let us know where you're going and we might be able to help. Both of the  
above  
books specialize in small (for lack of a better word) brewpubs  
(n., s.: Privatbrauerei) and put a great deal of emphasis on food and  
atmosphere  
in addition to beer. Franconia (Fraenkische Schweitz) has more breweries  
per  
capita than any other region in Germany. And ask to buy a mug, they  
usually'll  
sell one for DM5-DM7, and they make great presents and souvineers.

Tschuess,

Jeff

From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: Yeast nutrient is not yeast extract

As far as I'm aware, yeast nutrient is different from yeast extract. As the report of Dr. Pasteur's work in Lille described (HBD 949), all that yeast needs in order to grow is a carbon source (eg glucose, maltose), a nitrogen source (eg ammonium or nitrate salts), a phosphorus source (eg phosphate salts) and a supply of mineral ions (sodium, magnesium, potassium, etc) and trace elements (copper, iron, manganese, etc). Unlike humans, yeast can synthesize all their own complex organic compounds such as amino acids and vitamins from these basic ingredients (although they grow faster if provided with amino acids & vitamins).

Fermentables such as grape juice and honey are deficient in nitrogen and phosphorus and need these supplemented. The yeast nutrient I buy, therefore, is either simply ammonium phosphate or mixture of potassium phosphate and ammonium sulphate. I add this to wines at about 1 tsp per gallon. Malt extract contains enough of all of the basic ingredients to support yeast growth: maltose for carbon, amino acids (from hydrolysed seed protein) for nitrogen, and phosphate salts and hydrolysed nucleic acids for phosphorus.

Yeast extract, as the name implies, is an extract of yeast used in microbiological media, for growing bacteria and (somewhat cannibalistically) yeast. At work, I've used YEPD (Yeast Extract + Bacto-Peptone + glucose) medium in agar for yeast growth; at home I would use malt extract in agar as recommended by Jake S; I guess this also habituates the yeast to the malt constituents. I wouldn't recommend putting yeast extract into beer or wine as it smells (and probably tastes) pretty disgusting.

From: Ruth Mazo Karras <RKARRAS@PENNSAS.UPENN.EDU>  
Subject: Dry Hopping and Clearing

I dry hopped a Liberty Ale tastealike (I hope) with 1 oz. of Cascade pellets in the secondary. The pellets pretty rapidly expanded to form an inch-thick layer on top of the beer. If I shake the carboy they fall into suspension, but eventually float to the top again. Now that fermentation activity has slowed considerably, I think it is about time to bottle, BUT even when the hops are all at the top of the carboy the beer is very cloudy. Here are the questions:  
(i) does dry hopping tend to make beer cloudy, or should I look elsewhere for my problem and (ii) how do I bottle this beer without getting the hops in the bottles?

Thanks for any help,

Chris Karras (RKarras@PennSAS.UPenn.edu)

Date: Thu, 20 Aug 92 11:10:28 pdt  
From: SCHREMPP\_MIKE/HP4200\_42@pollux.svale.hp.com  
Subject: Hops and philosophy

I'm a first year hop grower and I've just finished the harvest. Now I've got observations and questions:

1. When to harvest. The book I have says to wait until the cones are starting to dry, look inside for lupulin, test the "squeezability", etc. I farted around, not wanting to pick too soon and ended up picking the first half of the harvest after many of the cones started to turn brown and were very dry, even crispy. The second half of the harvest, I picked when the cones were green and dried them. The new cones are dry and green, the older ones are dry and partly brown, but they both have the same wonderful hop aroma. So, what's wrong with letting them dry on the vine? I live in the dry Santa Clara valley where the chances of rain are nil this time of year.

2. My book said that after picking, my hands would be full of the sticky resins. This didn't happen at all. In fact, one of the ways I was testing for "ripeness" was to squish a cone in my hands and roll it around to see if my hands would get sticky. Any hop pickers out there with sticky fingers?

3. A lot of the cones in the first half of the harvest were HUGE, 1.5 to 2" long. All the hops I bought for brewing have been about .5-.75" (the size of the second half of the harvest). Are the little one better, or are the big ones better?

I also have another data point on Cascade hops. I planted two hop roots (although they looked more like rooted vines than rhizomes) this year, a Hallertauer and a Cascade. They are right next to each other (7'). The Cascade "root" was a dried out wimp but has produced all the cones, while the Hallertauer looked healthy at the start but has about 12 cones on it. So far, my

haul from the Cascade is 3 dry ounces from the first "half" and 6 dry ounces from the second "half"(gloat gloat).

Since I'm typing, here's my brewing and posting philosophy:

Every brewer brews for their own reasons and selects the techniques that suit their needs. Anyone that thinks they have the best method does have the best

method (for them), if it gives them the results they are looking for. So  
let's  
ALL remember this before letting someone else know what a jerk they are  
for sharing their opinions of what is "best". Different strokes for  
different  
folks. And so on, and so on, and scoobie doobie doobie...

For myself, I like drinking a good beer. I can afford to buy it, but I  
really  
enjoy brewing. I like orchestrating a pile of grains, hops and yeast into  
a  
symphony of flavors and sensations, then coaxing it into bottles. I love  
the  
sweet smells of the mash and the way the hops prickle my nose before they  
go  
into the boil. And nothing could be more melodious than the gentle rhythm  
of the

airlock at night. So to those who are looking for the fastest way to get  
the  
most extract to make the cheapest beer to get the best buzz... enjoy  
your  
destination, I'll continue to enjoy my journey (and leave me some  
pretzels).

Mike Schrempp

Date: Thu, 20 Aug 1992 16:49:58 EDT  
From: bob@rsi.com (Bob Gorman)  
Subject: B-Brite

A while ago someone (Stiv Stroud I think) asked if B-Brite had the same basic active ingredients as non-chlorine bleach. I don't remember seeing any replies to that post.

Anyhow, while I was farting around my basement last night, I saw a box of Chlorox non-chlorine bleach. So I decided to compare labels.

B-Brite contains:

Sodium percarbonate  
Sodium silicate

Chlorox NCB contains:

Sodium carbonate  
Sodium perborate

Now these aren't the same but look similar. Does anyone know \*anything\* about these chemicals?

FWIW, I also read the side of a box of Tide laundry detergent and it contained, among other things, two of the above chemicals but labeled as:

Sodium silicate (washing machine protection agent)  
Sodium carbonate (water softner)

Any insights?

Date: Thu, 20 Aug 92 16:28:56 CDT  
From: tony@spss.com (Tony Babinec)  
Subject: fest beers--ingredients & recipe suggestions

The AHA style guidelines for Fest beers tell us the following:

ViennaMarzen/Oktoberfest

SG 1.048 - 1.055    1.052 - 1.064  
IBU22 - 28        22 - 28  
color 8 - 12 Lovibond 7 - 14

In practice, there are relatively few commercial Vienna beers. Dos Equis amber is a good example, as well as Gary Bauer's star-crossed Ambier, which may or may not be available these days. While the Marzen style guidelines allow a gravity up to the low 1.060s, George and Laurie Fix state that most commercial Fest beers are in the 1.051-1.055 range. Notable commercial examples are Spaten's and Paulaner's Oktoberfests, available in bottle and sometimes on draft, at least in Chicago.

Beyond the above "objective" attributes, George and Laurie Fix maintain that a Fest beer should embody:

- elegance,
- softness,
- complexity,
- balance.

These characteristics are best obtained through the quality and mix of ingredients as well as attention to process.

As a Fest beer is an amber lager, the question arises as to how to obtain color. Here, the main alternatives are proportions of crystal malt versus Munich malt, with perhaps a touch of black malt thrown in. As the color contribution of crystal malt is more intense, crystal malt is proportionately less of the grain bill than Munich malt. Beyond that, there are flavor and body nuances attributable to the respective grains. Another point is that the color math of combining amounts and Lovibonds of different malts is not strictly linear. As a result, try a recipe that puts you in the ballpark and modify it until you get the right color. Or, see the appendix of the George and Laurie Fix book for a more technical discussion of color.

George and Laurie Fix argue that the base malt for the beer should be the best Pilsner malt. German or Belgian pilsner malt are fairly widely available. If you are not persuaded that pilsner malt is necessary, then perhaps U.S. 2-row malt might be substituted. They go on to say that the quality of available Vienna and Munich malts is highly variable, and therefore argue for using the best crystal malts you can find. Their recipes suggest a blend of "German Light Crystal," "German Dark Crystal," and "British Crystal Malt." The German Light and German Dark, I believe, are Ireks German malts with Lovibond ratings of 10L and 60L. I'm not sure about the British crystal malt except that it has a 120L rating. Maris Otter crystal malt, at least the one available from Liberty Malting, is a good crystal malt with a color rating of 80L.

If you have access to good Munich malt, such as the Belgian Munich

mentioned in previous HBDS, you might prefer to use some proportion of Munich malt in your grain bill to obtain color.

So, here are two recipes that assume 80% extraction efficiency.

"Crystal-Malt Fest" (derived from a George and Laurie Fix recipe)

10 pounds German or Belgian pilsner malt  
6 ounces German light crystal malt (10L)  
6 ounces German dark crystal malt (60L)  
6 ounces English caramel malt (120L)

3/4 ounce Tettnanger (alpha=4) at 45 minutes until end of boil  
3/4 ounce Styrian Golding (alpha=5) at 30 minutes until end of boil  
3/4 ounce Saaz (alpha=3) at 15 minutes until end of boil

Wyeast "Munich" or "Bavarian" lager

Starch conversion rest at 150-152F for 90-120 minutes.  
Expected SG around 1.060.

The extract brewer can substitute a good German extract for the pilsner malt.

"Munich Fest" (derived from a Dave Miller recipe)

6 pounds Pilsner malt  
3 pounds Munich malt  
3/4 pound cara-pils malt  
1/4 pound 40L crystal malt  
1/4 ounce black malt (for color)

6-7 AAUs of Hallertauer, Tettnang, Perle, or Mt. Hood (following Fix, in multiple additions with the last addition at 15 minutes until end of boil).

Wyeast "Munich" or "Bavarian" lager.

Expected SG around 1.054.

The extract brewer can substitute some good extract for the base malt, but ought to attempt a partial mash given the grain bill.

These recipes are merely starting points, and there is room for experimentation, including the "homemade" toasting of pale malt in your oven.

Subject: Yes, more about yeast

There has been ALOT OF TIME spent passing information back and forth recently about the care, feeding and breeding of our favourite micro-organism, the yeast. Since I am one of those tech-ies who work with them (biological control of plant disease with various yeast species) and need to grow up large amounts on a regular basis here is some info to various questions that have been asked.

Can I use bottle sediment, washed yeast from the primary, or any number of other sources? YES, of course you can with a few precautions.

If your technique is good and the brew produced was clean with no apparent bacterial growth and was produced with a clean commercial yeast culture (dry or liquid) go right ahead. But remember that each successive brewing past the original culture means your load of mutant yeast cells, wild yeast and bacteria will increase as your starter is no longer sterile. Your brew will likely get "funkier" with every successive culture.

From a bottle, open the bottle carefully and don't touch the lip. Pour the beer almost out ( enjoy your beer ) but leave some to suspend the yeast layer in and pour this into sterilized wort and cover. Pour quickly so that it pours straight out not over the "dirty lip". The same cautions hold. You may wish to go the the agar plate route as outlined in a recent posting assuming you know what a beer yeast colony should look like. However, if a multiple yeast culture was used you probably won't be able to distinguish between them as the characteristics used for separation of different strains are based on the effect of biochemical, metabolic (what carbohydrates can be fermented, alcohol tolerance etc.) and environmental variables which are not visible. Therefore, the complex character you expected won't be present if only one strain (one colony) is used.

Keeping cultures pure with no contaminants over the long term is difficult even when using antibiotics and the best equipment available. Luckily this isn't necessary for the homebrewer as your culture can be periodically renewed from a clean source. Solely for your information, the best medium for maintenance of yeast with least chance of mutation in fermentation ability is one with glucose as the sole carbon source. Glucose/peptone/yeast or GPY is the best as mentioned in The yeasts by Kreger-vanRij(editor) 1984.

#### YEAST NUTRIENTS

The best yeast nitrogen source is DIFCO yeast nitrogen base and will allow excellent growth of all yeast species known not only Saccharomyces. When combined with glucose a complete medium is created. This mixture contains a nitrogen source (ammonium sulphate 5 grams/litre), vitamins, trace minerals and growth factors, 28 in all. This medium has no smell when prepared but is very expensive at about \$50 a bottle (enough for 11 litres of media, buy it with a friend(s)?). Saccharomyces is definitely not a

demanding beast to grow so it's up to you if the price is worth it.

What is yeast extract?

Compressed brewers yeast mixed with water (sometimes a little organic solvent) which has been heated at 50-55 C for 3 DAYS with occasional mixing to explode the cells. Boiled briefly and allowed to cool and then filtered to remove solid matter. The liquid is then evaporated carefully to preserve the vitamins, proteins and growth factors present. This product is relatively cheap and is used at 0.1-4% by weight in media as an enrichment but be warned it smells disgusting however yeast love it. If your yeast nutrient is white with little smell it's likely only chemical.

Happy brewing,

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: Marcato Marga Mullino mill

OK here's notes from the field on the Marcato Marga Mullino grain mill.

I was in A&J imports in the North End (of Boston) last week. When I was in there the clerk in the store said they didn't have it. I told them I knew someone who had seen it there, so I left my name and number. The store manager called me back during the week and said that they indeed have the mill, and it is \$60.

Considering the price of the mill and it's quality I think this is reasonable. The mill however does have the following (all easily remedied) problems.

1) The grain did not seem to draw well into the rollers, even though they are scored in a spiral manner. The grooves for the scoring were too small compared to the grain size to effectively pull the grain in.

Solution: I went to the hardware store and got a disc shaped grinding stone. I used this to grind 4 small (~1/8 inch) grooves parallel to the length of the roller. These grooves are pretty shallow, but they work real well to pull the grain in. While I did disassemble the mill to grind the roller I now realize that that was not necessary at all, I could have simply used the table clamp that comes with it to hold the whole assembly in place, and have ground the roller in place with no problem.

Now I get fine throughput and a real good crush...

2) Small hopper size

Solution: make an extender out of empty coke or pepsi bottles..

3) Small catch tray size

Solution: either cut out one end of the tray and prop it up to make a chute to re-direct the grain into a pot or other container, or make something similar out of empty soda bottles...

Costs of modifications (assuming you already own a drill)  
\$1.85 for grinder head + cost of the soda bottles (you DO get to drink the soda). An additional \$2.50 or so for a 3/8 inch boring bit will allow you to drive the mill with a power drill.

I think this mill is very good. It is only slightly more than a Corona, but gives a far better crush for the extra \$\$, and is less expensive than some other mills on the market.

In all I am now really happy with this mill and plan to crush and brew as soon as I get back from vacation...

From: jdsgeoac@typhoon (Karen Jdsgeoac Hyrum GEOACOUSTIC)  
Subject: Brewing Disaster

This story is so terrible you may think I made it up, but its true. A friend of mine was so inspired by my HB that he decided to brew some of his own. He read Papazian and Miller, and watched me brew a batch. He was ready.

One fine Saturday he went to his dads house and brewed up his first batch. Not having a wort chiller, but wanting to cool his beer quickly, he filled the second floor wash tub with water and placed his brew pot in it.

Then disaster...The wash tub broke off the wall, landed on his foot, and spilled its contents. The wort/water mix quickly found the stairs and ended up in the family room. The builder had molly bolted the wash tub to the wall and counted on the plastic pipe to hold the weight.

This certainly was not a "Easy chill Method". Has anyone had a worse first brewing experiance?

From: dwatson@as.arizona.edu (Dan Watson)  
Subject: hops

Howdy all,

I have been interested in growing hops, and have read lots of good info on this digest. (This is largely academic, as I expect that they will not grow well here in Tucson.) Anyway, my wife Judy and I were out camping last week on the San Francisco river in New Mexico. One morning we hiked into a spectacular canyon called the Frisco Box; 600 foot cliffs about 30 feet apart, huge boulders, all in all a great spot. After climbing and wading thru about a half mile of the box we were resting on the rocks when I noticed something oddly familiar about the bright green vines along the cliffs... Yup, HOPS! They were vigorous and healthy, about 30 feet tall at least, and covered with soft green cones. I was amazed! Unfortunately they were unripe, but if anyone wants to try to harvest them, e-mail me for directions. I would love to try to use some of them in a "Frisco Box Bock" maybe.

From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Re: BEER CONCENTRATE

Jack Schmidling supplied some interesting information about Busch's claims about Coors' brewing processes (hang with it, it gets easier). I had seen the clipping regarding Coors' lawsuit against Busch, and intended to post it but left the newspaper at work.

Busch had made a commercial, or series of commercials, claiming that Coors prepared their beer in a concentrated form in Colorado, and shipped some of it to Virginia to be diluted to a conventional level and distributed from their plant there. Coors got an injunction against the ads, so they are no longer airing (i haven't seen them at all). I don't recall the wording of the article, but detailed in it were claims that either (a) Coors really didn't do it or (b) they did it but so did all other major brewers, including Anheuser-Busch. If the case were the former, then there is a relatively simple libel suit (...about as simple as two major corporations slugging it out can be!). If the case were the latter, then i'm more intrigued than scandalized.

Think of it... high-gravity Coors beer!

Jack writes:

] It seems that  
] Coors is claiming to use Rocky Mountain Spring Water in the beer that they  
] are "brewing" in Virginia

They may be hewing the the letter, if not spirit, of their claims. If Coors prepares a heavy wort in Colorado and then ships it to Virginia, the beer will, in fact, have some water from the Rocky Mountains in it, albeit not much -- more of a homeopathic dose.

] It is interesting to speculate just what "beer concentrate" might be.

My uneducated speculation is that they prepare a heavy wort, ready for fermentation, in CO and ship it to VA to dilute, ferment, and bottle. If i were covering the story and had the time to do so, i would take a tour of the Virginia plant to see what is done there.

AjD

In my first paragraph, substitute "Busch" with "Anheuser-Bush", please..

From: cestes@argos5.DNET.NASA.GOV (Chris Estes)  
Subject: Siphons

Hi all...

Regarding siphons, there has been some discussion that the plastic canes might be causing problems. The problem comes in where the flexible tubing meets the rigid cane and is probably due to a difference in the respective internal diameters of the cane and the tube (I'm a computer guy not a physicist!). I usually find that if you pinch the tube right where it mates to the cane, the bubble will be pushed out and you'll rid the tube of bubbles.

As far as bubbles appearing in other parts of the tube, my experience has shown that as long as the tube is descending over its entire length (not going up and down), this happens to a lesser degree.

And now a question on starting siphons... Starting siphons is a part of brewing that I WORRY about! Well, sometimes. I generally try to sanitize my tubes in a standard bleach/water solution. I fill them with tap water and start as recommended in most books. But, during the process of filling them with tap water, my hands touch the tubes. The tubes touch the sink. This worries me. Sometimes I don't fill the tubes enough and I have to start over. If I do this too many times I might start the siphon with my MOUTH! Then I really worry. I've made a few bad batches, and usually attribute it to bad siphoning techniques (except for the dropped thermometer which I retrieved with an unwashed hand...). Anyway... My question: Has anyone ever used a hand or drill operated pump for racking. I've seen them for pumping gas from one car to another and other dubious activities and wonder about their application in beer. Any comments?

From: blossomf@ttown.apci.com (Karl F. Bloss)  
Subject: More on CO2

Although I didn't catch all of the conversation on CO2 dispensing, I have a few comments: Almost any grade of liquid CO2 should only contain residual O2 and N2 in the head space since the normal boiling points (@14.7 psia) are -109, -297, and -320 deg F, respectively. So the small percentage of other 'stuff' in the CO2 will be hydrocarbons and similar organic stuff that comes in out of the air. I'll check for sure with distribution, but my guess is that it's just residuals from air separation.

Don't forget that cryogenic CO2 has the lovely property of turning solid if the pressure is taken off (i.e. dry ice)... we've heard of whole trailers doing that; then all you can do is wait for it to sublimate.

From: SCHREMPPE\_MIKE/HP4200\_42@pollux.svale.hp.com  
Subject: siphon bubbles

There's been plenty of talk about how to make a siphon so bubbles won't form, but these ideas don't help when there are bubbles forming in the tube. Here's what I do when this happens:

Pinch the soft plastic tube above the bubbles to slow the flow. This lets the little bubbles collect into a big one. Then let go of the tube and the wort that's upstream will push the big bubble out through the tube.

It's important to watch for bubbles early and pinch before things get too bad or this won't work. When I do get distracted, I follow the same procedure but bend the hose up past where I pinched it so the bubble will float up and allow more fluid behind the bubble. This way, you can work the bubble to the end of the tube.

At the early stages, when bubbles are forming right at the connection between the cane and the tube, pinch it right there at the joint then let go. The bubbles will flow right down the tube. Try it.

On another topic, I think the idea of a calssified section in this digest is interesting. Let's watch the experiment somewhere else and if it works, lets do it.

From: strasser@raj5.tn.cornell.edu (Tom Strasser)  
Subject: Bayreuth, Maisel

Just to set the record straight, Darryl and Mike should check out their maps, as Bayreuth, location of Maisel Brewery is \*north\* of Munich, actually in Franconia, the northernmost part of Bavaria, and where you would go to find the largest number of breweries per unit area in the world (for any reasonably large area). It is very near the border of Czechoslovakia with the two formerly separate German countries of East and West Germany (the DDR and the BRD). The area is famous for it's Darker beers, such as Schwartz beer. Also in the area is Bamberg, home of the Rauchbier (smoked beer). Perhaps the most famous beer from the area would be E.K.U. 28, made in Kulmbach.

I might even go so far as to say that, hard as it is to believe, \*both\* Mike and Darryl are wrong, as given the size of Munich, I don't think Bayreuth is even slightly east or west of it :-).

Auf ein neues,

A neat trick that was shown to me is just give the soft tubing a quick  
pinch right where it joins the racking cane. Any bubbles that have  
formed usually flows right out. In my case, once I have cleared the  
bubbles one time, they usually don't re-accure.

Hope this helps...

>I typically brew extract pale ales with and let the beer sit in the  
>secondary for 4-to-5 weeks. Could the yeast be settling out and not  
>in sufficient enough quantity for bottling? Any comments would be  
>appreciated.

Let some bottles sit for an extra month or two, and if the carbonation  
level increases quite a bit (it probably will), this is your problem.  
I usually let my ales sit for at least 2 weeks (typically 4) after  
all apparant fermentation has stopped, and just let time solve the  
slow carbonation problem. usually (at room temp, with something  
weaker than a barley wine), the beer is undercarbonated for around  
6 weeks, and then everything just seems to kick in all at once.

Recently (since reading "Belgian Ale") I've taken to adding the extra  
yeast at bottling time, and it seems to work pretty well - my last  
batch was carbonated after a week in the bottle.  
Just rehydrate a packet of yeast, and throw it in the beer when you  
prime.

(I haven't tried this with liquid yeast, and it prpbably wouldn't be  
too keen to make a sweet beer and then using a super-attenuative yeast  
to prime with) You can also try letting the yeast ferment the priming  
sugar a little to get it going and then bottle, but you have to either  
use malt extract or add yeast nutrient to get the yeast started.  
You also risk letting too much of the stuff ferment away,  
and under-priming/carbonating the beer. Remember - adding extra yeast  
at bottle time reduces the amount of time necessary to fully carbonate,  
but does not affect the final carbonation level. (i.e. cut back  
to <= 3/4 cup sugar when you try this)

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Yeast at bottling time

Like Bob and Chris, I had what seemed like excessively long conditioning times in the bottle. I'm now adding 1/4 tsp. of dry yeast to 5 gal at bottling time and shake the bottles every other day to keep the yeast suspended during the first 4 days after bottling. I was waiting 3-5 weeks for a reasonable level of carbonation, now there is some fizz at one week and good carbonation at two. I've had the same problem with root beer and ginger ale, but keeping the yeast suspended for the first several days seems to do it. One of the guys at The Cellar in Seattle suggested laying the bottles on their side to expose more bottom area for the yeast to spread out on.

I don't know what the cause of the slow conditioning was. Most of my beers are ales with OG ~1.06-7. We have very hard water with high levels of manganese. I frequently use 1 T. of polyclar in the secondary after the yeast has settled. The amount of time in the secondary has varied without a noticeable relation to conditioning time, though I've always waited for the yeast to drop in the secondary before bottling. It's a mystery to me...

> or was this just a random event? :-)

I bought mine at a surplus audio equipment auction B-) I think \$1 is an unusually good deal, but you might find a reasonable deal if you check out business equipment auctions in your area. I saw one of those tall party-sized coffee makers go for \$10 at another auction, so there doesn't seem to be much demand for used coffee urns. I suspect every time a business goes under, or expands, a used coffee urn enters the market.

One caveat: you may have to rewire the urn to work with your household electricity. The unit I bought is rated at 10kW (120v single-phase), thats 80 amps, my entire apartment is limited to 50 amps. I will simply disconnect 3 of the 4 heating elements, and plug it into the 30 amp stove circuit. This thing must heat up \*FAST\* when all 4 elements are dumping ~8 kW into the ~10 gallon water bath. Since I don't want to boil the water, I think a single ~2 kW element will work fine.

From: Jeff Benjamin <benji@hpfclub.fc.hp.com>  
Subject: Re: sparging manifold, Kolsch

"Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu> says of his new copper sparge manifold:

> It worked. Sort of. I had to "back flush" it with air (translation:  
> blow into the end of the siphon tube) to clear husks (I assume) out of  
> the slots to really get it started. It took over an hour to drain 4  
> gallons of first runnings from the cooler

My manifold is similar to yours, except perhaps the slots we cut with a hacksaw didn't go through quite as far (maybe 1/4 - 1/3 the tube diameter). I suspect that the grind of your grain is at fault; I've got a Marcato roller mill, and usually can drain as fast as if there were no grain at all. Also, did you put the manifold in *\*before\** you started mashing? I can easily see it getting clogged if you try to push it through all that wet grain.

waflovers@quantum.qnx.com (Bill Flowers) asks me to share my partner's Kolsch recipe. Here it is:

Fat Wanda's Kolsch Klone

7lb pale malt 1-3/4 oz Hallertau (5.0%)  
1-1/2 lb Vienna malt 1/2 oz Tettnang (4.5%)  
3/4 lb wheat maltWyeast European Ale

O.G. 1.042, F.G. 1.009 Yield: 5.8 gallons

To keep hop aroma low, the last addition of hops should come no later than 20 minutes before the end of the boil. The trick to this beer is to cold condition it. After 4 days primary and 4 days secondary fermentation at ale temps (~65F), rack again and cold condition at 40F for 12 days. Then prime and bottle as usual. This beer should be very pale, and taste "clean" like a lager but with an ale's body and fruitiness. This beer took first prize in the "pale ale" category at the local (Northern Colorado) AugustFest competition this year. It's not *\*exactly\** like drinking in Cologne, but darn close.

From: tahoma!dgs1300@bcstec.ca.boeing.com (Don Scheidt)  
Subject: Hamburg 'n' Bayreuth

In HOMEBREW Digest #952, Karl F. Bloss responds:

>In HOMEBREW Digest #951, Don Scheidt asks:

>

>>Where are you going in Germany?? There are more than 1100 brewers, and  
>>they collectively produce over 4500 different beers!

>

>Point taken! Specifically, I will be in Hamburg, but I'll be mobile  
>within that general vicinity. I do have a friend there who knows his  
>pubs, but if anyone knows of any great brewpubs that are not to be  
missed,  
>drop me a line.

Specifically to Karl - please e-mail me; I get a bounce when I try to  
e-mail to you. I'll figure out the return-path (with luck) and let you  
know what I've learned about the German Northland.

In general - for those who wish to know - the German Northland (the state  
of Schleswig-Holstein, the city-states of Hamburg and Bremen, and the  
state

of Niedersachsen, or Lower Saxony) has the lightest distribution of  
brewers

in Germany, as compared to the Big Three states - Bavaria is at the top  
(by

far!), then Baden-Wuerttemberg, then Nordrhein-Westfalen (North Rhine -  
Westfalia). The bulk of beer produced in the German North is 'pils', and  
there are some pretty good ones, and one that is, indeed, excellent, a  
world classic, almost on a par with Pilsner Urquell. Good pilsners  
include

Flensburger, the Astra beer from Bavaria Brauerei (a Hamburg brewery -  
not

from the \*state\* of Bavaria!), and a few others. Beck's is, of course,  
pretty common, being brewed just down the highway in Bremen; Holstein is  
ultra-common (the biggest Hamburg brewery, if I remember correctly). The  
pils to beat, though, is Jever, the hoppiest and most flavourful beer  
produced up there, in the town of the same name. There is also a Haus-  
brauerei (brewpub) in Hamburg - the name escapes me at the moment, but I  
think it's known for its unfiltered pils.

And In HOMEBREW Digest #952, Mike McNally sez:

>A chance to correct Darryl Richman can't be passed up! Bayreuth is  
>east of Munich, not west. It is the home of Maisel as well as the  
>huge opera house constructed by Ludwig II (I think) for Wagnerian  
>productions.

>

>(Now watch somebody correct me ... )

Everybody watching ;-)? I already e-mailed the original poster (Brian  
Cole), and he reported getting a veritable flood of postings on this  
subject (as well as a burning desire to visit Franconia). Bayreuth is  
\*not\* west of Munich (sorry Darryl) and it ain't east of 'the world-city  
with a heart' either (sorry Mike). It's quite a way from Munich,  
actually,

a good 2-and-a-half-hour ride on the Autobahn, even at German speeds  
(well,

you could do it in under 2 hours if the traffic is light, there's no fog,  
etc, but optimum conditions like this are pretty rare in that part of

Germany). In fact, it is well \*north\* of Munich, actually a bit north-east of Nuernburg; if you drive from Munich to, say, Berlin, Bayreuth is just a bit south of the half-way point on the Autobahn. And yes, Bayreuth is the home of Gebr. Maisel Bierbrauerei, home of Germany's 'steam beer' (Dampf-bier) and several other styles, all done quite nicely. And also a mecca for Wagner fans...

Now here's an idea a-brewin'. How many of you brewers and beer-lovers in general would be interested in the idea of some kind of semi-organised tour to some of these German shrines to brewing? I've already done one holiday in Franconia, and wouldn't mind being the instigator for another one... Just a thought for now, although if there was enough interest (and people with the cash, time, and wherewithal for a German holiday), I could put together a trip that would, once and for all, set in the minds of at least fifteen or twenty participants, just what is meant by Germany, history, and most of all... beer!

PROST!

Subject: Dark Malt Extract Brew

In Issue 952:

Bob Konigsberg asked about all Dark Malt Extract Brews.

Actually, my third batch ever was an all Dark Extract batch.  
One of my best extract batches ever. If I remember correctly  
it contained the following:

3.3 lbs M&F Dark UnHopped  
3.3 lbs M&F Dark Hopped  
3 lbs Dark DME (might have been 1.5 lbs)  
1 oz Hallertaur (60 min)  
1 oz Hallertaur (2 min)  
2 pkgs EDME dry yeast.

Sorry, I don't have my recipes here. It was good enough that I  
had a roommate learn to brew to make it! It came out as a  
heavier American Dark.

> little success - The labels seem to jump off of the bottles after a  
week.  
>  
> Thanks for the tip Mitch,  
> -Al

I have found that milk works to varying degrees, depending on the type  
of paper (and maybe the type of milk, % fat). I have never had a  
problem when I add a bit < 1/8 t of conr starch to the milk and mix it  
in with my finger. Also, you'll probably never get a label to stick to  
a bottle with condensation on it, using this method.

Let me try my previous question again. Maybe my mailer is in a good  
mood today. I am planning on "building" a bath chiller by syphoning  
the hot wort through my bathtub full of ice-water. Should I not use  
standard "food grade" plastic tubing for this? How much insulation am  
I fighting if I do? How much does copper tubing cost anyway?

Thanks,  
Jake.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: YEAST CULTURE

To: Homebrew Digest  
Fm: Jack Schmidling

I have been asked by several people about the need for a pressure cooker to sterilize equipment and media for yeast culture.

Like so many things in this hobby, there are "correct" ways and ways that work just as well or at least well enough for our purposes and I think this is one of them.

I really missed the target if people are turned off to culturing because they do not have or wish to purchase a pressure cooker.

Rather than not do it, I would suggest using any large pot with a decent lid and about a half inch of water. Put the petri dishes or slants on or in a cup or some such support to keep them out of the water and steam them for twice the time recommended for a pressure cooker, i.e. 30 mins instead of 15.

My guess is that no one will ever know the difference.

The important thing is DO IT. There is no longer any excuse for using contaminated or recycled yeast.

>From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>

>It worked. Sort of. Before I use it again, I'm going to widen the slots. Since it siphons 7 gallons of plain water from the cooler in about 20 minutes, I am assuming that the slowness is at least partly due to the slots getting blocked by husks or grain particles.

I think you are fighting the process that you so laboriously set out to create. The whole object is to create a filter, which by definition, will drain much slower than water through an empty cooler. You need patience not bigger holes or an.... no, I won't do it:) this time.

>Any other suggestions or comments (preferably based on experience with a similar setup) would be appreciated. (Jack, I know about your system, but I want to try to collect over the entire bottom of the cooler, especially as it is longer than it is deep.)

That is sort like trying to walk with two left shoes just because you happen to have two left shoes.

>From: "Ron Fresne" <FRESNE@washpost.wdc.sri.com>

>Subject: Re:siphoning

>I never liked the idea of siphoning twice. So, as a primary, I use a 7 gal. plastic bucket with a spigot installed about .5-1" from the bottom. I place a board or some magazines under the spout during fermentation so that most of the sediment collects away from the outlet, and then when the kraeusen falls and I'm ready to rack, I tip the bucket forward slowly, attach a hose to the spigot, and open the valve. (Just as a precaution to keep creatures out of the spigot, I cover it with plastic wrap or a sterile plastic baby bottle liner--I have lots of these--until racking.)

Another precaution you may not have thought of is to be sure that the connection between spigot and hose is tight. The smallest leak will provide a stream of air that will nicely oxygenate your beer at exactly the wrong point in the process.

Since buying a new 16 gal brew kettle, I now use my ten gal for fermenting.

It has one of those unmentionable things on the bottom and just makes brewing that much more easy. One less time to mess with a syphon. You learned faster that most of us.

From: hpfcla.fc.hp.com!digger!tcm  
Subject: Yeast and the nature of things

A lot has been recently said about how the list used to be and I think that in many ways the list has certainly changed. It would be too simplistic to say that it is better or worse, it is different, enjoy it as it is. I for one miss messages from Cher Feinstein, even though I had no personal interest in mead, but her absence from the list ( and the world :-( ) are facts of life.

It is inevitable that a forum such as this will introduce opinions that not everyone agrees with but we are free to pick and choose those we agree with and those we don't. I think the number and variety of textbooks on the subject is ample proof that even the "experts" don't always agree. If nothing else, this forum offers everyone a chance to discover tools and techniques they may never have found out on their own. If something works, tell us about it. If you see something here and it doesn't work, tell us about it too, but center your criticism around the thing, not the person who provided it. They will know, so will you, and others will be spared the embarrassment of watching you quarrel.

Now about the yeast. I posted a query awhile ago about dried yeast alternatives to Whitbread Ale, in light of this not being available anymore. Alas, no one had any help for me. Then this week, Great Fermentations' "Beverage People News" had a short piece on this and offered either Wyeast #1098 (the Whitbread yeast in liquid form) or "Nottingham" from Lallemand (a dry variety) as an alternative. Does anyone have experience with Lallemand's products? I use dry yeast because my brewing often occurs with little notice and liquid cultures require more preparation than I can give.

From: michael@frank.polymer.uakron.edu (Micheal Yandrasits)  
Subject: re: siphon woes, an easy solution

I think I have an easy solution to the "siphoning woes". When I siphon using a typical hard-white-platic-rod-with-a-red-cap-and-flexible-hose a small bubble forms at the junction of the two hoses, just past the bend, and will grow as the turbulence causes CO2 to be released. My solution is to pinch the hose as close to the junction point as possible then release. This causes the bubble to be carried with the beer all the way out the other end. It does not reform. I've siphoned brew at its most active stages of fermentation (usually to a larger carboy) with no trouble.  
It's counter-intuitive but it works.

Mike

Subject: First posting

This is my first time posting to this digest and I hope no one will mind if I ask some beginner's questions.

I was recently introduced to homebrewing and haven't been able to stop thinking about whether it would be something I would enjoy. So I'm determined to give it a go. Thus, I'm posting here to ask about how to get started in homebrewing.

First, I suppose I need to begin by getting the addresses of several homebrew catalogues. Would someone recommend one or two? I really don't think there's a homebrew grocer in my area (I've already checked the phone book). I reside in Madison, New Jersey.

Second, I realize that there is no single "correct" way to brew beer as there are infinite ways to brew and even more recipes. Nevertheless, I am hoping for some suggestions on how to get started. Please send me some suggestions either in the digest or privately. I should say that I'm a graduate student with few funds. I live in married graduate housing which means my amount of space is limited. What about a small starter kit?

For those interested, I would gladly provide my own hot salsa recipe (not in the digest, of course) in exchange for a good beginner's beer recipe. I can see it now--spending a weekend day concocting my salsa and brewing beer. Talk about healing! Incidentally, I've heard that beer is among the few beverages and foods which actually help counter the effects of hot peppers.

Any feedback you have is appreciated.

From: klumpp@casbah.acns.nwu.edu (David Klumpp)  
Subject: more hydrometer woes

I have noticed a different hydrometer phenomenon: when I measure density after racking to secondary and follow density progress daily, I find the density initially INCREASES after racking!!! Typically, sg increases ca. .008 within a couple days of racking, but then the level decreases as expected until fermentation is complete. I noticed this bizarre phenomenon

during my very first batch and have consistently observed this for every batch thereafter (I'm currently working on batch #8). However, each of these batches have yielded excellent product as judged by myself and others, so I've learned to relax anyway. All of my brews have used 4-7lbs

DME, Munton&Fison dry, Wyeast 1098 or Sierra Nevada Pale Ale yeast, and various adjunct grains. Here are the precautions I take to make sure I get

accurate readings:

1. All reading are corrected to 60deg (using  $(X-60F) \times 0.00025$ )
2. Temps are measured in the hydrom vial -- not the fermentor
3. The hydrom is tapped to release any clinging bubbles
4. The hydrom is pushed down several times and a reading taken each time the hydrom becomes stationary
5. The hydrom is not rinsed in H2O of extreme temps prior to use
6. The Hydrom reads 1.000+/-0.002 in H2O

If anyone has any ideas, please post or e-mail. Like I said, I've learned not to worry about this strange behavior.

Thanks,

Dave

Date: Sun, 23 Aug 92 10:23 CDT  
From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: WHO IS WHO IN CHIGAGO

To: Homebrew Digest  
Fm: Jack Schmidling

Friday's Chicago Tribune had a great article on homebrewing. There is a  
1/3  
page picture of Ray Daniels stirring a mash, another one of his cooler  
full  
of fermenting stuff and some insightful remarks about the quality of  
beer  
made my the "gurus" of the Chicago Beer Society.

"On a recent evening, club members shared 25 different beers they had  
brewed.  
Chris Campanelli got raves for his deliciously rich imperial stout, a  
strong  
brew that was originally exported from England to the court of Russia in  
the  
1700s."

"Al Korzonas, though, had a bad night. About his bock beer, concensus  
among  
club members was that it was "within style" but had several flaws, not  
the  
least of which was that it smelled like home hair-perming solution."

"His second offering smelled and tasted something like bananas. This  
was an  
interesting concept, except it was a mistake, Korzonas cheerfully  
conceded."

Among other things, this sort of confirms my opinion of the usefulness  
of  
brewing "to style". It also points out the idiocy of trashing  
someone's  
brewing skill based on a random tasting. It also reminds one of the old  
adage of living in glass houses.

The other thing that caught my attention was that, in spite of the fact  
that  
just about all named in the article own MALTMILLS and the process of all  
grain brewing was described in some detail, not one word was said about  
the  
need to mill the grain.

What was even more peculiar was that the third picture was indeed of a  
MALTMILL, but it was cropped in such a way that all one could see was  
the  
hopper full of grain and the logo carefully excluded.

Now this normally would not bother anyone except that there was no  
shortage  
of plugs in the article for gizmos for sale and places to buy,  
associated  
with others in the article.

Do I detect a conspiracy?

Subject: Re : pushing the limits

Bob asks :

>

As another experiment, I'm going to make a batch with 6 lbs. Alexander's light extract, and then go heavy (3 lbs) on the crystal malt to see how much it takes to get that "caramelly" flavor. Again, any others out there

who've done something like this? I'm trying to do some experiments to push

normal limits of ingredients to see what the effect of extremes are in order

to establish some scale for ingredients other than straight malt.

<

I make an old ale using 3-4 lbs crystal (unknown rating) and 6lbs malt. As I've

posted before, I get an extract of around 10 from the crystal, for some unknown reason. For my mashing/fermenting conditions, the crystal seems to

yield around 30% fermentables. I'm used to drinking my bitters 5 days after the

end of the primary ferment, but this sort of brew is one for the long haul. It

is sweet and harsh for about 3 months, then undergoes a fairly dramatic improvement in smoothness and integration. Head retention also seems to require

an uncommon degree of aging.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Wyeast Belgian

Over the past month or so there has been some discussion regarding the fermentation and flavor characteristics of Wyeast's Belgian strain. One report suggested it to be a slow fermenter that added a lot of banana flavor if not kept at low temperatures. Another called it a fast fermenter with a wine-like finish.

I am about to bottle a batch based closely on the extract recipe for a triple that appears in Pierre Rajotte's book, Belgian Ale. This called for all light malts, and a lot of them (6.6 lbs pale liquid extract, 3 lbs pale dry extract), as well as 1.5 pounds of corn sugar. So while the gravity is high, the malt (and hops also) are expected to take a back seat to the yeast flavors.

My own experience is closer to the second description above; I had an extremely active and rapid fermentation, dropping from 1.075 to 1.018 in less than a week. In addition, there was a lot of sediment in both the primary and secondary fermenters. (Fermentation took place at 70-75 degrees, with a 1-pint starter). This is clearly the most aggressive fermenter I've seen in my short brewing career.

The flavor so far is really very neutral--which I see as a bit of a disappointment. The fermented product has a very noticeable alcohol aroma, and a flavor that's very mildly brandy-ish. This latter may have arisen from the caramelization of my boiling wort, which is quite apparent (a risk, I guess, of using standard extract techniques on high-gravity clear beers).

Anyway, the stuff ferments great--and fast--but doesn't supply much in the way of interesting flavor. I'd use it in the future as a clean fermenter for high-gravity beers, but also make sure I use some interesting specialty malts or sugars to provide more flavor.

I'm not sure about ice in the wort, but I put my brew pot in a sink with  
ice  
and rock salt. From Chem 101 I remembered that ice and salt together  
will  
give you a temperature well below 32F. Something like 20F sticks in my  
head.  
I can cool down a pot with 3 gallons of just-off-the-stove wort down to  
70F  
in about 20 minutes.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Bringing beer back from Europe

Brian Davis inquired about the risks of becoming a small-scale beer importer (presumably for personal enjoyment rather than sale). I can't say that I've brought back cases and cases, but I have always brought back as much beer as I can carry; last trip this was 29 bottles from Belgium (in addition to 35 pounds of chocolate).

Duty: duties are levied as a percentage of the purchase price. The percentage varies depending on the item (i.e. 15% for vodka, 50% for cognac--these numbers are made up, by the way). What you need to do if you are planning to bring back a lot is call the U.S. Customs service and inquire about the duty on beer. I did this when I went to the Soviet Union (remember the Soviet Union?), but for obvious reasons didn't ask about beer. This also means that you should save your receipts, as you will need to document the actual value of the stuff. Beer you have received as a gift will also need to be declared, and duty paid on that value.

But: I have never, ever paid duty. (If there are any customs officials on this net, please skip this paragraph.) It is extremely rare that returning Americans get their bags opened. While this won't help you if you've got an obscene amount of booze, you can certainly stash a great deal. Moreover, the amount of work it takes to file the forms for duty on a small quantity of beer makes this singularly unattractive. For instance, on one trip I brought back a jereboam of Saison Regal from the Brasserie de Bocq in Belgium. This was my underseat carry-on luggage, and hiding it was out of the question. When I asked the customs officer what I should do about it, he replied (and I quote), "Get the hell out of here." I love New York. (By the way, jereboams are available in many Belgian supermarkets and cost about \$15, depending on the exchange rate.)

Other considerations: I think your biggest problem would be making sure your stuff isn't crushed in baggage. To be honest, I'd suggest you don't hassle yourself by trying to bring back so much. The exchange rate is lousy now, and all cases of bottles in Belgium require a stiff deposit. If you're sufficiently confident of your brewing skills, I think you should get 2-3 bottles of your favorite beers plus lots of candi sugar (available in supermarkets) and make your own with the yeast you culture.

This said, here's some beer info for Belgium. The best beer store I've seen so far is a small supermarket in Louvain-la-Neuve, which is accessible by train from Brussels. The store is named Cibex (or is it Cidex?). Anyway, LLN is a big college town, and Belgian students' drinking habits make Texas A&M look like a ladies' charm school. Do check for pull dates on the bottles, though--I got an extremely oxidized bottle of Saison Dupont there. They stock some of the Cantillon Beers, as well as Gueuze Girardin, which is about as authentic as you can get (tastes like leather, straw, enteric, you name it--great stuff!). I can't recall whether it takes credit cards.

I have a great fondness for the beers from the Bincheoise brewery, including Marie De Hongrie and Speciale Noel.

Finally, be prepared to do a lot of looking, and try to do so in out of the way places. Many very interesting beers are

regional, and you'll only find them in local grocery stores. And if you DO decide to go the case route, I suggest you get down to Rochefort and buy up a few cases of Rochefort 8. This is one of the great beers of Belgium, and will probably never be available here due to limited production. I mean, if you're going to go to all the trouble, you might as well get the best.

Brian, if you or anyone else wants more info, write me directly. When are you going, anyway? I'll be in Belgium in mid-October.

**Subject: more label the bottlecaps instead...**  
Full-Name: Michael J. Gerard

I use a "sharpie" pen to label the caps.  
You can get at least two letters down.

For example:  
PA=pale ale  
SA=scotch ale  
P=porter  
B=bock  
BA=belgium ale  
W=wheat beer

I also try to use different color caps for  
each batch (by buying bulk caps with every  
other order) but I've found the cap  
labeling much easier than putting on labels  
or trying to guess through a brown bottle.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Pre- or Post-boil Extraction Rate Measurement

Don't confuse extraction rate and specific gravity. It doesn't matter whether you calculate your extraction rate before or after you boil. Extraction rate is measured in units of points/pounds/gallons. When you boil, you're changing the points AND gallons. Your extraction number should stay the same. Ten gallons of 1.024 wort boiled down to five gallons should come out to 1.048, same extraction rate.  
 $24/X/10 = 48/X/5$ .

>  
> ... [silver solder] being 55/45 tin and silver.

First off, great post Al, I really enjoyed it. Nothing better then using  
an industrial approach to making things work. :-)

I was thinking of using the silver solder approach to adding an outlet  
to a keg. However, I boil my wort with a 160,000 BTU propane burner.  
Obviously I don't want to put the outlet on the bottom of the keg, but  
rather low down on the side. So I guess my question is what's the  
melting  
temperature of this silver solder?

I figure the side of the keg won't get much hotter then the boiling wort,  
it should be under 300F. And as long as the outlet and valve aren't in a  
direct flame then there shouldn't be any concern with the solder melting  
and the outlet springing a leak. Could someone who knows what they're  
talking about please substantiate or refute this claim?

Any constructive help would be appreciated. Thanks!

>eventually float to the top again. Now that fermentation activity has slowed  
>considerably, I think it is about time to bottle, BUT even when the hops are  
>all at the top of the carboy the beer is very cloudy. Here are the questions:  
>(i) does dry hopping tend to make beer cloudy, or should I look elsewhere for  
>my problem and (ii) how do I bottle this beer without getting the hops in the  
>bottles?

I just kegged my first dry-hopped batch (pale ale) and had exactly the same  
experience. I've made the exact same recipe before without dry-hopping and  
did not have any trouble with it clearing. It has been in the keg for two  
weeks and it still hasn't cleared so I guess it's going to stay that way.  
It tastes fine so I'm not worrying...

BTW, transferring to the keg wasn't any trouble. I wrapped a hop bag around  
the end of the bottling wand (with orange cap attached) and didn't have much  
trouble with clogging. I had to occasionally shake the wand to get the hops  
off the bag.

From: cd651@cleveland.Freenet.Edu (Wally L. Blume)  
Subject: Grandfathers and beer

Here goes nothing...

Most (all) of my limited knowledge of brewing has come from watching, listening and pestering my grandfathers whenever possible. One is now gone and the other recently had a stroke at the age of 76 and has lost most of his ability to speak. First a little background. My paternal grandfather was born raised and died in the mountains of southwest Virginia. For those who aren't familiar with this area, it is very rural. (Although they are no longer used my grandfathers house, which my grandmother still lives in, has an outhouse and a hand operated well pump in the back yard.). This is a man who courted his wife on horse back. My other grandfather was born in Mississippi, was raised in Alabama, and moved to Georgia to live from young adulthood to today. Since I have lived in close proximity to him all of my life my brewing is more influenced by him. He spent time in jail in the 1950's for being part of a large operation involving several politicians who ran moonshine. After his short time in jail he quit the moonshine business and hasn't made any since. He (until the stroke) has limited his alcohol making to mostly wine and a little beer.

My W.V. grandfather always made his beer the same way. I asked him if he had ever varied his methods or changed his sugar amount to see what happened, he said he had but had found that this way worked for him and he liked the end result. He always used an extract, he brewed his own beer because where he came from that was just about the only way to get it if you worked in the coal mines on a small paycheck. Being curious I asked him about the extract and what they did before extracts were available. He told me he couldn't remember when he couldn't go to the mercantile and get some. He said the big problem was always getting the money for all of the sugar. As I said, to him brewing was not as much a hobby as it was the way to get affordable beer. His real hobby was bottle collecting, and he had a few glass jars in his collection that once held extract many decades ago. One little side note, he always added about a tea cup of some liquid he used to mix himself that he said made it work a little better. I never found out what the mixture was, I asked my grandmother if she knew but she told me she was never allowed near his beer (that's another story).

My Georgia grandfather was more of a wine maker but occasionally made some beer. He always made it from scratch, and even growing his own hops. He was happy to show me the ways of brewing, however he refused to teach me the process of changing grain to wort before fermentation since this was very similar to the process used in making moonshine and if he told me once he told me a hundred times I didn't need to mess around with lightning. He did teach me a lot about wine and fermentation. From listening to their methods I got the impression early on that making wine or brewing beer was more than just following a recipe, it takes an understanding of the processes involved as well.

From: smanastasi@mmm.com  
Subject: 10 Step All Grain Process - Revised

Thanks to all who helped by adding refinements to this. I recieved almost as many requests for the final version as I did advice. This 10 step process for all grain brewing is ONE way of going about all grain - not THE right way. Of course, all of us "new allgrainers" will soon discover THE right way.

-----  
-----  
-----

#### All Grain Brewing for Extract Brewers

##### New Equipment:

- 5 (or 10) gallon cooler with a false bottom and improved spigot system.
- 10 gallon brew pot - preferrably stainless steel.
- Immersion or counterflow wort chiller.
- Grain mill (or access to one).

-----  
-----

#### EASY 10 STEP ALL-GRAIN PROCEDURE

0. Prepare grains: Crush grains such that each kernel is broken into several parts but not flour-like.
1. Place grain in cooler: Add 135F water and grain to cooler simulataneously kneading the grain into the water. All grain should be wet with no air pockets.
2. Protein rest (optional): Non highly-modified malts may required a protein rest. Let grain sit in 122F - 131F water for 30 minutes. Protein rest is required when using more than 40% wheat.
3. Starch conversion: Elevate the temperature to 155F - 158F by adding 170F - 175F degree water. Let sit for 1.5 to 2 hours. Don't let the water temperature drop below 150F. Try not to exceed 32 oz of water per pound of grain.
4. Mash out and Sparging: Add near-boiling water to bring water temperature up to 168F - 170F. Let this sit for 10 minutes. Set grain bed by slowly drawing 1 - 2 gallons of wort. Pour the wort back into the cooler.

Slowly draw wort out of the cooler while sprinkling 170F water (sparge) into the cooler. Wort should be dispensed very slowly at about 3 to 7 minutes per gallon. The water level should stay above the grains. Continue until 5.5 to 7 gallons have been collected. (Note: Using a 10 gallon cooler allows for all sparge water to be added at once.)

5. The Boil: Bring wort to a soft boil and add hops during boil as if doing an extract brew.

6. Chilling and cold-break: Use a wort chiller to cool the wort to 70F to 85F. Proteins will coagulate and drop out of solution forming the cold-break.

7. Transfer to fermentation vessel: Siphon cooled wort off of cold-break and into a carboy. Wort should be allowed to airate as it enters the carboy.

8. Etc.: Pitch yeast, dry hop, transfer to secondary, prime and bottle as if doing an extract brew.

9. Enjoy: Enjoy a far superior beer due to all sorts of "all-grain" advantages well documented in the Homebrew Digest.

From: Paul AndersEn <ECZ5PGA@MVS.OAC.UCLA.EDU>  
Subject: Large Gott thermos container as primary.

Hello homebrewers,

I am new to the list, so you will have to forgive me if I bring up a question that has already been hashed out a million times.

Has anyone ever tried using the large Gott 5 gallon thermos-like containers with a spigot on the bottom (commonly seen on the side lines at football games)

as the primary carboy? I am interested in scandinavian brewing techniques

(I am norwegian) which use a single bucket and a false bottom made of a wood

grate topped with hay and juniper branches primarily. The Gott container

seems like it would work well seeing as though it would keep all light out,

it already has a spigot at the bottom, and it is insulated. I was thinking of

buying one (about 25 bucks), adding the false bottom and the float valve and

giving it a whirl.

The possible problems I could see would be that the container is not large enough for a 5 gallon batch, and that the plastic it is made out of is not

"brew-safe." Any ideas or comments are appreciated.

From: russo@carlos.sps.mot.com (Russell L. Oertel)  
Subject: **Bottle-cultured yeasts**

I recently returned from a trip out of state (where I could actually find liquor stores that had a decent selection of beer) with several bottles that seemed to have some yeast sediment in them. I've now cultured the yeast, and was wondering if anyone could tell me something about my new cultures. For instance, I know that Sierra Nevada's yeast is the same as Wyeast's Chico Ale; so, can anyone tell me anything about the yeast used by Rogue (Portland, OR), Mendencino Brewing Company (Hopland, CA), or Anderson Valley Brewing Company (Boonville, CA)? Do I now have 3 more cultures of Chico Ale or some other brand of Wyeast, or do I have something more unique. Any info will be appreciated.

While I'm posting, I might as well repost a question I asked on rec.food.drink a long time ago. Has anyone out there ever heard of Oertel Beer? Apparently it was fairly popular around Kentucky in the 50's (and possibly before). I assume that it is no longer made, probably having been bought out by Budmilloors. (Gee, I hope they didn't buy out the name - I might want to revive it some day!)
