

Welcome to The Homebrew Digest Text Search and Retrieval System

To begin, click on the Search button above.

Notes about this helpfile:

The articles in this help file were gathered from the Internet and placed into hypertext format using a program we wrote. Since we let the computer do it, there was no editing of the message content whatsoever. This has been shown to be both good and bad since some of the articles are decidedly uninteresting. Fortunately, these are in the minority.

In general, you should maximize the help window when viewing this help so as to keep the lines from wrapping around.

In addition, certain punctuation characters were lost due to incompatibilities between the conversion program and the Rich Text Format. In particular, the curly braces { and } were changed to ordinary parentheses and the backslash (\) was changed to a forward slash (/) in all cases. We hope that this doesn't cause many problems.

Nearly all of the people who contributed to The Homebrew Digest are still reachable via their e-mail addresses. Feel free to write them and/or to subscribe to the HBD (see below). The Homebrew Digest is an open, and usually unmoderated forum where anything can, and often does appear. Some of the language used in these articles may not be suitable for children, but then neither is beer in general.

Subject: thanks for help (terms)

Hello all of you,

First I want to thank all the people who responded to my questions about terminology. Thanks. I even got information which I did not asked for! I though I knew what 'brown sugar' was, but when reading your replies I understood that there was a big difference between your and my culture. In the Netherlands 'brown sugar' is the not fully refined sugar. I have the idea that we do not have something like your 'brown sugar'.

Together with the answers, I got of course also questions:

- If you would like to know something about Dutch beers and its associations, please let me know, I can introduce you to some of these organizations (although there is not much e-mail in this part of the worlds [most e-mail is within the educational and research institutes]).

- In the Netherlands there are some 15 breweries which produce commercial beers (Heinenken, Grolsch, Raaf, Brand, Amstel and lots of smaller companies). Beside these commercial breweries, there are lost of people who brew their beer themselves (these people also have there own amature beer judges). I have the idea that the level of beer brewing is quiet good, but perhaps you have to find out yourself;-).

- Home beer/wine/liquor making is not illegal in the Netherlands (and in my opinion also not in Germany, Belgium, France, UK, Spain, Portugal, Austria, etc.). In the Netherlands one is allowed to distill even liquor up to an amout of Dfl 50,-- of alcohol (which is some 750 cl) per month (this is a new rule:-).

I hope that you can use the above info.

All the best,

Victor Reijs

From: Victor Reijs <Victor.Reijs@SURFnet.nl>
Subject: potassium sorbate

Hello John Wyllie and Rob Bradley,

In some juices, the producer has putten DMS or potassium sorbate to stop fermentation of a juice. So if you use such a juice for cider/wine, there is a big chance that it will not ferment.

Most yeasts are quiet tolerant on DMS, but potassium sorbate is a real killer. The maximum amount by law of it is 268 mg/litre in the Netherlands. 100 to 200 mgr/litre is enough to stop a yeast from working. (If using potassium sorbate to get a sweet wine/mead, one has to add some DMS to be certain that no eagly smells will form [geranium smell called in the Netherlands]).

All the best,

Victor

- > day. I am still experimenting with partial mashes
- > and thought, this is the one I've been looking for!
- > How do you go about replacing the push button valve
- > with one that allows a lot more control in sparging?

I've built several different kinds of lauter tuns, and am planning a comparison of their efficiencies and use. Unfortunately, I have yet to build the "cooler-type" lauter tun, so I can only pass-on information I've read. A good source for food-grade valves of all kinds (and perhaps food-grade adhesives also) are the places that sell campers and related equipment. Try there. If you use a rectangular cooler, I've read that you simply need to pick a copper tubing that snugly fits into the drain hole and then use a valve that has the proper-sized compression fitting on it to give you the control you seek.

- >
- > 2. What is a good extract/grain ratio for partial mashes.
- > 1 3# can to 3#s grain, etc. I guess I should say what
- > is standard.

Of course there are no standards, and it's not so much a ratio that you want -- what I mean is, you want some goodness from the grain and then you make up the difference with the malt extract syrup or dried malt extract. If indeed you used a 3.3 pound can of extract syrup and mashed 3 pounds of pale malted barley, you would get an original gravity of, say, 1.035 to 1.045, depending on the extract you use and your extract efficiency (see below). Your example is good start.

- >
- > 3. I've heard a lot of talk about efficiency, 90%, so many
- > points, etc. What's it all about.

All in all, it's just a measure to see "how you're doing." There are theoretical maximums for each type of grain and how close you get to the max is a measure of how efficient your procedure and system are. For example, you mash 5 pounds of 2-row lager malt and after sparging collect 5 gallons of 1.030 wort. According to David Miller, the theoretical maximum for 2-row lager malt is 35 points per pound per gallon.
 $30/35 = .857$, which is basically 86%. Therefore you have achieved 86% of the theoretical maximum, which, judging from the figures posted by various brewers in HBD and elsewhere, is not bad. Why is it important? Well, for all the work you put into mashing and lautering, not to mention boiling, cleaning, bottling, etc., you would like to get the most out of your grain.
Right?

If your efficiency is, say, 50%, then you know you need to reassess your procedures and system. Note that "bad efficiency" doesn't automatically mean any one thing. You could be overshooting your saccharification temperature and denaturing your enzymes, you could have very lousy grain (old or poorly stored), you could have an inefficient lautering system, you could have a bad hydrometer, or you could have any number of other problems. See what you get and if you're not happy with it, post

your procedures and setup and ask for advice.

>
> 4. And finally, does yeast really play that big of a role
> in taste? Excuse my ignorance, but I've always used
> the little dry yeast packet that comes with the cans
> (I did buy some liquid once) and my beers taste fine
> to me. Will they improve that much?

I personally feel that yeast is the most important factor in determining the flavor of your beer. Granted, changing from 12 IBU to 120 IBU will change the flavor of your beer, as will adding a pound of black patent malt (neither are recommended, by the way). My point is that changing from Wyeast #1028 to Wyeast #1056 or dry yeast to liquid yeast will make more of a difference in the flavor of your beer than adding an additional 1/2 pound of Crystal Malt or changing from Fuggles to Goldings hops. If you brew a very low-gravity beer, say an OG of 1.028, the effect will be less than a high-gravity beer, say an OG of 1.070. Also, if there are lots of dark malts or roasted barley in the batch, these will cover-up the flavors generated by the yeast too. One dry yeast that I feel is very good is the one that comes with Cooper's Kits. Two that I would not recommend are Red Star Ale (lots of banana esters) and Munton & Fison's kit yeast (lots of phenolics -- "band-aid (tm)" smell). The only way to tell whether the difference will be significant *to you*, is to try it and see.

Al.

Subject: R. Glidden Mashing question

R. Glidden asks how to keep a constant temp. I have placed my 20qt ss pot inside a 30 qt pot (alum will do) with the grist in the ss and the larger pot serving as a double boiler. It will bring the grist temp up rather slowly (compared to putting the pot on the burner), but it will help maintain a constant temp and also won't burn the bottom of the grist.

From: walter@lamar.ColoState.EDU (Brewing Chemist Brian Walter)
Subject: Pumpkin Ale

Howdy Brewers!

Made my second annual "It's the Great Pumpkin Charlie Brown" Ale recently, and it has turned out wonderfully. So good in fact, that I thought I would share the recipe. :-) Not trying to boast, just want to share with you other homebrewers.

Charlie Brown Pumpkin Ale

To make 5 Gallons:

7 lbs light dried malt extract
1 lb 40 L Crystal malt
2 lb pale ale malt
1 whole pumpkin (10 - 15 lbs)
1 teaspoon ground cinnamon
1 teaspoon pumpkin pie spice
2 oz fuggles (90 min)
1 oz hallertauer (90 min)
1/2 oz fuggles (5 min)

To Prime

1/2 cup brown sugar
1 teaspoon ground cinnamon
1 teaspoon pumpkin pie spice

WYEAST # ???? in a starter (Ale yeast)

Procedures:

Clean and quarter the pumpkin, bake for 30 minutes at 350 F. Puree the pulp in food processor or blender. The grains and pumpkin were mashed for 90 minutes at 154 F. This thick mess was then strained into the brewpot (a long process!), and then a standard 90 minute boil took place. When done, cooled with a chiller, and WYEAST starter was pitched. Sorry about the WYEAST number, I forgot to record it. I know it was an ale yeast, and most probably a German ale yeast to be specific, but I am not certain. Standard fermentation and bottling, except the spices were added at priming time with the priming sugar.

It made a wonderful fall beer. (Almost too good, as the wife and her friends like it a little too much!! :-) The spices were a little strong for about two weeks, but then they mellowed nicely. By far one of the best brews I have made (but then I always say that :-).

Thanks for listening,

- Brian

From: Barry_Gillott@DGC.ceo.dg.com
Subject: Wyeast European, dry hop sanitation

Joe Rolfe asks about European Ale yeast. I've got a 5 gallon batch using it that's glugging away right now. The Wyeast profile sheet at the homebrew supply store agrees that this yeast produces a more malty flavor.

My batch was (real) slow to start up, I suspect because the temperature fell below 60F the night of pitching. I used a starter but probably pitched it before it was ready. The next morning (12 hrs after pitching), no foam, so I raised the room temperature up past 70F. It eventually got going, but took more than 24 hours. The room temp is around 70F right now and the yeast seems quite happy, but I intend to lower the temp gradually over the next day or so to around 65F to minimize the chances of ester production. (I don't have any prior experience with this yeast's temperature range.)

I have a dry hopping question for y'all: Do I need to be concerned about sanitation of the hops? Can I just open a package of plugs and drop one in? I assume that the alcohol present after initial fermentation will provide some degree of protection, but... enough?

Date: Tue, 27 Oct 92 9:00:43 EST
From: Jim Grady <jimg@hpwalq.wal.hp.com>
Subject: pellet/leaf hopping rates

I have an answer and a question:

Laura Conrad asks in #999 about the different hopping efficiency of leaf vs. pellet hops. I have recently picked up Miller's "Brewing the World's Great Beers" and have just made the Kolsch recipe on pg. 50. In that recipe, he calls for 5 AAUs of pellets or 6 AAUs of leaf hops. Thus it seems that if you have a recipe you like with leaf hops, cut the hopping level by $\frac{1}{6}$ if you switch to pellets.

Incidentally, Dave recommends Wyeast #1007 (German Ale), Wyeast #1338 (European Ale) or one of the defunct MeV strains. The SG is supposed to be 1.046 and the FG should be 1.010. I got the SG he suggested but my FG is 1.017. (I used Wyeast #1338) I tried adding 1/2 c. corn sugar and some yeast energizer and it got going again but stopped at 1.017 again. Could the difference in FGs be due to the different attenuation levels of the recommended yeasts?

Wyeast #1007 = 73-77% -> FG = 1.011 - 1.012
Wyeast #1338 = 67-71% -> FG = 1.013 - 1.015

I figured the $FG = 1 + (SG - 1)(1 - AA)$

where SG = Starting Specific Gravity
AA = Apparent Attenuation
FG = Final Specific Gravity

Is this what the "apparent attenuation" figures in the Wyeast yeast profiles mean?

BTW, the beer tastes fine, just a little sweet. I will stop worrying about stuck ferments, bottle it and enjoy it!

Thanks.

I had the same reaction when I got this months beers (though I found the Penn Pilsner pretty tasty), so I did give them a call. I was planning on cancelling, but the person I talked to said that they would be sending out a lot more dark beers next year (porters & stouts, for example) . I got the impression that they were worried that their clientele wouldn't be ready for anything but a small step up from industrial beers. I guess enough people have called to complain that they've learned their lesson. I decided to keep my "subscription" for a while yet -- I'm looking forward to next year.

Don't worry! I brewed almost the same beer as you (all-grain, 90% pale, 1056 yeast) and it fermented slowly for weeks after dry hopping. It finally settled down and I was able to bottle it. It came out fantastic! So relax, bottle it when it's done and prepare yourself for some tasty brew.

Subject: RE: Decoction and Tannin Extraction

Hi All,

In HBD#999, Darryl Richman writes:

< many good points regarding tannin extraction and decoction deleted >

>(BTW, my experience with the imported continental malts available now
>is that there is little additional extract to be gained from decoction.
)

My experience with the imported continental malts is exactly the opposite, decoction mashing makes an enormous difference in extraction.

I typically get 30 pts/lb/gal using highly-modified English pale malt and infusion mashing. I've tried infusion mashing using the continental malts, my extraction is always a little lower, around 28 pts/lb/gal. BTW, I do utilize a protein rest during such mashes, in order to break down the protein matrix that exists in under-modified malt.

Due to the low extraction, I started using decoction mashing for my Euro-lagers about three batches ago. In each case, my extraction was over 35 pts/lb/gal, an increase of about 20% over infusion mashing, which sent me scurrying back to the calculator to re-compute my hop additions:
-)

As to the malt itself, I get it from a local mail order place that sells it under the designation "German 2-row pilsner malt". There is a number in the catalog beside each grain type that represents the degree of modification, this malt has the lowest rating. I cut open a few kernels the first time I used it, and sure enough there was very little acrospire growth, under-modified all right.

My guess is that Darryl and I are using two different malts. Some months ago, I read in this forum that some malt producers, reacting to the growing homebrew market, were beginning to highly modify *all* their malt. The reason given was that malt producers recognized the importance of extraction to homebrewers, and changed their product accordingly. I think if the malt is highly modified to begin with, there will be only a slight improvement in extraction if decoction mashing is used. In such a case, the protein matrix that holds the starch is already pretty much gone.

Comments and opinions welcome, no flames though.

Cheers,
Jim

From: raid5!limd@csn.org (Davin Lim)
Subject: Glycerol for freezing yeast?

I've heard that a product called the Yeast Bank uses glycerol to protect samples of yeast for storage in the freezer. Can anyone out there describe the steps and quantities needed to perform this process? I'd like to have a "homebrew" version of this product.

I'm interested in storing vials of yeast slurry from my primary. I've already gone the agar slants/petri dish route and have had very good results - but it's just too much work to keep multiple cultures going - especially when periodic re-culturing steps are required just to keep the population alive. I'm confident that my yeast slurry samples are likely not contaminated, so storing them for future re-use is very attractive to me.

Subject: keg questions

Brewers:

Here are a couple of questions about keggung with (I know it is stupid) a plastic keg. The first try produced plastic tasting beer; I pitched it. The second try produced a tasty amber ale but it did not hold pressure and I ended up re-priming and bottling, not a big disaster. Now I have a third try where I plugged the vent valve and now I have great pressure so much that I only get foam from the keg. So here are the questions:

1) Does anyone know of a pressure gauge that would measure in the right range (0 - 50 psi) and can you set it to release at a given pressure?

2) If such a gauge exists, then how does this sound for getting the beer ready to drink? First let the pressure get big and have the keg swell for the the first three (or two?) weeks and then letting the pressure drop down to, down to what? 5 psi, 10 psi?

The keg was a birthday gift from a supportive partner and I do not want to undermine her support.

Thanks for your help.

[excellent ASCII graphics omitted for brevity]

It seems to me that, while in the abstract, you are probably right about
certain designs resulting in less-than-perfectly-even flow of liquid, it
can be evened out by an occasional stir or shake of the pot or bag.

Fluid dynamics is a funny topic ... what with eddies and shifting grains,
I'm not sure the flow pattern is as deterministic - or the islands of
lesser flow, as static - as your diagrams suggest.

Ultimately, I would suggest that the metric for the efficiency of the
sparge
is the ultimate arbiter of sparge efficiency ... and this is up to the
home
brewer, whom either goes slack and lets his brew take care of itself, or
is
intimately involved in assuring that the grain is exposed to heat &
drained
evenly. I know of no design that can completely compensate for the
presence
of a concerned and involved homebrewer.

It might even be that by using one outlet, slightly raised, one might be
able to avoid the inevitable sediment, while achieving a very efficient
extraction. This, ultimately, is an individual and aesthetic choice.

From: R.Deschner%UIC.EDU@UICVM.UIC.EDU
Subject: Minnesota Results; Happy 1000th HBD!

A bunch of us from Chicago just got back from the Minnesota Homebrewer's Festival and Competition, at Sherlock's Home Brewery in Minnetonka (suburban Minneapolis), MN.

Best of Show, judged by John Isenour, Steve Hamburg, and Michael Jackson, (Why is he famous? He has a REMARKABLE palate, in addition to his encompassing knowledge of beer.) was won by a great Texas Brown Ale. Jackson commented on how the use of lots of hops in Brown Ale was an American peculiarity, pioneered by Texan homebrewers, but a tasty one. (hence the name "Texas Brown Ale")

All of us reveled in the beers of Sherlock's Home Brewery, especially the tremendous, hoppy, Bishop's Bitter, served from a hand-pull pump. The porter, also from the hand pump, was delicious, with just the right toasty dryness. The place is probably unique in the United States in doing this so completely, although the Wynkoop and Walnut brewpubs in Colorado also put some British ales on a hand pump.

Michael Jackson obligingly autographed copies of his books.

A complaint in general about homebrewers (and not just those in Minnesota - this is a general complaint): A great many of the entries were thin and underhopped, as though American homebrewers were timidly following the example of their large corporate brethren. During Best-Of-Show judging, John Isenour summed it all up: "I should have had two rubber stamps made up for the judging sheets - 'MORE HOPS' and 'MORE MALT'."

Also, use the right yeast. We who judged wheat beers were startled by the number of brilliantly clear weiss beers which we judged, even though the style is allowed to be hazy. The problem is that many of these crystal clear weissens had no weiss character, such as the familiar clove phenolic. Use of the right yeast might have produced some of these characteristics, although clarity could be sacrificed. Yeast is one of the least costly ingredients, so it pays to use the right one.

We did find a number of beers in the Minnesota competition which had sufficient hops and malt, and which were true to their style; some of these were not just good, but were great. By and large those were among the winners in each category. So, why should you use MORE MALT, MORE HOPS? Because you'll win.

Finally, I cannot resist the opportunity to wish

> fermentables in the batch, maybe by increasing the fermentability of
> the higher sugars.

Actually, it's 3) The tiny hop particles give the dissolved CO2 something to collect on, forming bubbles which then leave solution, producing the illusion of ongoing fermentation. You can confirm this by taking some SG measurements over the course of a few days.

Bottle it. If you dry hop and then wait for the bubbling to stop, you'll be too old to drink by the time you decide it's done.

Subject: Homebrew Filtering Questions

I've been looking into the idea of getting a filtering system for my homebrew but there is something I don't understand about them in general: If you filter your homebrew, how do you get carbonation? (I'm assuming it's done right after fermentation is complete. It doesn't seem like you'd want to do it after conditioning it.) Do you basically have to keg it with CO2 or are there ways to force CO2 into the brew at bottling time?

Believe it or not, I would actually prefer sticking with bottling rather than kegging, because about 75% ends up getting lugged around to friends' places! Side Note: Some of my friends have developed a voracious appetite for homebrew. I'm seriously thinking about making some of them start helping me pay for ingredients! It's nice to have people like my beer but it's painful to watch half a batch of "handcrafted" HB evaporate in one evening.

Also, as far as filtering goes, if anyone has any tips, suggestions, or experience with any of the filtering systems, please share. I'm currently thinking about getting the homebrewing filter kit from "The Filter Store" (they advertise in zymurgy) has anybody used it?

My basic goal is a sediment free bottle of beer. I'd "settle" for a sediment free keg (but it means I'll have to get a bigger car :-)

I am a recent HBD subscriber. I really enjoy having it in my mailbox when I arrive each day. I find many of the subjects fascinating. I find the occasional sniping amusing.
Can someone give this extract + adjuvant neophyte brewer some more detailed information on exactly what to do with oatmeal? Is it possible to put it in something other than a stout and not have a bizarre beer?

Thanks,

Sandy

From: gummitch@techbook.com (Jeff Frane)
Subject: Wheat Beer History and Banananose

The fershinlungin site was down for a week and I missed Darryl Richman's apparent statement that Anchor was the first "micro" to produce a wheat beer in recent times. Leaving aside the question of whether anyone should even notice such a pitiful wheat beer exists, I'd say Darryl was off by several years. Someone else has noted the Dunkel Weizen out of Wisconsin, but in addition Pyramid Wheaten Ale (they even did a bizarre Dunkel Weizen made with roasted wheat malt) and Widmer Weizen both appeared before Anchor's. Darryl was living in California in those days, I believe, and probably just missed it. Come to that Bert Grant's White Bear Wheat Beer was available on draught well before Anchor's.

To add a datapoint -- or maybe not -- to the question of the bananarama nose from WYeast's Belgian ale strain, my own very-banana beer (which was included, I believe, in the survey) *was* a high-gravity all-malt beer. I spoke to Tom Feller the other day, who told me he'd made two low-gravity beers with it and had no banana nose. I *think* they were also all-malt. So?

At any rate, now that nearly a year has gone by the bottled abbey-style beer has almost entirely lost the banana nose; the complexities I'd hoped for in malt and hops (and alcohol!) are moved to the front and I'm quite pleased with it.

Subject: Newbie AME query

Hi there. This is my first posting, and it's a pretty basic query.

What's the difference between Light, Amber and Dark Malt extracts?

I've looked through Papazian several times, and nowhere is this question answered. He gets very specific about the origins and characteristics of specialty grains, but ignores this (to me) very basic question.

The reason I'd like to know, I have a recipe that calls for 6# of AME, and I happen to have 3# of LME and 3# of DME. Can I substitute ?

Many thanks.

Subject: Barley-Free Beer ?

Does anyone have a recipe for a BARLEY-FREE beer (not mead or cider)?

I have a roommate who is violently allergic to barley (very sad), and thought I would try to brew up something sans barley. I have looked at a few wheat beers, but they all contain some percentage of the forbidden grain. I have not yet found a recipe that is 100% wheat.

As yet, I have not plumbed the mysteries of mashing, but as no commercial wheat-only extract kits seem available, this would be as good an excuse as any to get started.

Can anyone help me to introduce my roommate to the joys of quaffing ale?

Subject: keg to bottles

From: roy.rudebusch@travel.com

LW:>If you want to put some of your wonderful keged brew into a bottle
for
LW:>consumption elsewhere, what methods do you use? I am just starting
to
LW:>keg and would still like to be able to take some along occasionally.

Don't let anybody talk you into buying a counter-pressure filler!

The best way to put up a few bottles from a keg:

Sterilize bottles and caps
Chill bottles with caps on
Chill beer very cold
Attach a length of hose about 2 inches longer than the
bottle to the spigot.
Reduce CO2 pressure by turning out the screw on the regulator
Remove almost all the head pressure from the top of the beer
Slowly fill bottle, apply pressure if needed, little foaming should
occur.

I have filled 1 gal wine jugs with fully carbonated beer and it served
up well later at our local Brews club meeting. Be sure to keep it quite
cold.

Subject: Cats Meow 2 Update ready

Hello folks.

Those of you who used the PostScript files to print out your copies of Cats Meow 2 can now get an update with 142 new recipes in it.

The file is in the archives as Cat2up1.ps.Z (unless Stephen gave it a more intelligent name :-)

You'll also want a new index. This is in file CM2NDXu1.ps.Z

If you're not a PostScript user, it'll be a little while before the ASCII text file is ready....patience...

The update contains just about every recipe posted to the HBD through issue #999. The update contains ONLY new recipes. If you're retrieving Cats Meow 2 for the first time, you will need the original file to print out the bulk of the recipes in addition to the new update file.

Thanks to Ed Meeks and Jim Basara for reviewing early drafts and cleaning up a lot of mistakes that we'd overlooked.

As usual, if you run into problems using the update, let us know and we'll help you out as much as we can.

Cheers!

Subject: Wyeast European Ale Yeast

Joe asks about Wyeast European Ale yeast.

I just brewed a batch last Saturday of spiced ale. I used a quart of 1.020 sterile wort as the starter and pitched the puffed up packet in the wort about 28 hours before brewing. There was a thin head of foam on the starter and about 1/8 layer of yeast on the bottom of the jug. My copper-coil-in-a-bucket-of-ice-water wort chiller didn't cool my wort as well as it normally does and I'd say the wort was about 80F when I pitched the starter into the carboy. The weather here in Minnesota is warmer than usual for this time of year and my basement has been 68F. Within 24 hours, I had an incredible amount of activity in the carboy with lots of foam and swirling little hop pellet bits mixing around. Bubbles were coming out of the blowoff hose faster than 1/second. Three days later and it's still fermenting actively.

So maybe this yeast is temperature dependant...

From: joseph@joebloem.maple-shade.nj.us (Joseph Nathan Hall)
Subject: Yeast, etc.

) From: Joe Rolfe <jdr@wang.com>
) Subject: Wyeast European Ale Yeast
)
) any one used Wyeast European Ale Yeast?? any comments on it??
)
) it has been said (by i assume Wyeast) that this is a slow fermenter.
) it also said the is left a brew with a malty flavor (unattenuative).

It ferments at more or less normal speed, but clears slowly. It is very clean in flavor, even at 70-72F, but round instead of crisp. Mellow rather than acute. I have found it to be relatively attenuative. In a recent brew of O.G. 1.045, 1338 fermented down to 1.012, while Sierra Nevada yeast pitched into the same wort fermented down to 1.014. I don't know that I would characterize the two beers that I've made with 1338 as "malty" or "buttery" or "caramelly" or anything in particular;
it's more like a kind of indistinct smear of all of the above. 1338 is not particularly fruity. I'm not so sure I really like it, but it is a nice hi-temp yeast to add to the inventory. I wonder if it might make a nice yeast for brown ale or porter. Hmm....

) Subject: potassium sorbate
)
) According to the Merck index, sorbic acid, and it's potassium salt are both
) "mold and yeast inhibitors". Better luck next time! SJB

Yes, but from what I know sorbate won't prevent active yeast in a sugar-rich environment from fermenting, at least not in the concentrations that are used to stabilize completed fermentations.

) >a blood-curdling cry echoes throughout the house. The surface of the
) >beer is covered with a thin white scum. It's kind of lacy looking
with
) >little fuzzy nodules here and there with vein-like things extending
) >into the film. It looks like the stuff the people had on them when
they
) >crawled out of the pods in "Invasion Of The Body Snatchers."
)
) A pediococcus infection has a ropy, lacy appearance.
) Too bad you hopped the heck out of the batch, or you
) might have a shot at converting it to a pseudo-lambic.

Quick, someone send him a Brett culture!

) Two subjects:
) - crystal malt and caramel malt
) There is a big difference between these two!
) crystal malt: the grain is soaked in water and kept at 65
) Centigrade (for one hour), so that the starch in the
) grain is converted to sugar. After that the grain is
) heated to 110 - 120 centigrade. The water evaporates and
) the sugar gets a crystal like structure. (depending on
) the length of the heating the crystal malts gets darker)
) caramel malt: after the sprouting of the grains, they are
) heated to 160 centigrade. The grain gets the color of

) chocalate or caramel.

This conflicts with everything else I've ever heard. Your definition of "caramel" malt sounds suspiciously like Munich or Vienna or other high-kilned malts. I've never heard anyone suggest that caramel malt contained a significant portion of unconverted starches.

So, where's George Fix? Or maybe Darryl Richman would take a stab at this one ... ?

End of HOMEBREW Digest #1000, 10/28/92

Date: Tue, 27 Oct 92 13:57:28 EST
From: chuck@synchro.com (Chuck Cox)
Subject: Homebrewer Gran Prix

I know you all are anxiously awaiting the results from the Homebrewer Gran Prix. The Gran Prix is an official activity of the Dixie Cup which went Galactic this year.

The Malibu Gran Prix is an 'adult' kart track. We compete in a time-trial format. The cars are small open-wheeled fiberglass-body cars, similar to Formula 440 racers, but with less power. They use detuned snowmobile engines & drivetrains (2-stroke, centrifical clutch, continuously variable transmission). The track is very twisty (approx 15 turns) and is of similar size and complexity to a small autocross/solo course.

The number of competitors has basically doubled every year. The weather was excellent, and everyone seemed to enjoy themselves. I look forward to next year's competition.

There is a 'trophy' for the winner. I have a magnetic sign that says "World's Fastest Homebrewer". I displayed it on my car for the 92 racing season, and it'll be on my car for the 93 season. Maybe someone will take it away for the 94 season (NOT!). (I don't recommend leaving it on for street driving, it gets too much attention from the revenue collectors, er, cops).

Competitors are constantly asking me if there is a secret to winning. Winning at the Gran Prix requires the same skills as racing big cars, but is much safer. My tips for novices:

- practice, practice, practice
(if you have a safe, legal car, enter some local autocross/solo events)
- correct seat position
(the harness should hold you in place,
and you should be able to comfortably reach all controls)
- think ahead
(its too late to do anything about what the car is doing now,
you need to think about what you are going to do next)
- weight transfer & car control
(these cars are underpowered and tend to plow, but can be made to
seriously oversteer under braking. you need to maintain speed through
the turns and use the brake pedal to help steer)
- racing line
(the course is very twisty with a variety of complex turns, sweepers,
and
chicanes. you need to use the correct line to win. you need to know
which
turns are critical, and which turns to sacrifice.)
- instruction
(take a racing or driving school. local sports car clubs often offer
inexpensive training and practice)

SHAMELESS PLUG:

Have you ever dreamed of sponsoring a real race car? SynchroSystems is sponsoring the Silent but Deadly Racing Team which is designing and building an electric race car. This is not some flimsy little politically-correct pansymobile, but a full-fledged race car that will compete head-to-head with internal combustion cars in the New England autocross/solo circuit. If this car is reasonably competitive, national TV and magazine exposure is virtually guaranteed. I have sponsors for all the major components (chassis/body, motor, batteries, transmission, tires, generator, and control system). My original plan was to have the car ready for the 94 season, but there is a *LOT* of sponsor pressure to have something for the 93 season. In order to compete next year, we need about \$5k to buy a tow/support truck and car trailer. Sponsors will be provided space on the car (and truck/trailer) to display a logo (or whatever). Drop me a line if you are interested.

Subject: Re: Micah's magical starter

Brewsters,

I know that this goes back a little in the HBD history (~2 weeks) but that's life. Basically I'd just like to share an experience that I had this weekend using Micah's yeast starter solution of powdered sugar, yeast nutrient, and water.

This past Saturday I decided that I would compromise my dedicated football viewing time on Sunday, and brew up my first attempt at a Scotch Ale, while still focusing on the Raider game of course. I therefor decided to make up my yeast starter that day, so I could get my usual one day head start for my yeasties. Being the risk taker that I am I decided to give Micah's starter solution instead. This was a real big stretch for me since my standard starter solution is vastly different, using corn sugar in place of powdered sugar (what? me sarcastic?)

I made up about a pint of his starter and tossed it into my custom yeast starting receptacle (OK, so its an old mayo jar) to cool to pitching temp. I then sprinkled my standard dried Edme Ale yeast packet into the solution, and loosely screwed the lid on. Having accomplished this, I went all the way across the kitchen to go play with my petri dishes since I am now a neophyte yeast culturer. Not more than 5 minutes later, I turned to check on my starter, expecting to see whether all of the yeast had sunk yet, and to my surprise there was already a good 1.5" krausen bubbling away in the jar. At that point I thought to myself, 'Hey, this stuff is pretty good.' That turned out to be the understatement of the week. I left the kitchen for maybe 20 minutes or so and returned to find 'The Blob' oozing all over my counters. What we're talking about here is bionic yeast starter solution. Never in my experience have I ever seen yeast so motivated to spawn. After swabbing up the mess I looked inside the jar and there was a good half inch of slurry already sitting in the bottom, and the oozing krausen was still growing. I then went through a series of sessions where I tightened the cap, shook like a mad man, and then loosened the cap to relieve the pressure. Each time this managed to dissolve most of the foam back into solution, and removed most of the CO2 in suspension.

Like clockwork, every 10 minutes it was back at high krausen. This went on for 2-3 hours, and when it finally showed signs of slowing I had well over an inch of healthy yeast slurry on the bottom of the jar.

As I woke early Sunday morning (actually earlier than thought since I forgot about daylight savings) to go begin the brewing process, I started by checking on my starter. Low and behold it was dead to the world. There was plenty of slurry but no activity. I'm assuming that the rabid yeast feeding frenzy had already depleted its sugar supply. I was half afraid of opening the jar for fear of attack by the aggressive little beasties, but I took the risk and inserted my nose anyway. I was hit by the overwhelming aroma of fresh yeast so I was pretty confident nothing went amiss.

So the brewing went pretty well, but the Raiders lost to the ~~the~~ Cowboys. After immersion cooling the wort, stirring in a few cubic yards of O2, and pitching the bionic yeast culture, I set the carboy aside to do its stuff. A few hours down the road the airlock began that assuring bubbling. About six hours after pitching I took one last peek before retiring for the night. Sure enough there was a healthy 1/2" krausen forming and the airlock was cruising along at about a bubble every few seconds. Things were looking better, but I was still pissed over the Raiders lack of offense.

The following morning I woke and immediately ran down to check on progress (OK, so maybe I hit the head first...) and I discovered that gremlins had snuck in overnight and replaced my carboy with a fermented out batch of beer. I mean there was only the slightest remains of krausen to be seen, and the airlock was down to a measly little 45 seconds between clunks. Could this stuff have hit high krausen and actually fermented out in one night? I know that Edme tends to be quick, but by quick I usually think of 2-3 days of real active fermentation followed by a few more days of slowing down. The way things look right now, I might as well just dump a straw into my fermenter and chug away! This morning I sat and watched what was left of life in the carboy, and timed the airlock at 2:00+ minutes between glugs.

Pertinent details to set up questions:

- Grain bill was 7# 2-row, 1# munich, 1# 10'L crystal, 1/4# black patent
- Starch conversion: 15 min @ 130°F, 70 min @ 156°F, 5 min @ 168°F
- Sparged with 5 gallons H2O @ 165°F, acidified with citric acid
- Added 1 cup molasses to boil
- SG - 1.042 (a little disappointing, but attributed to watching football

- too much and not enough attention to sparge >:-)
- Fermented in garage @ ~60-70°F, maybe down to 55°F at night
 - I followed the same basic procedures that I've been using for the past several batches now. The only difference is that I've moved since my previous batch, so this is the first brew in my new house.

So here comes the questions:

- 1) Is this rapid yeast attack due to the encouragement from the starter?
- 2) Has anyone else ever had such rapid results?
- 3) Am I just a blessed brewer?

My plans are to rack to secondary tonight and at that point I'll take a gravity check. Maybe that will shed a little light on what happened. Of course I'll taste a little sample while I'm at it, so if you don't see a follow up then you'll now that something toxic was created >:-)

Brew on Garth,
Mark

From: KLIGERMAN@herlvx.rtpnc.epa.gov
Subject: dry hopping and fermentation

In regard to a posting in HBD#999,
I too have also had cases where after dry hopping in the secondary
fermentation seemed to continue indefinitely. This lead to a beer with
an overcarbonated and extremely large head. I believe this is
due to the introduction of wild yeast into the secondary along with
the hops. I don't think it is due to bacterial infection, since
there were no off flavors or ring at the bottle neck. This happened
about 50% of the time that I dry hopped. I believe that the wild yeasts
are fermenting the usually non-fermentables.

>From: joseph@joebloe.maple-shade.nj.us (Joseph Nathan Hall)

>I'm still looking for an answer to my "Crystal vs. Caramel" question of a week or so ago.

The answer may be so simple that it evades the experts. I read somewhere that in the UK they call it Crystal and in the US we call it Caramel, or was it the other way around. At any rate "they" forgot to tell us. I can believe that they are used interchangeably for a malt that is more or less pre mashed in the malting process and has no enzymatic contribution. There are many variations but I think using crystal vs caramel is not the best way to define them.

>From: iepubj!korz@ihlpa.att.com

>I thought that I had covered this before, but since there still seems to be some confusion as to the theory behind the statements, I have, through the magic of ascii graphics, illustrated the theoretical basis for my contention that runoff from a single point is less efficient (in terms of extract) than runoff from multiple points.

Unless I missed something, the only confusion seems to result from a lack of understanding of what I wrote in my response which was, the only response I saw. Perhaps, I didn't make myself clear so I will try again.

Al's nifty drawings and descriptions correctly describe what goes on in a STATIC system. Channels, tunnels, dead spots and dry spots will indeed develop in ANY lautering system. As Al noted, the more outlet points in the system, the less significant these problem areas become.

However, as I pointed out, the process I am promoting is NOT a static system and all the arguments brought up by Al are not relevant.

The unique screen pickup in this system does not demand a well settled grain bed to provide a clear run-off. Therefore the entire mash can be thoroughly stirred and mixed at regular intervals during the sparging process. This breaks up any channels that may have developed and redistributes the mash

within the water column. I suspect that this would actually provide a much MORE effective extraction regime then depending on the number and location of outlet points.

What seems to make this point so hard to grasp is the fact that the other systems all have large spaces under the grain bed that must be cleared of turbid wort before sparging can actually begin. Wort is recirculated, there are painfully complicated systems for flushing these areas out and endless discussions about how much wort must be recirculated to get it to work.

The EM system runs clear after only a few ounces are drawn off initially and continues to run clear even after thorough stirring of the mash.

I have only heard from a handful of people who have tried my process but so far, they seem to be delighted with the results. I offered Al an opportunity to tour the World's Greatest Brewery but unfortunately, he declined.

I will publicly extend my offer to Al or anyone else who wants to bring his/her favorite lautering device over here and do a side by side mash, under controlled conditions, to put to rest the notion that simple things just can't work.

From: djt2@po.CWRU.Edu (Dennis J. Templeton)
Subject: Re: Freezing yeast

In response to a recent posting about freezing yeast cultures, I'm posting the methods that we use in our research lab for freezing and recovering yeast. I have used similar methods for a while to culture ale yeast (1028) and I don't see why it should not work for nearly all organisms of importance to brewing. Translating the methods from the lab to the kitchen is another issue, and has been dealt with occasionally here.

We grow yeast in a rich medium, that can be substituted in the brewery with a simple wort: 1-2 tablespoons DME in a cup of water. In the lab we autoclave to sterilize the medium; in the kitchen I have found that making the wort up in mason jars with lids works well; I boil the jars and all in a covered kettle (better still a pressure cooker) for 45 minutes.

To freeze your favorite culture, make up two different jars with medium: 1 with DME in water, the other with DME in water:Glycerine (glycerol) 4:1 (i.e. 20% glycerol in water) Sterilize both. Inoculate the water culture with your best culture source; ideally, this will be a single colony from a petri dish (another topic altogether) using a sterile loop (or a long thin wire heat sterilized). Grow the culture for a few days at room temp, until it is distinctly cloudy. I don't worry about excluding air, since the culture is nearly absolutely sterile. If your innoculum is less certain (i.e. the dregs from your last bottle) there is a chance that you'll have other beasties in with your yeasties.

When the culture is dense, but before it's sat around too long (i.e. it is as healthy as it can be) pour the glycerol medium into the culture bottle, and mix. I dispense this into sterile vials using a sterile pipette.

Now, what to do in the kitchen. For sterile vials, I would recommend small glass vials, maybe 1/2 ounce with black bakelite caps. These can be sterilized in the oven (try one first) maybe 400 degrees F for an hour. Any small jar that seals well and can be heated should be ok. You might be able to boil them to sterilize, but this seems awkward. For a sterile pipette, you could boil a medicine dropper. Pharmacies sell these for giving medicine to kids, and they should be boilable. Fill the vials about half way.

Now, we store our cultures in the lab in an ultra-low freezer; -80 degrees

C. I have kept these cultures at -20 (my home freezer) with good results, but the liquid doesn't seem to freeze reliably. My 6 month old cultures have ice at the top and a brown liquid layer at the bottom, where most of the yeast are.

To use the culture, you CAN just dump it into the starter, since the glycerol (10% of 1/2 ounce (15 ml)) is less than a half teaspoon (1.5 ml).

Better, though, is to simply take a small inoculum from the vial. Take the vial out of the freezer and warm it until it just starts to thaw. Sterilize your loop (or wire) on the stove, and while hot, stick it down the side of the vial, to the bottom where the yeasties are. Then either streak your loop onto an agar petri dish for colonies, or dip it into a sterile jar of medium (wort) for your starter culture. Put the vial back into the freezer. This way, a few vials should last eons, as long as the vials are not fully thawed each time. I don't know the lifetime of the yeast in a kitchen freezer, but it is indefinite in the lab freezer.

Microbiologists know the advantages of working from single colonies, in that rare mutations are removed from the culture at the beginning of each experiment. I would highly recommend for those who maintain your own cultures learning how to streak for single colonies. I may offer suggestions for this if it seems useful. in the future.

good luck,

dennis

From: Phillip Seitz <0004531571@mcimail.com>
Subject: Plastic Kegs/Rotocasks

In HBD 1000 John Williams asked for help with his plastic cask. I assume he was referring to the gizmos sometimes referred to as Rotocasks--in effect, a fake plastic cask that often lies on its side and has a tap on the dispensing side as well as a screw-on lid on top. The screw-on lid has a built-in injector port for CO2.

I've just come back from England where we visited several homebrew shops (more on this in an upcoming post), and was fascinated by these things. In British-style homebrewing these are used as both secondary fermenters and kegs (ie a British cask). The idea is that following the primary fermentation the beer is racked into the cask along with the priming sugar, finings (isinglass, typically), and any dry-hopping. In theory the beer ferments to completion and clears, and in doing so creates sufficient CO2 to carbonate the beer and to provide pressure to push it out of the cask. If you run out of pressure you can top off the CO2 with a device that looks like a cigarette lighter refill and takes cartridges like those used for seltzer.

There's nothing shameful about using these--there's a photo of one on the cover of CAMRA's homebrewing guide--but there is a trick. The trick is that you probably can't use them to brew American-style beer--or more accurately, beer with American levels of carbonation. So don't fight it--just go British and dare to brew beer that isn't fizzy, as they would say. The Pale Ale volume in the Brewers Publications

series is full of advice, and suggests using slightly over 50 grams of corn sugar for priming 5 gallons. (A cup of corn sugar weighs about 160 grams, so 3/4 cup is about 120; I never use more than 100 grams, and for British-style stuff have gone as low as 80.)

Anyway, I found these casks to be quite interesting, and potentially a great deal easier than either bottles or kegs. The only problem is that you need to store it in a cool place; if not for the fact that we don't have a basement, I'd have bought one.

Subject: freezing yeast

Subject: Time:9:39 AM
OFFICE MEMOfreezing yeastDate:10/28/92
In response to:

>Subject: Glycerol for freezing yeast?

>I've heard that a product called the Yeast Bank uses glycerol to
>protect samples of yeast for storage in the freezer. Can anyone
>out there describe the steps and quantities needed to perform this
>process? I'd like to have a "homebrew" version of this product.

Here is a method for cryopreservation of yeasts. Required is a 0.5 mL
sample
that contains 10E6 to 10E7 cells/mL. To this is added an equal volume of
a
sterile 10% glycerol (glycerine) solution. The vials (sterile, plastic)
are
frozen in two stages. Primary freezing at -30C for two hours allows the
cells
to dehydrate. Secondary freezing in liquid nitrogen at -196C for
storage. At
-196C the average survival levels are 65% for Saccharomyces. Data is
scant on
the shelf-life but evidence suggests that losses are very slight for up
to 8
years.

Now for a homebrew version. Since most of us do not have access to
liquid
nitrogen our shelf-life is reduced considerably. You can either purchase
sterile glycerol or sterilize it in a pressure cooker. The same for
water.
Prepare a 10% solution and add about 1-2 mL to an equal volume of a good
starter culture to give a final glycerol concentration of 5%. The trick
is
finding sterile plastic tubes, although screw cap glass may work as well.
These can be stored in a non-defrosting home freezer (ca -20C to -30C).
Cultures should be rapidly thawed in warm water (35C) while mixing. I
have had
good luck with this method and have maintained yeast cultures for >2
years that
have still remained viable. The advantages are that repeated
subculturing is
not needed and therefore the integrity of the strains is maintained.

Subject: re: counter pressure filling

In the last digest, roy.rudebusch@travel.com (Roy Rudebusch) writes:
>Don't let anybody talk you into buying a counter-pressure filler!

>The best way to put up a few bottles from a keg:
 ^^^^

>Sterilize bottles and caps
>Chill bottles with caps on
>Chill beer very cold
>Attach a length of hose about 2 inches longer than the
>bottle to the spigot.

While this method apparently works to a certain extent I would have to object to the claim that this is the best method, clearly it is not. A counterpressure filler is a natural simple device that does exactly what it is supposed to when designed and used properly. The whole idea is to fill the beer under proper CO2 dispensing pressure without introducing oxygen. Any method that employs a "tube over the spigot" will reduce the CO2 level in the bottle.

I built a counterpressure filler using several "T`s" a shutoff valve and an extra CO2 tap. I fill 2L jugs in 30 seconds, keeping the Co2 level the same as in the keg. I have kept the jugs in the fridge for weeks (dont even sterilize!) and they are great. Cost: \$10.

From: Victor Reijs <Victor.Reijs@SURFnet.nl>
Subject: Re: chrystal malts

==> From: SOMAK@FITKJES2.bitnet

> Hello Victor| I am Markku Koivula from Finnland. I saw your
> definitions of the differences between chrystal and caramel
> malts, and I am wondering. C. Papazian says in his book (The
> New Complete Joy of Homebrewing) that chrystal malts are made
> by first gently kilning them a short time, then "mashing" them
> by raising the temperature in the oven to 100 - 110 Celsius,
> and finally kilning them as usual, in temperature of 80-100 C.

This process discription is totally diferent I see:

- sprouting of the grains (what is the english term?, the grains get small roots)
- then kilning them (that means at some high temperature)
- then mashing at 100 - 110 C
- then kilning them at 80 - 100 C

The process I describes for crystal malt was:

- sprouting of the grain
- the masking them at 65 C (1 hour)
- then kilning them at 110 - 120 C [EBC 10]

The temperature of 65 C is to get as much sugar in the crystal malt as possible. (65 C is the optimum temperature for the enzymes).

I have the idea that the method you are using is almost the same as for amber/biscuit malt (see further below, although the temps are different)

> He don't mention caramel malts.

The proces here is:

- sprouting the grain
- kilning them at 160 C [EBC 100] (light malt this is 80 C [EBC 3-5], dark/munchener malt it is 100 C [EBC 20] and black it is 200 C [EBC 1000])

> I am just making malts myself, because here in Finnlands it is
> nearly impossible to get good malts, and I cannot buy chrystal
> malts and other special malts nowhere. I have previously done
> as is told in Papazian's book, and I think my results have been
> good (alltough I cannot make comparisons).
> Now I just wanted to know which is your source of knowledge.

This information comes out of a few Dutch books (so a copy will not help;-). But it seems to be the normal parctice over here.

Beside crystal malt we also have amber/biscuit malt. The proces is:

- sprout
- kiln 80 C
- mash 65 - 66 C (1 hour)
- kiln 150 C

This malt has more taste and color (EBC 50-100) then crystal malt

> I have never heard that the grains that have not yet been kilned

> are mashed in water. But why not, I think it sounds logical.
>

As you see, every country has its own methods.

From: mtavis@saturn.hyperdesk.com (Mike Tavis)
Subject: When to add the fruit...

About a year ago I tried a fruit beer which unfortunately die of an infection. I suspect that the fruit which I added right after the boil is what contaminated the batch. For my next attempt I thought I would add the fruit earlier in the boil and hopefully remove the chance of infection. I've been reading different recipes in preparation and I've seen a wide variance in when people add the fruit. There seems to be the following four possibilities:

- in the mash
- during the boil
- as the boil is removed from the heat
- in the fermentor (primary and/or secondary)

What I was wondering was what are the relative advantages/disadvantages of these choices? Thanks in advance.

Subject: Cream Ale?

Hey There,

My friend and I were discussing cream ale the other day. He was asking what the difference was between "ale" and "cream ale". I couldn't answer him. Upon his ever so studious investigation, he discovered that cream ale was brewed with both ale and lager yeasts.

My question to all of you is if lager yeasts are used at lower temperatures for lager purposes and ale yeasts are used at room temperatures for ale purposes, then at what temperature does one brew a cream ale for the best results? This, I think, becomes important since lager yeasts tend to form esters at room temperatures. Are the presence of these esters desirable or undesirable in cream ales?

Thanks for your indulgence,
Greg Pyle

Subject: kegs, filters, bottles

Kent Dalton asked some questions about filtering.

Steve Daniel gave a good talk on filtering at AHA National in Milwaukee this year. A version of the talk should be in the latest Beer and Brewing (proceedings of the Milwaukee conference).

After reviewing the pros and cons of different filters, Steve Daniel came down in favor of the filter sold by The Filter Store. If I am remembering correctly, everything you need, including a 0.5 micron filter, costs in the neighborhood of \$80. You can call them, ask for the catalog, and mention that you're interested in the homebrew filter setup you read about in Zymurgy.

The process of filtering goes something like the following. Chill your beer. Rack it into a sanitized keg. Make sure the filter setup is sanitized. Using your CO2 tank, push the beer from the keg, through the filter, and into a second keg. Force carbonate the beer in the second keg. Steve said that in his experience the filter could be re-used up to perhaps a limit of 200 gallons, at which point the filter is clogged and should be replaced with a new one. Note that you replace only the filter, not the filter housing and tubing!

Thus, filtering seems to take you down the path of consuming the beer from the keg, and bottling from the keg as needed. And, this is good. Once the beer is siphoned into the first keg, you will keep it under CO2 and not expose it to air, wherein microbes and oxygen lurk.

For bottling, use either a counterpressure filler, or use the technique suggested in recent HBDs of attaching some hose to your cobra valve and quietly siphoning. The trick is to insure that the bottled beer has the right carbonation. A suggestion I've seen is to add 0.2 to the pressure you would otherwise aim for in the keg. Thus, if you intend a pressure of 2.48, pressurize the beer to 2.68 on the thought that there is some loss in transferring the beer to the bottle before capping.

For the very useful pressure-temperature chart, as well as suggested pressure ranges for beer styles, see Byron Burch's article in Beer and Brewing vol. 9 (?), "A Great System for Draft Beers," or the last chapter of Dave Miller's latest book, "Brewing the World's Great Beers." Both sources talk about keggings and bottling from kegs.

One final point: Should you filter? With good technique and ingredients, you can often produce a very bright, clear beer without filtering. However, in the case of some styles such as light American lager, you probably should filter the beer for the required clarity, especially if you intend to enter the beer in competition. Filtering will certainly produce a brilliant, bright beer, which will get you points on appearance. On the other hand, the downside to filtering is that the filtered beer has the yeast scrubbed out of it, putting it more at risk should it come in contact with any bacteria or wild yeast.

Subject: Question on Heineken's "Oude Bruintje"

Since Victor Reijs offered expertise on Dutch beers, maybe he or somebody else can answer this one:

In an Indonesian restaurant in Amsterdam, I had a Heineken beer I think was called "Oude Bruintje" ("old brownie"). It was quite sweet and not very strong (2% alcohol). Basically, it tasted like partially fermented dark beer, or maybe beer mixed with unfermented wort. Quite pleasant, my wife especially liked it.

We were not able to find that beer anyplace else, not even in pubs specializing in Heineken. Has anybody else tasted this before? How is it produced?

By the way, we also ran into a wheat beer (Valkenburg ?) that tasted just as sweet. Is that a style of beer common in the Netherlands?

From: "Bob Jones" <bjones@novax.llnl.gov>
Subject: Sparge system runoff

On the subject of sparge systems, I would point out that if possible you should try to minimize the hydrostatic pressure across the grain bed to minimize grain bed compaction. This can easily be done if you place your outflow slightly below the grain bed liquid level. Crude ascii graphic to follow.....

The type of false bottom you use is MUCH less critical in a system like this, IMHO. I use a pump in my system and can not use this technique.

Officially it is called "Oud bruin" (old brown). But just to order such
a beer you would indeed call it that way.

> and not very strong (2% alcohol). Basically, it tasted like partially
> fermented dark beer, or maybe beer mixed with unfermented wort. Quite
> pleasant, my wife especially liked it.

It is a typical Dutch beer, I think (if not let us know). It has 2 -
3.5 % vol. alc. Yeast is used which works at the bottom of the vessel.
Normally one step decoction, to mature some 3 weeks, you can store it
for some 4 to 6 weeks. To be drincken at 6 - 8 C. Furthermore it is
sweet!

>
> We were not able to find that beer anyplace else, not even in pubs
> specializing in Heineken. Has anybody else tasted this before? How is
> it produced?

A small recipe is (from a book called: The international beer brew
book, in Dutch):

(5 litre)
350 gram light extract
350 gram dark extract
100 gram brown sugar (the unrefined;-)
15 gram Hallertau hop
100 - 200 gram of lactose (unfermentable sugar)

With malts:
600 gram light malt
300 gram dark malt
50 gram black/chocaloate malt
100 gram brown sugar
15 gram Hallertau hop
100 - 200 gram of lactose

OG 1030
FG 1004
alc. 3.5% vol. alc.

>
> By the way, we also ran into a wheat beer (Valkenburg ?) that tasted

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Specialty malts

Terminology for speciality malts has not been uniform, and this has lead to some inconsistencies in product names at various homebrew outlets. Debating the appropriateness of the terms used strikes me as neither interesting nor useful. I personally like the approach taken by Victor Reijs, i.e., describe the grain by the way it is actually made. In this regard, there appears to be two major categories:

Class 1 - Grains are roasted.
Class 2 - Grains are not roasted, but they are dried at a high temperature in the kiln.

In Class 1 there are three important subcategories:

- 1a - Unmalted barley is roasted.
- 1b - "White malt" is roasted. (White malt is fully germinated, but either has not been dried in a kiln or only slightly so.)
- 1c - "Green malt" is roasted. (Green malt consists of germinating barley.)

During our visit to the UK this summer Laurie and I got to see several malting companies, and in particular H&B. The latter classified grains in category 1c as follows:

- i - light carastan 13-17 L
- ii - carastan 30-40 L
- iii - crystal 70-80 L
- iv - dark crystal 100-160 L

The traditional categories for Class 2 are the following:

- 2a - Vienna 5-10 L
- 2b - Munich 10-20 L

At the time Laurie and my book was written, the nonroasted malts (i.e., those in Class 2) that were available all came from high protein 6 row barley (typically Glenn or Morex in the US and Sonja in Germany). Thus, we were faced with a "garbage in, garbage out" syndrome. In particular, the results from a large number of competitions showed that English and/or German malts from Class 1c were preferred by a very wide margin. It is important to note that these malts come from top 2 row barley (Maris Otter and Archer in the UK, Triumph in Germany). Today the situation has dramatically changed with the color malts from Belgium. We are currently playing around with versions of our recipies where 2/3 of the color malts are replaced with the Belgium Cara-Vienna and 1/3 with Cara-Munich. This has given a Lovibond value (which is the same as SRM or ASBC color) in the range 7-9 L. Reversing the proportions is also of interest, and yields (at least for us) a color in the range 10-12 L. As noted in an earlier post, the color of the Cara-Munich from Belgium is well above the classical range cited above.

Laurie and I feel that the UK and German malts in the Class 1c tend to give a "toffee" or "caramel" flavor tone. On the other hand, we are picking up something like a "nutty" effect from the Class 2 malts from Belgium.

We would both be extremely interested in the results other brewers are getting from any of the Belgium malts.

Subject: SNPA Responses

I would like to thank all of you that responded to my SNPA question about the viability of the sediment on the bottom of the SNPA bottles. The consensus is that it is the same yeast that SN uses to do the primary. It seems that the yeast is excellent to use to brew an SNPA clone, as long as the bottles you use have been stored well, that is, not in a hot warehouse or in the back of a truck for a week. You could pitch the dregs from a couple of bottles into a starter to build up enough for a 5 gallon batch, but I would recommend plating it out to a petri dish to make sure you've got a single and active sample.

I was also told that Wyeast 1056, the American ale yeast, is the same or similar strain used by SN, and they call it Chico Ale yeast. For reproduceable results, spend the \$3.50 on a pack of 1056.

I'm going to make my first batch from the bottom of the bottle rather than from the 1056, just because it seems more difficult, and the more elements of complexity I can introduce into my project batches, the better I like it.

Here's an all grain receipie and some comments that I received:

10# Klages 2-row pale malt
 .5# Cara Pils Malt
 .5# Crystal (40L) Malt
1 oz Perle, 6.8% AAU, 60 minutes
 .5 oz Cascade, 5.5% AAU, 30 minutes
 .5 oz Cascade, 5.5% AAU, 5 minutes
1 oz Cascade, 5.5% AAU, dry hop in secondary (optional)
1 quart #1056 yeast starter
3/4 cup priming sugar

O.G. 1.048, F.G. 1.008 - 1.014, 33.6 IBUs

Mash temperature 153-155F.

Sierra Nevada Pale Ale, the bottle product, has a starting gravity of 1.052, while Sierra Nevada Draught Ale, the draft product, has an SG of 1.048. The draft product tastes a bit sweeter, too. Malts in the grain bill include pale malt, crystal malt, and dextrine malt (aka cara-pils). Hops used are Perle and Cascade. The yeast is their own, which you can culture from the bottle or obtain as Wyeast "American" ale.

Comments: the crystal malt is fairly dark for some color, the cara-pils is there for added body and sweetness. But, don't overdo it with the specialty grains. The relatively high starch conversion temperature will promote body and sweetness. Perles are the signature bittering hop, while Cascades are for flavor and aroma. If I remember, SNPA comes in at about 32-35 IBUs, and the above hop schedule should get you in the ballpark. I don't believe Chico dry-hops SNPA, but go ahead if you so desire.

Thanks again.....Glenn Anderson

Subject: Differences between Light, Amber, and Dark extracts

Randall Holt asks:

> What's the difference between Light, Amber and Dark Malt extracts?

Good question.

Unfortunately, extract producers do not list ingredients on the can. This uncertainty makes recipe formulation, at best, guess work.

You can make some educated guesses. The light extracts probably contain two-row, and maybe some filler, like corn sugar. The amber extracts probably have some crystal, or maybe some chocolate malt. The dark malt extracts? Roasted barley? Chocolate malt? 100L crystal? I dunno.

My recommendation is to pick a good quality bulk light extract. The bulk extract I use seems to make a good one for one substitute for two-row barley. At least the gravity and flavor characteristics are consistent. Then use specialty grains to provide the character you are looking for.

Another, less desirable method, is to select a light, amber, and dark extract, and make a batch of each one (say 5-7 pounds of extract, lightly hopped). Now you will have a flavor and starting gravity profile of each extract to base follow-on recipes.

Anyway, the uncertainty of the extracts contents that has driven me to partial and full mashes. Once the brewer becomes comfortable with the brewing process, its a natural progression to partial mashes.

Subject: Belgian Bannana Yeast

Last week I started culturing yeast, using the WYeast Belgian strain. Three days ago I made a 1.060 Brown Ale and pitched. Slow start, but then got into a good ferment, but after the first day when I took a reading I noticed a very different smell. My first fear was that the culture had violated sterile procedure, but by the second day, only a hint of the odor remained, and has persisted.

Then today I read of bannana ester tendencies of WYeast Belgian, and the connection is complete. The undefinable smell just became obvious. Thanks to Jeff Frane and others for pointing it out. I'll just have to wait it out and hope that long-term storage/conditioning mellows it.

From: Davin Lim <limd@csn.org>

Subject: Another yeast question...

I posted a question a couple of days ago about using glycerol for freezing yeast. Thanks for the replies sent (so far.)

Anyway, I forgot to ask a related question about cleaning yeast slurry samples. I seem to remember a posting a while back on doing sterile water washes of yeast. This procedure is done to remove excess trub, hop sediment, grain particles etc... from the rest of the yeast. Anybody out there have this info handy (or can point me to the proper HBD # so I can look it up in the ftp archives?)

I realize that one can take washing yeast a step further by doing acid washes to more effectively eliminate bacteria. This is also of interest to me, though I'd be pretty comfortable with the contamination risks involved without going to this extra process.

Thanks again!

Subject: Bluebonnet Brew-off

- ----- ANNOUNCEMENT -----

The Reports of the Bluebonnet's demise (in a publication associated with another Texas regional brewing competition) are greatly exaggerated. The Bluebonnet Brew-off is alive and well and living in Ft. Worth this year.

For those of you not familiar with the Bluebonnet Brew-off it is the regional competition held in the Dallas/Ft. Worth area and is sponsored by the Ft. Worth, Dallas, and Arlington homebrew clubs. It usually takes place around the end of February or beginning of March each year and rotates locations between the three sponsoring locations. This year it WILL be held in Ft. Worth on the 5th & 6th of March. The site is still under discussion, but will most likely be at the Texas College of Osteopathic Medicine. The Regular cut-off date for entries will be February 20th. The Late cut-off date (for which an additional fee is charged) will be February 27th.

The categories will conform to the AHA & HWBTA guidelines and a more detailed break-down will be posted later. We want to get as many entries as possible this year, so enter early and enter often. We also are putting out the call to all those in the judging program that are looking for points. If you are interested in judging (or just want more info) you can e-mail me and I'll get back to you as soon as I can.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)
Subject: QQ: modification, pumpkins

The recent thread on modification raises a question for this non-masher:

what is the advantage of less-modified malt that professionals use it? Darryl's ZYMURGY article on Pilsner Urquell mentioned that it used relatively undermodified malt; was the reason why one of the things that was cut to fit, or did I miss it? I would think professionals would be even

more interested than homebrewers in good extraction, as the barley is a significant fraction of their costs (yes, they get it in bulk, but they also ultra-wholesale the beer, probably at ~25% of what you pay for sixpacks) and full modification shouldn't take so much longer as to raise the cost significantly.

We're into the season when a lot of people are brewing pumpkin beers.

I tried one of these myself and didn't think much of the result, which gets me to wondering---how much flavor do you extract even from cooked&smashed pumpkin (let alone the steeped cubes recommended in the recipe I used)? We're talking about a gourd here, after all, relative of the summer squashes that are excellent receptacles for (e.g.) butter, pepper, and onions but blah on their own. The recipes I've seen mostly have pretty substantial amounts of spice in relation to the malt; has anybody tried a split/twin batch in which the only difference was the presence/absence of the pumpkin itself?

> grains and pumpkin were mashed for 90 minutes at 154 F.
> This thick mess was then strained into the brewpot (a long
> process!), and then a standard 90 minute boil took place.

My brew-ally, Rus, at Vandybilt recently bottled his first pumpkin ale, but he refrained from mashing the mush, and simply dry-pumpkin'd the beer in the primary. I think he said that the guy at the homebrew store warned him that mashing pumpkin meat would make a holy mess. (Rus also mentioned that this guy wore an expression that said "Uh-oh, another brewing-as-a-personal-statement type.") I don't remember offhand if he cooked it. We'll soon see how this works.

My brew-partner (no, not me, really) is about to embark on a project that could easily be a complete disaster: the thought of FERMENTING IN A PUMPKIN SHELL obsesses him. Normally, he makes pretty good, if not very straight beer. (His artichoke steam beer was surprisingly tasty!) Can anyone provide evidence that this project is doomed? If it matters (I don't think it does), he will be lagering it on our porch at about 40-45°F, which may slow the pumpkin's decomposition. Since I have never heard of anyone trying anything like this, I can't change his mind. "We'll soon see how well this works."

(I have a couple substantial, interesting, useful questions to post soon to make up for this last paragraph. Please bear with me.)

Cheers,
Jake.

>the least costly ingredients, so it pays to use the right one.

You shouldn't assume that the brewers made no attempt to use the right yeast.

I have entered several weizens in competetions, all made with Wyeast's Bavarian Wheat strain, and all with minimal (though noticable) clove character. In every case, at least one judge responded "No cloves=not a weizen. Use the right yeast next time" and didn't look any further into the beer's other faults and virtues. Since I did use the "right" yeast, this advice is less than helpful. Perhaps judges should not assume the worst of homebrewers. In this case, I know what a weizen is supposed to taste like,
I just don't have the skill to achieve it.

Sorry I thought that Dimethyl Sulfide was Potasium metabisulfide (a
desinfectant). Used by some wine brewer to kill unwanted bacteria and
fungi. So in my earlier mail about Vit. C and potasium sorbate you
should read this desinfectant. Sorry about this misunderstanding. In
future I will never use these difficult XYZ;-)

All the best,

Victor

Subject: going to colorado

I'm going to Colorado for Christmas. I will be in Evergreen, which is a suburb of Denver. I am very interested in visiting the brewpubs in and around Denver. Anyone who lives in the area or knows the area could please e-mail me a list of pubs and breweries I would very much appreciate it. You can leave COORS of the list ;-). I will be there from Dec 21 - Dec 31 . if there is any Can't miss event during this time period please send details.

Thanks in advance.

From: Phillip Seitz <0004531571@mcimail.com>
Subject: HBD Field Report #2: East Anglia

Our 11-day trip focused on East Anglia, particularly the counties of Suffolk and Norfolk, where breweries have taken more than their share of prizes recently. Black Adder from Mauldon's was CAMRA's Best of Britain last year; Woodforde's Wherry Best Bitter took the Best New Brewery prize in 1990, and their Norfolk Nog just took the 1992 Best of Britain; Adnams took the Bitter award in 1990.

THE BEERS:

1) Greene King & Sons (Bury St. Edmunds, Suffolk)

GK is the predominant brewer and pub owner in Suffolk and much of Norfolk. An independent (i.e. with fewer than 2000 tied houses), it is expanding and behaves like the big brewing companies. This includes efforts to acquire (and close) competing breweries, and a tendency to treat beer more like a product than a labor of love. Their main brews are XX Dark Mild (1.030, 19 IBU), IPA (1.035, 24 IBU), and Abbot (1.048, 36 IBU). Quality varied widely from pub to pub, mostly on the down side IMHO, and even the well-known Abbot was underwhelming.

The brewery itself covers 40 acres and includes 450 employees. GK does its own malting, producing 12 tons a day for in-house use only. Germination takes place in high rotating drums, and the malt is kilned at 70 degrees C. All the by-products of malting are collected and sold, including the acrospires.

GK also maintains wooden vats of a high-gravity beer called XXXXX, which is aged for one year and then blended with a brown ale for a gravity of 1.060 (+/-). The final product is called Strong Suffolk, and is available in bottle only (I haven't opened mine yet, sorry!).

GK also brews for others. As we toured the bottling line (2,000 dozen bottles/hour) they were bottling and pasteurizing Watney's Red Barrel for export to the US.

2) Tollemache & Cobbold (Ipswich, Suffolk)

The Tolly Cobbold brewery and all its tied houses were bought about three years back by Brent Walker, a food and beverage company, and brewing at the TC brewery was terminated. Soon it was clear that Brent Walker wanted to tear down the brewery building for a development. The city of Ipswich--not happy about losing the brewery--stepped in and declared it a historic site (it is a wonderful tall, gravity fed Victorian brewery), making it useless to Brent Walker. Two of TCs directors managed to buy the brewery back, and to re-hire some of the discharged brewery workers. They've now been on line for a little under two years, and are brewing quality beer.

But TC has lost its tied estate, and hence a ready market for the beers. The Brent Walker-owned houses takes some, as does the free trade, but currently they are way below capacity (400 36-gallon barrels is being produced per week), and only 8 people work in the brewery itself. However, the brewery has been repainted, a splendid public house and restaurant have been added, and the beer is quite good.

Brews include a mild, a bitter, a best bitter, a strong ale, and several specialty beers. (Because of the changes of management and related recipe changes I don't have the stats.) They produce a special bottled beer each year, starting with last

year's Ipswich Pride. This year's is Cobnut, a re-creation of one of their beers from years past. It is an intensely malty, nutty beer, similar in flavor to some of the richest barley wines I've tried--but 3.2% ABV. (This was my wife's favorite beer on the trip.) Also good was the Anniversary Ale, available for two weeks only. As an indication of their relations with Brent Walker, I never saw this beer in one of the former Tolly pubs. However, I saw it in two free houses where attention to quality beer was quite evident.

Tolly uses Challenger and Goldings hops, with stiff mashes. Strike temperature is 159 degrees farenheit, with an average mash temperature of 145 degrees. Sparge water is 175 degrees, with fermentation at 70 F. Tolly also manufactures its own isinglass.

3) Earl Soham Brewery (Earl Soham, Suffolk)

Small: the brewery is in the garage, and they have one pub which is deliciously shabby and filled with pictures of Victoria and Albert. A great place, with beer to match: Gannet Mild (1.030), with a bit of black malt in the palate and some perfumy hops character; Victoria Bitter (1.035), clear gold with a spicy aroma and very spicy hop flavor, but not very bitter; and Albert Ale (1.040), a deep russet brew with a spicy hop nose, full body, and a rich, spicy hop flavor. If you like hops, and especially hops flavor, this is the place!

4) Woodford's Norfolk Ales (Woodbastwick, Norfolk)

Another small brewery--doesn't accept visitors. The full range of their products is available at the Spread Eagle in Erpingham (Norfolk). Having just taken the Best of Britain for their Norfolk Nog (a black, sweet, aromatic brew) I hope their beers find wider distribution.

At the Spread Eagle I asked for a quarter pint of each of the six beers available. These included Spread Eagle (a special brew for the pub, probably dry hopped), Wherry Best Bitter, Nelson's Revenge, Norfolk Nog, Baldric, and Headcracker (a sweet, vinous, almost Belgian-style beer that can undoubtedly live up to its name). These beers ran the gamut of styles, from clear, light and hoppy to rich, red and sweet. All have outstanding hop character and flavor, many have substantial body, and most have a certain spicy quality that may be yeast-related. Having tried all the beers I was incapable of picking a favorite--they were all fantastic. So we started from the beginning again, but this time with full glasses!

5) Reindeer Freehouse and Brewery (Norwich, Norfolk)

An excellent brew-pub. In addition to six of their own brews they offer well-selected guest beers (this included Tolly's Anniversary Ale and Mauldon's Black Adder). The clientele ranges from ties to mohawks and the food is primarily Malaysian (and delicious).

We pulled the quarter-pint routine here, too. Brews included: Moild, 3.5% ABV (i.e., mild, but imitating the East Anglian accent--"Give us a point o' moild"), with a black malt tang; Bevy, 4% ABV, a gold/amber beer that was slightly sweet and hopped with subtlety; Gnu, a gold beer with full body and a good hop/malt balance; Reindeer, 5% ABV, copper red, sweet, and lightly hopped; Porter, near opaque black with a roast malt aroma and flavor; and Red Nose, 6% ABV, near opaque red with a slight alcohol aroma and a sweet, malty flavor. All were rated good to very good by our jury.

5) Fuller, Smith & Turner (Chiswick, London)

As a brewery tour this was less interesting, as there is a lot of expansion going on and because the guide was not very

knowledgable.

Fullers uses Challenger, Northdown, and Target hops in the kettle, and its Chiswick Bitter (1.034, 28 IBU) and ESB (1.054, 35 IBU) are dry-hopped with Goldings (their London Pride--1.040, 30 IBU--is not). Marris Otter malts are used throughout, with mash strike temperature at 69 degrees C (156 F?). Their strongest beer, Golden Pride (a very malty brew, and 9.2% ABV) is made from the first run-off only, while their other beers are sparged at 76 C (169 F?).

In the casking area we also encountered huge stacks of polypins (soft plastic beer containers in a cardboard box, with tap). Fullers sells these at near-cost to CAMRA members only.

6) Other

We were unable to visit the Mauldon's Brewery (Sudbury, Suffolk), and had difficulty finding their beers. The Adnams Brewery (Southwold, Suffolk) doesn't accept visitors. Their Bitter and Broadside have pretty general distribution, but I wasn't very impressed.

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>
Subject: Miller's kegging suggestions in B&B 12

Hey now.

I just finished reading Just Brew it! (Beer and Brewing, vol. 12), the 1992 AHA proceedings. Lots of HBDer's in it. Not only are several chapters written by contributors to this august forum, but it seemed like every few pages someone was quoting an HBDer, or thanking an HBDer, or revealing an HBDer's brewing secrets. Seriously. For those of you who haven't seen it, it's surprising how well represented the HomeBrew Digest is.

Anyway. Enough bragging; on to my questions. I, like many Cornelius keggers, have had problems with getting nothing but foam. Turn the dispensing pressure high, turn the dispensing pressure low--it doesn't seem to matter. Well, Dave Miller's chapter in Just Brew It looks like it contains The Answers. Briefly, his argument is that two things contribute to excess foam. First, if the line pressure is too low, gas escapes en route to the tap, foaming the beer. Second, if the dispensing pressure is too high, the velocity of the beer as it hits the glass bottom foams the beer. And if that's not bad enough, it's possible that BOTH of these conditions hold at the same time: Given the right set up, a pressure which jets out the beer (causing problem 2 above) might still be too low to prevent problem 1. Thus no matter how you finagle with the dispensing pressure, you still end up with foam. Dave's solution is to pick a line length/diameter/etc. such that the resistance provided by the line exactly equals the pressure in the keg minus one or two psi to dispense the beer. Pretty straightforward. Nonetheless, I have a couple of questions about his chapter.

1. What the heck is a "cobra" tap? He talks about two kinds of taps: "bar" taps and "cobra" taps. One of them requires a 2 psi adjustment, but I have no idea what this cobra gizmo is. My tap looks like the kind that you get on the hand pump of a beer ball. I suppose that if your imagination is whimsical enough, and if you've had enough homebrew, you could say that the tap looked like a spitting cobra, but geez I dunno.

2. What is line "width"? Dave talks about two factors that influence the resistance on a line: it's length and it's width. Makes sense. It takes more pressure to force beer over a long distance or through a skinny line.

But by "width" does he mean inside diameter? If so, why didn't he use this term instead of the ambiguous "width"? If not, what *does* he mean?

3. What's the deal on the material composition of the line? Dave has a table showing the resistance for different lengths and widths of line. No sweat. But the resistance for a fixed length/width varies according to whether the line is vinyl or polyethylene (more resistance in vinyl). Why? I can't think of any good reason why the composition of the line would make a difference. Maybe one is more gas permeable than the other, but if that's so then wouldn't the outside diameter also make a difference? For example, I've got two different 3/16" i.d. vinyl lines. One is fat, nearly 1/2" o.d., and the other is skinny, maybe 1/4" o.d. Will the resistance in these lines be different for an equivalent length? Relatedly, does anyone know the resistance for copper (1/4" i.d., 3/8" o.d.) for times when I want to use my jockeybox?

4. Is lift canceled out by drop? In addition to line length and width, you also have to consider whether or not you are pushing the beer uphill-- what Dave calls "lift" (it takes 1 psi to push the beer up two feet). From my college physics I remember that the work done in a closed path is zero (because the work going up is canceled out by the "negative work" going down). Does beer work the same way? For example, if my line goes up two feet, down three, and then back up one, is the net contribution to resistance zero? Or is the resistance gained by going up different than the resistance lost by going down? If the answer is a net of zero, then all I have to worry about is the height of the tap; if nonzero, then I have to worry about all the bobs and dives that the line takes.

All in all, a good chapter in a good book. Now if I can just get these questions answered

Wow! A "real" pumpkin ale. That I would have to see. Is he going to leave the seeds? He could take them out, malt them, and then use them in the brew! Has anybody ever fit an airlock to a pumpkin? Wow! We may be the midst of a brewing revolution. Call Papazain! He now has a story to rival his "cock ale" recipe! ;->

Seriously, I also doubt it will work. But what the hey? How much wort will fit into a pumpkin? 1 Gal max. I think it would be a great novelty if it works. We all brew serious brews most of the time, but also need time to relax, don't worry, and make that funky homebrew we have always dreamed about.

Good Day,

-Brian

>I would try to brew up something sans barley. I have looked at a few
wheat
>beers, but they all contain some percentage of the forbidden grain. I
have not
>yet found a recipe that is 100% wheat.

I beleive M&F has wheat malt extract - not sure if there's any barley in
it.
(I think it said 100% wheat malt...)

The (consensus on) the problem is: you need the barley husks to help
with the sparge bed. Try grinding up a mash of 100% wheat malt (it
does have plenty of enzymes if it's fresh & made right), and do
anything you have to to get the runoff out. stir like crazy; squeeze
the sparge bag; don't recirculate. Afterwards, let the runoff
settle, and siphon off of the particulate. (the procedure works
well for stuck sparges, put you don't get quite the efficiency).

Date: Thu, 29 Oct 1992 00:04:54 -0700
From: walter@lamar.ColoState.EDU (Brewing Chemist Brian Walter)
Subject: Barley-Free Brew

In HBD1K Randall Holt queries,

Are there any extracts which are 100% wheat? (paraphrased).

In reply, (and I may be wrong), but I have always heard that the IREKS Bavarian Wheat malt extract is 100% wheat. It comes in big cans, 7 or 8 lbs I think, it has been awhile. I brewed a couple wheats with just a can of this, few ozs hops, and of course the WYEAST Bavarian Wheat yeast. They turned out well. As I said, I may be wrong on this, (in which case I will login Thur to a mailbox full, I am sure!).

On a lighter side, (and I don't suggest this for your roommate!) While most American "beers" (BudMillCoors) are very low in barley content, they too are probably above your roommates allergenic threshold. But, there may be hope! According to the Fort Collins Coloradoan (Yes, the city with the BOMB at the Gore Speech, oh joy) on Sun 4 October, 1992, Coors is trying out a new "CLEAR" brew. The article says pretty much nothing substantial about it, brewing wise. It is called Zima ClearMalt, and is being test marketed in Nashville, Syracuse, and Sacramento. According to Peter Coors himself, "Customers have described Zima's taste in different terms, ranging from a gin and tonic mixed drink to Sprite. But, with hops and malts, it qualifies as a beer, and has a similar alcohol content of about 5%.

I believe they are making it mostly from high fructose corn syrup. As I understand it, Coors used to use cracked rice from CA to bastardize, uh, I mean, as adjuncts when they brewed. Supposedly they have found a way to use enzymes to process high volumes of corn into high fructose syrup. My guess is this is the main ingredient of Zima.

I think it is about time for an American Purity Law. How about you? I would venture to say this may make Bud taste heavy!!

Well, enough for now,

Good Day,

- Brian

From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: Trouble Getting Wyeast Going

Perhaps Micah or one of the other yeast gurus can give me some pointers. I recently started actually buying envelopes of Wyeast, rather than using an Nth generation culture I got from CAV@bnr.ca. While the Nth generation stuff (1098) took off like a rocket whenever I used it, my 1098 from the packet was essentially dead. It swelled the packet, and I pitched it into a starter and it seemed to ferment there, although the krausen was rather weak. But, nothing at all in the brew. Roused the brew, still nothing. Suggestions?

Actually, one relevant point was that the packet was 7 months past its code date. Is Wyeast that sensitive to shelf life? Should I use a yeast nutrient in the starter? Is it worthwhile to actively aereate the starter during the entire growth phase, eg by using an airstone/airpump system? Comments by email or posting if you think it worthwhile. thanks. P.

Date: Thu, 29 Oct 92 10:07:01 EST
From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>
Subject: Micah's Traquair House Ale recipe

Summary: Yum!

As my first all-grain batch, I brewed a batch of this in August and bottled it last night. Since my mash/lauter picnic cooler wasn't big enough for the whole recipe, I made a half batch (2.5 gallons). Particulars (if you don't remember the original):

9# British (M&F) pale malt 2# (M&F) crystal malt
1# toasted malt (350F/10min)
2oz roasted barley .5# chocolate malt
1 oz Northern Brewer @ 6.8% (75min) 3/8 oz Tettnanger @ 4.8% (15min)
1/2 tsp gypsum in mash water
Wyeast 1056 in 2c (1.020) DME starter.

Strike pale, crystal, toasted malts with 4 gal H2O @ 170F (160F initial mash temp), 45 minutes later, temp was down to 152F. Add roast grains, "mash out" with 1.5gal @ 200F (but only went up to 160F -- obviously I need a better mash tun). Take first runnings only (2 hours to collect ~4 gallons -- first time with this lautering system, too.) Boiled for 75 minutes total. Left with approximately 2.5 gallons (closer to 3, as it turned out), O.G. 1.094 (temperature corrected). Force cooled to 80F. Siphoned into 5 gal glass primary, pitched yeast. Fermented at "cellar temperature", around 70F.

3 weeks later, racked to 3 gal glass secondary (at this point, I noted that I definitely had more than 2.5 gallons to start, as about 2.75 gallons ended up in the secondary.) S.G. 1.026. The taste was heavenly! Wonderful malt notes in the nose, definitely alcoholic. It sat in secondary for about 5 weeks.

Last night, I bottled. The S.G. was down to 1.020. I added 1/4 c corn sugar for priming, assuming that the fermentation has now basically finished. I got 26 12oz bottles.

Besides bottling, I drew off a glass for immediate consumption (of course!). The malt was less evident in the nose than it was at racking (it may not help that I've got a minor cold, though), but was still there. It looks quite syrupy, but doesn't have a thick mouthfeel (but it's not "thin", either!). Hop bitterness is quite evident, with very little apparent aroma or flavor (see note about cold, above). There is a slight tartness, and surprisingly little sweetness. I'll have to go out and get a bottle of the original now, for comparison.

I'm definitely happy with it.

For those of us who are numbers freaks, here are some:

#malt in mash: 13
first runnings: 4 gal @ 1.066 (16 Plato)
Extract: 21pts/lb/gal (3gal@1.094 after boil gives 22pts/lb/gal)
OG: 1.094 OE: 23 Plato
FG: 1.020 AE: 5 Plato
RE = 0.1808*OE + 0.8192*AE = 8 Plato (G. Fix, HBD 880)
Attenuation: 65%
Alcohol: 8% w/w or 10% v/v
Calories/12 oz = (6.9*A + 4.0*(RE-0.1))*3.55*FG = 320! (G. Fix, HBD 880)

Subject: Re: Plastic Kegs

I've got one of these plastic kegs, they are fantastic! I brought it back from England (So, said the custom's officer as I passed through the green line with my Irish wife, just what exactly it that!) though it was manufactured in the US (Ohio). You do have to be very careful with the seals and I've found that unless you orientate the floating ballcock properly you'll get a lot of foam.

Date: 29 Oct 1992 10:08 EST
From: dab@donner.cc.bellcore.com (dave ballard)
Subject: snpa yeast/plastic petri dishes

Hey now- Just a little addition to the info on snpa yeast longevity. I have about 4 bottles left from a case given to me for my birthday in April. They were in the basement until about 3 days ago when I moved them up to the fridge. Last night I drank a bottle and dumped the dregs into a glass jug with about a quart and a half of apple cider that had started to turn. This morning there was a big foamy head not unlike a normal batch of brew pitched with 1056. Not too shabby for some spent yeasties that have been laying in the bottom of a bottle for almost a year.

Also, did we ever get a definitive answer (not that there is such a thing around here) about how to sterilize plastic petri dishes?

thanks

dab

Subject: Minnesota Homebrewer's Festival

Here are the results of the Minnesota Homebrewer's Festival and Competition, held last weekend at Sherlock's Home Brewery in Minnetonka, Minnesota.

This was the first year of what we hope will be an annual event. Special thanks to all of the Chicago area judges who came up to help.

There were 280 entries total.

Best of Show was awarded to Mark Konings for his Brown Ale by BOS judges

Michael Jackson, Steve Hamberg and John Isenhour.

Barley Wine 7 entries

1st - Brian & Linda North, Brewtown Brewmasters
2nd - Ken Kraemer, Minnesota Brewers Association
3rd - Jerry Bourbonnais, Boreal Bottlers

Belgian Style 14 entries

1st - Ken Kraemer, Minnesota Brewers Association
2nd - Tim Hultman, Northern Ale Stars
3rd - Kelly Kuehl, Minnesota Brewers Association

Brown Ales 17 entries

1st - Mark Konings, no club
2nd - Donald L. Seipke, Northern Ale Stars
3rd - Tom Burton & Peggy O'Neill, Prairie Homebrew Companions

English Style Pale Ales 35 entries

1st - Rick Larson, Minnesota Brewers Association
2nd - Joe Dols, no club
3rd - Todd Orjala, no club

English Bitters and Scottish Ales 29 entries

1st - David Williamson, no club
2nd - Patrick H. Lewis, WIS-SOTA Area Homebrewers
3rd - Andrew R. Ruggles, no club

Porters 27 entries

1st - Tony Lowe, no club
2nd - Carl Eidbo & Jim Gebhardt, Prairie Homebrew Companions
3rd - Neil Gudmestad & Ray Taylor, Prairie Homebrew Companions

English and Scottish Strong Ales 4 entries

1st - Peter Klausler, no club
2nd - John Burke, no club
3rd - <no 3rd place awarded>

Stouts 40 entries

1st - Lillian Gulbrandsen, no club
2nd - John Bjork, no club
3rd - Mike Kamrad, no club

Bock Beers 15 entries

1st - Andrew R. Ruggles, no club

2nd - Todd Orjala, no club
3rd - Mike Valentiner, Minnesota Brewers Association

Subject: Dryhops/Oats/100% wheat extract

Barry_Gillott asks:

> I have a dry hopping question for y'all: Do I need to be concerned
> about sanitation of the hops? Can I just open a package of plugs and
> drop one in? I assume that the alcohol present after initial
> fermentation will provide some degree of protection, but... enough?

I don't sanitize my dryhops in any way (just plunk them into the
fermenter 7 days before bottling) and have not had any wild yeast or
bacterial problems.

Sandy Cockerham

> Can someone give this extract + adjunct neophyte brewer some more
detailed
> information on exactly what to do with oatmeal? Is it possible to put it
in
> something other than a stout and not have a bizarre beer?

You will have to mash the oats -- just using it as a specialty grain
(steeping) will give you *oatmeal* -- a real mess.

Randall Holt asks:

> I have a roommate who is violently allergic to barley (very sad), and
thought
> I would try to brew up something sans barley. I have looked at a few
wheat
> beers, but they all contain some percentage of the forbidden grain. I
have not
> yet found a recipe that is 100% wheat.
>
> As yet, I have not plumbed the mysteries of mashing, but as no
commerical
> wheat-only extract kits seem available, this would be as good an excuse
as
> any to get started.

Ireks makes (what they claim to be) a 100% wheat malt extract in 6.6 lb
cans.

I've brewed a batch that contained only the can of Ireks and an ounce of
Hallertauer hops and the resulting beer was quite good (although I think
I scorched it in the kettle -- if yours comes out very dark, please post)
.

```

Correct me if I'm wrong, but digest #997 is the first I've heard that you stir the grain bed **DURING** the sparge. I recall from one of your first posts, that you have a bowl sitting (partially submerged) in the top of the grain bed into which you pour the sparge water. This seemed to imply

to me that you were not stirring. I also believe that you had mentioned that you used a knife or skewer of some kind to poke holes in the grain bed

to restart the runoff if the sparge got stuck (I'm not 100% sure, perhaps this was someone else). The reason this restarts the sparge is because poking things into the grain bed *creates* channels -- *direct* routes to the outlet.

> The unique screen pickup in this system does not demand a well settled grain

> bed to provide a clear run-off. Therefore the entire mash can be thoroughly

> stirred and mixed at regular intervals during the sparging process.

This

> breaks up any channels that may have developed and redistributes the mash

> within the water column. I suspect that this would actually provide a much

> MORE effective extraction regime then depending on the number and location of

> outlet points.

I had a personal email conversation with Chip Hitchcock in which I wrote the following regarding this same issue:

korz>Stirring the grainbed while the runoff is being taken will only korz>accentuate the channelling -- the sparge water will fill the "gorge" korz>created by the spoon or paddle, quickly making it's way down to the korz>outlet at the bottom. Stirring, then taking runoff, then stirring, korz>then taking runoff would minimize the problem of stagnant sparge water,

korz>but is certainly not EASY and will give you the cloudiest runoff you've

korz>ever seen. I plan a direct comparison of several systems, all with korz>the same mash *cycle* (unless I can find a way to make a mash big enough

korz>-- I can't with my equipment, maybe I can borrow a 30 gallon pot, a korz>Cajun Cooker and a canoe oar from somewhere).

chip> I can see that stirring would make a channel, but I would / think/ that

chip>the channel would be moving such that sparge water would still get to most

chip>of the grain.

korz>If the runoff valve was off, the stirring would just, as you say, be moving

korz>the sparge water around, getting the most out of the grain. If the valve

korz>was open, however, just the sticking of the spoon into the grain would

korz>cause a channel to form and the sparge water would all run down along

korz>it. Picture a lauter tun full of set jello. A knife is stuck into it

korz>and moved around in a circle. The slit left in the jello is the channel.

korz>If you were pouring water on top of the jello, you can see how it would

korz>prefer to go down the slit as opposed to forcing its way through the korz>jello itself. Granted, this is an exaggeration and the grain is more

korz>permiabile than set jello, but I just wanted you to picture the channel

korz>(the channel sticks around for a while -- once the water finds a way
korz>through the grain, it wants to take that same path).

> What seems to make this point so hard to grasp is the fact that the
other
> systems all have large spaces under the grain bed that must be cleared
of
> turbid wort before sparging can actually begin. Wort is recirculated,
there
> are painfully complicated systems for flushing these areas out and
endless
> discussions about how much wort must be recirculated to get it to work.

No complicated systems are needed. Draw off a quart or two and dump it
in
the top. The reason for the turbid wort is usually a too-fine a crush.
A rollermill (such as the modified Mercado Mill or yes, the infamous
MALTMILL)
is virtually essential to getting a good crush with a minimum of flour.

> The EM system runs clear after only a few ounces are drawn off
initially and
> continues to run clear even after thorough stirring of the mash.

It seems that if this needs to be done multiple times, and the first few
ounces are turbid each time (which I'm quite sure will happen), the
amount
of turbid runoff can add up, no?

> I have only heard from a handful of people who have tried my process
but so

> his/her favorite lautering device over here and do a side by side mash,
under
> controlled conditions, to put to rest the notion that simple things
just
> can't work.

Starting with a properly-crushed malt, it seems to me that a "start it
and
just add sparge water system" is simpler than one which requires
stirring.
Agree with you that a simple lautering system with a minimum of expensive
equipment is the best solution, so what's simpler than a couple of
buckets
with some holes in one -- you can even get the food-grade buckets free
from bakeries.

Nevertheless, perhaps the only way to resolve this is experimentally.
We should, for the good of homebrewing, compare these systems and report
back. We'll have to meet on neutral ground of course ;^).

Subject: SNPA Comments

In my haste to post a summary of the responses I received for my requests for information on the SNPA yeast, etc., I neglected to include the authors names that should have accompanied the comments. My apologies to the authors, and I therefore post:

Phillip Seitz (0004531571@mcimail.com) went to a Sierra Nevada tasting meeting and posted the OG, FG, grains and hops.

Tony Babinec (tony@spss.com) described the differences between the bottle and draught versions, provided a sample recipe, and provided the comments section.

Rick Larson (rick@melkor.uucp) was kind enough to compile and forward the above information. He also forwarded the recipe posted, which looks to be the best of the lot.

I also received tidbits of information reflected in the posting from other sources, too numerous to mention.

One last thing, apparently many folkes disagree with my neo-Gaelic spelling of recipe at the top of the recipe :). I'll put aside my Goidelic origins and promise to use the US version from now on.....

Thanks again.....

Subject: powdered brew

It's not homebrew, but maybe JS can freeze-dry some of his low alcohol brew and have another product to push :-). From Canoe magazine:

South Hills Dry Beer Flavored Dry Beverage, consisting of "malt and dried-beer extracts". It makes a modest head, and "packs enough carbohydrates" to justify drinking it (sounds tasteless). A 1/2 oz. packet makes an 8 to 10 oz. serving. Add vodka/grain alcohol to taste. \$.99 each. South Hills Dry Beverages, 765 Mimosa Ave. Eugene, OR, 97405, 503-343-3558.

I've got no interest in South Hills, and only a curious interest in their dry beer.

Subject: CP fillers, cooling fermentors

In HBD#998, Jay Marshall asks:

>A question to those of you who keg...

>If you want to put some of your wonderful keged brew into a bottle for
>consumption elsewhere, what methods do you use? I am just starting to
>keg and would still like to be able to take some along occasionally.

I strongly recommend using a counter-pressure bottle filler. When a C-P filler is properly used carbonation of the beer is maintained and oxygen is virtually eliminated from the bottle. They are simple to use and maintain and are the method by which almost all commercial carbonated beverages are packaged.

>joe

I have had some experience with big batches and one of the problems that has to be overcome is temperature control of the fermenter or its surroundings. It can be difficult sometimes to keep the temperature low enough but when things get to cold it can be even more of a pain. Your 40 gallons of liquid is a great big thermal flywheel and it will take quite a while for it to warm up, so just be patient. Low 60 won't hurt the yeast but it may take a while in recovering. Don't try to heat things up rapidly it will cause problems.

If you or anyone else out in hb land is planning on brewing big batches you need to come up with some sort of temperature control. I built a fermentation room (heavily insulated closet type room in the shed that I brew in) and use an A/C with a Hunter air stat to control it, it works great and didn't cost to much.

Also, I don't know what shape your fermenter is but that can effect fermentation efficiency as well. There is a lot of info on fermenter design in the commercial brewing texts, check the local library and with the MBAA for reprints.

From: bliss@csrd.uiuc.edu (Brian Bliss)
Subject: presidential beer jeopardy

One of my more important responsibilities here is the keeper of the happy hour list. This involves addition/deletions of name, and, of course, the weekly mailing on friday. Well, I came up with a good one this week (actually, I wrote last wee), and it was suggested that I post it to a more public forum for your entertainment:

Emcee: Ladies and Gentlem, will you welcome the host of our show,
Mr. Art Fleming!
<cheers>

Art: Thank you, Thank you. Today on the show we have three very famous people. May I introduce to you, on the left, Gov. Bill Clinton! In the center, we have independent presidential candidate Ross Perot! And on the Right, we have President George Bush!

[They had to put Perot Between Bush and Clinton to keep them from fighting:-) Also, did you notice in the second debate how they had Bush on the left and Clinton on the right? - ed.]

Art: Gentlemen, the categories for today are...

"Beers"! ...

"Bars"! ...

Clinton: No "Women" Category?

Art: Just a second, we aren't finished yet, the third category is...
"Women"!

Mr. Perot, you won the coin toss. [A 3-headed coin?]

Please choose a category.

Perot: I'll take "Bars" for \$100

Art: And the answer is: "A Pint of Foster's costs \$2.90 at this..."

Perot: BUZZ! What is the Central Tap?

Art: That the correct question! \$100 to you, Mr Perot...

Perot: Aw, chicken feed. You know, I've been doing some research, and the Central Tap only Pays \$122 per keg for Fosters.

Now that works out to just \$1 a pint. That's a 190% profit!

Even if you figure in labor and overhead -

Art: Please pick a category, Mr. Perot.

Perot: I'll take "Beers" for \$100.

Art: "This Bostonian lager beer was the winner of the Great American Beer Festival 3 years in a row"...

Perot: BUZZ! Hmmm. Let me take an opinion poll of the audience.

Who thinks -

Art: 3 seconds, Mr. Perot.

Perot: uh, Budweiser?

Art: I'm sorry, that will cost you \$100. Would any of the remaining contestants like to try?

Bush: BUZZ! What is Samuel Adam's Lager? Such a patriot, Sam Adams, I really identify with him...

Art: That's the correct question...

[For those of you who don't know, the Great American Beer Festival (GABF) used to be held in a big hall, with each brewery having a table, serving samples to the public. Each guest was allowed 1 vote as to what he/she thought was the best beer when they were finished. The tables were originally arranged in alphabetical order, so "Adams" was the first beer most people tried. There were so many breweries present that most guests could only sample a few, but nearly everyone tried "Sam Adams". Anyway, it is only fitting that Bush respond correctly since he has so much

experience rigging elections. - ed.]
Art: and that's \$100 for you, Mr. President. that puts you out
in front early on. Your turn to pick a category...
Bush: I'll take "Bars" for \$200
Art: "Bars" for \$200, and the answer is: Happy hour will be
held at this bar on Friday the 30th, at 6:00.
Perot: The Central Tap?
Art: Your reponse must be in the form of a question, like it
usually is, Mr. Perot.
Perot: What is the Central Tap?
Art: That's correct. That puts you back in the race.
Perot: Let me say that if you show up at happy hour, that I will
be showing you exactly what happend to your beer dollar -
Art: Please choose a category, Mr. Perot.
Perot: "Beers" again, for \$200
Art: This traditional English ale is kegged before fermentation
is complete, and can be characterized by weak carbonation -
Clinton: BUZZ! What are bitters? I tried some when I was a student
at Oxford.
Art: That's correct!
Bush: Such Sleeeeeeaze. I tell you, I really can't understand
drinking THEIR beer in a foreign country, especially when
Anheusier-BUSCH is losing millions of dollars in lost
revenue...
Clinton: I only tasted it - I didn't swallow!
Art: Your choice, Gov. Clinton.
Clinton: I'll take "Women", for \$100
Bush: Don't you usually spend more than that?
Clinton: (pointing at Bush with the 2nd knuckle of his index finger)
Mud Slinger! Mud Slinger!
Bush: I most emphatically deny that charge. I have never taken
part in Mud Wrestling, and just the thought of having to
resort to these tactics, um, I mean...
Art: Gentlemen, Gentlemen...
Clinton: If you'll pardon the interruption, Mr. Fleming.
Art: The category is "Women", for \$100. This 1980 Playboy
Centerfold -
Clinton: Who was Dorothy Stratten?
Art: And that's correct, Gov. Clinton. That gives you \$100,
bringing your total to \$300, giving you a \$100 lead over
Mr. Perot, and a \$200 lead over President Bush -
Emcee: BUZZ
Art: And we're out of time, so join us tonight, at the Central Tap,
6:00, where -
Perot: And I'll be buying everyone.
uh, Beer! I'll be buying everyone beer.
Bush: Darn it! Barabara probably won't let me out of the house.
I guess I'll just have one of the Secret Service men [SS men]
keep her "tied up", eh, eh, eh.

P.S. Y'all are invited to show up, if you happen to live in the
Champaign-Urbana, IL, area, or are just passing by.

From: "Robert Haddad" <RHADDAD@bss1.umd.edu>
Subject: Kegging and carbonation

Granted that draft beer should not be as carbonated as the bottled kind.

Nevertheless, I have not yet been truly happy with the level of carbonation in my kegged brew. I have lately tried to chill it a little more, but while that improved things somewhat, the brew is still somewhat still...

I have kegged stout, and various other ales. I prime the beer with 1/2 cup of corn sugar per 5 gal cornelius keg (with about 4.5 gal of brew in it). The pressure in there by party time is about 25lbs.

I recently read on the HBD that hose diameters may have something to do with carbonation, could someone expand on this?
Thanks,

Robert Haddad

From: "Bob Jones" <bjones@novax.llnl.gov>
Subject: Re:Kegging questions

In HBD 1002 Frank Tutzauer asks some kegging questions....

1. What the heck is a "cobra" tap?

Yes it is that black/cheap thing that goes on the end of a line for picnic use. These things are silly, go out and buy a real tap and mount it though your frig wall. Leave the picnic tap in the closet, and use it for picnics.

2. What is line "width"?

Dave is talking about ID here.

3. What's the deal on the material composition of the line?

Line resistance or pressure drop per foot of line is dependent on the material. PVC line is what I use and 3/16 ID line has a drop of about 3 psi per foot. Therefore 4 feet has a 12 psi drop.

4. Is lift canceled out by drop?

Yes, all you have to worry about is the height of the tap. I don't think it is that critical in a home system. It sure is in a pub where the beer may be pushed up from the basement.

I wrote a short article in HBD about a month or so ago that explains some of the details that Dave covered in his talk. These techniques have vastly improved my draft system.

From: arf@ddswl.mcs.com (Jack Schmidling)
Subject: Conversion Efficiency

To: Homebrew Digest
Fm: Jack Schmidling

Much is made of conversion/extract efficiency. If the brewer's numbers agree with currently accepted numbers, one can brag about it, if not, one is forced to make all sorts of excuses to avoid ridicule or worse yet, lie about it and cause no end of frustration for beginners.

The most important thing to keep in mind is that the variables involved are many and not only difficult to control but even more difficult to measure accurately.

The bottom line is that it is only an INDICATION of one's process quality and far more a test of one's measurement skills and equipment.

As one simple example, this weekend I compared the graduations on a number of beakers and flasks in my lab and measuring cups in my kitchen. The results were amazing.

I noted some of the beakers were labeled "approx" over the graduated scale." I had always assumed this applied to the capacity and not the overall calibration of the graduations. WRONG! I compared these with some others marked +/- 5% and the difference was a staggering 15%.

I performed the same tests on some kitchen measuring cups. The Pyrex brand was dead on and the "Ovenproof" was off by about 12%.

This may seem like trivia but in order to arrive at a meaningful result, every measurement error must be included in the result. Most people do not brew in beakers and flasks but some of us do use them for test and measurement purposes and it is useful to be reminded that what seems obvious is not always so.

I note with interest that Al K has defined percent efficiency as the extent to which actual extract agrees with the maximum possible as put forth by one author with a particular type of malt.

I find this a bit like defining the time it takes Santa to make his rounds based on the diameter of the author's chimney.

I suggest that we should stick to the points/per pound/per gallon to avoid one more variable that just makes the results that much less useful.

It is also useful to point out that the terms extract and conversion are a bit misleading and should be defined more clearly.

I define conversion as the amount of sugar that ends up in the wort after mashing is complete. If one drains the mash tun at this point, the pts/lb/gallon can be easily calculated and this provides an indication of the mashing process, the malt, the water and other variables I probably am not aware of. This would provide the conversion efficiency or ratio.

If one goes on to sparge out the mash and makes the measurements again, one now gets the extract efficiency or the ability to get the converted sugar out of the mash. This now depends on the lautering system and process and has nothing to do with conversion or malt type.

Most brewers only make the latter measurements and the results consequently reflect the entire process and the materials used.

The point of all this is that it is unwarranted to criticise a brewer's equipment or his process or his materials for extract/conversion problems based on end results. There simply is not enough data to make that judgement.

>From: "Bob Jones" <bjones@novax.llnl.gov>
>On the subject of sparge systems, I would point out that if possible you should try to minimize the hydrostatic pressure across the grain bed to minimize grain bed compaction. This can easily be done if you place your outflow slightly below the grain bed liquid level. Crude ascii graphic to follow.....

I won't argue with the physics of the approach but there is a fundamental end problem. You can not empty the tun below the outflow level unless you use a hose to gain the necessary head, at which point, you will be back where you would have been with the outflow on the bottom.

Subject: CAMRA Good Beer Guide Questions

After reading the 1993 CAMRA Good Beer Guide I purchased to prepare for a trip to London Thanksgiving week and have a couple of questions:

1) The CAMRA guide defines a "public bar" as "drink is cheaper" - my question is what is the price difference between a public and non-public pub and for the pubs not listed in CAMRA, how would one know if the pub was a "public bar"?

2) "Free Bars" are mentioned in the description of bars - what is a free bar and do most pubs charge cover?

Do any HBD's know of pubs not listed in the CAMRA guide one should not miss and of course which pubs serve the consistently best real ale?

Subject: Judging/Wyeast#3056

Rob Malouf brings up what I think is an important point:

>You shouldn't assume that the brewers made no attempt to use the right yeast.

>I have entered several weizens in competetions, all made with Wyeast's >Bavarian Wheat strain, and all with minimal (though noticable) clove >character. In every case, at least one judge responded "No cloves=not a >weizen. Use the right yeast next time" and didn't look any further into the

^^
>beer's other faults and virtues. Since I did use the "right" yeast, this
^^

>advice is less than helpful. Perhaps judges should not assume the worst of >homebrewers. In this case, I know what a weizen is supposed to taste like, >I just don't have the skill to achieve it.

If you think that a judge did a poor job judging your beer in competition, I feel that you should photocopy the judging form and send it to the competition organizer with a note, explaining your dissatisfaction. NOTE that I DON'T mean that you should complain that you thought you should have scored higher. What I do mean is cases like the one Rob mentioned above -- just a number on a line and a comment like "no clove nose." Also, if the judges are abusive, for example, "this beer is awful -- it tastes like urine." Judges who write comments like this should either clean up their act or get out of judging. Its up to us to give feedback to organizers so they can reprimand out-of-line judges and keep them away from competitions if they don't shape up.

For the record, I once used Wyeast Bavarian Wheat #3056, fermented at 68F, and got no clove nose. I have also tasted several Weizens at CBS meetings made with this same yeast that did have a great clove nose. Since this particular yeast is a mixture of two strains, perhaps freshness may be more important as one yeast will dominate if the other is sluggish. The package of #3056 I used was about three months old. Temperature is definately a factor with #3056 also.

Subject: Weizen Yeast, Wheat Beers

In HBD #1002, Rob Malouf (malouf@Csl.Stanford.EDU) replied to Roger Deschner's observations on weizen character:

>You shouldn't assume that the brewers made no attempt to use the right yeast.
>I have entered several weizens in competitions, all made with Wyeast's >Bavarian Wheat strain, and all with minimal (though noticable) clove >character. In every case, at least one judge responded "No cloves=not a >weizen. Use the right yeast next time" and didn't look any further into the >beer's other faults and virtues. Since I did use the "right" yeast, this >advice is less than helpful. Perhaps judges should not assume the worst of >homebrewers. In this case, I know what a weizen is supposed to taste like, >I just don't have the skill to achieve it.

Rob's comments on the Wyeast Bavarian Wheat (3056) are consistent with my own experience and that of many other brewers, namely, it does not instantly impart the signature clove character, at least not at first. Generally, I have found that the cloviness emerges after a couple of months of aging. Of course, even a not-clove-enough-weizen can taste pretty damn good, so this may try your patience! Rob, if you've still got a few weizens hanging around, crack 'em open and compare your tasting notes with the earlier samples. I'd be interested to see if you notice this as well. If you've decided to give up on the 3056, you might try the Wyeast European (1338 -- aka Alt). I know many brewers who swear by this is their weizens. My guess is you have all the skill you need to make an excellent weizen. Sometimes all you need is time or a slight change in recipe or process. How did I find out? I submitted weizens to competitions and got the same comments. I'm not getting them as often now.

Also agreed, judges shouldn't assume the worst of homebrewers, but frankly, since most of us ARE homebrewers, most of us don't. We try to give helpful advice, but we often fall short. Few judges, if any, would even attempt to reverse engineer a beer. In defense of Roger, there are times when the advice you give is generally good, but doesn't apply to a specific case. I judged a lot of beers in Minneapolis, including some of the weizens, and I'd say there were a lot of entries from new brewers. Naturally, this meant

that there were plenty of extract beers brewed with dry yeasts. New brewers also have a tough time with styles, and submit brews in the categories that they think best approximate what they've made. In general, the weizens were clear, refreshing, and under-carbonated. The winner, a dunkel weizen, was quite good. Most of the others would have done better as American Wheats. Unfortunately, the beers with the best clove character in the competition came from the Porter category! Nyaaah!

A final point on Wheat beers in competitions. In many events, beers submitted as American Wheats get lumped together with the German Weizens, and the judging sheets that get sent back to their brewers are full of comments on the lack of clove character. It's nice to see that more events have decided to separate the two, even moving the American Wheat to a subset of American Light Lagers (as in AHA Nationals). When you intentionally brew a beer NOT to have that clove character, you shouldn't be criticized for doing so.

Subject: Flow theory and Keg lines

Many thanks to all the HBDer's who responded to my questions on all-wheat extract and mashing and colored malts.

In HBD1002, Frank Tutzauer asks,

>1. What the heck is a "cobra" tap? He talks about two kinds of taps: "bar" taps and "cobra" taps. One of them requires a 2 psi adjustment, but I have no idea what this cobra gizmo is. My tap looks like the kind that you get on the hand pump of a beer ball. I suppose that if your imagination is whimsical enough, and if you've had enough homebrew, you could say that the tap looked like a spitting cobra, but geez I dunno.

I'm not sure, but I think the cobra tap has a pressure reducer built into the handle. I have a simple bar-style (ball/lock) tap which has similar foaming problems, and a pressure reducing tap which does slightly resemble a cobra. The pressure reducer allows the line to stay at a high pressure, while reducing the final pressure at the tap to prevent high velocity exit foaming. I got my tap from my local Cornelius distributor, I'm not sure what the catalog # is, e-mail me if you need it.

>2. What is line "width"?
>... But by "width" does he mean inside diameter?

He must. No other term is relevant, unless he's making inferences about the compliance (elasticity) of the hose, which for stiff flex-hose has negligible effect when compared to the I.D. for static (non-pulsatile) flow problems.

>If so, why didn't he use this term instead of the ambiguous "width"?

Maybe he's trying to de-jargonize for the engineering impaired.

>3. What's the deal on the material composition of the line? Dave has a table showing the resistance for different lengths and widths of line. No sweat.
>But the resistance for a fixed length/width varies according to whether the line is vinyl or polyethylene (more resistance in vinyl). Why?

Boundary layer slip. When a steady flow is set up along a surface, it is assumed that there is zero flow at the fluid/solid interface.

```

===== tube wall
* (no flow /or low flow at tube wall ) ^
- -----> * |
- -----> * |
- -----> * |
- -----> * |      'Width' or
- -----> * |      (max flow in center ) |      I.D.
- -----> * |
- -----> * |
- -----> * |
* _
===== tube wall

```

In reality, there is a tendency for some small amount of slip. Different materials have different "coefficients of sliding friction", based on physical (roughness/smoothness) characteristics (most chemical characteristics for are lumped in the viscosity of the fluid).

Of course, this is the simplest version. CO2 bubbles will alter the turbulence, and velocity profiles, as will the head pressure etc, and it is in non-Newtonian flow that slip seems to play a large role.

>I can't think of any good reason why the composition of the line would make a difference. Maybe one is more gas permeable than the other, but if that's so then wouldn't the outside diameter also make a difference?

The time scale for this problem makes wall permeability a negligible effect. Material friction coefficient (roughness and smoothness) is more important.

> For example, I've got two different 3/16" i.d. vinyl lines. One is fat, > nearly 1/2" o.d., and the other is skinny, maybe 1/4" o.d. Will the > resistance in these lines be different for an equivalent length?

1/16" vinyl is pretty stiff, and will only be a consideration for the flow if the pressure is somehow oscillating very rapidly.

>Relatedly, does anyone know the resistance for >copper (1/4" i.d., 3/8" o.d.) for times when I want to use my jockeybox?

Not off hand, but all of these calculations are only of use for well defined systems of pure liquids. Elbow joints and tube length between joints tend to complicate things, not to mention dissolved and undissolved CO2 and sugar/carbohydrate content. There are ways of calculating this stuff, but the most practical solution is to make a gross calculation based only on line length, I.D. and head pressure (including height differential) and then take a few measurements at different pressures.

>4. Is lift canceled out by drop? In addition to line length and width, you >also have to consider whether or not you are pushing the beer uphill-- what

>Dave calls "lift" (it takes 1 psi to push the beer up two feet). From
my
>college physics I remember that the work done in a closed path is zero
>(because the work going up is canceled out by the "negative work" going
down).
>Does beer work the same way? For example, if my line goes up two feet,
down
>three, and then back up one, is the net contribution to resistance zero?
Or
>is the resistance gained by going up different than the resistance lost
by
>going down? If the answer is a net of zero, then all I have to worry
about is
>the height of the tap; if nonzero, then I have to worry about all the
bobs and
>dives that the line takes.

You got it. You only need to look at net differences in height.

The only reason you wouldn't, would be if
a) you have pinhole leaks or leaky joints in the system line, or,
b) you are using a material that has anisotropic slip coefficients

Subject: Lincoln, Nebraska/ UN's Center for Biotechnology

Lincoln has a new brewpub called Crane River Brewpub and Cafe, which is owned by Kristina Tiebel and Linda Vesco. Many on this network will know both as top flight homebrewers. So what we have is yet another example of successful homebrewers turning pro. At the AHA conference in June it was suggested that if this trend continues, then by the time the 21st century arrives there will be precious few homebrewers left!

The Center for Biotechnology at the Univ. of Nebraska-Lincoln will have a seminar devoted to brewing on November 11, 1992. I have been asked to give this presentation. I know there are a few people on this network who live nearby. If you have the time, I hope you will stop by and say hello. The seminar is free and open to the public. The post seminar discussions are likely to be good, especially if they are at Crane River with Linda's and Kristina's beer.

>Does anyone have a recipe for a BARLEY-FREE beer (not mead or cider)?

>I have a roommate who is violently allergic to barley (very sad), and thought

>I would try to brew up something sans barley. I have looked at a few wheat

b>eers, but they all contain some percentage of the forbidden grain. I have not

>yet found a recipe that is 100% wheat.

>As yet, I have not plumbed the mysteries of mashing, but as no commerical

>wheat-only extract kits seem available, this would be as good an excuse as

>any to get started.

>Can anyone help me to introduce my roommate to the joys of quaffing ale?

Yes, I beleive that I can help. It is generally thought that malted wheat must be mashed with malted barley in order to get starch conversion, this

is not so. Malted wheat has plenty of enzymes on its own. The problem is that wheat malt has no husk to form a filter bed thus making lautering (the removal and collection of the sugars from the mash) almost impossible.

A solution is to mix whole leaf hops through the wheat malt in the mash to

act as the filter in place of the grain husks. It may take a little more effort to do but will get what you want. This has been used by commercial breweries that make high percentage wheat beers (70% or more).

have fun

From: jim busch <busch@daacdev1.stx.com>
Subject: re:real weizen character

The discussion on real HefeWeizen character got my interest going. The big flavor and aroma that is evident in the best german Weizens is attributable to the combination of esters and phenolics. The esters are typically noted by a distinct banana nose, the best commercial example is Paulaner Hefe-Weizen. The other contribution is the clovey/phenolic character (due to high concentrations of 4-vinyl guaiacol). Aside from using a good mix of Quality Malted wheat and quality german hops, the most important ingredient for a Weizen is the yeast.

The Wyeast strain used for making wheat beers seems to suffer from a variable amount of phenolics (sometimes imperceptible), a complete lack of banana esters, and a most annoying tendency to completely flocculate out. I have made all grain weizens with this strain and been shocked by the stunning clarity of the finished product. The answer, of course, is to use the same strain as that used in Germany: a Weihenstephan Weizen yeast. This strain will produce lots and lots of banana esters (very Paulaner-like) and a nice balance of phenols. The current strain I am working with produces more esters than phenolics, but it is still a nice balance. The other great thing is that this strain doesn't instantly floc out, thereby leaving a normal cloudy/opaque weizen appearance. BTW, this strain is a single cell clone, not a blend of *S. Cerevisiae* and *Delbrückii*!

Since I got on my Weizen soapbox, here are some pointers for anyone trying to replicate a Paulaner Hefe:

For all grain batches, use up to 70 percent Bavarian Wheat malt (or Belgium, I just got mine, so no report on Belgian wheat yet) and the remaining 30 percent pale malt (I still use domestic 2 row for this). Hop with a tiny amount of Hallertau Hallertau (or Hellsbrucker H.). Here are the style guides:

OG 1.047-1.056 (11.5 - 13.8 degrees Plato)
FG 1.010-1.020 (2.5 - 4 degrees Plato)
Alcohol by volume 5.0-5.6
pH 4.0-4.5
Bitterness, IBU 10-18
Color, SRM 3.5-9.5
Calories/12 oz 151-178

And this is what I would suggest:

For 5 gallons:
6-7 Lbs Malted Wheat
2-3 Lbs Pale malt or 6 row malt
1 oz Hallertau (or less!), boil 60 minutes
500 ml Weihenstephan Weizen yeast slurry
1 tsp gypsum (optional, depends on water supply)

Procedures:

Single Decoction Method:

Mash in crushed malt with 1 qt/lb 127-128 degree water. Add gypsum if used. Hold 122-124 for 25 minutes. Pull first decoction, 40% of the thickest part of mash. Heat to 160, hold 15 minutes for saccharification rest. Raise to boiling, and boil up to 20 minutes. Combine two mashes carefully, stirring constantly to avoid scorching. Combined temp should be 147. Rest 20 minutes, then heat quickly to the above saccharification temp, or slightly higher. Rest until conversion is complete. Raise to 170, hold 5 minutes and transfer to lauter tun. Lauter slowly to prevent stuck runoff.

Double Decoction Method:

Mash in at 128, maintain 122-124 for 15 minutes. Divide mash. Rest 15 minutes at 146. Raise to 161, hold until conversion is complete, but at least 15 minutes. Raise to boiling, boil 15 minutes. Combine mashes to result in 152-154. Divide mash again. Raise to 161, wait 10-15 minutes for conversion, then boil 10 minutes. Combine mashes to end up at 165-170. Lauter.

Infusion Method:

If you are going to attempt an infusion mash, keep the wheat/malt ratio at 50/50 until you get used to lautering the gummy mash. Mash in at 126-128. Hold 122-124 30 minutes. Raise to 152-154. Hold 60 minutes. Raise to 170. Hold 5 minutes, lauter.

Kettle procedures:

Boil 40 minutes before first hops are added. Boil 60 minutes after hopping. Hopping is usually in the 3-4.5 g/alpha acid per hectolitre or 1.2 to 2 oz per bbl. Typical hop bills incorporate the addition of two-thirds of the total hops at first hopping, and the remainder at 15 minutes until completion of boil. Alternatively, one-half may be added early in the boil, one forth at 60 minutes and the last one-fourth at 15 minutes until completion of boil. In either case, it is important to not add hops later than 15 minutes until end of boil as this style should not be overly aromatic. If decoction mashing is used, initial hopping may occur at the start of a boil but if infusion mashing is done a 30 minute initial boil prior to any hop addition is mandatory. If this is not done, hop utilization will be poor as the hot break will attach to the hop particles, coating the surface and reducing the extraction rate. Hot trub removal is important. Give the batch a real good stir to generate a whirlpool in the kettle, cover and let stand 20-30 minutes. Draw wort off sides of kettle carefully. Pitch active yeast as soon as first wort runoff hits the fermenter. Keep fermentation temperature below 68 degrees (60-65 is optimum).

It is important to use a decoction mash to break down the high molecular weight proteins and gums that will make lautering a high percentage wheat beer difficult.

This beer can be pushed rapidly through the fermentation cycle and bottled or kegged as soon as primary fermentation is complete (dont bother with a secondary on this style as you want the yeast to remain in suspension as long as possible). Alternatively, rack to secondary, chill to 32 degrees Fahrenheit, hold 3-5 days until clear, raise to 42, add culture of lager yeast and rapidly keg/bottle. This adding of lager yeast is the regular way to brew this style in Germany (and why you dont want to culture yeast from a bottle of Maisel-Weizen). Carbon dioxide levels should be above 6.0 g/litre or 3.1 percentage volume (v/v). This is about twice the normal pilsner carbonation level. If carbonation is achieved by krausening, about 9-15% of the initial wort volume should be added at bottling time.

Happy brewing!

Jim Busch

Subject: Handling liquid yeast

Hello all,

I need some help keeping my liquid yeast in good condition until I can brew. My brew-mates and I were all set to brew this last Sunday when we decided to postpone due to an embarrassing oversight (we forgot to get the specialty grains, oops! One of those days I guess). The next time we can all get together is this comming Wednesday.

My question is, what to do with yeast until then? The packet was started on last Thursday and transfered to a starter Friday or Saturday (I wasn't in charge so I don't know for sure). The starter we're using is pretty basic (only our second time using liquid yeast); some DME, yeast nutrient, and water. So what is a good way to keep those little yeasties hopping until Wednesday? (I realize that by the time I get replies it might too late to do the suggestions but any replies would still be good info to have for the future).

Thanks in advance,
Corby Bacco

Yes, Jack you are right about the final runoff liquid. I guess I wasn't
too clear in my original post. If you have a flexible hose you can just
lower it at the end of the runoff. This way you can have the best of both
worlds.

Subject: lift and drop

>4. Is lift canceled out by drop?

Yes, with a perfect fluid, but beer's not a perfect fluid,
it has a gas dissolved in it.

I imagine that there might be a problem if you had too much lift, the
low pressure on the down side would draw CO2 out of solution and I
don't know if it could be counted upon to re-dissolve before reaching
the tap. The pressure at the tap might be right, but the
carbonation/foaminess could get weird.

Make sense? or am I way off?

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: efficiency, SN yeast, judging

Jack, the problem with your points/pound/gallon efficiency calculation is that it doesn't take into account different grains. If you use all 2-row and I use 2-row, munich, roasted barley, rice, barley flakes, and wheat, we cannot truthfully use p/p/g to compare our efficiency. Some grains/adjuncts have more possible sugar available than others. The only true way to compare is to calculate the percentage of the theoretical maximum.

I've got a batch going with yeast cultured from 2 Sierra Nevada bottles. It is much more active than similar batches made with Wyeast 1056, which is supposed to be the same yeast. Has anyone else had a similar experience, or is this just a fluke?

Re. (mis)judging beer: As much as the AHA tries to standardize it, it is and always will be subjective. Your beer may be perfect, but humans are not. So we have to live with that.

> question about the cooler mash tun. If I make this thing (using the
> ascii graphics from a few weeks ago, can any one tell me which issue it
> was?) will I still need a lauder tun?

No, you won't need a separate lauter tun. One of the nice things about the cooler-with-slotted-copper-tubing-in-the-bottom system is that it's a mash tun and lauter tun in one. During mashing, the copper tubing doesn't do anything. The copper manifold come into play when you're done mashing; you use it to drain the sweet wort from the grain while you're sparging.

> One more question about the cooler. How big does it have to be? I'm
> talking about the rectangular kind with the copper tubing in the
bottom.

It needs to be big enough to hold your grain and the mashing water. For five-gallon batches, this is typically 8-10 lbs of grain and 2-3 gallons of water, for a total volume of perhaps 5-6 gallons. A 10-gallon cooler should be large enough to handle almost anything (except Micah's Traquair House recipe :-). The shape of the cooler isn't really that important.

Welcome to the world of all-grain brewing. I think you'll find the results are worth the extra effort.

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: barley free, wheat ales

Brian Walter beat me to the punch in recommending IREKS 100% wheat Bavarian extract for barley-free beer. I have seen it at Kedco on Long Island. I think it's 3.5 kg. That's 7 lb. 11 oz. and plenty for 5 gallons. I haven't tried the stuff myself, but I got the following wild & carazy idea when I saw the stuff:

- * Mash and sparge about 10 lb grain with porter-style proportions
- * Add a can of Ireks in the boil
- * Lots of Hallertauer and/or Saaz

The result: a dark half-wheat barley wine. The imagination reels!

The question: what yeast to use? Would Wyeast Bavarian be able to take hold in an 1.100+ environment? Presumably it wouldn't be able to finish; one could add champagne yeast in the secondary after 2-3 months.

On a related note (since one might have to use ale, lager or wine yeast for the above) is everyone really so sure that you can't get wheat character from an ale yeast? In 1987 I won best wheat beer at the CABA conference in Toronto with an ale with about 75% malt and 25% wheat malt. I used dry ale yeast (maybe Leigh-Williams? I don't have my notes at work). No doubt, the competition wasn't up to modern standards, Wyeast not then bewing available in Canada (although MeV was; I don't know if they had a wheat beer yeast, though). Nevertheless, the beer had a spicy, floral character; I believe I remember it being clovey. More objectively, one of the best of show judges paid me the following compliment after the awards ceremony: he said he thought the wheat beer was the category winner that best typefied it's style and voted it BOS. Presumably the other two disagreed, as Paul Dickie took BOS with a very fine pale ale. Paul took quite a number of awards in the late 80s, including "best homebrewer in Canada" in '88. I wonder if anybody out there knows if he's still winning ribbons?

Cheers,

Rob (bradley@adx.adelphi.edu)

I agree, I just wanted to explain the efficiency from the source to the final fermentable wort. I don't think that we should get all caught up with numbers. pts/lb/gal is a good measure of how you're doing, but I wanted the person asking the question to understand that with some malts, getting 29 points is a super-human feat whereas with others, you can get 33 points without much difficulty.

> It is also useful to point out that the terms extract and conversion are a

> aware of. This would provide the conversion efficiency or ratio.

That's called the "first runnings" and is also dependent on your mashout temperature (if it's cooler, the runnings will be more viscous and thus more will "stick" to the grain), your equipment and how stiff your mash was (a thin mash -- one with a large water-to-grain ratio will have lower gravity first runnings than a stiff mash -- one with a small water-to-grain ratio).

> If one goes on to sparge out the mash and makes the measurements again, one
> now gets the extract efficiency or the ability to get the converted sugar out
> of the mash. This now depends on the lautering system and process and has
> nothing to do with conversion or malt type.

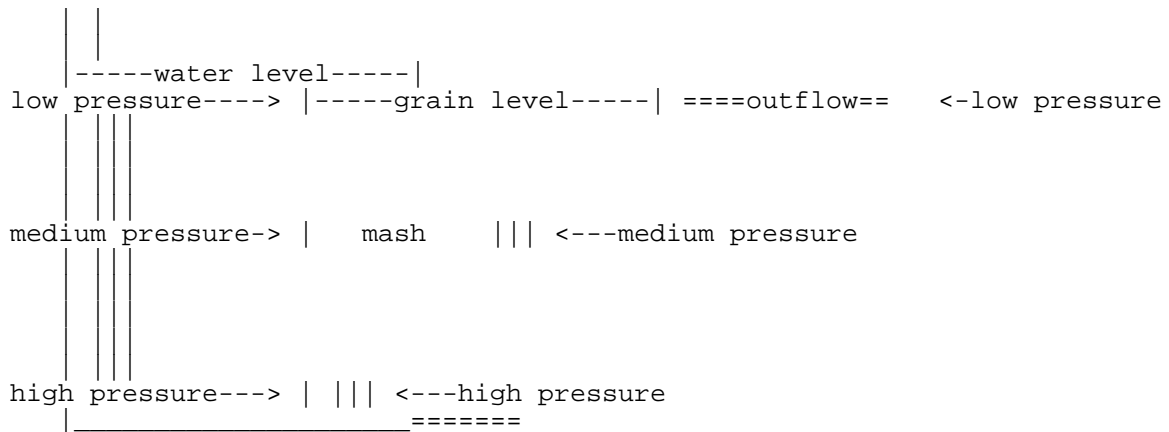

Sure it does. If you only converted 1/2 of the starches, you can only get 1/2 as much sugars out of the grains as you could have if you converted 100% of the starch. Your extract efficiency is bound by (as you called it) your conversion efficiency. Your extract efficiency is only as good as your weakest link which may be either your mashing or your lautering.

> The point of all this is that it is unwarranted to criticise a brewer's
> equipment or his process or his materials for extract/conversion problems
> based on end results. There simply is not enough data to make that
> judgement.

That's why I suggested that brewer's who are getting bad numbers post their procedures and ask for comments. 4000 heads are better than one.

> would have been with the outflow on the bottom.
```

But this is usually what you want to do with most lauter tuns, namely, to keep the grain bed under water (sparge water, that is). When you let the level of the sparge water drop below the level of the grain, the grain compacts and your chances of a set mash are increased by a lot. By keeping the inflow of water at the same rate as the outflow of the runnings, you can do this. The hydrostatic pressure gradient is the same across the grain bed the same no matter what the level of the outflow hose? Back to ascii graphics:

This won't help you keep from getting a compacted grainbed, but it *is* a good, inexpensive way to adjust the speed of your runoff. By the way, adding more hose to the end of the outflow hose and lowering the end of the outflow hose (while keeping the middle of the outflow hose high), will only speed up the runoff again. The speed of the runoff (just like on a siphon) is the difference between the height of the level of the liquid in the source vessel

and the relative height of the level of the liquid in the collection vessel
(or the end of the hose if it's not submerged in the collection vessel).

From: dipalma@banshee.sw.stratus.com (James Dipalma)
Subject: pin lock kegs, 3056

Hi All,

Last weekend I visited a friend who owns a restaurant. The conversation soon turned to beer (*why* do all my conversations invariably get to that topic? :-)), I mentioned that I had just started kegging my homebrew a few months ago, my friend ushered me into a basement room located directly under the bar. There were, I believe, some 20-30 stainless kegs with an assortment of hoses and fittings running up to the bar, and a few empty kegs sitting off to the side. My buddy offered me the empties, gratis.

Of course I grabbed the kegs, but there is one small (I hope) problem. All of my keg hardware is the ball lock type, the new kegs are pin lock. There are threaded fittings on the ends of the CO2 line and the beer tap lines, onto which the gas and beer connects fit. The connects are easy to remove, presumably for cleaning the hoses. It seems to me that I only need to purchase the pin-lock type connects in order to use the new kegs.

So my questions are directed to owners of pin lock kegs, or to those who own both types. Am I correct that the only hardware difference between the two types are the gas and beer connects? If not, what other differences are there? I noticed none of the new ones had a pressure relief valve on the lid. Is there anything different about the care and feeding of the pin lock kegs versus the ball lock?

Next point, I've noticed a thread in recent HBDs regarding the clove character, or lack thereof, in wheat beers that were fermented using Wyeast 3056. This point was discussed in this forum some months ago. One of the points that arose from that discussion was that higher fermentation temperatures seemed to contribute to the desired clove phenolic. Accordingly, I brewed and fermented three batches of wheat beer in the range of 70-75F. I kegged the first batch after two weeks in the fermenter, reasoning that my ales always finished in two weeks at somewhat lower temperatures. I force carbonated the beer, and sampled it two days later. It had a distinct residual sweetness, as if the yeast had not quite finished. I raised the temperature in the fridge, and let the beer alone for another week. The next time I drank the beer, the sweetness was gone, there was *plenty* of clove flavor. For each of the subsequent two batches, I left the beer in secondary for an extra week. Both of these beers were plenty clovey, and the clove flavor actually became increasingly distinct over the weeks it took me to finish drinking them.

My personal theory is that the *S. Delbrückii* (sp?) is somewhat more attentuative than the ale yeast with which it is blended in the Wyeast 3056. After the ale yeast quits the *Delbrückii* continues to break down sugars and produce the clove phenolic, which would explain the twin phenonema of reduced sweetness/increased clove phenolic that I have observed each time I've used 3056. If anyone out there can either refute or substantiate this, jump right in. In the meantime, my advice to those planning a wheat beer with this yeast is to ferment at 70-75F and give it an extra week in the fermenter.

For those of you interested in winning competitions, *taste* the beer before entering it as a German weizen. If it's clovey, fine, if not enter it as an American wheat. :-)

Cheers,
Jim

>Since I did use the "right" yeast, this advice is less than helpful. Perhaps judges should not assume the worst of homebrewers. In this case, I know what a weizen is supposed to taste like, I just don't have the skill to achieve it.

It is with great fear and trepidation that I bring up the obvious again but just perhaps, the politically correct yeast was at fault. All the skill in the world can not overcome bad yeast.

>From: dab@donner.cc.bellcore.com (dave ballard)

>Also, did we ever get a definitive answer (not that there is such a thing around here) about how to sterilize plastic petri dishes?

This provides a segue into another of my crusades. It's called THROWAWAYAMERICA. I put plastic petri dishes right up there with Bic lighters, hamburger clamshells and disposable cameras.

I have been using the same Pyrex petri dishes, off and on for 25 years and the idea of throwing them away after every use brings to mind one of the justifications for salughtering several hundred thousand Iraqis.

I would think that you could sterilize plastic ones by soaking them in bleach and rinsing them in clean tap water rather than throw them away. My guess is that you could get buy that way for the type of culturing we do for home brewing.

The preferred approach is to use glass ones, the problem these days seems to be getting them. I just received a catalog from Markson, at someone's suggestion and they have just about anything you would want in lab glassware, except of course, petri dishes.

Glass petri dishes seem to have disapeared from the market place. If anyone knows of a source, please post it and try to talk some sense into your friends who throwaway plastic ones.

js

p.s. Since writing the above, I went back to the Markson catalog and found I

had only read enough to be dangerous. In addition to the disposable polystyrene petir dishes, they offer to other plastic versions, including a "Polycarbonate, M-X271919, transparenc, reusable and autoclavable. They sell for \$36.75 for a package of 10. That is competative with Pyrex and probably a good alternative. Their toll-free number is 800 528 5114.

I would also insist that anyone you purchase cultures from, use these reusable dishes. They're three times the cost but will last forever.

jjs

sorry bout the subject but it would cost me 4 cents to check out, edit it and check back in and pennies do make dollars.

>Comments by email or posting if you think it worthwhile. thanks. P.

I say that it is very important that you use yeast nutrients in starters.
As to the Wyeast culture, I don't know their claimed self life but I
do know that duds and screw ups can happen. When I get a new Wyeast
package I grow it up and make certain that it has no unacceptable
problems.

If it proves good I will brew with it and take the yeast from that
batch, wash it and store it as a master culture in slurry form. From
this slurry I will take yeast to make my pitching cultures. The yeast
seems very stable in this slurry form (refrigerated) and this method
eliminates reusing the yeast into exhaustion while still working from
a known source. (and no I don't blindly trust Wyeast)

If you use forced aeration be careful it can help to things
other than your yeast. It is difficult to sterilize to air being used,
and clean may not be enough. When trying to optimize yeast growth one
walks a thin line in that what is ideal for the yeast is also great
for many unwelcome micro-guests.

micah 10/30/92

I would like to say that I have encountered this Zima clearmalt
beverage. I have to say that I find this to be a very disturbing incident
in the light of the neo-prohibitionist movement. I attended a local
social
event this weekend where this Zima was being promoted by the coors
people.
I overheard many, very positive responses to the Zima including the
lightest
beer yet, this is even better than Keystone, and from a woman who didn't
like beer but liked Zima because it didn't taste like beer. If this
product

is to be marketed as a beer this could be a bad trend. I believe that this is part of the declared mission of the BATF (Bureau of Alcohol, Tabacco and Firearms) to reduce alcohol consumption in the US by 10 percent this decade. It would seem that some segments of the brewing industry are moving to help expedite this. From the taste of this clear malt beverage, which is alcoholic, if the alcohol were removed you could not tell. In fact if the flavour were removed you could not tell. I see this as another move by the big companies to tell the masses that less and less is better. Perhaps I'm being paranoid but it seems that this is just another indicator of trouble ahead for those who like to appreciate beer with flavour.

From: dewey@sooner.ctci.com (Dewey Coffman)
Subject: Brewpub in Oklahoma City(Report).

I went to Bricktown Brewery in Oklahoma City this weekend. It opened three weeks ago, Oklahoma passed a Brewpub law where Texas can't. After the elections are over, I'll be beating on my Senators & Reps.

It's a very nice place, almost more of a restaurant than a Brewpub. The equipment alone is prominently displayed behind glass walls in the restaurant. I'd say equipment cost is 1 million+, lots of kettles, secondary fermenters, wort coolers and refrigeration units.

They only had two beers out of the five on the menu ready: I had them both, the Copperhead Premium Ale and the Santa Fe Rail Ale. My opinion here is that they serve the beers too damn cold, probably < 40 degrees. The Copperhead was fuller bodied with the Santa Fe probably closer to a lager. Note: Oklahoma has a law where this beer and MOST others on 3.2% alcohol content.

Other beers on the menu:
Read Brick Ale
Bison Wiezen
Landrun Lager

The Brewpub is more of a "Brass & Fern" atmosphere than pub-style, lots of starched shirts, course I went there on Halloween/Saturday night, so it could've been an "off" night.

Prices were \$2.10 for a tall draft, probably a sixteen ounce pint. I reccomend the place, it's very accessable from either I-35 or I-40 going through OKC. Take the downtown exit.

Subject: HBD Field Report #3: Two Belgian Breweries

BRASSERIE LA BINCHOISE (Binche)

There are three people who work here, brewing beer in 1,500 liter batches. All their beers are category S beers in the Belgian system (ie above 1.062). This is without question my favorite Belgian brewery.

They make: Marie de Hongrie, a darkish brown, highly aromatic ale of 8.5 ABV containing pale malt, Munich malt, and a small quantity of torrified malt for coloring; Fakir, a slightly less strong but equally aromatic blonde ale; Ours (French for bear), using wild honey for 2/7 of its fermentables; Speciale de Paques, a stronger but thinner-bodied blonde for Easter; and my favorite, Speciale Noel (for Christmas), a rich, highly aromatic brown beer, and rather orangey.

All use the same yeast, which has a distinctive flavor that reminds me of spice- and carrot cakes. It comes from a bank and is used six or seven times before replacement, with continuous checks for infection. Except for Ours the beers are all-malt; none contain candi sugar. Mashing is at 65 degrees C, or 150 F. I didn't catch the hopping rates (all this transpired in French), but by American standards they were rediculously low. Isinglass is used for fining, which I gather is unusual in Belgian brewing. In addition, the brewery adds essential oils to three of the beers at bottling (Marie, Fakir, Noel), giving them a fuller flavor and aroma. One of these oils is obviously orange, but I can't identify the others and the brewer was reluctant to tell all.

Yeast is also added at bottling, along with 1% beet sugar (i.e. 1kg sugar for every 100 liters of beer). This is 10 grams per liter, as opposed to the standard 6.3 grams/liter (3/4 cup @ 160 grams/cup). Note also that beet sugar has more carbonating potential than corn sugar, if I'm not mistaken. At the time of bottling a quantity of yeast (sorry, didn't find out how much) is added to a sugar solution and immediately mixed into the beer for bottling. The bottles are undergo a second fermentation in a specially heated room at 20 degrees C (70 F).

The brewery itself is located in a former maltings, of which only a portion is currently in use. It has three fermentation tanks, and they use the same \$0.89 fermentation lock on their 1500 liter tanks as I use on my plastic bucket. They use returnable champagne-type bottles for bottling, meaning that storage and bottle cleaning occupy the bulk of their space and time. They're working on a nice tasting/reception area located just underneath the old malt silos.

Coordinates:Faubourg St. Paul 38
B-7130 Binche
Belgium
064 / 33-61-86

BRASSERIE LA CARACOLE (Namur)

People from Namur have a reputation for speaking slowly, and their semi-official emblem is the caracole, a type of snail.

This is the smallest commercial brewery I've seen, making 400 liters at a time. Our guide was the business expert of the four-person partnership--though his brewing knowledge was substantial--and the brewery is located in his wife's grandmother's garage. They have to empty the garage before they

can work, but they manage to fit in a kettle and mash tun, as well as several large closets for fermenters. At the moment all the beer they produce is sold at our guide's store, La Table de Wallonie (Place de Marche des Legumes, Namur), but the partnership has just signed to buy a bigger brewery in Ciney.

Three beers are made: an amber ale, a brown ale, and a white beer. The first two are category S beers, brewed with pale malt and various special malts. The brown ale (16 Balling, +/- 1.064) instance, has biscuit and aromatic malts for flavor (the latter provides aroma, too) plus a small quantity of torrified malt for coloring. This also has a some candi sugar, allowing the brewer to raise the gravity of the beer in his kettle without having to boil more liquid (in effect, this helps him get the most out of his 400 liter capacity). He recommended not using more than 15% special malts or sugar in a recipe.

The white beer is made from pale malt and raw wheat only. He said using raw wheat is just a matter of getting good grain, properly crushed, and of handling it carefully. Since Belgian whites are a bit tart they drop the PH of the beer to 4.4, and various spices are added as well. Among these is dried orange peel, mixing sweet and bitter varieties. Our guide recommended a maximum of 1 gram dried orange peel per liter.

Since the brewery has no lab facilities, they buy their yeast from a bank at Louvain-la-Neuve every time they brew; this adds \$0.24 to the cost of every 75 cl bottle. The good news is that they can order exactly the volume of yeast they want, at specified cell counts; the bad news is that the yeast medium is jet black, wreaking havoc on their efforts to brew light-colored beer.

An upward step mash is used, with sacccrification at 63 degrees C (145 F), though he may have said that they use a two-step sacccrification (sorry--I had a cold and didn't catch everything). Various noble hops are employed, particularly Goldings and Saaz. No yeast is added at bottling--only sugar. Bottles age for three months in ANOTHER garage before sale.

NOTES

1) Corks. Both these breweries use champagne-type corks, which are not sanitized before use. The Binchoise folks said that cork doesn't offer anything for microbes to live on, and that such precautions aren't necessary. Neither brewery has ever had any problems.

2) Bottles. Binchoise's used bottles are washed in caustic soda prior to bottling. Caracole uses new bottles only, and rinses them with the equivalent of a bottle washer just prior to filling.

3) Fermentation temperatures. Neither brewery is fermenting at high temperatures; in fact, we had to wear sweaters and jackets in both places. This is more attributable to the cost of heating than to any particular fermentation philosophy, but it's clear that the beer was being fermented in the low 60s or so at most. Caracole does try for 70F, and has space heaters in its fermentation closets.

4) Torrified malt. I'd never heard of this stuff before, but I did see it. It looks like plump barley roasted to a nice coffee brown. It certainly has a roasted taste, but both brewers use it for coloring only and try to avoid the flavor. The grains are NOT "popped" like popcorn.

5) Orange peel and essential oils. My local food coop can order dried orange peel from Frontier Fruit and Nut--a major health-

food store supplier--for \$4.00/lb plus store markup. It also has essential oils in stock; a 15 ml bottle cost \$1.81. A single drop in a glass of my Binchoise clone showed instantly that it was (one of) the secret ingredient(s). Even one drop was too strong, though--I'll try one drop per quart first and report back.

Subject: Diacetyl and Wyeast 2308

I'm about to use the Wyeast 2308 for the second time in a batch of Munich Helles. My first venture with this strain produced a very good German lager, but it did have a slight diacetyl tone. I've either heard or read somewhere that the 2308 requires a diacetyl rest during the primary fermentation. This seems reasonable, but for clarity, would anyone be able to tell me what exactly a diacetyl rest does (other than reduce the diacetyl level), how it's done, the appropriate time during fermentation, at what temperature and for how long?

Another comment, I have seen a description of the Wyeast products on the HBD which is fairly brief. Is there a more detailed description of the products available?

Thanks in advance...

Glenn Anderson

Subject: Re: Sam Smith Pale Ale Recipe Needed

In HBD 1003 Kevin McCluskey writes:

> I've had a request for a SSPA knockoff... Anyone have an extract
> recipe that comes close ? I just got The Cats Meow, so if there
> is one inparticular in there thats close, please, let me know.

I like to second the notion (request). I've brewed Gene Schultz's "Samuel Adams Taste-Alike" and a variant of Clay Phipps' Anchor Steam-Style Amber - both from the Cat's Meow. In both brews I used Hallertau hops instead of those recommended in the recipes and in the case of Clay's recipe I used a Cooper's ale extract combined with light malt extract to equal his call for 7 pounds of John Bull light extract. I also used the dry yeast provided in the Cooper's ale kit for both brews.

I've done some taste comparisons between these brews and Samuel Smith, Samuel Adams and Anchor Steam. What I can say about my brews is that they have the crystal malt taste of Samuel Smith and Samuel Adams, but that there lacks another nuance which is highly obvious in both the smell and aftertaste of Samuel Smith which is lacking in my brews. This nuance is obvious in the smell of Samuel Adams but only just noticeable in the taste. As far as Anchor Steam goes, my brews weren't even close.

I've questioned a couple of colleagues here at work about the extra nuance (they gladly participated in the tasting sessions...) and got a number of weird (?) suggestions:

1. "a herbal aroma"
2. "smells like the factory where I used to work", a Swedish snuff factory which produces stuff similar to Skoal or Copenhagen tobacco found in the States
3. "a fruity aroma like cola or something"

I've looked at the Samuel Smith label and it states that the only ingredients used are malted barley, hops, yeast and water. I'm no beer judge or even experienced homebrewer (four batches under my belt now), so I'm at a loss to explain the nuance. The only thing I know is that Samuel Smith is damned good and I'd like to get as close as possible with extract brewing.

Subject: Kegging question

Hi all....

I've been using my soda keg setup for a few months now and am generally happy with my results. I have one problem, which is minor, but still a nuisance. I have the pin-lock connectors on my soda kegs. When I leave the gas supply hooked up to the keg, it always leaks a little at the connector. I know its there because if I disconnect the pin lock and leave the gas on, the pressure never changes. When I hook the keg up, that's when it starts leaking, very very slowly, but it still leaks.

Its hasn't been a problem until recently, when I got a beermeister which has very little clearance for the connectors and its a pain to connect and disconnect for each drinking session.

BTW, this happens on all my kegs (3 of 'em) and I've replaced all the rubber gaskets.

Any ideas or remedies???

Subject: Pyrex Petri Dishes

In HBD1004 Jack Schmildling asks:

> Glass petri dishes seem to have disappeared from the market place. If anyone
> knows of a source, please post it and try to talk some sense into your
> friends who throwaway plastic ones.

I found Pyrex Petri dishes listed in the 1992-1993 Aldrich catalog on page 1604. They have different sizes, namely,

o.d.XH(mm)	Cat. No.	Each	Pkg/12	Case
58X15	Z13,973-4	\$6.05	\$47.80	\$258.75/72
98X10	Z13,974-2	5.40	39.80	214.60/72
100X15	Z13,975-0	5.40	39.80	214.60/72
98X20	Z13,976-9	5.40	39.80	214.60/72

Their toll free number is 800-558-9160.

I am also interested in buying some pyrex test tubes, stoppers, pipets, flasks for growing yeast, etc. but the Aldrich prices seem high. Does anyone have a better (cheaper) source for such items. Either post or email me directly.

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: yeast cleaning

There is a method using 2 or 3 jars of sterile water to clean and separate yeast from trub, etc. for storage. I've done it and it works well. It is also common for larger breweries to wash their yeast in an acid bath as a way to kill off unwanted microorganisms (eg. bacteria), leaving only healthy yeast. As such, it would seem to be beneficial to acidify the water in the first method, using acetic or citric acid, for example.

The benefits vs. plating out a pure culture and building it up is that, with the acid wash technique, you will have a large quantity of healthy yeast free from contaminants. The down side is that you are relying on the original yeast being good. With pure culturing, you start with a known good yeast, but need to build up successive generations to get enough

for a healthy ferment, each time exposing the culture to possible contamination. Obviously, a combination of the techniques would be optimum.

I suggest a further evaluation of acid-wash technique as it applies to homebrewing might be in order, including yeast viability in low pH, contaminant viability in low pH, yeast viability wrt. changes in pH, "best" acidifying agent, temperature factors, etc. Any takers?

Subject: Easymash Review
From: llangreh@mitre.org (Larry L. Langrehr)

My personal experiences with Schmidling's EasyMasher system/concept: When I was first thinking about all grain brewing I gave a lot of thought to my requirements and the components needed to fulfill these requirements. I wanted the flexibility of doing both infusion and step mashing with the minimum number of components and steps needed for the process, and get a good yield in the bargain. About this time Schmidling offered directions to make his easy masher product. Not living in a big city and having good access to a "real" plumbing supply or hardware store (not Hechingers or Builders Square!) I bought Schmidling's apparatus (brass screen, copper tube with fitting, and all-brass small aircock). I also bought a 21 qt. enameled canner from the local supermarket for \$15. I drilled one hole in the side of the canner and installed the easymash apparatus in about 15 minutes. What I then had was a combination mash/lauter tun that I could also do step mashing all in one container. After the mash I opened the aircock slightly, ran off about a quart or so to clear and re-circulated it. I then added hot (165-170 degree) sparge water and caught the runoff in my boiler (dribbling down the side to prevent oxidation). I held a soup ladle just below the surface of the water and added water to the ladle to prevent disturbing the grain bed. I never stirred or moved the grain during the sparge. At the end of the sparge I quite un-scientifically chewed on several samples of grain taken from several depths and locations from the tun. I could not detect even the smallest resemblance of sweetness, just wet grain husks (great for your bods fiber requirement). I also scientifically measured the specific gravity of the 5 gallon batch after the boil just before pitching. Of the three batches I've done my yield rate falls in a narrow range between 27-29 points. This is with 7-8 lbs. of grain, the most adjunct I've used is a pound of crystal. When I calculated yield I used a theoretical maximum of 35 points for grain and 24 for crystal. I have a co-worker here who also has version 1 and gets yield in the same range. The difficulty in using the system was in the strength of the extended screen from the tube. I happen to get "very involved" with my mash and do a lot of robust stirring, I just can't let it set for more than 5-10 minutes. When I finally emptied the tun into my compost pile I noticed that the screen was bent upwards and had almost come loose from the tube. After correspondence with Jack he surprised me by sending an unsolicited second version. This one used stainless steel screen and was quite rigid. Comments after using the 2nd version: The runoff rate increased, so I just closed the aircock down a bit, and the screen didn't budge a bit even with my heavy-handed stirring technique (24" stainless steel spoon). This version is going to last me a long time. The yield rate stayed in the same acceptable range (at least for me if not for Dave Miller!). To clean after emptying the grain I just use water from a spray nozzle on the end of my garden hose, all particles come free from the screen without my needing to touch the screen. In lieu of payment for the second version (I paid \$25 for the first) I agreed to share my experiences with the digest (better get this out front in these sleazy times of electioneering). I believe the basic concept to be quite sound, it allows me to do step-mashing and lautering all in the same pot and I only had to drill one hole! Before the flames start, no one is pressuring anybody to buy this from Jack, he did share the detailed design of the thing at the beginning. By the way,

a good crush from a roller mill (my choice) is most important for the sparging process. Send mail to Jack for further details about his offerings, send mail to me if you'd like clarification on any of the above.

From: Peter Maxwell <peterm@hpdtlpm.ctgsc.hp.com>
Subject: racking off trub, aeration

I posted this article directly to rec.crafts.brewing but don't know whether there are people who subscribe to HBD and not the news group, so I've duplicated it here. Feel free to flame me if it's unnecessary and undesirable duplication. But please answer my questions along with the flame!

I've just started brewing using unhopped malt and have several questions on aeration and racking the wort off the trub.

1. How important is it to rack off the sedimented hot and cold break? Miller and Papazian both indicate it's optional but recommended. Is there a real difference in taste?
2. Is the presence of trub likely to interfere with fermentation and cause it to get stuck?
3. I read that the recommended practice is to pitch the yeast then wait 30 minutes or longer, then rack off the trub before fermentation starts. Why not simply let the wort settle for a while after it's been cooled and then rack into the fermenter? This means one less step.
4. When the yeast is initially pitched, does it go into suspension? My fear is that if I pitch and then rack very soon afterwards I'll be leaving some of the yeast behind.
5. Is there anything wrong in racking after fermentation has commenced? Is this too late?
6. Initial aeration is important for yeast growth. Is aeration while racking off the trub to be avoided? How long after pitching does additional aeration become bad?

Thanks for any help.

Peter

From: Pierre Jelenc@cunixf.cc.columbia.edu
Subject: torrefied malt

In HBD 1004, Phillip Seitz mentions "torrefied malt". The French word "torrefie" simply means "roasted", and is used for things like coffee, nuts, and grains, that are roasted dry and with stirring. I suspect therefore that the brewers were merely talking about some kind of roasted malt or roasted barley.

Subject: Undeliverable Mail

Friday night was the first formal meeting of a new homebrew club, "Whatever Ales You" in Westchester County, New York. Almost all of the members brought homebrews along for all of us to taste, including my brew partner and myself who brought what we had planned on being a traditional bitter.

Sadly, when our beer was presented, it had a strong yeast aroma and flavor. To me, it almost seemed to have the characteristics of a Weisse beer, but others were not so kind and likened it to eating a piece of bread. When I asked if anyone thought that this flavor/aroma would dissipate with time, most thought that it would not. I have heard a yeasty flavor been described as sulfer-like, but this was not the case. It was definitely more bready, and a little fruity.

The recipe was a M&F Traditional Bitter kit that consisted of a 3.3 lb. can of hopped malt extract and a package of dry ale yeast. To this was added an additional lb. of amber DME, and a 1/2 oz. of Goldings hops for aroma in the last 2 minutes of the boil. (Hop aroma is barely noticable through the yeasty smell)

This was the recipe that I used for my very first batch of beer, and it has yeilded some pretty tasty beer in the past, for such a simple recipe.

The beer was fermented in primary for 7 days at 73F and was racked to secondary for an additional week. The beer is very green and has been in the bottle for just over 2 weeks. Carbonation is good and there is an average amount of sediment on the bottom of the bottle.

Is there any hope for this beer? Will the yeasty flavor dissipate over time? What could have caused this problem? Was it the yeast, a sanitation problem (bacterial infection), or something completely different. Thanks for any advice.

>From: iepubj!korz@ihlpa.att.com

>Correct me if I'm wrong, but digest #997 is the first I've heard that
you
stir the grain bed *DURING* the sparge.

That's because you have never bothered to ask me for the detailed
procedures
via email. There is a limit to what can be posted in the Digest without
incurring the wrath of the anti-commercialism gang. Furthermore, any
process
or product that is worth the name, changes and improves as it evolves.

> I recall from one of your first posts, that you have a bowl sitting
(partially submerged) in the top of the grain bed into which you pour
the
sparge water. This seemed to imply to me that you were not stirring.

It's not real hard to move the bowl or stir around it during sparging
and
after all the sparge water is in, I take it out and give the whole mess
a
good mix.

> I also believe that you had mentioned that you used a knife or skewer
of
some kind to poke holes in the grain bed to restart the runoff if the
sparge
got stuck (I'm not 100% sure, perhaps this was someone else).

The sparge has NEVER stuck with this system. I "cut the mash" to
re-distribute the water/mash, i.e. stir.

korz>Stirring the grainbed while the runoff is being taken will only
korz>accentuate the channelling -- the sparge water will fill the
"gorge"
korz>created by the spoon or paddle, quickly making it's way down to the
korz>outlet at the bottom.

Wrong.

> Picture a lauter tun full of set jello. A knife is stuck into it
korz>and moved around in a circle. The slit left in the jello is the
channel.
korz>If you were pouring water on top of the jello, you can see how it
would
korz>prefer to go down the slit as opposed to forcing its way through
the
korz>jello itself. Granted, this is an exaggeration....

That is not an exaggeration, it is totally off the wall. There is not
the

slightest relation between the two. When a mash is stirred, we have a swirling suspension of particulate material in a sugar water solution. It is more analogous to tea leaves in a cup of tea than it is to jellow. How you can visualize "channels" in a swirling cup of tea, totally escapes me.

>No complicated systems are needed.

I agree they are not needed, I was referring to the many articles posted here on the subject.

>Draw off a quart or two and dump it in the top.

I prefer an ounce or two.

> The reason for the turbid wort is usually a too-fine a crush.

I disagree with this. If you have an inch or more of dead space under the false bottom, this space will always be full of trubid stuff no matter how you crush it. The bare minimum would be to recycle this stuff. In my system there is ZERO dead space because there is no false bottom.

>A rollermill (such as the modified Mercado Mill or yes, the infamous MALTMILL) is virtually essential to getting a good crush with a minimum of flour.

Interesting choice of words, "infamous" and juxtaposition of the two. As I recall, you own MALTMILL. Are we to gather that you prefer the modified Mercado?

> >The EM system runs clear after only a few ounces are drawn off initially and continues to run clear even after thorough stirring of the mash.

>It seems that if this needs to be done multiple times, and the first few ounces are turbid each time (which I'm quite sure will happen), the amount of turbid runoff can add up, no?

Wrong again. It's only turbid the first time and I only do it often enough to convince myself that it isn't really necessary anyway. The only reason I started the stirring procedure was to test the extraction effectiveness. Obviously, if the extraction does not change with or without stirring, than we can assume that the extraction of the system is adequate.

Fact is, there is no noticeable improvement in extraction if the mash is stirred. This seems to prove that this whole discussion is academic.

>Starting with a properly-crushed malt, it seems to me that a "start it and just add sparge water system" is simpler than one which requires stirring.

>Agree with you that a simple lautering system with a minimum of expensive equipment is the best solution, so what's simpler than a couple of buckets with some holes in one -- you can even get the food-grade buckets free from bakeries.

The process is simple but it requires two additional pieces of equipment, some effort and hardware to prepare them for the job and is prone to cause stuck sparges if not properly handled.

My "system" is simply an add-on to a brew kettle that is required anyway and the process is idiot proof.

But the bottom line is that I am not trying to re-invent the wheel or trash what works for others or get rich quick. What I am trying to do is take the voodoo out of all-grain brewing so that people are more inclined to give it a whirl.

The procedure I have evolved provides a natural and uncomplicated transition from extract to all-grain that is as easy as falling off a log.

>Nevertheless, perhaps the only way to resolve this is experimentally. We should, for the good of homebrewing, compare these systems and report back. We'll have to meet on neutral ground of course ;^).

I am giving a talk on KETTLE MASHING at the next Club Wort meeting on Nov 9. Perhaps we could discuss it there. I will also be bringing samples of WGB to this week's meeting of the Chicago Beer Society.... an ale made with Belgian malt, my first lager and an ale made with my home grown hops.

Subject: Homebrewer Hall of Fames

Well if there were a homebrewer Hall of Fame or at least an exhibit of famous people that were/are homebrewers, I would have a nomination. As it turns out Woody Guthrie brewed his own.

I recently borrowed a CD set of the Library of Congress recordings of Woody talking from 1940 and while I was playing with my kids and half-listening to the CD, I heard the words malt and yeast mentioned. After I backed up to the part that contained these words, I found out that at the age of 16 years old (1928) Woody and his buddies would make up batches of Prohibition brew while they were playing hookey. Since they wanted to drink their brew as soon as possible, rather than adding one cake of yeast and waiting three days to drink, they added three cakes and waited one. Belly aches all around according to Woody.

Just thought you might interested.

From: MEHTA01@SWMED.EDU
Subject: sparging principles and procedures questions

Hello

i have some questions about sparging: it's principles and procedures.
Principles of sparging:

1. Sparging is done to extract the sugars left in the grains
2. The grains must be in a pile, with water (hot) surrounding them for a while; this water is then run-off.
3. One of the added benefits (apart from getting more sugars) is that the grains clarify the wort by acting as a filter bed..

So, this is what i use, but i have never reached the efficiencies mentioned in previous postings: i have a styrofoam cooler, with a plug outlet at the very bottom. 1 inch from this bottom is a false bottom made of a wire mesh (not very fine, just enough to hold up the grain) and held up with rods that are imbedded into the walls. So, i have a false bottom sparging setup.

Now i transfer the grains from the mash into this sparging setup and add 1 1/2 to 2 gallons of hot water into this cooler, slowly, periodically opening the outlet plug.

Some points about procedures:

Should i recirculate these run-offs collected from the false bottom? Is this method of sparging efficient? (Oh, BTW, i spread the water all over the surface when adding it) Are there any recommendations or suggestions to improve this system? How is the procedure different from the copper tubing setup i have heard about in a lauter tun??

Please help this beginner all-grainer...

Subject: Re: CAMRA Good Beer Guide Questions

Attempts to mail gcw@garage.att.com have met with no success, so I'll post this here. This can be useful information for others who are UK-bound (especially for the first time).

In HOMEBREW Digest #1003, Mon 02 November 1992, gcw@garage.att.com asks:

>Date: 30 Oct 92 13:20:04 EST (Fri)
>From: GC Woods <gcw@garage.att.com>
>Subject: CAMRA Good Beer Guide Questions
>
>1) The CAMRA guide defines a "public bar" as "drink is cheaper" - my question is what is the price difference between a public and non-public pub and for the pubs not listed in CAMRA, how would one know if the pub was a "public bar"?

You're experiencing a bit of difficulty here with some British-English terms, mainly the words "pub" and "bar". A "bar", in American-English, is often any establishment where one can get a drink, usually alcoholic, occasionally accompanied by food (as in "Harry's American Bar and Grill")

This is not what is meant by the word "bar" in Brit-Eng, especially w.r.t. pubs; rather, a "bar" is a type of counter that one finds inside a pub, where one orders drinks. A "pub" is short for a "public house"; thus, there can't be any such thing as a "non-public" pub!

Now, there are different types of bars in pubs - often the "public" bar and the "saloon" bar. The public bar is characterised by a sort of basic (but not necessarily rough) "masculine" environment - a place to meet your mates (friends!) after work for a couple of pints. Public bars are usually simply furnished, often with stand-up tables (no chairs!), or at best with wooden high bar-stools, and can be a bit smoky and noisy when full. The saloon bar will be a bit more refined and comfortable, the kind of place where a gentleman might escort a lady for a drink, or one might stop for an after-theatre drink, and where comfortable chairs will be provided at tables, perhaps with a fireplace at one end. Since this will be a bit more nicely furnished and decorated, the price of a pint will be correspondingly higher. It may be the same beer, but you're paying to drink it in somewhat nicer or more comfortable surroundings. There is a little of the old class system at work here, too; the ordinary working-class bloke will have a pint or two in the public bar, whilst the more affluent professional person might prefer the discreet atmosphere of a saloon bar, especially if it is

outfitted with "snob screens" (a magnificent example of this is the Lamb in Lamb's Conduit Street, Bloomsbury, London) to screen one's private conversation from the bar-staff, and limit one's interaction with the bartender to simply ordering drinks.

>2) "Free Bars" are mentioned in the description of bars - what is a free bar and do most pubs charge cover?

"Free Bars" are usually referred to by the more prosaic "Free House". Pubs don't charge cover unless they are featuring live music or theatre. The meaning of "Free House" comes from that other British peculiarity, the "Tied House" concept, whereby the breweries are allowed to engage in a practice that is normally illegal in the USA: owning the pubs that sell their beer. Thus, a Bass tied-house will serve Bass ales, a Grand Met tied-house will serve Grand Met/Watney's brands, a Fuller's tied-house will serve Fuller's Chiswick Bitter and ESB, and so on. A free house is nominally independent, and thus not normally obliged to carry any particular brewery's products. In practice, many free houses will obtain financing for improvements and operations from a brewery, and in exchange for an advantageous rate on the loan, will feature that brewery's beers; it is still nominally a free house, but is now obliged behave somewhat like a tied house. Good examples of tied houses include the above-mentioned Lamb (tied to Young's) and the Olde Cheshire Cheese (tied to Samuel Smith's). Two good free houses are the Sun (in Lamb's Conduit Street, not far from the Lamb) and the Museum Tavern (just south of the British Museum). The Sun endeavors to keep a dozen good beers on tap, all cask-conditioned real ales, usually from smaller independent brewers (refer to the section in your Good Beer Guide on the independent brewers and the Big Six).

>Do any HBD's know of pubs not listed in the CAMRA guide one should not miss and of course which pubs serve the consistently best real ale?

Don't miss the Lamb! It is usually in the Guide, and for a good reason. Try the Sun, even if it isn't in the Guide (it wasn't in 1992). Absolutely do not miss the Black Friar, usually in the Guide, and for a very good reason - once visited, never forgotten! The Black Friar is only open on weekdays, by the way, so don't try it on Saturdays and Sundays. Try also the Phoenix and Firkin, one of the Bruce's homebrew pubs - it's not always in the GBG, but it's a great place. Then there's the Magpie and Stump, near the Old Bailey (Central Criminal Courts), and the Salisbury in the heart of the theatre district. I'll be in London on December 26th (Boxing Day), and as it's a holiday, I guess we'll just have to make do with a good old-fashioned pub-crawl; I know it's a tough job, but somebody has to do it :=) !

There is another pub guide published; the name escapes me at the moment, but it is an independent guide, something like "Guide to Britain's Best Pubs", and not affiliated with CAMRA. The guide is put together with contributions from the general public (CAMRA or not), and is fairly

reliable. It's quite a bit thicker than the _GBG_, as its format is different - the descriptions are much more complete, mentioning things like atmosphere, food, music (or absence of same), and amusements (the ubiquitous "fruit machines", (slot machines), pinballs, electronic games, etc.). E-mail me if you want the proper name, author, and ISBN of this book - it's worthwhile for the same reason as the CAMRA _GBG_. This other guide often lists perfectly good pubs that may not make a given year's _GBG_.

End of HOMEBREW Digest #1005, 11/04/92

Date: Wed, 4 Nov 92 10:46:13 +0100
From: dejonge@geof.ruu.nl (Marc de Jonge)
Subject: questions, questions...

in HBD#1005 Peter Maxwell asks: a lot of questions.
I'll try to answer them to the best of my knowledge (everybody is hereby invited to flame/correct/supplement/ridicule my erroneous ways)

>1. How important is it to rack off the sedimented hot and cold break?
> Miller and Papazian both indicate it's optional but recommended. Is
> there a real difference in taste?

Depends on the amount of break material and the time you want to store your beer. If you used an extract or highly converted malt for a beer that you'll drink in three weeks, the trub will not have a great effect. In General: You don't want a decomposing proteine bouquet in your beer, so racking of the break material is the safest way.

>2. Is the presence of trub likely to interfere with fermentation and cause
> it to get stuck?

I'd say on the contrary, yeast may find some nutrients in the trub, but so will bacteria etc..

>3. I read that the recommended practice is to pitch the yeast then wait
>30

>minutes or longer, then rack off the trub before fermentation starts.
Why

>not simply let the wort settle for a while after it's been cooled and
>then rack into the fermenter? This means one less step.

I use the second method, sometimes even let the wort settle (in a cold place) overnight. The risk is that you take is contamination, the reward is a beer with less chance of chill haze.

>4. When the yeast is initially pitched, does it go into suspension? My
>fear is that if I pitch and then rack very soon afterwards I'll be
>leaving some of the yeast behind.

Not sure about the suspension for lager yeast, but top fermenting yeast is supposed to multiply in suspension. Besides, in favourable conditions your yeast population will double in an hour, so perhaps you only increase the lag time a little by losing some yeast.

>5. Is there anything wrong in racking after fermentation has commenced?
>Is this too late?

This is what you do from primary to secondary (and from secondary to lagering for some beers), never had fermentation stop on those occasions. But see below for effects of air contact.

>6. Initial aeration is important for yeast growth. Is aeration while
>racking off the trub to be avoided? How long after pitching does
>additional aeration become bad?

This has come up a lot of times. I think net.common.wisdom boils down to :())

1 No problem with oxygen in cold wort while yeast is reproducing rapidly, the yeast will get at first.

2 Avoid oxygen in hot wort (oxydation) and almost-finished beer (oxydation & contamination)

>Thanks for any help.

not sure if this is any, but: my pleasure

From: abirenbo%lyra@rigel.CEL.SCG.hac.com (Aaron Birenboim)
Subject: belgian yeast

I have been hearing a lot of talk about WYEAST belgian, and annoying banana production. I was no big fan of belgian ale until I had Celis beers from austin texas, and some of the New Belgium brewery products of Ft. Collins, CO. The commonly available belgain trappists and specials... namely Deuvel, Chimay Red, and Orval, all leave me cold. They are just TOO severe. Celis and New Belgium ales have a more subdued and mellow spicyness that i would crawl naked on my hands and knees through shards of broken glass for.

I recently bought a bottle of Chimay red, and hated it... just as i remembered. I cultured the yeast anyway. WOW... what a success! I poured about 10 oz sterile wort into the chimay bottle. In onlky a little over 24 hours i had noticeable airlock movement! I have plated out the yeast... but have yet to use it. I let the bottle culture finish out... and drank it this morning. quite nice. a pleasent mellow spicyness... much like that of celis of New Belgium. However, this was just S.G. 1.020 wort. A higher gravity may differ.

This lead me to wonder if the WYEAST product really is a chimay yeast? Or is it possible that the yeast used for bottle conditioning of chimay is NOT their primary yeast... but a yeast that I may PREFER to their primary yeast. we shall see. just another data point.

BTW: My chimay culture had NO banana at all. In fact... it had very little fruit either. more of a mellow undefinable spicyness. somewhere in the annise/fennel/corriander/clove area.

Subject: samuel smith

Michael Jackson's Pocket Guide provides a good, concise description of the Samuel Smith process.

Samuel Smith's products have a "Yorkshire" character, imparted by their fermentation system, choice of yeast, and hopping. Samuel Smith ferments in double-deck slate vessels which make for a circulation of the yeast. I believe Terry Foster's Pale Ale book briefly describes this system, and some past HBD has a long posting on the brewery setup. Jackson maintains that the character developed by the yeast in this system produces brews with a very full texture and roundness. And, the beers have a great deal of interwoven hop character. Try Samuel Smith's Pale Ale or Nut Brown Ale and see whether you can taste these flavor components in the beers. The beers are very artfully done, in my humble opinion!

Does anyone know of an available ale yeast that is NOT highly flocculant and has an appropriate fruity/yeasty character? One could attempt to keep such a yeast roused by swirling the carboy from time to time. Wyeast "Irish" ale yeast might be used to impart a bit of the buttery, diacetyl character these beers have. Multiple late hop additions in the last 20 minutes of the boil, plus some dry-hopping, might impart some hop complexity.

Samuel Smith beers go by different names in the U.S. and Great Britain:

Britain's Museum Ale (OG 1.048) is Samuel Smith's Pale Ale;
Strong Brown (OG 1.048) is Samuel Smith's Nut Brown Ale;
Nourishing Strong Stout (OG 1.048) is Samuel Smith's Taddy Porter.

In Britain, Museum Ale is available as a cask-conditioned real ale! Britain has no counterpart to Samuel Smith's Oatmeal Stout (1.048) or Imperial Stout (OG 1.072). As I understand it, the American importer, Merchant du Vin, convinced Samuel Smith that there was a market for these beers and encouraged SS to brew them.

Subject: Source for Pyrex tube, fairly large diameter?

Anyone know of a source for Pyrex -- or some other temperature resistant, transparent material -- tube? I'm looking for something that can handle steam (about 212F), and something that can handle air at about 500F. Diameters need to be about 2-6" or so.

I've asked at plastics/plexiglass places and they indicate it's not adequate for the 500F degree range.

Thanks.

Subject: Beginner kits at Price Club -- inexpensive

Last time I was at Price Club, I noticed they had a beer making kit -- and this is on the conservative, behind-the-times, brewpub-poor Right Coast :-)

Anyway, seemed a good deal for beginners. It had a carboy, rubber cap with a couple hoses coming out of it (like a BrewCap?), brush(es?), a high-quality capper, malt extract, and ``brewing sugar''; probably some other things I've forgotten, too. I think the cost was about \$40, but I can't recall exactly.

Subject: #44 Not-So-Botched Brown Ale

In HBD# 963, I wrote:

>ObBeer: I aborted the Botched Brown last night. :- (The batch made
>with uncrushed grain.) I'm going to do it right on Saturday...

Well, I did it right on Monday instead. I replaced #41 Botched Brown
with #44 Not-So-Botched Brown. To my surprise, it won first place in
the Brown Ale category at Brewmaster's Oktoberfest a couple of weeks
ago! (I wasn't terribly impressed with the beer, but then, I'm not a
judge... :-)

So here goes...

#44 gak & gerry's Not-So-Botched Brown
(Replacement for #41)

Brewed 9/7/92 OG 1048
Bottled 9/14/92

8# pale
4oz chocolate malt
4oz black patent
8oz 90L crystal
1oz Cluster (60 min)
1oz Cascade (30 min)
0.5oz Cluster (finish)
Wyeast British

Slow sparge, but otherwise OK. Fermented in plastic.

10/10 Has a tang like an extract beer. Otherwise, tastes like a dry
Brown Ale. Maybe should have skipped the black patent. A
lingering (but faint) bitter aftertaste.

gak Der Herr Buergermeister gibt bekannt, dass ab
gak@wrs.com Donnerstag Bier gebraut wird und deshalb ab
attmail!gakhaus!gak Mittwoch nicht mehr in den Bach geschissen

Subject: Belgian Delights in Livermore

Belgian Delights in Livermore

Last night I was fortunate enough to participate in a dinner so inspiring, that I feel compelled to share a description. The event took place at Mrs. Coffee's Belgian Bistro in Livermore CA, and was prepared by Christian VanHoutryve, the proprietor. The best description probably begins with the menu.

Petite Casserole of Steamed Mussels
with Boquet of Spices & Lemons
Blind Tasting of Interbrew Hoegaarden & Celis Wit

St. Arnolds Flemish Leak Soup
Four Year Old Celis Hoegaarden

Lambic of Pheasant a la Framboise
Fresh Raspberry Sauce Lindemanns
Scallops of Pommes Frites
Vlezenbeek Farm Vegetables
Lindemanns Gueuze

Petite Roulade of Pineapple Crisp
Chantilly De Chimay
La Chouffe Belgian Spiced Ale

Cordials au Chocolat with Belgian Grapes
Digestive de Rodenbach a la Grenadine

Tasting of Bourgogne de Flanders

Christian has worked for many years perfecting his food and beer combinations. Last night he was in top form. The complex interplay of the different flavors was a true gastronomical delight, and I wouldn't hesitate to recommend this place to anyone. Ahhh, "But what of the beers?"
" you ask.

The blind tasting was very enlightening. It was my first taste of Celis Wit, and I was quite impressed, although one would expect nothing less of the man who single-handedly revived this style. The Interbrew Hoegaarden was softer and breadier, whereas Celis' beer was crisper and more refreshing. Both were very aromatic from the coriander and orange peel. We all preferred the Celis and are anxiously awaiting its appearance in CA, which should happen in the next week or two.

The next brew was the four year old Hoegaarden, brewed when Celis was still at the helm of the DeKluis brewery, before the takeover by Interbrew.

Needless to say, a four year old wit is well past its prime, but it held up surprisingly well. The aromatics were largely diminished, but the beer was still tasty and refreshing. On a recent visit to SF, Pierre Celis sampled some of this brew from the same cellar. He too was surprised by its relatively fresh condition.

We moved on to the Lindemann's gueuze. This is, in my opinion, not truly representative of the style. I prefer the harder lambiks with more acidity and Brettanomyces character. In contrast, Lindemann's is overly sweet. It did however, complement the food well and was enjoyable in its own right.

The LaChouffe was one of the evening's truly outstanding beers, which is saying alot. It is a specialty brew produced by an upstart brewery that defies easy categorization. It's fairly full bodied with a good deal of residual sweetness, balanced by a substantial dosage of herbs and spices.

I read somewhere (Jackson?) that this beer was made with honey and a blend of six spices. It was a very complex balance of flavors, and hard to single out any of the spices, although some detected hints of clove and cinnamon.

A shame this one's not available in the US.

I'd had Rodenbach many times before, but never with Grenadine. The unadulterated beer is quite tart, but the sweetness of the Grenadine took the edge and added a fruity character. The flavors integrated quite well. I'm generally reluctant to add flavorings to beers, but Christain insisted that this was the proper way to serve Rodenbach after a meal. I must admit that the resultant mixture was absolutely delicious at the time.

Finally we finished the evening with another specialty brew, Bourgogne de Flanders. On my recent trip to Belgium, this was one of the few beers that

I drank more than once. Its deep reddish brown color and full spectrum of flavors make it worthy of the noble title Bourgogne. It has a very present fruity flavor although no fruit is used. Even with its big flavor, this award winning brew remains fairly light in body and is quite refreshing.

Overall it was a delightful evening that we won't soon forget. If you get the chance to get out to Livermore, Mrs. Coffee's is definitely worth a visit.

Subject: Re: racking off trub, aeration

Peter (peterm@hpdtpm.ctgsc.hp.com) asks:

>1. How important is it to rack off the sedimented hot and cold break?
> Miller and Papazian both indicate it's optional but recommended. Is
> there a real difference in taste?

I've read that if yeast ferment the trub, it will increase fusel alcohol (higher, more complex alcohols) production. In some beers, like Belgian Strong beers, this is part of the style's flavor. It has been also theorized (proven?) that these fusel alcohols are, at least partly, responsible for hangovers.

>2. Is the presence of trub likely to interfere with fermentation and
cause
> it to get stuck?

No. I can't see how it could.

>3. I read that the recommended practice is to pitch the yeast then wait
30
> minutes or longer, then rack off the trub before fermentation
starts. Why
> not simply let the wort settle for a while after it's been cooled
and
> then rack into the fermenter? This means one less step.

There are a lot of nutrients in the trub that the yeast can use during their respiration phase (the first phase of their life cycle) and so IDEALLY, you would like them to feed them some of the trub, then take it away before they go into the fermentation phase.

>4. When the yeast is initially pitched, does it go into suspension? My
> fear is that if I pitch and then rack very soon afterwards I'll be
> leaving some of the yeast behind.

Yes. You'll leave a few hundred thousand behind, but what's that compared to a few trillion.

>5. Is there anything wrong in racking after fermentation has commenced?
> Is this too late?

No, but you could have trouble keeping a siphon going -- the CO2 that's being produced can form a bubble in the line and break the siphon. My personal opinion is that increasing the height difference between the source and destination vessels as big as possible will increase the velocity in the hose and reduce your chances of breaking the siphon.

>6. Initial aeration is important for yeast growth. Is aeration while
> racking off the trub to be avoided? How long after pitching does
> additional aeration become bad?

You don't need to avoid aeration until after fermentation has begun and even then, any excess O2 that gets dissolved will be scrubbed out by the escaping CO2. Once fermentation begins to subside, then additional

aeration is bad.

Subject: CAMRA INFO

I had several request on where to obtain the the 1993 CAMRA Good Beer Guide, why from CAMRA, of course! They take Visa and Mastercard orders and remember to phone during UK office hours (approximately 4am-noon Eastern US time). The guide cost about \$18 US and for a extra buck or two they will send it by air.

Their phone number from the US is:

011+44-727-867201

Also thanks for the responses to my questions:

To summarize "Free Pubs" in England are pubs which are not owned or "tied" by one of the big brewers, so they are free to serve any beer they wish.

To my other question - nobody knew why the CAMRA guide list "public bars" as "drink is cheaper" - is guess I'll find out when I get there. I don't care what it cost - I demand "real ale". (I wrote this before Don Scheidt's response in HBD 1005 - thanks, since I'll be with the wife I'll have to check these places out myself while she is shopping because she will prefer the nicer places).

Another point is that several people corrected me on the use of the word "bar" and said it should be "pub" - well the reason I put the statement in quotes was because it is a quote from the CAMRA guide.

they remove the alcohol from their NA beer. Turns out they use dialysis.

Sorry, wasn't able to get more details. Another data point to experiment with.

Yah, right. Amazing how many obscure processes they come up with and how they

never have any details on them. The truth of the matter is that they simply

add water till the alcohol content is less than .5% then carbonate it.

>From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

> Jack, the problem with your points/pound/gallon efficiency calculation is that it doesn't take into account different grains. If you use all 2-row and I use 2-row, munich, roasted barley, rice, barley flakes, and wheat, we cannot truthfully use p/p/g to compare our efficiency. Some grains/adjuncts have more possible sugar available than others. The only

true way to compare is to calculate the percentage of the theoretical true way to compare is to calculate the percentage of the theoretical maximum.

Except that you have to do a separate calculation for each grain type and you

must then compare them to what someone else claims to be the max for each

type and somehow integrate them into an overall average. If someone else

comes up with different numbers, chaos will reign. I am not suggesting that

it is not useful information, I am simply saying it is not a universal standard.

Finally, it leaves someone else hanging who only has the other number. He

has no way of comparing with what you did. It would be far simpler to state

the p/p/g ratio and as no recipe is complete without a grain bill, the info

is there for those who need it. It is virtually impossible to work backward

from the per cent number.

>From: korz@iepubj.att.com

>> If one goes on to sparge out the mash and makes the measurements again,

one now gets the extract efficiency or the ability to get the converted sugar out of the mash. This now depends on the lautering system and process and has nothing to do with conversion or malt type.

>Sure it does. If you only converted 1/2 of the starches, you can only get 1/2 as much sugars out of the grains as you could have if you converted 100% of the starch. Your extract efficiency is bound by (as you called it) your conversion efficiency. Your extract efficiency is only as good as your weakest link which may be either your mashing or your lautering.

I only disagree with the opening sentence. IF you measured the conversion efficiency before sparging, then the final extraction will measure your ability to get the KNOWN sugar out of the tun. I simply separated the whole process into two separate steps for analysis purposes.

>> The point of all this is that it is unwarranted to criticise a brewer's > equipment or his process or his materials for extract/conversion problems > equipment or his process or his materials for extract/conversion problems > based on end results. There simply is not enough data to make that > judgement.

>That's why I suggested that brewer's who are getting bad numbers post thier procedures and ask for comments. 4000 heads are better than one.

I couldn't agree more but perhaps you have forgotten that this started out as an allegation of a "design flaw" that results in "poor extract efficiency" in a system that works just fine and suffers from no such problem.

Subject: smithwick's

There have been a number of postings lately on Smithwick's, mostly from Canadian HBDers. I had the good fortune to visit Ottawa recently, and wandered into the Earl of Sussex. They have a dozen beers on tap, all from keg, not cask. But, these included Smithwick's Bitter, John Smith's Yorkshire Bitter, and Stone's Bitter. All were quite good.

Upon returning to the States, I looked up Smithwick's in my CAMRA guide, and found nothing. Then I looked it up in Jackson, and found Smithwick's listed under Ireland. According to Jackson, Guinness and Allied Breweries have formed Irish Ale Breweries, with breweries in Dundalk and Kilkenny. Smithwick's tasted like a bitter, not an Irish ale. It is a very drinkable beer. To my knowledge, it is available in Ontario, but not the States. Maybe some importer will wise up!

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: when to rack off trub?

In HBD #1005, Peter Maxwell asked about trub and racking off it, prompting several replies in HBD1006. My usual brewing procedure (for ales) is to make 5.5 gallons and brew in a bucket primary leaving the beer on the trub. I rack off the sediment into a 5 gallon carboy, typically on day 4 or 5, and get a full 53 or 54 bottles, unless I add a lot of dry hops. I'm generally pleased with the results.

As has been pointed out (in 1006 by Al Korz as well as others in earlier issues) trub contains nutrients which can be beneficial in the initial, aerobic phase (respiration). As well, I have found the trub doesn't compact very well, so that even after a few hours (much less 30 minutes!), racking either carries a LOT of trub to the new vessel or leaves a LOT of good wort behind. So, after various attempts racking off the trub in 1987 and 1988, I stopped worrying.

In 1990, I experimented racking off the trub in the 12-24 hour range. I believe this was recommended in the HBD around #600. I didn't notice any particular improvement the first couple of times and then I got a batch with an INCREDIBLE, UNDRINKABLE amount of diacetyl. End of experiment. Back to racking on day 4.

I would be interested to hear the experience of others:
* as to how completely one can get rid of the trub when racking within the first few hours, and
* racking after respiration.

Cheers,

Rob (bradley@adx.adelphi.edu)

From: Peter Maxwell <peterm@hpdtlpm.ctgsc.hp.com>
Subject: SG readings

The idea of taking SG readings on successive days to determine when fermentation is essentially complete sounds a good one. Up until now I've simply waited for bubbling to cease. I'm nervous about continually opening the secondary fermenter to siphon off a sample, and I tried putting the hydrometer in the fermenter but couldn't read it properly.

The thought then occurred to me : why not take a sample at the time the wort is being transferred and simply keep the hydrometer sitting in this, taking a reading each day? The assumption is that the sample has all the same characteristics as the main batch, including fermenting yeast and will continue the same way. My question is: is this reasonable? Will such a small volume continue fermenting at the same rate as the main brew?

Comments, opinions, past experience?

Peter

From: STROUD <STROUD%GAIA@leia.polaroid.com>
Subject: Brewing Celis White beer

So, you want to homebrew a witbier, eh?? Well, five members of the Wort Processors who recently attended the Dixie Cup also had the good fortune to be taken on a personal tour of the new Celis Brewery in Austin. The hosts, including Pierre Celis himself, were most gracious and were very open about the brewing procedures used in their beers, especially their terrific witbier, Celis White. I was able to gather the following information:

The grist is made from 50% Belgian 6-row malt & 50% Luckenbach hard red winter wheat. After being milled it undergoes a simple infusion mash at 149 deg. F for 1 hour (no protein rest!). The mash is sparged, then the wort is boiled for one hour. The hops (Saaz, Cascade) are added only for the last 15 minutes of the boil. We were not told the hopping rate, but it must be very low. The spices (coriander and orange peel -pulverized in a hammer mill) are also added for the last 15 minutes of the boil, at a rate equivalent to 2 gms coriander and 2.1 gms orange peel per 5 gallon batch. After the boil, the beer is whirlpooled to remove hot break, then is chilled and transferred to the primary. OG is in the range of 12 Plato.

The Celis wit yeast is then pitched and the beer fermented in the high 60's F for 7 -10 days, then transferred to a secondary, and a strain of lactobacillus is added and allowed to work until the pH of the beer drops to 4.4.

The beer is then pasteurized; dextrose and yeast (same yeast as primary) are added, and the beer is allowed to condition.

Celis White should be available in Boston and California in the near future; the yeast in the bottle should still be viable, assuming that it hasn't been killed off sitting in some hot Texas warehouse.

I hope that this helps you brew your own wit beer!

- Steve Stroud

PS - the Celis Brewing Co. had brewed a Grand Cru just before our visit, and it was happily fermenting away in the primary. We were told that it was all barley, no spices were used, OG was about 18 Plato, and the Celis White yeast was used. It should hit the Texas market around Dec. 1.

Subject: yeast & trub

>1. How important is it to rack off the sedimented hot and cold break?
> Miller and Papazian both indicate it's optional but recommended. Is
> there a real difference in taste?

Other people in this forum have done blind taste tests, and the consensus is that it is very important to rack off the trub, especially if you don't use a blowoff. (don't ask me why the two factors are connected) I think it makes a big difference, even when using a blowoff.

>2. Is the presence of trub likely to interfere with fermentation and
cause
> it to get stuck?

No. In fact, the presence of the trub will actually help the yeast during the aerobic phase (but does it produce off-flavors in the process?).
As to whether or not you should rack before, during, or just after the aerobic phase is still an open question. (I rack before)

>3. I read that the recommended practice is to pitch the yeast then wait
30
> minutes or longer, then rack off the trub before fermentation
starts. Why
> not simply let the wort settle for a while after it's been cooled
and
> then rack into the fermenter? This means one less step.

Many people simply siphon off the trub from the brew kettle, and it works just fine. I don't because I can't see through my brew kettle. My 6-gal fermenter is taller and narrower than my brew kettle (i.e. making for a smaller layer of wasted clear wort on top of the trub), and I can see exactly what I'm doing.

>4. When the yeast is initially pitched, does it go into suspension? My
> fear is that if I pitch and then rack very soon afterwards I'll be
> leaving some of the yeast behind.

Yes, you do leave much of the yeast behind, but the yeast that falls out of suspension isn't as healthy as the yeast that stays in suspension (and plenty will stay in suspension).

>5. Is there anything wrong in racking after fermentation has commenced?
> Is this too late?

A vigorous starting yeast (i.e. whitbread ale) will mix the trub back into solution, and even if there's still a good layer of trub on the bottom and not much has been mixed back into solution, your siphon will keep stopping from the expelled CO2. Aside from that, the aerobic phase is complete at this time and the trub layer has already affected the yeast growth. Again, as to whether this is bad is still an open question.

>6. Initial aeration is important for yeast growth. Is aeration while
> racking off the trub to be avoided? How long after pitching does
> additional aeration become bad?

Siphoning off the trub is an ideal time for the added aereation. The yeast use up all the O2 in solution during the aerobic phase; as soon as they run out, they switch to anerobic fermentation. Re-aereating can induce the aerobic phase again. It's best to aereate liberally, perhaps shaking the fermenter several times over the first few hours, but once the anerobic phase has started O2 should not be introduced into the wort.

- - - - -

>Is there any hope for this beer? Will the yeasty flavor dissipate >over time? What could have caused this problem? Was it the yeast, >a sanitation problem (bacterial infection), or something completely >different. Thanks for any advice.

Give the bottles a week or two in the fridge, to get the yeast to settle out of solution and for a nice hard cake on the bottom. (and be careful when pouring). Since the beer is still quite young, chances are that an incorrecatable case of yeast autolysis has not yet occurred.

- - - - -

>>A rollermill (such as the modified Mercado Mill or yes, the infamous >MALTMILL) is virtually essential to getting a good crush with a minimum of >flour.

I own a MALTMILL (well, 1/3 interest in one), and am a satisfied customer, although switching to it from the Corona did not have as big an effect on the sparge as I had expected. I just like its speed, the fact that my arm isn't ready to fall off when I'm done, the fact that the little dust produced is kept in the bucket with the grain, and the extra couple of SG points/lb that it buys you.

>> >The EM system runs clear after only a few ounces are drawn off initially > and continues to run clear even after thorough stirring of the mash.

But how clear is "clear"?

>Nevertheless, I have not yet been truly happy with the level of
>carbonation in my kegged brew. I have lately tried to chill it a
>little more, but while that improved things somewhat, the brew is
>still somewhat still...

>I have kegged stout, and various other ales. I prime the beer with
>1/2 cup of corn sugar per 5 gal cornelius keg (with about 4.5 gal of
>brew in it). The pressure in there by party time is about 25lbs.

You might want to try using CO/2 from a cylinder.

There are 2 ways of doing this.

1) Charge up your keg to about 45 psi and shake it for about
5 minutes. Let it sit cold over night and it is ready to serve.

Pros:

This will give beer in about 12 hours.

Cons:

This method gives you courser bubbles
(more similar to the bubbles in calistoga water vs perrier).

2) Charge up your keg to about 45 lbs. and let it sit cold for about
48 hours recharging it about every 12 hours. About 2 hours before
serving bleed off the pressure to serving pressure.

Pros:

This gives you beer that for my money can not distinguished
from naturally carbonated beer. The bubbles are small and
you get a good head on your beer from a keg.

Cons:

It takes a little longer
(iIf this is a problem then why are you making beer ;-)

Good luck,
Daveb

From: pmiller@mmm.com
Subject: Lost spices

I had an interesting experience last weekend while I was washing up a carboy which I had used for primary fermentation of a spiced ale:

I had made a spiced ale using spices (obviously) and orange zest. I dumped the spices in the brewpot about 10 minutes before the end of the boil. The aroma that those ingredients created during the boil was wonderful and strong.

The batch of beer ended up being about 4 gallons which I fermented in a 5 gallon carboy using a blowoff hose. Because of all the extra head space, though, a lot of 'gunk' ended up on the carboy shoulders that would have normally been forced out of the hose.

When I went to clean the carboy, I noticed that wonderful aroma again as soon as the hot water hit the 'gunk'. The obvious conclusion is that a lot of my spices didn't stay in the beer. I know that I wouldn't have noticed this if I hadn't happened to make a 4 gallon batch and I just wanted to bring it to everyone's attention.

The problem, as I see it, is that vigor of fermentation could change the 'spiciness' characteristic of my beer in the future if I continue to use this method. An active fermentation will blow a lot of spices out the hose while a quiet one will result in most of the spices staying in the beer. Now, if you're already making wonderful spiced beers with great consistency, then skip to the next article, otherwise here are three ideas to improve homebrewed spiced beers:

- 1) Don't use the blowoff method. Ferment in a 6 or 7 gallon carboy and you'll retain everything you put into the beer. [This, of course, will be unacceptable to the people who swear by the blowoff method to remove fusel alcohols, etc., but it's your call...]
- 2) Boil the spices longer to capture the spice flavor directly in the wort. [The problem with this is that you could lose all your spice aroma due to the extended boil.]
- 3) Boil the spices and what-not separately in a small amount of water to make a spiced 'tea', cool, and dump the 'tea' into the secondary to flavor your brew.

I like 3) the best due to the disadvantages that I pointed out for 1) and 2). I think I'm going to try this next year, but I'll probably have to reduce the spice level somewhat. Has anyone ever tried this approach and how did it work for you?

Subject: commercial beers to report alcohol strength?

I don't have the news clip in front of me, but earlier this week it was reported that Coors won a court ruling permitting the reporting of alcoholic strength on its packaging. The article suggested that Coors wants to do this to dispel a perception that its beers are "weaker" than the competition's. Allegedly, commercial brewers are (were) forbidden from reporting alcoholic content because of "prohibitionist" concerns that the consumer would gravitate to the stronger beer in a quest for drunkenness. Yet, spirits and wine have known alcoholic contents! I welcome the reporting of alcoholic content as a step toward "truth in packaging."

From: jdg@grex.ann-arbor.mi.us (Josh Grosse)
Subject: Diacetyl Rest

A couple of HBDS back, a question was asked about the purpose and technique for implementing a diacetyl rest.

Purpose:

To reduce the level of diacetyl (butter/butterscotch flavor or aroma), a ketone, below the taste threshold. Most often done with lagers. Diacetyl is produced by yeast, but given time (and temperature) the yeast can reduce diacetyl to flavorless diols.

Technique:

After fermentation completes, the wort's temperature is raised from lager fermentation temperature (approx 48-54 F) to room temperature, and held there for 24 hours or so, prior to racking to secondary.

Subject: Beer in history

An A.P. story, seen in the Boston Globe, 11/5/92:

- ---
Find in Iran suggests beer from 3000 B.C.

New York - Hey, Sumerians, this brew's for you!

Scientists say they have found the earliest known chemical evidence that ancient people quaffed a few beers: yellow deposits on the inside of a jar more than 5,000 years old.

Tests suggested that the deposits were calcium oxalate, a substance that settles when barley beer is stored or fermented, the researchers said.

[Gee, didn't the digest *just* decide that vinegar was the way to go on those unsightly deposits?]

The finding supports other evidence of beer at the same time, around 3500 B.C. to 3100 B.C., at the same archeological site in western Iran and at several sites in Iraq, study co-author Patrick McGovern said.

McGovern, an archeological chemist at the University Museum of Archeology and Anthropology at the University of Pennsylvania, reports the work with Rudolph Michel of the museum and Virginia Badler of the University of Toronto in today's issue of the journal Nature.

Badler said researchers had already found that barley was common at the site.

The jar came from the same room at the site where researchers had found evidence of wine in other vessels.

Subject: Dialysis and non-alcoholic beer

Fm: Jack Schmidling

>From: "Daniel Miller" <dmiller@mailbox.syr.edu>

>I had the opportunity to talk with an employee of the A-B brewery here
>in sunny Syracuse at a Halloween party last Friday... , I did find out
how
>they remove the alcohol from their NA beer. Turns out they use
dialysis.
>Sorry, wasn't able to get more details. Another data point to
experiment
>with.

Yah, right. Amazing how many obscure processes they come up with and
how they
never have any details on them. The truth of the matter is that they
simply
add water till the alcohol content is less than .5% then carbonate it.

Dialysis it hardly an obscure process, woudn't it be sufficient to
allow that you are unfamiliar with it? I personally have no knowledge
of what A-B uses to produce their non-alcoholic beer, but dialysing out
the alcohol makes perfect sense.

Dialysis is based upon the fact that some thin membranes are permeable
to small molecules but not large ones. Examples of the latter are
proteins and complexe carbohydrates and B-complex vitamins. Examples
of the former are water and alcohol. By placing normal beer in such a
semi-permeable membrane and placing the membrane in pure water the
alcohol
with diffuse out of the beer and into the water while the water on the
outside will diffuse in. This continues until the concentration of
alcohol
is the same on the outside as on the inside. If the water on the outside
is
constantly renewed such as by keeping fresh water flowing around the
membrane then the alcoholic strength can be reduced to a very low level
while not loosing any of the components of beer that you want to keep
except perhaps some of the aromatics from fragrent hops, but then there
is
not exactly an abundance of those in A-B stuff anyway :-). Another *
big*
plus is that the beer does *not* need to be heated.

There are several important uses of this sort of
'better-living-though-chemistry' technology. Perhaps the best know is
kidney dialysis. There the waste being removed is urea and a few other
components. Another very important use is water desalination and
purification. This is often called 'reverse-osmosis' since the water
is driven out of the water/salt mix under pressure across a membrane
and collected on the other side. The normal tendency would be for
water to want to dilute the sea water but pressure on the inside of the
membrane opposes this; maintaining this pressure is one of the things
that makes this process expensive.

Most of these techniques require flow conditions that are carefully
controlled and monitored. The beer would flow from one direction on

one side of the membrane and water from the other direction on the other side. The membranes can get expensive and the whole process becomes a chemical engineering problem to do well. It should be cheaper and better than evaporation. I tend to doubt that A-B dilutes their regular beer by about seven-fold in order to reduce alcohol from 3.5% to 0.5%. A simple test should help to discover this, evaporate down a bottle of regular beer and a bottle of non-alcohol beer and weigh the residue. A diluted bottle will have seven times less residue. Nor do I think they would dilute it and then evaporate back down. Dialysis would be much cheaper.

Smithwick's
>listed under Ireland. According to Jackson, Guinness and Allied
Breweries
>have formed Irish Ale Breweries, with breweries in Dundalk and Kilkenny.
>Smithwick's tasted like a bitter, not an Irish ale. It is a very
>drinkable beer. To my knowledge, it is available in Ontario, but not
>the States. Maybe some importer will wise up!

A drinkable, but unremarkable Irish Ale.
Smithwicks is more an Irish Ale than the piss produced by Coors or the
stuff made in France or Canada. Smithwicks is the best example of a
commercial Irish Ale, and if it tastes like a Bitter that's because
it's a very similar beer, and the only difference is country of origin.
It is possible to get MacArdles in a few places in Ireland, but Phoenix
ale is only found in the vicinity of Waterford. There are now no
other Ales produced, to my knowledge, in Ireland, apart from Bass in
Belfast.

In Ireland Ale sales are dropping like a Lead balloon, suffering market
share loss to lager. Stout sales are relatively strong, but that is
because
the Guinness sold in Ireland is usually a lighter, more drinkable beer
than
export Guinness, and is more easily drunk in copius quantities than other
beers.

In Ireland we say Smithwicks is like making love in a canoe, but then I
have heard of people calling Watney's Red Barrell a good beer. What is
laughable is that these self same people will criticize Bud drinkers for
having no taste. By coincidence Guinness make Bud under licence at the
Smithwicks brewery in Kilkenny!

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: efficiency

At the risk of beating this to death, let me try again. We must first agree that different types of malt have different "theoretical maximums" of extraction. For instance, 2-row pale malt may be 36pts/lb/gallon, whereas 6-row lager may be 31pts/lb/gallon, and wheat may be 39ppg. So if someone makes a batch with all 2-row, and gets 30ppg, he has a percent efficiency of 83% (30/36). If someone else makes a batch with 6-row lager, and gets the same 30ppg, his percent efficiency is a whopping 97%. An all wheat batch with 30ppg would be 77%. Each batch had the same ppg, but each was *differently efficient in the amount of available sugars that were extracted*. Percent extraction (%E) is the only way to compare the true efficiency of the 3 batches.

The obvious chink in the armor is agreeing on just what those theoretical maximums actually are. But even so, let's take an example:

tm=theoretical maximum points/pound/gallon
Calculations are based on points per one gallon.

10 lbs. 2-row, tm=36 10x36=360
1 lb. crystal, tm=30 1 x30= 30
.5 lb. black, tm=29 .5x29= 14.5

404.5 maximum possible points in one gallon

Let's say we extracted 6 gallons of 1.050 wort. That's the same as 6x50=300 points in one gallon. Percent efficiency would be 300/404.5, or 74%.

Now, let's say the above tm's are wrong, and they should be 32, 27, and 25 respectively. That would give 359.5 maximum possible points. The percent efficiency this time would be 300/359.5, or 83%. So yes, the %E depends on the tm's, but even with variations, we don't see the wild fluctuations that can result from a straight ppg efficiency rating. And there is *some* consensus among brewers of just what those tm's are (Dave Miller is too high :-).

The point is, we are trying to measure the efficiency of our *process*, of our crush/mash/sparge. Because %E takes into account the vagaries of the different grains, it eliminates that factor in the final result, and allows a true, and comparable, measure of efficiency.

Subject: Bulk prices on Dry Malt Extract

I've been looking for a place to buy spray dried malt in bulk, to save on the overall cost. The dried malt gives me a higher OG per dollar over malt syrup. I recently found a Home Brew distributor located in Merrimack NH, "Merrimack Brew Haus" (603-424-9854). Their prices are the best I've come across. A 55lb box of Munton & Fison dry malt extract goes for \$130 (\$2.36/lb). This compares with the \$3.30/lb I have been paying. The MBH sells other brands of dry malt for less, but I've been happy with the M&F brand and am waiting to hear of a good comparison on the HBD before I switch. Prices on other goods seem reasonable also; hop pellets: \$0.75/oz; 3.3lb M&F plain syrups: \$7.80; etc.

Insert normal disclaimer here! I have no connection with this distributor. I just like their prices.

From: "Tom Childers" <TCHILD@us.oracle.com>
Subject: Belgian White Beers, Charlie-style

(Thanks to Steve Stroud for posting some excellent information on Celis beer hopping and spicing!)

I recently got hooked on Belgian beers, and just did a batch of Papazian's "Who's In The Garden Grand Cru". This extract recipe came out extremely well, even though there is no wheat in it, and the recipe only calls for a partial (1.5 gallon) boil. Instead of wheat, the recipe calls for almost 3 lbs of honey, which seem to add a lot of complexity and lighten the body a bit in somewhat the same way wheat would. Also, the recipe includes 1-1/2 oz crushed coriander and 1/2 oz orange peel (considerably more than the 1/3 oz quantities per 5 gallons that Celis uses) and uses Hallertauer instead of Saaz and Cascades. I fermented with Wyeast Belgian at 70-73 deg F.

Comparing this beer side-by-side with Hoegaarden White was kinda fun. Both beers are slightly hazy, with a similar mild spicy scent. The real thing had a distinctive wheat flavor, and was somewhat lighter-bodied than the Papazian imitation, however the hop type and intensity seem identical. I'm going to try adding wheat, reducing the honey and going for a full boil next time (with smaller amounts of hops and spices). I highly recommend the recipe, which I will dutifully reproduce for those without a copy of the book:

Who's In The Garden Grand Cru (Charlie Papazian, TNCJOHB)

- 5 lb light/extra light dried malt extract
- 2-3/4 lb light honey
- 1 oz Hallertauer (boiling), 5-6 HBU
- 1/3 oz Hallertauer (flavor)
- 1-1/2 oz freshly-crushed coriander seed
- 1/2 oz dried orange peel
- 1/2 oz Hallertauer (aroma)
- Belgian ale yeast

Use 1-1/2 gallon boil for first three ingredients, 45 minutes; add flavoring hops and 3/4 oz coriander, 10 minutes; add 3/4 oz coriander and orange peel, 5 minutes; add aroma hops, 2 minutes. Add to 3-1/2 gallons cold water in primary, ferment as usual. OG 1.055-1.059, FG 1.004-1.008.

Subject: SG in test jar

A question came up about SG readings and if you could put some fermenting wort in the test jar with the hydrometer and just monitor the test jar to when the beer is done.

This probably will not work, I just bottled a stout which showed some real strange behavior.

The stout turned out to be just under six gallons, I have a five gallon carboy, slight problem. What I did was put the yeast in the five gallon container and started racking, when the bottle had around four gallons in it I stopped. I then racked one gallon off of the four (this had all the yeast in it) so I had a one gallon jug with 1/4 (approximately) the yeast. I then finished racking the last bit from the brew pot. This gave me five gallons with 3/4 (approximately) of the yeast. The two bottles were stored next to each other so the temperature was the same. The next day the five gallon batch was blowing off, while the one gallon never did. The one gallon did ferment, the air lock did bubble. Two weeks later the five gallon had stopped bubbling, but the one gallon was still going slow and steady (as it did the whole two weeks). The FG on the one gallon jug was a few (3) points higher than the five gallon jug. You explain it, I have no idea why this happened but it did. If this is normal I don't think your Idea will work.

From: rstya@map.mda.ca (Roy Styan)
Subject: trub filter

I've recently redesigned my hopback. It is now a long cylindrical tube (made out of stainless steel wire mesh), pinched off at one end, with the other stuck in the outlet of the brew kettle.

Works great for hops, but all this talk about trub started me thinking. What if I filled the tube with some sort of material that would let the beer through, but not the trub? The tube has a large surface area and I suspect it won't get clogged. Does anyone out there do something like this? If so, what material do you use? It would have to be something that allows cold wort to run freely by gravity, and can withstand a vigorous boil. Stuff it with cotton balls? Wrap it with a few layers of cheese cloth?

Subject: re: SG readings

Peter Maxwell says:

>I'm nervous about continually opening
>the secondary fermenter to siphon off a sample...

I've had the same concern. The idea that came to mind was to have a two hose system and an airlock that has a lot of `slack' in it so that I could draw off a sample without drawing air or water back through the lock.

I thought about this for a while, and then discovered that it was already out on the market. It's the Brew-Cap. I like it 'cause it lets me close the fermenter once and leave it closed until I bottle, while allowing me to draw off the trub and yeast and take samples for readings whenever I want.

Beyond being a happy customer, I'm not connected in any way with the Brew-Cap folks. (I thought of it way too late :)

>

Was this diacetyl produced BECAUSE you racked off earlier? What
happened?
How could racking earlier than day 4 result in this?

You also mentioned that this was your procedure for ales. How does it
differ for lagers? When the weather gets colder here I intend to try a
lager and would like to know if there are any other gotchas regarding
racking off trub.

In general, it doesn't work out that well. In particular, if you draw
off
the sample early, the main batch and the sample will diverge fairly
quickly
(at least in my experience). Moreover, the divergence seems to go in the
wrong direction for estimating when you've fermented out--the sample
ferments faster.

[Why the divergence? Probably at least the following two factors: The
main
batch will have substantial top-to-bottom gradients of yeast and sugar
con-
centration; it would be hard to get a "representative" sample, esp. with
comparable gradients. The surface:volume ratio is different for the
sample
and the main batch.]

Subject: oxygen absorber caps

I bought some of these from the AHA a few months ago - it seemed like a good idea for beer that might be aged for some time, like the ollalieberry wheat beer that I used them for. The most recent Williams catalog lists them and says that they are activated by moisture. I have 2 questions: 1) do these things actually work or are they just another attempt to extract a few more pennies from homebrewers? 2) if they are activated by moisture, then sterilization by boiling (or autoclaving) would render them useless, no? Any thoughts?

Subject: Rejected posting to BEER-L@UA1VM

I have had an interest in getting into the homebrew 'business' for sometime, and have been lurking here for about a week now. I would like to know the equipment I would need to get started, and the approximate cost.

I make my own bread and find it hard to find special flour, so I am concerned that it will be hard to find the proper materials for brewing beer. Is this the case? (Anyone in Baltimore than can offer locations to purchase equipment and supplies?)

Finally, the local Price Club has a 'MicroBrewery' (which prompted me to finally look into the idea, although I have wanted to brew my own beer for quite some time). Any experiences with this? Would I be wasting my money on a 'chemistry set' like this? (i.e. would I be better off buying my equipment separately).

Any help you can offer would be greatly appreciated.

Subject: Godzilla vs Mothra

A funny thing happened the other night. I went to a fight and a hockey game broke out. Rather, I went to a homebrew meeting and a calm discussion took place. Big deal you say? Big deal I say considering who was doing the discussing. The two parties involved were Al and Jack.

Really.

This Clash of Titans took place at the monthly Chicago Beer Society homebrewers gathering. The two met, exchanged beers and talked about this and that. Each brought an array of beers and it was deemed by many that the beers from both sides were decent. No knives, guns, chains or keyboards.

Who would have believed that a calm, orderly exchange of ideas and opinions could occur without any trouble whatsoever. I personally had expected otherwise and wore body armor in anticipation.

Far be it for me to be optimistic but I would venture to say that at this point anything is possible. Peace in the Middle East, democracy in South Africa or maybe another Olympics in Sarajevo. Sometimes one can hope.

The funniest thing about the whole night was the reactions of several HBD subscribers who saw Al and Jack for the first time. The common observation was that they always thought that Al was a lot older and that Jack was a lot younger.

chris campanelli

PS. I just bet that Al and Jack become best buddies in the whole world and that they and their respective wives all get together and play bridge or something. Just you wait and see.

Subject: Pre-cooking wheat??

Several posts recently have described the procedures used at the Celis brewery to make their Texas style wheat beer. The description is of a grist that is 1/2 belgian 2 row malt and 1/2 hard red wheat. No mention is made of pre-cooking the wheat.

I have always used rolled wheat flakes from the local food coop since these are pre gelatinized (cooked) but I would use whole red wheat if I didn't have to boil it for 45 minutes or more. What is the story, does Celis cook the wheat? or have I been misled into thinking cooking is essential when it really isnt?

thanks,
dennis

Subject: The Cat's Meow 2 - Updated Text version

For all of you fine folks that have been waiting for the plain text version of the updated Cat's Meow 2, it was finally completed over the weekend. The file has been uploaded to sierra.stanford.edu and is available for anonymous ftp under /pub/homebrew/recipe-book/cats_meow_ed2.

For those who need to use the listserver they can send a message to listserv@sierra.stanford.edu with

```
get homebrew recipe-book/cats_meow_ed2
```

as the body of the message.

Due to an unfortunate oversight with the original CM2 text version, there was no easy way to provide update files as with the PostScript version. Discovering this, I bit the bullet and completely re-formatted the whole kit-and-kaboodle. This time the page numbers are formatted "chapter-page", so in the future simple update files are all that is required.

I am very sorry for the delay in getting this file finished as problems have abounded. About a third of the way into the job, my computer glitched and started to eat the data on the hard drives, and I lost everything. (backups? what backups?) At least it's done and I have seen to it that this problem will not occur again. (ordered a tape drive!)

Enjoy, one and all...

Subject: Flat beer

Greetings:

I've a bit of a carbonation problem. My problem is that I bottled a spiced ale (nutmeg cloves & orange peel) about a month ago. The ale is completely flat. Not a bubble. Thinking that I had relaxed a little too much and enjoyed one too many homebrews I thought perhaps I forgot the priming sugar. So I opened every bottle carefully and added a bit of sugar. Two weeks later... NO CHANGE. I'm thinking about starting some yeast and repitching. Any thoughts on this. I know I have a pretty good chance of contamination.... BTW there is almost no sediment in the bottles.

Thanks in advance.

Subject: Colorado Brews

Howdy,

The mention of CO brews being weaker is left over from an old law, to best of my knowledge. I know CO at one time sold 3.2 beer, but do not know if this was a ruling for all beer, or just for 18 - 21 year olds, or ... I know you can get "normal" strength beer here though. I personally have not bought anything from the giants since moving here in August, but was assured that the beers are not 3.2 beers. I KNOW that some of the stouts and porters and ambers and ... that I have bought here are over 3.2%, as well as my homebrew! ;->

I will look into the laws and get back to the HBD with some more definite information.

- Brian

P.S. Incidentally, the student union here on the CSU campus sells beer, but it is 3.2 beer. So, it is available, but supposedly the stuff you get in the liquor stores is "full" strength.

Subject: off the trub = off the yeast?

Thanks for all the responses regarding the trub issue. I brewed a batch over the weekend, trying to "do the right thing" and got peculiar results. I'd be interested in reading comments on the experience. I brewed an extract/specialty grain batch on Saturday, siphoned off the wort into the fermenter leaving most of the hop pellets behind and a lot of the trub. I pitched the yeast around 2 pm. At 11.30 pm I noticed that the airlock was showing signs of slightly higher pressure so I thought I'd rack off the trub then rather than leave it until the next morning when fermentation might catch up with me. Well, not only did this make me later for bed than I wanted to be but it seemed to stop everything! By 5 pm the following day (i.e. 27 hours later) it was as dead as a doornail, and was showing no signs of life, so I pitched some more yeast. This morning it seems to be starting to ferment. The temperature is around 67 degrees.

This is wierd. It seems as though the racking took most of the yeast with it. After I pitched the new yeast I noticed that very soon afterwards there was a noticeable sediment on the bottom. It looked as though the yeast has sunk to the bottom. Maybe I was racking off the yeast rather than, or as well as, the trub.

Any feedback on this is welcome. I'm very tempted after all this to simply forget all about it.

Peter

Subject: Yeast Culturing and Storage Question.

I recently received an Advanced Yeast Culturing kit for my birthday. I am concerned about running out of the pre-poured wort agar plates. The plates are used for propogating and purifying yeast cultures. The plates are made out of plastic and are not reusable. In the future I would like to continue using plates. I have contacted a medical supply company for a catalog listing glass plates and culture tubes. Now the big question: How does one make the sterile brewers wort agar? As you can see, I am trying to avoid purchasing the pre-poured slants and plates. I would rather save the money for other brew-related purposes (all grain goodies). Greg.

Date: Tue, 10 Nov 92 08:58:50 -0500
From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: racking after respiration

I posted the following on Monday morning; it seems to have ended up in Tumbolia:

"B followed A, therefore A caused B."

This fallacious form of reasoning is very common, and I plead guilty your honor, with an explanation. Peter Maxwell and I have had the following back-and-forth in #1007 & #1008:

```
>> ....then I got a
>> batch with an INCREDIBLE, UNDRINKABLE amount of diacetyl. End of
>> experiment. Back to racking on day 4.
>
>Was this diacetyl produced BECAUSE you racked off earlier? What
happened?
>How could racking earlier than day 4 result in this?
```

I never claimed a causal connection, although I had hoped to get some evidence one way or another from other HBDers. I'd love to find the time and patience to test scientifically the effect of racking at 24 hours on diacetyl production.

My 1990 experiment came to an end based on laziness, not scientific method. Brewing a batch of beer requires so much work that I hesitate to take a chance on an experimental method that ended in failure -- even once -- when I've successfully brewed scores of batches another way. Unscientific, but in keeping with a hobby I view as being 45% art, 45% science and 10% magic.

Here's my experience racking within 12-24 hours of pitching. All batches are full-mash, using only malt and specialty malts.

Batch	Style	When racked	Comments
187	Pale Ale	Morning after (12-16 hrs.)	Up to my usual standards.
188	Mild Ale	" " " " " " " "	" " " " " " " "
189	Pale Ale	24 hours after pitching	Overpowering diacetyl.
190	Stout	planned at 16 hours	Was fermenting too actively to siphon.

After being unable to rack #190, I bottled #189 and discovered the diacetyl. I have never since attempted racking after respiration.

```
>When the weather gets colder here I intend to try a
>lager and would like to know if there are any other gotchas regarding
>racking off trub.
```

Me too, except that mine will be a steam beer. Advice, fellow HBDers?

```
++++ In HBD1009, Peter told us how a batch that was racked
9 1/2 hours after pitching apparently died. ++++++
```

When I racked off the trub in batches 187-189, I seem to recall that it also had the apparent effect of halting the fermentation.

Temporarily, in my case, as it always re-started itself.

I think it may be something like this: until high krausen, even our top-fermenting friends tend to sit on the bottom, along with the trub. If you rack too early (9 1/2 hours, in your case), there's not enough yeast in suspension. If you wait until high krausen, it's too late, because the furious bubbling makes siphoning impossible. Someone like George Fix can probably tell us if this is accurate. If so, then the whole procedure is like toast: "...just cook it 'til it burns, and 20 seconds less."

>In future I'm leaving it alone.

A good piece of advice I read in Northern Brewer (the CABA quarterly) about six years ago: "don't bugger with the beer". Once the yeast has been pitched, leave it be until you're ready to bottle/keg/rack to secondary. As a lapsed Catholic, I have a residual belief in the efficacy of ritual, and always say a "domine" when I pitch my yeast. Then it's out of my hands, at least until the krausen falls. I wonder if there's a suitable pagan deity whom I can invoke instead? Perhaps this Sumerian beer goddess mentioned in #1008-9, or some ancient Celtic fermentation "spirit" :-)

Cheers,

Rob (bradley@adx.adelphi.edu)

Subject: Candi sugar experiment

I'm planning to conduct a kitchen experiment to determine just what it is that candi sugar contributes to beer. However, I'm no scientist and my supplies of candi sugar are limited, so I'd welcome any comments on the following "experimental design":

3 test batches of 1 quart each

Each batch will have 1/4 lb DME (+/- 1.040), plus 100 grams of sugar

Batch 1: Corn sugar (the "control")
Batch 2: White sucre candi
Batch 3: Brown sucre candi

Ferment each batch with 50 ml starter from plated Sierra Nevada/
Narragansett
yeast (the idea being to use something healthy but neutral in flavor)

Ferment to terminal gravity and bottle with 1/2 tsp corn sugar per bottle
(hard to rack and bulk prime with such small quantities)

Does this sound like the right way to go about it?

Date: Tue, 10 Nov 92 10:15:20 EST
From: jim busch <busch@daacdev1.stx.com>
Subject: re:celis wit

According to recent information from Hoegaarden Wit brewers, they do not gelantize the raw wheat prior to mashing. What I was told is that they employ very long rests (45 min each) at protein stage (123-ish F), beta rest (144F-ish) followed by saccharification rest (60 min? 152?) and a mash off. Normal lautering follows, without a special lauter tun.

I realize this differs with the information from the Celis post. One would assume similar techniques in each brewery, but since they are owned by different interests, anything is possible. I did find it quite interesting that the Celis information claimed a simple one step infusion. Note that the Celis post claimed using 6 row malt, not two row. As someone who has brewed a Wit using 45% raw spring soft wheat and 5% raw steel cut oats, I can attest to the difficulty of working with the grains. Now maybe my mistake was using soft wheat, since the Celis post indicated hard wheat. I also gelatinized the grains, but I believe the temp got too low, resulting in a hardened mass. My next go at this style will follow the multi-step mash bill, keeping the consistency loose and skipping the grain boiling step. Since this is a very low gravity beer, it may not be necessary.

Any comments/experiences with the pros & cons of hard versus soft wheat????

Jim Busch

Subject: Re: efficiency

>At the risk of beating this to death, let me try again. We must first
>agree that different types of malt have different "theoretical maximums"
>of extraction. For instance, 2-row pale malt may be 36pts/lb/gallon,
>whereas 6-row lager may be 31pts/lb/gallon, and wheat may be 39ppg.

Oke, there is a theoretical maximum of extraction. We define extraction
as
being the amount of stuff which can be extrated out of the grains. So
this
includes (un)fermentable sugars and of course all other kind of stuff. Is
this
interpretation of extraction oke??? If yes, then ...

>So if someone makes a batch with all 2-row, and gets 30ppg, he has a
>percent efficiency of 83% (30/36).

Oke, this figure (Eff) will presumable be the same for that method of
brewing
a single brewer is using. This figure will be quiet constant to the
brewer and
type of malt, in my opinion. (real breweries will have high efficiency,
perhaps 100% and beginners lower).

This $TM \cdot Eff$ gives a figure for the OG, correct??? (be aware I do not have
the
custom of using pts/lb/gallon, but I am trying to get the Papazian book
[what
is the ISBN-number?]).

To get an idea about the FG one needs to know how much of the extract is
fermentable. This figure (Fer) is also different percentage for every
malt.
E.g. lager malt 65% of the extract is fermentable, for white sugar this
is of
course 100%, for crystal (the European term!) it is 60%, brown sugar it
is
95% and dark malt it is 60% (I have more info, but just as example;-) .

Using thus $TM \cdot Eff \cdot Fer$ for every ingredient in the recipe, it is possible
to
get a figure for the amount of fermentable sugar and thus a figure of the
amount of Alcohol. Furthermore having the a figure of UNfermentable stuff
and
the amount of alcohol, one can calculate the FG.

All the best,

Victor

Subject: St. Louis Beer

Hi Estes --

Unfortunately, there is only *one* brew-pub in St. Louis. Fortunately, they make good beer. The brewmaster is none other than Dave Miller, author of two books on homebrewing, and all-around nice guy.

Anyway, the pub is called "The Tap Room" and it is two blocks south of Washington Avenue on 21st Street. As for landmarks, there really aren't any. This is not particularly close to the hotel -- maybe 16 blocks. Any cab driver should be able to get you there from the Adams Mark. It helps to approach the pub from the north, because 21st Street is one-way south. Expect to spend \$10 on a big hamburger, plate of spicy fries and a pint of brew. Just north of the hotel is an area called "Laclede's Landing". There are bars, dance clubs, restaurants, etc (but no brew pubs) up there. The Hotel desk should be able to direct you. I'm not much of a "night life" person, so I really can't make any specific recommendations. If you like jazz music, one of the lounges in the Adams Mark itself has a reputation for bringing in good players. If you like live Rock & Roll, check out Mississippi Nights. The Riverfront Times newspaper is the best place to look for information about Laclede's Landing entertainment. It'll probably be available (free) in the hotel lobby.

Hope this helps.

Subject: Swedish Nightmares!!!!

HELP!!!

I'm stuck in a non-brewers land full of watery lager and can't find the ingredients for a good Stout!!!

Chocolate malt has now become (temporarily?) impossible to get in Sweden and I'm dying to brew a good Stout for some friends.

Does anyone out there have any ideas for suitable alternatives??
Anyone tried Cocoa or real chocolate??

I've got 10 kilos (20 lb) of crystal malt if anyone has any ideas on a conversion process (have plenty of pilsener / normal malt as well)

I hope someone out there can help me out !

P.S. Is there many other folks out there in Sweden with the same problem? So far I've tried ringing around both here in Stockholm and in Goteborg.

Thanks in advance for any suggestions

Rick Zydenbos.

Subject: Wyeast Bavarian Lager fermentation temp

Last Wednesday I tried to brew an extract/specialty grain marzen loosley based on Papazian's Winky Dink Marzen. OG was around 1.050. I cooled to around 70 degrees F and pitched Wyeast Bavarian Lager yeast. I then placed the fermenter in a refrigerator at 45 degrees F. No action for the first 12 hours. I then raised the temperature to around 50 deg. Still no action. Then I turned off the fridge which is outside and the temperature stabilized at around 55 deg. After 72 hours there were no signs of fermentation. At this point I brought the fermenter inside in hopes that warmer temperatures would activate the yeast (73 deg.) Still no action :(

It is now going on the 6th day and my concern is growing with each passing minute. Is the yeast dead or is it dormant? As far as I can see I have 4 choices: 1) Keep waiting in hopes that fermentation starts. 2) Pitch more yeast. 3) Add some kind of yeast nutrient. 4) Give up. I would rather not choose option 4 as I was looking forward to drinking some good beer.

Has anyone experienced this problem with this yeast (or any other lager yeast)? Should I have waited for active fermentation to start before chilling? or should I have just left it alone in the fridge? I know that some lagers are brewed over the course of many months, but how long does it take for the primary fermentation to take place?

Any advice would be greatly appreciated.

Erik Zenhausern

Subject: Colorado Blue Laws

Brian Walter writes:

> The mention of CO brews being weaker is left over from
>an old law, to best of my knowledge. I know CO at one time
>sold 3.2 beer, but do not know if this was a ruling for all beer,
>or just for 18 - 21 year olds, or ...

Before the drinking age became 21 for everything a few years ago, 3.2% alcohol by weight (about 4% by volume) beer was the only alcohol 18-20 year-olds could buy. There were no other restrictions on alcohol strength. 21 and older could then and still can buy any kind of beer, from Miller Lite to Samichlaus. We don't even have to call the stronger stuff "Malt Liquor," as many (most?) other states do.

3.2 beer is still around, though, because it's the only kind of alcohol grocery stores and convenience stores are allowed to sell in Colorado. This is a bit annoying. Since 21 is now the age for everything, I would like to be able to buy all types of beer and wine in grocery stores. Two factors prevent this from happening. First, the political climate is such that no law making drinking more convenient is going to get passed, no matter how much sense it makes. Second, the liquor stores will lobby hard against such a change, as they are now the only source of wine and good beer.

Other blue laws in Colorado are nothing stronger than 3.2% beer can be sold to anyone on Sunday (except in bars), and nothing at all can be sold between midnight and 6 am (bars can sell 'til 2 am) every day.

Subject: Texas-style wheat beer?!?!

Just because the world's foremost authority on Belgian Wit beer has taken up residence in Texas doesn't suddenly change the name of the style does it? Just kidding. No, really -- Wit beer is a recently -revived style (by Pierre Celis at the DeKluis Brewery in Belgium before the Belgian industrial-brew giant Interbrew bought him out) that has been around probably longer than Texas has.

I don't know about the cooking of the wheat in Witbier, perhaps Steve could follow-up, but the wheat in traditional Lambiks (another very old Belgian style of beer) is not pre-cooked... the only "cooking" of the *unmalted* wheat that appears to occur is during the decoctions (this is from memory -- I believe that Martin Lodahl first noted this -- Martin?)
so the extraction is quite low from the wheat.

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: gravity/trub

I recently brewed an extract-based Bass-Ale clone (supposedly) recipe that was posted here a couple hundred issues ago.

It went like this:

6 lbs. English Light Xtract (William's)
1.1 lbs Demarara sugar
1 lb crystal
Northern Brewer & Fuggles (I forget how much offhand)
3 tsp gypsum, 1/2 tsp irish moss
Wyeast British

I got an O.G. reading of 48. After about a week in the primary I racked to a secondary last night and got a reading of about 18.

So here's the question: in the past I've used Wyeast California and American. In both cases after a week or so in the primary I got gravity readings much closer to the eventual finishing gravity of around 12, even with a heavy Christmas ale I brewed which had an OG of 60 or so (American used with that). Does the British work more slowly? Does it generally result in a higher FG? Is there anything about the recipe design that would suggest a finishing gravity in the neighborhood of 18?

Not "worrying," just curious.

Also, I've been interested in th thread on yeast nutrients in trub. I generally rack off the trub into my bucket primary as soon as the wort is cool (about 30 minutes for me) and then stir in the yeast. I've been using Wyeast in standard wort starter solutions and I get excellent starts (usually within 6 hours) and, to my relatively untrained palate, pretty good beer. If I were to pitch into the cooled wort in the brewpot, wait 30 minutes and THEN rack into the primary, as I think has been suggested, what specific improvements could I really expect in my finished product, and would those improvements be worth the additional risk of infection from waiting the extra time before sealing up the beer under the airlock?

Wizards of Wort, please advise!

>Dialysis is hardly an obscure process, wouldn't it be sufficient to allow that you are unfamiliar with it?

No.

> I personally have no knowledge of what A-B uses to produce their non-alcoholic beer, but dialysing out the alcohol makes perfect sense.

It only makes sense if A-B had a tradition of using the best technology to produce the finest tasting product. In light of the fact they seem to use what ever technology it takes to produce the cheapest beer no matter how insipid it tastes, I humbly stick to my accusation that they dilute it as a major part of the alcohol reduction process. Osmotic process such as you describe are notoriously expensive and I know of no commercial use on the scale of a major brewer.

>I tend to doubt that A-B dilutes their regular beer by about seven-fold in order to reduce alcohol from 3.5% to 0.5%.

I did not mean to imply that dilution was the only measure taken to get there, just that it was the most easily overlooked.

My experiments with NA make it abundantly clear that dilution is one of their secret weapons.

The NA I made simply by heating to 170F and letting cool to 150F reduced the alcohol in my beer to 1.3% according to mass spec measurements made by Jean Hunter at Cornell.

By diluting this with equal parts water we end up with .65% and a perfectly drinkable beer. It is not hard to imagine how they get it down to .5% with a little more water. Nor is it hard to believe this is their "secret process" when one considers the insipid taste of their NA beer.

On the other hand, if we start out with a malty, hoppy homebrew and process it as I have described, we end up with an NA that has far more flavor and character than even their premium stuff.

>Subject: Godzilla vs Mothra

>A funny thing happened the other night. I went to a fight and a hockey game broke out..... Who would have believed that a calm, orderly exchange of ideas and opinions could occur without any trouble whatsoever...

Just a good example of one of the evils of the "electronic revolution". It's a lot harder to be unfriendly when you're eyeball to eyeball. And it's a lot easier to be objective about beer when you have a glass of it in your hand than trying to reconstruct what it probably tastes like based on keyboard entries.

Nice thoughts, Chris...

Subject: **First Time Brewing Jitters**

Thanks to all of those who answered my mail on first time brewing jitters. I drank one at five days, one at seven, and a few at twelve - WOW what a difference a few days make.

The first was flat and kinda bitter.
The second had more carbonation but still a little bitter.
But the ones at twelve days were well on there way to full carbonation and surprisingly very smooth. The difference in just a few days was dramatic.

I will slowly drink these as time goes on as I begin the wait for another batch, now in the secondary, to age.

Once again thanks - Gerald Wirtz - Stratus Computer

Subject: NJ Brewpub News

New Jersey brewpub news - the "issue" has been introduced to the state senate and the bill number is S-614. The bill is now in the Law and Public Safty Committee and in the People's Republic of NJ, only a select few bills get out of this committee. Once this is accomplished the bill must be passed by the Senate and then the Assembly and if the Assembly adds amendments, then it goes back to the Senate - isn't politics fun! To top this fun off, every time the political process adjourns (I think every 2 years) the bill must be reintroduces again. I believe the homebrew bill had to be reintroduced 2 times for example.

If anyone knows who we can abuse --- I mean encourage to help this bill along and if anyone knows what the bill actually says (any political science majors at Trenton State listening) that would be most helpful.

In other news a brewpub has just opened in the area:

Mountain Valley Brewery
Route 202 (ie Orange Ave/Franklin Turnpike)
Suffern, NY.
914-357-0101

Hours: 11:30 - 2 M - Th
11:30 - 4 F & Sat
12 - 12 Sun

Suffern is located just across the broder from Mahwah, NJ near route 87 and 17. They just opened 2 weeks ago and have a porter, pale ale, copper, copper light (less malt) and an octoberfest will be up by the end of the week. Have not made it there yet, but will ASAP.

Subject: Brettanomyces in Porter

Hi Gang,

I have come across numerous references to Brettanomyces being one of the yeasts present in the beers of Old England, notably Porters and Old Ales. I assume that they are still used in beer such as Thomas Hardys. If one wanted to make an 'authentic' porter then I imagine that the process would be similar to making a p-lambic. The question is ... does anyone have any idea which strain of Brettanomyces to use?

Just some remarks on this:

- I think chocolate malt is named after the colour, not the taste. Using chocolate (or rather no-fat cocoa) in a stout is probably not the way to go. (I'm not saying that it doesn't taste great, it's just not really like a 'true-to-style' stout)

If you want real dark malt or (unmalted) barley, roasting it yourself is a fairly simple operation. I often do this because I don't use it often enough to bother buying kilos of the stuff.

For stouts I'd suggest roasting unmalted barley, though malt will probably also do (I use roasted crystal malt in a favourite 'dubbel' variation).

The roasting is easiest in an oven:

- .Heat oven to 180-190C
- .spread out layer of grains (not more than a cm)
- .spray with a little water every 5 minutes or so
- .leave in oven for 30-60 minutes, depending on starting grains and desired colour (like dark chocolate for chocolate malt).
- .(reduce heat if the grains start to 'pop' this is not what you want)
- .leave outside oven to cool (and loose possible burnt smell).
- .store in (airtight) container.

You can also do this in a (thick bottom) frying-pan, but it requires some practice and a lot more attention.

I hope this helps

Marc de Jonge.

From: wood@marble.rtsq.mot.com (Dan Wood)
Subject: Party Balls, Bionic Yeast

Kenneth Haney asked about using party balls. I have a commercial product based on party balls, called a "brewball". They are made by the Marc Fritz brewing company, and were reviewed in Zymurgy a couple of months ago.

From their literature, it seems like the main problem with using beer balls was resealing them. The brewery's crimp seal is difficult to reproduce. They solved this problem via their (patented) invention of the "batch latch", a clamp that fits the neck of the ball, plus a disposable cap made of rubber and metal that is pierced by the tap.

Parts are available separately, or in kits. When I ordered a few months ago, the kits were on sale. The "party system" consisting of a brewball (choose 2 or 5 g), batch-latch, tap, and 5 seals is \$34.95, marked down from \$54.95. The brewball and batch-latch setup (needed to store a 2nd batch) is \$19.50, marked down from \$27.50. I didn't ask how long the sale lasts. Their number is 800-762-2560. This tap is identical to those used on the beer balls, except the tube to draw the beer is shorter on the 2 gallon model. They also have CO2 caplet based taps available.

I'm very pleased with mine: I have the 2 gallon model. It's great for parties, and especially camping, as long as you're not backpacking :). With the air driven pump, you only have about 2 days to drink 2 gallons, so you'd have to be really thirsty to try it solo. I'm sure that it doesn't compare to kegging systems, but you can't beat it for the price.

Just a satisfied customer, no commissions for me. :(

New topic: I've been using Edme dried yeast ever since Whitbred quit making dried yeast a few months back. For my last few batches, I've been hydrating the yeast prior to pitching, but haven't tried making a starter. Perhaps it works "too well" without one: I'm looking for opinions.

The hydrated Edme yeast takes off in just a couple of hours, blows off tremendously, and finishes in about two days. I racked my last two batches to secondary on the second day, but didn't get any additional bubbling during the subsequent week. I promise, next batch I'll take hygrometer readings. One annoying point: the last batch, an extract-based amber with caramel malt and honey, blew off about 3 quarts! That's alot of homebrew that never made it to my glass. :(

I welcome any comments and suggestions, with one exception: don't suggest all-grain brewing. I prefer to spend my (scarce) spare time drinking homebrew, not making it. This may change when I'm as old as Jack, though. :)

Happy brewing!

From: blossomf@ttown.apci.com (Karl F. Bloss)
Subject: Molasses Priming

I had asked in a previous HBD about using sugar beet molasses and received limited response. So, I just got creative and primed a few of my last amber ale batch with molasses individually in the bottles. The color is *much* darker than the rest of the batch, but the difference in taste is negligible. I didn't want to use copious amounts because of the explosion hazard. I just thought that Papazian says to be careful with using too much molasses. Comments or experiences? I planned to add a cup or two to my next amber batch, along with a lb. of chocolate malt and see what happens.

Prost! -Karl

From: gcw@granjon.att.com
Subject: Wyeast 1056 Problems

Having a problem with Wyeast 1056 (American Ale), I have used this yeast several times before with no problems, but this time -- 2 nights ago I popped the bulge and was planning to add it to a premade starter the following night. In the morning I noticed it was already very swollen, but did not have time to add to the starter. Last night I added the Wyeast to the starter (it looked like it was going to blow) and this morning it looked like nothing happened. But when I looked closer at the bottle (clear 750ml) there was sediment at the bottom which was not present last night.

The Wyeast was very fresh (OCT 21) and by the quantity of sediment it looks like the yeast did not ferment at all in the starter bottle it just settled down to the bottom. The Wyeast and the starter wort were at the same temp and the wort OG was around 1025, so I don't think the yeast was shocked. So my plan tonight is to add some new wort to the yeast cake if there is no activity.

Has anyone seen 1056 ferment so fast or could have the yeast die out in less than 24 hours in the package and if so what are my chances of reviving it.

Geoff Woods
gcw@garage.att.com

By the way I posted a very complete US/Canada brewpub/micro list on alt.beer yesterday if anyone is interested!

> Ferment each batch with 50 ml starter from plated Sierra Nevada/
Narragansett
> yeast (the idea being to use something healthy but neutral in flavor)

> Does this sound like the right way to go about it?

In Pierre Rajot's book Belgian Ale, he says the belgians use candi
sugar to lighten the flavor of their higher-gravity brews (does this
negate the need for your experiment? :-). But anyway, if you want to
experiment, I think you should try to make a brew like one of which
candi sugar is intended for - something in the 1.060+ range. I don't
think candi sugar is used at all in the lower gravity belgian beers.

Great book. Highly recommended.

Subject: Aluminum

(Flame-proof suit on...)

The November 5 issue of the journal Nature has an article titled "Absence of aluminium in neuritic plaque cores in Alzheimer's disease." The authors used nuclear microscopy to try to detect aluminum in the brain plaques characteristic of Alzheimer's disease. They didn't find any (that is, no more than in "control" tissue). The method is allegedly significantly more sensitive than chemical techniques that were used previously. They conclude that previous experiments had introduced the aluminum as part of the staining process (their method doesn't require staining), and that aluminum neither causes Alzheimer's nor is it associated with Alzheimer's.

Clearly more research is needed...

If you don't believe me, or don't trust my summary, look it up yourself. Nature is available at any university science library, and should be at good public libraries. The reference:

A couple of pieces of data are missing and may be significant. Before I go on, I don't mean to imply that any of these issues were the cause of Rob's batch of artificial butter flavor -- I just felt this was a good opportunity to point out some causes for high-diacetyl.

First we need to understand that all yeast produce diacetyl in some amount. Later, when the yeast begins to run out of sugar, it re-absorbs the diacetyl taking it out of your beer.

1. Was the yeast all the same strain? Some yeasts are much more likely to produce diacetyl than others. Some (like Samuel Smith's yeast) are very flocculent and have a high tendency to fall out of suspension. Even though the brewer's at the Tadcaster brewery (Sam Smith's) rouse the yeast, the yeast still does a poor job of reducing the diacetyl -- try SS Pale Ale.
2. Were they all equally aerated? Oxygen-deficient yeast is much less effective at re-absorbing the diacetyl.
3. Could fermentation have completed in the first 24 hours? One way to make a beer with a lot of diacetyl is to rack it off the yeast as soon as fermentation is over -- there will be less yeast to re-absorb the diacetyl and more will be left in the beer.

Victor writes:

>To get an idea about the FG one needs to know how much of the extract is

>fermentable. This figure (Fer) is also different percentage for every malt.
>E.g. lager malt 65% of the extract is fermentable, for white sugar this is of course 100%, for crystal (the European term!) it is 60%, brown sugar it is 95% and dark malt it is 60% (I have more info, but just as example;-) .
>
>Using thus $TM \cdot Eff \cdot Fer$ for every ingredient in the recipe, it is possible to get a figure for the amount of fermentable sugar and thus a figure of the amount of Alcohol. Furthermore having the a figure of UNfermentable stuff and the amount of alcohol, one can calculate the FG.

It's true that the amount of unfermentables is dependent on the grain, but it's mostly dependent on your saccharafication temperature. High-temp conversion (e.g. 158F) will retard Beta-amylase activity and thus give you a highly dextrinous wort (more unfermentables, higher FG). Low-temp conversion (e.g. 148F) will promote both Alpha- and Beta-amylase activity and thus the two enzymes will combine to break virtually all of your starches down fermentable sugars (less unfermentables, lower FG).

Here's what I suggest. Since it's been a *long* time now, at least
seven days by the time you get this, I suggest:

1. Taste it. If it tastes awful, dump it. If it's just sour, make
a batch of wheat beer and mix it with this one in the secondaries for
a Berliner Weizen (by the way -- I tasted a commercial (German) one (that
Steve Hamburg brought to the CBS/BOSS competition) for the first time in
ten years -- it was fantastic -- guess what my next experimental beer
will
be...).
2. If it tastes okay, you can do one of two things:
 - A. *Aerate* and pitch more Wyeast Bavarian Lager, or
 - B. Boil it to kill anything that got in, cool, *aerate* and
pitch more Wyeast Bavarian Lager.

I made a batch of Bock with the Wyeast Bavarian Lager which did well
at the CBS/BOSS competition, despite the fact that when *young* it

smelled like home perm solution. I pitched the yeast (without a starter) into 70F, WELL AERATED wort and put it in the crawlspace at 57F for 24 hours. At this time, it was just, just beginning to show activity. I put it into the beer fridge and set the thermometer at 50F for about three days. At this time, it was bubbling well and the smell in the fridge was like rising bread dough. I lowered the temp to 45F and racked to the secondary after three weeks. It was in the secondary for (I believe) two months at 45F. At bottling time, it smelled like home perm solution, but that smell went away after four months in the bottle at 40F.

From: garti@mrg.xyplex.com (Mark Garti mrgarti@xyplex.com)
Subject: hop back, sparging

I had asked about using my lauter tun as a hop back several issues ago. I received many replies from brewers who successfully use this technique. All of these brewers were using hop leaves or plugs. Being used to pellets only I over looked this and ended up with a totally clogged hop back. The pellet sludge had completely plugged all of the holes in the inner bucket. Was this a fluke experience or should the lauter tun hop back be used for leaf/plug hops only. I have since not bothered to use a hop back at all. Was my first mistake to believe that one was needed with pelletized hops?

How does one know when to stop sparging? I remember some line a while back that spoke of tanin extraction with excessive sparging? I sparge 10# of grain with the recommended 5 gallons of 77C water and was still getting good??? wort. After another 3/4 gallon sparge water (actual sparge water was 5.75 gallons) later I was getting 1.014 wort that was still tinted brown. My lauter tun is insulated and maintains temp well. My flow rate was such that it took almost 30 minutes to sparge, was this way to fast? Does the flow rate contribute significantly to extraction efficiency? How can I improve my extraction efficiency? After boiling down to 5.5 gallons I had 1.034 wort (65F). I used 8.5# british pale malt plus equal parts crystal and carapils. I believe this yields an extraction of about 19 ppg, way below any kind of numbers i've seen posted. Any pointers on sparging technique would be greatly appreciated.

Thanks,
Mark mrgarti@xyplex.com

> . . .
>Has anyone experienced this problem with this yeast (or any
>other lager yeast)? Should I have waited for active fermentation
> . . .

I don't claim to be an expert at lagers but I'll share my limited experience. I am currently brewing a lager (also a Marzen) and the first thing I noticed was that the yeast took longer to grow in working up to a one liter starter. My fermentation temperature is 52 degrees F and the yeast was from Dr. Schiller's Yeast Culture Kit (Strain L2 German Lager). The total time for this yeast to grow under these conditions, being transferred from agar to 1.5 ml., then to 50 ml. then to 1 liter, took about 6 days, (2 days growth in each container before fermentation was evident). The ale yeast I've used usually takes only 3 or 4 days to be ready to pitch from the one liter starter.

After boiling, I siphoned the hot wort through an immersion in ice chiller and got the temperature down to 62 degrees F in about 15 minutes. (There was still some ice left in my bucket which suggests that a cooler temp was possible if either the flow was slowed down or the coil was longer.) Since most of the hot break was still in the kettle, I wasn't planning on racking until the x#\$ rubber stopper fell into the carboy after I pitched the yeast. (Why do homebrew stores sell #6.5 stoppers for carboys which require #8 or higher stoppers, and why was I stupid enough to try using it more than once?) Since it was late Sunday night I decided to let the stopper sit in the carboy and rack the next morning. The carboy was put in the refrigerator at 52 degrees. During racking I found a fair amount of sediment on the bottom, probably consisting of yeast, trub, and hops. However, by Monday

evening there were some bubbles on top of the wort, and by the next morning, the krausen was pouring through the blowoff tube. It was still fermenting vigorously this morning (Wednesday).

>From this limited and still ongoing experience I conjecture that

1. The lag time will generally be longer with a lager at a reduced temp than an ale at room temp.
2. Therefore, pitching from (at least) a one liter starter is more important with lagers than for ales. (I'm not saying it isn't important for ales too.)
3. Racking off the trub after 8-10 hours does not cause any gotchas regarding fermentation for a lager.

I don't have any good advise for Erik, but I would try pitching more yeast if no infection is evident yet.

Subject: breaking down kegs

I have some soda kegs that I'm trying to get cleaned up so I can use them, and I ran into a problem last night. I was trying to get the fittings off of the keg and was unable to. I thought that these things came apart so that you could remove the stem, but after cranking down on it pretty hard I still couldn't get it to budge. These things do come apart don't they? Do you turn them counter-clockwise to loosen? Should I use something like WD-40 or Liquid Wrench on these things to help break them loose?

I guess the larger question is whether I need to do this at all, or will running some sanitizing solution through be ok?

>Now the big question: How does one make the sterile brewers wort agar? As you can see, I am trying to avoid purchasing the pre-poured slants and plates.

Go to your neighborhood "oriental" food store and ask for agar agar. You must say agar agar or they will not understand. I got blank stares when I asked for agar. It is sold in sticks about 10 inches long and 1 inch square. It is a dollar or so a stick.

Heat up one cup of sweet wort, i.e. from your last batch or make it from extract, in a pan and place half a stick (about 5 inches) in the wort. It will eventually melt completely, at which time, pour it through a tea strainer into a storage bottle and refrigerate till needed.

There is a great debate about the "proper" gravity of the wort but I use whatever I saved from the last batch and the same stuff I use for starters.

I have a detailed article on yeast culturing for beginners, that I will be happy to email to anyone interested.

>From: bradley@adx.adelphi.edu (Rob Bradley)

>I never claimed a causal connection, although I had hoped to get some evidence one way or another from other HBDers. I'd love to find the time and patience to test scientifically the effect of racking at 24 hours on diacetyl production.

I am curious to know what would motivate one to rack at such an early stage.

One of the objectives of two stage fermentation is to leave as much stuff behind after each stage and primary fermentation would just be well under way in 24 hours.

>I wonder if there's a suitable pagan deity whom I can invoke instead? Perhaps this Sumerian beer goddess mentioned in #1008-9, or some ancient Celtic fermentation "spirit" :-)

Try chanting, "The World's Greatest Brewer" three times while facing Chicago. You can also obtain the standard WGB hymnal and community prayer book by email.

>Does anyone out there have any ideas for suitable alternatives?? Anyone tried Cocoa or real chocolate??

Chocolate malt has nothing to do with cocoa. It is a reference to the color only.

You can roast regular malt in the oven and get a great coffee aroma and flavor. You can make it any color you want. Try 400 F for 30 minutes for a pound.

A better alternative is unmalted barley. Roast it the same way but roast it at least until it becomes crunchy. At this point it is just starting to smoke and turn color.

You can play with this for ever as there is no end of possible combinations of time and temp.

From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: Re: Swedish Nightmare

Just a suggestion on how to obtain dark malts in Lager Land. Why not make it yourself? There are good instructions on home roasting of malt in (I believe) a book called "Old English Beers and How to Brew Them" (or something like that) that was abridged and posted a while back. The basic method is:

- 1) dry the malt at 200-250F for about 20 mins
- 2) raise oven temp to ca 300F or above until desired degree of darkness obtained.

This is so simple that you can easily try many variations until you get what you want. I have made a couple of amber malt batches in this way, and I am sure you can make chocolate too.

BTW, I was told that this useful book is available from some outfit called "The Beverage People" somewhere in the USA. However, their 1-800 number does not work from Canada (where I am) and I have no other means of contacting them. Anybody out there have any help?

Date: Wed, 11 Nov 1992 18:30 EDT
From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: Dialysis vs Heating

Jack Schmidling suggests that dialysis is expensive. His alternative is to heat the brew to 170 F (if I recall correctly) to get it to 1.3% and then dilute. The energy costs for heating industrial quantities of brew (even Coors) are tremendous, while dialysis systems, once installed remove alcohol in a flow process which only requires pumping. Dialysis membranes are not in any sense unusual or obscure technology, and since Coors is in the business of making money (not beer) I suggest that they are indeed very likely to use dialysis rather than heat-based processes in removing alcohol from their product simply because they are CHEAP.

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>
Subject: On Plates and Decoctions

In HOMEBREW Digest #1010, a couple of items caught my attention.
First, Greg Habel is entering the wild world of yeast culturing:

> I am concerned about running out of the pre-poured wort agar plates.
> The plates are used for propogating and purifying yeast cultures.

Well, propagating, anyway. Sure, if you have more than one strain
in your inoculum you can sometimes separate them by doing a
single-cell streak and using colony morphology as an indicator of
the different strains you wish to subculture, but the technique
won't help much if you have bacterial contamination.

> The plates are made out of plastic and are not reusable. In the
> future I would like to continue using plates. I have contacted a
> medical supply company for a catalog listing glass plates and culture
> tubes. Now the big question: How does one make the sterile brewers
> wort agar? As you can see, I am trying to avoid purchasing the
> pre-poured slants and plates. I would rather save the money for
> other brew-related purposes (all grain goodies). Greg.

I got my Pyrex plates from Carolina Biological Supply. Their prices
aren't rock-bottom, but they don't have the violent allergy to small
quantities that most suppliers of this sort of stuff do.

The "pros" will use Difco MRS or some similar medium for this job,
available only in lifetime-supply quantities at steep prices. If
you want to play in style, who am I to say nay? I'm a cheapskate and
use a bargain-basement approach:

Dissolve a tablespoon of dry malt extract into about 375ml of hot
water, add a pinch of the yeast-extract-type yeast nutrient, and
a teaspoon of agar-agar (available in any health food store). When
it's all dissolved, put it and your plates in a pressure cooker for
20 minutes at 15 pounds. Be a little careful when you bleed down
the pressure; go too fast and your medium will end up all over the
inside of the cooker. Sanitize a work space in a draft-free area,
banish kids and dog, line up the plates with covers in place, then
working as quickly as you can, lift the cover of a plate as little
as you can to do the job, and pour in enough hot agar/wort to cover
the bottom to the depth of a couple of millimeters, then replace the
lid. Repeat until all plates are poured; there's enough media in
this recipe for about 10 standard 100mm plates. When the agar sets,
turn the plates upside-down, and keep them stored in that position.

Slants are even simpler, as you can use the same solution, and
sterilize after pouring the tubes.

====

And Algis Korzonas got my undivided attention:

> I don't know about the cooking of the wheat in Witbier, perhaps Steve
> could follow-up, but the wheat in traditional Lambiks (another very old
> Belgian style of beer) is not pre-cooked... the only "cooking" of the
> *unmalted* wheat that appears to occur is during the decoctions (this
> is from memory -- I believe that Martin Lodahl first noted this --
Martin?)

> so the extraction is quite low from the wheat.

Well, I did mention it in the presentation Mike Sharp and I gave at the National Conference. When I first saw the "cooker" at a lambik brewery I thought they must be doing the same sort of mixed-mash that North American industrial lager brewers customarily use, but learned that it was used solely for the decoctions. A double decoction, with no other cooking, does indeed appear to be the usual method. Needless to say, that leaves a lot of complex starch in the mash that is never available for conversion. By the time I noticed this, I had given up asking lambik brewers the rationale for their methods ...

Subject: CORN SUGAR

Terminology: US "corn" = rest of world "maize".

Corn Sugar is dextrose. I'm really not sure what the UK equivalent would be.

Corn Syrup is (I think) a very heavy solution of dextrose in water (but could include some other sugars). It usually is clear, but can be gotten in a "dark" variety that is a medium, clear brown color. Probably just has caramel coloring added.

Corn Starch is just that -- the starch extracted from corn (maize). It's a very fine powder, with no graininess/grittiness at all. If we have something called corn flour (terminology varies from one part of the country to another), it would probably be what I call "corn meal" -- ground hard corn kernels.

Subject: Hop Back vs Dry Hopping

Good Morning HBD'ers,

Recently, there has been a thread about Hop Backs. The first time I heard about a Hop Back was in the recent Zymurgy Special Issue (Gadgets), so I obviously have no experience with them. Hence, this posting.

As I understand it, a hop back is used to impart a wonderful Hop Aroma and Flavor to one's beer. When is it used (before or after fermentation)? How does this technique compare to Dry Hopping (do they do the same thing)?

I've always used hop pellets during boil and have never been really satisfied with my hop nose or flavor. Recently, I tried a Pete's Wicked Ale from a micro in Minnesota (Montana? Well, large state that begins with M) whose name escapes me. I was VERY impressed with both the wonderful hop aroma and flavor in this ale. Now I really know what I've been missing.

What's the best way to get this? Will a hop back or dry hopping do this?

Better living through Zymurgy,

Pete Oehler

Subject: Aluminum pots, Wyeast purity

hey folks.

Last weekend I was about to start a batch o'stout, so I pre-boiled 4 gal. of water and put it in a carboy to cool overnight. I boiled tap water in my 12-quart aluminum pot for 10 minutes for each of 2 batches. The resulting water was cloudy, with scum on top (my tap water is clear when it comes out). The next morning, the cloudiness had mostly settled into a layer of furry white precipitate at the bottom. The local water chemist thought this stuff was CaCO_3 but I don't understand why it came out of solution. Maybe the water was acidic and the aluminum catalyzed some sort of reaction? "Dammit Jim, I'm a rocket scientist, not a chemist!" :)

Anyway, my reaction was to hit the local restaurant supply house and buy a Vollrath 12-qt stainless pot (for \$17.67, pththth, gotta love used equipment). Someday I'll find a huge pot and go for full boil, someday.

About yeast: I've been brewing with Edme for a couple of years now with no infections. So of course, the first time I try Wyeast, I get little white rings in all my bottles. Bleah. I'm going back to Edme; I couldn't taste any difference before the rings appeared, either. I don't know where this "switching to liquid yeast improved my beer 100%" business came from but it sure didn't do much for me....

Subject: corn starch/corn sugar/corn syrup

First, let's be clear on "corn." Corn is the American cereal plant "Zea mays." What we call corn you might know as maize.

Corn starch is literally that. It is widely available. You can use it in recipes that call for corn, in lew of using flaked maize. Just measure some, and sprinkle it in your mash. American brewers use corn for a "smoother" flavor in their beers, although the fact that it costs less than malt probably has something to do with it. >From reading Roger Protz's "Real Ale Almanac," it's clear that some English brewers use corn in addition to malt.

Corn sugar is "dextrose" or "glucose." It is commonly used for priming at bottling time. It can be added to the boil to increase the gravity, and it ferments completely.

Corn syrup is also refined from corn. It comes in syrup form, and its contents may vary. For example, there is "high fructose corn syrup." In food processing, corn syrup is used as a sweetener in lew of cane sugar or beet sugar.

Subject: Rehydrating yeast

> New topic: I've been using Edme dried yeast ever since Whitbred quit
> making dried yeast a few months back. For my last few batches, I've
> been hydrating the yeast prior to pitching, but haven't tried making a
> starter. Perhaps it works "too well" without one: I'm looking for
> opinions.

Before pitching Edme or Whitbread ale yeasts, I always rehydrate by adding the yeast to a cup of boiled water which has been cooled to 100 F. In half an hour, the yeast solution is rehydrated and resembles white froth, and is ready for pitching. My starts using this method have always been fast. I would still recommend starters for liquid yeast, however, since it is not necessarily as hardy as yeast which can survive dehydrating.

An article was posted on yeast hydration some months ago, which I can dig up if you like. It was felt that the presence of sugars and nutrients in the wort would actually be detrimental to yeast in the rehydration phase; something to do with the cell walls.

Good luck,
Jim Buchman

Subject: A New Variable!

In this morning's mail I had a response to my posting on pouring plates in HBD 1011. Cush Hamlen has been doing similar work, and observed:

> The last batch I made used one tablespoon of Agar to one cup of
> wort. I found the resulting gelatine to be too soft: the slants
> had A LOT fluid in them, and the gel actually started to sag (i.e.
> not keep the slant shape). Also, the yeast managed to get *under*
> the gel as the stuff started to develop cracks.
>
> I had decided to make another batch using TWO tablespoons of Agar
> per cup of wort. But here you come saying to use one *teaspoon*
> of agar for 375 ml (where a cup is about 250ml)!

This brings up a factor that had frankly eluded me altogether: the variability of food-grade (as opposed to lab-grade) agar. All of the agar I've used in the last few years has come from a single shop and has performed consistently, but that doesn't at all mean that everyone's agar will perform the same way. You may have to experiment a bit.

Another thought that occurs to me is that storage conditions can have a considerable effect on the agar. I live in an area with fairly low relative humidity year-round, and I keep my slants and plates in the 'fridge except when incubating right after inoculation. When I first started culturing I kept everything at room temperature all the time, and in the dry heat of Sierra foothill summer I had problems with the agar shrinking and cracking. The sagging may be a humidity effect, but we don't have much of that here.

Anyhow, as I should have said in my original post, your mileage may vary; experiment.

Subject: Re: Wyeast 1056 Problems

In HOMEBREW Digest #1011 gcw@granjon.att.com wrote about his problem with Wyeast 1056. Last month I had the same problem also with a fresh package.

I poured in the puffed up package into my starter, the next day no apparent activity but alot of trub left behind. Since I had 5 gallons of wort just aching to start bubbling I shook up the starter and poured it in. Twelve hours later things were going nicely with a 1/2 inch layer of foam and growing. And yes the beer is good.

Subject: Wyeast Bavarian Lager problem

Thanks to all of you who responded to my last post about Wyeast Bavarian Lager. Happily, the beer is now fermenting. Apparently, from what everyone has told me, the yeast probably went into temperature shock. The yeast was pitched at 70 deg. and then put into a 45 deg. fridge. I should have cooled the wort to a lower temperature before pitching the yeast, and had the fridge at a higher temperature. Say, cool wort to 60 and put in 55 deg fridge. Please correct me if I'm wrong.

The wort is now bubbling away at room temperature. My question now is, should I ferment in primary at room temp. or can I now put the beer in the fridge while active fermentation is taking place? If I let the active fermentation take place at room temperature, can I then place directly in fridge for lagering or should I rack to a secondary vessel before putting in fridge? Alternately, I could just ferment at room temp and forget about lagering and make a steam beer. As always, any suggestions are greatly appreciated.

Thanks for your support,
Erik Zenhausern

> be toasted (in 350F) to get close to 60L crystal? All comments

I'd just like to note that crystal malts and pale/lager malts are VERY different. Roasting crystal is much different from roasting a pale or lager malt. Crystal malts are sort-of "mashed in the husk" and thus are virtually all sugar (albeit some being quite complex dextrins). Pale and lager malts are still mostly starch. Therefore, if you roast crystal, you are caramelizing sugar, whereas if you roast pale or lager malts (or especially unmalted barley) you are mostly toasting starch. Caramelized sugar tastes like, well... caramel, whereas toasted starch tastes like, well... toast (toasted bread). Two very different flavors!

Martin writes:

>US UK

>What exactly is Corn Syrup and Corn Sugar? It doesn't seem to be
>generally available in the UK.

Corn Sugar is basically glucose. In the US, it is sometimes called by it's trade name "dextrose." (Sounds like someone let their trade mark lapse.) Corn Syrup is just glucose syrup -- think of it as a highly-refined Lyle's Golden Syrup.

I wrote:

>3. Could fermentation have completed in the first 24 hours? One way to

More accurately:

One way to make a beer with a lot of diacetyl is to fine it and then
(correction) ^^^^^^^^^^^^^^^^^^^
rack it off the yeast as soon as fermentation is over -- there will be
less yeast to re-absorb the diacetyl.

(Fining is the addition of finings like gelatin, isinglass or Polyclar (tm) to precipitate out something -- usually either yeast, protein or tannins -- in this case yeast. Note that most (I believe) finings work electrostatically, so you would need to use the right one for yeast --

I'm quite sure that gelatin and isinglass work.).

Jack writes:

> I am curious to know what would motivate one to rack at such an early stage.
> One of the objectives of two stage fermentation is to leave as much stuff
> behind after each stage and primary fermentation would just be well under way
> in 24 hours.

There has been much debate about this issue, but the theory is that fermenting on top of the hot and cold break (which consists of all kinds of proteins, hop resins, tannins, etc.) will cause the creation of more fusel (higher) alcohols. Another camp (one in which I'm firmly entrenched) is the one that says that these fusel alcohols and hop resins will exit the ferment through the kraeusen (the blowoff), which is why I use the blowoff method of fermentation. In numerous places, HBD being a popular one, many have written that "if you ferment on the break, you MUST use the blowoff method or skim the kraeusen." Well, as we all know, nothing is really a *must* , but I have noticed in test batches that I've made from a single wort, that (while fermenting on most of the break material) the non-blowoff sub-batches taste much harsher and more astringent than their blowoff counterparts. An underhopped batch actually tasted better in the non-blowoff sub-batch than in the blowoff sub-batch. If I had hopped correctly (for an IPA), the non-blowoff sub-batch would have been undrinkable.

Personally, I chill with an immersion chiller and try to leave as much of the break in the kettle or funnel sieve -- I then ferment with the blowoff method. It may be good to wait till all the break has settled or to let the yeast munch on the break during *respiration* as I've written before, but I tend to not worry about it that much -- I don't always follow the best *theoretical* practices and I think my beer turns out quite well.

Al.

Subject: Anchor Porter questions

I'm rather glad to see the subject of Anchor Porter come up as I have been formulating a porter recipe that I would like to closely approximate it. I looked in Rich Cook's account of his Anchor brewery tour and noticed that he mentioned seeing bags of Northern Brewer and Hersbrucker hops. Are both of these used in the porter? Perhaps Northern Brewer for bittering (with maybe a bit of Hersbrucker as well) and Hersbrucker as a finishing hop? Rich also mentioned that he thought they dryhopped all of their beers. Is this true of the porter as well? Or am I totally off-base here and only Northern Brewer are used? Thanks for any input, public or private.

From: jmellby@iluvatar.dseg.ti.com
Subject: Pub List Update

For those of you who want a listing with more than just brewpubs on it, I have put up on the Homebrew archive at sierra.Stanford.EDU (courtesy of Stephen Hansen) the latest version of my listing of beer-related establishments. This file contains

- Brewpubs
- Pubs/Bars
- Restaurants
- Beer Stores (Liquor stores and Wine stores)
- Microbreweries (not complete)
- Breweries (fewer of these)
- Importers (still fewer of these)
- Misc (like the Scotch Whiskey Society)

The file itself is in compressed format and is in pub/homebrew/incoming (although Stephen will probably move it to pub/homebrew) named pubs-nov92.Z
I am still inputting more bars from the latest BarleyCorn, as well as trying to fix errors I detect in the latest Brewpub listings.

For most of these the database contains names, addresses, city, state, zip code, area-code and phone number, the type of entry, and notes. Since some of these are from other people's listings or listing in the beer magazines (especially the California Celebrator) there is only the name, address, and type of establishment.

The notes are either my own, notes from Usenet/News, or Homebrew digest, or things I extracted from reviews in magazines. The last few years I have tried to attribute the notes or information to the original poster. If I missed anyone's name I apologize now.

I have been keeping this file for some 5 years now. Major sources of input have been various issues of the California Celebrator (I cannot recommend this paper enough) and the Cascade Beer News. I have also put in information from reviews in magazines like "All About Beer" and the "Whole Beer Review", both good magazines. This last year I have also got copies of "Rocky Mountain Brews" and "BarleyCorn" centered in the Rocky Mountain states, and Washington D.C. I haven't tried to input information wholesale from books listing pubs because I have an underlying feeling that I wouldn't want to cut into their market. The magazines/newspapers have so much other than pub listings to offer that I cannot see this impacting their business.

My format is:

```
COUNTRY
State -- City:
  pub name - address; (areacode)phone
  Type-of-entry further notes
  Continued notes.
```

The reason for this format is that I have a (unstable) program to extract listings in various ways. My most common usage is to ask for entries with 30 miles of a given city. This helps when you're in the SF Bay Area, which has lots of differently named cities

in close proximity, and a traveller to the area doesn't know which California cities are really near SF.

Subject: Hops?

What's the HBD wisdom on hops???

Its time for me to buy hops for the next few months and I've been thinking about what varieties to get. I have access to whole cones from Hopunion: What's Brewing in Boulder has several varieties for \$9.50/lb. Some of the varieties I've tried, some I haven't, so I thought I'd ask the HBD readers for their perceptions of the flavor and aroma of the possible choices.

Here's a listing of some of the varieties with their usual alpha acid range, my comments, and the comments from Hopunion data sheets:

Centennial:

alpha: 9.5% - 11.5%
my comments: nice cascade-like aroma, clean bitterness
Hopunion: medium floral and citrus aroma

Chinook:

alpha: 12% - 14%
my comments: the pellets I've tried resulted in beer with little hop aroma and a harsh bitterness
Hopunion: a high alpha hop with a highly acceptable aroma profile; mild to medium-heavy, spicy aroma

Galena:

alpha: 12% -14%
my comments: never tried it
Hopunion: excellent high alpha hop with balanced bittering properties combined with an acceptable aroma profile; medium but pleasant hoppy aroma

Hallertauer:

alpha: 3.5% - 5.5%
my comments: US grown Hallertauers have an ok flavor and aroma, but it doesn't produce "That German Taste" in lagers
Hopunion: traditional superior aroma hop; very mild, pleasant, and slightly flowery aroma

Liberty:

alpha: 3% - 6%
my comments: haven't tried them yet
Hopunion: aroma variety with close similarities to imported German aroma varieties; still under evaluation but very positive comments from some major brewers; mild and pleasant aroma, quite fine

Mt. Hood:

alpha: 5% - 8%
my comments: smooth bitterness, mild flowery aroma; very good in a pale ale
Hopunion: aroma variety with marked similarities to the German Hallertauer and Hersbrucker varieties; mild, pleasant, and clean aroma

Perle:

alpha: 7% - 9.5%

my comments: never tried it

Hopunion: German type aroma properties combined with moderate bittering potential; pleasant and slightly spicy aroma

Tettnanger:

alpha: 4% - 5%

my comments: smooth bitterness, mild spicy aroma; very good in a German pils

Hopunion: a true noble aroma variety; very fine and slightly spicy aroma

Willamette:

alpha: 4.5% - 7%

my comments: clean bitterness, not much flavor or aroma

Hopunion: a quality aroma hop; mild and pleasant, slightly spicy aroma

I'd appreciate comments from other brewers who have experience with any of these varieties, especially in the ones where my perceptions and Hopunion's comments don't agree (Chinook, Hallertauer, and Willamette) and the ones I haven't tried (Galena, Liberty, Perle).

From: billm@scorpio.sps.mot.com (Bill Moyer)
Subject: kegging v.s bottling, try2

Recently posted this to rec.crafts.brew,
with a whopping 2 responders. Maybe this
try will fare better... -- billm

I'd like to open a discussion with those of you
who use cornelius kegs for kegging homebrew. Our
brewing outfit (Driftwood Brewers, Driftwood Texas) has been
experimenting with split batches of homebrew in a variety of ale
styles comparing kegged vs. bottled homebrew for
taste differences. We've compared:

- 1) a nut brown ale
- 2) classic IPA
- 3) czech (read -heavy- saaz) style ale (dry hopped)
- 4) an english red bitter
- 5) a lighter american style ale (rice solids as adjunct)
- 6) an american style bock (but with ale yeast)

These have been extract/specialty malt brews
using primarily dried (EDME) yeast, and hop pellets,
not whole hops, with a range of aromatic hopping rates.
At least one batch utilized Wyeast liquid yeast.

Our experience has been that the kegged beer has been
very good to excellent until compared to the bottled versions
of the same batch. No comparison, bottled wins unanimously
with a crisper, cleaner, fuller taste. We have tried variations on
kegging techniques to eliminate some differences.

Forced CO2 priming and 3/4 cup corn sugar priming (with a 5lb sealing
change of CO2 after purging) produced no discernable differences.

Half full vs. full to the top kegs were compared to eliminate
the effect of a difference in gas space above the liquid,
again no perceptible differences.

Different CO2 pressure tanks were tried to eliminate the possibility
of that as an effect.

Different stainless steel cornelius kegs have no influence,
all new seals installed in all (a debateable improvement in some minds).

Perplexed at this point, we are wondering if any other
homebrewers have benchmarked the flavor and overall characteristics
of bottled vs. kegged homebrew from the same batch, and perhaps
can share their opinions with us.

I sure enjoy the labor savings of kegging, but at thisN 26 bar point
am unwilling to continue given our experiences with the alternative
of bottling.

This experience is in direct opposition to my experience with
micro-brewed ales. If any of you have the chance to compare
Rouge Brewery's New Porter on tap in Ashland, Oregon with a fresh bottle
of the same brew (both excellent porters IMHO), the kegged wins
hands down, and not due to the age of the bottled version or

its handling. I'm sure this is also true of many other micro-brewed beers. Shiner Bock in Shiner,Tx. is another example (although not quite "micro").

From: sherpa2!BMOORE.ELDEC@mailsrv2@sunup.West.Sun.COM (BMOORE)
Subject: EDME YEAST

Dan Wood notes in #1111 that EDME dried yeast is a fast fermenter.

I have used EDME quite a bit in the past few years and have developed the following techniques to deal with it's "frisky" fermentative capabilities:

1) When using a carboy with a blow-off, do not fill beyond the point where the carboy begins to taper down to the neck. This as about 4.8 gal with a standard carboy. With a thick brew, fill a little less. The EDME will raise a Krausen to the top of the carboy and glue a bunch of brown gunk to the top surface, but actual blow off will be minimal. I have found my brews have better head retention if "Blowoff" is minimised.

2) EDME responds well to minimal hydration: About 10 minutes before pitching I throw 2 packs into a mason jar with 1/4 cup sterile water at about 100 deg F. As the wort starts coming out of the chiller (about 5 minutes later), I put another 1/4 cup in the jar, screw the lid on and shake vigorously. 5 minutes later, when the carboy is about 1/3 full (my chiller is slow), I pitch the slurry and shake the carboy like there's no tomorrow.

I usually notice bubbles in the blowoff tube in about 2 hours and rack to secondary in 36 hours (the fermentation is still quite active at this point).

Hope this helps...
Cheers

From: Pat Lasswell <patl@microsoft.com>
Subject: Real Ale from a Carboy(?)

I have an idea, and I thought I would bounce it off y'all before I tried it:

The apparatus:

In the crude ASCII drawing below, there are two carboys, each with a BrewCap attached. The top one, inverted, contains the beer; the bottom one is the CO2 reservoir. The top carboy has the usual BrewCap installation, with a long pipe extending to the top of the carboy to allow gas to escape and also with the usual beer/crud output. (Disclaimer: I have never used a BrewCap, so my description of the "usual installation" is surmised from reading the HBD.) The gas output of the top carboy is connected to one of the openings in the bottom carboy's cap. The other opening in the bottom cap is connected to a copper pipe that runs first up and into and then down a 10' column of water to its bottom.

Here's how it works:

When the beer is in primary fermentation, the level of water in the column is low, about 6", allowing various undesirable yeast emissions to escape. After primary, all of the crud is drained from the bottom of the beer, and the column is filled up to the top with water. This would carbonate the beer to just below 5psi. Once accomplished, carbonated beer could be drawn from the top carboy. The bottom carboy would act as a CO2 reservoir, so that the beer would not stale as the carboy emptied of beer and filled with gas. Clearly, water would be drawn from the column into the lower carboy. In order to maintain carbonation, the level of water in the column would have to be maintained as well. Since the bottom carboy originally contained 5 gallons of gas, the water should never enter the top carboy unless the system cools substantially.

Potential problems/Uncertainties:

- -- Will the CO2 draining from the top carboy mix with the gas in the bottom carboy, rather than sinking to the bottom and filling the carboy with CO2?
What is the volume of CO2 released from 5 gallons of fermenting beer? (Assume OG 1.040, FG 1.012) [That is, if the gasses mix, is the volume of CO2 so much greater that it makes no difference whether they mix or not?
]

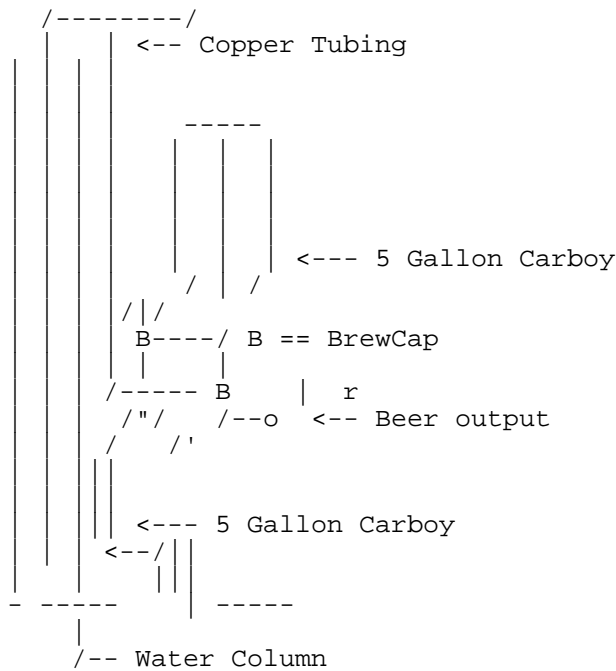

- -- Can a carboy hold 5psi without bursting? (If anybody has the equipment to test the bursting pressure of a carboy, I'll mail the cost of a carboy just to know the answer.)

- -- Can the BrewCaps be kept on the carboy and sealed against 5psi?

- -- If the top carboy spewed gunk into the bottom carboy, it would need to be sanitary, lest mold develop and spores enter the beer while one was drawing a pint. What would be the best way to accomplish this? An Idophor rinse left to dry? (Campden tablets and bleach would have their active ingredients flushed away by fermentation.) The carboy would have to stay sanitary, even when water was being drawn into it from the column. Bleach would be very bad here, as the chlorine would be sucked into the beer carboy; again iodine seems the proper choice. Are there any other persistent, non gaseous sterilizing agents?

- -- Why not just get Cornelius or Firestone kegs and be done with it? [Back
off man -- I'm a scientist! -- NOT; just curiosity....] It would be cheaper than a kegging set-up (probably < \$50) and less work than bottling, though cleaning the system may be difficult -- I haven't worked it in to the design yet.

- -- If this is not an original idea, has anybody tried it? ...not tried it for what reason? ...tried it and had problems?

???

Subject: Efficiency vs Winners

To: Homebrew Digest
Fm: Jack Schmidling

Now that we are all experts on extract efficiency, I thought it would be usefull to put our new found wisdom into proper perspective.

The current issue of Zymurgy lists the winners of the 1992 national competition along with the winning recipes. There is enough data in the article to calculate the extract efficiency of each of the winners. Not only is it obvious that high extract efficiency does not make winning beer but a case might just be made for exactly the opposite position.

I ran the published data on the all grain beers through my calculator and here is what I found. The lowest was 17 pts/lb/gal and the highest was 28. The arithmetic average was 23 and the actual numbers were: 17, 20, 21, 23, 23, 25, 25, 26, 26 and 28. What is also interesting is that the highest (28) was about 60% wheat.

So, the next time the gurus make derogatory remarks about your "poor" yield, just tell them you're working on a winner.

Subject: What would you call this ale?

Last night I stopped at the homebrew store to get some supplies along with the John Bull kit I mentioned before. I was going to do a recipe that so far has been my best, in my opinion, an Amber Oktoberfest.

The recipe calls for:

6.6lbs Bierkeller Amber malt
4oz. toasted pale malt
3oz. roasted barley
2oz. crystal malt
Hallertau
Tetnanger
Yeast from Bierkeller kit.

Thing is, I was working from memory at the store and wound up with Norther Brewer pellets (1oz), Hallertauer Leaf plugs and no pale malt to toast.

So I checked Papazzian's chart and saw that I had ingredients that were closest to an Alt so I used what I had:

6.6 lbs Amber (Irek's Bavarian instead of Bierkeller that was called for in the recipe)
1/2 lb crystal malt
1/3 lb chocolate malt
2 oz. Hallertau (2.9% alpha)
1 oz. Northern brewer (6.0% pellets)
Whitebread Ale Yeast

What would this beer be called? If it's any good, I'll let ya know...

Subject: traquair left overs

re: high gravity beers

When doing a high gravity beer like traquair, one can continue to sparge for a second, lower gravity, beer. But 2 boils in a day is a definite detriment. How about simply storing the sparge'd wort in a carboy to boil another day. It would be subject to infection but after all, you will eventually boil it.

re: mashing specialty grains

notice some do NOT mash these, but steep separately in the water being heated for mash-out temperature elevation. Are there negative implications to mashing chocolate/roasted, etc.

Subject: Sierra Nevada = Narragansett?

Someone mentioned "Sierra Nevada/Narragansett" yeast. Is the yeast that Sierra Nevada uses now originally from the Narragansett brewery in Rhode Island? Hard to believe, since Narragansett's are often referred to as Nasty-gansetts, with good reason. Although I did once have a few 'Gansetts at a bar in RI, near the brewery, and they tasted surprisingly good, a lot like Bass ale.

From: tony@spss.com (Tony Babinec)
Subject: worthington's white shield

Some English colleagues of mine recently sent me a bottle of Worthington's White Shield, a bottle-conditioned ale being relaunched by Bass. Note that this is a 4-star beer in Jackson's Pocket Guide.

The beer comes with pouring instructions attached to the neck of the bottle. I thought HBD readers would be interested. Here they are:

Storage.

The ideal storage temperature is 60F or a little over. To this end storage in a cool cupboard will suffice. The bottle should be allowed to stand for at least 24 hours to allow the sediment to settle and the beer to condition before serving.

Step By Step Pouring Instructions.

1. Select a clean glass (ideally a 12 oz Worthington glass).
2. Hold the bottle firmly and remove the crown cork using a hand opener.
3. Raise both the glass and the bottle to eye level and preferably to a light source--you have to watch for the sediment.
4. Keeping the bottle off the rim of the glass, gently pour the beer along the glass very slowly. Remember that once you start to pour, you cannot stop!
5. Gradually straighten the glass as it fills--avoiding any violent movement of the bottle which may disturb the sediment.
6. As the bottle is gently tipped, watch that the sediment is trapped in the shoulder of the bottle. Ideally you should leave a tablespoon of beer in the bottle with the sediment.
7. This should leave you with a clear, sparkling, delicious glass of Worthington's White Shield.

On The Other Hand...

There are two other schools of thought to the pouring of a White Shield. One is practised by the White Shield brewers. That is to pour it in the approved manner leaving the sediment in the bottle--Drink the beer and then knock back the sediment at the end. The other is to pour in the approved manner, but then tip the natural sediment in and watch the goodness start to sink to the bottom!

History.

Originally known as Worthington's India Pale Ale, Worthington's White Shield was first brewed in the early 19th Century. The name White Shield is taken from the Worthington's original trademark, a dagger in a white shield. White Shield is a unique real ale that matures in the bottle just as cask beer matures in the cask. The natural fermentation of the product, which continues in the bottle

after packaging, causes a small amount of yeast sediment to form in the bottom of the bottle. Herein lies the secret of White Shield because the continuing fermentation helps to develop the distinctive, smooth, nutty flavour of the ale. The sediment in the beer means that the bottles should not be shaken before opening so that the sediment sinks to the bottom, for this reason White Shield requires careful pouring--Knowing when to stop is the key.

Subject: Smithwicks

Smithwicks (pronounced smith icks, no w, and a 'leathery' kind of th sound) is indeed available in Canada, specifically Ottawa. Most of the pseudo-English type pubs have it on tap, and it is also available in the LCBO (liquor store) for about CDN\$7 / 4 (ouch). It is my favorite English (oh, OK, I know it's Irish) beer. The color is rather dark, kind of amber-brown, with a really impressive malt character. I can't really identify the type of hops used, but will keep on quaffing so I can try to identify them. My recent attempts at a clone were good, but not really close.

IMHO, the bottled version is better, as I suspect some bars water the draught beers down.

If anyone has an all-grain clone, I'd like to hear of it.

Subject: Re: Wyeast purity

James writes:

>About yeast: I've been brewing with Edme for a couple of years now with
>no infections. So of course, the first time I try Wyeast, I get little
>white rings in all my bottles. Bleah. I'm going back to Edme; I
couldn't
>taste any difference before the rings appeared, either. I don't know
where
>this "switching to liquid yeast improved my beer 100%" business came
from
>but it sure didn't do much for me....

When you say "white rings" I assume you mean "ring around the collar" the
ring of stuff that forms on the inside of the neck of the bottle at the
level of the beer. This is always caused by an *aerobic* biota, my guess
would be either acetobacter, sherry flor or mold. There is absolutely
no question in my mind that liquid yeasts produce better tasting beers
than
dry yeasts -- if your sanitation is good. One source of problems that
many
who switch from dry to liquid yeast is that good sanitation is more
important when using Wyeast especially without a starter. 1. Dry yeast
is
super-oxygenated before drying and is READY TO GO as soon as it hits the
wort -- 2 hour lag times are not uncommon. 2. Dry yeasts have a tendency
to be quite voracious eaters. 3. Dry yeasts tend (in my experience) to
be
more attenuative (leave less sugars behind).

Okay. 1. Longer lag times mean that molds, bacteria and wild yeasts
have much more time to get into your fermenter and take hold. 2. Slower
ferments mean that your cultured yeast is less of a competitor. 3. Less
attenuative yeasts leave more sugars for bacteria, wild yeasts and molds
to eat.

Given this, you can see that switching to Wyeast can be a test of your
sanitation and how many airbourne nasties there are living in your house.
To get the full benefits of Wyeast you should use a starter and be very
cautious of your sanitation procedures.

I've used Wyeast exclusively (except for a test batch made with M&F yeast
that was so clovey it was undrinkable and, of course, my pseudo-lambiks)
for the last three brewing seasons and have never had an infection.
Year-old beers are still carbonated properly (albeit a bit oxidized).

If you need proof as to the quality of Wyeast, I suggest that you check
the dry/liquid yeast statistics of the AHA National Competition prize
winners.

From: hjl@gummo.att.com
Subject: Pumps and other gadgets

There's been some conversation about brew pumps in the digest lately. IMHO the only type of pump which could be adequately sanitized is the peristaltic type wherein boluses (lumps) of the pumped liquid are captivated between pinched constrictions in a hose and are driven along by moving the constrictions in the desired direction of flow. This is a little like manually milking a cow. The ones I've seen (pumps, that is) accomplish this by means of a pair of rollers affixed to opposite ends of a bar which is attached at its center to a driven shaft. This assembly is axially mounted in a cylinder whose inside diameter is just large enough to accomodate the bar with its rollers and four thicknesses of the hose (two pinches). The hose is arrayed a little more than halfway around the inside of the cylinder and axially restrained to stay between the rollers and the cylinder wall. Rotation of the shaft pinches the hose, captures the liquid and moves it along. Nothing touches the liquid except the inside of the hose, which is easy to clean. If memory serves, the first application of this technique was to pump blood in heart-lung machines but it now has wide industrial application. The pumps are available in many sizes and aren't all that expensive.

Another sanitization subject...

Measuring specific gravity with a hydrometer to ascertain the completion of fermentation always exposes the beer to possible contamination. Sterilizing the sampling hose isn't a big problem but nicks and scratches can harbor the nasties. And then you have to throw away all that beer (or drink it). But then you have to top off the secondary to keep it full (you do use sterile water, don't you). An alternate is to use a refractometer. This is a gadget which determines the concentration of a sugar solution by measuring its refractive index. The attraction is that the required sample size is only one drop. The absolute accuracy is quite good for sugar solutions but not after alcohol has begun to form during fermentation. Day to day changes are readily observable and accurately indicate activity or lack thereof. I take samples with a sterilized glass rod (passed slowly through a gas flame) exposing the beer to air for only a few seconds. Downside? Best current price is \$200. It's also great for OG's though.

From: korz@iepubj.att.com
Subject: Stout recipe

I got a couple of requests for my stout recipe, based upon my claim that it was a "dead ringer for Guinness." Well, first off, I'd like to submit a disclaimer -- since this was three seasons ago, and my memory of that beer has faded quite a bit, I cannot guarantee that it will taste anything like the bottled version of Guinness Extra Stout -- I can guarantee it will be a tasty stout, though!

Here goes:

Al's Medium-dry Stout
5 gallons

6.6 lbs John Bull Unhopped Dark Malt Extract
0.5 lb Roasted Un-malted Barley
0.5 lb Black Patent Malt
1/3 oz Wines Inc. Burton Water Salts
3 oz Cluster Pellets (60 min boil)
6 gal Soft Tapwater in brewkettle
1 pkg Wyeast #1084 Irish Ale yeast
1/2 cup Corn Sugar for priming

OG/FG unknown

Brewer's specifics: I just strongly suggest using the blowoff method, because if you don't I feel this beer will be much too astringent.

Comments: There was a time that I thought this was a dead-ringer for Guinness, but that was a long time ago and I've switched to brewing sweet stouts since then.

fittings
>off of the keg and was unable to. I thought that these things came
apart
>so that you could remove the stem, but after cranking down on it pretty
hard
>I still couldn't get it to budge. These things do come apart don't
they? Do
>you turn them counter-clockwise to loosen? Should I use something like
>WD-40 or Liquid Wrench on these things to help break them loose?

They've got thread sealant on them - it takes a lot to break them loose,
but once you do, they will screw off easily. WD-40 and what-not won't
help - it won't penetrate the sealant. Someone out there is HBD-land
took a socket and put a few slices in it where the pins go (for pin-lock
kegs) and said that worked fine.

>I guess the larger question is whether I need to do this at all, or will
>running some sanitizing solution through be ok?

sanitizing solution works fine - boiling water is fine too.
(and you don't need to rinse if you're bleach-paranoid)

From: Jack Thompson <76520.3531@compuserve.com>
Subject: Re:corn sugar

Martin Noble asks about corn derivatives. First off, corn starch is not corn flour; lack the protein, etc. that comes from flour. Good starch (i.e. not the chemically derived stuff) can be manufactured at home by adding an excess of water to flour; when it begins to ferment, pour off the water and add fresh. When it stops fermenting, what is left at the bottom of the bucket/barrel/container is starch. Of course, if you leave starch in water long enough, it will go off.

Corn sugar is dry, granular stuff; corn syrup is corn sugar with water added, more or less.

Subject: First batch - boil/water questions

Hello all,

I am getting ready to brew my first batch, and I would like some clarification on boiling, and I have a question on water. First, I have a 5 1/4 Gallon pot that I will be using for my boiling. I have read that all I need to boil is 1 1/2 or 3 gallons. Will I be alright just using three gallons in the boil?

And second, I have a water softener installed at my house. I also have an RO (Reverse Osmosis) unit installed in my kitchen. I was going to use the water from the RO unit for my beer. This is basically the same water you get at a water store. Can I use it, or do I have to boil it before using?
- Our water before getting the softener had a hardness of 23 (Extremely hard).

Thanks in advance,
Bill Danforth

Subject: lagers without lagering?

With cooler weather here, I would like to open a thread about producing lagers.

You see, I have a cold-cellar, but not a refridgerator dedicated for lagering.

Originally, I thought I could use the cold-cellar for lagering, but it only gets down to 40-50 (cannot controll the temp!). I can therefore do a cold ferment, but am not really able to do a *real* lager step at 33-35F.

The question is this: I want to produce a bock. Can I use, for example, Wyeast Chico ale yeast, fermented at 55F or so, then age at 45-50F in the cold cellar? Chico ale supposedly ferments *clean*, and will work down to about 50F. Alternatively, could I use a true lager stain, and just do a cold ferment at about 50F, and age (sort of 'lager') at 40-45F? I know this is not low enough for a true lagering step, but would time at that temperature still produce some significant reduction of diacityle (sp?) ??

What methods have people used to approximate a lager without being able to do a true lager step?

On another vein, Miller notes that most commercial breweries lager in the secondary, with the beer under pressure. He questions the wisdom of homebrewers lagering in a 'secondary' carbouy: the reasoning being that bottle conditioning results in the yeast doing their thing, and producing 'unclean' flavors along the way. He recommends doing a primary, a relatively short secondary, then bottling, and doing the lagering in the bottle. As he says, the bottles become an approximation to the pressurized secondary fermentors the big guys use. The drawback to this approach is that perhaps too much sediment accumulates in the bottles, perhaps leading to an autolysis problem. But he claims that he has had little trouble with this

Again, what are the options here. (I also do not have a keggung system. ..)

From: gjfix@utam.uta.edu (George J Fix)
Subject: SN= Narragansett?; Whitbread

I believe the production yeast at SN is the same as the Siebel strain BRY-96. This strain was brought into the US from the UK by the Ballantine family, and was used to brew their XXX and IPA. In their primes these were very much the real thing; e.g., the XXX had a SG around 1.053 (13P), a IBU in the mid 30s, and was dry hopped to boot. I do not know what happened after Falstaff obtained these brands. Both the IPA and XXX were brewed at Nargansett, but whether this was with the original formulations or not is in question. The current versions are bottom fermented, and pale in comparison with the originals (at least on paper vis-a-vis SG, IBU, et al.)

The Biologist at Ballantine who was responsible for maintaining their ale yeast was a person by the name of George Leaver. I meet him in the 1980s when he was working at Pittsburgh Brewing. He retired and moved to Portland, and shortly after that I moved to Texas. I lost contact with him after that. Jeff Frane and the AHA are trying to track him down, for he would make an excellent conference speaker. The "Eastern ales", and most notably the Ballantine ales, had a glorious history and it would be great to have this documented by someone with firsthand experience. If anyone ever runs into George Leaver tell him to contact me, Jeff, or the AHA.

Until last Jan. the heat dried Whitbread yeast was distributed by Siebels. It was produced in a Canadian plant, and Siebels acted only as a distributor. Unfortunately, the Canadian firm developed a serious wild yeast infection, and Siebels promptly dropped the line. The producer is still having QC problems, and this is resulting in highly erratic batch quality. I am currently negotiating with Cosby and Baker to establish a testing program whereby the heat dried Whitbread yeast would be accepted or rejected by C+B based on microbiological analysis of statistically significant samples from each batch sent to them. You should be hearing more about this in the near future.

My understanding from Crosby & Baker is that Whitbread will be back with
their dry ale yeast in wholesalers hands at the end of November. The
lager
version should also be available by the end of this year. This should be
good news for those folks taken to brewing with dry lager yeast.
Whitbread
has had technical difficulties in producing the lager yeast. I understand
that the dehydration was more than the yeast could stand.

Subject: info on beer in the news

Hello All brewers,
I am in a college bind. I have not yet started the research on the paper due next tuesday on an ancient artifact. I am planning to write on an egyptian brewing vessel and i need to discuss its function and purpose in society. the timely news from iran will help but i have found little else in the way of sources. can anyone out there recommend any sources?

I noticed mention recently of a beer brewed from an ancient recipe by sierra nevada. is this available in chicago area? i thought that by including one of these with my written presentation i could add some flavor to my research. I was not able to find the digest that included mention of this beer so i do not even know its name. Any help will be greatly appreciated. If i complete this semester (and degree) i can get back to brewing

Subject: re: Demise of Whitbred?

The homebrew shop near my house in Baltimore, Maryland, also still stocks Whitbred ale yeast; only the package is slightly different. The rumors that Whitbred is no longer selling their yeast to homebrewers tempts me to buy massive quantities of it, but there seems to be no sign of its going away. Does anyone know whether Whitbred intends to continue selling their ale yeast?

Thanks,
Jim Buchman

Subject: Harringtons or Klages?

In my recent quests to get a cheap pound of 2 row, I came upon a source that retails directly from Canada Malt. I can get the malt for about \$.60 (Canadian\$) per pound and it comes in 100 pound sacks. I checked out the bag at the suppliers and noticed it didn't say what variety of barley it was. I had the fellow look into this at the malters and he reports that it's Harringtons. I asked if they had Klages, since since many recipes call for Klages. He said that Klages is not grown anymore, only Harringtons 2 row. This is because the variety becomes less disease resistant with successive plantings and therefore the farmers swap batches every 10 years.

Now I was skeptical to hear that farmers sprayed Ammonia on their soil, but since found out this is true, it's some sort of nitrogen thing. I therefore beleive any farming lore told to me.

Many brewers supply outlets in Canada and the U.S. sell Klages. Is this a misnomer or is it Klages, and if it is how old is it? Is this a Canadian thing, is it bunk, is there difference between Canadian and US Harringtons or Klages and is there a difference between Harringtons and Klages malt. Sorry for the huge question, but maybe a pseudo-agriculture brewing person would be able to let me know.

Subject: Aging Beer

To: Homebrew Digest
Fm: Jack Schmidling

The following is excerpted from THE NEW BREWER, May/Jun 1992. The article is by Fred Scheer, Frankenmuth Brewery.

.....

"In my research of draft beer, I found that one of the biggest problems is the age of the beer. As with bottled beer, draft beer does not improve with age!"

"Draft beer is at the peak of freshness and taste the day it is put into the keg. Ideally, a brewer would be able to fill his kegs in the morning and get them back empty at night. But because this is not the case, the beer loses quality each day after it is kegged."

.....

This view seems at odds with the conventional wisdom of homebrewers and I see two possibilities:

1. His "research" is seriously flawed.
2. People who claim that their beer improves with age are simply confused by the fact that the defects in their beer sometimes mellow out or become less obvious with time.

Subject: Aging Beer Temperature

I have a question as to what temperature you should age beer (Ales) in bottles. I'm storing the beer in my basement with temperatures between 45 and 55 degrees. Is this OK? or should I keep them warmer?

What effects do lower temperatures have on aging?

Same questions for fermentation stages. If I let the temperature drop below 60 at night is this a bad thing?

So far all seems to be going well but with Winter approaching I was just wondering.

Jack says (about the study which claimed draft beer doesn't improve with age)
that either:

- > 1. His "research" is seriously flawed.
- > 2. People who claim that their beer improves with age are
> simply confused by the fact that the defects in their
> beer sometimes mellow out or become less obvious with time.

I can see a third possibility -- we are comparing apples to oranges. Most commercial beer is filtered to remove the yeast. Perhaps the residual yeast is what contributes to the maturing process. As every homebrewer knows, beer develops tremendously in the bottle from the end of the first week (its probably not carbonated prior to that, so its not in the running) to its fourth or fifth week. The taste difference is so dramatic it could not be missed. Therefore I bet it wasn't checked. Draft home-brewed beer also improves with age, though much more slowly than bottled beer (never have figured out precisely why, though I understand the same thing happens with wine -- splits mature years earlier than full bottles from the same barrel -- and we are dealing with a much larger ratio here).

And even a fourth possibility -- and this one is pure speculation -- heartier, more strongly flavored beers benefit most from aging, though eventually they do go downhill. A major part of this seems to be the degradation of hop flavor (I had a two-year old bottle of 'bitter' I made that was anything but -- and it was **very** bitter when I made it). Perhaps the beer he checked is so lacking in character that there is nothing for aging to bring out.

Just some random thoughts,
Geoff Sherwood

From: Greg.Winters@EBay.Sun.COM (Greg Winters)
Subject: RE: lagers without lagering?

In response to the question about making a bock/lagering in a cold cellar,
I offer the following humble opinions -

1. If you are in the 45 - 50F range that should be fine for producing a bock using a true lager yeast (might I suggest Wyeast Bavarian -;). I don't think I would try with the 1056 ale yeast, at least not for a true bock, although it may make an interesting beer. You also probably don't want the temp to fluctuate more than a few degrees daily.

2. Attached is an excerpt from a yeast summary for the Bavarian strain -
2206. Bavarian Yeast Strain used by many German breweries. Rich flavor, full bodied, malty and clean. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

As you can see the recommended fermentation temp is 48F, which should be just right for you. I have a fridge and just made one at this temp and so far the results are wonderful (still bottle conditioning).

Personally I don't think you need to go down to the 32-25F range to produce a good lager. I have produced several and never went down quite this far. The bottle conditioning also takes much longer. Mine take 5-6 weeks at about 42F.

3. Regarding diacytle production - there has been some discussion regarding this recently. I believe the end result was to raise the temp towards the end of the secondary to about 60F for a day or so then take back down. I'm sure someone will correct me if this is in error. I have tried this twice, but am unsure of the difference it made.

So, give it a try!

Greg

Subject: Re: Beer aging multiple choice (C)

On the topic of beer improving with age. I'd go with
"C"

Where C is: The beer going into the keg is already
aged[Either lagered or what ever]. Since many bottle
before aging the beer can improve with age upto a
point. This is of course a rather obvious point.

I assume what the quoted source was trying to say
is that finished beer is at it's best when it's
finished aging. He was also talking about HIS beer.
I doubt his research is relevant to high gravity
ales that are intended to be put up for several
years after bottling.

Of course beer is at it's best coming out of a hand
pumped wooden cask. But thats my research-)

Perhaps all that is "wrong" is that Mr. Scheer is talking about a very
narrow
part of the continuum that is beer. Filtered beer is DEAD. It will not
change much with time other than to become more and more oxidized (the
extent
of which is dependent on how well it was handled during production).

Some styles of beer indeed are meant to be consumed almost immediately -
-
Bitter is a classic example -- however, it should be consumed only after
it
has conditioned not (as Mr. Scheer contends) the day it is kegged. In
England,
a pub is only as good as its Cellarmaster, who skillfully alternates
between
soft and hard splines (porous and non-porous "plugs" that either let CO2
escape or not) until the beer is properly conditioned. Once conditioned,
yes, they would prefer to have it consumed all in one day.

Other beers are meant to be aged. For example, lagers need to be, well.
..

lagered! Perhaps George Fix could comment on the exact chemical reactions that take place during lagering, but its net effect is to make the beer more stable so it could be stored and consumed during the summer when brewing before re Fridgeration made summer brewing impossible. Another beer that improves with age is the strong ale. Lambiks are often aged three or more years before serving -- the 200 or so chemical reactions that take place in a modern lager or ale are NOTHING compared to the number of reactions taking place in a gueuze or kriek!

Our beer is undoubtedly ALIVE. It will change in character as time marches on in different ways, some positive, some negative. Jack-- your second point is in part true -- tannins, to various extents, are extracted during sparging and steeping (in the case of specialty grains used in extract/specialty beers). They impart an astringent flavor to the beer which does indeed mellow over time. Tannins and their mellowing are why red wine improves with age. One negative aspect is the oxidation I mentioned earlier (in Chimay Grand Reserve it is welcomed actually, but that's another story).

Bottom line -- I feel that Mr. Scheer is being a bit narrow-minded concerning beers and although the Frankenmuth beers are better than virtually all of the industrial beers I've tasted, Frankenmuth Brewery tends to be a bit narrow-minded when it comes to brewing also (e.g. their Bock is nothing more than an American Dark Lager).

Al.

From: chuck@synchro.com (Chuck Cox)
Subject: AcoustiMash Debut

You may recall my descriptions of the AcoustiMash. It is an industrial coffee-maker that I bought from Bose for \$1, then converted to a semi-automatic half-barrel mash tun.

I had an opportunity to brew the first batch about a month ago. I brewed a stout because the roasted flavor can conceal a number of sins. I brewed only 10 gallons just to be cautious.

Basically, the system worked as expected, with no nasty surprises. I can't tell much about the efficiency, because I used way too much mash water, and had to reduce the sparge (misread my own calibration marks, and overrode the automatic timer). Instead of 10 gallons of 1050 wort, I ended up with about 12 gallons of 1040. The system should easily handle half-barrel batches. It was no problem to operate the system solo, but a brewing partner/assistant would make things go smoother and faster.

The grain mill handled 19 lbs of grain in less than 5 minutes. The output was indistinguishable from hand-ground Corona crush. The automatic mash-in and sparge timers worked great, and the flow rate out of the showerhead was just right. The coffee spigots are very controllable, it was easy to maintain the sparge flow. Stirring a large batch could get troublesome, I need a stronger spoon or some automatic stirrers. The custom-made false bottoms worked great. Because of the shape of the urn bottoms, only 1/2 inch of offset is required. Some solids did clog one of the valves, but it cleared by jogging the handle. The burner brought the wort to a boil in about 15 minutes, and the welded-on support arms were very stable. I miss being able to watch the fermentation, but I'll get over it.

Here's a quick overview of the new system:

Grain mill:
motorized Corona with large hoppers

Hot water/mash/lauter tun:
double urn 16 gal automatic coffee maker with 12 gal water jacket
pair of stainless steel mesh false-bottoms

Brew kettle:
keg with a large hole cut in top, and matching stainless steel lid
35000 btu Cajun Cooker propane burner with extension arms

Fermenters:
kegs with cores removed

Coming improvements:
transfer/recirculation pump
rolling platforms for fermenters
more precise thermostat

Well, 2 brews back my freshly bottled version was overpoweringly caramel
in
taste, due, I'm told, to the particular malt extract I used. Now, almost
3
weeks later it's amazingly more mellow. If the original was a "defect",
so
be it, but as far as I'm concerned the beer has improved with age.

There are several other possibilities:

- * Scheer is exaggerating the smallness of the window of prime taste.
- * Homebrewers bottle their beer well before the peak time described by Scheer, and can taste the improvements as it reaches that peak.
- * Homebrewers store their beer more carefully than most warehouses/
dealers/
shippers/retailers, allowing it to keep for a longer period of time.
- * Scheer's work applies to weak commercial beers and not to the heartier
styles favored by many homebrewers (consider the difference between a
light
white that is drinkable a few months after bottling and dead in two
years,
and a noble red that takes up to a decade to begin to mature and may be
good for fifty years).

Note that another advocate of up-to-the-minute freshness is Jim Koch
(who has been lambasted here as a marketer who happens to contract
beermaking, rather than a brewer as he describes himself); he's gone so
far
as to claim that at a brewers' conference in Seattle everybody /chose/ to
drink Olympia (which I think falls somewhere between Coors and Bud)
because
it was so fresh.

Subject: Grainmill

Does anyone have any experience using a KitchenAid mixer with a grain mill attachment to crush malt? I'm not sure it would be appropriate since the manufacturer's literature says that one should only grain 10 cups of grain into flour at a time. Perhaps the load on the machine for a coarse grind is so much lighter that the much larger volumes needed for all-grain brewing would be possible. Is its coarsest setting coarse enough for brewing purposes?

Perhaps, instead, the various components of beer are not universally
affected by aging. Some flavor components will improve (nuances due
to spices in a holiday beer, for example) while others will decay.
A beer will thus appear to improve over time only if it has substantial
components of the former nature.

That said, I prefer my beers fresher than not.

Subject: mashing specialty grains from Micah Millspaw

> re: mashing specialty grains

> notice some do NOT mash these, but steep separately in the water being
> heated for mash-out temperature elevation. Are there negative
implications
> to mashing chocolate/roasted, etc.

I believe that there are some possible unfavourable side effects to mashing chocolate malt and darker caramel malts. When mashing the specialty grains along with the normal part (pale grains) I've noticed a tendency for the finished beer to have metallic notes. When the chocolate malt is added only in the mash out, the metallic notes are not present. Nor does my water contain significant traces of iron. It is however possible that the extraction of metallic flavours from the darker malts is related to my high calcium hardness water. But what ever the cause, the mash out only use of the darker specialty malts is a cure. I've had no problem with roasted barley in the mash itself, but have on occasion put it in the mash out in order to get a more subtle effect from the roast.

Subject: Candi sugar availability

I recently brought back 14 lbs. of light and dark candy sugar from Belgium, and took a box of the dark stuff into my local specialty store to see if more was available. Both the proprietor and I have noticed a distinct resemblance to rock candy, and reference to Rajotte's Belgian Ale appears to indicate that they are made by an identical process. This entails dangling cords into a vat of slowly cooling sugar solution, which encourages the sugar to crystalise around the string.

As far as we can tell these two products are the same thing, though the Belgian variety comes in substantially larger chunks. Rock candy is available in light and dark, as well as in flavored varieties, and can be purchased by the pound. The only drawback is that since its a confection rather than an industrial brewing ingredient it still has the string. Presumably this would have to be fished out of the brew kettle once the sugar has been dissolved, but might offer the advantage of letting you dangle the sugar in suspension while it melts. (Belgian candi sugar is about the size and consistency of small gravel, and makes a hell of a racket as I stir it around the bottom of my pot.)

Of course, leaving the string in would give a new definition to "ropiness".

Those interested can inquire at their local specialty stores. If you're without one, you can contact:

Al Lann
King Street Gourmet Cellar
210 King Street
Alexandria, VA 22314
(703) 683-5439

Al says the stuff would cost about \$3.00/lb, and that he'd be willing to ship. Standard disclaimers apply--I derive no benefit from any sales he might make, and have no financial or other interest.

Subject: Culturing those yeasty boys

I'm a new yeast culturer, and just brewed my first batch with cultured yeast.

I have some specific questions, but I would also like to outline my procedures so that you all can comment on them, good or bad. Here's what I did:

First, I've been freezing yeast in glycerin, er, that blue stuff (glycerol? Dammit, Jim, I'm a social scientist, not a chemist). For my first experiment, I chose Wyeast Irish Ale. It has been frozen for 5 months. I thawed to just where I could get my inoculation loop (read very long needle) through the ice, scooped out a glob of yeast, and put it in a just boiled and cooled starter, and affixed an airlock. Question 1: Is this step necessary, or can I go straight from the freezer to the agar plate?

Well, I had too much starter--about 150 ml--but it seemed too hard to prepare a smaller amount. (Next time I'll either prepare small amounts and can them or I'll prepare it fresh and dump the excess.) Anyway, it took a long time to get any visible activity--about a week. Finally, I got something that looked like a real starter. I know that part of the problem is the small pitching amount compared to the size of the starter, but, Question 2: How much of the lag time is due to the fact that the yeast was frozen?

Well, after the starter got going, it looked, smelled, and tasted just great, so I flamed my loop and streaked my plates (actually, half-cup canning jars). I used the "thirds" method: Dip the needle in the starter, streak a third of the plate, reflare, draw the loop through the streaked portion, streak a second third, and repeat for the final third. I gotta work on my technique; this was harder than it sounded. Also, the agar was softer than I suspected, making dragging the loop tough. Question 3: How solid should it be? I can look up my recipe, but I suspect enough variation that it probably won't be that informative. Just tell me how hard the agar/wort should be.

Ok, a few days later, I had yeast growing in my streaks, but I also had a thin film of yeast covering the whole surface of the agar. It was definitely yeast, it looked and smelled yeasty, and there was nothing else growing. Still, there were no isolated globs. There were thicker parts in the streaks,

and the thin film. Question 4: Should I change this condition, and if so how?

Having learned my lesson about too big a starter, I boiled up some more wort, and poured off about 15 ml into a small (30 ml) jar. I scooped a glob of yeast from the plate and put it in the jar. A day or two later, I dumped this ministarter into a 6 ounce starter, and thereafter treated it like a Wyeast package. I built up to about a pint and a half. The starter seemed to be of exceptional quality and I'm looking forward to the beer it produces. After grabbing the yeast I put the agar plate sealed, upside down, in the refrigerator. Question 5: How long will this last? Is it worth trying to brew from the plate again, or should I go back to the freezer and start over for my next use of this yeast?

Thanks for answering these questions for me. Also, if you have any general comments about my procedures, feel free to make them. Thanks.

Finally, because of all this yeast-culturing activity, I dragged out my copy of Rog Leistad's yeast culturing book and noticed something very strange, but that's a little off topic, so I'll ask about it in a separate message.

From: "Stephen E. Hansen" <hansen@Sierra.Stanford.EDU>
Subject: Anchor's Sumerian Beer Project, Essay II

[The following is a bit long but I think will be interesting to many of you.]

My wife used to work for the Stanford library's development office (e.g. fund raising). One of her responsibilities was working with a "Friends Of The Libraries" group known as the Library Associates. After she left there she kept up her membership in the Associates. Anyway, last month we got an invitation to one of their fund raising events and one look told me that we would have to make the sacrifice and attend. This group of aging book lovers was going to the Anchor Brewery! The event was to begin with tasting and a tour, a light supper, and then a talk by owner Fritz Maytag about his Sumerian Beer Project. It turns out that Fritz is on the Stanford Library's "Visiting Committee" (whatever that is) and hosted the whole event.

The event started at the tasting room with hors d'oeuvre's and any of Anchor's products you cared to try (the Maytag Blue cheese was a nice touch). The tour that followed was essentially the same one I had about a year earlier, but that one wasn't followed by a catered meal. After a light supper we grabbed a beer and settled into the thirsty work of listening to Fritz Maytag tell us about Anchor's Sumerian Beer Project. He had someone walking around with a 35mm camera taking pictures throughout much of the baking and brewing and used them to illustrate the talk.

Back in 1987 Fritz Maytag read a couple of articles by the University of Pennsylvania's Professor Solomon Katz about a newly discovered Sumerian tablet containing a hymn praising Ninkasi the goddess of beer and brewing. This 'Hymn to Ninkasi' looked to contain just enough information to determine the brewing processes of the time. Maytag, Katz, and various other scholars spent two years researching Sumerian and other ancient brewing techniques and in 1989 brewed up what Fritz called Ninkasi Essay One. The resulting beer was served at the conference dinner of the 1989 Microbrewers Conference.

Well, they've done it again. Ninkasi Essay Two was made earlier this year and unlike Essay One which was made from about one third "bappir" bread and two thirds barley malt, this batch was, if I remember correctly, a 60:40 mash of bappir and emmer wheat malt. Their researches led them to believe that this type of wheat was common to ancient Mesopotamia and was likely to have been used in conjunction with barley. Another change was that this time the bread was baked in a wood fired oven up in Mendicino, CA. This gave the resulting bread a darker caramelization and the beer a malty liquid bread flavor. After the talk was over we headed back the tasting room where we were treated to a taste of Ninkasi Essay Two. It was quite drinkable and the little old ladies in the group loved it. This is an unhopped beer, and while Anchor's heavily hopped Liberty Ale is more to my taste, I was surprised just how tasty it was.

If you make it over to the brewery don't expect to find some Ninkasi on tap as I got the impression that is was only brought out for special events. But there were probably a few lucky people who took the tour the following day and got a taste as there was one bottle that didn't get emptied that night. I was fortunate enough to walk away with an empty with the specially designed label.

Back in 1989 Chuck Cox got a copy of a six page paper describing the project and posted the following to rec.food.drink.

> The first few pages of the paper explain how they researched the

Fred Scheer's research is not necessarily flawed; nor are the homebrewers necessarily wrong in claiming improvement with age.

Filtered, artificially carbonated draft beer is, of course, at peak fresh-
fresh-
ness and taste from the moment it is kegged. There are no longer any yeasts
yeasts
doing their thing in the beer, so it is a "dead" product in that is no longer maturing and aging on live yeast. This is not necessarily a bad thing, as a lot of the most famous beers around are packaged like this, including Pilsner Urquell and Jever Pils; this is the way of modern lager brewing. Most continental lager brewers, even the German and Czech makers
makers
of 'Helles' lagers and Pilsners, will say the same thing: the beer is aged
aged
and then clarified, and the filtered beer, freshly packaged in the kegs, is
is
at its peak at the moment of packaging, and it's downhill from there. This
This
does not necessarily imply that it's an immediate, steep path downhill, just that the beer is no longer improving, and is slowly deterioration.

This is not meant to be a put down the Frankenmuth beers, BTW. I've had the Dark and the Pilsner in bottled form here in Seattle; my first recommendation would be to package the Pilsner in dark brown bottles, instead of the current green package. It would also be nice to get it unpasteurised (which I hope is the case with their draft beers). The Dark was reasonably good, somewhere between a Bavarian 'Dunkles' and a Vienna Amber Lager. In either case, these beers are quite vulnerable to the elements, especially heat and light, and benefit most from attention to packaging and handling.

As a personal aside, I recently had the opportunity to compare Pilsner Urquell, purchased in a Prague supermarket and brought home, with an imported Pilsner Urquell bought here in Seattle. There was simply no comparison: the P.U. sold in Prague was packaged in a standard brown half-liter 'Euro-bottle', the kind in which you see many of the German imports packaged, and was not pasteurised. The P.U. sold here was pasteurised and sold in the green glass bottle, and stored in the usual harsh lighting environment of the well-lit grocery store. The Prague bottle was fresh and clean, and clearly near its peak of flavour; the Seattle bottle was skunky, with a cooked-cereal flavour. The recent arrival of unpasteurised kegs of P.U. in our fair city was a pleasant occasion indeed, but the ultimate in flavour of this beer is to be found as close as possible to the brewery.

Now, this seems at odds with the 'C.W.' of homebrewers, because a lot of us continue fermentation and conditioning nearly all the way to the day of consumption. Even some of us who add carbonation to our kegs still prime the beer; this packaging of beer, that continues to aging on live yeast cells, results in a "living" product, akin to Sierra Nevada's bottle-conditioned ales, the unfiltered German Hefeweizens, and the Belgian Trappist and abbey ales. The British are perhaps more keenly aware of this, and not just in home-brewing circles; the largest brewers in the UK tried foisting the infamous "keg" ales on the public. These "keg" ales were top-fermented like the famous cask-conditioned beers, but after a short period of aging, they were filtered and sold in pressurised kegs. The resulting bland, gassy, "dead" product resulted in the formation of CAMRA, and the rest has been history for over twenty years now. The British brewers' reasoning was the same in this case: it was easier to market a product already at the 'peak' of its freshness, than to train pub workers in the ancient art of maintaining and serving "live" cask-conditioned ales at their peak of aging and flavour. Homebrewing revives this art of packaging and drinking "live" beer. There was also a recent discussion here in the HBD about

Worthington's White Shield, a bottle-conditioned ale. There is also a good example of bottle-conditioned lager available in the USA as an import, that being Christoffel beer from the Netherlands. The French and the Belgians also have several specialty beers, bottle-conditioned, that are called "bieres de garde", or laying-down beers, meant to be kept for several months - even as much as a couple of years - before drinking.

Thus, as per the second statement, those people who claim their beer improves with age could have a valid point. "Live" unfiltered beer *does* improve with age. Flavours mellow and meld, and these beers reach a peak of flavour weeks and months after packaging, whether in the cask or the bottle. Similarly, Fred Scheer's research holds true for "dead" filtered beers, which are at their peak upon packaging, and are best consumed as soon as possible.

Subject: Yeast pitching question & thanks

First, I would like to thank all the people that gave me suggestions on getting started. I appreciate your help thus far. (Someone at a homebrew store said that beer people are extremely helpful, but that wine people are really stingy with helpful information..., any similar experiences?)

Now, my question / story for the day:

I am an extreme novice. I am following the directions that I have been given, and what is written in Papazian's book. However, my fermentation times are only about 1/2 of what they say I should be getting. On the batch that I am fermenting now, I started it late Sunday, and it has almost completely subsided bubbling by this morning.

Also, contrary to opinion, my massive activity does not start in 24/48 hours, but in a matter of 2 or 3 hours.

What am I doing wrong? The instructions that I have been following say to hydrate the yeast, and then pitch into the carboy. I have also seen that I should wait until the solution in the carboy has cooled. Which is correct? (I would suspect since the way I did it (hydrate & pitch) is not working, the other way must be better). If I should wait, what temperature should I wait for?

Could someone please describe the event steps (and length of time) between the time you turn off your burner and put the blowoff tube onto the carboy?

Finally, I local distributor gave me a taste of his India Pale Ale, and I really would like to make this. Any suggestions on a recipe (other than Papazian's)

Thanks again.

From: holloway@ucs.indiana.edu
Subject: Brew query: Detroit and Windsow, Ontario

Greetings. A friend with a taste for beer (but, alas, no network connection) asks that I poll you for recommendations on where to find interesting brew/brewpubs in Detroit and Windsor, Ontario. Thanks in advance.

I was delighted with your unanimous recommmendation of the Cleveland brewpub, Great Lakes Brewing Company. Of the close to half-dozen brews on tap, their IPA-style topped my list -- rich, **very** hoppy, full of body. It wasn't available in the bottle, but they filled a gallon jug from the tap; our brewclub back in Bloomington, IN, enjoyed it almost a week later. It held up superbly. GLBC's a very hospitable place. Don't miss it if you visit the Cloven Land! --Jan (holloway@ucs.indiana.edu)

> lew of cane sugar or beet sugar.

Since I once worked at a corn wet-milling plant in Germany, I believe I can shed some light on this process. In the old days corn processors found they could take the starch they separated from the rest of the corn kernel, and break it down into sugar solutions (by an acid hydrolysis?). With typical marketing hyperbole, they called this "glucose" syrup, even though a lot of it was not glucose (ie a six carbon sugar monomer) but rather maltose (a dimer) and other stuff. I'm not sure if they ever solidified this stuff.

Then as technology progressed they became able to use enzymes to break down the starch virtually 100% of the way to a simple (monomer) sugar. This became "dextrose" even though chemically dextrose and glucose are the same. Thus dextrose syrup and crystalline dextrose.

By the way, my dictionary defines "corn sugar" as dextrose and "corn syrup" as the mixture of dextrose, maltose and other sugars mentioned above.

Forget about it, it's not suitable for the coarse grinding (cracking
really) needed for beer making. I've considered heavily modifying one
but it does not look to be worth the expense or effort if it can even be
done. For what it costs you are better off getting the Marcato or
something (unless you got one as a gift already and don't mind hacking
it up).

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>
Subject: Re: beer vs ale

There are differences of opinion here. The "modern" view seems to be that all fermented (hopped?) malt beverages are "beer", while "ales" are fermented with top-fermenting "ale" yeasts. However, I have seen some writers use the term "beer" to mean exclusively "lager beer" (thus "it is a beer and not an ale").

Lt. Col. Robert Gayre, who wrote the book "Wassail! In Mazers of Mead," makes the distinction thusly: beer is a strong (in alcohol), hopped fermented beverage, while ale is weaker and *not hopped*. In his opinion, both terms originally applied to a honey-based beverage, but came to refer to malt-based beverages as mead-brewing declined from the Middle Ages (and before) to the present. His view would seem to be in a distinct minority, at least in this country. Any British readers care to comment?

From: shaver@zeppelin.convex.com (Dave Shaver)
Subject: Inconsistent carbonation in bottles.

A little over a month ago I bottled a dark ale. I used a scant 3/4 c. of corn sugar to prime after dissolving the sugar in 2 c. boiling water. I'm pretty sure that I mixed in the priming sugar well enough. I capped with a Brev wing capper after boiling the caps for about 10 minutes. Since bottling the bottles have been stored at about 65-70 deg F.

The problem is that about half of the bottles have good carbonation and great head retention while the other half are more-or-less flat. (The "flat" half do have a little carbonation, but they form only a very weak head when decanted. The head quickly disappears and the beer tastes flat when drinking it.)

I'm wondering if:

- I need to relax and hope the batch carbonates more evenly.
- I capped some of the bottles wrong.
- I didn't mix in the priming sugar well enough.
- I did something else wrong.

Any suggestions?

Subject: An editorial

EDITORIAL

Geez, I'm getting tired of hearing everyone hail "candi sugar" as some Belgian miracle. If it is indeed just rock candy, then it is simply sucrose--TABLE SUGAR. Everyone's got that in the house! Just use sugar--
-
it's cheap. It doesn't matter if it is in rock form, granulated form or even powdered. Sucrose is sucrose. Just because someone once used a foreign spelling, and everyone else propagated it, doesn't mean it's anything special.

Look, if I were a candy maker (in any country) would I use some strange and harder to get (read: expensive) type of sugar? No, I would use sucrose. It's cheaper and more readily available. What other kinds of sugar are there? Fructose, lactose, maltose, glucose--when's the last time you saw candy made from them? When's the last time you saw them in a grocery store?

There is a very bad tendency in this forum to take what one contributor says, and increase it's credibility as people respond. By the time you see several articles on the subject, the word of the first contributor is considered FACT--written in stone. Hail, hail, I must go to Belgium and get some of that miracle stuff, or else my pseudo-lambic's will be terrible. Look, there are a lot of WAY more important factors in creating something as complex as a Lambic.

People, use a little judgement.

Subject: RE: How long does steam beer take?

In response to Rob Bradley :

>I'm planning to brew a steam beer soon, using Wyeast California,
>brewing in the low 60s and having an SG in the high 1040s.
>I'd appreciate any estimates on how long I can expect it to
>take to ferment to completion.

I've just bottled the second of two batches using that yeast and about
your SG
and temp. The first batch surprised me in that it wasn't quite finished
after
three weeks, and I had to wait another before I had time to bottle. I
dry
hopped (1 oz Mt. Hood) that batch after one week in the fermenter (single
ferment), and the CO2 from the continuing fermentation must have scrubbed
most
of the aromatics because it has very little hop fragrance. I tasted that
batch against Anchor and I was fairly pleased -I went overboard with the
bittering hops, and the Anchor has a more complex flavor, but they were
clearly
the same style of beer.

The second batch fermented for two weeks in the primary at slightly
warmer
temps (upstairs instead of cellar) then I racked to a secondary. It
finished
in another week, and I then dry hopped and let it sit a fourth week. At
bottling (last night) it had much more hop aroma than the first and it
tasted
GOOD.

I think this yeast can take higher temps, and it might even be more true
to
style if it is fermented warmer.

From: alan@math.sunysb.edu (Alan McRae)
Subject: copper wort coolers and oxidation

While reading the latest special issue of Zymurgy I noticed an add for a stainless steel wort chiller. As the price was rather high I called the seller to ask why he thought a wort chiller should be made of ss. His explanation was this: After the boil, wort is oxidized by contact with copper. On the other hand I know that Pilsner Urquell, a beer of unquestioned quality, stores the beer after cooling (I don't know what material their coolers are made out of) in shallow copper containers so that the cold break may settle. So the question is whether or not the copper wort chillers that many of us are using are in fact compromising the quality of our brews.

Joel writes :

> My experiments have so far resulted in brews very similar to the
scruffy
> "scruffy".

English traditional cider is often called 'scrumpy' (in the sense of
'rough').
This is because it is fermented with a mixture of wild yeasts and
bacteria,
the apples are particularly high in tannin, the fruit pulp is
occasionally
fermented (which increases tannin), and it is served cloudy, warm and
flat.
Apple juice naturally makes a drink of around 7% alcohol by volume, yet
some of
the French cidre I have tried has been much weaker. This suggests to me
that
the drink has been diluted (and maybe fermented with a refined wine
yeast,
using eating apples), which would tend to reduce the rough character.

Subject: Aging revisited

Oops! I forgot one important point on aging beer: acetaldehyde.

Very young beer usually has acetaldehyde levels that are well above its 10 ppm flavor threshold. Acetaldehyde has a "green apple" flavor and aroma and is in the normal anaerobic fermentation cycle:

glucose -> pyruvic acid -> acetaldehyde -> ethanol

Quoting from another of George Fix's articles in the Zymurgy Special Issue on Troubleshooting:

"Thus in a normal fermentation, the acetaldehyde level will rise, typically well above its flavor threshold of 10ppm, and then decrease as it is converted to ethanol."

Then later goes on to say:

"For example, Budweiser is kraeusened after the primary fermentation and is given only a brief cold storage [then, of course it's filtered and pasteurized (killed), packaged and shipped]. Thus more acetaldehyde tends to 'spill over' into the final product than normal. Extensively aged beers, for example Salvator and EKV-28, typically have acetaldehyde levels that rarely exceed 2 ppm."

Typos and the text in brackets are mine.

Subject: Smadams Cranberry Lambic, Xmas brew pix

To whomever warned us about Sam Adams Cranberry Lambic:

Did you check if it was an old batch? There's a sale going on at a local liquor store, a case of Smadams assorted brews for \$14.99. It was too good to be true. Everything they had was at least four months past the expiration date. (Leave it to the FDA to let sleazy packies sell spoiled beer while they crack down on "health" food stores and neglect to inform the public about the consequences of irradiated foods. FDA: Either keep your laws off my life, or at least pretend you care about the people you're supposed to be protecting!)

'Scuse me.

My roommate and I ended up buying a six of Cranberry Lambic for \$4. By the way, it was packaged just like the assortment packs they sold last Xmas. One Cranberry per six. Hint, hint. The stuff was more sour than bitter or malty, and tasted nothing like cranberries. It was bad, old beer. I don't think Smadams has even released this year's Xmas brew yet. At least not in Chicago.

On a related note, does anyone have any favorite Xmas brews? I have tried Sam Smith, Aass and Sierra Nevada so far. Sam Smith's was by far the best of these three. Can anyone suggest how to get that kind of Xmassy hop character in a homebrew without spices, following Reinheitsgebot?

Ho ho ho,
Jake.

Subject: Hopback Wort Aeration

Subject: Hopbacks and Wort Aeration

I have a paradoxical question for the digest. I have a very experienced brewing friend (12+ years) who is a self-proclaimed hophead. He uses a hopback during his brewing procedures. His setup is such that after the boil is over he has a pump which moves his hot wort into a strainer containing an ounce or two of fresh leaf hops. As the hot wort filters through the hops (picking up valuable aroma) it falls about a foot into his hopback (a 5-gallon soda keg with the top cut off). The bottom of the hopback has a valve which is attached to a counter-flow wort chiller. He has won numerous AHA awards over the years for outstanding pale ales and many other fine beers.

So the now the question: Everything I've ever read says aerating *hot* wort is very bad, but aerating cool wort before yeast pitching is good. So how come his hopback doesn't introduce massive oxidation since the wort is still hot as it falls into the hopback and then cooled very quickly as it falls into the fermenter (aerating again)?

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Beer aging

Jack brought up the subject of aging beer in today's HBD. The problem? Why does commercial beer get worse with age, while Homebrew gets better (up to a point)? The answer, of course, is that homebrew is not filtered, and continues to mature in the bottle or keg. Commercial beer IS filtered, so that a) no more yeast settles out of suspension, b) no more carbonation is produced, and c) no more yeast by products are released into the beer, all of which happens in homebrew while it ages in the bottle. If you filter and bottle your beer under pressure, then it is best consumed fresh. My homebrew is bottle conditioned, and is best aged for at least 2 weeks if not a month or more to get nice and clear and carbonated.

>> notice some do NOT mash these, but steep separately in the water
being
>> heated for mash-out temperature elevation. Are there negative
implications
>> to mashing chocolate/roasted, etc.
>
>I believe that there are some possible unfavourable side effects to
mashing
>chocolate malt and darker caramel malts. When mashing the specialty
grains
>along with the normal part (pale grains) I've noticed a tendency for the
>finished beer to have metallic notes.

I always associated the metallic notes with adding too much water at
the end of the boil to bring up the total volume, instead of doing a
full boil. It only seems to happen with dark malts.

>When the chocolate malt is added only
>in the mash out, the metallic notes are not present.

I never tried adding chocolate malt only to the mash out.
Mashing definitely reduces the astringent flavor as opposed
to not mashing dark grains, but this may have to do with the
fact that a grain bed filters the particles out more
effectively than a fine strainer.

> Nor does my water contain
>significant traces of iron. It is however possible that the extraction
>of metallic flavours from the darker malts is related to my high calcium
>hardness water.

Dark malts reduce the ph of the mash, and hard water can be quite acidic.
The dark malts also tend to discolor ph paper and make it read higher
than it actually is. mashes with a ph below 5.0 can easily occur (if
your mash water has no chlorine).

My batches that were metallic all had gypsum (or at least
burton water salts) added to them, just because it was part of
the recipe. This further lowers the ph. I no longer treat my
mash water, except to boil it to remove chlorine, but I've only
made 1 dark beer lately (a dry stout that turned out fine),
and that only had roasted barley in it, as far as dark malts go.

> But what ever the cause, the mash out only use of the
>darker specialty malts is a cure. I've had no problem with roasted
barley
>in the mash itself, but have on occasion put it in the mash out in order
>to get a more subtle effect from the roast.

I've also noticed the problem mainly when using chocolate malt,
more so than with black patent or roasted barley.

On a final note, slight overcarbonation seems to exaggerate
the "metallic" effect.

Subject: RE: Real ale from a carboy

Conn writes:

| Well, I'm no physicist, but here goes. (Taking a breath). Your system
| doesn't
| appear closed to me, and therefore won't pressurise. Ie, CO2 will
| dissolve in
| the water column, and eventually will reach equilibrium with the
| atmosphere.

Excellent point. The system is not closed and with sufficient time would
EVENTUALLY reach equilibrium. How long is eventually? I have no idea.
At 60degF, what would be the rate of diffusion of CO2 through 10' of
water,
from a 5/16" dia. 5psi CO2-water interface to a 3" dia. water-atmosphere
interface? Since most of the time, the bottom carboy would have some
water
in it, and since the copper pipe would be filled with water, what is the
rate of CO2 diffusion through 10' of water at 60degF over a 5/16" dia.
from
water saturated with 5psi CO2 to water saturated at atmospheric pressure?
The rate of diffusion in answer to the latter question is (I suspect)
sufficiently low, but a real quantitative answer would be more
satisfactory
than just my gut reaction.

From: Phillip Seitz <0004531571@mcimail.com>
Subject: Candy sugar continued

Hmm. Have I just been flamed?

In Thursday's HBD Alan Edwards launched a diatribe concerning the alleged snobism of people who'd like to use candy sugar in Belgian style beers. He wondered if there really was any difference between this and standard sugars such as glucose.

While it is not the point I want to make here, he may be right. Having hauled plenty of this stuff back from Belgium (using valuable space I usually reserve for chocolate!), I have to say that the value of candy sugar in comparison with other types is not immediately apparent. While it does offer some color and melts slowly, it tastes pretty much like... sugar. It seems to me that what's important is what it contributes to the final fermented product, but I've yet to see or taste any good side-by-side comparisons (my own experimental plans notwithstanding). Herein lies the point.

Many contributors to HBD (and myself certainly among them) have a tendency to pontificate on matters they don't fully understand. This isn't as reprehensible as it might seem, because any scientist will tell you that understanding (and the proofs it must be built on) can be quite difficult to come by. Most of us (again, myself included) are too lazy, unskilled, or downright impatient to actually test our claims and assumptions. So we swap folklore and half-understood wisdom instead.

I totally agree with Al concerning his skepticism, and suspect that his ideas concerning glucose and candy sugar may be correct. But I suspect that he, like many of us, is expressing an opinion and does not have any more solid ground to stand on than the rest of us. How many of us have the patience and discipline to prove what we're saying, anyway?

I do recall reading good, solid reports on HBD. A number of homebrewing clubs have undertaken interesting experiments from time to time, and I've appreciated their reports. (My club, sadly, is less disciplined.) As another example, I think most of us appreciate George Fix's comments because he seems to be one of the few who really know what they're talking about.

How can we tighten this up? Can we? Should we?

As for candy sugar, some Belgian brewers certainly use it, and it's not the cheapest stuff you can get. Does this mean they know something we don't?

The truth is: I don't know (yet).

>readers care to comment?

Certainly. Your interpretation of Lt. Col. Robert Gayre was quite right
(although I'm not sure about the mead bit, nor the weak/strong link).
At the time that hops started to be used the unhopped fermented malt
beverage (usually with other herb instead of hops) was called ale. The
hopped drink was referred to as beer. Once hops became universal the two
words became (almost) synonymous. Now we have ales being different from
lagers but both being beers.

Well, I got one as a gift and its been working great for crushing grain. There is a dial on the front of the mill which allows you to adjust the distance between the plates. I've found that loosening the dial about 30 clicks (depending on the size of the grain) works fine. No hacking is necessary.

I didn't write the warning, but I think the point of the original poster was that the BBC was being picky about naming of beers and then was incorrectly naming their beer a "Lambic." My point is, that even if the Sam Adams Cranberry Lambic [sic] tasted great, and even if it tasted like a lambik, it would still be only a pseudo-lambik. It's just the same as the appellations "Cognac," "Bordeaux" or "Champagne" (the latter which has lost it's exclusivity). It's like a trademark. Lambik is more of a process than a style since even within the handful of Belgian breweries that still follow the time-honored traditional method, there is much variation in flavors. In short: "You can't brew Lambik without Belgian air!"

Sorry -- we all have our causes -- I know one of yours and now you know one of mine.

It sure does, but a lot of the hot-side aeration smell undoubtedly gets
covered-up by the wonderful hop nose your friend gets. I'll bet that
if he cooled before aeration and then dryhopped in the fermenter, his
beers would be even better and would taste good much longer (if they
don't get consumed first).

From: agerhardt@ttsi.lonestar.org (Alan Gerhardt)
Subject: SS Air "Stone" Source

I recently found what looks to be an ideal wort aeration "Stone".

It is made of stainless steel and looks just like an aquarium air stone, only a little coarser. I have not used it in a batch yet, because I haven't found any air filters, but I tried it in a pan of water and it worked very well.

I got it at: American Science & Surplus
601 Linden Place
Evanston, IL 60202
(708) 475-8440

Stock number: 21096, Description: Sintered Diffuser
price: \$2.25 for package of 2

The catch? They have a minimum \$10 order, but they do have lots of other toys of interest. I have no connection with them except as a satisfied customer.

Note: As was published in an earlier digest, they also have the Hunter airstat for \$24.xx including shipping.

Cheers,
Alan

48
> hours, but in a matter of 2 or 3 hours.

Dry yeasts tend to start much faster than liquid yeasts. Liquid yeasts are dormant until you give them food (i.e., pop the wort buldge in the case of Wyeast). Dry yeasts are fed lots of oxygen before dehydration and are ready to go when they hit your wort. Liquid yeasts need to respire and build-up their numbers before switching to fermentation.

Also, fermentation time is highly dependent on temperature and the yeast strain. The yeast strain I cultured from Orval dregs is VERY slow (3 weeks), whereas some dry yeasts I used in the past would ferment-out in 3 days.

>
> What am I doing wrong? The instructions that I have been following
say
> to hydrate the yeast, and then pitch into the carboy. I have also

> Which is correct? (I would suspect since the way I did it (hydrate
&
> pitch) is not working, the other way must be better). If I should
> wait, what temperature should I wait for?

Dry yeasts can handle slightly higher pitching temperatures. I've read that they should be rehydrated in 100F water, which would imply that you could pitch them in 100F wort, but you don't want to aerate your wort when it is that hot. Liquid yeasts are much more picky when it comes to temperatures -- you don't want the wort temp to be far away from the starter temperature. I use liquid yeasts and an immersion wort chiller to bring the wort to 70F. I then aerate the wort and pitch the yeast.

When using dry yeasts, I recommend that you rehydrate in 100F water before starting brewing. By the time you've completed the boil and cooled the wort to 80F, the yeast will probably hav cooled down to about 80F also. Aerate the wort and pitch the yeast.

>
> Could someone please describe the event steps (and length of
> time) between the time you turn off your burner and put the blowoff
> tube onto the carboy?

I use a wort chiller, and with Chicago tapwater my chilling time is

about 20 minutes for a 5 gallon (full batch) boil. Add to that carrying and handling time and we're talking about 30 minutes from end of boil to ready-to-pitch. However, I've been waiting 1 hour after cooling to allow the cold break to settle, but I think I'll drop this procedure (it seems to take much longer than 1 hour and I don't think my 1 hour wait makes much of a difference). Therefore, my next batch (Sat) will be about 30 minutes from end-of-boil to blowoff-tube-on.

1/3 oz Wines Inc. Burton Water Salts
1/2 lb 6 row Crystal Malt (40L)
5 gallons distilled water
1 gallon Chicago (soft) tapwater
yeast recultured from 3 bottles of Sierra Nevada Pale Ale

OG: 1071, FG: 1020

Procedure:

Nothing special -- crush the crystal (actually, I used a rolling pin and a ziplock bag) and put the crystal into a mesh grain bag. Suspend the bag in the pot from the spoon as the water and Burton Water Salts go from cool to 165F. Remove and let drain. Bring to boil, add malt extracts and hops in hop bags at the proper times. Chill as quickly as possible. Aerate and pitch. Use blowoff method.

Dave writes:

>A little over a month ago I bottled a dark ale. I used a scant 3/4 c. >of corn sugar to prime after dissolving the sugar in 2 c. boiling >water. I'm pretty sure that I mixed in the priming sugar well enough. >I capped with a Brev wing capper after boiling the caps for about 10 >minutes. Since bottling the bottles have been stored at about 65-70 deg F.
>
>The problem is that about half of the bottles have good carbonation and >great head retention while the other half are more-or-less flat. (The >"flat" half do have a little carbonation, but they form only a very >weak head when decanted. The head quickly disappears and the beer >tastes flat when drinking it.)

Sounds okay except for the boiling of the caps. I suggest that a minute in boiling water is more than enough. I use simple 200ppm Chlorine Bleach solution. Boiling will ruin SmartCaps(tm) and will soften the seals on regular caps. I've never had inconsistent carbonation and have been pretty relaxed about mixing in the priming sugar.

> - I capped some of the bottles wrong.

Could be another problem. Does your capper adjust to different bottles well? Mine is a bench capper and adjusts very easily. I had problems with my Jet capper in that it only accepted one type of bottle neck (it relied on the ring of glass at the top to be a particular width).

>which I picked up in Brussels. Not surprisingly, many people were
>interested.

>Flipping through "All ABOUT Beer" (the magazine) at a bookstore last
>night, I spotted a 1/4 page ad for the book, "Available for the first
>time in the U.S.". \$29.95, or \$24.95 pre-publication price. This was
>named a "second edition", so I guess I'll have to buy it. . .

I have both versions, and they are essentially the same. I wouldn't
recommend getting both. (I wouldn't have both myself, except the second
copy was a freebie!). The biggest difference is that the US release is
of the "quality paperback" variety. \$24.95 may seem like alot for a
paperback, but then I paid US \$42 in Brussels for the hardcover edition.

I wrote a short review of this book for the WORLD'S GREATEST BREWSPAPER,
which I'll include here.

CR

=====
==

Given the growing fascination for Belgian beers in this country, the
introduction of Michael Jackson's The Great Beers of Belgium couldn't
come at
a more appropriate time. This is a definitive work, and a must have for
any fan of Belgian beers.

Jackson has long had a passion for this tiny country's beers, and his
passion
shows in this well researched text. He begins by discussing the unique
beer
culture that exists in Belgium, and the relationship between food and
drink
there. There is a description of the ingredients typically used in
Belgian
beers, and then the bulk of the book focuses the widely varying beer
styles
that are uniquely Belgian.

Jackson proceeds to unravel the mysteries surrounding the major styles as
only
he can. Lambics, White Beers, Brown Beers, Red Beers, Saisons, Belgian
Ales,
Abbey Beers, Golden Strong Beers, and Regional Specialties are all
included in
this unprecedented work. There are stylistic descriptions as well as
highlights
of individual breweries, including all five operating monastery
breweries. If
you don't know your Faros from your Flanders Browns, this book will
definitely
set you straight.

Finally, Jackson rounds out the book with a discussion of Belgian Cafes. He describes some of the more famous cafes of Brussels, and then lists a few specialty beer cafes around the country. There is even a brief listing of establishments specializing in Belgian beers in other parts of the world, including San Francisco.

This masterfully written, 271 page work is filled with over 250 full color photographs. It is sure to occupy a place of pride in the library of any serious beer aficionado.

From: Paul dArmond <paulf@henson.cc.wvu.edu>
Subject: RE: inconsistant carbonation

Dave Shaver writes that he is having trouble with his bottles not conditioning. I had similar problems until I:

- 1) Added a small amount of fresh yeast at bottling.
- 2) Stirred the priming in with a *sanitized* spoon.
- 3) Kept the bottles above 65F for the first five days.
- 4) Shook the bottles twice during the first week to resuspend the yeast.

3 and 4 were based on advice from the Cellar in Seattle. They also advised storing the bottles on their sides to expose more surface area for the yeast. 2 was recommended by my friend Perry (Rev. 10X) Mills. He had noticed that SG readings varied between the top and bottom of his secondary. 1 was based on reading here in the digest that yeasts get "tired" when fermenting high gravity beers (mine range from 1.060 to 1.075).

All of these trick yeilded small improvements, and I am now very pleased with the results. Previously, developing good condition took as long as six weeks. Now my beers are tasteable (for the impatient) in one week, well conditioned in two. I have noticed that the high gravity dark ales improve with time. js may have been a trifle unkind to describe this as "hiding defects." Back in George Washington's day, porter wasn't really considered drinkable if it was less than a year old.

I don't know the reason for the conditioning hassles. The above tricks solved the problem and they may help you.

JS-

I think in this case the author was referring to kegging the light
american beers. In my experience only the darker, heavier beers improve
with age. I've had terrific american style ales really go down hill
after only a few weeks. On the other hand, I've had some stouts aged up
to a year and they've only gotten better.

I don't know the Frankenmuth Brewery, but as Americans drink very little
dark beer on tap, I'd say the author just assumed that one only kegs
lighter beers.

The reason no one responded is that your brother likely will be the first person in living memory actually moving to Charleston rather than away from it.

As an ex-patriot Charleston home boy, I have the sad duty to inform you that this town gives the term "beer wasteland" a whole new meaning.

I spent some time there recently because of a death in the family, and I found the situation worse than ever. Thank goodness I remembered to take along lots of homebrew.

There are no brewpubs, mini, micro, or mega breweries within 200 miles of Charleston (the nearest would be Cincinnati or Pittsburgh). The best beer store in town is the Cold Spot on Washington St West. It has a reasonable selection of imports. Next best is Campbell's Kwik Shop in Kanawha City. Last I remember, it actually carried Guinness and Bass Ale. One measure of the situation - There are exactly as many beer retailers listed in the phone book as there are bible retailers.

Don't even bother with the bars or taverns - nothing served but Budmillob and, occasionally, Bass Ale.

If you can get past all of that, Charleston does have a fairly good cultural and music scene. Check out Mountain Stage, recorded each Sunday at the WV Cultural Center at the Capitol. Also, spend some time at Trans Allegheny Books on Capitol St, one of my all-time favorite used book stores.

Subject: Corn Syrup, Oxidation etc.

>Then as technology progressed they (corn syrup manufacturers) became
>able to use enzymes to break
>down the starch virtually 100% of the way to a simple (monomer) sugar.
>This became "dextrose" even though chemically dextrose and glucose
>are the same. Thus dextrose syrup and crystalline dextrose.

Agricultural product manufacturers offer a variety of "corn syrup"
products
to commercial brewers. They can control the types and quantities of
sugars
to a remarkable degree, even approximating the sugar distribution in a
"typical" wort. This development has been met with enthusiasm by many
commercial brewers. One needs only to count the railroad tank cars
bearing
the name of a midwest corn processor in front of the Rainier brewery here
in Seattle.

>The problem is that about half of the bottles have good carbonation and
>great head retention while the other half are more-or-less flat. (The

>weak head when decanted. The head quickly disappears and the beer
>tastes flat when drinking it.)

>I'm wondering if:

>- I need to relax and hope the batch carbonates more evenly.
>- I capped some of the bottles wrong.
>- I didn't mix in the priming sugar well enough.
>- I did something else wrong.

I had uneven carbonation problems for quite a while and finally traced it
to inadequate mixing of the beer and the priming sugar. I was so afraid
of
getting oxygen into the beer that it wasn't getting mixed. I finally
started using a carboy for a priming vessel so I could throw a cork on
top
and gently rouse the beer without splashing it. The trick is to >
quietly<
siphon the beer into the carboy with the priming solution already in it,
shake lightly to cause the beer to foam a bit, thus filling the airspace
in
the carboy with CO2. Warm priming solution in the bottom the the carboy
helps this process

A neat trick for underprimed beer is to pour 2 to 4 oz of "commercial"
beer
(i.e. bland and overcarbonated) in the glass first. There seems to be
enough carbonation to go around and the flavor change isn't too drastic.
Better than throwing flat homebrew away, anyhow

>I was wondering if anyone can recommend any commercial
>holiday brews that I should sample.

Jubelale from Deschutes brewery in Bend, Ore and (I forgot the name of
the
beer) from Feinloffel (sp?) somewhere in California

>Are the copper wort chillers that many of us are using are in fact

>compromising the quality of our brews?

I Think the guy peddling stainless wort chillers is pulling your chain.

> Everything I've ever read says aerating *hot*
>wort is very bad, but aerating cool wort before yeast pitching is good.
>So how come his hopback doesn't introduce massive oxidation since the
>wort is still hot as it falls into the hopback and then cooled very
quickly
>as it falls into the fermenter (aerating again)?

The key here is that the wort is cooled >immediately< after the oxygen is introduced from aeration. If the wort was splashed around and then let sit around hot for a while , then trouble would occur. My understanding is that many commercial brewers introduce oxygen into the wort at the >HOT< end of their wort chillers without problems! Something about mixing in better. I imagine just as many introduce oxygen at the cold end too.

Hope this helps...
Cheers

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>
Subject: Closure on smoked beer

Hey, now. Last summer, I asked for hints about making smoked beers. The published literature is pretty scanty, but the help from the HBD was great.
Thanks to everyone.

Here is what I did and how it turned out. (I'm going to try to put the recipe in the format used in the Cat's Meow. If we all did that, maybe it'll save Karl and Mark a little effort down the road.)

Mongrel Ale (Smoked)

Source: Frank Tutzauer (comfrank@ubvmsb.cc.buffalo.edu)
Issue #????, 11/??/92

Ingredients:

1 lb smoked crystal (60 L)
1/2 lb smoked pale English 2-row
1 lb Munich malt
3 lbs amber M&F dried malt extract
2 lbs light M&F dried malt extract
1/2 oz. Galena pellets (alpha = 12.0; 60 min.)
1/2 oz. Hallertauer pellets (alpha = 4.5; 15 min.)
1/2 teaspoon, Irish Moss (15 min.)
1/2 oz. Hallertauer pellets (alpha = 4.5; 1 min.)
Wyeast 1007: German Ale
Heavy handed 3/4 cup corn sugar (priming)

Procedure:

Using a water smoker, I smoked the crystal and pale malt at about 170F over hickory wood for 3-4 hours using heavy smoke. When finished, the malt smelled smokey, but didn't taste smokey, so I took half the crystal and gave it another 3-4 hours. This smelled REALLY smokey, but still didn't taste smokey.

On brew day, I cracked all grains and steeped them in 3 qts. of water for 45 minutes at 150-155F. I sparged with 1 (US) gallon of 170F water, recirculating twice (I wanted that smoke, and was willing to get a few more tannins). I added the runoff and extracts to the kettle, and topped up to 5 and 1/2 to 6 gallons of water. I boiled 65 minutes adding the hops and Irish Moss as shown. I calculated the IBUs to be about 30, but the finished product doesn't taste 30 IBUs worth of bitter (maybe my calculations were off; also my crude measuring instruments mean that those quantities on the hops are, er, approximate). Cooled with an immersion chiller and pitched the yeast from a

starter.

Comments:

This beer was a big hit at my homebrew club. It is a beautiful amber, but has low head retention. The first taste sensation is a light sweetness at the front of the mouth; then a light bitterness, with a mild smokey finish at the back sides of the tongue. I personally think that it could use a little more smoke, but my wife thinks it's perfect. Also, I believe that the popularity of it at my homebrew club is partly due to the fact that the smoke is not overwhelming--most people just aren't used to heavily smoked foods. (But I am, which is why I think it can use more.) The consensus at the homebrew club was that if one did want to increase the smokiness, you should smoke more grains, rather than apply more smoke to the original 1 and 1/2 pound quantity.

About the name--I know that smoked beer is a German tradition, so I threw in some Munich and used German yeast. But, geez, I had all this English malt and extract laying around, hence "mongrel." Also, I decided to make an ale instead of a lager since it was the end of the summer and I hadn't yet gotten a refridgerator. Finally, I made a low gravity beer because I wanted to see how the smoke played out, and therefore didn't want a lot of other flavors, etc., to get in the way.

From: "Rick (R.) Cavasin" <cav@bnr.ca>
Subject: re: beer & ale

Actually, as I read Gayre, the distinction he makes (and it should be noted that it is rather heavily qualified) is that the word ale WAS used to signify an unbittered beverage, while beer WAS the bittered counterpart. While he speaks on their relative alcoholic strengths, he concludes that the use of a bittering agent (hops or other herbs) is the main thing that separated a beer from an ale. This distinction became blurred when hops became predominant in brewing, and ales began to be hopped as well. His contention that originally ale and beer would have been made with honey rather than malt must be taken with a decidedly bigger grain of salt since he's delving much deeper into the past on this one. (ie. long before the 'middle ages' I believe) It may be that the two words are effectively synonyms, used in different regions to signify the 'same' thing; differences in brewing style being incidental (ie. Region A says 'Hey ya know what? In region B they put hops in their ale! while Region B says 'Hey! In region A they don't put hops in their beer'). Kind of a chicken and egg sorta thing.

THE AUSTIN BEER CLUB

There is a Austin, Texas Beer club that sends out weekly notification via email. Contact beer@ctci.com to be put on the list. We meet every Tuesday Night (Starts 6:30 or 7:30 depending on the season) at the Dog & Duck Pub, 17th & Guadalupe in Downtown Austin. A diverse crowd shows up, The Celis Brewery people are sometimes there and it a social gathering more than anything else.

Commercial Networks:

COMPUSERVE

There's a very active beer and homebrew forum on the CompuServe Information Service, sharing online quarters with the wine forum. Unlike Internet, this is not a "free" service; CompuServe charges from \$6 an hour (300 bps) to \$21/hr (9600 bps) for online time, but the wide participation and quick interactivity make it another outstanding online option for brewers.

PRODIGY

In the U.S., there's now a dial-up service called Prodigy, run by IBM and Sears. It contains a number of BBSs, including one on Beers & Brewing (under the "Food and Wine" umbrella). It's much more informal than the internet forums, and there's a lot of chatter. Serious brewers might be turned off by the low signal-to-noise ratio. Prodigy costs \$14.95/month and requires an IBM-style or Macintosh PC. There are no hourly connect charges because each new display page contains advertisements.

BBS's:

There is a new BBS dedicated to brewing information. It post daily issues of Homebrew Digest and is in the process of archiving all information on brewing available.

>great head retention while the other half are more-or-less flat. (The
>"flat" half do have a little carbonation, but they form only a very
>weak head when decanted. The head quickly disappears and the beer
>tastes flat when drinking it.)

another thing to look for is how much headspace you left.
If you left too much, it will take a lot of CO2 to build up
enough pressure to keep the rest in solution. If you leave
too little, carbonation will begin quicker but you risk
glass grenades.

This assumes there is sufficient yeast in the beer
for "normal" carbonation.

Subject: Aging Beer

> Fm: Jack Schmidling

> The following is excerpted from THE NEW BREWER, May/June 1992. The
article is
> by Fred Scheer, Frankenmuth Brewery.

.....

> "In my research of draft beer, I found that one of the biggest problems
is
> the age of the beer. As with bottled beer, draft beer does not improve
with
> age!"

> "Draft beer is at the peak of freshness and taste the day it is put
into the
> keg. Ideally, a brewer would be able to fill his kegs in the morning
and get
> them back empty at night. But because this is not the case, the beer
loses
> quality each day after it is kegged."

.....

> This view seems at odds with the conventional wisdom of homebrewers and
I see
> two possibilities:

> 1. His "research" is seriously flawed.

> 2. People who claim that their beer improves with age are
simply confused by the fact that the defects in their
beer sometimes mellow out or become less obvious with time.

> js

First of all this is not a flame. I would however like to say something
about the article in question and the aging of beer in general.

The article in New Brewer (a publication for the commercial brewing
industry) was intended for a non homebrewing audience. I doubt that
Mr Scheer's research is flawed, he is a very reputable commercial brewer
and is concerned with something quite different than most homebrewers.

I have to agree that once beer is packaged
it will start to deteriorate and is subject to many detrimental outside
influences. This however applies to a finished beer. It does not apply
to bottle conditioned or cask conditioned beer or process similar to
methode champenois (sp?) these are the ways that most homebrewers
package their brews and aging is very important to mature those beers
properly. In the case of bottle conditioned beer, both commercial and
homemade, these tend to improve with a period of aging that has nothing
to do with hiding defects. To even suggest this implies that given
enough time, vinegar would become wine, NOT. Being able to achieving

the proper maturation of a beer is one the greatest skills a brewer can have, it is a artistry that takes time to aquire. In the case of most commercial beers the maturation process has been completed before the beer is kegged or bottled. If a beer is at it peak when it leaves the brewery where can it go but down?

I feel that this assertion by JS is unfounded

and is likely to only confuse others to whom, this does not apply.

So be patient, let your beer age properly and you will more greatly appreciate efforts, as the taste will reward.

micah
11/18/92

Oh, and Jack try your hand at the WG barleywine and see (taste) for yourself if aging improves it or not.

From: ml4051@mwvm.mitre.org (John DeCarlo)
Subject: Random musings

Re: Aging.

I mostly agree with everyone's postings, especially those pointing out that homebrew is alive and that stronger beers or those with different additives may take longer to peak.

However, let me say that since I have cleaned up my act (better sanitation, better ingredients, better yeast), my beers, IMHO, taste great going into the bottle. I just wait a week to get carbonation. Before that I had to wait for some off-tastes to mellow before the beer was any good.

Note that almost anyone can taste the difference in my beers between a week and a month--there is a "freshness" that can be tasted to really new beer. In a few styles, this freshness is probably inappropriate or unexpected. In particular, I made a batch of weizen beer for a club meeting, but put it off so that it had only been in the bottle four days at the time of the meeting. Everyone liked it, but few recognized it as a weizen. A few weeks later it was a good example of the style.

Re: Corn syrup

If you go out and buy corn syrup in a US supermarket, you should check carefully, as many brands have additives that would probably be unwanted in your beer, such as vanilla flavoring.

Re: Digital thermometers

I am really happy with the metal thermometer with a dial on top--mine is made by Taylor. Almost instantaneous readings (OK, so you have to wait a second for the hand on the dial to move to the new reading), and you can keep it in your shirt pocket for the extra-nerdy brewer look :-).

P.S. Be careful not to let the plastic dial cover get too close to the source of heat while brewing.

From: pmiller@mmm.com
Subject: Suspended Animation

Greetings.

I've found that the guidelines on Wyeast packages for the time required to "grow" them are often wrong. You know, 'Allow 1 extra day for each month past the manufacturing date'. My experience is that the pesky things swell up 1" thick in about a day regardless of how old they are. However, I know I'm going to get burned one of these days if I just assume a one day incubation time.

Here's the question: Suppose I start a package 3 days before I brew (assuming 2 days incubation time) and the package swells to bursting after 1 day. Am I better off pitching the package into my starter and letting it sit there for 2 days (so that I end up pitching the starter into the carboy after high krauesen) OR is it possible to chuck a swollen package of Wyeast back into the fridge for a day and then pitch it into my starter 1 day before brewing like usual?

Subject: Ale vs Beer/Lovibond Questions

G.A. Cooper very nicely summed up the ale vs beer question, but perhaps one more comment is in order.

We in N. America tend to refer to that mystical time when Hops Arrived On The Scene as if it were a definite thing. And, to the extent that our brewing traditions come from England, this may be so. Hops seem to begin to gain acceptance in England in the early 1500's, and are universal by the end of the 1600's. HOWEVER... on the continent, the use of hops goes back far earlier, in some places, anyhow. There is a mention of a hop garden associated with a brewery in the Hallertau district which dates to about A.D. 730! So, the point is, "Ale" styles and "Beer" styles developed along different paths in different places at different times. This is really no big surprise;-).

Anyhow, I have a question. None of the retailers I have purchased malted grains from in the Toronto/Ottawa/Eastern Ontario area seem to have heard of the Lovibond scale. They do not post the data for their products, and when asked, either stare blankly or just say "Our suppliers don't divulge that information to us". So, how can I get at least an estimate of the degree of colour in the malts I use? Is there a comparison chart for Lovibond colour available? And, what suppliers Do in fact ship malts with the Lovibond numbers attached?

Thanks all, P.

From: Mark N. Davis <mindavis@pbhya.PacBell.COM>
Subject: Strange infection?

Brewsters,

Alas, I have bragged too much. My latest batch appears to be a disaster. Not only did it come out a completely different style than I intended, had a lower SG than targeted, and apparently fermented out leaving too high of an FG, it now has a rather strange type of infection.

Floating on top of my more-like-a-porter-Scotch-ale is a clear membrane. You can see parts of it about 1/4 inch up the sides of the carboy as well. Not only that, but there are several pachinko ball size bubbles protruding through, looking like domed buildings on a colonized planet. You can gently nudge the carboy and watch the waves rock underneath the membrane, much like you could with a waterbed mattress. What in the hell is this stuff?

A little background on this batch:

It was to be an all grain Sctoch Ale (first attempt at style), using nothing too exoctic except maybe 1 cup molasses. I was forced to do a rather stiff mash since I didn't use my normal 4 gallon mashing kettle, and had to fit 8 pounds of grain into my 2.5 gallon pot, with just enough water to fill to the top. I think it was just a tad over 1 quart/pound. Anyways, this made for some tricky heating, and I managed to burn some of the grain. I assume that at least some of the mash was converted at very high temps, which would account for a final gravity of 1.018 from an original gravity of 1.042. I pitched my 'bionic Edme starter' which I described maybe 20 issues back, and it took off with no holds barred. It then dropped dead 2 days later, and I finally racked to a secondary after another 3 days. I let it sit there for another week where a gravity check showed it had dropped only .001 point since racking. I figured that it was just in slow-mo so I left sitting for a while. Its now 2 weeks later and I discovered much to my chagrin this foreign scum floting in MY beer. On the other hand, it smells very good, with an excellent malty nose. Previous tastes from racking and gravity measurements show that its got potential to be a very tasty porter (which the color matches anyway >:-)
Another data point is that this is my first batch in a new house, following my standardized procedures.

Back to the original question: What's growing in my beer? If it still smells and tastes good, should I bottle anyway and hope for the best? If each bottle then grows its own little membrane, it would be kind of cool to watch people

try to pour the bottles, only to have them react more like ketchup!
ould it just be time to toss my old hoses, siphon gadgets, spoons, and
any
other inexpensive pieces and get new ones? I try my best to sanitize each
of them before and after use (using predominantly Clorox), but maybe deep
in the recesses there is a lurking beastie? My last few batches all do
seem
to have a lingering harshness to them which could indicate a recurring
mild
infection from somewhere, although I've been rather hop-happy as well of
late.

In a state of beer denial,
Mark

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: single-stage vs. two-stage fermentation

I'm wondering about comments I have seen with posted recipes in this forum and in brewing books as well which say something like, "this recipe lends itself to single-stage fermentation."

Such statements lead me to the following questions.

(1) I've noticed that the darker brews seem to have this said about the more frequently. Is secondary fermentation then of importance primarily (sorry about the pun (:)) for clarification of lighter colored brews?

(2) Or, do some types of brew ferment more quickly than others?

(3) Or, is secondary fermentation always desirable, but the benefits less noticeable with certain types of brew (i.e. you can get away with single-stage fermentation more easily).

My beer has improved considerably since I started using a secondary but I also started using liquid yeast, and not splashing my hot wort and a few other things all around the same time.

Any thoughts?

Jonathan

From: Paul dArmond <paulf@henson.cc.wvu.edu>
Subject: Brewers Publications Quality

The recent opinions on Pierre Rajotte's book, *Belgian Ale*, have brought to light something that has been troubling me for the last year. The editorial quality of the Brewers Publications books and *Zymurgy* magazine have been declining. The flaws in Pierre's book are mainly editorial. The

unclear passages, the horrible typography in the recipes section, and the poorly written and ineptly laid out captions to the photos are the responsibility of the editor and layout staff. Similarly, the recent *Zymurgy Annual* is offensive to the eye, with its spindly typeface and uneven illustration style.

The prime responsibility of an editorial staff, particularly when producing a series, is to ensure that all of the books are as even in tone and design as possible. Were it not for the covers and the price, you really wouldn't know that these books all came from the same publisher.

There are some things that could be done to improve the quality of these publications:

1) Get some experienced writers to work with the authors. This is a standard practice in producing technical books. These writers should concentrate on the clarity and readability of the writing. There should be a clear description of the target reader, level of reading ability, amount of detail, standards for citing other authors (sadly lacking in all but the *Fixs'* book on Vienna), and the other features that distinguish a series from a group of books with similar-looking covers.

2) Update the glossary with each new book. Currently, the glossary is just a piece of useless boilerplate. For example, there is no entry for candi sugar or knockout in the glossary of Rajotte's book. If it is in the index, it had better be in the glossary as well.

3) Establish some guidelines for overall graphic design, the use of illustrations, recipe typography and the content of captions. The picture on p.27 of *Belgian Ale* is meaningless without a caption. The uneven layout of the recent annual on *Gadgets and Equipment* sacrifices readability to meaningless "artsy" design elements. Both *Belgian Ale* and *Porter* have serious problems (including massive typos) in the recipe sections.

4) Employ some reviewers to go over the drafts before the book is set in type. One gets the impression that these books are being rushed to press. A book needs to be read by the editor to be sure that it meets the requirements of the series; by the proofreader to catch the mechanical faults; by the consulting writer (see 1 above) for clarity and style; and by the reviewers to make sure that the expectations of the audience are being met.

Hopefully, the second editions will remedy the faults of the first.

Subject: Filling Bottles

To: Homebrew Digest
Fm: Jack Schmidling

Like most really good ideas, they tend to survive the Momily buster.

I recently evaluated and posted my rather negative comments about counter-pressure bottle filling. Although my evaluation was based on a particular commercially available filler, I basically wrote off the general process as a solution to a problem that doesn't exist. In summary, I claimed that I got acceptable results just by adjusting the pressure and tapping right into the bottle. As I only bottle to take out, it really was not a big deal to me.

Although my bottled beer had adequate carbonation, it never had much head and occasionally it was foam city trying to get a couple litre bottles filled.

I returned the filler to the producer (MM) and my money was cheerfully refunded but upon re-examining the problem, I came very close to sending another check to get it back but that would have been a bit too much. So, I put together some bits and pieces and made it work and am now a believer.

The major problem was making it work through my cold plate as I have no way of chilling a keg at will. One advantage to the cold plate is that I can carbonate and bottle at much higher pressures because of the small diameter of the flow in the plate. The final product is slick and simple, with quick disconnects for easy cleaning and setup. I can fill one bottle or a case with no foam and no mess. The bottle goes pffft when I pop the top and the head is as thick and creamy as a fresh tapped mug.

The only question is, when will the EASYFILLER be introduced? :)

From: fjdobner@ihlpb.att.com
Subject: Belgian Beer

To any of you interested in Belgian Beer of all types, I have a book that I bought while I was living in Holland in 1986 called "Belgisch Bier." Rather an encyclopedia of Belgian Beer than any discussion, it is written by Julien van Remoortere from 1985 with ISBN 90-6798-012-9. I bought it, with strong interests in commercial plans of importing some of the beers I tasted, into the U.S. We used to drive across the border to a small distributor and pick up cases of Westmalle Dubble and Tripple for about \$0.60 a bottle. Now I am lucky if I can even find the stuff here!

Basically the book is an alphabetic listing of about 348 different beers all not available in bottle, some brewed by the same breweries but quite a few nontheless. Each listing has a picture of the bottle if so packaged, the name of the brewery, color (basic dark, light etc.), volume, alcohol contents, general body characteristics, cellar recommendations, and serving suggestions (temperature that is). In addition, each listing shows the appropriate type of glass that it would be served in if one has such resources.

At the end of the book are the addresses of all of the breweries that brew these beers. Although I would probably not be willing to lend the book, I would be willing to offer myself as a lookup resource to anyone interested in any particular beer or brewery. If you are interested in writing or visiting Belgium breweries, I have the addresses.

One catch, the book is entirely written in Dutch. I can, however feably translate with whatever Dutch remains after years of non-use.

Subject: too dark to be pale

Here's a question for you judges/style gurus. I just bottled a beer which I had intended to be a pale ale. I often add 1/2 to 1 pound of crystal to a pale. I attempted to get the same color by using 2 ounces of chocolate malt. I now know that <= 1 ounce is the correct amount. So I now have what I consider to be a very fine beer, true to pale ale style in every respect but that the colour is a dark amber (actually, it's kind of an orange colour!). Suppose I was entering it in a competition (I'm not); what category would achieve best results?

NOT-SO-PALE ALE

8 lb Munton & Fison 2-row pale malt
2 oz U. S. Chocolate malt
1 oz Northern Brewer pellets (60 min. boil)
1/2 oz Willamette flowers (30 min. boil)
1/2 oz Herrsbrucker plug (15 min. boil)
1/2 tsp Irish Moss
1/2 oz Herrsbrucker plug (add at end of the boil; steep 15 min.)
WYeast 1098 (Whitbread)
Gelatine finings
1/2 oz Herrsbrucker plug (dry hops, last 5 days in secondary)

OG 1045 3 days in primary
SG 1016 at racking
FG 1012 11 days in secondary
finings and dry hops added after day 6.

Infusion mash for 75 minutes at 150-155 F.

Cheers,

Rob (bradley@adx.adelphi.edu)

You're on the right track. I've had pronounced lack of success even using rough-textured wooden poles an inch in diameter. The hop vines really want that twine to hold onto.

Why not see if you can throw a ball of twine over the crossbar (holding onto one end, of course) and anchor an end of the twine to the ground on each side of the pole? Then you could let the vines grow up the twine. Two or three vines per twine would normally be the max (they get pretty heavy after a rain in August or September).

From: Martin Wilde <martin@gamma.intel.com>
Subject: DMS and boiling

While at a brewery this past weekend, I was watching a brewer making a batch of beer and I noticed that after the boil, the flame was turned off and the wort left to "steep" for about 45 minutes. I first asked the brewer about the problems of DMS forming since the temperature of the wort had fallen below 212 degrees.

The brewer said they had never noticed a problem and he thought the DMS thing was a bit over hipped... The reason for the 45 minute "steep" was to allow further settlement of the hot break before they chilled the wort. They believed too much cold break in the fermenter would cause the yeast to be slower taking off (since the yeast could get buried in all the cold break in the bottom of the fermenter and inhibit its ability to rise up. Yes we know that ale yeasts are top fermenting, but they do fall to the bottom before rising to the top...).

Anyone care to comment?

From: fingerle@NADC.NAVY.MIL (J. Fingerle)
Subject: Pellet mush

Hello, everyone. A quick beginner question. I recently brewed my third batch using whole hops and had no problem straining them from the wort. I then used hop pellets in my fourth batch. When I tried to strain the boiling hop pellets out, all I had was a "mush" at the bottom of the pot, and this "mush" went right through the strainer. The best I could improvise was to remove the wort from the heat and let it settle, then carefully pour the wort out, leaving most of the mush behind.

Are these pellets supposed to dissolve in this manner? Do I need a "finer" strainer? And, more importantly, if I left some hops behind in the wort, will they "over-hop" my brew? Will they settle in the muck so that I might leave the excess behind when I rack to the secondary? Inquiring minds want to know.

Thanks in advance.

From: Pierre Jelenc@cunixf.cc.columbia.edu
Subject: sucre candi a.k.a. candy sugar

The following is a paraphrase of my recent article on the same subject on Compuserve.

Candy sugar, known in French as "sucre candi", is pure sucrose that has been made to crystallize slowly into large crystals. The Encyclopedia Britannica defines it as "very large white sugar crystals, obtained by slow crystallization from very high purity liquor; it is used mainly by the brewing industry."

(The liquor in question is a syrup obtained as an intermediate in the sugar refining process).

The word "candi" in French and Italian comes from the Arabic "qandi", which simply means sugarcane. The verb "to candy", "candir" in French, is a back-formation from "candi/y" and has come to mean "to treat or cover with sugar".

The reason why candy sugar was used originally by the brewing industry is that at the time brewers were beginning to put strange things in their beers, candy sugar was the purest available sucrose on the market. The alternatives were sugarloaf sugar, a less purified product that did not crystallize well, and brown sugar or molasses, even less pure products that impart a pronounced taste of their own. The point of candy sugar is that it was the most neutral tasting sugar available.

I would not put it back in the fridge, although it has been used with success by some. I would pitch it into a starter, but only fill the starter bottle half-full. One day before brewing, add the other 1/2 of the starter volume and the next day your starter will be at high krauesen -- which is when you ideally want to pitch.

For example: Two Fridays ago, I took out two bottles of my homebrew, made with 1st generation Wyeast #1028, drank them, added 6 ounces of 1020 wort to each and affixed an airlock. Sunday, they would have been ready to pitch, but I was not ready to brew, so I let them ferment out (they were at 70F). This last Saturday, I was going to brew in the evening, so at 3pm, I made some more 1020 wort and added 4 more ounces to each starter bottle. By midnight (pitching time), they were going again. Sunday morning, at 9am, the batch was already producing blowoff. Less than a 9 hour lag time... I'm happy with that.

In my opinion, it's mostly (2) and (3). I feel that beer will clear just as quickly in the primary as if it was racked to a secondary, maybe faster.

Of course ales ferment faster than lagers because of the fermentation temperatures. I use a secondary only for lagers -- I brew all my ales (except my pseudo-lambik) in single-stage, glass, 5 gallon primaries with

blowoff hoses. Whether to use single- or two-stage is a game of benefits vs. drawbacks. All beers benefit somewhat from two-stage, but if you will be keeping the beer in the carboy less than two (or three) weeks, I'd use single-stage. The added risk of infection and oxidation are not worth it, IMHO.

>My beer has improved considerably since I started using a secondary but I
>also started using liquid yeast, and not splashing my hot wort and a few
>other things all around the same time.

I'd say it's mostly the liquid yeast and not splashing hot wort that made your beers improve -- not to mention added experience and confidence. For ales in the fermenter less than 3 weeks, the cons outweigh the pros for two-stage, in my book.

I don't understand where the problem was. Generally speaking, if your beer has adequate carbonation and adequate amounts of proteins and dextrans, it should have an adequate head. Consider industrial lagers. They are highly carbonated, yet have no head to speak of. On the other hand, look at Orval. Again, highly carbonated, yet a head that you could float a bottle on (not just a bottle cap ;^). Then there's beer's like Bateman's XXXB, which is low in carbonation, yet also has a good head. I ensure a good head on my beers with ample additions of crystal malts and many of my ales are very low in carbonation.

It's true that the temperatures and pressures need to be correct to get the right carbonation and it seems that you've found them for the lengths of lines and diameters you have in your system, Jack, but I still don't understand where the change was made that would increase head retention.

>that?
>
> - John

I called Hunter customer service (901-743-1360) and they said no, the "Air Stat" was designed for use with a room air conditioner and Hunter does not manufacture refrigerator thermostats.

There are other devices that will control in the lower ranges but the less than \$30 price tag on the Air Stat was too hard for me to pass up. So I took the Air Stat apart in search of a method to alter it. As it turns out, the sensor is a Thermistor that appears to function in the same range as one sold at Radio Shack, 10K ohm at 25 degrees C. You cannot change the Air Stat range but you can offset the sensor calibration. According to the thermistor data sheet, at 32 degrees F the resistance is 27.28K and 22.05K at 41 degrees F. The resistance decreases as the temperature rises so if you make the air stat think the sensor is 22k when its really 25k the air stat will say 41 but the sensor temp will be around 35 degrees F. This is done by simply putting more resistance in parallel with the sensor. Using ohms law,

Subject: Novice Brewer

I am a new brewer and I need as much advice from master brewers as I can get. My question concerns carboys. Is it better to use plastic or glass? I'm thinking about using a glass one for primary fermentation, then a plastic one for secondary fermentation. Does the plastic effect the taste at all? Do I have to be concerned about the porous nature of plastic absorbing impurities which can then be passed onto the beer? Also, I need to know if there are any reliable suppliers in the Baltimore, Maryland, or northern Maryland areas? Thanks in advance. Jim

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: yeast packages, scots brown

With regard to Phil Miller's question about Wyeast packages that swell too quickly, I have had the same experience, and I HAVE tossed them in the fridge to slow them down, then removed them and let them come up to room temp again while making the starter. I've also let the starter sit too long before pitching. In each case, my fermentation started off quickly and the results (some of them still pending) seemed o.k. However, I don't consider my palate yet finely-tuned enough to recognize any problems in the finished beer that may be traceable to clumsy handling of the yeast. (Maybe that's a blessing? --

hey, it still beats the hell out of Bud.) I posted a similar question awhile back and one respondent said that one ought to be careful about letting the starter sit too long so that the yeast don't pass out of their reproductive cycle into their fermentation phase, or something like that, if I'm remembering correctly. I'm no biologist, I just cook beer.

However, I too would like to cook a scots brown ale and Mark Davis' post about Scots/Porter reminded me that I'm a little confused about the difference between the two. Any help on this point would be appreciated (from an extract point of view).

Al, thanks for the help on the single stage/two stage question. I may try single-stage for awhile now that my procedures are fairly consistent and see if I like the results just as well. Anyone care to save me from this heresy?

I get the same reaction with pellets. What I do is take three circular
coffee filters (pleated Mr. Coffee style- not conical Melita style) and
place them in the strainer so that they overlap just a little, but cover
all
of the mesh. It does slow the straining process down by tenfold.

But when I just leave them in the wort, the brew is both very hoppy and
often has little bits of leaf that never settle out.

Subject: ORVAL

REGARDING ORVAL

Al writes in HBD#1017:

> The yeast strain I cultured from Orval dregs is VERY
slow (3 weeks), whereas some dry yeasts I used in the past would
ferment-out in 3 days.

I'm interested in the results of your (and others) Orval culturing. The first time that I tried it I got a brew that was VERY Orvalish, no mistaking where the culture came from. In fact, it seemed far stronger than the original. A subsequent brew was split, half was fermented with a more neutral yeast (Coopers ale) and was blended at keggling. This produced a far softer and more true to type Orval clone. Next time I may just use the Orval culture for conditioning, giving the brew plenty of time for the beasties to do their thing.

Has anyone else had similar experiences? Am I correct in assuming that Orval uses more than one yeast strain and perhaps the one we purchase as a bottle culture is not the culture used for the main fermentation?

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: searching for "Brew-bits"

When I bought my Electrim Brewing Bin (a Bruheat clone) in 1987 I got a sparging bag with the trade name "Brew-bits". It's cylindrical in shape, with an impervious side and a fine mesh bottom and a drawstring with four loops at the open top. It's not as deep as the usual sparging bag as it has to hang above the electric heating element. It's a great sparger and I used it for more than a hundred batches. It is now lost -- I fear it was thrown out with a batch of spent grain. [What's the ASCII pictogram for a sheepish grin?]

The standard Bruheat bag all the local shops seem to sell has a mesh side instead of an impervious one. The mesh is finer than on the bottom, but some wort still gets out the side (I think). This is a bod thing. Furthermore, it is not as sturdy and got a tear on only the second use!

Does anybody know where a "Brew-bits" sparging bag, or similar, can be purchased?

Thanks,

Rob (bradley@adx.adelphi.edu)

I don't have my style descriptor sheets here with me at work, but from memory, having never tasted it (hop utilization is unpredictable), I would guess either Classic Pale Ale or Texas Brown Ale. Color is only two points out of 50. I rarely mark-off for color unless it's a brown-colored weizen or an amber imperial stout.

Jimmy asks:

No.

>Will they settle

>in the muck so that I might leave the excess behind when I rack to
>the secondary? Inquiring minds want to know.

Yes. Well, hopefully -- the turbulence of fermentation can stir them
up, but eventually, they will sink to the bottom.

I use a hop bag for my kettle hops. It's made of some synthetic
material,
and is quite heat resistant. I know that I get a bit lower utilization
of the hops because there is less mechanical action of the wort on the
hops when they are in the bag, but cleanup could not be any easier.
Actually, I just ignore the lower utilization and things work out just
fine.

Al.

Subject: Mash transition

I am a first time caller . . er, um, I mean poster, and I think that HBD is excellent.

I have been homebrewing for about eight months now and have found an excellent hobby !! In that time, I've been learning and drinking and learning and drinking and have progressed to a point where I am considering going to full mash brewing. I have always done the partial mash route.

However, from reading HBD and other books, I am wondering if I am making some mistakes in my current brewing process. I want to be fairly certain that my assumptions and techniques will insure good brew when I make the transition.

First of all, I brew in a 5-gallon tub with an airlock. Should I be using one of those water bottles so the krausen can be blown off ?? Is that important ??

Second, all my beer has a distinctive flavor. I am sure that everyone's does, but I am not sure my flavor is positive. I am wondering if chlorine in the water is leaving its mark. Should I be filtering my chlorinated city water thru charcoal filters ??

And certainly my biggest question is related to the cost of transitioning to the all mash brewing. I read a lot of articles about special equipment and other items that I do not have. How many new items do I need and where can I find more info. on these setups ?? I am reading Papazian, but he seems to lack equipment details and innovations that help the homebrewer.

And the bottom line, if I ignore the fact that I am making a better brew, does all mash beer cost less than partial extract ??

Thanks for any replies.

Regards,
Kevin

From: Richard Childers <rchilder@us.oracle.com>
Subject: Oregon Pub Crawling

I took a week off recently and headed north from San Francisco, up towards Oregon and points north, via various routes, exploring the wilderness and tasting the ales of the great Northwest. It was great.

I didn't make it any farther north than Vancouver, Washington, where my dad works, so I didn't make it to any of the Washington breweries - this time - but Oregon satisfied my thirst for gustatory adventures.

The high point of the trip was Steelhead Brewery, in Eugene, Oregon, where I enjoyed the freshest fish and chips I've had in decades, along with a few pints of something called Bombay Bomber, their interpretation of India Pale Ale. I don't know a lot about IPA, but this had an intriguing taste, a hint of spiciness that I'll have to try to reproduce.

However, don't get me wrong ... the only thing that put Steelhead over the top was the fish. The beer was excellent, but it wasn't any better, in my opinion, than some of the excellent beers I had at the Lighthouse Brewpub, on the coast, in Lincoln, Oregon.

Lighthouse is a member of the Mcmenamin (sp?) family of brewpubs, what might be called a 'chain' except that each pub has little in common with the others, excepting only the format of the menu, and a few of the available brews. Each brewery provides its own unique creations to its customers, as well as a few of the established favorites.

Some of the beers that come to mind, in connection with Lighthouse, are the excellent Terminator Stout (tm), although I liked Hammerhead Ale much better, and they also served a Crystal Ale that was deep reddish in color and very sweet, as ales go. Allegedly, it was brewed entirely from crystal malt ! It appears to be popular enough that it is available elsewhere, also.

At another Mcmenamin pub, in Eugene, I tasted what I think was called 'Blue Heron Ale' ... which name was also in use at Steelhead, confusingly enough. I also tasted a brew flavored with boysenberries, I think they were, which was underflavored, in my opinion, but allowed one to savor the bouquet of the

berries in the ale's scent. All in all, a very flavorful evening.

In general, I have to recommend the Mcmenamin pubs. My impression was good ...
the employees seemed very enthusiastic, more like co-owners than wage slaves.
They obviously enjoyed what they were doing, and liked their customers.
The
whole ambiance of the Lighthouse Brewpub was that of a brewpub taken over
by
friendly Deadheads ... tie-dyes were prominently splashed across the
ceiling,
the beat of Bob Marley and the Whalers as background music, the
fermentation
tanks were painted with floating eyes and other Deadhead imagery, and,
all in
all, it was a very friendly place. The only reason I describe it in such
detail, is because I am confident that, once everyone sees where Lincoln
is,
they will be unlikely to try to reach it ... and the Lighthouse will
continue
to be a haven for weary and thirsting travellers, pleasantly uncrowded.

In any case, there must be another 20 Mcmenamin pubs in the Portland
area,
none of which I have ever visited, except for the Blue Moon, a year ago .
..
so there is no lack of good places to go if you're in Portland, or
Oregon.

Perhaps Jeff Frane might see fit to contribute his opinion of Mcmenamin's
?
I would be interested in knowing how they are seen by resident experts .
..

From: othon@ial7.jsc.nasa.gov (Bill Othon/LinCom)
Subject: Bursting liquid yeast packages

Regarding dbreiden inquiry, I got a "pop" my first try with liquid yeast. It wasn't a big pop, and produced a small pinhole in the package. Most of the nutrient was crushed, so I transferred the whole thing to a sterilized tupperware dish with a tight lid. I pitched it the next day; no kraeusen. It did start up a couple of days later. Which brings me to my question:

After two batches with liquid yeast, I have still not used a starter. I obviously never did before with dry yeast, which seemed to start up effortlessly with warm water and nutrient. I took the instructions on the l.y. package for granted, and pitched straight in. After a day or so, the yeasties would start up, and by day 4 it seemed to be ready for the secondary (these are ale batches). I would like to see if using a starter would improve the beer, so someone post a no-frills, simple, household-items-only starter process please.

On another subject: I'm glad to hear about the new Austin brewery! Maybe the Texas "starter" is starting to hit high kraeusen, and we'll be able to do away with those silly anti-brewpub laws. Now that would be something worth being thankful for. If any Texas brewers hear news of the upcoming legislative session and the brewpub laws, please post the info.

Thanks
-Bill

From: rush@xanadu.llnl.gov (Alan Edwards)
Subject: Re: candi

Phillip Seitz wrote (in HBD #1017):
| Hmm. Have I just been flamed?

Not really.

| In Thursday's HBD Alan Edwards launched a diatribe concerning the
| alleged snobism of people who'd like to use candy sugar in Belgian
| style beers. He wondered if there really was any difference between
| this and standard sugars such as glucose.

Actually, what I said was sucrose.

My main point was that it seems to be common in this forum that as time goes by, more and more credibility is heaped upon a statement, until it becomes a "factoid", which then becomes fact, as more people reference it.

I do admit, though, that I was quite fed up with other (arf) problems (arf) with the HBD at the (arf) time, and it (excuse me, I seem to have something in my throat) came out in my post. I humbly apologize. I realized that I was a being a jerk when Jack congratulated me on the post.

Maybe the "candi sugar" thing was not a good example. But, what I was trying to do was apply logic to the situation. Phillip said that it looked like rock candy. Using that and the assumption that it was named candi sugar because it was used for making candy, or was itself considered candy, I concluded that it was sucrose.

Pierre Jelenc wrote (in HBD #1019):

| Candy sugar, known in French as "sucre candi", is pure sucrose that
| has been made to crystallize slowly into large crystals. The
Encyclopedia

| Britannica defines it as "very large white sugar crystals, obtained by
| slow crystallization from very high purity liquor; it is used mainly
| by the brewing industry."

Phillip Seitz continues:

| While it is not the point I want to make here, he may be right. Having
| hauled plenty of this stuff back from Belgium (using valuable space I
| usually reserve for chocolate!), I have to say that the value of candy
| sugar in comparison with other types is not immediately apparent. While
| it does offer some color and melts slowly, it tastes pretty much like
| . . . sugar. It seems to me that what's important is what it

contributes

| to the final fermented product, but I've yet to see or taste any good
| side-by-side comparisons (my own experimental plans notwithstanding).

Great. I applaud you for conducting experiments to determine what it really does for beer. In your experiments, though, may I suggest that you use sucrose (white table sugar) as your control. If the candi sugar is a little darker, then I would suggest that you try a mixture of white sugar and light brown sugar, to simulate the color and flavor effects. I have a strong suspicion that the original intent of the Belgians who add candi sugar to their wort was just to raise the gravity without adding

too much maltyness.

| Many contributors to HBD (and myself certainly among them) have a
| tendency to pontificate on matters they don't fully understand.

I'm guilty!

| I totally agree with Al concerning his skepticism, and suspect that
| his ideas concerning [sucrose] and candy sugar may be correct. But I
| suspect that he, like many of us, is expressing an opinion and does
| not have any more solid ground to stand on than the rest of us.

Exactly my point. Don't trust me any more than anyone else.

Of course, some contributors include their sources, or back up their
claims with their own experiences or experiments (like you, Phil), and
deserve respect. I just want everyone to use a little care in sifting
through the (arf) BS. (excuse me...someone get me a cough drop)

Subject: Mailing List

The recent ZYMURGY special issue, in all it's artsy glory has an excellent article by Rodney Morris on his recirculating infusion mash system (RIMS). I've pondered moving from my existing mash system, simply the stovetop pot system, to the cooler method. I've taken an interim step and made a home version of JS's easymash, which works fine for coarse crushes, but tends to stick with finer crushes. The flaw to this system is that you cannot do step infusions. Without generating a conversation on decoction versus infusion, I'll say simply that I would like to do two step mashes, protein rest and conversion. It would be nice to be able to fiddle with conversion temps too without leaning out the mash by adding water.

The RIMS looks like just the thing and I'm seriously considering making one. Has anyone on the net made one of these gizmos, anyone care to comment, have an alternate solution, or could suggest a good source for parts, either mail order or in Toronto?

Thanks, as usual.....

Subject: Telluride Beer

What's the scoop on this stuff? I picked up a six-pack of it one night in Bruno's on a lark, all the while assuming that it was brewed in Telluride Colorado. I was surprised to read on one of the bottles that it is brewed somewhere in the midwest (the place escapes me now). It did not list *any* ingredients, not even the standard "barley, hops, yeast, and select grains" that the big boys use. What is in this stuff? While it was not a big step above the mass produced adulteration of barley I did find it to have a bit more character. I seem to recall tasting a bit of sweetness similar to crystal malt and that the hopping rate was more than simply holding up a bag and "showing it" to the wort. Unfortunatley, I don't even recall if it was an ale or not (if it was indicated anywhere - there was precious little info on any of the packaging). Anyway, I meant to ask this when my memory of the brew was still fresh but I forgot. Just wondering if anyone is familiar with it.

Subject: Strike Water Hint

Greetings.

Last weekend I brewed my first all grain batch and I have a hint for those who are about to try this themselves:

Most books tell you to add 1 - 1.3 quarts of strike water per pound of grain. If you mash in a picnic cooler set up, make sure that you also add in the volume of water that your false bottom will hold.

For instance, I've got a 10 gallon Gott cooler and my false bottom is a little over an inch above the bottom. I have nearly 1 gallon's worth of space under my false bottom. If I mash 10 pounds of grain I'd need between 3.5 and 4.25 gallons of water.

1 quart X 10 + 1 gallon = 3.5 gallons
1.3 quart X 10 + 1 gallon = 4.25 gallons

I've never seen this written out explicitly in my books (maybe because both Charlie and Dave advocate the mash-on-the-stovetop method) and learned it this weekend -- the hard way...

I hope this helps other new all grain brewers.

Subject: DMS and boiling

Martin Wilde writes:

> The brewer said they had never noticed a problem and he thought the
> DMS thing
> was a bit over hiped...

Well, I was at a local micro-brewery last month (Detroit & Mackinac, the only active brewery in Detroit) and the brewer there is extremely careful to try to get DMS out/keep it from forming in his beer. He whirlpools the wort out of the boiler and sends it through a heat exchanger immediately. He's also got a "steam trap" in the exhaust steam pipe leading the steam from the boiler outside. The theory is that any condensation in the flue will drip back into the trap, rather than into the boiling wort, so the DMS going "up the chimney" will stay gone.

From: Joe Rolfe <jdr@wang.com>
Subject: DMS, Whirlpools

hi all,

another data point for the whirlpool->dms:

i do basically the same thing strike the kettle (heat off), add any finish hops, oar the kettle for about 5 min to get a good whirlpool going, add finings

(in my case i rehydrate irish moss for a couple of hours and add it - contrary to popular belief - i do not add it 5,10,15 min left to the boil).

in most cases the only negative result of doing this is a loss in aroma as

the finish hops are usually in contact for about 90 minutes. the dms issue

does appear to only come about when the temp of the wort gets to a certain

temp - from what i have read and heard - temp gets below 190F. in my case the temp only gets to about 195F on average (again depending on the brew length).

most every large scale brewery that i have ever visited performs this whirlpool

, wait for the "junk" to settle then begin chilling. the other way to remove

the "junk" quickly would be to filter the hot wort and some breweries do this

also - filtered thru hops (hopback), centrifuged(??), or a plate/frame filter.

well this is just another coupls of cents worth....

Subject: hunter airstat, klages vs. harrington, hops

Hi All,

In HBD 1019, Mike Kenny writes:

<good post for the electronically inclined deleted>

For those who may be leery of taking apart and modifying an electronic device, there is another method of getting a refrigerator equipped with a Hunter Air-Stat to operate at temperatures below 40F.

Within every refrigerator, there are some areas that are colder than others, specifically the bottom-center is roughly 5 degrees colder than the upper-sides. What I do is tape the temperature sensor to the sidewall of the fridge, about 3/4 of the way to the top. Don't place the sensor too close to the freezer compartment, or this doesn't work. I set the airstat to 40F, the temperature at the bottom-center (where the beer is sitting) gets down to about 35F, as verified by readings taken by several different thermometers. I have two fridges set up this way, it works the same for both of them. Your mileage may vary, but the bottom of every fridge should be the coldest area.

In HBD 1014, Glenn Anderson wrote and asked about the difference between Klages and Harrington malt. I want to brew an Anchor steam clone, and was planning to use domestic 2 row. I've been looking for responses to Glenn's post, as I have pretty much the same questions, and I'm a little disappointed at the lack of response. I know some of the readers of this forum have a fair amount of expertise regarding malts, would one of you folks be so kind as to enlighten us?

Aaron Birenboim writes:

> I just got a street lamp installed in front of my house.
>I was wondering... could i grow hops up this pole? or do they
>need something thinner like a string to twine up?

This past spring, a friend of mine obtained some hop vines, planted some of them in his yard, and put the rest in some large pots behind his shed. A few weeks later, I went to his house to get the ones in the pots. He had sort of forgotten about them, so when we went around to the back of his shed, we found that they had grown up on *everything* in the immediate vicinity. Scrap lumber pile, sawhorses, the vines were everywhere, including around the trunk of a very large oak tree. The diameter of this tree was about twice that of your average lightpole, and the vines had entwined themselves around it and had grown about 12 feet up the tree. We had to hack at them for 15 minutes to liberate the pots. Aaron, I'd go ahead and plant them (well, wait 'til next spring), as they seem to be able to climb on anything.

Cheers,
Jim

> special equipment and other items that I do not have. How many new
> items do I need and where can I find more info. on these setups ?? I
> am reading Papazian, but he seems to lack equipment details and
> innovations that help the homebrewer.

Moving to all-grain brewing is often perceived as being more difficult than it really is. Assuming you already have all the equipment for extract brewing, the only new equipment you'll need to go all-grain is:

1. A larger pot (probably). You'll be boiling 6 or so gallons at once, so I'd recommend at least a 7-gallon pot. You can spend ~\$130 on a nice 10-gal stainless pot, but I've also seen 7-gal enameled pots for ~\$30 (US). In a pinch, you can use two smaller pots, but ideally you want to be able to boil the entire amount of wort at once.
2. A lautering system. There are numerous possibilities for this: the Zapap system of nested buckets with holes (~\$20 to make), the slotted-copper-tubing manifold (~\$5), and a screened spigot in the mash tun (aka Easymash, probably ~\$10). None of these are expensive or difficult to put together. My personal preference is the copper manifold; it's the cheapest, easier to use than the Zapap system (which I've used), doesn't require you to modify your kettle, and the only tool you need to make it is a hacksaw.

After the lautering stage, the process is identical to extract brewing. There are a couple more items that may make your all-grain brewing a little easier:

1. A grain mill. If you can't get pre-crushed grain, or don't want to pay someone to crush it, it may be worth your while. Prices range from \$40-\$120 or so. Corona, Marcato, and the MaltMill are the most commonly used mills.
2. A wort chiller, if you don't already have one. You can make a simple immersion chiller for ~\$30 in about 15 minutes, or spend \$50 or so to make a more efficient counterflow chiller (this one might even take you a couple of hours to make, and require use of a propane torch. Great fun!).

So, you can spend anywhere from \$35 to \$320 to go all-grain.

> And the bottom line, if I ignore the fact that I am making a better
> brew, does all mash beer cost less than partial extract ??

You will save some money (all other ingredients being equal, you can usually buy the grain for a given recipe cheaper than buying extract), but you will spend more time making each batch.

But don't ignore the fact that you're making better brew! It's worth the extra time.

From: parsonsl@husc.harvard.edu
Subject: Kevin's and Bill's questions

Kevin, in #1020, asked if he should go on to all-grain brewing. Do it, Kevin. I won't say much about it, since you'll probably get a dozen responses from avid brewers eager to encourage and advise you. I'll just recommend a few things. After Papazian's book, go to Dave Miller's first book. Read the whole thing, but try to ignore him at his more pedantic moments (otherwise you will always have the idea that, without state-of-the-art microbrewery equipment, all your beer will turn out crappy). Get the latest issue of Zymurgy, which is all about equipment for all levels of brewing. You will find this useful. I would make one recommendation about buying things, though, and that is Get experience and basic technique down before concerning yourself with little details. I am referring to your concern about chlorine content perhaps causing off-flavors in your beer, and your interest in carbon filters to reduce it. First, call your city's water chemist and ask for an analysis. You may not have much THM (trihalomethane is a gaseous form of chlorine) in your water at all. Even if you do, a good boil will get rid of most of it. Off flavors are most often caused by a fermentation temp that is too high, or not racking the beer off the trub soon enough, or poor sanitation, &c. If your boil is good, and you do things right, you will see that the filter is not necessary.

Go for greatness. All-grain is cheaper; tastes better; gives you more control; is messier; and is generally more fun.

Bill asks about a no-frills, simple, household starter. Liquid yeast, as most people who have experience with liquid and dry yeasts will agree, is definitely the way to go. But by not introducing a big enough population into the fermenter, you will increase your lag-time, and thereby perhaps undo all the benefits of a finer yeast culture by letting other little beasties have a chance at your beer. For a starter, I just use two tablespoons of dried malt extract boiled in one cup of water. Put this in an extremely sanitary bottle with an airlock fitted to it. When it's cool enough, pitch in the yeast from the bag. It should take another day in this bottle to reach full krausen, at which point you should shake it around a little (to stir up the slurry at the bottom) and pitch it right into your just-brewed and cooled wort. This is all very easy, and reduces your lag-time to a few hours. Ideally, you want to make the starter out of the same wort you will pitch it into. This is often (for me at least) impracticable. It can be done if you have a good refrigerating system, or if you brew the same beer a lot (save a little of the wort in a capped bottle in your frig, and when you brew next, use that as the starter).

Sorry this reply was so long. Good luck. Have a good holiday, all.

The concept of third or fourth cousin is not really appropriate in
describing plant relationships. However, according to "Flora of the
Pacific Northwest" (Hitchcock and Cronquist 1973), Hops (*Humulus lupulus*
L.) and Hemp (*Cannabis sativa* L.) are both members of the Moraceae, the
Mulberry family. I do not know anything about their evolutionary
relationship beyond their familial association, but I would like to hear
about it from somebody who does know.

Precisely why I brought it up. Any homebrewer that read the article would have been confused. I posed the two obvious conclusions that the casual reader would come to but allowed ample room for others which followed in abundance.

The objective was to stimulate a discussion not to generate flames.

>So be patient, let your beer age properly and you will more greatly appreciate efforts, as the taste will reward.

Standing by itself, this is just as confusing. It implies that one can go out and get a six pack of Bud and let it age properly.....

>From: korz@iepubj.att.com
>Jack writes:

<>Although my bottled beer had adequate carbonation, it never had much head and.....

>I don't understand where the problem was. Generally speaking, if your beer has adequate carbonation and adequate amounts of proteins and dextrans, it should have an adequate head..... but I still don't understand where the change was made that would increase head retention.

The problem here is that I never said anything about head RETENTION. I said head, period.... When I pour[ed] the beer from the bottle, no head formed. Now, when I pour the counter-pressure filled bottle, I have to pour down the side of the glass to control the head.

It's the same beer but they behave very differently. When I tap a glass, I can build up a three inch whipped cream topping and there is at least 1/4 inch left in the bottom after nursing the beer down. I got hung up on this silly procedure at a demonstration at Baderbrau and it really makes an inviting glass of beer. BTW, I have never been able to do it with bottled Baderbrau, just from his private tap.

I am not sure what happens when bottled directly out of the tap but perhaps I was just content with less carbonation than most people are used to. As an aside, if I shook the bottle a bit before pouring, it would form a head but that is a bit much.

>Subject: What size stock pot?

>I plan on starting up all-grain brewing sometime early next year So my question to you is, what size will I need for all-grain brewing (5 gallon) and what size would be nice to have?

The short answer is, the bigger the better. It's like so many other things, you didn't know you needed till you got it. If money is tight, my advice is to go for size rather than material. The 32 qt enameled canner is the best value but just barely big enough for 5 gallon batches. I started with one of these then graduated to a 10 gal SS and now also have a 16 gal ss.

>Is there any point for getting something larger (I don't foresee brewing in larger quantities anytime in the near future)? What advantages would there be with a 7, 8 or even 10 gallon pot.

The mess of a boil over for one. But more importantly, you can boil down larger quantities of wort to concentrate it and improve the yield or make larger batches.

> I am not sure exactly how I plan on mashing (don't know if it will make a difference or not).

I just so happen to have a suggestion but I will email it to you.

>From: Brian Michael Cors <corsbria@student.msu.edu>

>Supposedly he has heard that hops are the third/fourth cousin to the cannabis plant. Is there any truth to this??

The term "cousin" has little scientific meaning but hops and pot are in the same family (Cannabaceae). But before you try smoking hops, bear in mind that pear trees and rose bushes are not only in the same family (Roseaceae) but in the same genus.

They are however, closely enough related so that one can be grafted on to the other. This had exciting prospects in the 60's but I am not sure what advantage could be gained from the graft. Don't know how many potheads really wanted 20 ft pot plants in their closets.

>From: rush@xanadu.llnl.gov (Alan Edwards)

>I do admit, though, that I was quite fed up with other (arf) problems (arf) with the HBD at the (arf) time, and it (excuse me, I seem to have something in my throat) came out in my post.

I suspect that far more people object to this sort of ad hominem crap than objective criticism.

> I realized that I was a being a jerk when Jack congratulated me on the post.

Although your stock just took a tumble, the cudos were well deserved. The article was well thought out and to the point. To deny everything you said just because I agree with you is pretty petty.

> I just want everyone to use a little care in sifting through the (arf) BS. (excuse me...someone get me a cough drop)

Sure, we can excuse you but not perhaps, for the same reasons.

>From: SynCAcct@slims.attmail.com

> I've taken an interim step and made a home version of JS's easymash, which works fine for coarse crushes, but tends to stick with finer crushes.

Not sure what "finer crushes" means but I am now using a 30 mesh SS screen which is considerably finer than the original window screen and may help those who don't use roller mills. I never had any problems with window screen but it just seemed a bit crude.

> The flaw to this system is that you cannot do step infusions.... I'll say simply that I would like to do two step mashes, protein rest and conversion. It would be nice to be able to fiddle with conversion temps too without leaning out the mash by adding water.

Do not understand this at all. The easymasher is installed in a brew kettle which sits on the stove. There is no limit to the number of steps you can do, simply by diddling with the heat. Total control of this end of the process is one of its major advantages.

Subject: orval yeast

Jackson's Pocket Guide claims that a single yeast is used in primary and secondary, while a blend of four or five bottom cultures is used for bottle conditioning. So, if one were to pitch the dregs from the bottle, which yeast would take off? If filtering is done before bottling, and if that first yeast contributes essential flavor notes, then there would be something missing from your built-up yeast. Once, I did attempt to culture the dregs from Orval, and what I got was a very slow fermenting yeast in my starter wort. I tasted it, and threw it out. It didn't taste bad, but I didn't want to pitch a slow yeast into my wort.

There are, to be fair, a few McMenamins that have more of a chain
atmosphere in the fact that they share a name and general interior
decore.
Something like 10 or so. But as you say, most of the pubs owned by the
McMenamin family have quite a unique character.

McMenamins has also purchased (recently) a winery, the Edgefield Winery
in
Troutdale, and added a brewery and movie theater to it. And, McMenamins
owns three other theaters in Portland now. For those of you who might be
wondering why theaters and microbreweries coexist in a post... the deal
is
you pay \$1 to get into the movie, and they are generally movies that have
been out for a while, but not necessarily obscure or second rate movies.
The seating is less densely packed than a standard theater, and there are
tables between the rows of chairs. You buy a pint or three of your
favorite
micro brew, order one of the marvelous items off the menu, and sit and
enjoy your movie. I must admit, beers are 30 or 40 c more than at their
regular locations ;)

Why do I sound like an ad for McMenamins? *Ack* I just love what they
have
done for Portland, I'm not in other ways associated with them... wish I
was.

>Some of the beers that come to mind, in connection with Lighthouse, are
>the
>excellent Terminator Stout (tm), although I liked Hammerhead Ale much
>better,
>and they also served a Crystal Ale that was deep reddish in color and
>very
>sweet, as ales go. Allegedly, it was brewed entirely from crystal malt !
>! It
>appears to be popular enough that it is available elsewhere, also.

Ahem... soap box. There is this wonderful Deshutes Black Butte Porter,
some
of the creamiest I've had, that is normally available at McMenamins
outlets. However, McMenamins is now producing their own porter, called
Black Rabbit. Well, it just does not come *close* to the Deshutes!!! And
I

hear they're trying to replace the Deshutes at all their outlets with their own! Let the masses revolt!

>At another Mcmenamin pub, in Eugene, I tasted what I think was called 'Blue Heron Ale' ... which name was also in use at Steelhead, confusingly enough.

Blue Heron is also the standard pale ale produced by the Brideport Brewing company in Portland (they run a pub in the NW industrial part of town, out of their brewery, for those interested, and their XX Cask Conditioned Stout is **fine**). McMenamins does at several of their outlets sell beer not produced by them, and it's quite possible that both places you were in Eugene carry Bridgeports Blue Heron.

Blue Heron is served at many small bars throughout Portland. It's quite good, so you have this concept that must be strange to many Americans. Namely, walk off the street into any pub, and god forbid, you get something other than Budmilob! I call this evolution ;*)

>Perhaps Jeff Frane might see fit to contribute his opinion of Mcmenamin's ?
>I would be interested in knowing how they are seen by resident experts .
..

Perhaps the Portland HBD community should get together for a weekend of **serious** research into just how many pubs there are and compile statistics of exactly what is served ;)

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: Sierra Nevada and fruitiness

In October I brewed two batches with WYeast 1056 (American); they were pale ale and porter. They were my first batches with this yeast. It is no coincidence that Sierra Nevada brews pale ale and porter with the same yeast; I was trying to clone these SN beers, or at least get close. When the pale was a 1.5 months old and the darker beer a month, I decided the moment of truth had come. I tasted my beers side by side with the SN beers in the company of a knowledgeable beer taster.

If I said there was no difference or that my beers were just as good, you could rightly suspect me of lying. I was pleased at how close I did come, though. My pale ale was overhopped by comparison and used only Cascade -- no Perle -- but was still in the right ball-park. The porter was much closer; in fact, the porter was tasted three ways with Anchor porter. With the Anchor as foil, my porter showed as very similar to Sierra Nevada's.

The only striking difference between my porter and SN was a fruity/malty spectrum of tastes in the SN that was absent in mine. It was also present in the SNPA and absent in my pale ale. Fruitiness has been an active topic on the HBD. My impression was that yeast was the main factor, and I had that covered by using 1056. I suppose temperature is another? I fermented in the 60s. Does anybody know at which temperatures SN brews pale and porter?

Ultimately, fruitiness derives from the malt. I used Munton & Fison 2-row malt from the UK in my beers as well as UK crystal (in both) and US chocolate (in the porter). I believe I read that SN uses American pale malt and dextrine malt as the pale components of the grist. Can anyone confirm? Could this account for the difference in the yeast's production of esters? I guess the dextrine malt is the more likely candidate?

And what about the difference between European and American malt? The late Dave Line made a big deal about it in his books. I gather that they are actually different sub-species (or even species?), with North American malts related to the Manchurian strains and the stuff west of the Urals being entirely different. In direct comparisons, I've found UK 2-row to have more flavor than Canadian 2-row and more yield than US 6-row. That's as far as my research goes. Viv Jones, formerly brewmaster at Upper Canada in Toronto, has said that North American malts are too enzymatic and it is easier to get a high final gravity using European malt. Roughly speaking, this is why I pay extra for British malt in ales.

So, is it possible that my malt won't produce the same fruity esters as the mix of US pale and dextrine malt (or whatever the mixture is) that Sierra Nevada uses?

Another factor that occurred to me is age. For all that my beers were mature, I'm sure the SN bottles were older. As we all now know, live beer does change with age, improving throughout a period of time; the length of time depends on many variables. Perhaps in another month or two my beers will be just as fruity as the SN beers?

Happy Thanksgiving all,

Rob (bradley@adx.adelphi.edu)

Subject: Humulus & Cannabis

In response to yesterday's question about the relation of hops to Cannabis: This subject always seems to provoke giggles and averted eyes, but it's really pretty straightforward stuff. I found it interesting enough to look it up in "Hops" by R. A. Neve (ISBN 0-442-31187-7)

Quoting from Neve's definitive tome on the subject:

"Humulus [hops] and Cannabis are the only two genera in the family Cannabinaceae and there are many similarities between hemp (Cannabis sativa) and the cultivated hop. The nettle family is also rather less closely related being in the same order, the Urticales. It is possible to produce viable grafts between hops and hemp and it is reported that pollination of hops by hemp, annual nettle (Urtica urens) or perennial nettle (Urtica dioica) stimulates cone development but only abortive embryos are produced."

Later, he mentions:

"It was reported by Warmke and Davidson (1944) that hop scions grafted onto Cannabis stocks produced cannabinoid resins and this led to interest in the technique as a means of producing such material while avoiding legal restrictions."

He goes on to talk about how other studies showed that the rootstock in these grafts has essentially no effect on the type of resins produced by the plant grafted on the root (in either direction).

Bottom line: Yes, they are related, and you can graft one to another. I surmise that the intent behind interest in the subject is to graft hop plants onto hemp roots and harvest cannabis resins from a legal plant. Unfortunately, it doesn't work. Good question, though!

>to slow them down, then removed them and let them come up to room temp again
>while making the starter. I've also let the starter sit too long before
>pitching. In each case, my fermentation started off quickly and the results
>(some of them still pending) seemed o.k. However, I don't consider my palate
>yet finely-tuned enough to recognize any problems in the finished beer that may
>be traceable to clumsy handling of the yeast. (Maybe that's a blessing?
--
>hey, it still beats the hell out of Bud.)

Just an aside, there are two ways to interpret the AB slogan: "Nothing beats
a Bud." The first one is, that "No other beer has the capability to surpass
Budweiser in any respect." The second is, that "Drinking nothing is superior
to drinking Budweiser."

You choose.

>I posted a similar question
>awhile back and one respondent said that one ought to be careful about
>letting the starter sit too long so that the yeast don't pass out of their
>reproductive cycle into their fermentation phase, or something like that,
>if I'm remembering correctly. I'm no biologist, I just cook beer.

The key is not pitching the starter before it goes from reproduction to fermentation (although I would suspect that pitching just short of this transition may be the ideal), rather that it is most important to pitch before the yeast have consumed all of the starter food and gone dormant again. Common wisdom says to pitch at high krausen, which is smack dab in the middle of the fermentation phase. Primarily because it is the easiest
to identify, I propose that, while it may be the second best theoretical choice, pitching at the *beginning* of the fermentation phase would be the
best practical choice, slightly better than at high-krausen and *far* superior to waiting too long. Note that if we were to agree that this would be the best practical timing, it would imply that Wyeast should be pitched when the packet *begins* to swell. Comments?

DanM writes:

>I'm interested in the results of your (and others) Orval culturing.

According to Jackson, Abbey d'Orval uses a single yeast strain for

fermentation and four or five strains at bottling. I feel, quite confidently, that one of the bottling strains is the fermentation strain. I added 1020 starter wort to 6 bottles of Orval dregs (individually) and tasted the results. Three did not start, three did. Of the three that did, two smelled and tasted ok, but not Orval-like. One smelled and tasted just like Orval. Note that you should be able to control ester intensity in any yeast using temperature -- lower temps, less esters -- higher temps, more esters.

Tim writes:

>I figure minimum size needed to be 6 gallons. Is there any
>point for getting something larger (I don't foresee brewing in
>larger quantities anytime in the near future)? What advantages
>would there be with a 7, 8 or even 10 gallon pot. I am not
>sure exactly how I plan on mashing (don't know if it will make
>a difference or not).

For mashing, you only need perhaps room for 1.5 quarts per pound of grain that you intend to use. For the subsequent boil, you need quite a bit more room. Note that after the sparge, you may have 7 or even 8 gallons for a 5 gallon batch. You need additional room for the "head" that forms during the boil. Recently, I tried to boil 1/2 gallon of wort in a 1 gallon pot. Forget it! What a disaster! I managed to avoid boilover (just barely), but to do so, I needed to have the boil so mellow that I don't think I got much out of my hops at all. I was doing a test recipe with 2 Lallemand dry yeasts and did not want to brew two 5 gallon batches. I'm not sure that my results will be useful at all.

To answer your question, ideally, you would like a 16-quart, copper-clad (for better heat conduction) SS pot for mashing and a 10 gallon (forget copper-cladding here -- you couldn't afford it if you could find it) SS pot for the boil. This would allow you to do (with a bit of difficulty) 10 lbs of grain. If you can only get one pot for both, you should probably go with a 10 gallon SS pot.

Kevin writes:

>First of all, I brew in a 5-gallon tub with an airlock. Should I be using
>one of those water bottles so the krausen can be blown off ?? Is that
>important ??

First of all, please limit your line length to <80 characters. Not only can some people not read anything beyond 80, but it makes quoting you pretty tough.

Back to your question: Blowoff. I say yes -- it makes a difference if you use blowoff. Does it make enough of a difference for you? Try it and see. I feel, that my beer made with blowoff is much less astringent than without.

>Second, all my beer has a distinctive flavor. I am sure that everyone does,
>but I am not sure my flavor is positive. I am wondering if chlorine in the
>water is leaving its mark. Should I be filtering my chlorinated city water

>thru charcoal filters ??

That's house flavor, but it can be minimized by good sanitation and, as you suggest, by removing the chlorine from your water. If your plastic fermenter has any scratches in it (and after a few batches, it certainly does) the scratches can harbor bacteria even with intense sanitation solutions. Boiling water is what Darryl Richman uses on his plastic fermenters and brews prize-winning beers. You don't need a carbon filter... you can remove chlorine by boiling -- that's what I do -- I boil all my water.

>And certainly my biggest question is related to the cost of transitioning to the all mash brewing. I read a lot of articles about special equipment and other items that I do not have. How many new items do I need and where can I find more info. on these setups ?? I am reading Papazian, but he seems to lack equipment details and innovations that help the homebrewer.

His latest book "The New Complete Joy of Homebrewing" (why "new" Charlie. . . why not just second edition?), I feel is much better. You said "I am reading" which may mean that you have not reached the advanced sections which, I thought described the equipment well. However, I was reading it with most of the necessary knowledge in hand -- perhaps it is not as clear as I thought? Miller has a slightly different setup described in his book as does Noonan.

>And the bottom line, if I ignore the fact that I am making a better brew, does all mash beer cost less than partial extract ??

A lot less if you don't count you time -- perhaps a little less if you do. For me, however, cost is not the bottom line.

Al.

>generating a conversation on decoction versus infusion, I'll say
>simply that I would like to do two step mashes, protein rest and
>conversion. It would be nice to be able to fiddle with conversion
>temps too without leaning out the mash by adding water.

Since I'm the resident expert on the flaws of Jack's system (;^), I'd have to say that this is not one of them. There's no reason that you could not choose a strike temperature to get you into the protein rest range, followed by heating to get you into the saccharafication temps, in fact, you could do as many steps as you want.

Hmmm? Two cases of Al defending Jack in one post? Well, before you two or three people try electing me president of the JS fan club (I think Jack president for life ;^), I want to say that I enjoy it when the HBD is clean and hate it when people are mean to each other. A sense of humor helps, but let's not pick on anyone just the same, okay?

>From: KLIGERMAN@herlvx.rtpnc.epa.gov
>Subject: clearing cider

"I have made some apple cider about a month ago and have not seen any clarification taking place. It is in the secondary and I've lowered the temperature to about 40 F., without noticeable clearing. Can anyone suggest methods for clearing the cider aside from filtering?"

I've had success - I don't know exactly why, yet - by transferring the cider to a secondary fermenter (after doing a few one-gallon batches, this is less of a problem as one becomes inundated with one-gallon jugs) and adding a boiling-hot solution of honey diluted into water - which I was using to fill up the airspace left from the transfer, which left a lot of yeast and other precipitates behind.

Within a few minutes of adding the hot honey-and-water combination, the clarity improved dramatically, almost as if the hot liquid had provoked a 'break'. Since the volume added was no more than one cup, there's no way this could have possibly killed all the yeast, the heat was absorbed instantly and contributed very little to the thermal mass that the full jug represented.

Fermentation picked up thereafter, as the yeast responded to the honey, and I bottled at that time, since I wanted carbonated cider. The results were magnificent.

End of HOMEBREW Digest #1021, 11/26/92

Date: Tue, 24 Nov 92 11:20:35 CST
From: whg@sunf99 (Walter H. Gude)
Subject: 1-stage/Trub Rack

Yes ladies and gentlemen I can't help it, it's time for another round of discussing the merits of 1/2-stage and racking off the trub.

In yesterdays digest (1017?, as well as several previous digests) I read with interest a post by Al Korzonas (korz@iepubj.att.com):

Al,

I read your post today and was very interested that you've determined that a single stage ferment is all that is required. After several years of automatic racking to secondary I started experimenting myself. I've never had the patience to make "exactly" the same beer twice changing just one thing, but some of the best beers I've made in the last year used my normal process with only a single stage. Clarity, astringency and any other fermentation characteristics were indistinguishable from 2-stage.

I also read with interest (correct me if I'm wrong) that your practice is to pour the wort through a strainer into the carboy after chilling. I usually put the lid on and let the trub settle for 30-60 minutes and then siphon, leaving as much trub as possible. However, given the "yumminess" of your brews I'm re-evaluating the need for this step. It's not too hard but if its not needed why bother. I'm I wrong about your methods? What to you think about the 30 minute settling time? Is it worth the risk?

BTW, this question is directed not just to Al but the Digest as a whole.

Thanks,

Walt

Subject: cider clearing

Thanks to all those who answered my post by E-mail. I will be patient and let the cider clear naturally over the next half year (if I can wait!).

Date: Wed, 25 Nov 92 21:11:19 PST
From: Richard Childers <rchilder@us.oracle.com>
Subject: A clarification on clarification

I just finished repeating, successfully, the experience described earlier today in a posting the HBD, where I responded to someone's request about how they might clarify their home-brewed cider.

What I'd said is that all one needed to do was add boiled water and honey.

This is true. However, the first time I did this, this evening, I omitted a step I'd carried out the first time, letting it cool for a few minutes, and the result was cider foaming out of the bottle as it reacted with hot water and honey, or, more precisely, nearly boiling water and honey.

After cleaning up, I did it again, this time letting the mixture cool for a very few minutes before, very slowly, dribbling it into the jug. Within a few minutes, clarification again began and is proceeding as I speak.

When I get some time and energy, I'll try water alone, and maybe honey alone, and see if I can isolate the cause of this clarification. It seems to me that this could be used repeatedly to sweeten and clarify a cider, along with transfer to another fermenting container ... I'd guess flavoring

agents could also be added at this time - spices, fruit extractions, et caet

...

I have to note that it was Jack Schmidling's description of some fruit wines that really got me started on this path, and, realistically, there are few boundaries to this brewing thing ... the only constants are fermentables, adjuncts, yeasts and water. Thanks, Jack !! Your freewheeling imagination is not unappreciated, I think.

From: "Rick (R.) Cavasin" <cav@bnr.ca>
Subject: re: clearing cider

Regarding Richard Childer's observation that adding a hot honey solution seems to clear his cider:

I think you may be onto something here! I've been wondering what to make of a similar observation. I had a strawberry melomel that had been aging in the secondary for some months, which, on tasting, I had decided was too dry. So I figured that I'd rack it and add some concentrated honey solution to fill the headspace. Although the melomel still had a bit of haze to it, the racking and adding hot honey made it drop clear as crystal. I've noticed that although I skim my honey when it's boiling, I still get a considerable amount of 'cold break' from it. What may happen is that the formation of the cold break 'catches' the haze and draws it to the bottom. I suppose that this is analagous to adding gelatin. I also have a hunch that this is dependant on the amount of honey/water added being small compared to the total volume. IE. the cooling must be quite abrupt, so that the formation of the break is very sudden. This, because I still thought the melomel too dry (I'm trying a less attenuative yeast now) and tried to do it a second time. This time the volume added was larger, and the result is that the melomel has gone from crystal clear to slightly hazy again (curses!).

Subject: San Francisco microbreweries
AND hops/cannabis answers

I'm going to San Fran soon (YAY!) and would like to know about microbreweries in that area...can anybody help?

Why do people pass on recipes that they have not yet tasted? A friend of mine has a penchant for wierd beer ingredients-- cilantro, peppermint, pomogranate, basil. We've tried to dissuade her, but those published basil beer recipes (EVEN THOUGH THEY WERE NOT TASTED) only encouraged her. The basil beer she made IS pretty tasty, reminiscent of pesto, but she is keeping her recipes secret. We have yet to taste the pomogranate lager...I admire her willingness to make a potentially disgusting brew in the search for the unusual. She doesn't get the digest, so if you are interested in her recipes, write her at <ALEIMANI@SUVVM>.

Actually, Andra (the above mentioned) and are "swamp queens" (our masters thesis research) and would like to know if anybody out there has used swamp stuff (besides spruce and fir) in their brews (and tasted it!).

Now for the word on cannabis and hops...they belong to the same botanical family, Cannabaceae. THE BOOK (Gleason and Cronquist's 1991 Manual of Vascular Plants of Northeastern United States and Adjacent Canada) lists two genera in this family, Cannabis and Humulus. There is one species of Cannabis, C. sativa, and two species of hops, H. lupulus (and several varieties) and H. japonicus. I'm not so sure this makes them second cousins, consider yourself and see what you think. You and chimps belong to the same order, Primates, but to different families. People belong to the family Hominidae. There's only one extant genus, and only extant species of humans, Homo sapiens. Other species like H. habilis, and other genera like Australopithecus (A. afarensis is "LUCY") are extinct. So, if you consider yourself a second cousin to Lucy, then perhaps hops and cannabis are second cousins.

I had to infiltrate Ming-chung's account becuae mine is not big enough to handle the digest mail.
Thanks, Lisa St. Hilaire <MARS@SUVVM>

From: cush@msc.edu
Subject: what happened to my efficiency?

Here is one for the cumulative wisdom of the all-grain brewers on the net:

I just brewed a batch of porter, was shooting for an OG of 1.046...but got 1.040. That is 25 points/lb./gal. :- (I usually get 29 - 30 points.

This is especially disappointing, because I have just finished studying Miller, and had decided to go for the best efficiency I could get.

Specifics of the process are:

9.5 pounds of grain (8.5 lbs. 2-row pale, 1/2 pound each, crystal and black malt)

Mash-in at 153F using 9.5 quarts water (that's 1 quart per pound)

PH started at 4.6, raised to 5.0 using 1 teaspoon CaCO₃

Mash rest, 1 hour at 153-146 (infusion mash done in rectangular cooler)

Iodine test indicated full conversion.

Add boiling water to mash-out at 170F (5 minutes)

Sparged to 8 gallon total - water at PH=6.7 (took about 45 minutes)

boil down to 5.75 gallons (about 1.5 hours - hops only boiled last 60 min)

Cool and pitch

OG=1.040 at 5.75 gallons.

bummer!

When I checked the grains afterwards, it looked like many of them had been cracked in half, but the starchy material was still in the husks. The grind looked alright, i.e. few whole grains, but in some the starch had not been released.

Causes I can think of are:

- 1) strike temp was not high enough to gelatinize the starch
- 2) the crush was actually too coarse (I WANT a roller-mill!!!! Santa???)
- 3) I should indeed have done a step-mash and raise the temp to 158 for 15 min.
at the end of the mash.
- 4) I sparges too fast.
- 5) the mash was too tight. Miller recommends 1.33 quarts per pound.
This was indeed the tightest mash I have yet done (Micah??? you say you usually use a rather tight mash.....)
- 6) As I said, this same sparging system has turned out 29-30 points, so I am pretty confident that I am not suffering from dead spots in the lauter-tun.

Does anyone have any other ideas, or care to comment on which of the above is the most likely culprit?

I left the kitchen in a really bad mood, and ran four miles to blow off my frustration. Geez....I almost felt like giving up if my best effort would turn out my worst results. Oh well...1.040 is low, but alright, and I pitched a nice healthy starter, so that after eight hours it looks like

the yeast is just coming out of respiration stage. Maybe in a few weeks
I
will be able to drink away my frustrations!!!

Subject: Harrington Vs Klages

In HBD1021 James Diplama comments on how I posted in 1014 asking about the differences between Klages and Harringtons malt, and was dissappointed with the response. So was I Jim, although I did get a few responses, none were difinative.

I called the maltster at Canada Malt to get the goods. Klages malt is not grown anymore and hasn't been for a few years. All malt grown in North America is the Harringtons variety. This is exclusive to commercial barley, and private farmers can grow Klages if they have the seed stock, but no new Klages seeds are sold.

The reason is that Klages became disease intolerant as crops have a tendancy to do and is systematically replaced about every 10 years with a new variety. This happens to be Harringtons right now. In a few years it will be the another variety.

Harringtons malt yields the same extract as Klages, tastes the same and is the same color. For all intents it is Klages. Perhaps it is better to refer to it as Domestic (we call it Canadian) 2 Row Malt, rather than Klages or Harringtons.

Unless someone cares to dispute, this is what I'll believe.

I believe what is being referred to here is the all too common belief that one should only pitch yeast at high krausen. This is, in fact, NOT the ideal time to pitch. You DO want to pitch the yeast when its in the stationary phase. Why? As the yeast is quickly multiplying its glycogen level decreases. Yeast in their stationary phase are able to rebuild their lost glycogen supply. There is a direct correlation between the glycogen level and the lag phase of the fermentation. The more glycogen stored the shorter the lag phase. (assuming constant cell density of course)

Subject: Doppelbock recipe

Here's a really good Doppelbock recipe.

Irrumator Doppelbock (makes 5 gals)

6# Dutch dme
4# Pilsener malt
2# Munich malt
1# German crystal
1# Chocolate malt
1.5 oz. German Hallertau (4.9% a) (30 min)
.75 oz. Hallertau (15)
.25 oz. Hallertau (5)
Wyeast Bavarian Lager (make a starter with 2 tbsp pdme)
.75 c. corn sugar for priming
OG 1.084

Raise 10 qts water to 128 F and add grains for mash in and 30-minute protein rest at 122F.
Saccharification rest 1/2 hr. at 153F, then 1/2 hr. at 149F.
Mash-out 169F, then sparge 4 gals at 170 F.

Primary ferment 51.5F
After Kraeusen head falls, lower temp (5F/day) to 40F
Raise temp for 52F diacetyl rest, 1 week
Lager in secondary at 36F for 2 months
Bottling: raise temp to 55F, prime with corn sugar and active yeast culture.
Keep filled bottles at about 55F for a week or two

Making this recipe, I was shooting for something like the Celebrator. I think this is a pretty close approximation, although I don't have a Celebrator on hand for comparison. In any case, I love this beer.

Subject: Easymash and Step Infusions

I must apologize to JS for posting misleading or incomplete information about the Easymash. My comment in the HBD was that I could not do a step mash using the Easymash. This is in inaccurate statement on my behalf.

What I should have said is that it is impossible to do a step mash with my application of my reproduction of the component JS sells to manufacture an Easymash. The Easymash is a simple and effective device which, simply, is a tap, tube and screen. It works elegantly, but JS mounts his in a stove pot. If one were to mount his Easymash in a cooler or large plastic vessel, as I do, heating on the stovetop is impossible and therefore step infusions are impossible.

Hope this clarifies this issue, Jack. :)

What I meant by "finer crushes" is exactly that. Not everyone that mashes also crush their own grain. If you buy precrushed grain from more than one source it is likely that the crush will be of varying consistency. I have purchased grain that looked like the barleycorn was simply broken into 4-6 pieces and I've bought grain that was more the consistency of large table salt. I don't want a discussion on the merits of proper crush, I'm well aware of that. My comment reflected a problem that happened to me with improper, finely crushed grain. I would also like to comment that the same grain was used by a fellow brewer in a Zapap lautertun and he reports no problem with his sparge. I would also like to say that I have used my easymash with properly crushed grain and it works flawlessly.

Subject: Freeze Distillation

PD:>> How would that freezing technique work anyway? I thought water
PD:>>>and alcohol were fully miscible, so why would the water freeze but
leave

I made some Apricot brandy from some leftover Apricot wine that I had
made. Freezing the wine turned the entire volume into a slush that
caused the alcohol to be almost inseparable from the ice. So I put it
into a colander, and let it partially thaw and collected the drippings.
Needless to say it was not very efficient.

Next time I will do this:

Put the wine (or dopple-bock!) into a shallow vessel and cool to 32F.
Place ice cubes into it and drop the temp below freezing. The ice
cubes will act as a nucleus and draw water to it. Pluck the enlarged ice
cubes out and add more ice cubes.

Cheers!

Subject: Culturing Chimay Yeast

I saw recently some mention of using yeast cultured from a bottle of Chimay. So, naturally, I rushed out for a bottle of the same, consumed it while making up a Belgian style brew one Sunday, and put some sterile 1.025 wort and some yeast nutrient into it. After about 2 days, I had a nice krausen and activity in the lock. Today, when all activity had ceased, I went to decant the stuff into (sterile) beer bottles in order to put it to sleep in my fridge for a while. To my horror, I found what appeared to be floaters in the liquid. They did not look like other bacterial infections I have seen, and the stuff smelled clean, and recognizably like Chimay.

Questions: One: could this just be low-density fermentation byproducts?
Two: I read in the Zymurgy Yeast Issue that Chimay uses a mix of yeast and bacteria in bottling. Could this be the bacteria?
Three: if Chimay does in fact use such a mixture, is there any point in trying to plate out the yeast? Is Wyeast 1214 more or less similar to Chimay minus the bugs?
Four: Can I plate out a clean yeast from this stuff even if there is other microfauna present?

Thanx, P.

Subject: WYEAST 2112 - Problems ?

I have a couple of questions to pose to the users of liquid yeasts in particular WYEAST 2112 - California Lager.

DISCLAIMER: Last weekend was the first time I have ever used a liquid yeast and as such I do not know what to expect from it.

Basically I am worried about viability of the yeast itself.

As per the instruction of the packet and readings from various newsgroups I performed the following steps:

- 1) Broke inner bag and gave yeast-wort mixture a thorough shake(day 1).
- 2) Continued to give bag a good shake every few hours.
- 3) Waited till bag swelled to approximately 1 inch thick (day 4)
- 4) Mixed up a starter bottle containing water-wort-sugar.
- 5) Pitched yeast into starter(day 4).
- 6) Waited for signs of high Krausen.
- 7) and waited (day 5)
- 8) and waited (day 6) - yeast was producing CO2 but not bubbling enough to produce that characteristic froth.
- 9) Made up batch of all-grain and pitched starter anyway.

My questions are thus:

- 1) How active is such a yeast - should I expect to see that bubbling froth on the surface of my fermenting beer which always happens with dried yeasts.
- 2) What lags times can be expected with WYEAST 2112.
- 3) Do lager yeasts generally exhibit such relaxed fermentation behaviour.

I really am at a loss here. I have 5 gallons of Munich Lager sitting in the fermenter with a yeast I am not too confident about. Should I have faith in this yeast or go and pitch a packet of dried yeast into it before it gets infected?

Thanks for any help

MC

YEAST PROFILE: WYEAST 2112 - CALIFORNIA LAGER YEAST

Warm fermenting bottom cropping strain, ferments well to 62 F while keeping lager characteristics. Malty profile, highly flocculant, clears brilliantly. Apparent attenuation 72 - 76%.

Subject: Yeast Nutrient Questions

In the spirit of Never Leaving Well Enough Alone, I picked up some yeast nutrient powder from my local homebrew supplier with the intent of seeing what it could do for my yeast starter performance. Can anybody give me information on the following?

Background Info: I make SG 1020 starters from dry malt extract and hops. The procedure is similar to Papazian's in TCJOHB. The starters usually work fine (hence the "Leaving Well Enough Alone" comment above). The yeast nutrient package is labelled as follows: "Contains: Thiamin, All other Vitmain B Complex, Biotin, Pasteurized Yeast cells. Use 1/2 teaspoon per gallon".

1. Is the stuff even useful given that I use malt extract already? Does anyone have any theoretical knowledge or before/after anecdotes to report?
2. Does anyone have additional or contrary information to the instructions I got?
3. If I add the nutrient to the starter wort before boiling and then boil to sterilize, will I end up denaturing any of the nutrients?

Thanks in Advance

Al Marshall

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)
Subject: re THM's

> You may not have much THM (trihalomethane is a gaseous form of chlorine) in your water at all.

THM and chlorine aren't totally unrelated, but they are a LONG way from equivalent.

Chlorine /is/ a gas; in everything from filters for large swimming pools up to water supply systems it is kept as a gas and force-dissolved in the water as it goes through the system. (Small swimming pools use bleach, just like homebrewers, but it's applied either as crystals or as a concentrated solution delivered by tanker trucks.)

THM is mostly trichloromethane (aka chloroform). It's called THM in water analyses because the analysis isn't sensitive enough to separate out bromoform and iodoform (fluoroform and astatofrom are possible but very unlikely)---both of which aren't pleasant, but it's chloroform that is generally considered carcinogenic. THM's are volatile, but generally liquid at room temperature. THM's can show up in water supplies from contamination of the water source (chloroform has various lab and industrial uses); I /think/ chloroform can also come from careless chlorination (reaction with waste organics in the supply).

From: thutt <thutt@mail.casi.nasa.gov>
Subject: Yeast Hydration, oak chip steaming & Hawaii(?)

During this past weekend, whilst making a batch of IPA, I accidentally overfilled my carboy. By overfilling, I mean that I did not have enough room to pitch the rehydrated yeast.

Fortunately, I had not actually rehydrated the yeast at this time, so I simply (using proper sanitation) siphoned off a small amount of wort, and used that to rehydrate my yeast.

So far (day 3), everything seems to be normal. My only conclusion is that this was not a bad thing.

Question is: If this works (as it seems to), why would I not want to do it? (After all, I have not seen this prescribed in writings or postings). Does anyone else perform this rehydration technique? What are your results?

Also, during the creation of my IPA, I found the need to steam my wood chips. Since I was doing about 4 things at once, I really did not need another pot to watch on the stove, so I frantically searched for a simpler way to steam my wood chips.

The answer which popped into my mind was quite simple, effective, and painless. I popped them into my rice cooker added some water, and turned the sucker on. It will steam the rice, er..., chips for about 30 minutes, and then it will turn itself off, keeping the heat applied until you are ready to use the wood chips. (I am seriously contemplating putting some oak chips on top of my rice next time; wonder what type of flavor that will lend to the rice...)

Turned out quite aromatic (and hopefully well sanitized). Anybody else have experiences of this sort?

Finally, any brewers from Hawaii subscribed to this list?

Subject: Plastic Boilers

I would like to solicit opinions from those who boil their entire collection of wort. We all know the price of eight-gallon pots can be daunting, especially if they are of stainless steel. And for those of us who have small-burner, low-output electric ranges, and no propane "King Cooker," the prospect of doing a full boil can be intimidating.

How about using one of those food-grade plastic fermenting buckets with an electric heating element? This would be similar to the "Bruheat" setup, but without the \$80 price tag. I am concerned about the plastic's resistance to prolonged boiling temperatures. A quick experiment in which I filled my bucket with a couple of gallons of boiling water resulted in a slight softening of the plastic, but there were no alarming structural problems.

To sum it up,

Advantages:

- Dirt cheap, full-boil rig.
- Potential to mash, and with the addition of a double bucket, to sparge all in the same apparatus.

Disadvantages:

- Possible structural failure?
- Wort carmelization due to the element's localized heat concentration.
- High worry factor. :-)

Comments? Suggestions?

Subject: oxidation

An anecdote pointing out the need for care to not oxidize your wort:
Last winter I made a beer close to Papazian's Doctor Bock. It got a
28 in the first round of the AHA National, even though it was quite
young (one of the comments was that it was yeasty tasting) and not
malty enough for the style. I entered it in the Michigan State Fair
competition (in July), where it got a 35, and the comment that it
tasted oxidized. I have to agree -- there is a definite "cardboard"
taste to it now. (I have also had oxidized beers with a nice
sherry-like flavor, but not this one.)

What did I do to get this flavor?

I think it happened because I just poured the hot wort into the cold
water
in the carboy. There was lots of splashing and foam. Fix claims that
dark beers are at greater risk of oxidation because the melanoidins
(certain dark-colored compounds) can become oxidized, and later act as
oxidizing agents as the beer ages. I think this is what happened to
my beer, because the cardboard flavor definitely took several months
to develop.

Since then, I've built a wort chiller, so it won't happen again (I
hope).

From: martin@gamma.intel.com (Martin Wilde)
Subject: Caramelly taste with crystal malt and McMenamins

I would like to get a big caramelly taste from the usage of Crystal (Caramel) malt. I have heard using large quantities of Crystal 20L will give you a caramelly taste and a dark color is this true?. Normally I would use about 5% of crystal 80L to get the desired color, but the amount of caramelly taste is not as high as what I am looking for and would probably be too sweet in large amounts.

I ran the numbers through the Lovibond formulas and about a 20% mix of Crystal 20L will give me the color I desire. My only worry is will I get the desired caramelly taste? I suspect I will need to mash at a lower mash temperature (148 degrees) to avoid getting too sweet of a beer with all that crystal present.

On a different subject, the McMenamin brothers have created a fine institute for craft beers here in Oregon. Since Oregon allows minors in most pubs up until 8pm or so, the McMenamin folks have gone out of their way to make their pubs a wholesome family place (they now even have a childrens menu, including peanut butter and jelly sandwiches!!!). As far as them not selling anything other than their own beers, I don't believe they would do that, since they have a hard time keeping up with production of their own beers. The only complaint I would have against them, is that their beers seem to be getting thinner. Maybe they are just trying to satisfy the majority of people.

From: Jim Grady <jimg@hpwalq.wal.hp.com>
Subject: Diacetyl problem

I have a problem with diacetyl in a recent batch I made. Here are the specifics:

- * recipe was the extract based Kolsch recipe in Dave Miller's "Brewing the World's Great Beers."
- * yeast was Wyeast European Ale (I can never remember the numbers)
- * the F.G. was higher than expected (1.017) but seemed about right given the minimum attenuation specified in the yeast profiles from Wyeast.
- * bottled on 30 Oct.; stored at about 60 deg. F
- * 1 week later, carbonation was fine and tasted fine to the best of my recollection (a little sweet though)
- * started cold conditioning at 40 deg F on ~8 Nov.
- * tasted on ~22 Nov and there was a pronounced butter flavor.

My question, naturally, is what do I do?

I have read about diacetyl rests at ~70 deg F but they all seem to be at the end of the secondary, not in the bottle after a couple of weeks of cold-conditioning.

Thanks in advance for any suggestions.

>In HBD 1014, Glenn Anderson wrote and asked about the difference between Klages and Harrington malt....

I guess the reason no one answered is because it is another one of those well guarded industry secrets.

All I know about it is that after about ten orders of Klages from Minnesota Mining, I was told that it was no longer available and has been replaced by Harrington. The only answer I could get as to why was that the brewers like it better.

My experience with it (for what that is worth) is that I can not tell the difference. It looks the same, tastes the same, performs the same and the beer tastes the same. After using Belgian malts for a few batches now, it is probably safe to say that comparing Klages with Harrington is sort of like comparing Miller with Bud.

> that is a bit much.

I think I know what the missing factor is regarding getting a head when
pouring from a tap (er, faucet actually -- the tap is the gizmo that
attaches
to the keg): pressure drop. If you only partially open a faucet, you are
restricting the flow and thus causing the beer to flow through a smaller
opening. The resulting flow is higher in velocity. This is called the
venturi effect. When the flow finally crosses the constriction, the
flow slows and the pressure drops and much of the dissolved CO2 comes out
of solution. This is "slow pour" that Baderbrau retailers are taught to
offer their customers. The resulting beer is less carbonated than it
would
have been with a "fast pour" where the faucet is opened full-throttle.

My theory, then, of why your "bottled-from-the-keg-without-a-counter-

ressure-bottle-filler" beers did not have a head, would have to be that it was because of the loss of dissolved CO2 when you filled the bottles. For those who are unfamiliar, counter-pressure bottle fillers work by keeping the beer under pressure during the whole transfer process, thereby eliminating (actually minimizing) the loss of CO2 (i.e. carbonation).

>30 minute settling time? Is it worth the risk?

I think I responded to Walt directly, but it may be of general interest, so I'll post. I used to cool to 70F, wait an hour and then pour through a strainer into the fermenter, leaving the last quart or so of wort (the part with most of the hot- and cold-break in it (trub)) in the kettle (sometimes more sometimes less -- different extracts, by the way, produce different amounts of trub). I've since (very recently) decided that the 1 hour rest after cooling does little, since only very little of the total cold break settles in the first hour (it seems to take much longer).

Partly because I've read that blowoff (which I use) eliminates much of the undesirable compounds created by fermenting on the trub (higher alcohols) and partly because I refuse to worry (I take Charlie quite seriously on this point), I simply chill to 70F, measure OG and run it through a sieve/funnel into the carboy.

Cush writes:

>the yeast is just coming out of respiration stage. Maybe in a few weeks
I

>will be able to drink away my frustrations!!!

I'll re-use a phrase I used on a complaining co-worker today -- it has a
double-meaning in our world: "...could be worse... you could be homeless."
"

Let's not be too proud with our allgrain batches here folks: if the
gravity is lower than you would like, add some malt extract.

Since we're on the subject of extract efficiency, I'd like to make one
more point regarding the importance of knowing your extract efficiency.
This was brought up elsewhere, so I can't take credit for remembering
it, nor can I remember who should be getting the credit (sorry):

Probably the most important reason for knowing your extract efficiency, it is so you can compensate when you are trying to duplicate someone else's recipe. If you see that they are claiming 30 points per pound per gallon (judging from their grain bill and OG) and you know you only get 25, you add 20% more of each grain ($30/25 = 1.2 \Rightarrow 120\% \Rightarrow 20\%$ more needed).

A1.

Subject: "Stationary phase"

In the last HBD I wrote:
> You _DO_ want to pitch the yeast when its in
> the stationary phase.

This generated a lot of e-mail questions, so:

What I referred to here as the 'stationary phase' is really the very beginning of the dormant phase. In other words, let you starter ferment out _then_ pitch it. Don't let it sit too long or you'll have other problems.

As far as the argument that vigorously multiplying yeast will start your wort faster, the yeast have a limited supply of glycogen and it gets depleted through culture growth (multiplication). If you then pitch this starter with an already depleted glycogen level into your wort then you'll have more of a lag since the cells won't be able to multiply as quickly (due to the low glycogen levels)
[think of glycogen as the fuel that drives the cell] By letting the cells reach stationary phase they have stoped multiplying, begun storing up glycogen again, and just generally getting ready to go dormant.

At least thats the Reader's Digest version of what I go out of:
> Impact of Yeast Handling Procedures on Beer Flavor During Fermentation
> Pickerell et. all.
> American Society of Brewing Chemists (ASBC) Journal, Vol 49:2, 1991,
pp.87-92

For those of you who asked about the ASBC address, I don't have it here. I'll post it later. Personally I've found more usefull information for what I do [I'm keeping a _BIG_ yeast bank] in the J of Inst. Brew. Your mileage may vary. I'll post at address if I can find it. Be warned that these journals are not cheap!

From: Peter Maxwell <peterm@hpdtlpm.ctgsc.hp.com>
Subject: whirlpools to clear wort

A lot has been said about how certain places/people whirlpool the wort before chilling. My simple-minded question is that if formation of DMS is deemed to be problem, what's wrong with chilling first and THEN whirlpooling prior to racking into a fermenter. That would seem to avoid both DMS and oxidation problems. There must be some reason for whirlpooling before chilling but I'd like to know what it is.

From: Alan B. Carlson <alanc@cs.chalmers.se>
Subject: Weird Yeast Starter

I started a yeast culture the other day. Took the dregs of two bottles of homebrew from a batch of beer that was brewed with first generation Wyeast Bohemian pilsener. The "wort" I used was a approximately a pint of water and a little less than a half a pound of granulated sugar that was boiled for 5 minutes. When it cooled I threw in a teaspoon of yeast nutrient as well. The day after the starter was starting to bubble, I noticed some almost clear agglomerations floating at the top of the wort. Some of the same stuff was in suspension as well as lying on the bottom. The stuff reminded me of the meat of a lemon (you know, floating around in ice tea) although it is absolutely colorless. The gas emanating from the airlock smelled like yeast.

Yesterday, I threw the stuff out since I didn't want to waste a batch of beer not knowing whether it was an infection or not. Before chucking the stuff into the sink, I poured the starter into a glass. The agglomerations that were present before dissolved completely. Not a trace of them in the glass.

Can a starter look like this without being infected? Can it be some sort of bacterial contamination or or can it be the yeast nutrient? I've never seen a bacterial infection before so I have no idea what one looks like. The brew that I cultivated the starter from was the first batch I've done with liquid yeast and the starter I used then sure didn't look like this last one.

Bob Jones writes:

>I have noticed that bees seem to find their way into my garage when I brew.

>I especially notice them after the wort is boiling. Anyone else notice this?

Yes, I've had bee problems during the summer, but I notice it mostly when mashing and sparging, attracted by the sugars. A few have been lost in the boil (worker bee ale?) and fished out. I have also noticed that when the sky becomes overcast the bees go away. I've never been stung though, so I assume that they approve of my efforts. Try making perry in the fall if you are thrilled by the prospect of happy bees crawling on you (just don't let them down your shirt collar or up your pant leg).

On another note- I am flying to Boston this weekend. I'm not sure where I will be staying-somewhere near Harvard/Mass. Gen. Hosp., I assume. What are the beer-highlights of the area, assuming that I can escape for some free time? I have been to Commonwealth and will try to return. Are there any other (or new) brewpubs within subway distance? Any interesting (rare) imports that are not available elsewhere (Michigan)? Thanks for the help.

Subject: Carbonating Mead

Hello,

I have just brewed my first batch of mead. So far, I have racked it twice.

I know that traditional mead is uncarbonated, however, I thought that carbonating it might be a nice touch. I got to thinking that if the yeast is all dead (and assumably it is, since the alcoholic content is in the order of 12-13%) and all of the suspended yeast has settled out, how will the mead carbonate if I simply prime with corn sugar at bottling time? My questions are as follows:

- 1) Should I carbonate the mead and if so how?
- 2) Does all of the yeast settle out? What happens in the carboy?
- 3) Is the alcoholic strength of the mead too strong to support any yeast activities?

Thank you,

Greg.

Subject: Baderbrau stock

James P. Buchman asks about buying shares of Baderbrau.

There was some chatter about it on Compuserve a few months ago. It is (or at least was) on NASDAQ under BRAU. Art Steinmetz did some digging around about Baderbrau's financial situation and posted the following:

From: Art Steinmetz/NYC 76044,3204

I just pulled up some stats on BRAU on my handy-dandy screen. Pavichevich Brewing has yet to make a profit. The stock has been trading, I think, since 10/89 although the company has financial results going back to 1987. The stock price ran up to 6-1/4 in 4/90 and promptly crashed to 1-1/2 by the following Jan. It's quoted between 2-1/2 and 2-3/4 for the last year. Price action is non-existent. Volume is invisible. 1.56mm shares outstanding.

In October 1990 they defaulted on bonds they issued and owe \$250k in back interest on those.

They owe \$1.25mm to Steel City National Bank of Chicago.

As of this Jan. they were in a capital crisis since operating revenue was insufficient to meet operating needs. They were trying to arrange \$1.5mm through a sale-leaseback of the equipment. Didn't happen. Around June they raised \$426,000 in a private placement of stock. They're still up to their eyeballs in debt. Total liabilities are \$2.3mm vs. assets of \$2.7mm as of 1992Q1. They must have some more debt somewhere 'cuz my screen shows a negative book value for the stock of \$-0.20 per share.

Sales in the quarter ending April 30 were \$227,000 vs. \$237,000 previously. Beer unit sales were up 6% but prices declined pursuant to their distribution deal resulting in the drop in revenues.

Paterno Imports Ltd. has been their national distributor since June 1991.

They're hanging on by a thread. Caveat Emptor.

I'll bet that a lot of US micros are in similar shape.....

Subject: Removing Chlorine

My brewing water comes off a private water association. I went in to the county health department to get a water analysis, just out of curiosity. The analysis was just puzzling, all of the substances tested for were low, but the total dissolved solids was 450 ppm! No idea what the unknown goobers in the water are, but the district is out of compliance...

Anyway, I'm talking with my friend who works there and telling her about my homebrewing... I ask her about the chlorine levels, since I know the water association has been docked for not controlling it properly. I've been concerned about getting the chlorine out of my mash and sparge water, so I've been boiling it beforehand. She tells me that boiling only removes chlorination by pure chlorine gas! Our water association uses sodium hypochlorite (bleach). This is not removed by boiling. She says that hypochlorite can be removed by two methods: exposure to sunlight and evaporation, and adding sodium thiosulphate (photographic hypo).

Setting my water out for a couple of days is not real practical (among other things, I live in NW Washington state, so we won't see any UV for another seven or eight months...), and I don't really want to add hypo to my beer. Ick!

The other thing that I learned is that there are three ways to chlorinate water: gaseous chlorine, sodium hypochlorite, and chloramine (sp?). I don't know anything about chloramine, but my friend tells me that it is a more stable form of chlorine compound. She also tells me that < 4ppm chlorine has little or no purifying effect, and > 8ppm is too much and will taste of chlorine. Supposedly, if it is done right, you can't taste the chlorine... We always have a strong taste of chlorine in the water and 2 out of 3 beer judges tell me I have phenols in my beer (sob...)

Does anybody know:

- 1) What are the reaction products of sodium hypochlorite and sodium thiosulphate, and is this safe in beer? (I suspect not...)
- 2) What will remove the chlorine from my water?

Thankz,
Paul.

> * 1 week later, carbonation was fine and tasted fine to the best of
>my recollection (a little sweet though)
> * started cold conditioning at 40 deg F on ~8 Nov.
> * tasted on ~22 Nov and there was a pronounced butter flavor.
>
>My question, naturally, is what do I do?
>
>I have read about diacetyl rests at ~70 deg F but they all seem to be at
>the END OF THE SECONDARY, not in the bottle after a couple of weeks of
>cold-conditioning.
>
>Thanks in advance for any suggestions.

I also had a diacetyl problem. I believe Miller advocates doing
the diacetyl rest in the primary after fermentation subsides.
Something to do with the lack of oxygen causing the yeast to
absorb the diacetyl (speeded up with a temperature boost). If
you rack to the secondary before the diacetyl rest, then some oxygen
will be introduced and prevent the absorption of the diacetyl.

My current fermentation schedule is (for ales):
1) 3 day primary fermentation at 65F.
2) 2 day diacetyl rest at 70F in the primary.
3) 7 to 21 days in secondary (in the coldest part of the
house) for clearing & dry hopping.

I haven't tasted any of the batches since switching to this
schedule, but I'm hoping that this schedule solves my diacetyl
problem. I did notice the strong butter-scotch odor emanating from
the air lock disappear during the diacetyl rest period.

Subject: RE: Wyeast 2112, counter pressure bottling

Hi All,

In HBD 1023, Rob Bradley asks:

>I'm planning an Anchor Steam clone. I welcome any hopping suggestions
>that have been tested, including unconventional ones.

Quite some time ago, someone posted to HBD describing a tour they had taken of the Anchor brewery in San Francisco. This post went into such detail that it sounded like a report from an industrial espionage mission. The poster reported that Anchor uses Northern Brewer for bittering and Hersbrucker for aroma. According to Fred Eckhardt, the bittering level is 40 IBUs. Anchor Steam(tm) :-)
also has a considerable hop nose to it, so dry-hopping is indicated.

Rob also asks:

>Has anyone else had the same problems Murray Robinson experienced with
>WYeast 2112? Maybe I'll have to change my weekend brewing plans :-)

Re-reading Murray's post(HBD 1022), my interpretation is that he was using liquid yeast for the first time, and was concerned that the *starter* was not showing much of a krausen.

Murray didn't specify the gravity of his starter, but my understanding is that starters with a gravity of 1.020-1.025 won't display much of a krausen. I've used liquid yeast exclusively for the past year or so, with starters of that gravity, and have never gotten the large krausen one normally associates with primary fermentation. At most, I see a small ring of bubbles around the edge of the liquid, and some bubbles coming up through the solution, yet I've always gotten good vigorous fermentations using these starters.

Coincidentally, I used Wyeast 2112 to brew an Anchor Steam(tm) clone this weekend. The temperature in my basement is 58-60, I pitched the yeast mid-afternoon, when I checked it just before bedtime there was foam forming on top and bubbles in the airlock. Looks good so far,

so my advice to Murray and Rob is to relax.

Also in HBD 1023, an interesting discussion between Al and Jack on counter-pressure bottling and carbonation.

Until recently, I was one of those people who bottled from the keg without a counter pressure bottle filler. Several HBDS ago, I posted a procedure for doing that which involved chilling the bottles and filling right to the top. These steps are an attempt to minimize the CO2 passing out of solution due to the pressure drop that occurs when the beer comes out of the tap.

A few weeks ago, I obtained a counter pressure filler, and I've noticed the same phenomena that Jack reported. Beers bottled with the counter pressure filler are much better carbonated than those bottled straight from the tap. I agree with Al's conclusion that counter pressure fillers minimize the loss of CO2 by keeping the beer under pressure during the whole transfer process.

Another advantage of the counter pressure fillers is that the bottle can be purged of oxygen prior to filling. When bottling straight from the tap, the presence of oxygen in the bottle assures

some amount of oxidation will occur, regardless of how quietly the bottle is filled. If the beer is going to be consumed within a short period of time, this may not be significant. However, if the beer is to be kept for several weeks, or submitted to a competition, I'd recommend a counter pressure filler.

One more anecdotal point about the filling straight from the tap method, it's not exactly foolproof. Some months ago, I went to a friend's house to help him bottle some beer from his keg. He had used forced carbonation, and had gone a little overboard, as he kept the beer under 40 psi at 40F. The beer was so highly carbonated, it foamed violently as soon as it hit the end of the tap, making it impossible to fill a bottle. After about 30 minutes of trying, all we had achieved was an incredible mess, one-half gallon of homebrew sitting in a catch basin, another half-gallon sprayed about his cellar floor, six bottles half-filled with foam, and two very chagrined homebrewers.

Cheers,
Jim

Subject: Plastic boilers

In regard to Jeff's idea to install a heating element in a plastic bucket and use that to mash/sparge/boil.

Well, I've got experience here. I've done just that. Twice. My suggestion is not to do it.

I did this for mashing - nowhere near enough heat was produced for boiling.
(I boil on a stovetop, and even wimpy stoves put out more heat than the element ever did) My experience with mashing in it was bad - the mash was too hot near the element and too cold away from it, stir as I might. Both of these Bruheat clones have been relegated to sparging duties, and I now do the mash and boil on the stovetop.

As far as structural integrity, I made these 2-3 years ago and just recently one sprang a leak around the spigot. No worries there!

In sum, I advise against.

From: arf@ddswl.mcs.com (Jack Schmidling)
Subject: Mash Thickness

To: Homebrew Digest
Fm: Jack Schmidling

After reading an interesting article on barleywine by Micah in the current issue of the Celebrator, I began to wonder about the reasons for thick mashes. He recommends using a megadose of malt in a mash of about normal consistency, to produce a high gravity wort without sparging. George Fix has also written about the advantages of minimal sparging.

So I ask, why do we sparge at all? Why not just mash 10 lbs of malt in 10 gallons of water, drain it off and start boiling?

The search through my references was not very satisfying on the subject. It seems that the most repeated reason is that the enzyme efficiency is reduced. But like so many other "problems" that claim this as the evil, the solution is to simply mash a little longer or use more malt.

Noonan goes one step further and says a "thick mash improves enzyme performance. In a thin mash, proteolytic and other heat-labile enzymes are destroyed in the course of the rest: in a thick mash, they may survive into the saccharification range."

This makes no sense at all. It reads more like a description of the survival rate of wildebeasts as a result of herding than of chemistry.

Can anyone support this legend with actual experience?

Sparging is a "simple" and efficient way of extracting the sugar from the grain but all other things being equal, it would be more convenient to use a thin mash and just a small final sparge to rinse out anything left behind.

It would also greatly simplify that first plunge into all grain beer.

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: SN clone recipes, fruitiness revisited

I posted in HBD 1021 about my Sierra Nevada clones and asked questions about fruitiness. Some people have asked for recipes:

Pale Ale	Porter	
7 lb	7 lb	UK 2-row pale ale malt (Munton & Fison)
1 lb	1/2 lb	UK 2-row crystal malt ("Wine Inc." brand; Lovibond=?)
----	1/2 lb	UK 2-row chocolate malt ("Wine Inc.")
1 3/4 oz	1 oz	Cascade flowers, 1 hour boil (all hops 5.5% alpha)
1 oz	1/2 oz	Cascade flowers, 30 minute boil
1/2 oz	1/2 oz	Cascade flowers, 15 minute boil
1/3 oz	1/2 oz	Cascade flowers, add after boil & steep 15 minutes
1/5 oz	1/5 oz	Cascade flowers, dry hops

Wyeast 1056 for both

1048	1050	Original gravity
1012	1014	Final gravity

Day 6	Day 6	Rack to secondary
No fining	Day 7	Gelatine finings
Day 6	Day 8	Add dry hops
Day 12	Day 18	Bottle

Infusion mash: Strike with 2 gallons at 167F
Hold at 150F for 75 minutes
Mash-out at 172F.

Sparge with 4 gallons at 172F.

Brew length was slightly more than 5 gallons.
Exactly 5 gallons racked to secondary.

What I would change: For the porter, nothing :-)
For the pale ale, I would use Perle (as SN does) in the first hop addition and fewer HBUs of it. 1 ounce of Perle at 7.6% was suggested by Brian Batke. He also suggested Perle for the 30 minute addition.

Other notes: I like the effect of a 15 minute steep after the boil; some might worry about DMS. Some would think 5 grams of dry hops insufficient; perhaps I would use more if I didn't have the steeping hops. The slightly higher yield from the same weight of grist in the porter may be explained by a different grain bag (you may recall I lost my Brew-bits bag)-:

Tony Babinec suggests that an all-Cascade pale ale of this sort is more in the style of Liberty Ale. I agree, but I would add even more boiling hops and finishing hops if I were trying to clone it.

Some have suggested that SN is not very fruity beer. I agree. The fruitiness I was referring to was subtle. The beer in question was about 60F. I had another SNPA this weekend. It had been in the fridge and then left at room temp for 30 minutes (so <50F?) and at that temperature, there was no evident fruitiness.

Plenty of hop aroma and maltiness, though.

Finally, I said in 1021 "Ultimately, fruitiness derives from the malt", or words to that effect, your honor. By this, I never meant to downplay the importance of yeast and temperature in ester production. However, the chemical constituents of the esters don't fall from the heavens, they come from the malt. I was only wondering if what effect, if any, the malt might have on ester production.

Cheers,

Rob (bradley@adx.adelphi)

From: Bruce Hoylman <bruce@advtech.uswest.com>
Subject: What exactly is oxidation?

I would like some information on what exactly is oxidation of wort and what are the effects (both ill and otherwise) on the flavors of the beer, how does it occur, how to avoid/prevent it, etc.

Also, now that I've got your attention here, I noticed a slight metallic aftertaste on my last batch (a wheat). It was only barely detectable, but definately there. What are some of the possible culprits that might have given the beer this characteristic?

If you email me I can post a summary. Otherwise, whatever flips your trigger.

Thanks for any input, and Peace.

Subject: Mashing & sparging from Micah Millspaw

Mashing/sparging problems?

>Causes I can think of are:

>1) strike temp was not high enough to gelatinize the starch

If this was actually the temp it should not be a problem, I've seen my highest yeilds from lower temp mashes 148-50 F.

>2) the crush was actually too coarse (I WANT a roller-mill!!!! Santa???)
)

This is probably less than ideal but is not as likely a culprit as would be a too fine crush.

>3) I should indeed have done a step-mash and raise the temp to 158 for 15 min.

at the end of the mash.

Yes, a mash out should help because it tends to get more sugars in solution

which makes for more effective sparging. I think that the mashing end of grain brewing is less of a problem than the sparging side, but it gets the blame anyhow.

>4) I sparges too fast.

This is possible but not usually a physical possibility.

>5) the mash was too tight. Miller recommends 1.33 quarts per pound.

> This was indeed the tightest mash I have yet done (Micah??? you say
> you usually use a rather tight mash.....)

What I consider a tight mash is 24oz water /pound grain and not to exceed 32oz/lb in a normal mash. The stiffer the mash (with in reason), better the more effective the enzyme activity. This also allows for more water to be slated for use in the mash out and sparge without add to the total amount of water used.

I would consider 1.3 qt/lb to be a very loose mash.

>6) As I said, this same sparging system has turned out 29-30 points, so I

> am pretty confident that I am not suffering from dead spots in the
> lauter-tun.

I would not change this system then, but I would look at changing the allocation of your mashing/sparging water.

micah

>Put the wine (or dopple-bock!) into a shallow vessel and cool to 32F.

>Place ice cubes into it and drop the temp below freezing. The ice

>cubes will act as a nucleus and draw water to it. Pluck the enlarged ice

>cubes out and add more ice cubes.

I would just like to point out that any atempt to concentrate alcohol

by any means, including freezing is not legal in the USA. And that
regardless
of the volumes involved, it carries the same property forfeiture and
penalties
as the manufacture of illegal drugs. So be careful with this topic.
Don't tempt the BATF!

If you have a plastic container that will stay structurally sound at the proper boiling temperature (a little above the boiling point of water because of dissolved materials), you will have to be sure that the element cannot come too close to the plastic.

|A quick experiment in which I filled my bucket with a couple of
|gallons of boiling water resulted in a slight softening of the
|plastic, but there were no alarming structural problems.

I would consider a slight softening with water that has started to cool down from boiling as an alarming structural problem.

1. The temperature during the boil will be a little higher.
2. A full batch will exert more force on the plastic than a couple of gallons.
3. The boiling time is probably longer than your test.

If you are still intent on trying it, I'd suggest a test run using the more water than you intend, adding salt to bring up the specific gravity of the water above what you normally use, and boiling for about twice as long. Maybe doing this whole test in a bath or wash tub and watching it the whole time would give you some confidence.

From: John Fitzgerald <johnf@ccgate.SanDiegoCA.NCR.COM>
Subject: leaving the trub in your wort

I know this has been covered before - about how the trub contains valuable food for the yeast - but I ususally ignored the issue because I wanted to get as much junk out of my beer as possible. So I usually siphon the cooled wort from the brew pot to the primary, leaving the slimy stuff behind. But this last batch I did something a little different.

I pitched the clear wort in primary with an 8 oz. starter of Wyeast European Ale (1338) that was at full krausen. I then took the muddy layer of trub, including lots of hops residue (from pellets), and transferred it into a sterilized 2 litre soda-pop bottle. I had about 1/2 gallon of mud. I added a few drops (8-10) of yeast that was left in the starter bottle, and placed the muddy concoction under fermentation lock.

Ten hours later very differnt things were happening in the 2 'batches'. The muddy half-gallon had separated into 1/3 sediment, 2/3 fermenting beer. The 5 gallons in primary hadn't done anything. The yeast came from the same source, the wort came from the same source, the temps were all the same, the only difference appears to be the trub contained in the half-gallon batch. I didn't try to estimate the volumn of the 'few drops' of yeast, but it seems that 8 oz in 5 gallons is a better ratio than 'few drops' in half-gallon. My last experience with batch 1338 took 24 hours to show signs of fermentation, but that was siphoned off the trub also. I ended up siphoning the active wort off of the sediment, and into the non-active batch, and sometime during the night the 5 gallon batch took off.

I'm not saying that this proves anything, but since I do 2-stage fermentation anyways, I'm thinking of leaving any cold-break material, hop residue, etc. all in primary and then siphoning off of it when going to secondary. I figure I will be at higher risk for producing chill haze, but it might be worth it.

Any comments/advice would be appreciated.

Subject: Brew Bees

Bob Jones brought up an interesting observation in regards to bees and garage brewing. I too brew in the garage, not out of choice but because of a fascist, anti-brewing female thing. Well, that and maybe the Wave of Wort debacle, but I'm sure its mostly the female thing.

I have bees visit when I brew. A lone bee will show up around mid-mash, soon to be followed by its friends. By end of boil the bees number about a dozen. They appear to like the wort and things that come into contact with it. The stirring spoon, thermometer and spent ph strips all get surreptitious inspections. When wort drips on the floor, the bees fasten around the droplets like spokes on a wheel. I assume its the malt sugar they're after.

At first I thought having bees around while brewing was a bad thing, what with sanitation and all that. I went so far as to try to rid the garage of bees via a badminton racket. It became a war of diminishing return and I soon gave up. Although the bees never noticed me running around in circles swinging a badminton racket, the neighbors sure did.

I once asked an entomologist friend about bees and brewing. He went on and on about nectar, chemical receptors, wind direction, sun elevation, hive dancing and food stores. All well and good I guess. The next-door neighbor's ten year-old explained it differently. She said that bees like sweet stuff. And they say the smart ones have college degrees.

I no longer mind having bees around when I brew. We both go about our own business. I'm careful not to step on them, I politely shake them off the utensils and I keep my pint covered with a coaster. In return they've never stung me and they've never once asked for free beer. Not yet anyway.

From: kensiski@nas.nasa.gov (David L. Kensiski)
Subject: can I rescue this batch?

A colleague and I have brewed a lager pilsner that suffers from a lack of carbonation. It tastes really great for about the first 10 seconds after you open it, then it goes flat. We have been experimenting with the amount of priming sugar in the batch; that's the likely culprit.

We brewed it way back in September, then fermented it for 6 weeks. The SG went from 1.042 down to 1.007, so the yeasties seem to have done their work. We then primed with 2/3 cup of corn sugar and bottled it. It's been in the bottles now for about 6 weeks.

But I'd like to try to rescue the batch. Can I just open each bottle and add a tad more sugar solution? If so, how do I determine how much and at what concentration? Should I add more yeast as well?

Any advice would be appreciated.
Thanks.

Subject: WYEAST 2112 - Problems Solved

Thanks to everyone concerned with regards to the apparent problems I had had with WYEAST 2112 - California Lager. What has become perfectly clear is that when using a liquid yeast you must allow the yeast to reproduce to the maximum extent in the original packet if you wish to avoid lag times in the starter culture and finally the fermenter. I must admit that I probably pitched my yeast into a starter for two reasons:

- 1) I had a new toy that I was itching to use and so probably pitched it a little early.
- 2) Autralians work in metric units not imperial so a 1 inch thick yeast packet is and arbitrary measure of thickness to me.

Premature pitching of the yeast from packet to starter IMHO obviously results in significant lag times (in my case more than 48 hours) which then exposes the starter to potential spoiling by harmful bacteria. Fortunately, my Munich Lager is now fermenting away furiously in the fermenter with no off smells or flavours.

thanks again,

MC

Subject: plastic boilers and hot water heaters and floating mashtuns

Hi all,

I have been thinking of a setup similar to that proposed by Jeff Berton in HBD1023 and based on a suggestion in Dave Line's, 'The Big Book of Brewing' for a floating mash tun. My setup is perhaps a little more ambitious (or is that over-engineered? :-)) The idea here is a vessel which can be used to mash and boil, and is constructed primarily out of food grade plastic.

Well, here goes... First off, a large FG plastic "boiler" is made out of a pail of capacity aprox. 75L (about 20 US gal). RubberMaid sells a garbage pail of this size but it is of commercial grade plastic (Anyone care to comment on the difference?) Install a tap and a hot water heater element in the bottom of the pail. An immersion wort chiller is placed into the boiler so that the coils run along the inside wall of the pail. To cut down on the time it will take to bring this water to a boil, a lid and insulation is also strongly recommended.

For the mash tun, a smaller 15L (about 4 US gal) FG plastic pail with an air-tight lid is used. A tap is placed in the base of this pail and it is fitted with a grain bag suitable for mashing in. (ie. Canvas sides/Nylon bottom)

The procedure is simple, First you fill the boiler with your brew water (remember to allow for the water that boils away). Bring the temperature up to your desired strike water temp. Draw off the needed quantity of strike water and adjust your thermostat to the temp required for the first stage of your mash. Add your strike water to the goods in the grain bag, contained in your mash tun. Seal the lid and submerge in the boiler when you reach the desired temp. Allow the mash to complete. After the mash, remove the mash tun from the boiler and adjust thermostat to sparge temp. Transfer the sparge water to another vessel and sparge through the mash tun back into the boiler. Boil your wort. when it's finished chill and drain into a primary.

Benefits:

- 1) inexpensive
- 2) mash/boil in one
- 3) no need to pre-boil water, chlorine will be liberated during the mash

Problems:

- 1) Carmelization of the wort. (as Jeff suggested)
- 2) Long time to raise water temp with electric heating elements

Possible Solutions:

- 1a) Use a thermostat similar to the one in the Bruheat setup, where the heating element is pulsed so that the wort is not in prolonged contact with the hot element.
- 1b) install a stirring mechanism to the boiler (also would help in reducing "hot spots").
- 2) use hot water heater elements rated as high as your household wiring will support.

BTW, when using immersion heaters of high wattage, it is a

good idea to keep everything WELL grounded (you know that third prong on an electric plug...) as to give the electricity an easier path to travel to ground than through you if it feels so inclined! Furthermore, calculate what current you will be drawing and install a fuse rated to that current. ie. use $I = P/V$, where I is the current the fuse should be rated for, P is the power of the element in Watts, and V is the voltage supplied by your household circuits. (for standard circuits , 120V, for electric stove/dryer/etc.. it is 240V)

Any insight/comments/concerns/criticisms/etc... would be appreciated.

P.S. sorry about the length, I'll try not to ramble on next time.:-)

From: parsonsl@husc.harvard.edu
Subject: Cleaning blowoff tubes

In the last HBD, Dave Ballard expressed an interest in the glass blowoff tubes which are advertised in Zymurgy. I don't remember the name of the company which makes these, and all my Zymurgy magazines are 20 miles away :(. Anyway, Dave was interested because they would be easy to clean. I suggest, as an economic and equally easy alternative, using Iodophors for sanitation purposes in your brewing. At a rate of 0.1 oz per gallon, these things not only kill every little beastie around, but they also dissolve organic garbage on your equipment. Thus soaking a nasty tube in this solution is an easy way to clean it. Another nice thing about iodophors is that you don't have to rinse them off. Just let them dry on their own, or even leave the equipment wet (including fermenters, starter bottles, or anything).

You can get a year's supply of this stuff for about three dollars, and cut the cost of b-brite, chlorine, or whatever you use now.

Subject: making spice extracts

Dear Brewers,

'Tis been a while sinse I last posted to this forum, and it's good to be back!

A while back I and some others (Erik, are you there?) were discussing the making of a Christmas Ale with the addition of a spiced extract to flavor the brew with a Swedish Glo:gg essence. Erik mentioned that he had a few 25 ml. bottles of 65% alcohol Glo:gg essence (extract) and planned to add one or two to his brew just before bottling. I, on the other hand, couldn't fine any such bottles, even though I live in a section of Chicago known as the Swedish Village (Andersonville). The best I could do is find Glo:gg "mixers" to which are added wine and/or vodka, and the raw spices.

I opted to get a bag of these spices - cinnamon, cardamom seed, rasins dried orange peel, and some others I can't remember now - and a bottle of Ever Clear grain alcohol to soak them in with the hopes of making my own "extract" or "Glo:gg essence". Here's the question, though: How exactly do I go about making such an extract? I know there's some soaking/steeping of the spices involved, but for how long? and at what temperature (if at all a concern). Plus, wouldn't I need to press the spices to squeeze the flavors out of them after steeping? Then, what about diluting the extract a bit so that it's addition to the brew before botteling doesn't completely kill off any yeast that are still at work (rendering a flat brew) and/or overpower the flavor of the ale with the spices.

As you can tell, I'm completely in the dark on this one. I've already brewed the ale (a relatively heavy (O.G. = 1.056) nut brown) and it's resting comfortably in the primary. I plan to rack within the next few days, and bottle within a week or two after that, so there's still time.

Thanks,
John

Subject: Bay Area Brewoff Competition

***** Competition Announcement - Bay Area Brewoff *****
**

This is your second notice for the Bay Area Brewoff hosted by The Draught Board homebrew club. This is a medium size competition, last year we had 150+ entries. We always have good, experienced judges at this competition.

The competition will be held at Lyons Brewery in Dublin, Ca. The competition will be held on Jan 23, 1993. Last year we had a Holiday beer category as an experiment. The response was so good, we are going to do it again.

The entries are to be shipped to arrive the week of Jan 2-9. An entry consists of two 12 oz bottles. Entry deadline is Jan 9, 1993. The entry fee is \$5.00 per entry. Label each entry with the category, your name, address, phone number and club affiliation, if any. For entries in the Holiday Beer category, specify any spices/herbs/special ingredients used. For entries in the Mead category, specify melomel, cyser, or metheglin as necessary. If you have any questions, you can call John Pyles (competition coordinator) at (510) 791-0589.

Entries should be shipped to -

Lyons Brewery Depot
7294 San Ramon Road
Dublin, Ca. 94568

The categories are as follows -

India Pale Ale
Pale Ale - American & English
Dry Stout
Porter
Barley Wine
Amber Lager (Steam style)
Mead (all types)
Holiday beer

Subject: "bees" are not bees

I'm going to guess that what most people think are "bees" are not bees. If small, they are probably yellow jackets, and if large, they are probably hornets. Both are in the wasp family, with yellow jackets nesting in the ground and hornets nesting in trees, eaves, and so forth. The nests are typically "paper" made from chewed wood. A bee nests in a hive, which it builds from wax secreted from wax glands. A tell-tale sign of a bee is a pollen sac at the point where the hind leg joins the body. Most bees you see outdoors are busy collecting nectar or pollen from flowers. Adult yellow jackets and hornets are most likely searching for food, which for them could be something sweet (soda, ripe fruit, wort) or the typical American picnic food. Their population swells through the summer and into fall, at which point the first good freeze kills all the buggers except for some fertile queens, who will start another colony the following spring.

Date: Wed, 2 Dec 92 10:29:14 CST
From: tony@spss.com (Tony Babinec)
Subject: hops & pot thread

I'm surprised no one pointed out an obvious parallel between hop and hemp. The female hop plant is valued for its "flowers." It is kept segregated from the male plant so as not to seed. The hop cones become the collection point for the sticky resin so prized for its alpha and beta acids that contribute the bittering, flavor, and aroma to beer. The female cannabis plant is kept isolated from the male plant so as not to seed. The plant secretes a sticky resin which contains the substance THC which has the mild "stimulative" qualities for which pot is consumed.

Subject: quality of extract varies wildly

A number of HBDers have posted requests for what could be termed "consumer information" on available extracts. There hasn't been a response so far. I'd like to make a comment that covers what is probably familiar ground for some brewers.

Malt extract can be defined as concentrated wort prepared from malted barley. Extract syrup is liquid, while dry malt extract is dry. Either type is created by some form of evaporation. Ideally, the malt extract has a very similar carbohydrate spectrum to the wort that all-grain brewers obtain from a mash. When added in measured amounts to water, the extract ought to produce a wort "as good as" one obtained via an all-grain mash. However, because of a lack of ingredient labeling, and variability in how extracts are actually made, the naive user doesn't really know what s/he is getting, and is not necessarily going to be able to produce a good wort.

Professor Mike Ingledew of the University of Saskatchewan reviewed over 40 different commercially available malt extracts and compared them to malt wort. He performed chemical analyses on the samples, and he ran standard fermentation tests using a dried yeast. I don't have access to his report, but it was summarized in the Winter 1991/92 Lallemand Newsletter. I believe there was also some write-up in *Zymurgy*, but I don't have my issues with me. Here is a summary of some of his findings.

In all cases, the malt extract brews did not ferment as fast as the commercial wort. The standard 12 Plato wort finishing at 3 Plato fermented out in 51 hours. The average for the extract brews was 75 hours, with some extract brews taking as long as 173 hours.

The Free Amino Nitrogen in the extracts varied from 80 to 317 mg per liter. One industry standard is 120 mg per liter. Too low a FAN measure, and the wort has insufficient nutrients, which can lead to fermentation problems such as slow or stuck ferments as well as problems with head retention in the beer.

Ingledew divided the worts into 3 categories based upon contents as declared either on the package or by the vendor:

- pure malt extract,
- barley syrup with or without malt extract,
- malt extracts with sugar hydrolysed starch adjuncts.

Using high pressure liquid chromatography, he obtained the carbohydrate spectrum of the worts expressed in terms of fractions of D-glucose, D-fructose, iso-maltose, sucrose, maltose, malto-triose, and malto-tetrose.

In the "pure" malt extract group, some had about 2.5 times the glucose one would expect. This might have come about if the producer of the extract used a long saccharification time, or added alpha amylase to the mash, or had simply added glucose. Another set of extracts had up to 88% of its carbohydrates as glucose. This group showed no D-fructose, sucrose, maltose, or malto-triose. Apparently, it had been highly adulterated with glucose on purpose or was perhaps mislabelled. So, in other words, as the buyer you

think you are using malt, when for all practical purposes you are using corn sugar.

The barley syrup extract group was generally in line with what should have been expected except that dextrans were a little bit higher.

The malt extracts with declared adjuncts group varied wildly. Some were labeled as containing glucose or corn syrup, and showed the presence of glucose and dextrans but no maltose--a malt with no malt!

In sum: no names were named, but the message is "Buyer Beware." In a sense, things have never been better. We have great malts with known color ratings, hops with labelled alpha acid ratings, and yeasts with freshness dates. On the other hand, there is still woefully too little known about much of the available supplies. Homebrewers and commercial brewers ought to press the retailers, wholesalers, and ultimate suppliers for more information as well as truth in labeling. Reputable suppliers ought to be congratulated and patronized, while the others should cease to be!

Extract brewers ought to move at least towards partial mashing. Use a syrup or dry malt extract from a reputable supplier. Use light, unhopped extracts. Obtain color by added grains, and do your own hopping. Use specialty grains and perform a partial mash for a better wort. This conclusion comes not from any bias towards all-grain brewing, but because of the greater control over ingredients and process.

Kevin Krueger asks for style and recipe information about Sprecher's
Black
Bavarian.

I was chatting with Charlie Papazian during the pre AHA Conference bus
tour in
June when someone thrust a bottle of BV between us and asked, "What kind
of
beer is this, anyway?". Both Charlie and I were hard pressed to give a
definitive answer. It is promoted as a lager, in the German style (all of
Randy's products are supposed to be German in origin), however it is far
too
roasty to fit any existing category. If it were given to me in a blind
tasting
I'd probably call it a porter in the traditional sense, tho it would be
under-hopped for that style.

I have no idea what the grain bill or hopping rate is for it.

Subject: Lambic Alert

It appears that beers from the Brasserie Cantillon are now available in the Washington, D.C. area. Just a few minutes ago I was speaking with someone at Cairo Liquors (17th Street near P, 202-387-1500) who had splits of Kriek and Lambic. I can't get up there until Friday at the earliest (hmm, could call in sick. . .), so I don't know who the importer is. My specialty beer sources in Virginia haven't heard of the stuff. Further reports will follow if nobody beats me to it.

total
> cold break settles in the first hour (it seems to take much longer).

The cold break I get usually settles out in about 15 minutes,
at least when doing all grain. It's a little slower when using extracts,
and doesn't happen at all unless I boil the *\$%^ out of the wort.
I almost always bring to a good rolling boil for 2 full hours,

Up until my last batch, I would pour the wort through a strainer
to remove the hops into a 6-gal fermenter, pitch the yeast & shake
to aerate, let the break settle, and rack into a 5-gal fermenter,
and re-aerate.

With the last batch I brewed, after cooling, I created a whirlpool
in the kettle, let the break settle, and then racked off the hops
and cold break into the fermenter, pitched the yeast & aerated.
I plan on doing this in the future, since I didn't spill a drop,
and cleaning up took about an hour less than it usually does.

Don't bother with seeds & stems, they don't have any 'fun' stuff in them, and your beer will taste pretty lousy. Simply use buds & trim leaves as a hop substitute with a late dry-hopping. Don't boil or cook. Since the alcohol is doing the extraction, its best to use a strong beer. The better quality of ingredients, the better tasting beer.

Your best bet is to befriend a grower, and get his final trim leaves (the tiny leaves that are pulled from buds, but have lots of glands stuck on them, but taste lousy to smoke). You can usually get these for free in exchange for a bottle or two of the finished product.

Ask Michael Jackson about 'Brain Death Barleywine' someday. It seemed to make quite an impression on him.

Subject: Wyeast . . . I need help.

I am trying Wyeast for the second time and am a little concerned as my first attempt failed. So I guess I am a little gun shy or over-worried about some stinking yeasties. However, maybe someone can see a potential problem or relieve my yeastly concerns.

I have the "break the seal, wait until package is 1" thick" routine down quite well. I am confident I did that right. I mixed the yeast with an 85 degree solution of 1 cup water and two teaspoons of m.e. and airlocked it in a sterile bottle. I saw activity in one day. The activity stopped at the end of the same day. Did it run out of food ??

I prepared the wort the next day. Threw the yeast mixture (70 degrees F) into the wort (78 degrees F) and there has been no activity for 12+ hours. I guess I am curious what stage my yeast ended up at in the bottle and what happens to it when I pitch it. I have heard that I should pitch at krausen so my yeasties are active when introduced to the wort. On the other, there are other theories about pitching the stuff, so I guess there may be no right answer. However, I have a little sheet from my local homebrew shop about starting yeasts and I'd like to post here for any comments. It is supposedly reprinted from some big yeast co. like Red Star. The interesting info. on the sheet is the fact that they recommend restarting the yeast with water only. I'll post tomorrow for any comments.

It seems to me, at this stage anyway, that the dry yeast is almost worry free since you know right away if it started. I guess I'm paranoid because I paid three bucks for this stuff and it didn't work last time. S'pose I shouldn't worry since . . . since . . . I AM A HOMEBREWER !!

Regards,
Kevin

Subject: Caramel from Kraft

To: Homebrew Digest
Fm: Jack Schmidling

>From: martin@gamma.intel.com (Martin Wilde)

>I would like to get a big caramelly taste from the usage of Crystal (Caramel) malt.

That is something that has alluded me also. I had just about concluded that the only way was to drop a Kraft cube into a glass of beer. It seems that most of the variations in crystals are there simply for the color freak. They taste pretty much the same.

On a recent trip to Tim Norris to pick up some Belgian malt, he talked me into chewing on a bit of Cara-pils and it set off all sorts of bells. It is very hard to chew but once it gets worked over, it is most interesting. Instead of crumbling and dissolving in the mouth like other malts, it gets gummy and chewy. It also has a taste all its own and may be what you are looking for.

Not being very subtle, I used two pounds in the first (7gal) batch along with a pound of regular (Cara-vienna) crystal and the result was stunning but a bit over done. I hesitate to use a loaded word to describe the taste because it will lead some to assume that it is infected but it had a strong flavor of bandaids during primary and when pumped to the secondary. Not the least bit unpleasant but probably too much at this point. Don't know if it will mellow out upon aging but the bandaid flavor is pretty much what the malt has when chewing it.

In the last batch, I only used one pound of Cara-pils plus the pound of Cara-vienna and I may chip this one in stone. It's been in the primary only two days and I can not keep away from that evil little spigot. This is already, without a doubt, the World's Greatest Beer.

I would be interested in hearing what others have to say about carapils, what it is, how it is made and a more euphemous description of the flavor it imparts.

BTW, this stuff is straight from hell as far as crushing is concerned. It

takes a gorilla to turn the crank of a fully loaded mill but I find that just sprinkling it in while turning the crank works just fine. A second pass through the mill also helps get a better "crush".

Subject: Freezing to concentrate alcohol

Just to follow up on Micah's comment yesterday...

It should be pointed out that freezing not only concentrates the ethyl alcohol, it also concentrates some of the more toxic compounds (known as heads and tails in distilling jargon) that exist in the ale/wine/etc/ as well. These include fusel alcohols, ketones, aldehydes, etc.

When this was done to hard cider, the result was known as cider oil, large quantities of which, over a period of time (constant consumption, I'm ignorant of the specific pharmacology) were definitely toxic.

From: djt2@po.CWRU.Edu (Dennis J. Templeton)
Subject: Bleaching action of Campden tablets

I haven't seen Campden tablets mentioned in this forum... maybe for good reason, but here is my latest tale of woe.

I've wanted to use the raspberries from my garden to make a raspberry ale (no, not a lambic, just a wheat ale tinged with the color and aroma of the berries) so I set one up last week. I started with a 1.056 wort from 60% wheat flakes and 40% belgian pale malt, and hopped with 1 oz of cascade. Using Wyeast 1056, it fermented well.

After the krausen fell, I wanted to add the berries and let it ferment out. I took 2 quarts of fresh frozen berries (I know, more would be better, but that's all I had) and picked through them. I know that some of them had the tiniest spots of mold on them when they were picked, and I didn't want to contribute these wild fungi to my brew, so I wanted to sterilize them. Papazian recommends "Pasteurizing" fruit, but the high temp may liberate the pectin (o.k., so raspberries are very low in pectin anyway) and I chose instead the method winemakers use to kill wild yeast and bacteria, Campden tablets.

The berries were crushed in a total of 1/2 gallon, and were bright red. I added 2 campden tablets (the label suggested 1-2 per gallon, but I wanted to be *sure*) and within minutes the color had faded to a pale wimpy yellow :=(

The mixture still smelled of raspberries (and the SO2 from the campden tablets too) when I added it to the wort a couple of hours later, but the color seems to be gone for good. The fermentation is still bubbling steadily the next day.

I presume that the Sulfite from the Campden tablets has bleached the red from the berries... has anyone else observed this? is it because I used too much? Do winemakers risk losing the color from their fruits too?

and the biggest question.... will he add food coloring to this batch (gaack!)

Anyone with insights or similar experience is welcome to reply...

thanks

dennis

From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: Chemistry and Beer

Paul dArmond recently wondered about the use of thiosulfate to destroy bleach, and thought that perhaps he didn't want the products of this reaction in his beer. I beg to differ somewhat.

The reaction of bleach (sodium hypochlorite) and thiosulfate or bisulfite or other related compounds gives as products sodium sulfate and sodium chloride plus a small amount of water. It is possible if there is excess thiosulfate present with respect to bleach that some sodium sulfite or sodium bisulfite will be produced. Bisulfite is commonly known to brewers as Campden tablets. I don't intend to discuss whether one wants to use Campdens or not, but the point is, chloride, sulfate, and possibly (bi)sulfite are not things which one would not expect to find in beer etc.

So, the method of destroying bleach described by Paul would not be expected to cause trouble unless one had such a large amount present that the chloride and sulfate products were in excess of the desirable amounts in beer.

I would also like to remind all of us that just because something has a "chemical" name doesn't mean it is some horrible poison. Everything we do as brewers is a CHEMICAL REACTION, and everything in our beer and indeed around us in our daily lives is a CHEMICAL. I am not criticizing Paul for his comment, but that comment betrayed a common feeling that there is a difference between CHEMICALS (BAD) and OTHER THINGS (POSSIBLY GOOD) and that as a brewer one wants to exclude CHEMICALS (ie bleach, Campden tabs etc) but it is ok to use for example chalk (calcium carbonate) or epsom salts (hydrated magnesium sulfate) or salt (sodium chloride) etc.

Enough of that. ANTI DISCLAIMER FOLLOWS: I am a chemist, I make all my money from chemistry and chemicals.
DISCLAIMER FOLLOWS: I do not approve of pollution or unnecessary use of synthetic products. Don't get me wrong...

From: akcs.chris@vpnet.chi.il.us (chris campanelli)
Subject: Homebrewing Hubris

Every once in a while I am confronted with a deeply troubling situation. It involves a homebrewer who beats up on a non-beer drinker. This situation usually presents itself in two forms, the first being a homebrewer who forces a homebrew on some poor soul who has clearly stated a negative desire to try such a product and the second being a homebrewer who scoffs and ridicules the other fermented beverages such as wine and champagne and the people who drink it.

This deeply disturbs me as it ultimately hurts homebrewing more than it helps.

These qualities often embody the novice homebrewer but not exclusively. A novice homebrewer can be excused as he is simply acting out the age-old role of over-zealous champion of a new religion. The experienced homebrewer who is guilty of such action deserves far worse as its clearly a case of snobbism.

In the case of the homebrewer who forces a beer on a non-beer drinker, I can only say that it's a horrid example impoliteness. If one in your company clearly refuses to try a homebrew, fine. Let it go. Respect the choices of others.

For those homebrewers who ridicule fermented beverages other than beer, their loss. They're missing a great and varied spectrum of flavors and sensations. Wine is the blood of the earth and champagne is the gunpowder of festivity.

I'm by no means a saint. I'm guilty of those crimes associated with being an over-zealous novice. I remember with absolute clarity how, years ago, I forced a homebrew on my in-laws. Neither of them liked the homebrew and neither have asked for a homebrew since. If I had held my in-laws in a headlock, pinched their noses closed and poured the homebrew down their throats, it probably would have been a far less damaging act.

I have since learned a more subtle approach to introduce people to homebrew. It's based on a simple observation of mine that curiosity outlasts coercion. When having guests over, I find it easier to place all the beverages out so that people may help themselves. Gee, somehow the homebrew got put out as well. Eventually someone notices the "plain brown wrapper". A capped beer bottle with no label? What is this? One thing leads to another. In the end the guest's own curiosity does more than all of the homebrewer's coercion could ever do.

As homebrewers we have a responsibility to promote homebrewing and to financially support quality commercial brewing. Diplomacy and civility are the tools with which we must work with although sometimes a smidgen of cunning helps.

Dave Ballard writes:

> ... I curently use a 1" i.d. tube that works really well
> but is a total bitch to clean,...

Try this:

Put the hose in a sink, so that both ends are up -- a 'U' shape. Boil about 1 cup of water. (I use a Pyrex measuring cup in the nuke to make it easy to pour.) Put about a teaspoon of DRY dishwashing detergent in the hose, and pour in the hot water. The gunk should dissolve within a few minutes. For especially messy batches, sometimes two treatments are required, but I have never had to scrub. Some sloshing helps to loosen the stuff, but don't forget that the water was boiling not long ago.

Brew long and prosper

Date: Thu, 3 Dec 92 00:23:42 PST
From: Richard Childers <rchilder@us.oracle.com>
Subject: Apple Cider - The Saga Continues

I've gotten enough response that I'm guessing others are interested in the cider experiments I've been doing recently, so I thought I'd summarize my recent tests.

I've been waiting for the most recent batch, bottled in 22 oz. bottles, to become drinkable. Generally, I test for 'drinkability' by examining the cap curvature - if it is depressed, or concave, it has room for further natural carbonation. If convex, IE, puckered upwards, it's definitely ready. (I like my homebrews with a head.) This also helps identify bottles ready to blow ..

I have another batch, made strictly from those yeasts on the apples when they were pressed, acquired from a batch of unpasteurized apple cider purchased in Northern California. As has been noted previously, this natural yeast population is not composed of one strain, more, many strains, possibly even a complex ecosystem unto itself in the wild. I'm brewing cider to see what the difference in taste between natural and Champagne ciders might be, and I'll see if it's possible to maintain this culture across multiple generations - or, using that starter culture, to evolve towards another culture derived from the first one that is stable and produces quality cider, if the culture as it is, is not a stable ecosystem within the microclimate that is the cider jug.

It occurs to me that a microecosystem composed of many interacting parts might be more resistant to mutation, as each niche occupant would be dependent upon its divergent - but still coresident in the ecosystem - niche occupants, which would collectively reject it from the ecosystematic interchange - IE, refuse to participate with its nurture, and thus, cause it to not flourish, where those which did not diverge from the norm, as enforced by N divergent but related microorganisms, would flourish ... a sort of additional natural selection.

That is, where a single culture might be subject to mutation, there might be in the set of all possible combinations of yeasts, certain yeasts which, when

combined in the correct proportions, formed stable ecosystems naturally
resis-
-tant to mutations, using the above mechanism. A home brewer's dream,
and per-
-haps an explanation for why, long, long, ago, brewers seemed to have
selected
for such combinations (a mysterious business, no one seems to know how
these
came about as far as I know, they're kind of hand-me-downs from whomever
start-
-ed thew brewery or acquired from other breweries) - or Nature helped.

Speaking of nature, maybe I should publish in Nature. (-:

Back to cider ... the latest batch was made with champagne yeast, and
although
it's not yet fully carbonated, it was effervescent, with many very
small
bubbles throughout and a deliciously sweet, fruity taste, the bubbles
likely
a consequence of the champagne yeast.

I've been recycling the champagne yeast and the batches seem to be
evolving
towards an improved quality ... or maybe I just waited longer this time.

From: "Bob Jones" <bjones@novax.llnl.gov>
Subject: Brewing Safety

As Wayde Nie pointed out in the last HBD brewing safety IS important. I like beer, but I wouldn't give my life for it. I would not use ANY electricity around a brewery setup of any type without all electric devices

being connected through a GFI. Water + electricity = DEATH! I have had several thing in my brewery cause the GFI to trip, possible saving my life.

I don't think safety is mentioned often enough to brewers, I ask Terri Farendorf to give a talk on safety at an AHA conference several years ago.

She did mention safety in her talk, however, she seemed hesitant to preach

about it. She was severly burned with hot water at a brewery. There are lots of thing to get you while brewing, hot water, breaking glass, electricity, heavy objects on your toes, grain mills milling your fingers,

high pressure CO2 tanks, gas explosions from propane or natural gas, etc.

Think about safety before relaxing,

Bob Jones, stepping down from soapbox

> them. I went to the beer store to buy some long-necks and noticed
> something. All of the longnecks from the big guys had SCREW-ON caps.
> Is this just in our area, or has someone else noticed it?
> (Please, no preaching.)

I think that you'll find that the biggies make two types of longnecks.
The
first type, the kind you saw, are for sale to the general public. The
second
type are sold to drinking establishments and are often called (at least
in this
part of the country) 'bar bottles'.

The first type have twist-off caps, and are intended for disposal or
recycling.

The second type use the traditional gotta-use-a-bottle-opener crown cap,
and
are intened for reuse. They tend to be much sturdier than the first
type,
because they are to be reused (refilled), as opposed to recycled, where
bottles
are melted down to make new bottles.

Anyway, the upshot is that you want the second type and not the first.
You
might find them at a liquor, but more likely you won't. You will be able
to
find them at a bar or restaurant. The trick is to get someone to give or
sell
you the bottles.

By the way, these bottles usually come in heavy duty, waxed cardboard
cases
that are quite good for the storage of homebrew.

Subject: Yeast . . . who is right ??

As I stated in my previous post on HBD, I am relaying the info. for restarting yeast that was given to me by a homebrew store. I am doing this because I am confused about when to pitch yeast in the beer. I have heard two different stories and I believe there is a correct answer since yeast culturization is supposed to be a science. Here goes it . . .

"To rehydrate, use water only, not wort, approximately 1/4 cup water to 1/4 oz. yeast. The optimum temperature range is 104 to 115 degrees F. Temperatures below 84 can create "cold shock", and too hot a temperature can kill the yeast cultures.

- 1) Add the yeast to water, not water to yeast.
- 2) Allow the yeast to sit in water for 5 to 10 minutes before stirring, never longer than 30 minutes.
- 3) If the wort temp. is 16 or more degrees greater than starter temp., gradually add quantities of wort to yeast, waiting 5 to 10 minutes between additions.
- 4) Add starter to same temperature wort to avoid phenolic aroma and plastic taste."

Now correct me if I'm wrong, but Papazian's book says that the wort should be 78 d. F or below in order not to kill the yeasties. I have always done it that way, but my homebrew store guy says that it is not correct yeast technique.

Does anyone have any thoughts on this ?? Any references would be great so as I can have a clear mind on yeast.

Kevin

Subject: sprecher black bavarian

Russ Wigglesworth mentions Sprecher Black Bavarian in a previous HBD. A number of us in Chicago are big fans of that beer--it's arguably Randy Sprecher's best beer. I think of it as being roughly in the Kulmbach style. In broad terms, this beer is "bigger" than a Munich Dunkel, and gets some of its color and flavor from highly roasted grains. Randy has described the grain bill on brewery tours, but I don't recall it

now. Russ's characterization of BB as a lager counterpart to a porter is probably a good one. Between Sprecher Black Bavarian and Lakefront's East Side Dark, Milwaukee has two delicious dark beers with way more character than American Dark or the popular imports (e.g., Beck's Dark). The only difficulty is getting your hands on these beers, as they are only available in the Milwaukee area.

Subject: Re: making spice extracts

XLPSJGN%LUCCPUA.bitnet@UICVM.UIC.EDU writes about trying a gloegg essence from scratch:

]I opted to get a bag of these spices - cinnamon, cardamom seed, rasins
]dried orange peel, and some others I can't remember now - and a bottle
]of Ever Clear grain alcohol to soak them in with the hopes of making
]my own "extract" or "Glo:gg essence". Here's the question, though:
]How exactly do I go about making such an extract?

first, the beer will do a fine job of extracting flavors and odors from the spices on its own: i've simply added them at the end of the boil and let a few bits float in the primary.

Second, (if the beer's already brewed), try making a tea with the herbs: boil them in water for 5 or 10 minutes, and add the tea to the beer.

Third, (if you're dedicated to making an alcoholic extract), there are several ways to go. The easiest is to simply put the spices and alcohol in a jar and leave it be for several weeks or several months. Swirl the jar every so often. A somewhat faster method is to use a double-boiler to heat the alcohol and its contents. Do not let the water in the heater pot boil! The ingredients will still have to cool and steep for a while. Note that the final alcoholic content of this stuff will be far greater than the 65% of the commercial gloegg mix: you will have to thin it down with water (and possibly sugar if the commercial gloegg mix is sweet).

I would be wary of adding alcohol to beer, because the final mixture combined at bottling time might kill the yeast and produce a batch of flat beer. Since there are other methods of adding spices to beer which are known to be successful and require less work, making an alcoholic extract seems extravagant.

Subject: Starting liquid yeast

In #1025, Kevin asked why his starter cultures were wimping out. First of all, you should add 2 tablespoons, not 2 teaspoons of dme to 1c. of water. You probably aren't giving the little beasties enough to eat with just 2 tsp. The paper you got from Red Star recommends restarting yeast with water. This would be useful advice if you were using dried yeast (which needs to be rehydrated before primed). There is no point in adding plain water to a liquid culture.

From: tony@spss.com (Tony Babinec)
Subject: belgian cara-pils/belgian malts/revival porter

The Belgian Cara-Pils ARF mentions in a previous HBD is best thought of as a light crystal malt. It has a color rating of 8L. It should not be confused with U.S. Cara-Pils, which has very little color, is very hard and "glassy," and is generally used to add dextrins, and therefore body, to the beer.

It seems that the way to get caramel/crystal malt flavor is to add larger proportions of a lighter crystal malt to your grain bill. The Belgian Cara-Pils, at 8L, and Belgian Cara-Vienne, at 20L, are two good lighter crystal malts for this. Being crystal malts, these malts can be steeped.

To get malt flavor, use Belgian Munich (8L) or Belgian Aromatic (25L), or equivalent German light or dark Munich malts, in some proportion. Note that these malts must be mashed.

The Belgian Biscuit malt can be used in recipes that call for "amber" malt. It has a color rating of about 22L, and has a "biscuity" flavor.

To make "brown malt," take pale ale malt and toast it in your oven for 50 (that's right!) minutes at 400 degrees F. This is a suggestion from Randy Mosher.

Some old recipes for porter called for 9 parts pale malt, 5 parts amber malt, 5 parts brown malt, and 1 part black malt. So, in that spirit, we offer the following recipe:

Revival Porter

5 pounds pale ale malt
2.5 pounds amber malt (Belgian Biscuit)
2.5 pounds brown malt (homemade, see above)
0.5 pound dark (80L or dark) crystal malt
0.5 pound black patent malt

10-15 HBUs Fuggles for bittering, plus whatever flavor and aroma additions you want

ale yeast

Your mileage may vary with the above grain bill. Also, given that this is a revival porter, you might adjust the grain bill so that your starting gravity is higher, say 1.070, rather than adhere to current AHA porter style guidelines. You'll be brewing a stout porter.

Subject: Spray malts ?

The last two batches I have attempted to make a bitter similar to Red Hook. I have purchased bulk (55 pounds) of Laaglander Extra Light spray malt, my problem is that both batches OG were 1.050-1.055 and finished at 1.028. I used both a Wyeast (Irish) for first batch, and Muton and Fison dry (2 packages) for the second batch. My question is are there a large amount of unfermentables in spray malts in general, or is this a problem with the Extra light variety ? I have not had a problem with cans of malt extract finishing so high.

Subject: The Real Weizens Reveale

Today, my eagerly awaited copy of Eric Warner's book on Weizens arrived from Brewers Publications. As some of you may know, I share Eric's enthusiasm for german weiss beers. While I have brewed quite a few all grain weizens, including employing decoction mashing, a quick reading of the book has shed lots of new insight on the process of replicating an authentic weiss beer. I wholeheartedly recommend this book to any brewer who wants to learn more about this wonderful and challenging style of beer.

Some of the more interesting points that I caught during my skimming of the book:

Weizen yeast is indeed a single cell clone of *S. Cerevisiae*, and NOT *delbruckii*. *Lactobacillus delbruckii* is indeed used in the production of Berliner Weiss, but in Bavaria the weiss beers are made with *S. Cerevisiae*, and not *S. delbruckii*. This has been a misnomer in the homebrewing community for some time, and it is nice to find an authoratative source to dispel this.

It is very important to begin the mash cycle at around 100F. This is due to the desire to produce a significant amount of 4-vinyl guaiacol during fermentation. The precursor to this is ferulic acid, which is decarboxylized into 4-vinyl guaiacol by the yeast. In order for this to occur, the ferulic acid must be present in its free form. In order for this to happen, the ester bonds that bind ferulic acid to pentosanes in grains must be broken. This occurs optimally at 111 F and 5.7 pH. Since I had been ommitting the dough in at 95F, I was not optimizing the reduction of these bonds. I had been doughing in at 128F for a protein rest at 122. It would seem that it is beneficial to dough in at 99F, raise to 117, then 122 and finally 127 during the protein rest stages. Single or double decoctions would then be advised. If a single decoction is employed, the boil(malt) stage should be 30 to 40 minutes!

Another benefit of doughing in at 99F, is to maximize protease enzyme activity. This will aid in protein breakdown and lead to an easier lauter.

Another interesting note is that use of an open fermenter will aid in the production of esters, phenols and higher alcohols. And as has been mentioned here in the past, elevated temperatures increase this effect.

Much has been said about the quality of some of the books from Brewers Publications. While I hesitate to endorse the entire line of classic beer styles, they are certainly well worth the small cost when a product like Eric's or George & Laurie's is published. Well done! Prost!

Fm: Jack Schmidling

>From: dipalma@banshee.sw.stratus.com (James Dipalma)

> One more anecdotal point about the filling straight from the tap method.. He had used forced carbonation, and had gone a little overboard, as he kept the beer under 40 psi at 40F. The beer was so highly carbonated, it foamed violently as soon as it hit the end of the tap, making it impossible to fill a bottle. After about 30 minutes of trying, all we had achieved was an incredible mess, one-half gallon of homebrew sitting in a catch basin, another half-gallon sprayed about his cellar floor, six bottles half-filled with foam, and two very chagrined homebrewers.

Believe it or not, the solution would have been to increase the keg pressure.

It is hard to overcome the resistance to increasing the pressure when you get too much foam but that's the way it works. No matter how much co2 pressure it was carbonated with, there is always a higher pressure at which the beer will flow without foaming. The problem is, it may flow so fast that it blasts the bottom of the bottle and foams there. I know the feeling you describe because I have been there and that is what drove me to trying counter pressure filling again.

>Subject: Mashing & sparging from Micah Millspaw

>2) the crush was actually too coarse (I WANT a roller-mill!!!! Santa???)

<This is probably less than ideal but is not as likely a culprit as would be a too fine crush.

Far be it from me to argue with a certified expert but this is contrary to the physics of the process. The efficiency of the mash conversion is inversely proportional to the particle size of the starch granules, i.e., the finer the crush, the higher the extract efficiency. Large particles do not get properly wetted and can go through the entire process and remain dry starch.

Just for the hell of it, I brewed a 500 ml test batch with uncrushed malt and got a gravity of 1.002. The efficiency was not worth calculating.

The problem with too fine a crush is not efficiency, it is potentially cloudy beer and stuck sparges. It is also highly over-rated as a problem and this opinion comes from one who sells roller mills.

I have previously commented on the fact that the perceived evils of too much flour are all out of proportion to reality. Flour actually promotes extract efficiency as long as there is enough husk to keep it out of the runoff. This not only depends on the mill but also on the mashing process and lautering system.

>using Wyeast 2206 bavarian lager. Now, on the third day of primary I
have
>a strong sulfur-like smell coming from the brew.
>
> 2. Is my batch ruined or is this just a phase it is going thru

It's just a phase. Wyeast Munich has a similar phase in which it smells like home perm solution. Let it ferment out, bottle it and then lager it at 40F for 4 months and everything will be forgiven. In the case of my home perm solution bock, four months of lagering got it in the best-of-show at one competition and a 2nd place in the Bock category in two other competitions.

Kevin writes:

>I am trying Wyeast for the second time and am a little concerned as
>my first attempt failed. So I guess I am a little gun shy or over-
>worried about some stinking yeasties.

Well, concern about the health of your yeast is good -- especially liquid yeast because it is a bit more fragile than dry yeast.

>I have the "break the seal, wait until package is 1" thick" routine
>down quite well. I am confident I did that right. I mixed the yeast
>with an 85 degree solution of 1 cup water and two teaspoons of m.e.
>and airlocked it in a sterile bottle. I saw activity in one day. The
>activity stopped at the end of the same day. Did it run out of food??

I think that 85F is a bit high, but it seems okay if the yeast actually still made CO2 for a day. Two teaspoons is not very much DME -- I use 1 ounce (weight) per 8 ounces (liquid) of water. I hope you did not simply heat water to 85 and then add the DME. You should boil it for a couple of minutes to sanitize the water and the DME. I think it did run out of food. 1 ounce (weight) of DME lasts my yeast about 2 days.

>
>I prepared the wort the next day. Threw the yeast mixture (70 degrees F)
>into the wort (78 degrees F) and there has been no activity for 12+

Again, you need to be careful with temperature differences -- they will shock the yeast into dormancy or worse! It's not so critical going from a room temp starter into a slightly warmer wort. I'd say you were within a reasonable temperature, but a few degrees more or if the wort was 8F LOWER than the starter, you could have been in trouble. A 12 hour lag time with liquid yeast is not bad. I've had 36 hour, even 48 hour lag times with Wyeast and the beer came out delicious! Note that aeration is much more critical with liquid than dry since the dry yeast is well oxygenated before drying.

>hours. I guess I am curious what stage my yeast ended up at in the

>only. I'll post tomorrow for any comments.

The little sheet is for dry yeast -- the rehydration is completely
different from the starter used for liquid yeasts. You could use
a starter with dry yeast, but you would still have to rehydrate first.

>It seems to me, at this stage anyway, that the dry yeast is almost worry
>free since you know right away if it started. I guess I'm paranoid
>because I paid three bucks for this stuff and it didn't work last time.
>S'pose I shouldn't worry since ... since . . . I AM A HOMEBREWER !!

A few years ago, in the Yeast special issue of Zymurgy, there was a
comparison of liquid and dry yeasts. The dry yeasts all came up with
bacterial infections. These days, we have quite a few more dry yeasts
to choose from, Coopers, Lallemand Nottingham (which was used by Dick
Van Dyke to make this year's 1st place stout in the Nationals) and
Lallemand

Windsor, to name three that appear to be very good. I don't know if
these yeast's bacterial counts are down to acceptable levels, but in the
short term, they make great beer. Many brewer's swear by Whitbread dry.

What I'm trying to say is that some dry yeasts make bad beer and some
make good beer. Less than a year ago, I posted that I would never use
a dry yeast again, but have since reconsidered after tasting some beer
made with Coopers yeast. I've also made some with Nottingham and
Windsor, but have yet to taste it. I still use Wyeast for most of my
brews and I simply could not get the woody character of my Pale Ale
without Wyeast #1028 London Ale, but I look at it as having three more
yeasts (Coopers, Nottingham and Windsor) to choose from in addition to
the yeasts from Wyeast.

P.S. I don't use Whitbread not because I think it's a bad yeast (it's
not)
rather because I'm not that fond of the very "bready" flavor of Whitbread
beer.

Subject: Carbonating Mead & No-sparge mashes from Micah Millspaw

Subject: Carbonating Mead from Micah Millspaw

>1) Should I carbonate the mead and if so how?

Sure, sparkling mead is a very nice option. I have been making mead for some time and have found that the only consistent way to carbonate the mead is by artificial means. Trying to bottle condition mead can be dicey.

I like to filter the yeast out of the mead and then force carbonate in a soda keg. I later counter-pressure bottle the mead to avoid exposure to oxygen, as meads are quite sensitive to oxydation.

10
> gallons of water, drain it off and start boiling?

> Can anyone support this legend with actual experience?

Well Jack, I'll take a shot at it.

IMHO there are many advantages to the first running type of mash some of these being that its easy and less equipment oriented than the sparge type. Also there are some very definite effects as far as beer stability is concerned, there is less opportunity for hot oxygen reactions, there is the ability for greater and more stable melanoidins to be formed, as well as the collection of greater concentrations of lipids to be collected (lipids can greatly effect head retention).

The down side is that it is not very efficient for brewing a single batch of beer, (since it takes a *#\$\$ pot of grain) unless it is a high gravity one and then you are trading off grain cost with the convenience of a shorter boil (with out the volume reduction problem).

It is possible to make this more viable by making more than one batch of beer from the same by remashing the same grain. I think that this work quite well it just takes more fermenters and two boils and a long day.

From what i've read, sparging is relatively new to brewing, only the last 200-250 years. Prior to this time beers were made separately from the first, second and third runnings of a mash. According to T. Foster

porter was the first type of beer to be produced by a sparged mash.

By sparging less grain could be used to make more beer of an intermediate gravity. The advent of the sparge to brewing made it less time consuming and less labor intensive. This made it possible to produce more beer in what appears to be a more efficient manner, and it was the eve of the industrial revolution in Europe.

So this might be it, Jack, the origin of industrial beer and its host of sins.
I say blame it on budmilco.

10
> gallons of water, drain it off and start boiling?

The simple answer is, to extract more sugars. We could, theoretically, compensate for the lost sugars with more malt, but it would be a waste.

Some history is needed regarding Barleywines and English brewing in general.

First, some nomenclature: the wort that comes out of the mash, without sparging is called the first runnings. (Although I don't recall it used elsewhere, J.X.Guinard's "Lambic" refers to second and third runnings (I believe) which would be the sparge -- and one style of Lambic ferments the first, second and third runnings separately and then combines them. But I digress). In England, they used to (and some may still do, as well as some breweries in the US) make up a BIG mash and then use the first runnings for a Barleywine and then sparge the grains to make a wort for a Mild. We could do that too if we have the capacity and time.

> The search through my references was not very satisfying on the subject. It
> seems that the most repeated reason is that the enzyme efficiency is reduced.
> But like so many other "problems" that claim this as the evil, the solution
> is to simply mash a little longer or use more malt.

I don't have my books here at work, but I believe that Miller says a thick mash favors one of the amylase enzymes (alpha or beta, I don't recall) and a thin mash favors the other. I think this might be the data you're missing for the complete picture on this.

>
> Noonan goes one step further and says a "thick mash improves enzyme
> performance. In a thin mash, proteolytic and other heat-labile enzymes
are
> destroyed in the course of the rest: in a thick mash, they may survive
into
> the saccharification range."

Note that Noonan is implicitly talking about a *decoction* mash. Naturally, since he's the homebrewing's biggest proponent of decoction mashing -- note that at the time he wrote the book, pilsener malt was much less modified and a lot of what he writes needs to be read with that in mind.

>

> This makes no sense at all. It reads more like a description of the survival rate of wildebeasts as a result of herding than of chemistry.

Consider it in the context of a decoction and it tends to make a bit more sense -- but I agree with you, it's a bit confusing. I have a number of gripes with Noonan -- many things he has written in his book "Brewing Lager Beer" are COMPLETELY wrong and this one borders on wrong -- I would need to re-read the whole chapter to know what he tried to say and see if he's just overcomplicating it or he goofed again. Don't get me wrong, Noonan's book is still very valuable, I feel that ideally, you need to read Charlie's, Miller's, Noonan's and George Fix's books (in that order) to really get a complete picture. There's a lot of minor discrepancies between these authors' books and after reading all of them and brewing a few years, only then does the truth rise to the top.

>

> Sparging is a "simple" and efficient way of extracting the sugar from the grain but all other things being equal, it would be more convenient to use a thin mash and just a small final sparge to rinse out anything left behind.

> It would also greatly simplify that first plunge into all grain beer.

Sure -- the added benefit of a thin mash is that it has more thermal inertia and if you stir well, you have less chance of overshooting temperatures.

Bruce writes:

>Subject: What exactly is oxidation?

>

>I would like some information on what exactly is oxidation of wort and what are the effects (both ill and otherwise) on the flavors of the beer, how does it occur, how to avoid/prevent it, etc.

Oxidation of cooled, finished beer (i.e. at racking to the secondary or during bottling) will give your beer a wet-cardboard aroma or a sherry-like aroma. In most beers it is unwelcome (Chimay Grand Reserve being one exception). Hot-side aeration (aeration of hot wort) causes a darkening of the beer (the oxidation of melanoidins) and a different flavor change (one that was discussed recently, most notably by George, but I'm afraid I didn't quite understand the flavor description and was going to ask him about it in person next time we could have a beer together -- I'll bring the Bateman's).

Avoiding oxidation is simple in concept -- don't aerate the beer while it is hot (above 80F) or after it begins to ferment. In principle, this means siphoning gently, avoiding splashing and purging with CO2 prior to transfer if this is available (don't go out of your way -- this is extreme).

>

>Also, now that I've got your attention here, I noticed a slight
>metallic aftertaste on my last batch (a wheat). It was only barely
>detectable, but definately there. What are some of the possible
>culprits that might have given the beer this characteristic?

Several things can give you metallic flavors. The most common are
contact
with iron, mild steel (not Stainless) or aluminum, metals in your water
supply (try filtering or buy bottled), and "hydrolysis of the cereal
lipids
followed by oxidation of unsaturated free fatty acids," according to Rao
Palamand in the Troubleshooting Special Issue of Zymurgy (Vol 10, No 4 -
-
BUY IT! IT'S VERY INFORMATIVE!). The solution to this last source is
to use fresh grains or grains that have been stored well (not oxidized).

> is. My specialty beer sources in Virginia haven't heard of the stuff.

This is being imported by World Wide Imports (aka Maurice Coja of the Brickskellar) I believe World Wide lists its address as somewhere in VA, but I don't know for sure. Odds are good these are in short supply. Usually (from what I've seen so it may not be fact) the Brickskellar folks bring in beer mainly for themselves and only sell a little bit of it to stores.

I had a few bottles of this from the Belgian diner given a few months batch in Boston. I've still got at least one bottle in the fridge.

Cantillon is a wonderful example of what a lambic should be (IMHO). It is a traditional lambic NOT a syrupy sweet product for the mass market (like some lambics that will be left unnamed). The only products that I've had that are Cantillon's equal (and possibly better) are the Frank Boon products and these should be available early next year if my sources are right. (a company in NY will be importing Boon) That's not to say I'd turn down a Timmermans, St. Louis, or any of a host of other lambics.

>like this last one.

I think what you might have had there were perhaps sugar crystals. It
seems
to me that you had quite a hefty gravity for your starter. I use 1 ounce
of light dried malt extract per 8 ounces of starter (boiled about 10
minutes).
That gives me about a 1020 wort. My understanding about the negative
effects
of high-gravity starters is that the yeast have trouble multiplying in
them
(and while I'm on the subject of yeast, it's highly UN-recommended that
you
re-hydrate dry yeast in anything other than plain 100F water).

dab writes:

>the gunk out. I currently use a 1" i.d. tube that works really well
>but is a total bitch to clean, especially after a particularly violent
>batch.

I haven't used the glass tubes, but I don't have a lot of trouble
cleaning
my blowoff tubes. The ones I use for regular (non-fruit -- long, messy
story)
beers are 5/8" OD, and 1/2" ID. After use, I just soak them in 200ppm Cl
bleach solution (1 tbs per gallon) overnight then run hot water through
them. They get stained from the blowoff and turn whitish from the
bleach,
but I don't worry about it. If one gets really gunked-up, I use a method
mentioned a few years ago in the HBD by someone: a wire and a piece of
cloth
(just like cleaning a rifle).

Steve comments, after an informative post on Pavichevich Brewing's financial troubles:

>

>I'll bet that a lot of US micros are in similar shape.....

I think that Pavichevich's problems are a bit worse than many others. I have not been there, but I've heard from those who I trust and have visited. It seems that Ken went whole-hog when buying the equipment for the brewery. All the equipment was purchased new and of the finest quality. Conversely, I have been to Chicagoland's newest and smallest brewery, Golden Prairie (I believe that's the name). Not nearly the size of Pavichevich, of course, but it's solvent. Everything was purchased used or built by the brewmaster/owner, Ken (a different one). It's a small place that brews a good, tasty beer and selling at a volume (kegs only, for now) that pays the bills. Quite a contrast.

You don't need to worry too soon about changing the temp of the water.
Draw the strike water directly into the mash tun, adding the goods as
normal. Seal the lid and submerge in the boiler. Only now do you need
bother about the temp of the water in the boiler. Strike temp is higher
than initial mash temp so you now simply add cold water into the boiler
(and adjust thermostat) to get correct temp. The thermal inertia of the
goods in the mash is quite large and having it submerged in water that's
a little bit hot for a few moments won't alter its temp.

>Allow the mash to complete. After the
>mash, remove the mash tun from the boiler and adjust thermostat
>to sparge temp.

Again, no need to remove the mash tun from the boiler. As the water comes
up to sparge temp, the goods will only rise in temp a little - and that's
no bad thing because it's desirable to raise the temp for a "mash out"
anyway. (rather than let it stand for a short while and cool down a
little)

>Transfer the sparge water to another vessel and
>sparge through the mash tun back into the boiler. Boil your wort.
>when it's finished chill and drain into a primary.

It could be done by sparging into another vessel and then transferring
into
the boiler after sparge, but the benefit of your way is that you can
begin
to bring the first runnings of the wort to the boil before sparging is
complete.

I like to keep things simple, I hope that is of help. I have come to like
the floating mash tun method. But I suppose that's a personal choice.

>BTW, when using immersion heaters of high wattage, it is a
>good idea to keep everything WELL grounded

Excellent safety advice - and compulsory in the UK

> my beer. Ick!

I suspect that setting your water out for a few days is easily practical.
Fill a sanitized carboy with water and put an airlock on it. Set it in
front of a window. There's at least some UV, even through clouds.

I used to remove chlorine this way (except without sanitation) to
prepare water for adding to a fishtank. I couldn't smell any chlorine
after a day of waiting (there will be some smell when you first remove
the cap, but that will go away). Later I started using sodium
thiosulphate. The fish didn't die ;^)

Perhaps you should boil the water beforehand, so that you'll be sure
to have sterile dechlorinated water to add to your wort later.

Subject: cold break and malt extract

Regarding yeast nutrients in trub, and in particular one poster's experiment with making a yeast starter with trub in it (am I remembering right?) which started more quickly than one without: I am wondering if that is why I get such explosive starts when I pitch a fresh batch of cooled wort onto a yeast cake off of which I have just siphoned & bottled.

I've tried this a couple of times but generally I haven't been impressed with the results - a certain coarseness of flavor seems to occur which I might guess would be attributable to kicking all that yuck up through the beer one more time.

What about cooling, racking off the trub and pitching, but siphoning off just a LITTLE of the trub into the primary for some nutrients? Any comments?

Regarding malt extract: I've been using William's stuff (syrup) largely because it's inexpensive and seems to be reputable. Anybody want to confirm or dispute that? Can I do better (other than going to partial or full mash, which I'll get to eventually but not just yet)? The various canned syrups seem to be substantially more expensive than William's pouch-ed syrup. Apparently they buy theirs in bulk ("big drums") and then package in plastic pouches for shipping - but I don't know where they get the stuff from originally. Been meaning to ask.

Beerily yours,

Jonathan

Tony Babinec writes:

The berries were crushed in a total of 1/2 gallon, and were bright red. I added 2 campden tablets (the label suggested 1-2 per gallon, but I wanted to be *sure*) and within minutes the color had faded to a pale wimpy yellow .

Painful isn't it? I've never had the problem with beers, only meads. Watching 10 lb of hand-picked black raspberries fade is not a happy sight. For this reason I have sworn off the use of campden in meads and now use only gentle heat (minimum past.temp) or NO TREATMENT at all. I have had no spoilage problems most likely due to the high alcohol concentration. I know this is not much help as far as beers go, BUT in the case of bleached meads (and wine for that matter) the alcohol formed in the fermentation extracts enough color from the fruit skins that the beverage again becomes colored, although obviously not as intensely as it would have been.

Subject: hydrogen sulfide is yeast culture

Hello,

I have a few questions about culturing yeast. A friend of mine was nice enough to give me a few cultures of Wyeast. [Wyeast is impossible to get around here.] One of the slants he gave me has Wyeast 1007 in it.

I received them about 2 weeks ago and I occasionally vent them so they don't blow up, I also keep them in the fridge. Today when I vented it I found a really strong rotten egg smell come from that slant only.

I remember reading something about hydrogen sulfide some time ago but I can't remember what it said. Can someone enlighten me to what is causing the production of hydrogen sulfide.

BTW, the slants were made and autoclaved in a microbiology lab at a local Univ. and proper aseptic technique was used to streak the slants.

Thanks

Carlo Fusco

Subject: priming agents

On a recent Sunday afternoon, my brewpartners and I were getting ready to perform a ritual bottling of a London-style ale when a conversation like this occurred:

"Hey! This is going to be a great beer! I can't wait to get this bottled!"

"Me too! Let's get started... Where's the corn sugar???"

"I thought you were going to buy the corn sugar?!?!"

"No, I thought you were going to swing by the store and get it!"

"Aw, sh_t!!!"

So, we ended up with an aborted attempt at bottling. (We did realize that we were without corn sugar before doing anything with the secondary ==> no lost beer.)

However

We realize that there oughtta be a way to use a bit of DME or other non-table-sugars as a priming agent. We thought about using DME at the time, but the technique for doing so was not in our brewing repertoire, so we erred on the side of caution and decided to wait until we could get some corn sugar.

My question to the HBD is: Other than corn sugar, what are other acceptable priming agents and what is the technique for their use???

10Q!!!

Subject: Boiling Hops

In yesterdays digest Rob (bradley@adx.adelphi) outlines his SN clone experiments. The following struck me:

>or the pale ale, I would use Perle (as SN does) in the first hop addition and fewer HBUs of it. 1 ounce of Perle at 7.6% was suggested by Brian Batke. He also suggested Perle for the 30 minute addition.

>Tony Babinec suggests that an all-Cascade pale ale of this sort is more in the style of Liberty Ale. I agree, but I would add even more boiling hops and finishing hops if I were trying to clone it.

I've always lived under the assumption that the 60 minute addition will basically just give you bitterness. (ie. 2 oz of 5% cascades will be indistinuishable from 1 oz of 10% clusters) And that only in the later additions would different hop types cause significant differences. Specifiacally, about > 30 minutes of boil would drive off all aroma and most flavor, >10 minutes would drive off much aroma and leave flavors,
and <10 min boil was required for significant aroma.

I've seen a theory advanced that the above assumptions are false. That the bitterness derived from high AA hops has a different characteristic than the same IBU derived from, say, noble hops.

What does the Digest audience think? Are 30 IBU of cascades and clusters the same when derived from a 60 min boil? At what point (minutes) do you drive off most off the flavor? aroma?

The DeWolf-Cosyns Belgian Cara-Pils grain is very different from most
other
Cara-Pils or "Dextrine Malts" as they are sometimes called. Most are
crunchy
whereas the Belgian is indeed chewey.

>
> Not being very subtle, I used two pounds in the first (7gal) batch

That bandaid flavor is phenolics. The most common source of them is from
your yeast (Munton & Fison yeast is notorious for them) but the
Troubleshooting
special issue of Zymurgy mentions that wheat malt can cause them also.
Perhaps there's something in the Belgian Cara-Pils that does this also.
However, I have not noticed this problem -- granted I've never used 2
pounds
in a batch!!! It could simply be a reaction between your strain of yeast
and
something in the the Cara-pils.

> In the last batch, I only used one pound of Cara-pils plus the pound of

Much more reasonable -- I hope I get to taste it at tonight's CBS
meeting.
If it is the world's greatest beer, I'll be honest and tell you I think
so.

> I would be interested in hearing what others have to say about
carapils, what
> it is, how it is made and a more euphemous description of the flavor it
> imparts.

To make a long story short, Cara-Pils is the lightest-colored of a series
of
Crystal malts. They are "mashed in the shell" so to speak by being
kilned
at mashing temperatures first, before being dried. The temperature of
the
drying is what determines the color of the final product. DeWolf-Cosyns
make four Crystal malts:

Cara-Pils	5 - 10	Lovibond
Cara-Munich	15 - 30	L
Cara-Vienne	70 - 80	L
Special B	150 - 250	L

> BTW, this stuff is straight from hell as far as crushing is concerned.
It
> takes a gorilla to turn the crank of a fully loaded mill but I find
that just

Amen.

Question:

Does anyone know how to measure the Lovibond rating of a malt?

P. writes:

>I don't intend to discuss whether one wants to use Campdens or not, but
>the point is, chloride, sulfate, and possibly (bi)sulfite are not things
which
>one would not expect to find in beer etc.

You correct yourself later, but chloride and sulfate are very common in
beer indeed, especially in Burton Ales. I agree, that not all chemistry
is
bad, but the thought of drinking fixer is beyond me, and I'm crazy enough
to make Lambics (which look like sewers while fermenting).

David Peden writes:
Subject: Spray malts ?

The last two batches I have attempted to make a bitter similar to Red Hook. I have purchased bulk (55 pounds) of Laaglander Extra Light spray malt, my problem is that both batches OG were 1.050-1.055 and finished at 1.028. I used both a Wyeast (Irish) for first batch, and Muton and Fison dry (2 packages) for the second batch. My question is are there a large amount of unfermentables in spray malts in general, or is this a problem with the Extra light variety ? I have not had a problem with cans of malt extract finishing so high.
David Peden

I reply:

Dave I have had similar results with Laaglander malts. They tend to produce a low Original Gravity and a high Final Gravity. This is also confirmed by Papazian in TCJOHB and by many other homebrewers. My old standby is Munton and Fison. I've had excellent results with M&F and it ferments out well. My typical FG is in the teens for Pale Ale (using 7 - 8 lbs of M&F light). Greg.

>I'm going to be moving to the Greater St. Louis area in about 5 days.
Can
>anyone suggest worthwhile brewpubs, micros, and hb stores in the area?
What
>are the good local brands? I don't want to waste any time!!! Thanks
>Jim Jedrey

Welcome to St. Louis, Jim. In St. Louis, many natives consider a beer not made by Anheuser Busch to be "imported". A severe case of "buy American". But things are looking up.

There is one brewpub in St. Louis, called (suprise) St. Louis Brewery. Dave Miller, the author of two well-known books on homebrewing, is the brewmaster there. The restaurant/bar part of the business is called The Tap Room. It is located at 2100 Locust Street. Telephone 314/241-BEER. The beer is quite good, but the character is never "up front" or "you CAN'T miss it obvious". Remember, this is the land where Bud is the King. Dave says his biggest seller is the Wheat Ale, followed by a Pils. This despite a really good Oatmeal Stout that's nearly always available. See how that works? A big cheesburger, plate of spicy fries, and a pint of your favorite will run you about \$10. Standard disclaimers apply.

Homebrew suppliers: There are two in St. Louis. Their addresses and a couple comments were in yesterday's Digest, I think. Maybe the day before. If you missed it, send me e-mail and I'll forward the info. Homebrewing is still technically illegal in Missouri, but it seems the State has bigger fish to fry, and they leave us alone. Some people are working on this sad situation, though. Maybe there'll be more suppliers once this vestige of prohibition is eliminated. After that, we go after the extortionary tax laws, right? \$7 tax on a barrel for small producers. I don't know what AB pays. More, I suspect. Just think, at least \$7 tax on each barrel of..... water!!

Good local brands? HaHaHaHaHaHa!! The only *good* local brand is St. Louis Brewery's brand: "Schlafly". This is of course, opinion. An appeal to the majority would reveal Bud, Busch, Michelob, etc to be the good local brands.

Oh -- the St. Louis Brews homebrew club meets at the Maplewood Community Center

the first Thursday of each month at 7:30 PM. If you want directions after you move here, just send e-mail to tell me where you're driving from, and I'll give you directions.

Welcome to town!

Subject: re:plastic boilers,hot water heaters and floating mashtuns...

I have been using a simple floating mash tun successfully for a number of years now. Earlier I had mashed with a Burco but didn't find it to be very "relaxing", mash-wise(lots of temperature spikes, etc.etc.) as well as boil-wise (not enough "oomph").

The device you describe sounds interesting but I wonder how well it would work with a step-mash. Line's system is for simple infusion mashes only. Bitters are really the only thing I brew (I'm a lazy kind of guy + I can't relax enough to wait for a lager). The reason this system works so well for a simple mash is that the large volume of water in which the mash vessel floats effectively dampens any major changes in temperature. The strike temperature and ratio of water to goods that I typically use yields a mash temp of 151-153F. After two hours in the immersion bath, I find that the temperature of the mash will have only dropped to about 147-148F (the vessel is well insulated + I don't add any additional heat during the mash). Your heating element would have to be capable of getting a large volume of water (approx. 5 gals is needed to float a mash kettle holding 7-8 lbs of grain + water) up to temperature in short order. You mentioned this as a potential problem and, although I'm really not experienced in doing step mashes, I do know that raising the temperature of 5 gals of water is a job.

Where I live, electricity rates are outrageous. I use a Cajun-cooker type of arrangement, both for rapidity of boil as well as economy. I also realize that these devices would probably be frowned upon in the middle of an apartment floor! :>)

Subject: Dick Van Dyke?

Is it the real Dick Van Dyke who made the winning stout. the photo in zymurgy makes me think it's an imposter. although my recollection is that those van dyke boys are from Illinois.

also, Al touts the virtues of the new Lallemand dry beer yeasts. before we fall for the fancy titles and nice product brochures, let's remember that the same company has been making Doric for years and noone is raving about Doric. I'm always skeptical when the ads give no info whatsoever that would suggest the process has been changed or cleaned up to produce better yeast.

I've only tasted one beer made with Windsor and it was poor. not a very scientific sample, but enough to deter me.

It's also noteworthy that the winning stout was made with Red Star dry champagne yeast, at least that's what's in zymurgy. it's also noteworthy that the recipe has an incredible 14+ ounces of hops and licorice and molasses. hardly a beer to even begin to look for off-flavors in. Looks like a very original recipe and a beer that could be set aside for a year.

From: card@apollo.hp.com
Subject: hop utilization

In experimenting with different hops styles, and getting help from Brew-digesters.

* pellets Utilization factor ~ 30 and don't require full boil ie. 20 minutes still yield approximately full utilization.

should be boiled no longer than 45 minutes.

* leaf UF ~ 25 and need ~ 60 minutes to obtain full utilization at 20 minutes, bitterness contribution is small.

* plugs UF ~20 -same timing as leaf.

* any hops in a typical high gravity boil yield a substantial reduction in UF. 25%? This is real important to consider when going to all-grain.

Hops oz. = gallons x IBU x 1.34

%Utilization x alpha

4.5 if you assume Utilization of 30

/

IBU = HBU's (3.75) --- this assumes a utilization factor of 25

HBU = IBU/ (3.75) --- this assumes a utilization factor of 25

I'm still experimenting and would appreciate inputs. I believe this is important since most recipes don't call out hop style. therefore, your AAU's could increase dramatically (30-50%) - More than enough to ruin a good effort.

From: rich@bedford.progress.com (Rich Lenihan)
Subject: Mash thickness, Blow-tube cleaning, Plastic cases

Mash thickness:

I've read differring opinions re: thin mash vs. thick mash. Miller states that thick mashes (1.33 qts water / lb. grain) encourages initial starch conversion but discourages complete conversion. Well, as time goes on I find myself referring to Miller more and more and my mashes are thick. Also, a thick mash allows me to turn off the stove when the mash reaches temp., cover and leave alone for 15-20 minutes, knowing that the thermal inertia of the mash will keep the mash temp. within range. For a recent batch, however, I mashed for 30 minutes at 122 F (approximately), then 90 minutes at 152 (again, approximately) but conversion wasn't complete (according to iodine test). So, my brainstorm: I heated about 1.5 gallons of water to 152 F and added it to the mash, stirred, covered, and let sit for another 30 minutes. Voila! Conversion complete.

Since then, I've done two mashes with a 30-minute sugar rest at the initial thickness (approx. 1-1.33qts/lb, I measure by consistency), then decrease thickness (to about 2qts/lb) and mash for another 30 minutes, then mash-off at 168F. Of course, I use less sparge water, but my extract efficiency has gone up (slightly) with these last batches.

I figure that this method gives me the best of both worlds - a thick mash for initial starch conversion and a thin mash for complete starch conversion. The down side is that I have to twiddle with the mash to keep the temp within range, but I can live with that.

Blow-tube cleaning:

I find a carboy brush to very good for 1" OD tubes. Also, it's probably a good idea to replace your plastic tubing every so often.

Plastic Cases:

Some of the cardboard cases for my beer bottle collection are becoming "structurally unsound". I'd like to replace them with plastic cases. These are like milk crates, but with slots for 24 beer/soda bottles. I've seen them in Europe but not in the States. Any ideas?

Hops & Cannabis can be grafted, but both plants develop their
interesting resins in the flowers, so a cannabis root won't produce THC
in hop flowers. Or so I'm told B-)

Subject: **Bottle sources.**

Bottle sources have recently been mentioned and I thought that I would add my two cents worth.

I walked away with just under 40 cases (12 bottles per case) of Sapporo and Kirin bottles from a local Japanese restaurant. I had a beer with dinner and asked what happened to the bottles, and could I have some if there wasn't a deposit or something. They asked how many I wanted, and I told them as much as they had. 40 cases was what fit in my truck :-)
They said if I needed more just come back anytime.

I also went to a local German place called the Snitzlebonk (sp?) and have acquired a case or two at a time of Pauliner bottles. Mexican restaurants are good places to get Dos Equis and similar bottles.

Most of the restaurants I have asked have been quite nice. They think I am hauling off trash for free. Now if I can just figure out how to get soda kegs this easy :-)

Subject: Thomas Hardy Ale

Does anyone have a good recipe for Thomas Hardy Ale that is all or mostly grain based? I have the Dave Line recipe for a 2 gallon batch but it is based on English pale malt whereas I am using American 2-row lager malt. I am thinking I will need to add some crystal malt to make up for the lighter roast in the lager malt, but I see that Jackson says Thomas Hardy Ale is made without any colored malts. Has anyone gotten close? I would also appreciate any good recipes for barley wine and would be especially interested in recipes that clone Big Foot or Foghorn.

Subject: smooth stout

I've made a stout that has been called "Guinness-like, but smoother, like a draft". A nice enough compliment, but not what I was trying for. It had 1 lb. of roasted barley (about 10%), so I was surprised by it's lack of "bite" (I like that bite). I mashed all the grains. My theory is that the sparge filtered out most of the tannins from the rb. Steeping the rb after the sparge would give back the "bite". So, mash for the smoothness of draft, steep for the bite of the bottle variety. The wonders of homebrewing.

Subject: Cleaning Blow-off Tubing

To clean 1" ID blowoff hose, I've had good luck by forcing a plug of paper towel through the hose a few times:

Wet a piece of paper towel, and form it into a plug that fits fairly snugly in the tube. Now put the end of the hose over your faucet tap: if you have a garden-hose adaptor on your sink, the tube should fit snugly over it.

Use one hand as a hose clamp (omit at your peril), while turning on the hot water. Let the pressure force the plug through, scouring the goop off. Repeat as necessary.

It's fast and seems to work for me. I also have pushed the plug in a couple of inches, and poured bleach into this space, before putting the tube onto the faucet. I don't know if this helped, though.

You are kidding right?

Just in case you're not, the above is not a 'fact'. There are no reputable studies that prove or even suggest that THC stays in your body forever. Hell, THC is so unstable it breaks down in hours. There are some non-psychoactive metabolates that will stick around for a week or two, but that's it. In fact, there is absolutely no proof of any long-term effects from marijuana, even though most researchers believe smoking is harmful.

As consumers of an oft-maligned drug (alcohol), we should be very wary when prohibitionists start making absurd claims about other drugs.

> Line's, 'The Big Book of Brewing' for a floating mash tun.

My experience is that a metal tun supported by blocks conducts the heat much faster than a plastic tun, and, besides, floating the tun is a bit of a dubious proposition anyway. A thermostat is largely superfluous as the total volume of goods plus water jacket has such a high thermal inertia. Regarding boiling, use the highest wattage element for which your wall socket is rated. A 3000W element will boil 5 galls of cold water in around 1/2 hour. I don't really understand the complaints about this method being slow, as few stove top elements put out any more power. I also don't understand the complaints about wort caramelising on the element, unless people are pouring undissolved extract in there. (Mashing with the grain in contact with a naked element is another matter).

Subject: Re : quality of extract varies wildly

One of the problems I have noticed with many extract brew pubs is that even high gravity brews seem to taste thin and insubstantial. This had led me to theorise that some of the problems of extract (apart from adulteration) are due to overboiling during the condensation stage, ie, too much protein gets precipitated. It would be interesting to test whether diastatic malts, boiled under vacuum at low temperatures, are liable to the same problems. Another possible implication is that powders may contain 'less' than syrups. It also calls into question the advisability of homebrewers boiling the extract even further. I made a series of mini brews in milk bottles last week, which basically involved pouring boiling water onto extract powder and hop pellets, then fermenting. All cleared without a hitch (and had adequate bitterness, incidentally). Maybe one sign of extract quality, contrary to some peoples' notions, is the amount of trub which it liberates. Another yardstick, again somewhat unintuitive, could be lightness of colour. That is, if your taste buds suggest the darker colour is not due to use of roasted malts or caramel, then it is possible that the extract has become oxidised, which generally means less malt flavour.

Subject: diacytl, dough-in, freezing

JimG has a diacetyl problem, and described his final gravity as 1.017, which is high for medium-strength beers. I think the FG may be an indication of a weak ferment, caused by lack of oxygen. Lack of O2 will also increase diacetyl production (or is it decrease the amount of re-absorbtion of diacetyl by the yeast). Either way, the beer is buttery. Solution: Aerate the cooled unfermented wort better.

Most all-grainers seem to add water to the grist. I add grist to the water. Seems this way would allow better mixing, with less dry spots. I see very few (or no) clumps when I stir it up.

Freezing beer to concentrate it will also concentrate the "bad" things, such as fusel alcohols, which can be toxic. My question is, what is the difference between drinking a glass of concentrate, as opposed to drinking the 6 beers it took to make that concentrate?

Subject: funny taste??

I have a question..... I've made four batches of homebrew so far and they all seem to have something in common ----> a slight off taste and smell. The taste and smell seem to be kinda "yeasty". The smell is exactly the same but not as strong as when you leave a 1/2 inch of brew on the bottom of the bottle and swirl it to mix it with the sediment. I am very frustrated in that not only it has this slight "off smell" but it can taste very "home-made". The thing is I use single stage fermentation with no blowoff tube. I chill boiled water, add it to the fermenter, add the slightly cooled wort to the fermenter, and pitch the yeast (the temperature was within range for an ale or lager). I put it in the 7 gallon plastic fermenter and put an airlock on top. Fermentation usually starts within 24 hours and I let it sit in the same plastic fermenter for approx. 10-12 days. At that point I bottle. I've tried ales and lagers (both were fermented in the basement - temp 62 deg F).
The
lager was the liquid California type and ales were rehydrated dry type.
Can
anyone see an obvious flaw in this procedure? Can it be no blowoff tube?
No secondary? Anyone have the same problems? Any fixes?

>I'm surprised no one pointed out an obvious parallel between hop and hemp.

Just a few odd pointers here...

> The female cannabis plant is kept isolated from the male plant so as not to seed.

The vast majority of "hemp" is grown for its fiber and not the flowers. From the growers' point of view, hops has the advantage of vegetative propagation and a perenial growth habit. This means that one can stay in the hops business forever without ever allowing pollination.

This is not true of pot. If you do not allow some pollination, you get no seeds and extinction is inevitable. I believe most pot is harvested as soon as the flowers open and I do not see pollination as an issue. The female plant is supposed to have more THC but as they must be planted from seeds, there is no way of predicting the sex. The male plant can be identified at flowering time and a removed by growers interested in maximum potency but not by those motivated by maximum tonnage.

>As homebrewers we have a responsibility to promote homebrewing and to financially support quality commercial brewing.

I was with you 100% up to this point. It seems to me that as homebrewers we have only the responsibility to support homebrewing. If I never spend another

cent on "quality commercial brewing", I will consider my victory complete.

.....

Now for something completely different.....

Sometime ago I suggested that one might be able to sterilize petri dishes in a nuker in mere seconds, without water because the organisms are so small that they would be instantly fried. Well, in an unscientific experiment, I have concluded otherwise.

My wife noted a fruitfly in the nuker and made several attempts to shoo it out before heating a cup of coffee. It persisted in flying back in so she gave up and nuked the coffee for one min. When she opened the door to take it out, guess what FLEW out?

From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: Spice Extracts, Adding Alcohol

The question of making spice extracts was dealt with at length by Arthur Delano, and very nicely. Just a couple of comments (\$0.05?):

Arthur suggests steeping spices in alcohol for several weeks to months. This MAY work out, but should be monitored closely. My wife and I have made several spice "brandies" by steeping herbs and spices in vodka, and we found that many herbs yield their best flavours in only a few days. Longer steeping gives bitter tastes and dark colours. So, if you are steeping herbs etc, check on the taste after a couple of days, and decide how long to soak based on the flavour at that point.

The other thing is the concerns raised about adding high alcohol content to a fermentation killing the yeast. Consider a spice extract which is "100%" alcohol. How much would be added? Perhaps 200-300 mL of a strong extract? A typical batch of homebrew is (in round figures) 20 litres, or 20,000 mL. So, you have added 200/20,000 or 2/200 = 1% of alcohol to your brew. I don't think this is likely to kill your yeasts :-) Relax...

Cheers, P.

>Subject: 21 year old stuff from Micah Millspaw

On the topic of keeping vintaged barleywines for your childrens future birthdays, I think that this is a great idea. I brewed a batch of barleywine a month before the birth of each of my children. One case (for each) was bottled and sealed over with wax, against time and put in the basement. Also one case of each was left to me to drink as I see fit. So far they have aged quite well, with no ill effects to date. I expect the barleywines to go the distance of at least 18 years maybe 21.

As for the Thomas Hardy's I've read (Michel Jackson) that they will go 25 years. I have personally drank 7 year old Hardy's and it was excellent. I infact have some Thomas Hardy's in the 10 year range that might just be due for a pre-chirstmas tasting.

So give it a try, your kids might appreciate it.

Subject: Holiday Beers (CCASTELLOW)

There have been a couple of questions concerning commercially available Christmas/Holiday beers. The following beers are currently available in the Seattle area:

Jubelale - Deschutttes Brewery
Winter Welcome - Samuel Smith
Winterhook - Redhook
Wassail Winter Ale - Hood River
Celebration Ale - Sierra Nevada
Snow Cap Ale - Hart Brewing Co. (Pyramid)
Cold Cock - Big Rock
WinterBr u - Thomas Kemper
Festival Ale - Felinfoel
Christmas Ale - North Coast Brewing Company
Aass Winter- Aass
Grant's Spiced Ale - Yakima Brewing Company
Winterfest - Coors
Winter Lager - Samuel Adams

So far, I still haven't seen Wasatch Winter Ale, Young's Winter Ale, and Anchor's Special Ale.

Which would I recommend? Try them all! Every one on the list is either what I would consider a good beer, or at least an interesting beer (except for the Samuel Adams). (Even the Coors is a step up from their usual product, and is something they should consider making all year long.) Sampling a large variety will help you decide what you want to make in your own Holiday Homebrew.

Since James Spence gave a source for sweet gale seeds yesterday, I was wondering if anyone has made Santa Claus' Magic Potion. If so, please report on the results. Also, does anyone have a commercial example of a brew with similar spices?

Subject: starter size

In 1026, Al Korz twice recommends 1 oz. (by weight) of DME
in a 1 cup (8 fl. oz.) starter.

1 oz 16 oz 1 lb
---- = ----- = -----
8 oz 128 oz 1 gal

Now doesn't DME give about 40 points per pound?
So this sounds like a recipe for a 1040 starter to me.

I use 1 oz of DME to make a one pint starter (16 fl. oz.).
This gives about the 1020 recommended by Wyeast and many HBDers.
I have noticed that 1 oz. of DME is about 3 tablespoons.

:-) Now let's have all that in metric for our European friends and
:-) younger British Commonwealthers. And in imperial for the older
:-) members of the commonwealth.

[Remember: 1 US fl oz. = 25/24 Imperial fl. oz.]

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: 2112 data point

I brewed a batch of beer with Wyeast 2112 on Saturday. I didn't worry, and everything looks great right now. The package was dated October 21, so it was exactly six weeks old when I took it out of the fridge on Wednesday night. I broke the seal and put the package in a bowl of 80F water. Overnight it cooled to ambient (low 60s) and was well puffed out at 20 hours. I made a 1 pint 1020 starter and pitched about 40 hours later. At that point there had been noticeable activity for a day but no krausen, only isolated colonies on the surface. The wort was 76F when I pitched and slowly cooled to ambient. At 18 hours there was a nice white krausen on top and it smelled great.

Thanks to all who wrote me concerning hops for this beer. I still haven't decided whether or not to dry hop. Opinions? Does anybody know for sure if Anchor dry hops its Steam Beer? I have a nice 1/2 oz. Herrsbrucker plug handy, and it has been suggested that this would be a good variety. My hopping schedule so far has consisted entirely of Northern Brewer pellets: 1 oz. (6.8%) for 1 hour, 1/2 oz. (6%) for 30 minutes, 1/2 oz. (also 6%) for 5 minutes.

From: parsonsl@husc.harvard.edu
Subject: Question about non-attenuative ale yeast

Brewing this Winter, I want ales with a high terminal gravity. I like heavy, malty beers when it's cold out. I just brewed a holiday batch using Wyeast London Ale, which is too attenuative. I used 10 # English pale malt, hoping that the low enzyme content would make it difficult for the yeast to ferment the wort entirely; I also used 1 # crystal and about 1 # of choc. and roasted barley combined, 1 c. brown sugar, 1 c. molasses (I also threw in ginger root, brewing licorice, birch root extract, spruce essence, and Centennial hops).

I kept the saccharification rest at about 154, thinking that a midpoint between too light and too heavy.

Nevertheless, with an OG of 1060, it was down to 1014 when I racked it to a secondary after one week. I suppose (since looking back is easy) I could have held the saccharification rest at about 157 - maybe that would have helped.

My question is whether this yeast is particularly attenuative, and what I could use instead. Wyeast has some good non-attenuative lager yeasts (e.g. Bavarian, which made a nice malty doppelbock for me); what is their most non-attenuative ale yeast? What characteristics does it impart on the beer?

Thanks

Jedparsonsl@husc.harvard.edu

Paul,

My first question to you is are you using extract, kits or all-grain? I'm a UK brewer who experienced similar frustration to yourself during 10 years of brewing from kits, until I switched to all-grain 18 months ago. Now I would never switch back unless desperate. The improvement in flavour was dramatic!

The only way I was able to minimise the disappointing "off, homemade" flavours from kits was to buy the most expensive available. These used the very best malt extract and lots of it. I soon got used to these and enjoyed my beer, but never felt happy about offering it to friends unless I didn't mind a few disparaging remarks. Now I am only too proud to show off each latest batch, revel in the compliments and crow "it only costs 25p a pint!" (barely 20% of pub prices). Many kit brewers do very well however and win competitions against the best all-grain brewers. It's just I don't know how they do it. (I'd be glad to find out if anyone knows, as all-grain takes quite a bit of extra time and trouble). The great thing about grain is that you have far greater scope for experimentation and brewing wonderful and exciting beers.

I don't think you can do much to improve on what you are doing already, but you might like to check whether boiling your water introduces any unwanted flavours. Taste at every stage of your procedure and you may pin down the point at which the off-flavours appear. I believe secondary fermentation is necessary for lager-type beers but British bitters certainly don't need it.

Try all-grain if you can find the extra time and cash for the additional kit. It doesn't require any greater skill, and you will find the results far more satisfying.

Subject: Baking yeast == Brewing yeast? Brewing REAL small batches?

Hi folks,

If you recall, in my very first post, I said that I was a person that made my own bread. As such, I am curious to know the physical differences between a baking yeast and a brewing yeast. That is, why shouldn't I use a baking yeast to make some fermented beverage?

Has anyone ever attempted to do this? What was the outcome? I ask this because I will be making some sourdough very shortly, and quickly realized that several people are trying to create a 'sour' beer, apparently in the Belgian style. (I've never had a sour beer, 'ceptin Guinness).

For bread it is a simple matter to create a sour dough proof, and I can extrapolate and figure out an equally simple way to make a sour beer proof. Would this be recommended? Has anyone tried it? (Surely, someone else has thought of this, right?)

Since I am interested in experimentation with beer, I am also wonder the practicality of brewing real small batches of beer. I am currently brewing 1 gallon of mead in a milk jug. Is it feasible to do the same thing with beer? (I'm not sure I want to make 5 gallons of an experiment!) I know I can get a 3 gallon carboy, but I think that may be too much also. I want something where I won't feel bad by pouring it all out.

Comments and suggestions from other experimenters will be gladly accepted.

I can only gather from the decided lack of response that there are no home brewers in Hawaii. If this is not true, please let me know.

Subject: **Bottle cultures**

I have had good success with using SNPA dregs as a starter in ale brews. BTW I find Centennial(bittering) and Cascade(flavor and aroma) a delicious substitute for Perle and Cascade- the "official" recipe for Sierra Nevada.

This past weekend I obtained a 6/pk of "Ironside Ale" which had the following info on the bottle(s).

*Brewed in Ft. Mitchell, KY by permission of the Old Time Brewers Inc.

'
of Boston, MA.-using the "first run process" of barley malt, hops, and yeast.*

The ale is not a Sierra Nevada (what is?) but as an ale it is above average, good hop nose and a slight yeasty aftertaste. There is a yeast sediment layer on the bottom of all the bottles which is much larger than that found in a SN bottle. My question is: Has anyone cultured an "Ironside" or does anyone know if the yeast is a brewing yeast or a conditioning yeast? BTY I understand that Worthington White Shield Ale uses a conditioning yeast.

Please post to HBD with any info regarding the above or any other bottle yeast worth culturing, a listing would be really great. The process is so time consuming a weak or wrong yeast culture can take the fun out(temporarily) of a hobby I really enjoy.

Thanks in advance,

Tom Rush

I tried a 6/pack
of "Ironside Ale"
over the weekend and although it is not a Sierra Nevada (what is?) it is
above average whatever that is. Not as hoppy as SN but it is not
a pale ale and its has slight yeasty taste.

> interesting resins in the flowers, so a cannabis root won't produce THC
> in hop flowers. Or so I'm told B-)

I read a book in the early 70's, I think it was called The Child's Garden of Grass, that went into a fair amount of detail about the grafting of Marijuana onto Hops roots. They gave every impression that it produced Hops that contained THC.

Also, while the flowers have the greatest concentrations of THC, they're far from the only part of the Marijuana plant to contain THC.

Subject: Dry hop anarchy

Hello Brewphiles,

Yesterday I dry-hopped an ale which had been sitting in the secondary for a few days (after a 6 day primary ferment) and within minutes of throwing in the (frozen) hop pellets the beer began frothing like crazy and spewing out the hops!
I quickly replaced the air-lock with a blow-off tube for a few hours until the activity stopped.

Prior to this, it looked like fermentation was all but done. What could have caused this? Is it hop tannins reacting with proteins in the beer?

Is it the introduction of a little oxygen to the carboy? Is it some sort of re-awakened stuck fermentation (doesn't seem likely). Or some really rude bacteria hiding in the hops (even less likely).

I've dry-hopped before and never experienced this problem.

Subject: Bitter End?

I am presently at the end of the sixth day of a 2ndary fermentation on a batch of M&F Gold Old English Bitter from malt extract. Everything went as expected in the usual 3 day primary (FG plastic bucket) and the secondary in a glass carboy has progressed as usual with the exception that it isn't clearing. My last batch of pilsner had this same problem, and still hasn't cleared after 4 weeks in bottles. No visual or taste indication of infection. In the Bitter batch, there are still bubbles coming to the surface, the SG is at 1.020, and there are large bubbles dragging ropy globs of the yeast from the bottom that seem to keep things mixed up.

What to do? Leave it longer until I get to SG 1.010 and then bottle? Siphon back to the FG plastic? What? This is only my third batch of beer and I'm feeling a little disheartened. The first batch of Porter was perfect!

Please copy me directly as well as HBD as I'm feeling compelled to bottle by Wednesday before anything else goes wrong. Thanks.

Subject: warning about blowoff

Yesterday I decided to try the blowoff method to see how it improved my beer. I had an oatmeal stout in a secondary 5 gal carboy that had a wyeast irish ale yeast cake. I racked out the stout into a bottling bucket, and replaced it with a Belgian Ale that I had just chilled. The temp. was about 85 degrees. I attached the blow off tube, gave the carboy a couple good shakes, put the end of the tube in some water and left it alone. I came back an hour later to see the most vigorous fermentation imaginable. I sat there in amazement for an hour watching my precious brew shoot out the tube like some contraption in willie wonka. This morning, the fermentation is starting to slow. I figure I lost about a gallon of brew through the blow off tube.
Moal: If your trying to save some money by getting double duty out of your wyeast, I suggest significantly decreasing the yeast cake before racking onto it.
I realize that I lost a lot more brew than I was supposed to, but can the benefits of blow off really out weigh the loss of a six pack?

Subject: Re: Making smooth stout

In HBD1027 Russ G. spoke of smooth stouts. I tasted a stout I brewed recently that was 1 week old. I tasted as I racked to keg. I couldn't believe how smooth this beer was at 1 week old! It had 2 or 3 lbs of roasted barley in a 10 gallon batch. I put the roasted grain in the mashout! I think the smoothness can be attributed to two things, putting the grains in the mashout and the fact that I kept the black malt quantity small, about 8 ozs in 10 gallons. The black malt was also put in the mashout. There was even some chocolate malt in there too.

Subject: Aerating the wort

I have had fermentations stop short in the past and one of the consistent potential explanations is the lack of aeration of the wort. My last two batches (and incidentally, my first two batches) used Wyeast and fell short of full fermentation. In both situations, it seemed to have a very active fermentation for a short time and then it stopped very abruptly. I am wondering if my aeration is not sufficient. What is the recommended technique ?
Is it sufficient to use a spoon and really the stir the wort up before sealing the lid ?? Thanks for any replies.

Cheers,
Kevin

Subject: sparging. NOT!

In HBD 1026 Micah responds to Jack's query as to why we bother sparging at all. It was a good question and, as usual, Micah's response was interesting and informative.

Reading Line's The Big Book of Brewing for the umpteenth time, I came across this quote:

"Ideally, it would be nice if all the sweet wort would drain naturally from the spent grain. In practice, though, about 40 percent of the extract could be retrieved in this manner."

He then goes on to give a non-technical description of how the sugars get stuck in the grains, speaking of "cups" and "umbrellas".

Line doesn't say where the figure of 40% came from. Perhaps he got it from an English brewery which still uses the "frist runnings" method to produce strong ale. Perhaps he calculated it, either from theoretical considerations or homebrewing experiment.

In any case, it caused me to think of the traditional pre-sparge method used by English breweries in centuries gone by. I came up with the following process based on 3 items from Line's book:

- * the 40% figure quoted above,
- * 3 IMPERIAL pints per pound of strike liquor; that's a whopping 58 US fl. oz.!
- * a theoretical maximum of 36 points per pound of UK pale malt

Disclaimer: This is an untested recipe, based on the above hypotheses.
- ----- I suspect that the volume of sparge water is too great.

Traditional Ale Triple Batch
- -----

Yield (all volumes are US gallons)

5 gallons Strong Ale: OG 1072
5 gallons Pale Ale: OG 1043
5 gallons Shandy:OG 1026

25 pounds UK pale malt (replace a fraction with darker malts if desired)
11 gallons sparge water at 162-5F

Hold at 150F for 90 minutes.
Raise temperature to 172F.

- 1- Drain first runnings.
- 2- Replace volume drained in step 1 with water at 172F. Let steep and drain again.
- 3- Repeat step 2.

Boil all three batches down to 5 gallons (5.5 if using a primary followed by a 5-gallon carboy as a secondary). Hop appropriately to the gravity with Fuggles, Goldings, and Northern Brewer. Optionally, add lemon zest to the shandy.

I intend to try this recipe some day, probably scaled down by a factor of 5. I expect it to be some weeks or months after the holidays. I'll post when the time comes.

One could combine the second and third runnings to get a wort with an OG of 1035. This is suitable either for mild ale or (just barely) ordinary bitter. One could therefore halve this recipe for a batch of bitter and a half batch of strong ale.

As a variant, one might choose to sparge after collecting the pale ale, so as to get a stronger shandy. Interestingly enough, it wouldn't be very much stronger: the total efficiency from the above process is 28 points per pound. I only got about 29 on Saturday sparging Munton & Fison pale ale malt.

Here's another variant that should work well for people set up to brew 5 gallons of all-grain beer. Mash 10 pounds (scale the above down to 40%) and use the first runnings to get 2 gallons of strong ale (ferment in 2 1-gallon jugs). Sparge the grain thoroughly (5-6 gallons) and make a 5 gallon batch of bitter with these runnings and a pound of dry malt extract. The gravity should be about 1036-1038.

From: Jacob Galley <gal2@midway.uchicago.edu>
Subject: Cannabinated homebrew

One (hopefully) final note on the marijuana-and-yr-beer thread:

One method suggested for cannabinating your homebrew was to "dry-pot" it in the secondary, and let the cannabinoids leech out into the water-alcohol solution we like to call "beer". Though I do not know first-hand how well this will work, it seems to me to be very inefficient. Anyone making Zauberbrau* by this method should not assume that all of the magic has left the cannabis. After soaking, the herb should probably be saved and used in a brownie recipe or something.

*My apologies to anyone who really knows German.

Cheers,
Jake.

(PS - Now that I am old enough to legally possess as well as make my own beer, I have found something less sacrosanct than Reinheitsgebot to berate regularly in my signature.)

Subject: Wheat Beer

Hi All,

I recently made a wheat beer, and have had many positive comments, as well as encouragement to post the recepie, etc. Here goes a newbie`s first post to HBD! This was my second batch of beer; I'm proud of it!

Azkicken Weizen:

8 # Wheat malt
6 # Pale malt
0.3 # Crystal malt

Hops Schedule:

T-	quantity	type
30	1 Oz	Fuggles pellets
15	1 Oz	Tettngang pellets
5	1.5 Oz	Saaz whole

Wyeast 3056, started in wort 4 days before pitching.

Procedure:

Mash-in at 126f, dropped to about 122f and held there for 30 minutes (protein rest). Used about 3 gallons H2O.
Up to 156f, held for 60 minutes (starch conversion).
Up to 168-170f, for 10 minutes.
Sparged at 165-170f with 5 gallons.
(Used a modified lauter tun as an experiment. Sparge was inefficient, extremely so. Took about 30 minutes to sparge, at most. Would have been faster if I hadn't regulated the flow.)

Boiled from 7 gallons down to 5 - about 90 minutes total.
(including hops!)

Immersion chilled to about 70f.

After chilling, let it rest for about 1 hr (had to pick up friend from bart!).

Single Stage Ferment:

Racked into primary, pitched 4 day old starter. Starter had been in "resting" phase for about a day. (krausen had fallen the day before, appx. Really slow for a starter!)

Bubbles like mad within about 12 hours, krausen in about 24. Bubbles stopped almost dead at about 3 days, most of the trub had settled out.

After one week, racked into bottling bucket, krausend with appx. 2 quarts of wort (saved for this purpose). Bottled. At this point the protoBeer was fairly "cloudy" with an amber-ish color.

After one week, it was fully carbonated.

Notes:

SG: 1.051-ish
FG: 1.014-ish
%alc: about 5

week1:

Hop Hop Hopppy! Tasty, too! Nice wheaty flavor, not too much hop. white-cloudy in the bottle and in the mug!

week2:

Cleared up, for the most part. Not as much bitter taste as last week, but the hops come through in the finish. A nice amber beer.

week3: some fruity tones have developed, but it still retains it's wheaty flavor and a nice hops finish.

Although the beer cleared up after about two weeks in the bottle, it still has the characteristic cloudiness after chilling.

I had been disappointed with my extract, a low of about 17 pts/#/gal. The beer is extremely tasty. Not at all bad for a second try. I think I'll do this again, with a less-modified lauter tun.

In fact, my teacher and brewMentor sez:

>Date: Tue, 24 Nov 92 11:06:17 PST
>To: miked
>Subject: Results are in...

>GOOD WHEAT BEER!

>thx
>gak

So I'm fairly happy.

Lessons learned:

- 1) too much drainage in the lauter tun will "ruin" the extract efficiency.
- 2) a "ruined" sparge on a grain-heavy beer can produce an outstanding result!
- 3) using a starter to pitch can drastically reduce lag time, and overall time-to-tummy (amount of time from boiling to drinking!). I could have bottled at day4! (Had to wait for the weekend, tho!)
- 4) beer making is fun, easy, and hell - if I can do it, so can you!

At this point that batch is about gone. A few extra bottles have been "squirrelled" away, two might get entered in a local home brew competition in Jan `93.

My advice is, if you know anyone who's expressing a interest in brewing, invite them over for a run. My boss did this once, and offered some advice. Between his advice and Miller's book, I've done three full-grain batches, krausend and all, and not had a bad experience YET!

"A Mexican newspaper reports that bored Royal Air Force pilots stationed on the Falkland Islands have devised what they consider a marvelous new game. Noting that the local penguins are fascinated by airplanes, the pilots search out a beach where the birds are gathered and fly slowly along it at the water's edge. Perhaps ten thousand penguins turn their heads in unison watching the planes go by, and when the pilots turn around and fly back, the birds turn their heads in the opposite direction, like spectators at a slow-motion tennis match. Then, the paper reports, "The pilots fly out to sea and directly to the penguin colony and overfly it. Heads go up, up, up, and ten thousand penguins fall over gently onto their backs".

Subject: Re: diacytl, dough-in, freezing

In HBD #1027, Russ Gelinias writes:

> JimG has a diacetyl problem, and described his final gravity as 1.017,
>which is high for medium-strength beers. I think the FG may be an indication
>of a weak ferment, caused by lack of oxygen. Lack of O2 will also increase
>diacetyl production (or is it decrease the amount of re-absorbtion of diacetyl
>by the yeast). Either way, the beer is buttery. Solution: Aerate the cooled
>unfermented wort better.

I had a problem similar to this once. The Diacetyl finally was reduced after about three months in the keg. My problem occured (I think) because I fined, primed with fresh wort, kegged and stuck in my lager refer before the carbonation was complete. Anyway, the yeast was dropped out of suspension before it could do it's job (diacetyl reduction). For the longest time I could get a good glass of beer if I waited a week between pours!.

What is the point of this? Maybe the solution is to stir up the yeast in you beer and store at a reasonably warm temperature and wait. Another possibility is to aerate you finished beer slightly and then prime it with a little corn suger to get the yeast active again. Then let it sit long enough to completely ferment out before tasting it again. The course of action would depend upon how you packaged your beer.

From: arf@ddswl.mcs.com (Jack Schmidling)
Subject: Band aids

>From: korz@iepubj.att.com

>That bandaid flavor is phenolics. The most common source of them is from your yeast (Munton & Fison yeast is notorious for them) but the Troubleshooting special issue of Zymurgy mentions that wheat malt can cause them also.

I tried to fend off the knee-jerk reaction of a defect by pointing out that the malt, when chewed, has the same taste and it is probably my inability to properly express the taste.

>Perhaps there's something in the Belgian Cara-Pils that does this also.

If anyone has some on hand, give it a chew and tell me what it tastes like, if not bandaid.

BTW, I have a good handle on the phenolic taste and what I called bandaid is totally different. Unlike the phenol, this is a pleasant taste and seems to belong in beer.

>However, I have not noticed this problem -- granted I've never used 2 pounds in a batch!!! It could simply be a reaction between your strain of yeast and something in the the Cara-pils.

I am using Pilsner Urquel yeast, for what that is worth.

>Much more reasonable -- I hope I get to taste it at tonight's CBS meeting.

If it is the world's greatest beer, I'll be honest and tell you I think so.

You will have to wait till the next meeting. Even the world's greatest brewer would not serve a beer before its time.

Something came up anyway to prevent me from attending but after a customer told me that what I could have brought, "tastes just like PU", I wish I had.

It will be long gone by next month.

>From: Chris McDermott <mcdermott@draper.com>

>A while back, I think I remember, someone posted detailed instructions (or offered to give them) on building a CP bottle filler for some short change.

Could the person who offered these please send me the instructions.

I am sure someone else will provide the valving and control arrangements but

I thought I would describe a real cheap and dirty way to do the business end of the filler.

Get a #3 rubber stopper with two holes in it. Poke a piece of 1/8" tubing in one hole far enough to reach the bottom of the bottle and the other end goes to your beer dispenser valve. Poke another piece of tubing into the other hole, just far enough to clear the bottom of the stopper and attach the other end to you CO2 line.

The rest is a bunch of valves and pipe fittings to make it all work together.

Micah has come up with a slick setup for those who don't want to hunt down

the parts. I would caution against the Fox filler because the valves used

require a tedious amount of twisting. The CO2 release valve can and should

be a needle valve but you want a quarter turn valve or the squeeze type Micah

uses for the beer and CO2 line. Fox uses all needle valves because they are

cheaper.

From: THOMASR@EZRZ1.vmsmail.ethz.ch
Subject: re: breadyeast

In today's HBD someone (thutt@etc) asked about breadyeast compared with beer yeast (Sach. Cervisiae). Well, as far as I'm aware, bread yeast is also usually Sach. Cerv. strain, but it is often bred (pardon the pun) to give the best bread possible (not always as I'll mention in a bit). That is, it produces a very yeasty taste, and doesn't flocculate well. I've tried (in desperation, having forgotten to get some 'real' stuff) a number of breadyeasts, some with reasonable success, some not. In the UK many breadyeasts bought in supermarkets are actually supplied by the brewers, and hence is an ale yeast. These can be quite good, but are often full of other bugs as well. Over here (Switzerland), the bread yeast is bottom fermenting, hence presumably a lager yeast. They didn't know who the supplier was in the shop where I bought it, maybe Hurlimann? Anyway, as to taste, yes the beers were a little yeasty, those from UK yeast took ages to clear, the batch here cleared quickly, and settled to an excellent yeast cake in the bottles. This batch was a 1095 winter spiced ale (using only the first runnings incidentally). It finished at 1028, which was unexpectedly high. I bottled half, and put champagne yeast in the other half. 2 months later, the bottled half tastes wonderful, not really sweet, and certainly warming. The other half is still bubbling!

The upshot is, give it a go on an amount of wort you're prepared to waste!

P.S. Any brewers in Switzerland?

P.P.S. Sorry about the massive message.

Subject: Mercato vs. Maltmill

I got a look at a Mercato grain mill this past weekend at a store here in Boulder and while it appeared to be well built...for the price (\$100) I wouldn't bother. I've used Jack's Maltmill (standard disclaimers apply) and of the 2...would go with Jack's. Why???? Jack's is built to mill grains for brewing...the Mercato has a miniscule hopper and a 1 inch by 1/2 inch slot! Jack's is designed to fit over a bucket to catch a bunch of grain. .. the Mercato sits on a table top...I guess you could rig a little tray or something to catch the milled grain..but after the \$100 outlay, I'd want something I could get in, turn the key, and go! The rollers were almost identical, grooved to grab the grains, with one notable exception. The Mercato rollers are barely 5 inches wide..if my memory serves me, the Maltmill has rollers closer to a foot wide sitting under a 4 inch by 2 1/2 inch feed chute (sorry if those aren't the exact dimensions, but the difference is obvious). So...for those of you who have been wondering...for those of you looking for an "alternative" to the Corona...if you've got the cash...get a Maltmill! Now, if only some sharp businessman who understands the value of a great testimonial would "comp" me a Maltmill (this being the season of giving and all)..... ;-)

Subject: Bottling "Competition" Brew

>if you recall, in my very first post, I said that I was a person that
>made my own bread. As such, I am curious to know the physical
>differences between a baking yeast and a brewing yeast. That is, why
>shouldn't I use a baking yeast to make some fermented beverage?
>Has anyone ever attempted to do this? What was the outcome?
>I ask this because I will be making some sourdough very shortly, and
>quickly realized that several people are trying to create a `sour'
>beer, apparently in the Belgian style.

I'm curious about this also. I always keep a sourdough starter going in
the 'fridge and it smells like it would make a wonderful yeast starter
for a beer with a "sour" character.

On another topic, I'm looking for advice/comments on the best way to
bottle beer to send to a homebrew competition. I normally transfer my
beer from secondary to a soda keg and keep it under pressure. Should I
bottle a six-pak or so out of the secondary, or should I fill a couple
bottles straight out of the keg?
Thanks in advance,

Jami

Subject: Laaglander DME and high OG - what to do?

Greetings all ...

I have been following the high final gravity reports with interest. I have a brew that's "done" fermenting at 1030. Its a pale ale created with 8 lbs of dried malt extract and 1 lb crystal. It started at 1064 and is done fermenting at 1030. After seeing the remarks about Laaglander DME finishing higher than Muton&Fison, I checked my notes to see what I used. Here's the breakdown:

- 6 lbs Laaglander extra light DME
- 2 lbs Muton&Fison light DME
- 1 lb Carmel Malt (40L)
- 1056 Wyeast

(plus assorted hops of course, for around 20 HBU).

This is my 8th extract brew and I am determined to get the OG lower. I bottled one batch at 1024 and it was the only batch I couldn't drink.

Here's what I've done so far.

Upon seeing fermentation slowing at 1030, I racked to secondary. After doing this, fermentation came to a halt. (No action on the fermentation lock).

I read in Papazian that one approach to fixing stuck fermentations is to add yeast hulls and fresh yeast. So I popped another Wyeast 1056, let it bulge and added it along with 1/2 ounce yeast hulls. Fermentation picked up for a little bit, the SG maybe dropped to 1029. I fair amount of sediment fell out to the bottom of the carboy.

I then concluded that the yeasties don't have enough nutrients or that all the O₂ is gone from the wort and the yeast needs O₂ during its aerobic phase.

So, deciding that an introducing O₂ is better than not having a drinkable beer, I racked again and was careful to suck up all the bottom trub and let the beer splash into the carboy to re introduce O₂.

Still, no more fermentation.

NOW WHAT?

I figure there are a few things left I could do:

- a) Add some yeast nutrient on the chance that that's why the second yeast starter did not start fermenting.
- b) Change to a different strain of yeast
- c) Follow the suggestion of the "brew store guy" and add hop extract to make it more bitter and bottle it.

I've already decided that I don't want to do c) if there is anything that I can do to get the OG down. If all fails, my last resort will be to dilute it with boiled/cooled water and bottle.

Does anybody have any better ideas? BTW, I also have a batch going

with 10 lbs Muton&Fison with chocolate and black patent malt using
Wyeast 1098. It started at 1078 and has been in active fermentation
(with kreuzen) for 12 days. Its SG is around 1035 right now but
I'm not worried ... the f-lock is blooping every 8-10 seconds.

Subject: re: iodaphor and blowoff

In HDB #1028 Joe Johnson asks about iodaphors:

>Can anyone advise me on the use of iodophor as disinfectant for brewing
>equipment?

Joe,

I use the iodophor sanitizer to sanitize all of my brewing equipment which will come into contact with 'clean' wort. This includes my primary fermentor (6 1/2 gal carboy), my secondary fermentors, siphon hoses, funnels, and of course bottles. The concentration of iodine in the sanitizing solution (12.5-25 ppm) is well below both FDA approved ingestion limits and the perception threshold (unlike chlorine) so that rinsing is not necessary.

Also Tom Tomazin asks:

>[snip] can the benefits of blow off really out weigh the loss
>of a six pack?

Tom,

I have been doing my primary fermentations in a 6 1/2 gal carboy (no blow off) for three years now. My beers (at least, according to my biased friends) are great. Try a closed fermentation a couple of times and see for yourself if it makes any difference.

Subject: Wort aeration

In HBD 1028 Kevin Krueger asks about wort aeration. In the Zymurgy special issue I came across a wort aeration device by Larry Barello that's so simple it's brilliant. Take an old racking tube (we've all broken a few, let's admit it), cut it down to about a foot or 18", drill four holes around the end of the tube closest to the siphon hose. This acts like a carburetor and sucks air into the wort as it is siphoned into the primary. Larry claims he gets his entire head space filled with foam. Now that's aeration! And no pumps, and no bubble stones to sterilize...

Subject: Addr: carboy

I brew about five gallons of beer a month and I have a question maybe someone can answer. I been using a 5 gallon glass carboy for primary fermentation and have the problem with the airlock blowing out and smacking into the kitchen ceiling (a particularly memorable occasion concerned a M&F stout whose blackened spots remain to this day above my head). My solution has been to simply fill the carboy up with wort only about three-fourths of the way, and after fermentation has subsided, fill the carboy the rest of the way with boiled, cooled water. What do you all think? I haven't had any problem, but I wonder if this is simply dilluting good beer in an inappropriate manner. Also, the water naturally causes a bit of splashing, even though I try to keep this to a minimum. Could air bubbles from this process be detrimental to the final product (which, after all, tastes pretty darn good). I'd be glad to hear anyone's opinions about this.

Also, in response to someone's comments about improving their brew, the BEST thing I ever did was when I began to boil ALL my water (it is well water, after all). My beer improved dramatically with this simply process. I usually boil it 45 minutes to an hour.

I just subscribed to HOMEBREW DIGEST and I this it is a terrific way for a novice like myself to learn. Mashing sounds so complex for me right now, but someday...

Thanks for any help.

Paul Yatrou writes:

> Yesterday I dry-hopped an ale which had been sitting in the secondary
>for a few days (after a 6 day primary ferment) and within minutes of
>throwing in the (frozen) hop pellets the beer began frothing like crazy

I wish the homebrewing books would warn people about that.

Your fermented beer will have varying amounts of CO2 in suspension.
By dropping hops into the liquid you give those CO2 molecules a
collection point causing them to combine and come out of suspension.
You may have seen something similiar when bottling. CO2 will collect
in
the tubing, because of turbulence, and eventually create quite a froth
in the bottle.

I've had this happen, in varying degrees, everytime I dry hop. My
question is: why do some beers seem to hold more CO2 in suspension
than others?

Subject: Flat Beer

Well, I'll try one more time...

I recently made a batch of EDME Strong Ale. After two months in the bottle, I opened one and... it was completely flat. Not a bubble.

The taste is fine. The S.G. dropped ok. I'm not sure what happened (I primed it with dextrose), but it's never happened before.

Can I attempt to carbonate it by adding more sugar and/or yeast?

Assuming this worked, would it affect the taste?

Any help would be much appreciated.

Brian

From: tony@spss.com (Tony Babinec)
Subject: ironside ale

In a previous HBD, Tom Rush mentioned Ironside Ale.

Ironside Ale, available in the Boston area, is contract-brewed by the Oldenberg Brewery in Ft. Mitchell, Ky. I visited the Brewery on a business trip in October, and Oldenberg was serving 4 beers:

Blond--a light lager
Wheat--a light American wheat
Premium--a good, fuller-tasting lager with a slight yeast-sulphur note
Vail Ale--a good American ale.

Oldenberg also brews a seasonal stout and a bock, and was brewing a Winter Warmer.

I got an impromptu tour of the brewery and tasted some Ironside Ale from the bright beer tank. Ironside Ale is less-hopped than Vail Ale or many of the left-coast ales. Other than that, it's a pleasant beer. I don't know whether the yeast in the bottle is the same one they use for fermentation.

Artesian wells are wells that pump themselves because they are below the water table level. Webster's explains it better:

artesian well: A well drilled through impermeable strata to reach water capable of rising to the surface by internal hydrostatic pressure.

This water shouldn't be any better or worse than regular well water, as far as I can tell.

Subject: Hops Grafted to Marijuana

Well, since nobody out there seems willing to believe those that have said grafting hops onto marijuana roots will not produce psychoactive hops plants, all I can say is, please go ahead and try it. It seems really fruitless to me for questions to be asked, and then the answers discounted and ignored. I might point out too, that "The Child's Garden of Grass" is hardly a definitive treatise on marijuana cultivation. The technology and knowledge of dope growing has come a long way in 20 years. In 1970, the best pot came from other than the U.S. These days, the best pot *in the world* is grown right here at home. Cloning, hydroponics, CO2 systems, etc. have made the U.S. the highest potency pot producer. I sincerely doubt anyone will find any cultivation book written (not updated) in the last 5 years that'll support the notion of grafting.

But like I said, knock yourself out trying. Oh, and the flowers are definitely NOT "far from the only part of the Marijuana plant to contain THC".
You have a lot more reading to do.

Subject: Vintage Thomas Hardy's

>Subject: 21 year old stuff from Micah Millspaw

> As for the Thomas Hardy's I've read (Michel Jackson) that they
>will go 25 years. I have personally drank 7 year old Hardy's and it
>was excellent.

I'd proceed with caution here. Recently I was fortunate enough to do a vertical tasting of some eight different vintage Thomas Hardy's. While it was really a blast, I have to confess that the results were somewhat disappointing. Some of the brews were excellent, and had the smooth marriage of flavors and sherry qualities that can only come with with aging. Others however, had gotten cardboardy, and a couple had gone (horrors) sour. One was decidedly unpleasant and the other was downright vile! These beers came directly from the cellar of the importer, and had been stored under the best of conditions.

After that experience, I'm doubtful that any vintage Hardy's will go a full 20-25 years. Fortunately, there is an obvious approach to all of this. Buy (or make, as Micah did) two cases of barleywine, and use one to monitor the progress of the other. When it peaks, have a party!

Cheers,
CR

From: Pierre Jelenc@cunixf.cc.columbia.edu
Subject: raspberries and sulfites

In hbd 10025, Dennis Templeton recounts his problems with raspberries and Campden tablets.

Undoubtedly, the sulfite has bleached the raspberry color, that's what sulfites do after all.

Instead of Campden tablets, I strongly recommend using potassium permanganate on the uncrushed berries. 10 to 15 min in a solution of KMnO4 concentrated enough to be frankly purple will take care of all the nasties. A good rinse with clean (boiled, if necessary) water, and you're ready for the crush.

Incidentally, I routinely sanitize all my salads and raw vegetables in this manner, since exotic parasites and germs are apparently rather common in New York City, from what I've read.

Unless they have changed the name, Edme calls their diastatic malt
extract
"EDME DMS" (diastatic malt syrup). I share your concern for beginners,
but in this case, if the beginner did use EDME DMS in place of DME, the
only harm would be that they would get an OG 20% lower than expected
(for 7 lbs, that would be 1.043 instead of 1.053). Not what they
expected,
but not tragic.

Rob writes:

Yes it will, but it's not recommended to use it from the Bigfoot.
They use the same yeast for all their ales and harvest yeast from
all but the Celebration Ale and the Bigfoot (the high alcohol reportedly
causes increased mutations). Therefore, I suggest that you get some
Sierra Nevada Pale Ale (Wyeast #1056 would work too) and make a starter
from a couple three bottles.

Jed writes:

their

>most non-attenuative ale yeast? What characteristics does it impart on
>the beer?

I think you've got all the answers to your questions except the number
1338.

Wyeast's least attenuative ale yeast is Wyeast #1338 German Alt. "A full bodied complex strain finishes very malty. Produces a dense rocky head during fermentation. High flocculation & apparent attenuation of 67-71%." There is some similarity between this yeast and Wissenschaftliche #338 ; ^).

As you said, you could have held the saccharification rest at 157F or even 158F, to get a more dextrinous wort.

Desmond writes:

>(barely 20% of pub prices). Many kit brewers do very well however and win competitions against the best all-grain brewers. It's just I don't know how they do it. (I'd be glad to find out if anyone knows, as all-grain takes quite a bit of extra time and trouble). The great thing about grain is that you have far greater scope for experimentation and brewing wonderful and exciting beers.

Due to time constraints, most of the beers I've brewed lately have been extract + specialty grains, and quite a few of those have won awards at competitions (in fact all 5 medals I won at the latest BOSS/CBS competition were for extract + specialty grain brews). I think the keys are:

1. use quality yeast (all these were done with Wyeast, but there are some very good dry yeasts out now too),
2. use quality specialty grains (I used various crystal malts from Munton & Fison (UK) and DeWolf & Cosyns (Belgium), and Chocolate and Black Patent from M&F), and
3. use quality extract (I use Northwestern, Munton & Fison Plain, M&F Old Ale, Alexanders and John Bull Unhopped Dark, M&F Light DME and Laaglander Light DME almost exclusively).

I would like to have the time to do more all-grain batches, but I think that with all the varieties of yeast, hops, specialty grains and malts available, there is just a great a scope for experimentation with extract + specialty as with all-grain. If I live to be 200, I won't have the time to brew every combination even if I never brew another all-grain batch.

Don't get me wrong -- since getting into all-grain, I've dicovered that there are as many types of grains as extracts. DeWolf & Cosyns, Maris Otter, Munton & Fison, Minnesota Malting, Schrier, Breiss... just to name a few -- each with their own character. You've got to love this hobby!

Al.

Subject: Re: Dry hop anarchy

Another data point for seemingly re-activated fermentation when dry-hopping.

I dry-hopped for the first time on the first of this month, in what I thought was a normal way - wait for primary fermentation to calm down, put hops in the bottom of the secondary, and rack. Well - it started fermenting again! It's still going! I admit, it's slow, but it sure looks like fermentation - 1 1/2 weeks later. The yeast is M&F dry yeast, usually pretty quick. What's going on? Does anybody know?

From: cbacco@ursa5.cs.utah.edu (Corby Bacco)
Subject: First Lager

Hello all,

My brew-mates and I have embarked upon our first lager (Kulmbacher recipe from the Winner's Circle) and I'm a bit curious as when to rack.

I know that there has been vigorous debate recently about racking but we decided to just do the same as we do for ales. Problem is it ferments a bit differently (like I said, first try at a lager). We usually rack after about 3 days, when active fermentation slows. Well, its been a week and the lager is still chugging a long pretty good.

Question: Should we

- a) rack now even fermentation is still active
- b) wait until fermentation slows more
- c) not rack at all
- d) flip a coin

The only thing I was really wondering about was if racking now will stop fermentation (whether it's done or not), after all lager are bottom fermenting yeasts right? Please pardon my ignorance if this makes no difference.

Thanks in advance,
Corby Bacco

>
>(....)
>We realize that there oughtta be a way to use a bit of DME or other
>non-table-sugars as a priming agent. We thought about using DME at the
>time, but the technique for doing so was not in our brewing repertoire,
>so we erred on the side of caution and decided to wait until we could
>get some corn sugar.
>
>My question to the HBD is: Other than corn sugar, what are other
>acceptable priming agents and what is the technique for their use???

One cup (maybe 1 1/4 cups) of a 'pale' DME dissolved in sufficient water will achieve much the same affect as the corn sugar. One caveat: it seems to take a little longer before the desired carbonisation appears. It does contribute to the formation of a good head, and is just the thing for those who insist on all-malt beers. Another technique is the art of krausening, where one adds some fresh wort to the fermented flat beer prior to packaging.

Good old corn syrup will do quite nicely, place of corn sugar. Fruit-flavoured syrups will also do a good job, and will add that touch of fruit to your beer (if that's desired!), and are also obvious choices for fruit beers made with cherries, raspberries, peaches, and plums.

I have used a combination of DME + syrup to good effect; I recently bottled and primed two fruit ales with 1/2 cup of pale DME + 1/2 cup of peach syrup. I made a 'peche' and a christmas-style 'sugar-plum' ale (plums, cinnamon, nutmeg, and cloves), and the peach syrup did an excellent job of accentuating the fruit flavour.

>Plastic Cases:

>
>Some of the cardboard cases for my beer bottle collection are becoming
>"structurally unsound". I'd like to replace them with plastic cases.
>These are like milk crates, but with slots for 24 beer/soda bottles.
>I've seen them in Europe but not in the States. Any ideas?

You've seen 'em in Europe because the plastic bootle crates are used for almost all beer and soft-drink delivery, including both retail and private accounts (and the notion of having beer delivered to one's home certainly has merit). Since most brewers use the same size of bottle (mostly the

half liter 'Euro-flasche'), they can use the crates and the bottles inter-changeably, and they can deliver and accept returns using the same crates.

For Americans, the only idea I'd have is to use cardboard or plastic dividers in milk crates. I've never seen the plastic bottle-crates here in the USA.

Subject: Dry Yeast Profiles

Most people on the digest have probably seen the Wyeast profile sheet that's floating around. I've been wondering if any such list exists for dry yeasts. Specifically, I'm interested in profiles for: Coopers, Lallemmand Nottingham, Lallemmand Windsor, and Whitbread Ale. Does Whitbread Ale have the same profile as the Wyeast version? Individual descriptions would be welcome as well as complete list would be welcome. I really like the fruity, minerally effects of Wyeast London Ale (1028) will any of these give me a similar finished product?

Subject: Sparging

>From: bradley@adx.adelphi.edu (Rob Bradley)

"Ideally, it would be nice if all the sweet wort would drain naturally from the spent grain. In practice, though, about 40 percent of the extract could be retrieved in this manner."

>Line doesn't say where the figure of 40% came from.

It would be easy enough to make a batch both ways and compare the difference.

If all the expert opinions are now in, it seems safe to conclude that there is no fundamental reason for the process other than eliminating waste.

However, other than that, Line's comments do not really address what I was getting at. Obviously, if one runs 5 gallons of sparge water through a mash containing 3 gallons of water one will get more sugar than if he just drained off the 3 gallons.

I am suggesting that in the same situation, one could mash with 8 gallons of water and drain it all off. The more diluted wort would more effectively scrub the grain of sugar and the loss would probably be nowhere near 40%. One could still add a gallon of hot water and stir it up to get a little more out of it but the sparging step could basically be eliminated.

End of HOMEBREW Digest #1029, 12/09/92

Date: Wed, 9 Dec 1992 08:32:56 -0500
From: mgx@solid.ssd.ornl.gov (Michael Galloway)
Subject: re: closed fermentations

In HBD #1029 Richard King asks about closed fermentations:

>[snip] I been using a 5 gallon glass carboy
>for primary fermentation and have the problem with the airlock
>blowing out and smacking into the kitchen ceiling (a particularly
>memorable occasion concerned a M&F stout whose blackened spots
>remain to this day above my head). My solution has been to simply
>fill the carboy up with wort only about three-fourths of the way,
>and after fermentation has subsided, fill the carboy the rest of
>the way with boiled, cooled water. What do you all think? I haven't
>had any problem, but I wonder if this is simply dilluting good beer
>in an inappropriate manner.

Richard, I do all my fermentations closed, in a 6 1/2 gal carboy. If you cannot get one of those, try splitting the batch between two 5 gal carboys. When the primary fermentation activity abates, siphon the two 'splits' into a single 5 gal carboy and procede as normal.

Richard also asks:

>Also, the water naturally causes a
>bit of splashing, even though I try to keep this to a minimum. Could
>air bubbles from this process be detrimental to the final product
>(which, after all, tastes pretty darn good). I'd be glad to hear
>anyone's opinions about this.

Try siphoning the boiled and cooled water into the carboy.

Subject: Baker's yeast conclusions & Alabama brewing

Thanks to all who responded to my query about baking yeast. The responses generally said that the two yeast types (baking / brewing) were physically the same, but cultured to perform differently. Some people said they had (or knew someone) tried to use a baking yeast. The results varied on the Baking beer quality. From: bland, to no better or no worse than Brewer beer.

One respondent wanted to know how to make sourdough starters! I guess I will give it a try (once I get enough milk jugs to break my experiment into parts). Can anyone give me the name of a sour beer so that I can see if I really want to do this. Alternatively, if you have had a real sour beer, please describe it. (The sour-est beer I have had is Guinness. I guess you can use this as a benchmark.)

Finally, I'm getting my father a brewkit for Christmas. He lives in Huntsville, Alabama. Can anyone tell me if there are brewstores in the city? What's the closest, if none are in Huntsville.

Thanks again

Taylor

From: jim busch <busch@daacdev1.stx.com>
Subject: re:bigfoot alcohol content

Thanks to the person who posted the info on Sierra Nevada products.
The information looked accurate up to the Bigfoot entry:

Bigfoot Ale

alcohol content: 10.1% by weight
starting gravity: 23 plato (1.092)
ending gravity: 6 plato
yeast: ale yeast
bittering hops: nugget
finishing hops: cascade
dry hops: centennial and cascade
malts: 2-row barley malt, caramel malt

Either I'm missing something, or the strength of this
beer is not 10.1 by weight. I get 8.77 by volume,
 $23-6 * .516 =$ alcohol by volume (very roughly). Maybe
this formula doesn't hold for high gravity??

Jim Busch

From: "Dean Roy" <DEAN@alpha.uwindsor.ca>
Subject: Diversol

I recently purchased a Cornelius keg system from an out of town homebrew supply store (hurray no more bottling!). The guy at the store gave me a packet of "Diversol" which he said to use to clean the kegs with. He told me that this was a detergent used in the dairy business to clean vessels.

Can anyone tell me exactly what this stuff is? It is bright pink powder and the instructions say to mix it up at a rate of 2 ounces per gallon of water. They also state that this solution is reusable.

Any information on this stuff would be greatly appreciated.

From: tony@spss.com (Tony Babinec)
Subject: thomas hardy's ale

Roger Protz of CAMRA has a nice description of Thomas Hardy's Ale in his "European Beer Almanac":

alcohol by volume: 12%
degrees plato: 31
original gravity: 1125

Ingredients: Maris Otter pale ale malt and crystal malt. Fuggles, Goldings, and Styrian hops. 60-70 units of bitterness. Top fermenting yeast.

Tasting Notes.

Nose: 'Brisk as a volcano.' (quote from Hardy's "The Mayor of Casterbridge.")

Palate: 'Full in body; piquant, yet without a twang; free from streakiness.'

Comments: Thomas Hardy wrote with evident enthusiasm about the beer of 'Casterbridge' (Dorchester) in his Wessex novels. Eldridge Pope have repaid the compliment with their classic bottle-conditioned beer named in his honor. It was brewed first in 1968 to mark the 40th anniversary of the writer's death but interest and demand has meant that it is now brewed on a regular basis. It is dry-hopped and warm-conditioned for 3 months and is pitched 3 times with yeast, twice during fermentation and then during conditioning. It continues to condition in the small nip bottle and the brewery recommends that it is laid down for 5 years. A new vintage is brewed annually and each bottle is individually numbered. When opened there is a rich sherry or Madeira note beneath the intense peppery hop aroma. It is a remarkable example of British craft brewing.

Michael Jackson states that some vintages have been aged in sherry wood. He gives the beer 4 stars.

This used to be a big selling point for Olympia beer, and they promoted their Artesian Well Water on their labels. "It's the water, and a lot more." (Yeah, right..."it's the water, and that's about all.")

Anyway, I guess they figured that nobody knew what an Artesian well was, therefore it must make their beer better. (Sort of like "Cold Filtering".)

From: YATROU@INRS-TELECOM.UQUEBEC.CA (Paul Yatrou)
Subject: More on dry hop anarchy

Thanks to all who replied on dry hop anarchy. So, there are two possible effects when you dry hop:

First, the immediate liberation of CO2 due to nucleation. If you don't want too much of a mess make sure you have enough head space in your secondary so the froth doesn't invade your airlock. Or, if you like to kepp the carboy topped off, rack to another carboy which contains the hops.

Second, the re-awakening of dormant yeast. I'm not sure what causes this, but I guess it depends on the amount of fermentables left in the carboy when dry hops are introduced. Maybe the CO2 scrubs away enough of the yeast-toxic higher alcohols so that the little buggers wake up, who knows?

From: dratchen@std.MENTORG.COM (Daniel Ratchen)
Subject: citrus flavor from hops

Are there any hop experts out there? I am trying to identify what type of hop can be used to impart a citrusy aroma and character to a brew. I have tasted this in several Northwest micro-brews and I am curious what the brewers did to get this flavor.

My interest is not entirely academic. When I tasted my latest brew, on the way from the primary to secondary, I was astonished to note that a citrusy flavor dominated. I cannot identify for sure where this came from, because I used 3 varieties and an ungodly amount of hops in the finish. The brew was intended to be dubbed 'Hop Bag Ale'. I enjoy the variety of flavors that hops can provide, but this latest development was truly unexpected.

I have looked in all my brew books for the aromatic qualities of various hops and cannot find 'citrusy' listed for any of them. If any of you have run across this scrap of information in your beer travels, please tell.

Thanks!

From: Mike Leclere <mssl@orca.rose.hp.com>
Subject: RE: Cold Break Process

In response to Brian Bliss' post in HBD #1025...

I have been using a technique for some time which combines whirling, settling, and syphoning the cooled wort with a secondary settling after syphoning into a temporary container (a plastic fermenter) for 2 to 4 hours (depending on the recipe). In other words, my process is:

- 1) cool the wort to near room temperature (I use a wort cooler which takes my boiled wort down to about 85F in about 45 minutes)
- 2) remove wort cooler and whirl wort (with a sterile, plastic oar of course)
- 3) let settle for about 30 minutes (covered in the boiling vat)
- 4) syphon into temporary container (sterile, closed plastic fermenter)
- 5) let settle for 2 to 4 hours (I do this in the same place and ambient temperature where the yeast starter is running - which is also where the actual ferment will take place. This I feel minimizes the thermal shock to the starter when I pitch.)
- 6) syphon into primary fermenter (7 gallon glass carboy) and pitch yeast

Perhaps this is overkill, but I have been concerned in the past with the off flavors I seem to get when ANY significant amount of the trub gets into my primary fermenter. Of course, the beers in which this occurred could have had some other cause at fault, but since I have been doing this the problems I had attributed to trub in the primary seem to have gone away.

As you can see I have opted for a very thorough trub elimination process, but the down side is I have a relatively long period (2 - 5 hours) between when the wort is cooled and when I pitch the yeast. You see, I am also concerned about disturbing the yeast by syphoning after it is pitched, so I don't pitch until the cold break settling and final syphon into the primary is completed. I rationalize this by doing a good job with starting the yeast, and I usually see the end of the lag phase about 6 to 8 hours after I pitch.

Any comments or feedback on this method? I have been brewing all grain ales and lagers like this for about two years now, and I seem to get consistently good results, or at least my friends and I find the results acceptable. Still, if there is a good reason to change this - for example I realize I may be optimizing the wrong part of the process - I'm interested

in suggestions. I will be starting my favorite (and most familiar) Nut
Brown
Ale recipe this weekend, so experimentation is likely...

Subject: profile of Redhook Beers

So I'm sitting here, contemplating working on that neverending thesis project. But no! I have a better idea!

Enjoy.

The Redhook Ale Brewery
3400 Phinney Ave North
Seattle WA 98103
(206) 548-8000

They give tours at, what was it, 3pm? Every day. The sampling at the end of the tour is quite reasonable, and they have a pub attached to the brewery, so you can wait for the tour to start.

The tour in itself isn't too impressive, what you see is a state of the art brewery imported straight from Germany. The labels on the machinery are still in German. You can apparently operate 90% of everything from a single control panel that looks like it ought to belong into a nuclear power plant. Ya know, the kind Homer Simpson sits behind? They stress that their process is not computer controlled, but hey, imagine being able to push a button that says 'mash out'. :)

(This is straight off their flyer except for my opinions)

name: Redhook ESB
malt: 2-row Klages, Caramel 60L (they mean crystal, really!!!)
hops: Willamette, Tettnang
yeast: top fermenting english
available: year round
flavor: rich, round, toasted malt with pleasant finishing sweetness
food: all manner of fowl, great with game and cheese
color: copper
area: west coast
formats: bottle, keg, cask conditioned
since: 1987
alcohol: 4.3%
SG: 1.054
additives: none
IMNSHO: Excellent. True to the flavor profile they suggest. Maybe a bit flowery for a bitter?

name: Ballard Bitter
malt: 2-row Klages, Caramel 40L
hops: eroica, willamette, cascade
yeast: top fermenting english
available: year round
flavor: aggressively hopped, dry crips finish
food: seafoods, highly spiced entrees
color: brass
area: west coast
formats: bottle, keg
since: 1984

alcohol: 3.8%
SG: 1.0445
additives: none
IMNSHO: I had a hard time deciding that I liked the ESB better.
Actually, side by side, I had a hard time figuring out
which is which? It's slightly more bitter, but then
Americans seem to think 'Bitter' implies 'bitter' which
it most certainly does not.

name: Blackhook Porter
malt: 2-row klages, caramel 40L, black malt (chocolate???)
roasted barley (in a porter!!!???)
hops: willamette, eroica, cascade
yeast: top fermenting english
available: year round
flavor: highly roasted chocolate malt character balanced by
lively hopping
food: charred and grilled meats, oysters
color: garnet (*chuckle*)
area: northwest
formats: bottle, keg dry hopped
since: 1983
alcohol: 3.9%
SG: 1.047
additives: none
IMNSHO: I'll drink this as an ok dark beer. Don't serve it to me
as porter, tho. I'm not sure what to call it. I recall it
being underhopped? It's been 8 weeks since the tasting,
sorry.

name: Red Hook Ale
malt: 2-row klages, caramel 40L, black malt
hops: cluster, willamette, eroica, cascade, yakima, hallertau
yeast: top fermenting belgian (yeah, right... see below)
available: once in a while (good!)
flavor: nutty and spicy, long full malt flavors
food: savory pastries, cheese
color: amber-red
area: washington state
formats: bottle, cask conditioned
since: 1982
alcohol: 4.5%
SG: 1.05
additives: none
IMNSHO: Ahehem. (gets a soap box) Now at least they have the
guts to print a banana right on the label! In the years
past, when I lived in that part of the country, (82-86)
I would every once in a while buy this beer, take a sip
and go... 'what the hell is it!' My theory is that they
used to have a nasty nasty infection in their beer.
They stopped making it when, gosh, they moved to a brand
new state of the art brewery, with decent sanitation.
Now they're producing it again, but I'm sure they had to
go scrape the floor of their former brewery to find that
yeast strain again! Or is it really a yeast? Hmm...
At any rate, the banana esthers are undeniable, and you
really must buy a bottle of this and read the label. They
have quotes from papers, magazines, etc., some are along
the lines of what is this amazing stuff! Others... what
is this stuff!!! Amazing! And then there's Michael
Jackson giving it I think a 4 star rating. Must have been
the guy with the glove...

name: Winterhook Ale

malt: different every year ('92 recipe not available yet)
hops:
yeast: top fermenting english
available: fall and winter
flavor:
food: roasted chestnuts, thanksgiving and xmas dinner
color:
area: washington state
formats: bottle, keg cask conditioned
since: 1987
alcohol: 4.8%
SG: 1.0575
additives: none
IMNSHO: Usually an excellent brew, tho I've not had it in several years.

name: Wheathook Ale
malt: 2-row klages, malted english wheat
hops: tettnang, hersbrucker, german hallertau (are there others?)
yeast: top fermenting english (Hm...)
available: year round
flavor: delicate mild hopping, distinct wheat in finish
food: soups, lightly seasoned entrees, corn based dishes, polenta
color: straw
area: northwest
formats: bottle, keg cask conditioned
since: 1989
alcohol: 3.7%
SG: 1.034
additives: none
IMNSHO: not what you would call one of your finer wheat beers.
I don't know what style they are trying to emulate...
Certainly not a trace of delbruckii, but then they never claimed that, either.

Questions: What the hell is 'polenta'?
Does anyone else think their food suggestions are weird?

Cheers,

Mike

IMNSHO: Ahehem. (gets a soap box) Now at least they have the
guts to print a banana right on the label! In the years
past, when I lived in that part of the country, (82-86)
I would every once in a while buy this beer, take a sip
and go... 'what the hell is it!' My theory is that they
used to have a nasty nasty infection in their beer.
They stopped making it when, gosh, they moved to a brand
new state of the art brewery, with decent sanitation.
Now they're producing it again, but I'm sure they had to
go scrape the floor of their former brewery to find that
yeast strain again! Or is it really a yeast? Hmm...
At any rate, the banana esthers are undeniable, and you
really must buy a bottle of this and read the label. They
have quotes from papers, magazines, etc., some are along
the lines of what is this amazing stuff! Others... what
is this stuff!!! Amazing! And then there's Michael
Jackson giving it I think a 4 star rating. Must have been
the guy with the glove...

name: Winterhook Ale

malt: different every year ('92 recipe not available yet)
hops:
yeast: top fermenting english
available: fall and winter
flavor:
food: roasted chestnuts, thanksgiving and xmas dinner
color:
area: washington state
formats: bottle, keg cask conditioned
since: 1987
alcohol: 4.8%
SG: 1.0575
additives: none
IMNSHO: Usually an excellent brew, tho I'ven not had it in several
years.

name: Wheathook Ale
malt: 2-row klages, malted english wheat
hops: tettnang, hersbrucker, german hallertau (are there others?)
yeast: top fermenting english (Hm...)
available: year round
flavor: delicate mild hopping, distinct wheat in finish
food: soups, lightly seasoned entrees, corn based dishes, polenta
color: straw
area: northwest
formats: bottle, keg cask conditioned
since: 1989
alcohol: 3.7%
SG: 1.034
additives: none
IMNSHO: not what you would call one of your finer wheat beers.
I don't know what style they are trying to emulate...
Certainly not a trace of delbruckii, but then they never
claimed that, either.

Questions: What the hell is 'polenta'?
Does anyone else think their food suggestions are weird?

Cheers,

Mike

From: "Bob Jones" <bjones@novax.llnl.gov>
Subject: Recipe for smooth stout

Ok, for those that ask, here is the recipe for a Stout I made recently. This is the Stout that was drinkable at 1 week old. I believe several things make this smoothness possible; adding roasted grains to the mashout, keeping black patent malt quantities small, adding some calcium carbonate and adjusting sparge water ph.

Batch size=10 gals

21# Pale malt (GW)
2# Roasted Barley (added at mashout)
5# Black Patent (added at mashout)
10oz Chocolate malt (added at mashout)
2# Cara pils
2# British crystal malt (80l)
2t Gypsum (in mash)
1t non-iodized salt (in kettle)
2t calcium carbonate (in kettle)
14grams Whitbread dry yeast (rehydrate in 100f water for 15 min)

Hops -

2oz Perle (AA7.6)
1oz cascade (AA6.7)

Brewing details -

- * Single temp infusion mash at 154f for 60min
- * mashin with 7.8 gals water at 171f
- * add specialty grains noted above and mashout at 170f for 10 mins
- * sparge with 9 gals 168f water to collect 13 gals wort (sparge water treated with lactic acid to ph 5.7)
- * Boil 90 mins
- * Boil Perle for 75 mins
- * Boil Cascade for 60 mins
- * Total IBU approx 40
- * ferment at 68f for 1 week, rack to keg, CO2 to 2.6 volumes

OG = 1068 FG = 1023

Enjoy,

Bob Jones

First off, I think you're lucky you didn't have a 5-gallon beer
grenade go off in your kitchen. Seems like a more reasonable solution
is get a 7 gal. acid jug, which is what I use for a primary fermenter.
Many HB shops sell them for about \$20 and they take a no. 7 stopper.
This allows me to ferment the full 5.5 gal with a fermentation lock.
Only once, with a barleywine, did the krauisen head reach the airlock.

Subject: sparging

Jack suggested:

> one could mash with 8 gallons of water and drain it all off.

which reminded me of a post from florian who said in #720:

>From time to time, I read and note various techniques for settling the mash and sparging. The usual technique mentioned in the books involves spraying or sprinkling 178 F water over the mash to sparge. In former times, I did this, but was always unhappy with the results, which were cloudy finished beer. In the last year, I have been using a different technique suggested by my brother-in-law. Its success in my case has been born out by 20-30 batches of beer. It is the following:

The mash is performed in a picnic cooler of the rectangular variety, large enough to hold all of the mash and all of the sparge water. After the mash is complete, I add all the sparge water at once, at the temperature 178 F. Then, I stir it to evenly distribute the grain slurry throughout the water. I then let it sit for a "long time", usually 1/2 to 1 hour. When I can open the lid and see that the mixture appears clear on top, I begin to draw off wort from the tap at the bottom of the picnic cooler. This initial runoff (about 1-2 gallons) is poured back into the top of the cooler, making damn sure that the contents of the cooler are not violently disturbed. After that, the wort is allowed to run out at whatever rate it wants to into the boiler pot. I don't pay any attention to how fast it comes out. My only objective is to get it out. As soon as I have half of it run out, I begin to heat it on the stove, using a second pot to catch the second half of the runoff. By the time it is all run out, there is only a little while left before the boil begins.

This technique differs from the usual in that I don't use fresh sparge water to rinse the "end" of the grains. Noting once more that my conversion efficiencies come out close to the theoretical values and also that the clarity of my final beers has improved, I must conclude that this 33/1399 technique is better. It certainly makes mashing more enjoyable for me, since I don't have to let the runoff go at some attenuated rate in order to improve sparging efficiency. Being an impatient person, I hated that part anyway.

Explanation? Perhaps the "long time" sitting in the cooler allows the water to fully dissolve the available sugars, so that longer runoff times are not needed. In any case, it sure works for me!

Florian

Which all makes me think that it might work well to perform your favorite kind of mash, drain off the first runnings, then dump in all of your sparge water, let it set for 'a long time', then drain it off as florian describes.

Just an idea, maybe I'll try it someday.

Carl

When I stop learning, bury me.

From: korz@iepubj.att.com

Subject: Phosphoric acid

I checked Noonan's "Brewing Lager Beer" again last night and my memory did not fail me this time. In the chapter on Sanititation, he has sections on each type of equipment material (Stainless, glass, wood, plastic, etc) and then on each type of sanitizer or cleaner (chlorine bleach, sodium metabisulphite, sodium hydroxide, etc.)

Under "Glass and Glazed porcelain," he says you can use virtually any cleaner and virtually any sanitizer, but specifically says not to use Phosphoric acid. He could have meant just for glazed porcelain, but he was not specific.

Later, under "Phosphoric acid," he says specifically to not use it on glazed porcelain, and did not mention glass.

Therefore, I guess based on this and all the posts by those more knowledgable in chemistry than I, my fears were unwarranted.

I did know about hydrofluoric acid. I know that before modern plastic, they used to store it in quartz containers -- it was in quartz bottles in my grammar school chem lab (we didn't get to touch anything -- the teacher (Mrs. Rudner) did the experiments at the "podium").

Thanks to all.

Al.

>and Anchor's Special Ale.

Well, Naneenanana-na. We actually get Young's winter ale here in
Champaign, IL, and also Anchor's christmas ale (same as special ale?).
It only serves us right, since the only other beers on your list that
we get are Sam Smith WW, SN Celebration Ale (excellent, btw), and Coor's
Winterfest :-). (I'm envious)

To my palate, Anchor's christmas ale is spiced with cinnamon and
nutmeg, and possibly coriander. per chance, I made a similar
tasting ale 2 months ago spiced with 4 tbsp coriander, 1 cinammon
stick, and peel from 1 fresh orange. they taste quite similar, but
mine had 2 lb turbinado sugar in it and was fermented with Wyeast
Belgian;
OG 1.085, FG 1.017 => anchor's pretty light by comparison.
(btw, no banana in this one)

Young's Winter Ale has that distinctive Young's lip-smacking sweet
diacetyl character to it, multiplied by 1000. Some say it's oxidized
(I for one); my friend loves it.

>So this sounds like a recipe for a 1040 starter to me.

A 1.020 starter may be best for your yeast, but it tastes watery
and should the starter get infected, you may not be able to discern
the off flavors from the yeasty taste (until you've pitched it (in the
fermenter, not the wastebasket)) A higher SG starter fermented out
longer may not be the best for your yeast, but at least you can detect
infection easier and pitch it (in the wastebasket, not the fermenter).

I throw out about a third of my wyeast starters...

From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: Sparging

Recent postings have wondered about why sparge the mash. It was suggested that instead of using x litres of mash and y litres of sparge, just use $(x+y)$ litres in the mash to get the same effect. THIS WILL NOT GIVE THE SAME EXTRACT. Sparging is a more efficient way of removing the sugars from the grains than is single batch extraction.

The reason for this is rather difficult to explain without pictures, but maybe can be demonstrated by example. When the mash water is drained out of the grain, it contains sugars at a concentration "C". Any residual water left in the grain also contains sugars at this concentration. If you stop here, you lose all the sugars dissolved in the residue. Now, if you sparge, as the liquid at "C" drains away, it is replaced by liquid at a lower concentration "c". This more dilute liquid will be more able to extract sugars from the grains than the more concentrated solution (chemists: think equilibrium and solubility). The concentration of sugars drops off down the grain bed as the sparge continues. After a short while, it is "0" at the top, and this area of "0" concentration moves down the column as more sparge water is added. Recall that (naturally) the sparge water has no dissolved sugar initially. This gradient effect drives the extraction from the grain, since it is not possible for an equilibrium to develop.

This argument holds for many industrial and laboratory processes in which it has been well demonstrated that flow elution (ie sparge-type) systems are more efficient in terms of time and volume of solvent used (in our case, sparge-water) than are batch extractions.

Of course, you still can brew excellent beer using a batch extraction method. People did it for centuries. A recent test I did of this indicated I was getting about 80% of the total sugars available when I used the $(x+y)$ method rather than a sparge. Beer tasted fine. But, a well run sparge will give more value for your money, and more goodness for you to drink!

Subject: Re: Marcato vs. Maltmill

In digest #1029, Steve Lacroix compare the Marcato grain mill and Maltmill, and concludes that, both being the same price (\$100), the Maltmill is a better deal. I agree, if both were the same price. However, \$100 is an awful lot to pay for the Marcato when it can be had for \$60.

Within the last month, I ordered one from Zabar's in New York City ((212) 787-2000) and had it delivered to Wisconsin for \$6 shipping. My total cost was \$66. I won't use a mill enough to justify spending \$100, but I can justify spending \$20 more than I would have spent on a Corona.

Jay Hersh published an article in digest #954 where he discusses just the differences Steve mentioned. I have found that I don't need to make any modification to the rollers. They suck in the grain as fast as I can get it through the chute.

Subject: Diversol / citrus hops / .Z archives

Dean Roy asked about Diversol, and described it as a pink powder. Sounds pretty much like Steri-Clean, which is also a pink powdered chlorine bleach/detergent. I use Steri-Clean almost exclusively. I never had good luck using Bisulfite, I always got infections. I have had very few problems while using Steri-Clean, and most of those were my fault anyway. About re-using it, I tend not to. I will make up a few litres of the stuff, soak and rinse the carboy and all equipment for fermenting, then toss it. At bottling time I mix up some more, rinse the carboy, then pass it serially through my bottles, sterilizing funnels and siphon hoses in the process. (I don't do one bottle at a time, by the way, I'll take a gallon of solution from the carboy and fill a bunch of bottles, and from these do serial transfers). I rarely fill the carboy full of sanitizing solution. I'll make up a gallon or a gallon and a half and slosh it around a lot.

*** **

Daniel Ratchen asked about citrus flavoured hops. I think you'll find fresh cascade hops have a very citrusy flavour. I have found the pelletized hops don't quite have quite as much of it, so try to get fresh hops if you really want that flavour.

***** **

Someone asked about the .Z designation in the archives. Read the README file. I think the .Z files are auto-extracting, you type the filename and first extension, leave out the .Z and they are decompressed as they are sent. It's explained in the README file, so double check.

There is one store in Huntsville with brewing supplies. It is really
a natural foods store called Pearly Gates. Their inventory is not too
large, the stuff is not very fresh, and prices are not great either. Still, it is
there if you need it in a pinch. I mail-order the vast majority of my brewing
stuff mostly from St. Patrick's of Texas. I have also ordered from Alternative
Beverage, The Home Brewery, and The Brewhaus from time to time. Most of
the homebrewers I know in Huntsville mailorder their supplies. I have no
ties with any of these suppliers except that I have been a satisfied customer
of all of them.

Subject: Dry Yeast Profiles from Alt. Bev.

On Monday, Walter asked about Dryeast profiles similar to the Wyeast profiles floating around (sorry; couldn't resist). Well, today I just got my new catalog from Alternative Beverages. Here are their blurbs (verbatim):

Glenbrew Special Ale Yeast - Specially designed for use in "all malt" beers. Contains a special enzyme to obtain extremely low terminal gravities.

Edme Ale Yeast - Starts quick. Produces some fruity esters. Attenuative.

Lallemand Nottingham Yeast - This yeast is remarkable for its high degree of flocculation. It settles out very quickly and firmly.

Lallemand Windsor Yeast - Produces a dried beer which is clean and well balanced. This yeast produces an ale which is estery to both palate and nose with a slight fresh yeast flavor.

Munton-Fison Ale Yeast - Starts quick. Produces some fruity esters. Attenuative.

Whitbread Ale Yeast - Limited supplies of this yeast are still available. It was taken out of production in 1992. [That's what the catalog says.]

Lambic Yeast Cultures & Bacteria are available by SPECIAL ORDER. Call for availability.

Lallemand Konig Lager Yeast - Produces a clean beer with a fresh yeasty character. Ferments well at temperatures from 45-85 degrees; however, flavor is best at the cooler temperatures.

Their blurbs for liquid yeast are straight from Wyeast, with flavor profile, apparent attenuation, etc. I have no idea where they got the descriptions for the dry yeasts, but I thought you would be interested.

About the catalog itself: It's pretty much the same as it's always been, although prices have gone up a bit. (It's the way of the world, I'm afraid.)

One interesting new feature is that they have taken all of the recipes from Charlie's TNCJHB and bundled them as kits, making "no adjustments ... except when necessary due to the unavailability of a particular malt extract or hop variety." Pretty cool, if you ask me.

>Questions: What the hell is 'polenta'?
> Does anyone else think their food suggestions are weird?

Polenta is a very popular regional italian food, best described as a corn meal mush. It translates literally as "plenty," since corn meal is very cheap and can feed quite a few people. It is made by sifting corn meal flour sloooooowly (so it won't lump) into near-boiling water. A batch takes about a half hour to cook, until it has the consistency of pudding. Nearly constant stirring is required so it doesn't burn.

I like it poured over a nice brie, with some sort of a tomato-based stew subsequently poured over the polenta. An italian sausage stew is what I usually make. The polenta will later harden and may be sliced and fried. This is the way many restaurants serve it, since it demands too much attention to serve it the way it should: soft and piping hot.

I have a new microwave method for polenta that I haven't tried yet. It's supposed to require much less attention. I'll have to try it with a Wheathook Ale. :-)

I just started all-grain this year, but I've used this procedure on all my batches so far. The original intent was to raise the temperature to 170F for a mash out, and it seemed that it took a large amount of water to do that, so I just went ahead and dumped in all my sparge water. I add 180F-185F water, which brings the whole mess to about 170F, and I let that sit for 1/2 hour. Then I do as Florian does, except that I haven't been draining it out real fast. Maybe I'm wasting time; I think I'll try a 1 hour rest and then a faster drain next time.

My extraction has been around 29-31 and my beers have been nice and clear, so I'm happy with this procedure. If someone more knowledgeable can offer reasons for not doing this, I'd be interested to hear them.

Subject: Late Grain Additions, citrus, pH Time:8:04 AMDate:12/10/92
>as alternatives to very high mash temperatures, S. Thomas
>recommended adding crystal only in the mash-out rest,
>so the big sugars don't get reduced

This comment, via Jed Parsons, raised a question in my mind. Is there sufficient time in the mash-out for the sugars in the crystal malt to dissolve?
Wouldn't it be better to separately steep the crystal malt during the mash cycle and then add it to the mash? Since the reason for the late addition of the crystal is to preserve the non-fermentables I would also say it is to maximize their extraction. This would not hold for dark grains as the purpose of late addition of these (as Bob Jones has demonstrated) is to minimize the contact time with the water and reduce the extraction of their harsher characteristics while still picking up color and flavor.

So, those of you who add late additions of grains, how do you do it? Dry or pre-soaked (steeped)?

Daniel Ratchen: I think you are looking for the effects of dry hopping with Cascades. I find beers so treated have a distinct "grapefruit" character both in aroma and flavor. You may also get it from very late kettle additions. This is not to be confused with the "lemon" character which is created by bacterial infection. If your palate can not distinguish between the two one way to determine which you have is: Hop character does not increase with age, bacterial infection does.

Tom Ciccateri: I have a digital pH meter from Omega (model PHH-1X, \$44) which is similar to the one Williams sells. I am quite happy with mine. They have a new model which has a wider temperature range and sells for a bit more. Omega can be reached at 1-800-826-6342.

Subject: 21 year old stuff...a summary

Hi y'all,

I have received a bunch of requests to post a summary of the results from my question on Thomas Hardy Ale, so here it is. But first, I would just like to thank all the people who took the time to respond. I got so many responses, all of which were interesting and appreciated. I tried to respond back personally to the messages, but I started getting too many, so I apologize to those I couldn't send back to, please do not take it personally. So, here are the results. The only thing everyone agreed on was that there indeed exists a Thomas Hardy Ale. It is brewed in Dorset, England by the Eldridge Pope brewery. It is a strong drink, of the barleywine variety. The label on the bottle states it will last for 25 years. That all said, the opinions now start to vary.

Noone seems positive that it will last that long. The oldest someone had personally tasted was 16 years, and he stated that it was excellent. One said Michael Jackson quotes a positive review on a '68. Many had tasted it new, at stated that it was very good. But, many had had some from 5 - 10 years old and they were not pleased with the results...however, it is unclear that this is simply from age and not from poor handling and storing, although someone stated that they heard Thomas Hardy of greater than 15 years has started to go down hill. As far as that last statement, I don't believe there is any personal experience to back that up from any of the responses. Just about everyone had expressed concern with the storing. I plan to store it at my parents'

house. There is a back room (area more like it) in the basement...it is only 3 feet high, has concrete floor and cinder block walls, and no windows. They have absolutely no plans of moving, so I should not have to worry about moving it around. I believe this should do the trick, but does anyone know an optimum temperature to keep it at? like, don't let it get it temp higher than 70 degrees? Another concern everyone had was its availability. I don't know what that's like around here, but I have two brothers that work in liquor stores, and both said they could special order it for me, in either 6 or 12 oz bottles. The sizes the responses mentioned are 6 oz, 6.4 oz, 7 oz, 250ml, and 750ml. 6 and 12 oz are the only ones I can verify. As far as price, they said roughly \$30 for the small. For my purpose, many suggested a port because they are easier to store. So, what I think I'll end up doing is getting a case of the small (a cheaper investment), and a port, to be on the safe side. A few people mentioned Whitbread's Celebration Ale, but that sounded a little to expensive for something that may not last. Thanks again to everyone.

Jeanne Reil

p.s. I was browsing through the past issues that I've missed, and I have to say to Chris Campanelli, you are a riot. I read those accounts on brewing mishaps (yep, its been a while) and I was so embarrassed...I started laughing out loud, sitting in front of my terminal. My co-workers just looked at me like I was losing it. Oh well, it was worth it.

Subject: blowoff

A question for all you blower-offers.

I generally do primary fermentation in my good ole plastic bucket. Because of gettin some yuck up through the airlock a couple of times, I've been using semi-blowoff - that is, I have an old racking tube with a stiff part joined to a flexible part, and the stiff part fits down through the airlock hole in the lid. I use this for "blowoff" although the larger capacity of the bucket means relatively little stuff is actually blown off.

Now, if I want to try a real blowoff - that is, with a 5-gal glass carboy - can I just use this hose in my regular stopper? Do I need the 1-inch tube I read about occasionally because the small i.d. of my present device might lead to clogging and possibly a very large and messy grenade? If so, what kind of equipment do I need for the carboy mouth and where do I get it?

Thanks again for all of your Greate Wisdomme.

Jonathan

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

Subject: florian's technique

I also use Florian's technique of adding the sparge water all at once, though in a slightly different manner than what was described. After pouring the mash into the cooler (I use a round Gott water cooler), I add *boiling* sparge water (I believe Florian does this also). In my setup, this settles at 170 degF, ie. mash-out. So the 30-60 min. settling rest is also a mash-out. It's a great technique: efficient (I get 29 ppp with 2-row) and time-saving. Highly recommended. 2 thumbs up. 4 stars....

Subject: question

After reading the recent article in Mother Earth News about home-
brewing,
my husband wants to try it. We're currently gathering together the
equipment we'll need, there is a place nearby that sells everything
needed
to make both beer and wine. We already have a 6-gal. carboy, and we have
a 5-gal. stewpot. The article suggested a stainless steel stewpot, the
one we have is graniteware, or whatever they call the dark blue cookware
with white specks. Can we use that, or does it have to be stainless
steel ?
Any advice or suggestions would be appreciated.
thank you
Judy

> flavor.

Cascades. They are the most citrus-like (grapefruit, IMHO) hops. I was re-packaging 3 pounds of Fuggles tuesday night and noticed a faint grapefruit nose also, but among other bouquets. Anyone else feel that Fuggles have a bit of grapefruit nose in them?

A few days ago, Jack wrote that he tasted bandaids when chewing DeWolf & Cosyns (Belgian) Cara-Pils malt.

I waited to post till I remembered to chew some at home (I should bring some malts to work, maybe). I, personally, did not taste any phenolics at all, including bandaid smell/taste.

On the subject of phenols, there seems to be a bit of confusion. There are many types of phenolic aromas that can be in our beer, from medicinal, to clove-like, to bandaid, to solvent-like. George Fix's article on Phenolics in the 1987 Zymurgy Special Issue on Troubleshooting is a great source of concentrated information on phenols. There are "good" phenols and "bad" phenols. Of the "good" phenols, there are hop alpha acids and 4-vinyl guaiacol (which contributes the clove-like flavor to Bavarian Weizen). Of the "bad" phenols, tannins are a popular one. A common cause for increased tannins in your beer is too high a sparge temperature. As I recall, Jack, you were (are?) a proponent of using boiling water for sparge (noting that your temperature measurements at the top of the grain bed were still around 170F -- if memory serves correctly).

From: John Fitzgerald <johnf@ccgate.SanDiegoCA.NCR.COM>
Subject: Re: white stuff appearing in bottles

I bottled my spicy Christmas ale recently, and within 1 week of bottling, something ugly is happening in the bottles. There is a thin white oil slick on the surface of the beer, climbing about 1/8" up the glass on the inside.

Is this definitely from an infection? I've never seen anything like it in the

past 3 years/25 batches. I was wondering if it could be a by-product from

one of the spices. The recipe was a conglomeration of things that looked good from the Cat's Meow II spiced recipes. It included zest from 4 oranges,

5 oz. grated ginger root, 1 tsp cloves, 1tsp nutmeg, 1tsp vanilla extract,

and about 15" cinn. stick, all in a pretty standard 1.050 brown ale.

There

was a very strong sour smell from this batch when transferring from primary

to secondary, and a very strong cinn. taste, but nothing else out of the ordinary (although it did require a record-breaking 9 days in primary).

If it

is due to infection, it must be something I picked up at bottling time, because

I have re-used the yeast (european ale 1338) to pitch a batch of cider, which

tastes clean, and a batch of pale ale which tasted fine going from primary to

secondary (on the same day I bottled). The spiced ale is still muddy, and

admittedly I am starting to worry. Maybe this stuff just has to sit for a long

time and will be ready for next Christmas. Anybody know what the white oily

stuff is?

Any comments/advice would be appreciated.

John Fitzgerald

P.S. Apparently some of the Chicago Beer Society (CBS) members have gone national! Our newspaper, the San Diego Union-Tribune, carried an article today by Michael Lev all about homebrewing, including a picture of Ray Daniels

cooking up a batch. Also mentioned were Randy Mosher, Steve Paeschke, Chris

Campanelli, Chris Nemeth, and Al Korzonas. And of course it wouldn't be a

decent article with a few quotes from Charlie Papazian. (Sorry to hear about

Al's bock-style home perm solution :). Great job guys! Keep spreading the word!

From: John_D._Sullivan.wbst311@xerox.com
Subject: Starch test, Wyeast ,Crystal

My Wyeast European developed such a thick Krausen (not deep but creamy) that 4 days after fermentation is complete it's still sitting on top.

Nothing

wrong with head retention here. Is this normal and would this eliminate a need

for blow-off since so little of it is in contact with the beer? Also, I ordered

a Wyeast Pilsen not realizing it's a lager yeast. Will this work good at 65 deg

F or will I get off flavors? if I needed to I guess I could give it to my

buddy who lagers .

Also, does anyone know the lovibond ratings of M&F crystal vs.

Telford's crystal? M&F is much much darker but the ratings aren't on the pkgs.

Lastly, I've been doing the starch conversion test via TNCJOHB using tincture of iodine and was wondering why after 1/2 hour at 155 deg it was never

failing (Mr. P. says to continue after 1/2 hour if conversion isn't complete).

So last time I decided to test before boosting from 122 to 155. (BTW, I put a

little on a dish, let cool and put a drop of iodine in. If it's clear, it's

done , if it turns dark it's not. That's all there is to it, right?)

Anyway, it

was already clear before boosting to 155. Am I doing something wrong or am I

the Magical Mystery Brewer?

Thanks Much,

John

From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: More on Sparging

In HBD #1030 Carl West describes a method for rinsing out sugars from a mash. It works for him, wonderful. But I would like to point out that it is still intrinsically less efficient than a sparge would be. This may not matter to homebrewers, but we should bear it in mind.

The problem is that once all the water has been added, and mixed up, the solution contains sugars evenly throughout, at some fixed concentration.

The amount of water absorbed by the grain (quite a lot, see TCJOHB) will also contain this sugar, which is thus lost to the brew. In a sparge, fresh water is constantly being added, and the result is that "no" sugars are left in the grain.

Please note, in this and my previous posting, "0" and "no" are approximate and relative terms. I do NOT mean that you can ever get 100.000000% extraction.

Still, if it works for you, :-)

P.

Subject: Re: Sparging

>From: arf@ddsw1.mcs.com (Jack Schmidling)

>I am suggesting that in the same situation, one could mash with 8 gallons of water and drain it all off. The more diluted wort would more effectively scrub the grain of sugar and the loss would probably be nowhere near 40%. One could still add a gallon of hot water and stir it up to get a little more out of it but the sparging step could basically be eliminated.

js

I think the point is that there is some optimal water to grain ratio for conversion. Below a certain ratio, you'll end up with "dry" spots etc. Above a certain ratio, you dilute your enzymes and may have to wait a looong time for complete conversion. If you've got the vessle to hold 8 gal, a simple compromidr may be to mash with 3-4 gal of water and then top off with 4 more gallons, stir (?), and drain.

Or not.

End of HOMEBREW Digest #1031, 12/11/92

Date: Fri, 11 Dec 92 07:51:40 EST
From: fingerle@NADC.NADC.NAVY.MIL (J. Fingerle)
Subject: yeast

I'd like to open a thread concerning the culturing of yeast.
If there is enough interest, this could be done via the
digest, but I suspect private email might be better.

Anyway, I just recently bought some liquid yeast and was a bit
shocked at the price; not that it is outlandish, or anything,
but after using the dry yeast that comes free with the extract
syrup, it seems like its a lot of \$. So, my next thoughts turn
to culturing yeast.

Using Papazian, 2nd edition, I have no problem with the explanation
of the preparation of the medium. Now, on p279, under the heading
"Culturing the yeast", he says to open the container of pure yeast
culture and pour it into your previously prepared medium (6 oz of wort
in a 12 oz vigorously sanitized bottle.)

My liquid yeast has the two sections of liquid, one of which
your supposed to break, then let the package swell up. Do you do
do this, allow for the swelling, then dump the entire thing
the bottle? Or do you break the inner part
and immediately dump both sections into the bottle? Or do you
ignore the inner part and just dump the one section in?

Once the liquid yeast is in the bottle, you place a fermentation
lock on it, according to Papazian. Fermentation starts, but then what?
Papazain says stick it in the refrigerator, then repropogate in 2 to
4 weeks. When do you use it? When you repropogate, do you split
the bottle contents in half and propogate two cultures? Do you drain
off the liquid in the top half of the bottle and just use the sediment?
Do you have to let everything get to room temperature?

I have so many questions, about this, that I may as well stop at this
point. Can anyone give me some pointers and/or step-by-step
instructions? And, perhaps, can anyone render an opinion: I'm
still a beginner, having only brewed 5 batches, am I getting
in over my head to quickly?

Thanks!

From: thutt <thutt@MAIL.CASI.NASA.GOV>
Subject: .Z extension

Since there has been no concrete answer to the .Z question, I'll answer it once and for all.

The .Z is a file compressed using the Unix(tm) 'compress' program. If you have a Unix(tm) machine, there are two ways to generally uncompress the file:

- 1) compress -d filename.Z
- 2) uncompress filename.Z

When the decompression is complete, you will be left with a 'filename', and 'filename.Z' will have been deleted.

If you are using a 16 bit PC, you may have some problems. The method required to compress/decompress the data uses a table of a specified bit size. On most Unix(tm) machines, this table size is 16bit. Unfortunately, this is generally too big for a simple recompile of the program on a PC. There are specific recompilations of the program that will allow you to use 16bit compress on a PC.

You can FTP several PC versions from the wuarchive.wustl.edu (ip not known at this time) server. The simtel site will also have these.

If you cannot FTP things, and you really need the software, you can send me a disk (any format) and a SASE, and I'll be happy to send you the versions you require (actually, I'll send you all the versions I have)). If you are interested, drop me a line, and I'll give you my address.

Sorry, due to our network (don't get me started on this subject...), I cannot send files via email at this time. I am working on a custom version of uuencode that will work with c(rappy)c(rappy):Mail, but it is not done yet.

Hope this helps.

Subject: pots

In hbd #1031 Judy Bayliss asked about cooking pots for brewing:

>The article suggested a stainless steel stewpot, the
>one we have is graniteware, or whatever they call the dark blue cookware
>with white specks. Can we use that, or does it have to be stainless
steel ?

>Any advice or suggestions would be appreciated.

Judy, both stainless steel and enamelware are good for homebrewing. The
stainless will have a longer lifetime. Don't use the enamelware if it
has

been chipped and shows rust. Aluminum pots are ok for producing hot
water

for sparging, but should not come in contact with the mash or wort.

Judy, I tried to email u directly but it bounced. Please try to email
me

so my mailer can get to know yours! :-) Good Luck with the beer making!

Subject: Maltmill vs. Mercato Round 2

Well, I'm not usually one to sing the praises of a gizmo for very long but the response(s) to my previous post seem to require a further comment.

To the person who is happy with his Mercato...Great! I was just as happy brewing with my old thin aluminum kettle...until I got a better one. And I remember how happy I was when I got my first bottle filler, and how neat it

was...until I got a Phil's Philler. My point wasn't that some people would

not be happy with their Mercato (or for that matter their Corona!).

Having

USED the Maltmill, I just don't think I would be happy trading a Maltmill for

a Mercato. That little hopper (how big is it, about a cup??) and that tiny

crank (do you hold it with 2 fingers or 3??) just don't to be a lot of fun

to mill 20 or so pounds of grain...but then again, different strokes...

Finally, I would use the same logic you used when trying to get the biggest

bang for your buck...if the Mercato is worth the extra bucks over the Corona..

there is no doubt that the Maltmill is worth a few bucks more when "compared"

to the Mercato...but then again...what about the 300+ owners of the Maltmill??

What sez you guys???

Oh...by the way Mercato owners...how easy is it to get service from the company which makes the Mercato?????????????????

Subject: sparging technique

I use a zapapp lauter tun (bucket in bucket). It was made from 2 6.5 gallon buckets. all this talk about sparging and solution concentration had me thinking about my technique. when sparging and adding sparge water, are you supposed to let the water level start to drop below the the top of the grain before adding more sparge water. OR do you never let this happen. All the books are pretty grey here.

also no one touched my question about reasonable conversion times. i had asked if most people end up doing a conversion step of 45-90 minutes? papazzian had indicated a total time of about 25 minutes. is anyone getting decent efficiencies with this short a time. I'm not but i don't know if this is the problem, or if it's something else. i usually get 25 ppg.

From: Alan B. Carlson <alanc@cs.chalmers.se>
Subject: Weird Starter (summary)

I'd like to start out by thanking all those who responded to my post about "weird starters" in HBD-1024. All the responses agreed that the gravity of the starter wort was way too high - way over the generally agreed upon wort gravity of 1.020 - and that what I was seeing floating around in the starter was probably sugar crystals. So, this is another case where one throws out the recommendations of the local homebrew shop (I was, after all, just following their instructions :-)).

I would like to add one data point. After having posted my message to HBD, and being too impatient to wait for a response, I began another starter with the same immense gravity (once again using granulated sugar)

.
This time I used first generation Wyeast Bohemian Pilsener (as I had in producing the beer I took the dregs from in the original starter). After pitching the starter (which looked to be okay), it took 6 (!) days before I noticed significant fermentation - i.e. before it started bubbling in the airlock.

The same thing happened the first time I used Wyeast Bohemian Pilsener and followed the instructions from the local homebrew shop. So, I guess the lesson is: Keep your starter wort's OG down at a reasonable level or beware!

There's a snapping holding everything down. You can pry it out using a thin screwdriver with not much force at all; it's thin metal and has a cutout on which you can pry. Once it's out, the whole fitting and dip tube assembly lifts up and out, no problemo. Getting the ring back IN is the hard part, comparatively.

Subject: blowoff or blowup?

Since the topic has come up, here's one of my earlier experiences with first stage blowoff in a carboy. I had brewed a batch of something (you'll see why I've forgotten), dumped it into a carboy, which it almost filled. Mistake #1.

I went ahead and pitched it with dry yeast without draining any, and stuck in a

blowoff tube. Mistake #2. I put it in the guest room, the warmest room of the

house, and let it set. Mistake #3. The next night I had to work late, and ended up staying with a friend rather than drive home exhausted. I got a worried call from my wife, who said that the beer didn't look very active, but that the blowoff tube was clogged. Being my level headed self, I told her to just pull the tube out (meaning leave the stopper behind), rinse it w/ clean water, and replace it. Mistake #4. Fine, and she hung up. About 1/2 hour later, the PANIC call comes. Apparently she had pulled the stopper out and gone to the bathroom to rinse it. Nothing happened when she pulled the stopper, BTW. While rinsing, she heard a WHOOSH (as she put it), turned back, and saw a 2" column of "beer" spewing out of the carboy, bouncing off the ceiling, and splattering all over the walls of the room.

I came home after all that night.

Dave Hyde
davehyde@tecnet1.jcte.jcs.mil

BTW I can only store beer in the basement now.

I would definately use the 1" hose as opposed to the racking tube. The
amount
of gunk that gets pumped out through my hose would definately clog a
small
diameter tube and possibly lead to a mess. As far as equipment, all you
need
is a 3' length of 1" tube and a bucket of water. Make sure that the
carboy
is filled into the bottom of the neck, insert the tube 1-2 inches into
the neck
and stick the other end into a bucket of water to create an air lock. I
find
that it works best if the carboy sits higher than the bucket. I replace
this
setup with a 3-piece airlock when the kreusen falls.

I can't recall the brand name, but the brew shop where I get my supplies
sells a glass blowoff tube for \$19.95. It has a foam sleeve to protect
from
breaking against the carboy and is much easier to clean than the glass
tube.
I would recommend in getting one of these since the plastic tube needs
occasional replacement.

Subject: Comments on Belgian Ale Book

hi all,

having been close to being nuked on another net list about some comments i made in response to other comments regarding Pierre Rajotte's Belgian Ale book. the general consensus seems to be that the book failed to provide the level of depth and missed the mark.

If anyone has problems (other than editorial/publishing) please forward them to me at the address below. I will forward them to Pierre enmasse after a reasonable time period, to solicit clarification or whatever. You may or may not want to include some personal information (like number of years brewing, professional or as a hobby any other background you care to add that could be relevant to the response. (just tlaked to pierre he agrees to respond).....

I was under the impression the book was a success as the number of Yeah vs Nay articles posted in many different net lists was tilted to the yeah side.

i have no monetary interest in the book or Pierre's business matters, except that i am a satisfied customer of his brewing equipment.

Subject: La Chouffe

Recently, a friend of mine brought back some delicious belgium ale: La Chouffe. I am thinking of doing some experiments with the yeast that we cultured, and I thought Id ask if anyone out there in digest land has ever brewed with this yeast. I am particularly interested if anyone cultured it or brewed directly with the dregs.

FWIW, La Chouffe is a small craft brewery in Belgium. The beer weighs in at 7.8%vol, and it is actually available on draft in a few locations. I found it in Brugge, at the beer place that M. Jackson talks about in his book and video. A very well made beer!

Subject: results of vanilla brew

hey now- you may remember from a couple of months ago that i was looking to do a batch of brew with vanilla beans and was looking for suggestions. well, i went ahead and did it and wanted to let you know how it turned out. here's the recipe:

Vanilla Bean Stout (5 gal)

2 lb crystal (90L)
4 oz chocolate malt
4 oz black patent malt
2 oz roasted barley
6 lb dark dme

1.5 oz Northern Brewer (60 min)
.5 oz Eroica (finish)

Wyeast Irish (1098)

og = n/a

mashed grains for 45 min. @ 152 F, sparged to kettle, added dme, etc. i did a normal primary ferment for about a week and then racked to the secondary on top of 4 6" vanilla beans sliced lengthwise down the middle to expose the good stuff. after 3 or 4 days all signs of fermentation stopped with the gravity only at 1022. i let it sit a little while longer and got no improvement. i then pitched an 8oz culture of Narraganset ale yeast (from the yeast culturing kit) in an attempt to fire the thing up again. i let it sit for about 3 more weeks before bottling. the final gravity was 1018. hmmm.

anyway, the final product has a really nice blend of roasted malt and vanilla, almost like a vanilla-flavored coffee. i noticed a lot of oil from the beans in the secondary, though, and not surprisingly the head retention is very poor. when you swirl the beer around in the glass it foams up but then it just slides down the sides in a kind of oily manner. the aroma is outstanding. i'm extremely happy with the beer and will definitely do it again. i might cut back to 2 or 3 beans, however, especially if i do a porter.

so there you go. now go out and try it yourself, you'll like the results.

coming next week: kiwi wheat...

Subject: iodine test & buffering sparge water

I've used iodine to test a small piece of grain as an indicator of starch conversion and it seems to work. I pull out a grain sample and put it in a white plate. After adding a drop of iodine, I look to see if it remains light brown or turns dark blue (starch present). Sometimes it takes upwards of two hours for complete conversion! I think my mash is too dilute (around 2-3 gallons in 6-8 lbs pale malt).

I found that buffering my sparge water (2-3 gallons) with 1/2 teaspoon gypsum greatly increased my extraction rates. Does anybody else do this to? I live in Denver (rocky mountain stream water) so maybe our water needs a little mineral supplement?

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>
Subject: Brewpubs (almost) legal in Michigan

The MI State Senate passed the long-awaited "Brewpub" bill on the last day of the session this year. This bill creates a new class of brewery: the "brewpub". A restaurant or bar that *already has a liquor license* can brew beer *for consumption on the premises*. A given individual (or Inc.? After all, incorporated entities are usually treated as individuals in the law.) can only own a single brewpub. Despite the obvious limitations, many of us are ecstatic that we've gotten this far. (The bill needs to be signed by the gov, but I've been told that that's basically irrelevant. It was passed by both houses "with immediate effect", so he will need to explicitly veto it or it goes into effect in 14 days from passage, anyway. Since basically nobody is against the law (not even the commercial brewers), it is very unlikely he would veto it.)

In fact, there's a brewpub planned for Ann Arbor. These folks have been proceeding with their plans, on the assumption that the bill would pass (they did hire a lobbyist to help make that assumption valid). Shamelessly lifted from the Ann Arbor News, December 5, 1992:

By Dave Wilkins

A local couple has overcome the most daunting obstacle to their plans to bring a West Coast phenomenon, the brewpub, to downtown Ann Arbor.

The state Senate cleared the way late Thursday - the last day of the current legislative session - by passing a bill to allow brewpubs to operate in Michigan.

Barry Seifer and Jennifer Kirscht say the Senate's action, if signed into law by the governor, puts them on track to open Grizzly Peak Brewing Co. in a historically renovated downtown building on May 1. It would be the first such brewpub in Michigan and would employ an estimated 100 people. "We are ready to start construction right after the first of the year," Seifer said Friday about the proposed brewpub, which would produce specialty beers and serve them on the premises.

At Grizzly Peak, Seifer and Kirscht say they will serve high-quality, non-pasteurized beers, stock a full bar and offer both tavern food and a quieter upscale dining area. They plan a room for banquets and another featuring live music, while also operating a home furnishings store in a third-floor loft.

The site is at two buildings formerly occupied by the Cracked Crab restaurant in the 100 block of West Washington Street.

Subject: when to pitch a starter?

I'm about to embark on my first ever use of liquid yeast. I've made up a starter of 1 pint of wort and am waiting for the frothies to start. This raises the question on exactly when to pitch this starter. In particular:

1. The instructions indicate "at high krausen". Is this the normally done practice?
2. Why the above? What happens if one waits until the starter is fermented out and all activity ceases? I would have thought that the yeast are continually multiplying during fermentation, as well as during aerobic respiration, so that the maximum cell count would result from using it later.
3. In conjunction with 2, I gather the yeast go dormant at the end of fermentation, but so what? When beer is bottled, fermentation has definitely stopped, but the yeast happily rapidly ferments the priming sugar. So what's the difference between this and pitching fermented-out starter into fresh wort?

I'm confused, please help.

Thanks.

Peter

Subject: Sparging

>From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>

>Recent postings have wondered about why sparge the mash. It was suggested that instead of using x litres of mash and y litres of sparge, just use $(x+y)$ litres in the mash to get the same effect. THIS WILL NOT GIVE THE SAME EXTRACT. Sparging is a more efficient way of removing the sugars from the grains than is single batch extraction.

>The reason for this is rather difficult to explain without pictures, but maybe can be demonstrated by example.

You did a fine job without pictures. I painted one in my modest brain while reading your explanation and felt very humble not having figured it out myself. I could have probably even come up with the 20% loss without ever running the tests. If we run off 10 gals of wort at 1.040 from, let's say 12 lbs of grain, all we need to know is how much liquid is still in the wet grain. We know what the gravity is and I would guess that there is probably 2 gals of water. Close enough to 20% for discussion purposes and 20% is enough to make sparging worth the trouble.

Nice contribution Phil.

I will admit that I was expecting all sorts of expert testimony that it would make lousy beer for reasons of chemistry but there were only a very few feeble offerings in that realm.

Subject: Questions about imports

Hello everyone,

I have a few questions about imported beer in Canada. Tonight I tried Simpatico amber and golden. What confused me is that the golden is brewed in Mexico and the amber is brewed in the USA. Is Simpatico a Mexican or American company by origin? What rating is the amber for hops, assuming American Bud is a 2 and Pilsner Urquell is a 20?

A question for Canadians from Ontario. Has anyone tried importing beer by the Vinage's division of the liquor store? If yes, what type of mark up should I expect? I want to get a case [24] of Sierra Nevada Pale Ale [I would like to try it since I hear so much about it], but the people at the liquor store never heard of it.

Now a question for American's. I had the opportunity to try the Samuel Adams Boston Ale. What are people's opinions of this beer?...I liked it, there is nothing like it in Canada, from a domestic view point.

Finally, I have an update for the brewing on-line list I have been updating. My problem now is that the list is greater than the 8K allowed by the HBD. Is there a way around this limit or must I now submit it to the archive? If I have to submit it to the archive, how do I do it?

Thanks to everyone

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: yeast's tolerance of alcohol

I racked a gallon of cyser today. Using M&F dry, the gravity fell from 1082 to 1002 in only 3 weeks. I was somewhat disappointed: I used ale yeast instead of, e.g., champagne yeast to get a higher final gravity. I figured the alcohol would kill off the yeast somewhere around 8% alcohol by volume, leaving me an FG of 1020 or above.

Does anybody have any information as to the levels of alcohol our familiar yeasts (liquid and dry) find toxic? Would I have done better using some Wyeast? [Given that Bigfoot is made with 1056, that one's obviously not a candidate.]

Cheers,

Rob (bradley@adx.adelphi.edu)

From: Todd Enders - WD0BCI <enders@plains.NoDak.edu>
Subject: Perfect Brew! :-)

The subject line is a bit loaded, but bear with me. The results speak for themselves.

Yesterday I made a batch of Best Bitter/ESB, using the following ingredients:

Special Bitter #9

7# US 2-row pale malt
1# 60L Crystal Malt
0.5# Wheat Malt
1 oz. Black Patent Malt
1 oz. 10.9% alpha Centennial hops
Wyeast 1028

Mash in: 12 qt. @ 140F
Mash: 60 min. @ 150-156 F pH 5.2
Mash out: 15 min. @ 170F

Sparge: 5 gal. acidified to pH 5.8 w/lactic acid.

Boil: 90 minutes
Hops: 1 addition, 45 min. from end.

Nothing unusual at this point, but note well the following:

OG: 1.058 (!!!)

I used the theoretical values in Miller's CHoHB, and the SG points available from the grain bill were 290. Multiply 58 by 5 and be amazed as I was!
Yes, I got 100% of theoretical extraction, and only sparged 5 gal.! How? I'll describe my sparge procedure this time, because I believe herein lies the key.

For lautering, I use the bucket in bucket tun. I'd suspect that it's the same as many other brewers use. It isn't insulated, or anything fancy.
Sparge water was acidified with lactic acid ala Miller. Here's the difference.
I recirculated the initial runoff for the equivalent of 6 gal. Then I began the sparge with 1/2 of the water heated to 170F and recirculated it once. I finished up with the last 2.5 gal., which was also recirculated once.
Total sparge time was about 2.5 hours. The sparge was a good bit longer than usual, but those results!!! The runoff was reheated between recirculations, BTW.
The last runnings had no preceivable tannic taste.

The gods must have been watching over me, since after the boil and cooling I had *exactly* 5 gal. in the primary. Right on the mark, no question.

This was the first time I had tried Centennial hops. I've tended to lean toward Perle hops for bittering, but I've changed my mind! If you haven't tried them, they are a wonderful high alpha hop, with the bittering reminiscent of spruce/evergreen. Tasty! It might help that I have them from the 1992 crop. :-) They came from Freshops, BTW.

So is this **really** the perfect brew? I'll let you know in a few weeks!

Todd

End of HOMEBREW Digest #1032, 12/14/92

Date: 14 Dec 1992 09:21:02 -0400
From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: sparging / iodine test

Mark Garti asked about sparging:

>I use a zapapp lauter tun (bucket in bucket). It was made from
>2 6.5 gallon buckets. all this talk about sparging and solution
>concentration had me thinking about my technique. when sparging
>and adding sparge water, are you supposed to let the water level
>start to drop below the the top of the grain before adding more
>sparge water. OR do you never let this happen. All the books
>are pretty grey here.

I believe the accepted wisdom is to keep the water level about an inch above the grain bed. For my last sparge I placed the lid of a margarine container on the grain bed and poured the sparge water over that, so it spread out instead of stirring up the grains.

>also no one touched my question about reasonable conversion times.
>i had asked if most people end up doing a conversion step of 45-90
>minutes? papazzian had indicated a total time of about 25 minutes.
>is anyone getting decent efficencies with this short a time. I'm
>not but i don't know if this is the problem, or if it's something
>else. i usually get 25 ppg.
>Mark mrgarti@xyplex.com

Miller's theory, as far as I can tell, is that conversion should take 1/2 an hour or so, but by leaving it for 1.5 hrs you can be sure it's done. My friend brewed a porter following Papazian's technique, and I brewed a brown ale using Miller's. One thing about Papazian's protocol is that it takes time to heat up the mash on the stove doing a step mash, so that 15 min. protein rest + heating + 25 min at 150 + heating + 15 min at 156 adds up to about 1.5 hrs anyway. Our extraction rates were virtually identical at just above 25 (including all specialty grains), so the loss is in the sparge.

Scott James asked about iodine tests and conversion times:

>I've used iodine to test a small piece of grain as an indicator of
>starch conversion and it seems to work. I pull out a grain sample
>and put it in a white plate. After adding a drop of iodine, I look
>to see if it remains light brown or turns dark blue (starch present).
>Sometimes it takes upwards of two hours for complete conversion! I
>think my mash is to dilute (around 2-3 gallons in 6-8 lbs pale malt).

Testing grains with iodine will skew your results. The hard part of the grain contains starches, such as cellulose, which test positive but are not what you are trying to break down. Try the iodine test on a small quantity (1 teaspoon) of COOLED liquid, with as few grains as possible. I agree that your mash sounds a little dilute, I would go with about 1.5-2 gallons for 6-8 lbs grain.

The goal in sparging is to get the sweet liquid out of the grains.

Lauter tuns do this essentially by serial dilution through a filter bed. The filter bed is important in preventing unwanted insolubles from getting into the boil. But what I want to know is: Is there anything fundamentally wrong with centrifuging the grains? Just spin the sickers real fast in, say, a converted washing machine, while gently spraying the sparge water from the middle? If any particulate matter gets through the whole volume of liquid could be filtered through cheesecloth or filter cloth. Any reason for not doing this other than tradition?

From: paulg@cme.nist.gov (Paul Gilders)
Subject: Foul smelling brew

Hi folks,

Just thought I'd get some net wisdom on a problem that my roommate and I have recently experienced with our homebrew. We have only recently started homebrewing and are still using the simple kits with pre-hopped malt extract. We have however had two very successful batches in the past month - a very nice porter and brown ale. However, on our third batch we tried to produce something a little lighter and decided to go for a Scottish Ale. In our previous brews, we used an additional 2lbs of dried malt to our kits. This time, we added 3lbs of light malt to the wort and boiled for about 20 minutes. We noticed something strange when we transferred the hot wort to the sink for cooling - not all of the dry malt had dissolved. This was a little surprising to us because we had boiled up at least 2 gallons. Anyway, we decided to proceed as usual, thinking that the dried malt would eventually dissolve when we added more water and that it would not effect the action of the yeast anyway.

So, the following day, fermentation was already well under way and everything seemed to be going really well. The second day of fermentation also produced strong action in the fermenter, but by the third day all activity had stopped. We decided that we would leave the mixture a further day before bottling. On the 4th day therefore, we removed the top of the fermenter and were a little shocked to smell a disgusting stench from the top of the mixture. We were immediately worried about our results, since our previous brews had all smelt great at this stage. We took a reading with the hydrometer, which had only dropped from 1040 (before fermentation) to 1022. Complete fermentation had obviously not occurred.

We are always really particular about sanitation and are therefore suspicious of the quality of the yeast - dried yeast came with the kit. One friend of ours suggested that maybe the yeast had stopped, or maybe the problem is related to the undissolved dried malt, which was still present as solids in the brew. Are there any other explanations of what has happened and why? We did continue to bottle a few test samples, but had no extra yeast to try and continue fermentation. We decided to throw the rest of the brew down the sink.

Any helpful ideas would be appreciated.

Paul.

Could be, and I've done this, too. Of course, they sit there during
the whole sparge time. I normally only steep crystal for about
.5 hour when I'm doing an extract batch, so the sparge time should be
sufficiently long to extract the sugar.

Time for an experiment!

From: dipalma@banshee.sw.stratus.com (James Dipalma)
Subject: food grade buckets

Hi All,

I recently brewed my worst batch of beer ever, and I'd like some help identifying the cause.

With the onset of winter, the prospect of spending two hours in an unheated garage in sub-freezing temperatures huddled over a cajun cooker definitely puts a damper on the fun aspect of brewing. Accordingly, I decided to downsize my batches to three gallons, so I could boil the entire volume on the stovetop in my nice, warm kitchen.

I took the fairly obvious approach of multiplying the quantities on the grain bill of my favorite recipe by 0.6. The resulting 5.5 pounds of grist placed in a standard (i.e., 5 gallon buckets) Zapap lauter tun produced a grain bed with a depth of about 5 inches. I had read about (in Noonan, I think) the relationship between grain bed depth and good filtering, so I went to the local hardware store and found two 3.5 gallon buckets. These buckets are considerably smaller in diameter than the 5 gallon buckets, so I reasoned that the grain bed should be considerably deeper. They also *looked* just like the food-grade buckets I already had, so I dutifully brought them home, drilled them out, installed a tap, brewed a three gallon batch of pale ale, and put it in a three gallon carboy to ferment.

The beer sat in primary for three weeks before I bottled it, due to an unexpected business trip. I generally ferment 5 gallon batches in 6.5 gallon carboys, then rack to secondary. With the use of these oversize carboys, I don't need a blowoff tube. The first sign of trouble was the incredibly thick mass of trub that had collected in the neck of the carboy. There was even some trub in the airlock, though not much. As I racked the beer to a bottling vessel, little warning bells were going off in my head, "shoulda used a blowoff tube", "sat on the trub for three weeks", "can you say 'fusel alcohols?'". I decided to taste the brew before bottling.

Well, the beer smelled something like turpentine, and it's aroma was it's best feature. The flavor was so incredibly foul, I cannot find the words to describe it. Needless to say, the bacteria living in my septic system enjoyed an evening of drunken revelry, at my expense.

What went wrong? I have two theories:

1) The buckets I bought were not food grade. It's easy to imagine the horrible types of chemicals that may have leached into the beer, given the temperature and acidity of the mash during sparging. I recall a post on HBD from the dim and distant past, wherein someone explained that by federal law, food grade buckets are required to have certain information stamped on the bottom. An acronym, something like HPE? HPDE? springs to mind. Any net.brewers have this info?

2) The off-flavor resulted from sitting on the trub too long. Since I've always used oversized fermenters and racked to secondary, this is one problem (probably the only one) that I have'nt experienced. Anyone ever brew a beer that had this problem? What is the flavor like (assuming you were sturdy enough to keep it in your mouth long enough to taste it)??

Cheers,
Jim

The yeast will drop out of suspension and start
going dormant.

>3. In conjunction with 2, I gather the yeast go dormant at the end of
>fermentation, but so what? When beer is bottled, fermentation has
>definitely stopped, but the yeast happily rapidly ferments the priming
>sugar. So what's the difference between this and pitching fermented-
out
>starter into fresh wort?

You want the largest number of active cells. The
idea behind the starter is to get the ferment going
has quickly as possible. If the starter is already
dormant for awhile then you have to wait for
everything to get going again. In bottle
fermentation you are going to wait 1+weeks anyway
so it doesn't matter. Also with lagers that have
been sitting around for awhile pitching fresh yeast
into the green beer isn't unusual.

Well I've discussed it with Customs. It will cost
you 55% in duties and taxes if you go to Buffalo and
pick it up your self. Expect the LCBO to charge even
more- (I think the various SN products are something
like \$8-9US a six in Buffalo.

>Now a question for American's. I had the opportunity to try the Samuel Adams Boston Ale. What are people's opinions of this beer?...I liked it, there is nothing like it in Canada, from a domestic view point.

I'd also like an opinion of this beer. The two bottles I tried weren't very good at all. In fact I'd say they were either off or just rather bad. No head retentions and personally not a very exciting taste. Locally I'd suggest that any of the Wellington products are much better. I have a couple bottles of Samuel Adams Lager hopefully this will be better but I'm not holding my breath.

>Subject: yeast's tolerance of alcohol

>I racked a gallon of cyser today. Using M&F dry, the gravity fell from 1082 to 1002 in only 3 weeks. I was somewhat disappointed:
>I used ale yeast instead of, e.g., champagne yeast to get a higher final gravity. I figured the alcohol would kill off the yeast somewhere around 8% alcohol by volume, leaving me an FG of 1020 or above.

I think the bigger question here is what's in the batch. Honey will ferment out totally. How far will the cider go? A drop of 80points is quite large but I'd argue that unless the SG was much higher it would ferment dry.

From: HOWED@bcvax1.bc.edu
Subject: Cinnamon Stopper?

In mid-November I decided to brew a simple cinnamon beer for the holidays. It's basically a brown ale with some fresh ground cinnamon added during the end of the boil. There were no problems in the fermenters. The S.G. went from 1.040 to 1.014 with no problem. Nothing unusual when I bulk primed them seemed to happen either. The problem is that Christmas is coming, and the beer has yet to carbonate.

Could one of these factors be the problem? --->

I added 3/4 tblspn of cinnamon to the priming sugar because there was no cinnamon taste to the beer when I bottled. Did I bottle too quickly?

In an attempt to carbonate more, I tried adding 1/4 tsp of corn sugar to a bottle, and it foamed over, leaving a great head, but still no carbonation. I have since tried re-priming one six-pack worth to see what happens. Any suggestions?

From: arf@ddswl.mcs.com (Jack Schmidling)
Subject: Ham Brew Forum

I get many inquiries about my logon (arf) and herein furnish the explanation along with another idea for expanding the outreach to and of the homebrew community.

ARF is an acronym for the Amateur Radio Forum. This was a weekly talk show that I hosted for over 5 years on the 75 meter amateur radio band. It was 3 hrs of nonstop monolog and dialog on frequently outrageous and usually politically incorrect issues of the day. I was, for all practical purposes the Rush Limbaugh of ham radio. Unlike Rush, I got nothing (but fun) for my efforts and finally got bored with it all and gave it up this Fall. The acronym was a natural choice for my internet logon as I was also very active in political discussions on usenet and the continuity made sense at the time.

It now occurs to me that there could be enough home-brewers with ham licenses or at least short wave radios out there that we could get a home brew discussion goin on the radio. I had mentioned home brewing frequently during my ARF programs but never once heard from anyone with the slightest interest. It is entirely possible that the two hobbies are incompatible for some reason but it can't hurt to ask.

So, if there are any hams out there interested in talking about home brewing on the radio, please drop email to me and let me know.

From: STROUD <STROUD%GAIA@leia.polaroid.com>
Subject: Legality of Eisbocks

Two local brewing companies have both started advertising (and selling) what they claim to be eisbocks. In both cases the claim is made that the alcohol level of the final product is increased by actually freezing out part of the water.

I was always under the impression that the BATF considers this practice to be illegal, since it is a form of alcohol concentration and hence is synonymous with distillation.

Any comments?

Subject: RE: HBD 1032

Hi All,

In HBD 1032, Mark Garti asks:

>when sparging
>and adding sparge water, are you supposed to let the water level
>start to drop below the the top of the grain before adding more
>sparge water. OR do you never let this happen. All the books
>are pretty grey here.

I try to maintain 1-2 inches of water on top of the grain bed when sparging. If you let the water level drop below the top of the grain, the runoff will slow due to the lack of water pressure in the column. Also, when you add water to such a sparge set-up, you will disturb the grain bed and diminish the filtering.

>also no one touched my question about reasonable conversion times.
>i had asked if most people end up doing a conversion step of 45-90
>minutes? papazzian had indicated a total time of about 25 minutes.
>is anyone getting decent efficiencies with this short a time. I'm
>not but i don't know if this is the problem, or if it's something
>else. i usually get 25 ppg.

My conversion times are approximately one hour, with slight variances due to amount and type of malt used. 25 minutes seems a little low, are you using an iodine test to determine if conversion is complete?

Also in HBD 1032, Scott James asks:

>I found that buffering my sparge water (2-3 gallons) with 1/2 teaspoon
>gypsum greatly increased my extraction rates. Does anybody else do
>this to?

And Todd Enders writes:

>Sparge
>water was acidified with lactic acid ala Miller
>...
>The last runnings had no preceivable tannic taste.

There was a recent thread on this forum regarding the lack of tannin extraction during decoction mashing, the conclusion being that low pH environments minimize the extraction of tannins. Someone (Darryl Richman?) included an explanation of why tannin extraction is problematic during sparging, i.e., the pH of the mash increases as sparge water is added.

In my particular case, I have well water that is very hard. When I pre-boil this water, a large amount of white precipitate forms which I assume to be calcium carbonate. The pH of this water after boiling is still something near 7. During sparging, the taste of tannin becomes noticeable when the SG of the runoff is still 1.020-1.025. Clearly, there is still quite a bit of sugar present, but if I continue to sparge I get the tannins

as well. I saw the thread on tannin extraction, and decided to try acidifying my sparge water.

I got this stuff called 'Acidblend' from a friend who makes wine, and uses it for the same purpose, pH adjustment. I don't know what's in it, but it is certainly effective in lowering pH. I use 1/4 *teaspoon* per 4 gallons of water, which brings the pH from ~7 to 5.5 - 5.0!! I have used it for the last three batches, and while I did notice a slight improvement in extraction, the biggest improvement, IMHO, is that I now sparge all the way down to 1.005, with no noticeable tannin taste in the runoff. I can't taste any sugars at that point either, so I stop sparging at this point.

I have'nt noticed any unusual fermentation characteristics with these three batches, so it appears that the yeast is still working well, despite the somewhat more acidic wort. The first of the three batches was kegged this weekend, so I'll soon have some notion of what effects the acidification had on flavor.

Cheers,
Jim

>to culturing yeast.

Well, I personally think that it is worth it. I have lately been trying Nottingham and Windsor from Lallemund, and Cooper's, but I'm not about to give up my #1028 or the other Wyeasts. My recipes are formulated with specific yeasts -- that's because the yeast has *so* much to do with the flavor of the final beer. Splitting a package of Wyeast is a great way to bring down its cost.

>Using Papazian, 2nd edition, I have no problem with the explanation
>of the preparation of the medium. Now, on p279, under the heading

>do this, allow for the swelling, then dump the entire thing
>the bottle? Or do you break the inner part
>and immediately dump both sections into the bottle? Or do you
>ignore the inner part and just dump the one section in?

Pop the inner package, let it swell to about an inch and then pitch it into the starter -- that would be my advice. For the record, the yeast is in the outer package.

>Once the liquid yeast is in the bottle, you place a fermentation
>lock on it, according to Papazian. Fermentation starts, but then what?
>Papazian says stick it in the refrigerator, then repropagate in 2 to
>4 weeks. When do you use it? When you repropagate, do you split
>the bottle contents in half and propogate two cultures? Do you drain
>off the liquid in the top half of the bottle and just use the sediment?
>Do you have to let everything get to room temperature?

If you will not use it right away, I suggest letting it ferment out and store it in a cool (60-65F) place. When you're ready to brew, 12 or 24 hours beforehand, add some more 1020 wort to get the yeast re-started.

>I have so many questions, about this, that I may as well stop at this
>point. Can anyone give me some pointers and/or step-by-step
>instructions? And, perhaps, can anyone render an opinion: I'm
>still a beginner, having only brewed 5 batches, am I getting
>in over my head to quickly?

No. You won't be a beginner for long, but only by experimenting with different techniques and ingredients can you break out of beginnerhood. Liquid yeast is a great way to go.

Mark writes:

>I use a zapapp lauter tun (bucket in bucket). It was made from

>sparge water. OR do you never let this happen. All the books
>are pretty grey here.

You should *not* let the water level drop below the level of the
grain. The grain are partially supported by the water and thus
draining the water will cause the grain to compress.

>
>also no one touched my question about reasonable conversion times.

I believe that Charlie is talking about fully-modified malts (Pale Ale
Malts) converting completely at relatively high saccharification
temperatures. Sure, you can convert fully modified malt in 25 minutes
at 158F. On the other hand, if you use all Munich malt at 148F, you
can easily exceed 2 hours for conversion.

>>From: BLASS@bigvax.alfred.edu (YOU'VE GOT THE EGGS, I'VE GOT THE

>>I am interested in recipes for mexican beers, like Corona, and
>>how to make malt liquor. I tried a few different malt liquors, some
>>enjoyable (Mickey's Fine Malt Liquor), some not that enjoyable. How
>>is it made and are there any recipes?

Rather than have you be disappointed by your homebrew, I'd like to point
out that these two beers you have mentioned, are very light-bodied and
light-flavored. Most of the recipes you will find will make a beer that
is considerably more flavorful and heavier than these. The way to make
a very light-bodied, light-flavored beer is (as James put it, rather
tersely) to add alot of corn sugar. You may get a negative reaction from
many homebrewers regarding very light beers because, for many, it is just
the style of beer that we are trying to avoid -- I became a homebrewer
primarily because I could not find beers other than the American Light
Lager style in my area. I've since found suppliers.

Just a style note -- Corona is not a typical Mexican beer. Mexican
beers,
in general are more full-bodied, amber in color and more flavorful. Many
are of the Vienna style. Corona was created to fill a market need -- the
laborers in Mexico could not afford the regular beers, which contained a
lot of expensive malt. Corona was created as a cheap, high-corn-sugar
"beer" for the poorest people in Mexico. The lime, incidentally, was
introduced not to the beer, rather it was used by Mexicans to clean the
tops of dusty cans and then discarded. Some marketing suit saw them and
thought they were putting the lime in the beer. (Wanna make friends at
a fern bar? -- tell a yuppie with a lime in his beer these two stories.)

Dave writes:
>Vanilla Bean Stout (5 gal)
>
>2 lb crystal (90L)

of my
>stove? I've tried "Soft-Scrub" but it just doesn't cut it. Please, if
I don't
>get this off my wife might leave me else quit brewing. I'd really miss
her
>too. MIKE

In the future, you might try soaping-up the top of the stove before
brewing.
Any splatters or boilovers will not stick to the surface and then you
just
rinse after brewing. In the meantime, I suggest spraying something like
Formula 409 or Fantastic onto the stain and letting it sit for an hour.
Then rub-and-scrub till your arm gets tired and repeat with the spray.

Al.

P.S.

In digest 1031, John notes:

>P.S. Apparently some of the Chicago Beer Society (CBS) members have gone
>national! Our newspaper, the San Diego Union-Tribune, carried an
article
>today by Michael Lev all about homebrewing, including a picture of Ray
Daniels

As some of you may recall, I wrote a letter to the BBW attorneys this
summer expressing my opinion about this trademark infringement nonsense.
While the letter was never used, the BBC attorneys found out about it by
reading my postings to the net, and now they want to see it.

While issuing the above subpoena is perfectly legal, I think it is also
indicative of how absurdly litigious Koch & Co have become.

FYI: The above case is an appeal to the original trademark infringement
case which BBC lost. They are also suing the CBC for using the word
'Boston' on their labels.

Here is a copy of the letter that has them so worried...

- -----
-

5 June 1992

To whom it may concern,

In my opinion, consumers will not be confused by any similarity between "Boston Beer Works" and "Boston Beer Company". "Boston Beer Company" is not widely known by consumers, since most identify their products as "Samuel Adams". In addition, "Boston Beer" is a generic phrase and is part of the name of a variety of businesses, organizations and events in the Boston area.

Sincerely,

Charles Cox

End of HOMEBREW Digest #1033, 12/15/92

Date: Tue, 15 Dec 92 12:32:03 MET
From: THOMASR@EZRZ1.vmsmail.ethz.ch
Subject: three beers from one mash

Hello all,

I thought you might be interested in this recipe I dug up from a book on brewing by a man called F. Accum (second ed. published 1821!!!).

It details the "current method used to obtain a keeping ale, ale and table beer" from a single batch of grains. I have translated it into modern units, and scaled it down to give 5 gallons (UK) of wort for the keeping ale:

31# pale malt

12.6 oz hops

mash No.1

4.86 gallons (UK) water at 160 for 1/2 hr

then add 1.36 gall(UK) at 156

mash for a further 1.5 hr, and draw off wort --> 5 gall (UK)

mash No.2

5.14 gall (UK) at 175

mash 1.5 hr, and draw off wort --> 5 gall (UK)

mash No.3

add 0.56 lb grains to the mash tun

6.7 gall (UK) at 175

mash 1.5 hr, and draw off wort --> 6.43 gall (UK)

Boil the first two worts separately with 6.3 oz (!!!!) hops for 2.5 hr, and filter as usual

- --> 4.25 gall (UK) at 1100.6 and 3.8 gall (UK) at 1060

Boil the third wort with the used hops for 2.5 hr

- --> ca.6.43 gall (UK) at 1031.

By my calculation this gives 22 pts/pt/gall(UK)

- --> 27.65 pts/pt/gall(US)

1 gall(US)=.8 gall(UK)??

By the way, keeping ale was a strong ale brewed so that it would last through the summer when it was not possible to brew (heat --> bugs --> lousy beer), whereas table beer was the sort of stuff you had with breakfast (eg queen elizabeth 1, who drank a quart of it each morning).

Hope this is of interest / use to someone out there.

Rob Thomas

P.S. the book also contains other recipes, eg porter, old ale
If there is demand I'll send them in.

P.P.S. I haven't brewed this recipe so caveat brewer!

Subject: Belgian Wheat Beer

I have one question concerning belgian beers that use wheat in addition to barley malt. Michael Jackson says that they use (if I remember right) 40 or 50 % unmalted wheat. Now I wonder how do they mash it. Papazian recommends not to use more than 20 % unmalted grain, because otherwise there are not enough enzymes. Do they add enzymes, or do they have malts that have very much enzymes? Or is there some other explanation? Looong mashing time or something like that?

Nay, nay, I must disagree. Al may WANT the Vienna style to be typical of
Mexican beers, but the sad truth is that Corona is the much more more
typical
example. The light watery beers like Corona, Tecate, Superior,
Chihuahua, Sol, etc etc ad nauseum have been so wildly successful that
many of the more interesting beers are either no longer brewed or only
in small amounts. Dos Equis and Negro Modelo are certainly better, but
they only account for a small percentage of the total sales of Mexican
beers.

From: ml4051@mwvm.mitre.org (John DeCarlo)
Subject: Handling Dry Malt

Hello. I use dry malt extensively for priming my beers. If I fail to seal the bag completely, it gets hard and I have to break it up. I have noticed that if I put a chunk of this in water and try to dissolve it, half the time I have zero success.

The chunk will melt and become taffy-like, but never dissolve. Tastes OK, though, as a sort of candy. (Waste not, want not.)

Any hints on proper storage? Anyone ever get chunked up malt to be useful in the brewing process? Thanks in advance.

Subject: labels

Lou Casagrande writes

<< My co-brewer and I have been looking for the kind of gummed labels which must be wet in order to apply them (this is to make their removal easier) which are also arranged in sheets so that they can be fed through a laserwriter. Of course, we want to design our own labels, and since we brew a variety of beverages, we need to be able to easily print a variety of labels. Has anyone run across anything like this? >>

I have not come across any gummed labels for laser printers. What I do is make my labels on my printer with regular xerox paper. To affix them, I dip them in milk then apply them to the bottles. They stick just as if they had glue on them and they peel right off after dunking the bottle in warm water. Another advantage is that there is no gluey residue left on the bottles to clean up.

>know what's in it, but

It will be a blend of Tartaric, Citric and Malic acids (Can't remember the specific proportions but it could be something like 50%, 30%, 20%). I don't use these blends, I have all three (and some more) acids and add which I think is most suitable. The most suitable is usually Tartaric: if it is good enough for the grape it is good enough for me :-)
Most beermakers seem to prefer using Lactic acid, but commercially it is not unusual to hear of them using Sulfuric acid (and Hydrochloric some-times) for reducing pH.
A trivial technical point: winemakers add these organic acids to increase the titrateable acidity not to reduce pH (there is a difference). The titrateable acidity is a better measure of the effect of the wine on the palate.

Subject: Subpoena, Legality of Eisbocks, Kalamazoo Brewing

From: chuck@synchro.com (Chuck Cox):
>Well, I was served an interesting document the other day...

And I will document, right here, and right now, that I will *never* ever again engage in any form of retail trade that will result in my consumption of products made by:

>BOSTON BEER COMPANY LIMITED PARTNERSHIP,
>d/b/a THE BOSTON BEER COMPANY

a/k/a "Samuel Adams." Beer isn't about lawsuits anywhere else but the USA, and I'm fed up. I will not consume, nor recommend for consumption, any of Mr. Koch's products. Perhaps it is a bit late, but I recommend that we boycott the entire "Samuel Adams" product line, from okay-but-a-bit-bland lager, through utterly-bogus-marginally-cranberry-flavoured-pseudo-lambic. I notice that, out here in the west, we can have two products called "Blue Heron Ale" (from BridgePort and Mendocino) without having to invite a tasseled-loafer army of briefcase-packing attorneys into the fray. Jim Koch, GROW UP! Oh well, you can tell a Harvard man, but you can't tell him much...

>While issuing the ... subpoena is perfectly legal, I think it is also >indicative of how absurdly litigious Koch & Co have become.

Then make them pay for this stupidity out of their *own* pockets - don't contribute to Koch & Co's profits. The only other stupidity I know of equal to this is the issue of the use of the Budweiser name - those pikers from St. Louis can't stand the thought of a certain high-quality Bohemian beer with the same name being unleashed on the market, as it would show their beer to be the bland, under-flavoured, process-controlled pap that it is.

From: STROUD <STROUD%GAIA@leia.polaroid.com>:
With regard to a couple of American-made 'Eisbocks':
>I was always under the impression that the BATF considers this practice to be >illegal, since it is a form of alcohol concentration and hence is synonymous >with distillation.
>
>Any comments?

Who cares, except the BATF ;-)? If you're interested, go out and buy a sixer or two of the Eisbocks, and hide them in the 'fridge. Keep them for special occasions and *very* cold winter nights. If the BATF issues a 'cease and

desist' order to the brewers (distillers? :-), fine. Also, consider this:
similar restrictions exist in Germany on the production of hard liquor beverages by distillation, yet there is no problem with the production of Eisbocks - save for the technical difficulty of doing so, and the relatively limited market for such a strong form of beer.

Now, for a question of my own:

My brother moved from Michigan to Florida recently. One of the last things he did before moving, was to send me a couple of beers from the Kalamazoo Brewing Co., "Third Coast Beer" and "Bell's Beer." The "Third Coast" was not bad, basically what seemed to be a top-fermented blond ale with a substantial amount of Chinook and Cascade hops - quite bitter on the palate, with a spicy finish. The "Bell's Beer", on the other hand, was extraordinary - it seems to be fermented with either a Belgian ale yeast, or it undergoes a lactic secondary, I'm not sure which. It also has the characteristic flavour found in some Belgian wheat beers and triples. So, the obvious question: can anyone out there tell me about the Kalamazoo Brewing Co. and their products? Recipes? Maybe even send me some in trade for Christmas ale from the Pacific Northwest???

Thanks, and cheers!

Subject: For G. Fix: Clarification of DCI protocol

Any homebrewer interested in the chemistry of brewing is encouraged to check out the latest Zymurgy with an article by Dr. Geo. Fix on "hot side aeration". In the article, George describes a protocol ascribed to deClerk for measuring the redox state (a measure of oxidation of wort) using DCI, which the article expands into "dichlorophenol indolephenol".

>From my background in chemistry this sounded like an erroneous name, and I suspected a misprint, and that the actual chemical was dichloroindolphenol, hence the acronym. In the chemical catalogs, though I found that both names are applied to the same chemical. The price seems quite reasonable (e.g. Sigma D1878 is 10 grams for \$30.50, or 1 g for 6.30). It might be appropriate for some HB suppliers to repackage this for general use.

However, there seems to be some information lacking from Dr. Fix's otherwise excellent article. He describes adding 0.25 ml of DCI to 10 ml of wort, but the concentration of the DCI solution is lacking. I thought maybe that DCI was a liquid, and that it was meant to add the neat liquid, but the Sigma catalog describes it as "Sodium salt, crystalline". To follow these instructions we need to know the concentration of the DCI solution that is added.

I'm hoping that Dr. Fix or someone else who uses this method might clarify this point, and maybe post the protocol for those who don't read zymurgy.

BTW, the new color zymurgy format is quite impressive (they managed to get 8 color pages on the "cover"; that's 7 pages of ad income right there). Overall, though, it is clear that they didn't spend the money on editing, or even running their stories through a spell checker, since all of the articles are riddled with typo's.

The last page features an oh-so-humorous look at Charlie P. laughing, and lots of other people wearing Charlie P. masks. Maybe the next change in the Zymurgy masthead ought to be a sub title:

"Official magazine of the Charlie Papazian fan club"

Oh well, the quality of some of the articles makes up for the self-indulgence, I suppose.

thanks for your input

Subject: Acidifying Sparge Caution

Subject: Acidifying Sparge Caution Time:8:40 AMDate:12/15/92
With all the talk of acidifying sparge water it is possible that this is one of those practices which is on its way to becoming abused. Here is my caveat.

If your wort falls below a pH of 5.0 you may not get much of a hot break (Miller). The pH of the wort will go lower as a result of the boil (also Miller). Water is a poor buffer especially when it is in the neutral range (6.5 - 7.5) and will become more acid when added to an acid mash rather than the reverse. Dark malts are naturally acid and mashes which include them often need to have their pH raised in order to maintain the 5.0 - 5.5 range.

My local water is soft and runs in the pH range of 6.3 - 6.8. My pre-boil wort tends to be right at the lower edge of the acceptable range (5.0) even without any dark malt. I tend to get a very poor hot break.

What this is leading to is this: Don't acidify your sparge water just because other brewers do it. Check the pH of your water and your runnings to determine if it is necessary. Certainly if you have hard water and you detect a tannic flavor in the runnings you may want to make some adjustments, but a simple pre-boil of the sparge water may be all you need. Even if you do acidify your sparge, you may not need to do so for every recipe. If you do it for a pale ale you may not need to do it for a stout or porter. Monitor all the points in the process so you know what's happening.

Now, no doubt someone will ask, "What happens to wort pH after the addition of the hops?" I don't know. I'll have to take some readings the next time I brew.

Perhaps George Fix (et al) will comment on my observations and add some expertise to the discussion.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: acidifying sparge/wyeast specs

The past few HBD's have had a lot on sparging and acidification of sparge water. Has anyone out there used ascorbic acid to acidify the sparge water? It occurs to me that it may also help to reduce the amount of oxidation from splashing the recirculated wort. I seem to recall vaguely that Miller was opposed to using ascorbic acid, but I don't recall off hand why...

*** **

There has been mention of a spec sheet for the different yeasts, their attenuation and flavour profiles and so forth. Is there a copy of this archived somewhere? If not could someone post it to r.c.b or HBD? Or mail it to me?

Thanks,
Ed Hitchcock

From: jrd@research.att.com (James Driscoll)
Subject: ASBC Methods of Analysis

John Decarlo asks about certain citations to a publication of the American Society of Brewing Chemists (ASBC).

What he is probably seeing referenced are analytical methods from Methods of Analysis of the American Society of Brewing Chemists, Eighth Revised Edition (published by the American Society of Brewing Chemists, 3340 Pilot Knob Road, St. Paul, Minnesota 5512-2097)

This is a three inch thick ring binder containing sections with names such as Malt, Beer, Sensory Analysis, and Microbiology. The methods are numbered, and have names like Yeast-8: Killer Yeast Identification and Hops-3: Aphids in Hops. My personal favorite is Microbiological Control-4B: Brewers Tomato Juice Agar Medium. Yuck.

These provide standardized methods for the brewing industry and as such are quite precise and easy to follow. The bad news is that it costs \$400 and many of the methods require instrumentation and reagents not easily obtained by even the enthusiastic amateur brewer (or commercial microbrewer, for that matter).

This probably isn't something that an individual amateur brewer would want to spring for, but it is something that a "techie" type homebrew club might want to consider adding to their library. It is also interesting to anyone running a homebrew competition, since it contains a section on sensory analysis with such methods as Selection and Training of Assessors, Threshold of Added Substances - Ascending Method of Limits, and Flavor Terminology and Reference.

To give you a feeling for the book, below is reproduced their version of a familiar test: (The methods are, of course, copyrighted; but I hope they will find this a fair use in what is essentially a review of their newly issued Eighth Revised Edition.)

Adjunct Materials
Sugars and Syrups-8
Page 1 of 1

IODINE REACTION

Reagent

- (a) Iodine Solution, 0.02N. Dissolve 1.27 g iodine and 2.50 g potassium iodide in a little water and dilute solution to 500 ml. Solution should be made fresh every month and stored away from light. For daily use, keep portion of solution in small, dark dropper bottle.

Apparatus

- (a) Test tubes.

Method

Fill test tube to within 1 in. of rim with "10% solution" prepared according to method of Adjunct Materials, Sugars and Syrups-5 [which basically tells you to take a 50 g sample and dilute to 500ml with 20 degree C distilled water]. Carefully add 0.02N iodine solution (reagent a) from dropper bottle to form distinct layer on top of sugar solution. Report color developed at interface of two liquid layers by transmitted light. Blue indicates presence of starch, purple "amylodextrin," reddish color "erythrodextrin." Qualify result by using terms faint trace, trace, or strong trace according to whether color developed is faint, distinct, or strong.

Subject: Carboy filling levels? How high is too high?

Hi all,

Still no response from Hawaii brewers.... Rats...

Given the following crude representation of a carboy, to which letter should I optimally be filling?

With my first batch, I filled to C, and had no problems.
With my second batch, I filled to B and the blowoff cap popped off.
With my third batch, filling to A, resulted in a completely plugged neck.

I suspect that using Oak chips in batch three may have contributed to the plug, I was not able to investigate the actual plug (as I tried to clear it, it fell in.... (Yikes!))

Should I be altering my level of filling?

Point A is the last 2 inches or so from the lip.
Point B is all distance between the slant from vertical to point A.
Point C IS the slant from vertical (what I call the shoulder).
Point D is all points below C.

Subject: Addr: Problems

Can someone comment on a problem I may be having. The last two batches of lager I made turned sour on me. Extremely distressing (they, too, gave the bacteria in the septic tank a great binge). I think I got some contamination because my two-year-old got into the air lock (my fault, of course, both times), and I found it on the ground more than once. Now the current batch of ale I'm making (VERY two-year-old proof) has been in the primary for about one week and I was considering bottling it without even putting it in the secondary (everything looks so packed down there). Now, however, I am getting a resurgence of fermentation (actually, a very small bubbling action, but still fermentation starting again). Does anyone know why this is? Have I got yet another bad batch with wild yeasts on the way? Or, is it possible there are still a few fermentable sugars, etc. left in the wort that simply have not finished working yet? Any comments?

Second, in regard to the current yeast conversations, I want to mention that after the package swells up, if you don't want to use a starter, you can simply pitch the yeast right from the package into the cooled wort. I have done this and had great results, but I wonder if this is not a good thing to do. Any comments here? I admit making a good starter is better.

Third, I bought some liquid yeast that does NOT have the little diaphragm you are supposed to smack, and have been unable to get it going AT ALL with a starter. I bought it cheap from a supply store and still have a few packages in the refrigerator. But I can't get it to work. I wonder if it is dead and I should throw it away. Has anyone had any experience with this type of liquid yeast (it was cheap because it was several months past the expiration date--I took a chance)?

Thank you and best wishes for the holidays.

Subject: sparge/next day boil/too-dry cyser

>I use a zapapp lauter tun (bucket in bucket). It was made from
>2 6.5 gallon buckets. all this talk about sparging and solution
>concentration had me thinking about my technique. when sparging
>and adding sparge water, are you supposed to let the water level
>start to drop below the the top of the grain before adding more
>sparge water. OR do you never let this happen. All the books
>are pretty grey here.

Don't do it. All my sparges used to stick, until I (in order of
apparent importance:

- 1) stopped letting the sparge water level drop below the top of
the grain bed
- 2) mashed out at 168F & insulated my lauter tun to keep the heat in
- 3) stopped trying to fit 20 lbs of grain in the thing.
- 4) got a rollermill (a MALTMILL)

I shouldn't have used the word "stuck". the sparges just used to
take 4-5 hours :-)
Now they take about 1 hour (2 if I put 13 lbs of grain in)

- - - - -

>Don't just stash those second runnings to brew another day; it
>won't take long for them to turn sour. Yes, you will boil the
>wort. Too late: the damage has been done,

use them in a dry stout, or a belgian somethingorrether, where a
slight sourness is not objectionable. A 12 hr lag period until
the next morning does not seem to produce any noticeable off
flavors, anyway (at least for me), so you can't rely on them
producing the sourness, either.

- - - - -

>I racked a gallon of cyser today. Using M&F dry, the gravity fell
>from 1082 to 1002 in only 3 weeks. I was somewhat disappointed:
>I used ale yeast instead of, e.g., champagne yeast to get a higher
>final gravity. I figured the alcohol would kill off the yeast
>somewhere around 8% alcohol by volume, leaving me an FG of 1020
>or above.

Then keep adding sugar until it stops fermenting away. I started a
batch of cider at 1.067 a few months ago and pitched with bread ale yeast,
and have added ~900g extra corn sugar so far. Most of it ferments away,
but it leaves a little more sweetness every time. It's finally in the
dry stage (as opposed to the arid extra dry stage) SG ~ 1.002 or so.

Subject: Lion's Head Ale House

Upon recommendation of one of the Chicago area brewheads, I checked into the Lion's Head Ale House on the south side of Chicago. One word . . . excellent. This place is the homebrewers ideal hangout. Thirteen taps open of excellent American microbrews !! I had Celebration Ale from the tap . . . very tasty. In fact, I had the PA from SN right after that and I found them very similar in taste. The Celebration had a ginger flavor to distinguish it from PA. We also had an Oatmeal Stout straight from a freshly tapped keg . . . it was so sweet and delicious I would have put it on my cereal !!

To add to the excellence of the brews, the ambience was excellent. The place used to be a speakeasy in the 20's. Very old iron castings on the chairs and tables, mahogany woodwork, intricate ceiling artwork, etc.

I know everyone doesn't want to read this, but we've heard so much about the NW brewpubs that I thought I'd add a report from the heartland.

Ciao,
Kevin

From: "Knight, Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: thanks, yeast pitching, Anchor Steam, Sam Adams

First off, thanks to all the generous folks who responded to my queries about re-use of yeast and blowoff methods. I have, so far as I can tell, successfully "washed" some Wyeast Irish, and re-started and pitched 1/2 of it in a new batch of stout. Soon I will use the other 1/2 in a third batch of stout which will be fermented by gen-u-wine blow-off (5 gal. carboy w/ 1" hose stuffed in the neck). New horizons are wonderful things.

With regard to re-pitching, or pitching for the first time, I will re-iterate that so far, although there have been interesting discussions regarding the theoretical merits of pitching at "high krausen" vs. pitching later, I can't tell the difference in lag time or in finished product. I've only used liquid yeast for a few batches, but I always brew, cool and pitch in the late evening and when I get up in the morning, the beer is always bubbling no matter whether I pitched at H. K. or later. I also (knock on formica) haven't had any infections lately so I'm not *worried* about whether my lag time is 3 hours or 6, and I'm not going to stay up all night to find out, either. Again, does anyone have any reservations about pitching after high krausen that are based on practical experience, either looooong lag times or off-flavors or something?

With regard to brewing something similar to Anchor Steam beer, always one of my favorites, I have picked up from reading the HBD that Northern Brewer is used for flavor and Hersbrucker for aroma. I've also read that it's heavily dry-hopped. Does anyone know whether it would be better to (1) use N.B. for boiling and finshing and Hersb. for dry-hop; (2) use N.B. for boil, Hersb. for finish and Hersb. again for dry hop; (3) use N.B. for boil, Hersb. for finish, and N.B. again for dry-hop? I made a steam beer last year with nothing but N.B. and it was delicious; but I'd be interesting in getting something a little more Anchor-y and if Hersbrucker is the ticket, my question is where do I put it?

Finally, I have to say that I spent last summer in Boston drinking Sam Adams and liking it a lot. I didn't think all that much of the lager, and I didn't bother with the Wheat or Light, but I enjoyed the ale thoroughly and I indulged in a bit too much of the Doppelbock - it gives quite the warm fuzzies. However, I'm glad that my local wine shop can't get S.A. because if they really are being such litigious shitheads I'd have to exercise great will power to boycott them.

Sorry, that was too long.

Jonathan

Subject: Iodaphor problem

I just threw away my brand new bottle of iodaphor. Here's the sad tale:

Last week I used the stuff for the very first time, to sanitize my glass secondary fermenter. No problems, stuff worked great, everything seemed nice and clean, with no residual smells. As instructed on the bottle I used the cap to measure out the proper amount--2 capfuls for 5 gals.

Tonight I used it again to sanitize my bottling bucket. Not having a nice even 5 gallon container (6.7 gals, actually), I measured out 20 ml with a graduated lab vial and filled the bucket. Not only did the stuff come out darker than above, but when I emptied the bucket there was a distinct chemical smell and the bucket had been stained orange. Well, I rinsed many times, but still had the smell and color.

Here's where we add stupidity to misfortune. At this point I realized that

I could simply scrub the bucket and start over, sanitizing with chlorine. But then I thought about all those people who are supposed to know better than I, etc. who use it without problems. So I went ahead and racked the beer into the bucket anyway.

While racking I siphoned some of my beer directly from the carboy into a glass to taste and use for a gravity reading. Tasted great--smooth, clean.

Then when I tasted the beer coming out of the bucket I got an acid, slightly chemical flavor. The veil of depression set in. I bottled a case just against the possibility that the beer fairy might bail me out, and dumped the rest. The bucket still smelled chemical, though two good, soapy cleanings seem to have gotten most of it out.

Observations:

- 1) I could have mis-measured, but I really don't think so.
- 2) The bucket had last been used for sparging, and had been cleaned but not scrubbed. Could there have been a reaction to a residue on the interior.
- 3) Undetected stupidity on my part (always a possibility).

Despite the very real possibility of some slip-up on my own part, the convenience of fast contact time and no rinsing (in theory) is not sufficiently fool-proof for me to throw away a full day's work. (Or to undergo the depression.) I'm going back to chlorine.

Phil seitz
PSEITZ@MCIMAIL.COM

P.S. Anybody who wants to send me some beer to make me feel better is welcome to do so. :-)

P.P.S. Jack Schmidling will now give us a lecture on why we should trust our own judgement and not defer to "experts". He'll be right, too.

Subject: need some all-grain tips

Well, I've decided to take the all-grain plunge. My plan is to see what Santa brings me, and then fill in the rest myself over Christmas break. In the mean time, I've got a few questions.

1. I've pretty much decided to go Gott-cooler-with-slotted-pipes. My question is: Do I need a false bottom and/or grain bag? My brain says, "No, man, that's what the pipes are for," but my gut feeling is it would be pretty wierd to dump the mash straight on the pipes, plus a grain bag would help in clean up. So do I listen to my brain or my guts?

2. Instead of a copper manifold, what about PVC? Somebody in the latest-minus-one Zymurgy mentioned using PVC, but gave no details. I've never heard of anyone else doing it either, but it seems it would be easier to put together and take care of. Whaddy think?

3. Should I get a round cooler or a rectangular one. I know both are used. Is there any inherent advantage to one of them, or does it not matter? If I use a rectangular one, what is the optimal size? (I only plan on doing 5-gallon batches.)

4. To hit target temperatures, I know that you add water at above-desired temperatures. For you physics types: Is there an easy (or not so easy) formula along the lines of I've got X amount of grain in Y amount of water at Z temperature. If I add (I'm running out of letters) R amount of water at S temperature, the total will stabilize at the desired T temp? Surely trial and error will help me build up experience, but a formula sure would be nice.

Well, that's enough for now. I'm sure I'll have more questions later.

Subject: HSA

George Fix and Micah Millspaw, in separate articles in the current issue of Zymurgy, discuss Hot Side Aeration and steps to minimize it. Recent changes to the World's Greatest Brewery serendipitously put me one step ahead of the experts.

Lugging gallon jugs full of hot sweet wort downstairs to the boiler was not only a drag but sooner or later, dropping one (the first one naturally) would be inevitable and now I find that glugging the hot wort into the kettle was a great way to introduce HSA.

Two batches ago, I drilled a hole in the kitchen floor and ran a 1/8" FDA type plastic tube from the Easymasher spigot on the mash/lauter tun right into the brew kettle down below.

Assuming that these authors are correct, it appears that I need to extend the bottom end of the tube down to the bottom of the kettle to prevent splashing.

As I am not sure I want a plastic tube in my boiling beer, someone is going to have to convince me that this splashing is different from the normal turbulence of a good rolling boil. One of the authors advises, that even stirring the mash introduces HSA. What goes on in a rolling boil that prevents HSA compared to stirring a much cooler mash?

BTW, aside from the obvious convenience of the gravity fill, it has the advantage of not disrupting the boil everytime a gallon of wort is added. I light the burner when there is about three gallons in the kettle and once the boil is underway, it continues without interruption to the end.

The only problem is, I can no longer count jugs to know how much wort I have put into the kettle. As it boils continuously and I heat sparge water continuously as I use it, I really never know exactly but it really doesn't matter. I quit boiling when the volume and gravity are what I want.

My brewing is now more like monitoring a process than self-inflicted drudgery.

>I've pretty much decided to go Gott-cooler-with-slotted-pipes.

>Do I need a false bottom and/or grain bag?

My All-grain batches are mashed in a Gott 5 gal cooler. I removed the spigot that came with it (it required that you push a button to empty the cooler) with a plastic one I bought from a local HB supplier (turn a spigot and it stays open). At the bottom of the cooler I place this 'thing' that is used to make Cherry pie crusts, (har har). It's round, about 1/2 inch tall, perfed with about 1/2 inch square holes, fits perfectly in the cooler, and holds the grain bag off the floor of the cooler and above the bottom of drain.

The grain bag is constructed from two nylon meshes. The side (cylindrical part that goes up the inside of the cooler is a very fine mesh, while the round bottom is a coarser mesh. Sparging is very fast, and never, ever gets stuck.

>

>Should I get a round cooler or a rectangular one.

>

I like the round one.

>To hit target temperatures, I know that you add water at above-desired
>temperatures.

I store my grain in my basement. This tends to keep the grain at a constant year round temp of about 60 F. I heat my mash water to 168 F and use 1 quart/per 1 pound of grain plus 1/2 gal (the 1/2 xtra gal fills the space below the above describe 'thing'). So for 8 pounds of grain I'd use 2 1/2 gals or 168 F mash water. When mixed this result in a mash temp of 151-154 F. With a pre-heated cooler (hmmm) that temp will be maintained for a couple hours (or at least close enough).

I'd recommend you read Papazian's book. He does a good job of discussing target temps with infusion mashes. I started with his formula and adjusted.

While I cannot help him dissolve the malt extract bricks, I have been storing dried malt extract in Rubbermaid containers (3 or 4 qt Tupperware wanna bes) and have not seen any bricks so far. I only buy malt extract in 5# bags so far so this may not help you.

Subject: easymasher

I used Jack's EZ masher and was pretty impressed. I also used Florians/Russ Gelin's method of adding all the sparge water (close to boiling) at once/stirring/.5hr settle/ then just drain about 45 minutes. Just as Jack said, the wort was unbelievably clear, almost immediately. Not sure if entirely attributed to the EZ masher, the technique, or the fact that I switched to 2 row american from my usual British Pale.

The new system really took the drudgery out of sparging. It used to take me ~ 40 minutes of adding runnings to achieve such clarity. Thanks to all.

Subject: Brewpub in Troy, NY

Well, we've been reading articles about the brewpub in the paper and have been waiting patiently for it to open. In the last few months there hasn't been any hard news about the brewpub. The rumor on the street is that they have started brewing to build up some inventory before they open the doors.

Luckily I did have the opportunity to visit the Vermont Pub and Brewery in downtown Burlington, VT for the second time. All I can say is great food, great beer, great atmosphere, and very close to really great skiing (easter n standards apply).

As soon as the doors to the Troy brewpub open, I'm sure the news will shortly follow.

From: "Robert Haddad" <RHADDAD@bssl.umd.edu>
Subject: Stuck non-fermentation?

After three years of brewing ales, I have decided to attempt a lager, now that the temperature has dropped. I have 10 gals. of pseudo-pilsener in an enclosed backporch, with a stable ambient temperature of 50F.

I pitched a pack of wyeast 2124 bohemian in each 5 gal. carboy. The wyeast pouch had been burst and massaged the day before, as directed, and had expanded suggesting yeast was munching away.

That was then (sunday); this is now (wednesday)-- and still no sign of fermentation. When I brew ales at 65-75 F, I wake up the next day to the sound and sight of vigorous fermentation. Should I:

- -- (A) Pitch in another wyeast in ea. carboy? (another \$3.95 each!!)
- -- (B) Bring my wort in the heated part of the house to initiate fermentation?
- -- (C) Leave it alone and get back to my search for the meaning of life?

I read that lagers should ferment at lower temps to be real "lagers". How long before signs of fermentation appear?

Thanks a lot

and
>liquid onto the white surface before adding the iodine. Eventually, the
>iodine keeps it original color, and I continue. If I was testing liquid
only
>I would certainly quit mashing sooner. Comments?

>Norm

My experience with iodine testing is virtually the same as Ed's,
whenever I test a sample that has some small grain chunks in it,
it always tests positive, i.e, not converted. I've had this happen
after holding sugar rest temperatures for over an hour.

What I do now is to scoop out a small depression, an inch or two
deep and a few inches across, in the surface of the grain bed at the
beginning of the sugar rest. The liquid tends to collect in the
depression, so getting a grain free sample is easy. I've also found
that testing only liquid seems to be an adequate indicator of conversion,
as I have no starch haze problems with my beers.

Also in HBD #1034, Donald Scheidt writes:

>I recommend that we
>boycott the entire "Samuel Adams" product line, from okay-but-a-bit-
bland

lambic.

Recommendation seconded, but you forgot to mention the weak-insipid-
no-
detectable-phenolic-character-wheat-beer, the way-too-hoppy-for-the-
style-
Octoberfest, and the altbierNOT!-Boston ale.

Also in HBD #1034, Russ Wigglesworth writes:

>With all the talk of acidifying sparge water it is possible that this is one of
>those practices which is on its way to becoming abused. Here is my caveat.

>If your wort falls below a pH of 5.0 you may not get much of a hot break
>(Miller). The pH of the wort will go lower as a result of the boil (also
>Miller).

>What this is leading to is this: Don't acidify your sparge water just because
>other brewers do it. Check the pH of your water and your runnings to determine
>if it is necessary. Certainly if you have hard water and you detect a tannic
>flavor in the runnings you may want to make some adjustments, but a simple
>pre-boil of the sparge water may be all you need. Even if you do acidify your
>sparge, you may not need to do so for every recipe. If you do it for a pale ale
>you may not need to do it for a stout or porter.

All of these points are well taken, and this is why I mentioned that 1/4 teaspoon of acidblend had such a drastic effect on pH. It was out of concern that someone might overdo it, and end up with a wort that is too acidic.

I check the pH of the mash to ensure it is in the 5.0 - 5.5 range, and I acidify the sparge water to the same range. My reasoning is that if 5.0 - 5.5 is the proper range for the mashing stage, maintaining that same range throughout the sparging process won't harm anything. If anyone knows differently, please feel free to correct me.

Cheers,
Jim

From: Arthur Delano <ajd@oit.itd.umich.edu>
Subject: Keeping dry malt

In HBD #1034, John DeCarlo asks on how to keep dry extract from wadding up.

My preferred practice is to buy a 3 pound bag and divide it into three yogurt tubs, which i keep in the fridge. A pound of sugar fits a 32 oz. container almost exactly, and the sugar doesn't clump in the fridge. Another advantage of keeping sugar in a tub rather than a bag is that it is easier to dip into to measure out bottling sugar.

The problem of dried ME is that it absorbs water very easily (thus the clumping). I know that a fridge is not an arid place, but the dried ME seems to like it, whereas if the sugar is kept elsewhere in the house it tends to become bricklike.

On the third hand, dried ME is sold in sealed plastic bags; no matter how tightly a person tries to reclose the bag, air can get in. If the sugar is transferred to a ziploc bag (or another bag with a reliable closure), the air can be mostly squeezed out before sealing, and thus there should be less moisture to bother the sugar.

> secondary fermenter. No problems, stuff worked great ...

Then why throw it away?

> Tonight I used it again to sanitize my bottling bucket.

> ... but when I emptied the bucket there was

> a distinct chemical smell and the bucket had been stained orange. Well,

> I rinsed many times, but still had the smell and color.

One of the least advertised restrictions about iodophor: it does not
work well on synthetic materials like plastic or rubber. My old bottling
bucket is similarly stained and any more I'll use it only for sanitizing
other equipment. I also once stored the iodophor solution in a carboy
with a rubber stopper. A week later the exposed surface of the stopper
had turned black and the solution was noticeably paler.

The lesson: iodophor is great for glass and stainless, but not suitable
for most plastics.

>Is home brewing legal in the great state of Georgia? I called
>a few places - most seemed to think it was, but none were sure.

No, contrary to popular opinion, it is not legal to brew malted
beverages in Georgia. There is also a 3-tier distribution law
here which obviously prohibits brew pubs.

House Bill 62 would make it legal for a head of household to brew
50 gallons per year. The federal 200 gallon limit was halved by
two different committees. The chair of the rules committee refuses
to put the bill to the house for a vote, even though the committee
has approved it and recommends it's passage to the house. Between
the fundamentalist factions within the house and all the others who
are mortally afraid of a strong MADD lobby, I see no real hope of
ever seeing homebrewing legal in Georgia.

Yes, I voted libertarian.

From: rush@xanadu.llnl.gov (Alan Edwards)
Subject: Re: Mixing yeasts in one batch?

DONT add a new strain of yeast at bottling time! You will run the risk of exploding bottles. The yeast you add might have a higher attenuation and start working on sugars that the previous yeast left behind. If you want to try multiple strains, you should let it ferment out with the new yeast in a carboy and then bottle as normal.

Subject: Bad DME?

Hello,

I made up some yeast starters last week, 1 cup light DME to 1 gallon water. The hot break did not look right, it was more like a powder and had some sort of string-like floaters. I went ahead and bottled this in hope that it would turn out ok. A few days later I noticed some white growth on the surface and they smelled like sh*t. I chalked this up to bad sanitation and started another batch with unfiltered water. This looked the same as the last batch so I tossed it before I wasted more time. So for try #3 I used "spring" water from the store. This had the same break material as the other 2 batches, although it did not smell as bad as the first. It is now being used to build up a yeast culture but I don't know if I should trust it.

Does anyone know if DME can go bad? It is about 7 months old and has been double bagged inside a sealed plastic bucket. Does anyone know what the stringy substance is?

Thanks in advance,

Tom

From: parsonsl@husc.harvard.edu
Subject: Iodophor stain / beer paralysis

In response to Phil Seitz, who seems to have had a miserable experience with iodophors: You should clean all visible particles off your equipment before adding iodophors. Having done so, add the chemical after you have filled the bucket most of the way with cold water - iodophors will stain when warm: perhaps this is the source of your stain? It's possible that the nasty smell and taste is due to the chlorine treatment you gave the bucket. You wrote that you "scrubbed" the plastic, which, if your definition of scrubbing is the same as mine, will have caused you to score millions of small grooves into the material by means of some abrasive object. These grooves may harbor chlorine, among other things, which will not rinse, but diffuse into your beer slowly. I'm sorry to hear about the disaster.

I have a sort of related question on nasties in beer. Recently, I gave some homebrew to a professor of mine who is eager to try it, but told me that her daughter had heard of some case in California where seven people had suffered paralysis because they drank someone's (obviously not too pure) homebrew. Sounds pretty exciting - it gets better: they weren't cured of this until some smart person injected fetal tissue into their brains! Is this out of Weekly World News? Is it a story spread by Mr. Koch at Sam Adams? Or are there people putting smack, or Drano and baby laxatives in their beer or something? She observed correctly that I am still alive, and therefore deduced that she would not perish from my beer and that she might just as well drink it.

What can I tell her? What in the world must one do to one's beer in order to inflict paralysis on all those who drink it? I think I'll just tell her how lambique is made, or scrumpy.

Jedparsonsl@husc.harvard.edu

From: "Rick (R.) Cavasin" <cav@bnr.ca>
Subject: re: Handling Dry Malt

John Decarlo asks about storing dry malt:

I do alot of partial mashing and buy my dry malt in 25Kg bags (cheaper that way). I have always kept it in large zip lock storage bags in approx. 1kg denominations. I've kept them this way for over a year with no apparent change in the extract (ie. no clumping AT ALL). Try splitting your dry malt into several zip locks which are stored in your driest room. If you're only fishing out a cup or so at a time, the malt will pick up some moisture each time you open the bag so keep the denominations small. You could get zip lock sandwich bags, and bag the malt into the exact amount you need for priming. (BTW, the zip locks are easily rinsed and reused - no waste). For that matter, empty food containers (jars, yogurt tubs) etc. could also be used.

Cheers,
Rick C.

Subject: Cooler Mash Tun/Lauter Tun & sparging questions

I'm about to dive into all-grain brewing. I'm planning on building a combination Mash Tun/Lauter Tun out of a cylindrical cooler. I have several questions. A few people have mentioned Phil's Phalse bottem. How far off the bottom is it supported? How much is it? Does it work better than a stainless steel steamer?

On page 48, figure 3 of the Zymurgy Gadgets & Equipment Special issue is a picture of (what appears to be) a recirculating mash tun. Anybody know the details of this (or something similiar)? I plan on building a simple Mash Tun to start with, and eventually evolove it into something like this. So I'd like to know the details before I begin.

It looks like it has a built in thermometer in the dead space. Will that accuratly measure the temperature of the mash? He also has a tube running vertically outside the cooler. Is this to display the water level or to vent air out during sparging? There is also a screen and plate with holes in it. I assume one (or both) of these is to create a false bottom. If someone has built something similiar, I'd appreciate the help.

On a related topic, there's been some discussion about not disturbing the grain bed during sparging. Solutions to this range from resting plates and bowls on top of the grain to sprinkling water on top. Has anyone tried resting something like Phil's Phalse bottom on top of the grain so the sparge water doesn't disturb the grain, yet drains evenly through the grain. Seems to me, if you keep the water level above the grain it would distribute the sparge water better then if you had a plate or bowl on top.

Any and (almost) all related comments are welcome. Thanks for the help,

Neil

From: djt2@po.CWRU.Edu (Dennis J. Templeton)
Subject: Starch Iodine test.

Norm asks about the Iodine test.

When I started all grain, I thought I was the only numbskull to be able to foul up an Iodine test (after all, we did it in 8th grade science, not?) but now I know it is a common problem.

One of the books points this out too, I think it's Miller, but here is my version.

Yes, the husks will interfere. Miller says it's "cellulose" but paper (pure "cellulose") doesn't react with iodine. Nevertheless the husks do. I drain out some wort from my Gott cooler tun and recycle it on top, then take a drop from the tip of the tubing onto a white plate to test by adding a drop of iodine tincture. If converted there is NO color change, just the mixing of the two brown colors.

If you just take the cloudy liquid off of your spoon, there seem to be 2 iodine reactions, one with starch that is a bluish purple, and another with specks of husk or what not that results in a dark gray-green color, in particulate speckles. It is not easy to tell the difference between the two when the color is dark though. You are much better off to filter out the husks, and then test the clear wort.

Someone else gave a recipe from a chem book that included both KI and I₂; this is unnecessary. Use "Tincture of Iodine" from the drugstore; actually I just put a couple of crystals of I₂ in a little 70% Ethanol to make maybe a 5% solution. The exact concentration is immaterial. ("Tincture" means Ethanolic solution).

One of the books scoffs at the Iodine test and then recommends a 90 minute mash just to be sure. I feel better seeing a good test and then having an extra hour left at the end of the day.

good luck,

dennis

From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: Unmalted grains

Markku Koivula asked about high loadings of unmalted grains, and their effect on mash times.

Recently, I did an attempt at a Belgian Strong Ale, using about 40% of unmalted wheat. The mash was done at 65C in a single infusion, after gelatinizing the wheat separately. Full conversion, as judged by iodine test, took 3 hours. So, yes, you would expect things to take a tad longer.

The other thing, yes, one might wish to use a higher enzyme malt, such as a 6-row type. This is what I used. I imagine I could have put in even more unmalted wheat if I were more courageous, but... You can buy solutions of amylase enzyme in many homebrew stores, which might help salvage a case of miscalculation, though.

Good Luck! P.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>
Subject: Is this an "off flavor"?

I recently brewed what was supposed to be a nice, light ale. I made 3 gallons. For the boil I used a 3.3 lb tin of M&F light malt extract (which turns out to be significantly darker than John Bull light) with 1.5 gallons of water and Australian Pride of Ringwood hops, in for the full 45 minutes. No finishing hops were used. I used Nottingham Ale yeast and fermented at 68 degrees. Fermentation was pretty much finished in 3 days but I left it in the primary for 8 days because of the Thanksgiving break before bottling it. No secondary fermenter was used. I used a 5 gallon plastic water carboy for fermentation so didn't use any blowoff tube.

When I tasted the beer at bottling time it seemed quite pleasant but now, after 2 weeks in the bottle, it has a very strong flavor which I find difficult to describe. Sort of like caramel, although my wife says it smells like "resin". It is remarkably similar to the flavor (less pronounced) of a brew I made earlier, using different malt and different hops. The general consensus about that was that it was the property of the malt.

I'm disappointed in the result and would like to know the cause. Is this some sort of infection? Does M&F malt extract taste like this? Is this the sort of thing that happens without any blowoff? It seems that plenty of people don't use blowoff and get good results. In fact the two brews I made between these similar-tasting ones used essentially the same process and equipment and didn't have the same flavor.

I'm puzzled. Any advice would be much appreciated.

Peter

End of HOMEBREW Digest #1035, 12/17/92

Date: Thu, 17 Dec 92 10:13:50 MET
From: THOMASR@EZRZ1.vmsmail.ethz.ch
Subject: stike heat vs. mash heat

Hello all,
Here is a formula for calculating initial mash temperature
sorry about the strange units, but thats what I find
easiest:

$$I = (St + RT)/(S + R) + 0.5H/(S+R) + F$$

where

I is the initial mash heat

S is the specific heat of the malt

t is the temperature of the malt

R is the number of grams of strike water per gram of malt (ca. mils of
H2O / g
malt)

T strike heat

H slaking heat

F fudge factor. This is a fudge factor for those of us with less than
perfect

tuns which cool the strike water when it is put in. eg strike water = A
farenheit,

after being put in the tun = B farenheit, therefore $F=B-A$.

Here is a table of S and H:

malt moisture,%	S	H
0	0.3828	
1	0.3824.7	
2	0.3921.5	
3	0.4018.2	
4	0.4015.8	
5	0.4113.5	
6	0.4111.5	
7	0.4210.0	
8	0.428.5	

Usual % moisture for relatively fresh / well kept malt is 3-4 %.

From: THOMASR@EZRZ1.vmsmail.ethz.ch
Subject: history from rob

Hello all again,
Heres the info on the book I mentioned yesterday:
The London Practice of Brewing Porter, Brown Stout,
Ale, Table beer and various other kinds of malt liquor
by Fredrick Accum, Second Ed. 1821
Longman,Hurst,Rees,Orme & Brown,
Parernoster Row, London.
The book is available for viewing in the Courtold (sp)
Institute in London, but there is a copy on Fiche
in the Management library (??!!) of UCLA.
Here is a Store (keeping) Porter recipe:
3.3# Brown malt
3.3# amber malt
6.7# pale malt
7.9 oz hops
1st mash
2.5 gall at 156 for 1.75 hr
2nd mash
1.8 gall at 165 for 1.5 hr
3rd mash
1.2 gall at 175 for 0.75 hr
Sparge
3.6 gall at 180 for sparging
Boil 1st and 2nd with hops for 1.5hr
recycle hops and boil with 3rd and sparge for 1hr
gives 5 gall (all galls are UK) at 1058 -->1022 fg

p.s. brown malt can be approximated by baking
pale malt over an oak or beech fire (I'll try finding
more explicit instructions, but it's essentially a
darkish smoky malt)

I'll send more recipes as soon as I have time.
tata Rob.

Subject: Beer compatible solder?

|From: Ed Hitchcock <ECH@ac.dal.ca>

|

|I wanted to solder some copper pipes for shuffling wort around between
|mash, sparge, boil, chiller and primary. Lead is a no-no, and I
|understand tin is not so hot for beer either. Anyone know of a kind
|of solder that works on copper pipe that is not harmful to beer?

That's it for solder. You could try using an Epoxy adhesive instead of
solder. If you use one of the less viscous forms, you may be able to let
it "wick" into the joint like solder.

Have you considered PVC pipe? The type rated for hot water, of course.

Subject: Storing Dried Malt

John DeCarlo asked about storing Dried Malt. I keep my malt in the original bag (usually a 3 pound bag). After using it I close it tightly with a twist tie, put it in another plastic bag, and put one or two of those anhydrous salt packets (the kind of thing you get with electronic components, and sometimes found in dried food packages- the things that say DO NOT EAT!) which absorb moisture, in with the bag of malt. It seems to work pretty well. If the malt *DOES* become firm with this method, it has always been easy to break into a powder with the fingers, or by kneading the bag. I have not had a malt brick yet.

In response to questions about the Troy Brew Pub (HBD-1035)
I called the Pub and spoke to the Manager and got the low down.

The new Pub will be open "in about a month". Its called Brown & Moran Brewing (417 River Street, Troy, New York (518) 273-2337). Although not open the owners are very proud of their establishment and are willing to offer a tour (please call ahead). The place will seat 250 in the main bar area, which is in full view of the 2 story glass enclose brewery. Additional space is provided on the multi-tiered outdoor deck overlooking the Hudson River. They plan to offer Golden and Amber Ale, Porter and a wheat beer.

From: mcharry@freedom.otra.com (McHarry)
Subject: Adjuncts, Acid

My last batch contained 1/3 rice, precooked with part of the mash water. I used a 3# bag of rice and 7# of American 2-row. Conversion was complete in two hours at 150-155 (I mash in a warm oven that tends to increase the temperature slowly.) It seemed to work fine, but that much rice is a real gunky mess to handle. I did a similar batch with 2 pounds of rice a while back that was a more pleasant project. BTW, with this much malt it doesn't taste light, more of a bigger bitter.

My other current sin is in acidifying the sparge water. The water here is about 8.5 out of the tap. I got a bottle of 1N HCL and found that a tablespoon of this toothsome delight will take five gallons to about neutral. After that, watch out! It looks like the tablespoon knocks out all the buffers and after that you are adding straight hydronium ions. Maybe half a teaspoon more will send it to 5.5. The moral is that you probably have to play with your water to see how much it takes to acidify it--I don't think you can tell from a simple pH measurement.

From: parsons1@husc.harvard.edu
Subject: Fullers ESB aftertaste

Hi all. I am interested in the aftertaste of Fullers ESB. It seems to me very malty, with a pronounced caramel flavor and some licorice. I think, though, that the aftertaste of Fullers is much more robust than the taste of the beer, which needs perhaps more alcohol or more bitterness or something else. I'd like to try and rework the ESB, and would appreciate the help of anyone who knows how to effect these flavors. Dave Line talks about it, but I think he adds saccharin tablets for sweetness, which is something I will not do. Does anyone know what grains, adjuncts, not-very-attenuative yeast strain etc. are responsible for the aftertaste?

Thanks in advance

Subject: re:Mixing yeasts in one batch?

In the last digest:

<From: rush@xanadu.llnl.gov (Alan Edwards)
<Subject: Re: Mixing yeasts in one batch?

<DONT add a new strain of yeast at bottling time! You will run the risk
<of exploding bottles. The yeast you add might have a higher attenuation
<and start working on sugars that the previous yeast left behind. If you
<want to try multiple strains, you should let it ferment out with the new
<yeast in a carboy and then bottle as normal.

Well, yes and no. This is another case where a little knowledge
or lack of, can get you into problems. The risk of exploding bottles can
be

significant, but in most cases is overemphasized. The important points
are: FG of still beer to be krausened, amount of fermentables added at
bottling/kegging time, and the quantity of krausen yeast added. If most
of the fermentation is complete, and you are adding a brewing yeast, the
amount of fermentation in the vessal will be due to the fermentables
aded at bottling/kegging time and not from the still beer itself. Just
calculate the correct amount of sugars to add, add a very small amount of
healthy viable brewers yeast (were not talking litres here) and relax.

The

real problems arise if a non brewers strain is used and then you will be
fermenting the residuals that brewers yeast cannot metabolize. In fact,
krausening in this fashion (or with active krausen/wort) is the preferred
method when brewing Weizens and high gravity belgium ales/barley wines.
With weizens, we often want a lager strain to be in the vessal, with high
gravity beers, the fermenting yeast can be in dismal shape to referment
in

the bottle, and new yeast high in glycogyn reserves is called for.

This is totally incorrect. There are no known pathogens that can exist
in
beer. The incident you are refering to concerned homebrewed synthetic
narcotics which contained a chemical byproduct which fries dopamine
receptors
and mimics parkinsons disease. No reason to go into details here, there
was a
good summary article in "The Sciences" w/i the last year if anyone is

Subject: Brew pots

I tried submitting this about a week ago, it must've gotten lost. (?)
Anyways...

I am about to be a homebrewer, as soon as I get all the supplies that I
need.

I have a enamelware pot, about 5 gal., that would be perfect for brewing.
Several years ago I got desperate for container to store used motor oil.
Yup,
motor oil, probably 5w30, hehe. (Not funny!)

The pot is still slimy with the oil and I'm wondering if it's possible to
remove all traces of the oil to make this safe for brewing. I don't
expect a
postive response being that the oil has been soaking into the pores for
years
now, but I thought I would ask anyways. Has anybody got any ideas?

Or, does anybody know of a good, cheap mail order shop for a good brew
pot
(stainless steel or enamelware)?

Any suggestions would be appreciated!

Subject: Iodophor and plastics

Steve writes:

>The lesson: iodophor is great for glass and stainless, but not suitable
>for most plastics.

I have a notable exception to report. I used Iodophor in my Italian-made red-white-and-clear plastic bottle rinser. It's the type of device in which you pour the sanitizing solution into the clear bowl, submerge the red part of the red-and-white pump, put a bottle over the white nozzle and pump down on the bottle to squirt solution into the bottle. I used it for a year with Bleach solution and then did a part of a batch with Iodophor. No staining. I would really prefer to use Peracetic acid because I know that both Chlorine and Iodine are not the best things to dump down the drain. Peracetic acid is made from acetic acid and hydrogen peroxide both of which are much more friendly to mother nature than Cl and I. I'm still in the process of finding a suitable supplier.

From: gjfix@utam.uta.edu (George J Fix)
Subject: Acid sparge water; DCI

Russ Wigglesworth is right on target IMHO about the need for care in acidifying sparge water. I have had very unsatisfactory results with both ales and lagers when the pH of the finished wort was below 5.0. My preferred values are 5.3-5.4 for the mash, and 5.1-5.2 for finished wort. The low pHs will increase yield, and hence make us more efficient. Nevertheless, in brewing efficiency and quality are not always in harmony.

It is my belief that the drop in pH during the boil is primarily due to the interaction of inorganic minerals (most notably calcium) and malt materials. I have checked this a couple of times by boiling worts with and without hops.

I have a very high regard for the AHA and for the really great people on their staff. They are very serious about the recruitment of articles for Zymurgy from a diverse group of homebrewers. I hope everyone on this network will give serious consideration to submitting one. Having said this I must also say that doing volunteer work for them (via articles or books) can at times be a bit frustrating because of their sloppy way of handling publications. Nevertheless, they are a low budget nonprofit organization that is run on a shoestring. For example, I think most people on this network (except possibly for the grad. students among us!) would be astonished about Charlie P.'s very low salary. Thus, for me, tolerance for the AHA's weak points comes easy.

In any case, anyone who wants my HSA article in its original unbutchered form, let me know and I will send it by e-mail.

Dennis> I get DCI from one of the chem. labs at my university. Be sure to check out Vol. 2 of deClerck for an alternate version of the ITT analysis. My version is a "homebrew version" of his, and is based on materials available to me.

Subject: burning the wort

Further to my earlier note about off flavors I'm wondering if I managed to burn the wort. I use my 10 quart stock pot on an electric element and stir almost constantly while bringing to the boil. However, I heat the water up to almost boiling before taking the pot off the element and putting in the malt extract. Is this likely to cause any caramelization? There's no black stuff anywhere but the pot bottom does have darker stuff on it in the pattern of the element.

When one makes REAL caramel it doesn't go black, just brown so now I'm wondering. At what temperature does caramelization start to occur?

Peter

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

Subject: sparge pH

So, it looks like we've now got sparging options. The "normal" sparging technique of adding water/draining/adding water/draining/etc. has a higher efficiency than the technique of adding all the sparge water at once and then draining. BUT, the first ("step") technique leads to a more acidic sparge, which will extract more tannins from the grains, a bad thing. The second ("batch") technique, while less efficient, should be less acidic.

As I use the batch technique, I may have found an explanation for the lack of any sort of tannins in my brews, even when I want them there. Obviously the water plays a large part, but I wonder if certain brews would benefit from different sparging styles. Perhaps a stout should be sparged in steps, but a pilsner should be batch sparged?

Russ

Subject: homebrew paralysis

In HBD #1035 "parsonsl@husc.harvard.edu" wrote about a friends concern over 7 people in Calif. getting paralysis after drinking someone's "homebrew". I can assure you that your friend's daughter only got part of the story. the PBS program NOVA recently did a story about seven people who developed a parkinsons-like paralysis after using what they thought was heroin. It turns out that the stuff was created in a home lab, hence the "homebrew" connotation. Several of these people were treated with human fetal tissue because unlike normal parkinsons patients their disease was not degenerative. The fetel tissue was used to produce dopamine and I belive they had a certain amount of success. All of this happened in the late 80s as I recall. But beer was definitely not involved.

From: ryan%phmms0.mms.smithkline.com@smithkline.com (Dominic Ryan)

Subject: Sparging/Cleansers and Plastics/Boiling and Oxidation

I have some comments from the chemist's perspective that may be of help in a couple of the on-going discussions. This is another long post. I have not posted very frequently but I have had longish ones. If this is a problem for the list I will break up any futur ones.

The topics are:

Sparging/ Cleansers and Plastics/ Boiling and Oxidation/
a line like the following begins each one.

___Sparging:

The process of extracting residual sugars from the grain-bed is closely analogous to a laboratory technique known as column chromatography. In this latter method a mixture of products is separated by running them down a column of solid support materiel. This involves adding such materiel (often silica gel) to a long glass tube with a porous false bottom in it. Under this is a spigot to control the flow. First the column is filled with a solvent and the solvent is allowed to run out until it is at the top of the silica. Then the materiel is added and more solvent allowed to run out until the bolus of materiel is 'loaded' onto the column. This is followed by a little more solvent added in such a way as to minimize disturbing the top of the column. This is run in and and more solvent added until the sample is in the column. After that solvent is added up to the top of the column in order to make it easier to to manage and increase the hydrostatic pressure.

The column can also be filled with a slurry of silica and solvent much as sparging involved transfering a thick mash to the lauter tun.

Often clean sea-sand is added to the top of the column to prevent disturbing the bed. This would be a possibility in sparging to, although I have never tried this, and would substitute for the bowl or lid used now to prevent this problem.

Another detail from running a column that I follow is to add the water very slowly until no more color from the grain is leached up into the sparging water that I add to the top. Once that is reached I fill up the bucket I use with as much water as it will hold. This keeps the sparging at a more constant temperature and eliminates the cooling that results from spraying the sparge water onto the grain bed. If you only maintain an inch or so of water above the grain bed initially there is no disturbing of the bed if you pour it onto a spoon, bowl, lid etc. and the water does not cool, and you are assured much more even distribution that you could get by spraying it on. No matter what you do the liquid will follow whatever channels exist in the bed, so if you spray directly on top of the bed in an effort to distribute the sparge more effectively it will still flow as it would if you had poured in onto a 1" layer of water above the bed. If you have a very wide and short bed this will be aggravated. I have found the most important things for sparging to be (in roughly this order):

minimum 12-18" high bed get a narrow enough bucket if required, and a round bucket makes a better column than a square one.

175F sparge water insulate the sparge bucket
set bed well don't drain lauter too fast at first, let the grain-bed set uniformly
good crush pick your mill...

___Cleansers and Plastics

Cleansers fall basically into three categories:

caustic: sodium carbonate, (tri-)sodium phosphate, lye (which is sodium hydroxide) and sodium silicate.

very good at digesting organic matter like fermentation residues
works well on glass, steel, some plastics like HDPE

soap: Pure Ivory, which is a sodium salt of a 'fatty acid' an examples of which are lard and vegetable shortening. Both of these latter materials are converted to soap by treating with lye until you have a non-caustic mix.

Very good at removing greasy residues
Can be used on pretty much anything

oxidizer: Chlorine, Iodine, sulfuric acid, hydrogen peroxide and other organic peroxides (ozone).

Best used as a disinfectant on already clean surfaces in the strengths commonly available to the public.

Strong oxidizing agents are quite dangerous, concentrated peroxides can be explosive!

Keep away from rubber and plastics as most will be degraded.
Works well on glass and (stainless) steel.

Organic matter -fermentation residue for eg.- is cleaned most effectively by caustics, or caustics mixed with some soap. Oxidizers are usually much slower to act unless you can get them very hot as well. This is partly how sulfuric acid works as a drain cleaner. Large amounts of heat are generated when mixed with water and then this will chew up the clog.

B-Brite is a mix of sodium carbonate and sodium silicate, which is likely there initially as sodium meta-silicate since that form is more soluble. You could likely formulate your own easily. This is basically dish-washer

detergent without the added phosphates and ingredients to improve water condition and sheeting etc. Take a look at a box of dish-washer detergent

next time. B-Brite is very caustic as a result and if you use too much it

needs to be rinsed a lot, but it is very effective as a cleanser for brewers, and seems to dissolve and rinse better than dish-washer detergent

which relies in part upon greater temperature and volume of water.

In case you have not tried, B-Bright is also very good at cleaning up the baked on wort on the stove-top.

None of the above classes of cleaner will remove residual solvent and plasticisers very well from a bucket that might have contained them. Most plastics are reasonably porous and they will 'dissolve' oils, turpentine, gasoline, you name it, into the plastic only to have it very slowly leech back out over time.

When treating a plastic bucket with iodine (or to a lesser extent iodophors, which combine iodine with a surface-active agent and detergent) there will be some iodine deposited in the plastic and some will react with it, staining it permanently. Iodine reacts in this way much more easily than chlorine does (free radical for you chemists) and for this reason there will be less residual chlorine (from a bleach for example) than iodine. Still, it is best to keep them away from most plastics, although I think chlorine is ok on HDPE, which stands for High Density PolyEthylene. This is a very stable crosslinked polymer that does not swell, absorb much of anything, or deform easily with heat. Nor is it supposed to be soft or pliable and therefore never has plasticisers added to it. For that reason it is a very good substance for food grade plastic.

___Boiling and oxidation

On a final note, some have questioned why hot wort is not oxidized when boiling. When you boil any liquid you are by definition bringing the liquid into equilibrium with its gaseous phase. This will drive off all dissolved gasses in the liquid and then provide an atmosphere of steam above the work. This blanket of steam seems to be enough to protect the wort from such oxidation. The degassing of the wort during the boil is the reason air needs to be redissolved in order for yeast to undergo the aerobic reproductive phase. If you deliberately introduced oxygen into the boiling wort with a bubbler then you would definitely get more oxidation than with hot wort sitting around later.

Subject: Chicago Legacy Red Ale Yeast

T'sup?

I cultured the yeast from a bottle of Chicago Legacy Red Ale and used it in my latest extract batch of red ale (OG: 1.044). I pitched 10 days ago, and it's been fermenting steadily ever since at ~65-70 F, with no sign of slowing down. It's now at @ a bubble/10 sec. I took a gravity reading this morning: 1.033. My question is has anyone out there ever used this yeast, and if so, does it take longer to ferment out than other yeasts? I brewed a porter with Anchor Porter yeast the same day and that is ready to bottle. The smell out of the fermenter lock is yeasty (that's good). Wadda-ya-think?

> in addition to barley malt. Michael Jackson says that they
> use (if I remember right) 40 or 50 % unmalted wheat. Now I
> wonder how do they mash it. Papazian recommends not to use
> more than 20 % unmalted grain, because otherwise there are not
> enough enzymes. Do they add enzymes, or do they have malts
> that have very much enzymes? Or is there some other explanation?
> Looong mashing time or something like that?

I can only address what the lambik brewers do, as those are the only Belgian breweries I've personally visited. By Royal decree, a lambik grain bill must contain at least 30% unmalted wheat, and 35% to 40% is a more common figure. The malt used is a well-modified 2-row, but I have no reason to believe that its enzyme content is at all extraordinary. Though at least one producer uses an infusion mash, most do either one or two decoctions, and as these decoctions are the only actual cooking that the wheat gets, I really doubt that much of the starch is soluble. I know that in my experiments with unmalted wheat the actual value of the extract has always been quite low. A pretty standard mash time is about 2.5 hours, and the resulting wort contains quite a bit of unconverted starch, but in a lambik this really isn't much of a problem, as something in that microbiological witches' brew will eat it up in the year or two it sits in the barrel.

Hope this helps.

Subject: xmas beer/wierd floaters

Just another data point on this thread (sorry, I forgot who asked the question originally). I too brewed a brown xmas ale, with about the same spices as listed. I also had a strange whitish material floating at the top of the bottle, and sort of sticking to the neck. In addition, there were little chunky things floating around everywhere! This brew had another problem, which was that I primed with honey, and I used way too much (like about 1.5-2 cups) so that I was a little worried about explosion. I ended up putting all the bottles in the fridge about 3 weeks after bottling (it was at this time that the floaters were at their peak). Anyway, the good news is that after a few days in the fridge, this brew cleared nicely, and it tastes fine (except for being a bit over carbonated!). So, Don't...(oh, you know).

Subject: All grain tips, yeast pitching amount

Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu> asks:

> 1. I've pretty much decided to go Gott-cooler-with-slotted-pipes. My
> question is: Do I need a false bottom and/or grain bag? My brain
says,
> "No, man, that's what the pipes are for," but my gut feeling is it
would be
> pretty wierd to dump the mash straight on the pipes, plus a grain bag
would
> help in clean up. So do I listen to my brain or my guts?

Your brain wins. I've been using a copper manifold in a ten-gallon stock pot for some time, and I just dump the grains in right on top of it. The sparge has never stuck. Just make sure that the slots in the tubing aren't too wide (I cut my slots with a hacksaw) and that they face downward. It's amazing, it sucks up every last drop of wort.

> 2. Instead of a copper manifold, what about PVC? Somebody in the
> latest-minus-one Zymurgy mentioned using PVC, but gave no details. I've
> never heard of anyone else doing it either, but it seems it would be
> easier to put together and take care of. Whaddy think?

Probably would work the same as copper, assuming it's food-grade PVC (is there more than one kind?) and that any sealant you use is also food-grade.

There's also been some discussion lately on how much yeast to pitch (someone specifically asked about the amount in WYeast packages). I thought I'd post (without permission) some information I got from Jeff Lebesch, the man behind New Belgium Brewing here in Fort Collins, Colorado.

"Most references recommend a minimum pitching rate of 10 million yeast cells per milli-liter of wort, plus another 1 million cells/ml for every 0.004 gravity increase above 1.040. ...The 10...15 million cells/ml rate is easily achieved by adding 5 ml of thick yeast slurry per liter of wort. For ales, sometimes you can go as low as 3 ml/l, and for low temperature lager fermentations 10 ml/l is suggested.

"During a healthy fermentation, the yeast cell count increases to a peak of approximately 60 million cells/ml. Then it seems to me, that given the 10M cells/ml minimum pitching rate, the maximum wort volume increase should be six-fold.... However, many references suggest that a 10-fold increase is acceptable.

"...If 600 ml of starter culture is pitched into 18 l of wort (about 5 gallons), that is a 30-fold wort volume increase. In most situations, this is drastic underpitching. The only way it will work is if the yeast is at its peak activity and viability... plus wort conditions are optimal.

"OK, let's culture another generation, by adding the 600ml culture to 3 liters of wort, and adding that to the 18 liters. Now each generation has had a wort volume increase of less than 6.... But, adding 15% of a cheap culture wort to your prized wort will ruin it. One solution is that the culture wort must be of the same composition as the beer.... This is common in breweries where the same beer is brewed every day....

The other solution is to let the 3 liter culture ferment to completion, then refrigerate... then pour off the top beer, and collect the yeast slurry."

So to summarize, most homebrewers probably underpitch to some extent. The amount of yeast in a WYeast package is ridiculously small, but with careful sanitation and technique, you *can* start a beer with the yeast straight out of a single package. The downside will be a long lag time, since it will take the yeast quite a while to build up a sufficient population.

The best method I've found to get sufficient pitching rates is to simply save the yeast slurry from the bottom of my secondaries. I just put it in a sanitized bottle in the fridge, with an airlock. Not only is it cost effective, but there's almost no lag time. With that much yeast, it doesn't really matter how well you've aerated; it goes nuts right away.

Gentlemen (and ladies), start your yeasties!

Subject: Hypercard ideas for the Mac

Hi everyone,

I was looking through the archive at sumex-aim [Macintosh archive] and I found a couple of items that may be useful for homebrewers using a Mac. I found a 2 hypercard stacks, one is a record book and the other is a stack designed for yeast research. I tried the record book and it seems to work pretty good, there is also a calculator for converting SG to % alc.

which takes temperature into consideration. I have not tried the yeast research aid. They can both be found at the following locations using anonymous FTP.

sumex-aim.stanford.edu/info-mac/card
136479 Jun 7 1992 home-brewers.hqx
112265 Sep 3 19:01 yeast-research-aid-12.hqx

I did not write them...I just thought others might be interested in them. I am still looking for a recipe formulator for the Mac, but , I have had no luck. Does anyone know of one?

Can someone tell me how to submit something for the HBD archive.

Cheers.....Carlo

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: starch and iodine

Much of the starch stored in the grains is insoluble. This is converted to soluble starch, and then to complex sugars, and finally to simple sugars. The starches that remain insoluble at the end of the mash are the things you try to get rid of by sparging through a filter bed, and racking of the trub. The starch you want to test for with iodine is the soluble starch, since this is what is converted to sugars.

In HBD #1035 Jed (parsonsl@husc.harvard.edu) writes:

"Recently, I gave some homebrew to a professor of mine who is eager to try it, but told me that her daughter had heard of some case in California where seven people had suffered paralysis because they drank someone's. . . homebrew. . . . they weren't cured of this until some smart person injected fetal tissue into their brains!"

Well this story does have some basis in reality, but the daughter got certain parts of it wrong. According to NPR's "All Things Considered" broadcast 11/25/92 (sorry, I can't find a print source) several people in California ended up with severe Parkinson's symptoms after consuming a poorly synthesized batch of the drug Ecstasy (is it MDMA?). Some did show strong improvements after fetal tissue was injected into their brains, much more than regular Parkinson's sufferers. So I'm just planning to stay away from such home chemistry experiments and let my yeast do my work for me. I'd read her the section out of Papazian's book where he emphasizes that no pathogens can grow in beer. Short of using a lead counterflow chiller, I can't see how you could get anything worse than a hangover from homebrew. Though I remember one hangover where I *felt* paralyzed the next morning. :^)

From: Pierre Jelenc@cunixf.cc.columbia.edu
Subject: yeast respiration

I just read in "Yeast, a practical approach" that *S. cerevisiae* cannot metabolize oxidatively sugars at a concentration above 1%. This concentration corresponds to a gravity of only 1.010, and thus makes me wonder about the recommendation to use a starter at S.G. 1.020.

If it's going to ferment anyway, what's the point of a medium-low gravity? Will the yeast switch to respiration after having fermented half the sugar, and if so isn't an airlock self-defeating? Any comments by yeast experts?

(Incidentally, the book is lousy. Terribly edited, not proof-read, inadequate methods descriptions.)

I think we have three options, the third being draining *while* adding
water (i.e. adding water at the same rate as it's draining so that the
grain is always submerged (till you're done adding water)).

Russ-- could you elaborate on why the acidity of the sparge would differ
in
the different methods?

Subject: AHA

I have received a lot of private e-mail from people who have told me of horror stories about how the AHA has ignored their submissions to Zymurgy, or in other cases outright rejected them. What really frosts me off is that most of this e-mail came from people I admire, and who bring a lot to the table in terms of experience and insights. I always thought that the lack of diversity and less than ideal technical content was due to a shortage of submissions. This is definitely not the case. There are enough homebrewers out there with interesting material and unique experiences to keep Zymurgy loaded with good stuff for the foreseeable future. I am truly astonished and dismayed that the AHA has not made use of this diversity and wealth of talent. For what it is worth, I am going to complain loudly to anyone in that organization who will listen to me about this. This policy makes absolutely no sense, either for Zymurgy or for those of us who subscribe to it.

Subject: First tangle with the meadasaurus

I put a batch of basic mead into the primary 14 days ago. This consists of 1 gallon of boiled honey, yeast nutrient, acid blend, finings, topped up to 5 gallons. I pitched 1 package of wine yeast (rehydrated - no starter), attached the fermentation lock, waited expectantly. It took 6 days to start bubbling at the lock, but it's still going strong now. I'm worried by 2 things. First is the smell of rotten eggs, which I've never gotten with fermenting beers. Is this typical of wine yeast, or fermenting honey, or is something other than the intended micros thriving in there? The second worry (I know I'm not supposed to worry - but since I've already run afoul...) is the extended time in the primary. Assuming this stuff has a long way to go, am I risking off-flavors, etc. by leaving it in there on the trub? Should I rack to a secondary? I don't want the fermentation to stick. The temp in my Pennsylvania basement is about 63 degrees. About how long will mead take to ferment out at this temp.? What can I do in case of stuck ferment, or just to make sure the honey ferments out all the way - add new yeast at racking time? I want this batch to be as dry as possible. Any help from you mead masters would be wonderful. If anyone would like to discuss mead, contact me.

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: sparge correction

The concept was correct, but I had things backwards. "Step" sparging, ie. adding/draining in steps, or "continuous" sparging, ie. continuously adding and draining, will result in the sparge becoming increasingly *higher* in pH, not lower as I stated. The result is as I said: more tannins will be extracted with these methods than with "batch" sparging, ie. adding all the water at once, and draining it all off at once.

An easy way to remember is that water is generally less acidic than wort. So adding water to wort will increase the pH (decrease the acidity).

Perhaps I should change my terminology also. A "normal" sparge is not really done in steps; more often it is done in a way to produce a continuous outflow. So how about "Continuous" for the first two types mentioned above, and "Batch" for the third type?

In summary:
Continuous Sparge - higher efficiency, higher tannin extraction
Batch Sparge - lower efficiency, lower tannin extraction

Thanks to Al and Larry for pointing out the inconsistencies.

Russ

PS. I'm also dismayed by Zymurgy's lack of usefulness. 6 or 8 good articles in a year (if that) does not warrant *my* \$25. With their new binding and layout, I wonder if they're putting the emphasis on appearance rather than substance...

Is there a 'reasonable' extract rate? If so, what is it?

My last attempt to calculate my extract rate, led me to believe I'm not doing a great job extracting the 'goodies' from my malt. Here's the scenerio.....

10# of M&F 2 row Pale Grain Malt
1/2# M&F Crystal (sorry don't know the Lovibond).
Mashed in 3 U.S. gals.
Sparged with a little over 3 U.S. gals at 180 F.
Crushed with Corona Grain Mill.

I used about a 1 1/2 hour Infusion mash at 152F, (fell to 149F by the end).

For 5 U.S. gallons, this yielded on O.G. of 1.042. I had expected a higher O.G. out of this, whaddayathink? I don't know the details of my water, like hardness/softness/ph etc.

Possibilities

- 1) Everything's copacetic, don't change a thing.
- 2) Cruch is too coarse. This is a possibilty. I note some uncrushed grains, but also some powder.
- 3) Water's too hard/soft/acidic/alkaline.

>Now, the drawback of peracetic acid is that it will cost you something
>like \$100 for 3/4 lb. And, of course, it can't be shipped by UPS.

Why bother buying it? There's a thread in my Firearms list where someone
advocates mixing equal parts of vinegar (acetic acid) and drugstore
hydrogen
peroxide in a plastic mustard bottle, plugging a gun barrel on one end,
and then
filling the barrel with the mixture to clean out lead fouling. The writer
the
went on to state that the mixture will dissolve completely a .38
unjacketed
slug overnight, and won't faze glass, steel, or ceramics.

I suspect if you can unfoul gun barrels with the homemade stuff, you can
disinfect homebrewing equipment very easily.

Subject: Dopple Bock yeast suggestions?

Salutations!

I will soon be embarking on a journey of brewing I have not yet tried. I will attempt to brew a Dopplebock. I think I can work out the 'ator' name myself but was wondering if any of you could help me with the yeast selection as this will be my first lager. I'm attempting a dark bock with 12 lbs malt extract, 6 dark and 6 amber. 1/2 of each 40L crystal, toasted malt (going to roast it) and 350L Choc. malt. My hops are Halt., I was goin to use tettanger also, but my supplier ran out and substituted Bullion. Is this also ok? Anyway, I'm thinking of culturing a starter from a wyeast strain. Any suggestions would be great. Thanks!

From: Martin Wilde <martin@gamma.intel.com>
Subject: Length of time in keg vs. bottle

Whenever I force carbonate a keg of beer, the beer generally lasts about 2 months before the flavor begins to deteriorate. However when I bottle the beer using priming sugar as a carbonater, it can last up to 9 months before the flavor goes south.

I know having the beer sit on the yeast cake helps "preserve" the beer better. If I started using priming sugar in my keg to "naturally" carbonate will this make a difference and thus allow my kegged beer to last longer?

thanks

Subject: RIMS

] From: umehara@NADC.NADC.NAVY.MIL (M. Umehara)
] Subject: Recirculating Infusion Mashing System
]
] I'm looking for information on several topics. The first is
] the recirculating infusion mashing system (RIMS) in the last special
] issue of Zymurgy and I am thinking of building one. :-/ Has anyone
] out
] there built, used or seen one?

I built one from an previous article Rodney Morris wrote for the Maltose Falcons (LA, CA) newsletter. I have been using it for a year and a half, and am quite satisfied with the system. It gives very easy, sensitive, temperature control over the mash. There were a couple of minor mistakes in the article I made the system from, however I believe these have been corrected in the latest Zymurgy article. It takes a motivated person to get through the construction of one of these, but when finished I think it is worthwhile.

An observation on my part though...

The heating elements recommended are capable of scorching the liquid of the mash as it is heated during recirculation. This is mostly a problem in mashes where wheat makes up a substantial portion of the grist (> 50%). It appears that something in the liquor (possibly proteins, as they are abundant in such mashes) sticks to the heating element, and eventually scorches, leaving a residual burnt flavor in the wort (which is not pleasant, as other burnt or smokey flavors can be). This problem has been mentioned regarding non-RIMS systems as well, where someone (Jeff Frane?) reported wheat mashes scorching on a heating element in direct contact with a wheat mash.

The previous problem can be minimized by using lower heat density elements and maximizing the recirculation rate. I only pay special attention during a wheat beer mash, where I typically will use boiling water rather than the heater to raise the temperature of the mash. Other than this, I must say I have been very happy, and would recommend the RIMS to those ambitious enough to build one.

] ... Also, I purchased the counter-pressure
] filler from Fox and it works terribly. :-c How well do the others
] work?
] (ie. Melvico and Benjamin Machine Products)

There has been some negative press here regarding the Foxx filler, where apparently the large number of valves which require excessive turning are a problem. I use one from DeFalcos which is all stainless steel & uses a single valve to control two input sources (CO2, beer) and it only requires only 1/4 turn either way to go from no flow to fully open. I recommend this model highly.

That being said, counter pressure filling is a somewhat complicated process, where your problems may be arising from a source other than your filler. So if you could me more specific as to what your problem is, your problem may be solved without a new filler.

] ... And, I've kegged beer
] several times and I can't seem to get them to carbonate naturally and
] have to force carbonate them. Although they taste fine, why won't
] they carbonate naturally? :-t

You likely are not getting a good seal on your kegs after priming them. To check this, after sealing the keg, tip the keg on it's side while you are finishing your cleanup. After you are done, check

the sealed areas on the keg, and see if any beer has leaked out. If there are leaks (which are common) you should use your CO2 tank to put added pressure in the head space until the seal test is passed (typically 5-15 psi). It is likely good practice to do this with all your kegs, it's up to you. This is almost certainly the problem with carbonation, as otherwise it would indicate no fermentation was occurring to carbonate the beer, the result of a weak or absent yeast.

That being said I must say I now almost always artificially carbonate my beers in a keg. The reason being the control you have over the finished beer. When I started kegging I thought that forced carbonation was a shortcut which reduced the quality of the final beer. However with experience I can tell you that some of my best beers have been force carbonated, and the control you get by this process is invaluable.

Auf ein neues,

Subject: Gummed Labels for Laserwriters!

Steve Jacobs has finally provided me with the definitive answer for which I was looking:

SJ> I purchased a package of 25 pre-gummed, water-based adhesive sheets
SJ> of 8 1/2" X 11" paper specifically designed for making labels.
SJ>
SJ> The package states that it is photocopier safe (although they do
SJ> not guarantee compatibility with all brands of photocopiers).
SJ>
SJ> I bought mine for \$3.99 from:
SJ>
SJ> Brew America
SJ> 138 Church Street N.E. Suite F
SJ> Vienna Virginia 22180
SJ>
SJ> (703) 938-4805

I called them, and spoke to the owner, Miles. He confirmed this, and expressed happy amusement at the free advertising that this digest and other computer bbds offer. They do not yet have a catalog, but one is in the offing for this Spring. BTW, the sheets are unperforated, so you can create labels of any size up to 8 1/2 x 11, and they come in pink, green, blue, yellow, and white. I'm sure Miles won't mind getting a few more calls, especially if they are orders ;-).

Happy brewing, and happy holidays!

>YUK! -- *big* Potassium Sorbate - at least 1000 ppm.

>The taste stayed on my palate for a full hour.

>

>If that is what is being used in some Belgium brews, 'tis a shame".

I can assure you that Potassium Sorbate `tis not what gives Orval it's
bubblegum ester! I've successfully generated that ester with nothing
other than re-cultured Orval dregs and a few pounds of malt extract!

The answer, in my opinion, to JNH's question is: "THE YEAST," but I
thought
that the chemical name of the ester is what was requested, which is why
I did not respond originally.

It's unlikely that Potassium sorbate is added to Belgian brews. It's just a characteristic ester produced by the yeast strains. I brewed up a triple recently (and I can assure you there's no Potassium sorbate) with a ton of the bubble gum ester. This is fading nicely into the background leaving a wonderfully complex brew. :-)

From: arf@ddswl.mcs.com (Jack Schmidling)
Subject: INTERNET

To: Home Brew Digest
Fm: Jack Schmidling

The following information is in response to a discussion currently taking place in rec.crafts.brewing, the Usenet homebrew forum. It is provided with the intent of expanding the access of the homebrew community to computer networking. It is in no way intended to disparage or offer competition to any other network, private or commercial. It simply provides one more option.

I am not a computer geek so if what I say is incorrect, it is close enough to get an understanding of what is going on and how to get in.

Usenet is a user maintained network that supports what amounts to an international BBS with over 1000 "Newsgroups" that cover everything from kinky sex to homebrewing. It is connected by Unix based systems that exist at just about every university in the country/world? and many private companies including AT&T where it was originally developed. In addition, there are also private entrepreneurs who set up Public Access Unix sites and provide access to anyone with a modem willing to pay a nominal subscription "contribution" and abide by the minimal rules. Subscriptions range from free to \$100 per year and there are no other charges aside from the phone call. If you are fortunate enough to have a PA site in your local area, it is virtually free.

Depending on whom you believe, there are between 500,000 and 3,000,000 participants on Usenet, from all over the world.

PA Unix sites also have access to email via Internet. Subscribers can send and receive mail from/to CompuServe, Genie and MCI. Again, the only charge is the yearly "contribution" and the phone call to the site. There is also a gateway to Fidonet, another national user supported network with an active homebrew forum. The Home Brew Digest can be received either directly through email or read in the r.c.b. newsgroup on Usenet.

The only trick is to find the nearest Public Access Unix site and get together with the sysop.

There is a news group "pubnet.nixpub" which is a complete list of PA sites

but is too long to post here. The person who maintains it will send it to anyone who asks for it.

The list is available from:

--

Phil Eschallier Bux Technical Services
Inet: phil@bts.com P.O. Box 110
UUCP: ...![[dsinc|gvls1|widener]!jabber!phil Doylestown, PA 18901
+1 215 348 9721

To get the list, email to: phil@bts.com

That is the format for Internet mail. My address on Internet looks like:

arf@ddsw1.mcs.com

If I want to send mail to myself at Compuserve, from Internet, I would use 71543.1175@compuserve.com

For Compuserve numbers, the comma is simply changed to a period and the site and domain address follows the @. ddsw1 is the name of the site I use. There are a half dozen in Chicago to choose from.

Ask Phil for the Nix Pub "Short List". This contains enough info to find out if there is one in your area and a phone number. The long list has lots more details. There are ways of getting it automatically but I do not know how to do it. If he gets too many requests, I guess I will hear from him.

Any questions, just ask. However, I will answer via Internet... It's FREE.

Subject: Extract Rates

Jim White says:

>I used about a 1 1/2 hour Infusion mash at 152F, (fell to 149F by the end).

>For 5 U.S. gallons, this yielded on O.G. of 1.042. I had expected a higher
>O.G. out of this, whaddayathink? I don't know the details of my water, like
>hardness/softness/ph etc.

Hi Jim --

Do you know how to calculate an extraction rate? It goes like this:

pts = Original Gravity - 1.000

pts X Gallons
extract_rate = -----
lbs of grain

42pts X 5gallons
So your batch was ----- = 20 points/pound
10.5 lbs of grain

And as you said, this is on the low side. I typically get 28 ~ 31 points. I've heard claims of 33 from other people. So, possibility #1, "Everything's copacetic" seems to be out. Unless about 1/3 of the grains are un-crushed, poor crush wouldn't account for the problem. However, from your description, I think the crush isn't ideal. Another possibility is poor-quality malt. Might not have enough enzymes to do the conversion. This is unlikely. That leaves water chemistry and technique. Since technique is discussed to death on the net, I'll give you a couple suggestions about water chemistry.

If you live in a public water district, you should be able to get an analysis by calling and talking to the chemist. Be careful not to sound like an eco-freak out to hang him. Tell him why you want to know. You probably won't get a number; you'll get a range. You want to know pH, total hardness, calcium content, and sodium content. You can also go to your local aquarium shop and buy test kits to tell you pH and total hardness. These are the two main things to know, and pH is far-and-away the more important. In fact, if you just get a pH test kit and test your water, you'll probably get the answer you want. Your

sparge water should be around pH 5.7. Your mash, after the mash-in step, should be around pH 5.3 ~ 5.7 also. If its not, you'll want to adjust it before your starch conversion step. Generally, if you have moderately low total hardness (total hardness below 80 ppm or so) and fairly neutral pH (pH around 7.0), the natural acids in the grains will make the mash "just work". Its the sparge water that becomes important then.

ALL of the water you use for brewing should be boiled before use. If you fill your kettle with COLD water, with plenty of aeration (the normal sink aerator works fine), bring it to a boil, and maintain a hard boil for 30 minutes, this is sufficient. Leave the lid off, especially if you live in a public water district, so you can drive-off any chlorine or other volitile nasties that might lurk in the water. After boiling, cover the kettles and leave them sit overnight to cool. If you see a lot of white flakes at the bottom and on the sides of the kettle in the morning, your water was pretty hard. The white stuff is the precipitated hardness. Rack the water into another container, leaving the white stuff behind. You'll want to use Lime-Away(tm) or other bathroom cleaner to clean your kettles. Adjust the pH of your sparge water, and your mashing water if necessary. Now, try brewing. In your recipe formulation, figure 25 points of extraction. Hopefully, this will be low. If you don't get the gravity you want, stir-in enough dry malt extract to bring it up to snuff. This way you'll get a good beer even if your extraction wasn't what you wanted. If your gravity is too high, just add some water. But in any case, write down everything you did.

This is all covered in great detail in Dave Miller's The Complete Handbook of Homebrewing. I reccommend this book most highly. There's enough theory to help you move in the right direction when things go wrong, and plenty of pragmatic advice too. If you want a copy, you can send e-mail to "Roy.Rudebusch@travel.com" and order one. Other homebrew shops should have it too. If you have more questions, you can send me e-mail, and I'll do my best...

From: todd@thoreau.nsc.com (Todd Vafiades)
Subject: my trip to California

I've recently returned to Maine from a brief visit to the west coast. While I was out there, I was able to join a friend for a couple of days and check out a few of the greater bay area micro-brew-type-pub-places..

We went to the typicals like Gordon Biersch and Tied House which were both quite good and quite predictable... we then set our sights on Santa Cruz where we were targeting the Seabright Brewpub and the Santa Cruz Brewpub. However, and this is when all of the fun began, in order to get to Santa Cruz, we had to take Route 9 (I think it was) which funneled us right through downtown Boulder Creek. We looked at each other and said.."isn't there supposed to be a brewpub `round these parts" (remember, we're from Maine) Well, low and behold we drove right up to the Boulder Creek Brewery and Cafe.

Without getting to worked up here about details, suffice it to say that the head brewer and the bartender were VERY cordial and we had a couple of well

above average hand-crafted. While we were chatting and trading brew type secrets I remembered that I had a bottle of beer out in the car that I was willing to bet these guys would like to try. I'de picked it up down in San

Diego a few days prior at a Liquor Barn (just as a quick tangent, the Liquor Barn on Mission Bay in San Diego has, without a doubt, the most incredible

selection of beer I've ever had the honor of being near) This beer was a FelinFoel sp? ... a Welsh beer I've heard of before but not this particular

type as it was a Festive Ale (holiday time only a suspect). At any rate, I brought the bottle in, set it down and asked the head brewer if he'de like

to open it up and let everyone in the bar try some. It was a 20oz bottle and

there were only about six of us there. So we opened it up and rationed it out. WOW!!!!!! This stuff was intense. The nose was very simialr to a fine aged scotch and the fruityness and complexity of the palate was beyond my ability to describe...go out and buy some!!!!!! I'm sure most of the Liquor

barns carry it. So, as we were remarking about how remarkable our remarks were relative to the very fine festive libation, the head brewer asked us where we were going to which we answered "ultimately, San Fran" and before

he could say another word we immediately remembered to ask him where we could find the fabled "Old Foghorn" from anchor brewing. I had mentioned I couldn't seem to find it anywhere and he immediately responded with "that's because they don't bottle the stuff... you have to go to either the Anchor Brewery or some pub the serves the stuff draughtily"...

aahhhhh well Anchor was out as we had called to find that they were booked through

to January '93. So where are we going to find this precious fuel??? A placed

called (drum roll please) Toronado on Haight Street in San Fran. Well, we bid our beer wishes and to make a really long story just kind of long, we stopped by the two brewpubs in Santa Cruz (nothing really remarkable except that the Santa Cruz brewpub was serving any of there brews in a giant pitcher (must have been nearly 64oz) for \$5!!!! good beer, better deal! Ok, finally I get to the good stuff...let's fast forward to THE pub known now as the legendary "TORONADO" We walk into this place and the first thing we notice is 40 taps!! This is not like other places that claim 40 taps and have them but intermingled with the reasonable taps are the unreasonable budmilcos.... No! This place had all GREAT taps (now remember that we're from Maine and even though there are some really good brews to be had 'round these pahts, nothing even comes close to the variety and intensity of the selection at TORONADOs. Get ready..... (louder drum roll please) we're talking:

Anchor Old Foghorn B.W. mmmmmmmmmmmmmmmmmmmmmmmmm
 Celis White on TAP! OH MY GOD... we can die now.
 Pilsner Urquel everything you've heard about this is true...GREAT STUFF
 Sierra Nevada Bigfoot B.W. (my friend and I are quite partial to B.W.)

just to name a few... The list reads like something out of the Twilight Zone

I beleive they had 7 different barely wines... 7!

a bunch or stuff from Mendocino, Marin, Rogue, Big Rock, etc.. etc.. etc..
 We stayed there for several hours and the bartender was so kind as to let us try samples (in little 3oz shot glasses) of anything we wanted. My friend kept ordering pints of the Celis White... I kept just ording pints of "the next one on the list!" What this place didn't have on tap they did have in bottles. Chimays, Sam Smiths, Felifoel, McAndrews ... way too many to recount here!!

To close, If you've never been to TORONADO on lower Haight ST S.F., GO!! If you have been there, GO AGAIN!! and if you can't ever make it there.. well, maybe you'll leave this world a happy and contented soul, but I doubt it!

Please understand that I've been offered no compensation for this rather biased review (not that I wouldn't take a kick back) and also, If I was to open something like this on the East Coast, you all would be the first to know. Are you listening Sunset Grill guys?

happy happy joy joy :^))))))

Subject: Re: Subpoena

Thank you all for your supportive messages. I received a lot of private email about the subpoena I was served by the Boston Beer Company (Sam Adams).

There is something that I want to make perfectly clear. I will not disclose private communications to Jim Koch's minions under any circumstances. I consider your messages to be privileged communications, and are not public information. You may write to me freely, no one else will see your message. I will defend my privacy to the fullest extent that the law and modern armaments will allow. In fact, the only correspondence I will give them is the open letter I wrote for the original case.

Several of you are organizing boycotts and letter writing campaigns. I say go for it. Even Koch can't afford to subpoena every person who publicly criticizes him. I'm never going to drink a Sam Adams product again, not if its the only decent beer in an airport bar, not even if its free. Yes, I'll drink Bud or water instead of Sam Adams.

Obviously one of Koch's drones is reading the net for him: Do you have the guts to publicly defend your employer's actions, and your participation in this subpoena?

I have some unused advertising space on my new (soon to be famous) SynchroSystems SBD-1 race car. I'll put "Galaxy's Fastest Homebrewer" there. I am considering adding something like "Starve a lawyer - Boycott Sam Adams Beer", I would like to hear your suggestions.

(typically
>5-15 psi). It is likely good practice to do this with all your kegs,
>it's up to you. This is almost certainly the problem with carbonation,
as
>otherwise it would indicate no fermentation was occuring to carbonate
>the beer, the result of a weak or absent yeast.

Don't forget to cut back on the priming sugar if you pressurize the
headspace.
Some of the priming sugar in solution would be used to pressurize the
headspace if you didn't do it manually, and when you do manually
pressurize
the headspace, some of the added CO2 will make it into the beer, even
without
agitation. I've had good results with only 10-20g corn sugar per 5 gal
keg,
and pressurizing to 14 psi (and disconnecting the keg from the CO2
cylinder).

I wouldn't think that 15g is enough, and I'm 99% sure that if I ran
through the calculations they'd say it isn't, but when reality differs
from theory...

From: Phil Hultin <HULTINP@QUCDN.QueensU.CA>
Subject: Peracetic Acid

All this talk about peracetic acid as a sterilizing agent may be more trouble than it is worth. In our lab, we prepare the peracid using 30% peroxide and glacial (ie 100%) acetic acid. This reaction is very exothermic, and the product is rather hazardous, tending to be explosive in this concentrated form.

The home synthesis proposed recently (vinegar aka 5% acetic acid plus peroxide bleach - I don't know the concentration offhand, but it is quite dilute) would not be expected to give good yields of peracetic acid. It would probably behave essentially as the mixture of acetic acid and peroxide. This would be an effective sterilizing mixture, of course, BUT IS IT WORTH THE TROUBLE?

Neat peracetic acid would be one hell of a sterilizing agent. It seems to me, though, that the homemade stuff would not be any better than just using the plain peroxide bleach. It may dissolve lead slugs but you only need to kill bugs! If your equipment is that dirty, throw it out and buy new stuff!

Merry Christmas! P.

Subject: Sparging

>From: Jim White <JWHITE@MAINE.maine.edu>

>Is there a 'reasonable' extract rate? If so, what is it?

First of all, as has been stated here several times by several people, extract rate and beer quality are not necessarily directly proportional and

linear. Therefore the MOST reasonable extract rate is that which produces the best beer in YOUR system.

Having said that, your yield is on the low side of what one typically expects from the numbers you provided.

>10# of M&F 2 row Pale Grain Malt
>1/2# M&F Crystal (sorry don't know the Lovibond).
>Mashed in 3 U.S. gals.
>Sparged with a little over 3 U.S. gals at 180 F.
>Crushed with Corona Grain Mill.

>For 5 U.S. gallons, this yielded on O.G. of 1.042.

The one thing that is not clear is how much sweet wort you had before boiling and it is possible that you did not sparge long enough.

With a total of 6 gallons of liquid, I do not see how you could have gotten enough wort for an adequate boil that would yield 5 gallons.

10 lbs of grain will hold between 1 and 2 gallons of water which means you only got 4 to 5 gallons to boil. If you boiled for an hour or more this would leave you with 3 to 4 gallons. You may have left something out but based on what you said, my guess would be that you left a lot of sugar behind in the grain. It would be interesting to know what the gravity of the final runnings was. If it was over 1.010, you quit sparging too soon.

My suggestion is to increase your sparge volume to at least 6 gallons or what ever it takes to get about 7 gallons of wort to boil for a 5 gallon batch.

As a point of reference, I use 12 lbs of grain with 4 gallons of mash water and sparge till I have about 10 gallons of wort. I boil this to 7.5 gals and end up around 1.050.

>2) Cruch is too coarse. This is a possibilty.

That is easy enough to test. Grind it finer the next time or borrow

someone's roller mill.

>I note some uncrushed grains, but also some powder.

The uncrushed grains are a total loss but there is nothing wrong with powder.

It ENHANCES the extraction rate. The problem can be that if you grind it

finer on a Corona you also grind the husks finer and this can cause other

problems but it has nothing to do with extraction.

I would look to your sparging first.

From: Richard Childers <rchilder@us.oracle.com>
Subject: Proposed Standards for Pub Crawling

I would like to ask everyone who is about to go *somewhere* and feels it is appropriate to ask everyone in the entire Net, if they 'know of any good pubs in <wherever>' ... please don't.

It's getting tired and boring and suggests you don't know how to use a phone book, quite frankly.

May I suggest an alternative.

- (1) go someplace.
- (2) open the phone book, see what's there and check it out with the locals if possible.
- (3) visit it in person.
- (4) go home and then tell everyone about it.

This will do much to raise the information level and lower the noise ...

Thanks.

From: tony@spss.com (Tony Babinec)
Subject: fuller's esb tasting notes

Here are Roger Protz's (Real Ale Drinker's Almanac, The European Beer Almanac) tasting notes on Fuller's ESB...

OG 1054-1060 alcohol by volume 5.5-6%.

Ingredients: pale malt, crystal malt, flaked maize, caramel, and brewing sugar. Target, Northdown, Challenger and Goldings whole and pellet hops. Top-fermenting yeast.

Nose: An explosion of malt, hops, and Cooper's marmalade.

Palate: Enormous attack of malt and fruit with hop underlay; profound finish with strong Goldings character and hints of orange, lemon, gooseberry, and some tannin.

Brewing comments: Although Protz doesn't say so, I think that Fuller uses Maris Otter pale and crystal malt. If these are not accessible, use a good British crystal malt. I don't have access to Target, Northdown, or Challenger, but would be inclined to experiment with Perle, Northern Brewer, or perhaps Styrian Goldings ("peppery") for bittering and would definitely use Kent Goldings for late hopping. Surely Fuller's ESB has some dry-hopped Golding flavor too. For yeast, maybe a yeast-culturing buddy has Fuller's yeast in a test tube, but failing that, use a malt-accenting ale yeast.

From: rxh6@po.CWRU.Edu (Randall Holt)
Subject: Cold Basement Brewing of Ales

This is the first winter I've brewed in, and I'm a little disappointed to find that my basement hovers at a steady 52-55 degrees F. Sunday night

I started a brown ale that didn't seem to want to kick off, and my best guess was that the temperature was too low. I devised a simple, quick fix by placing the fermenter (plastic bucket) into the utility sink, plugging the drain and filling with hot water. 6 hours later we're makin' beer.

Now the long term solution would be a temperature controlled brew-fridge, but, I'll admit it, I'm cheap. It's one of the reasons I brew my own. So I had this offhand idea that I could use the utility tub if I could keep the temperature up, and then conceived of using a fish-aquarium heater to keep the temp up and steady at 62-65F.

So brewmeisters, has it been tried before? Can anyone think of major disadvantages other than monopolizing the utility sink all winter long?

Of course, with a 50-55 degree basement, I'll be making some real lagers next - rather than the steam beer I've been calling a lager, but I wouldn't mind a simple, cheap temperature control.

I'll let you know how it turns out.

>hardness/softness/ph etc.

Your extract rate is roughly $(5\text{gal} * 0.042) / 10.5\text{lhs} = 0.020$ or 20 pts/lb/gal.

This is not tragic, but you could do better. I'd say that if you aren't getting 0.024 or better, you should look for ways to improve your yield.

>1) Everything's copacetic, don't change a thing.
>2) Crush is too coarse. This is a possibilty. I note some uncrushed grains, but
> also some powder.
>3) Water's too hard/soft/acidic/alkaline.

I'd say it's probably a combination of 2 and 3 or maybe 2, 3 and the design of your lauter tun. If a rollermill is not in your budget, maybe your homebrew supply shop has a rollermill and you may be better off by getting the grain pre-crushed. It is best to use the grain right away, so there go your bulk savings, but the points you make up in extract may make this more cost-effective. Get some pH papers and something to acidify your mash with (like Calcium Chloride, Gypsum or lactic acid), measure your mash pH and adjust it down to the 5.3-5.7 range. Are there any brewer's in your area, homebrewer's or commercial? Ask them how they treat their water.

Bob writes:

>Why bother buying it? There's a thread in my Firearms list where someone

>also, but my supplier ran out and substituted Bullion. Is this also ok? Anyway,
>I'm thinking of culturing a starter from a wyeast strain. Any suggestions
>would be great. Thanks!

Woah! Time for a heart-to-heart with your homebrew supplier. Bullion is *NOT* a substitute for Tettnanger!!!! If your supplier insists they are then get a new supplier. Granted, the IBUs may be the same when you adjust for %AA, but there's a lot more in hops than Alpha Acids -- I think Bullion will give you a "rougher" tasting beer than you would like in a Bock, even a Doppelbock. The Hallertauer and Tettnanger would have been a good choice.

Bo^bs B. Birthday Bock:

In my last bock, called Bo^bs B. Birthday Bock, I used 6.6lbs of Northwestern (3.3 each of Gold and Amber) Extract, 2 lbs of Laaglander light DME, 1.35oz Cascade Pellets (not a traditional hop for bock either), 1/4tsp CaSO4, 1/4tsp NaCl, 1/4tsp MgSO4, 1lb 40L Crystal malt, 1/2 lb (~300L) chocolate malt and Wyeast #2308 -- Munich Lager yeast for a 5 gallon batch. This came out with an OG of 1074 and an FG of 1027 (thanks, in part, to the 2lbs of Laaglander). It was fermented (started, actually) at 57F for 12 hours, then 50F for two days and then 45F for two weeks. Then I transferred to a secondary for another two weeks at 45F. Primed and bottled -- lagered for *FOUR MONTHS* at 45F. (During bottling and even after two months in the bottle, it smelled like home-perm solution. This went away after two more months in the bottle.) [BTW, this is one of the "prize-winning" extract recipes I promised several of you that I would post.]

Note that 8.6 lbs of extract gave me 1074, which is just under the AHA doppelbock OG. I suspect that 12 lbs may be a bit high -- I think it will give you an OG of about 1100 (tripelbock?).

If you do use the 12 lbs of extract in the boil, you will have a boil gravity of about 1100. For 35 IBU of bitterness, I would recommend 2 oz of 5%AA Hallertauer Pellets or 2.4 oz of 5%AA Hallertauer Whole hops in a 60 minute boil.

Traditionally, German brewer's added hops in three phases 60, 30 and 15 minute boils (if memory serves correctly). Since utilization is dramitically diminished by shorter boils, you would have to increase your hop rate if you split the hops. I'm afraid I don't have the time to do all the calculations, but by gut feeling says: 1.25 oz of Hallertauer pellets for 60 min, 0.5 oz for 30 minutes and 0.5 oz for 15 minutes. Get the Zymurgy Special Issue on Hops and see Jackie Rager's article. Split the IBUs you want (30-40) into three parts and then work each addition separately through the formulas.

If you reduce the boil gravity, you will also have to compensate on the hop rates (the formulas in Jackie's article will show you how much).

Al.

)
) I can assure you that Potassium Sorbate `tis not what gives Orval it's
) bubblegum ester! I've successfully generated that ester with nothing
) other than re-cultured Orval dregs and a few pounds of malt extract!

Damn straight! This is a pretty goofy answer.

Now, I thought, what DOES potassium sorbate taste like, anyway? So
I went into my kitchen, opened up a jar of it, and put a substantial
fraction of a teaspoon into about 4 oz of water.

It tastes vaguely sweet, slick, and slightly astringent. But the
flavor is mild. At the concentrations normally used I doubt it would
be detectable.

So, what is the ester? Surely someone must know. Am I going to have
to order the big list of flavor descriptors from the ASBC? (Could
I even get it for < several hundred\$, i.e., without the rest of the
manual?)

Subject: EARLY CARBONATION?

I'm brewing up a batch of Zulu's Xmas Lager (Cat's Meow II), and encountered a problem when checking the S/G in the secondary and bottling. The beer appeared to have developed a small amount of carbonation already (!?!), and foamed slightly with every bottle I filled. Considering the batch was still pretty cold from being in the fridge (about 40F), I'm a little concerned that the final product will be overly carbonated after four weeks of conditioning in the bottle. What caused this early carbonation, and is it a problem? Guess the batch is destined for the sink, although I never give up on a batch until at least two months in the bottle.

Thanks!

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Pub requests / beer from near-beer

I disagree with Richard Childers. If I go somewhere, I do not want to check out every pub in the town, and the locals frequently drink swill, so they are not a good source of information. A two line request for good pubs or microbreweries does not tie up the net, nor use up a lot of space in the HBD.
As long as replies are mailed, what's the problem?

*** **

Ahmed B. M. Shuraim asked about making beer from non-alcoholic beer. There are two kinds on non-alcoholic beer: de-alcoholized and malt beverage. The first is regular or light beer which has had the alcohol removed, but there is still typically .5% alcohol left. Malt beverages are unfermented beer, are quite sweet, and contain no alcohol. If you have these, you can add yeast and it will ferment to beer. Brewer's yeast is of course preferred. Baker's yeast will make something vaguely like beer, but it won't taste very good. If this process is illegal where you live, I do not approve of breaking the law.

Ed

From: dipalma@banshee.sw.stratus.com (James Dipalma)
Subject: food grade buckets, subpoena

Hi All,

Last week, I related an experience with a bad batch of beer, and asked for help identifying the cause. One of the problems I suspected was the use of non-food grade buckets for a lauter tun. Many thanks to Greg Wageman for providing the following information:

The acronym you're probably thinking of is "HDPE", which stands for "High Density PolyEthylene", which can indeed be a food-grade plastic. I don't believe it is required that this abbreviation appear, but it is one of the standard recycling codes, along with triangular "cycle of arrows" containing a code number (in this case, "2" for HDPE).

Needless to say, there are numerous other types of food-grade plastic, including LDPE (Low Density PolyEthylene, often used in plastic milk cartons) and PETE (PolyEthylene Terephthalate, used in 2-liter soda bottles, amongst other things).

The important thing is that the manufacturer state that the plastic is "food-grade", because they can (and often do) add dyes and chemicals (additional "plasticizers" and softeners) to what would otherwise be food-grade plastic. These are not "food-grade" because the additives are not chemically stable and can be leached out of the plastic under the right conditions (e.g. sufficient heat and/or pH)

I think the only way to be sure is if a) the item was originally used to contain food or potable beverage or b) if purchased new and empty, the label specifically indicates that it can be used for food storage. Personally I wouldn't use anything that didn't meet one of these qualifications. (I know, for example, that some household cleaning products are packaged in plastic bottles that have the recycling code on them; I wouldn't consider them food grade by any means!)

Disclaimer: I'm not a chemist by any means, I've picked up the above information from various sources including local nature museums that promote recycling.

The buckets I used for the lauter tun were purchased in a hardware store and do not have "HPDE" or the triangular cycle of arrows with the "2" inside. I believe they are not food grade.

The moral here is make absolutely sure buckets used for brewing are food-grade. That said, anybody know a source for 3-4 gallon food-grade buckets? :-)

I also wanted to take this opportunity to publicly express my support for Chuck Cox and his position, as stated in the last HBD.

>I'm never going to drink a Sam Adams product
>again, not if its the only decent beer in an airport bar, not even if
>its free. Yes, I'll drink Bud or water instead of Sam Adams.
^

I totally agree, except that I can't distinguish between Bud and

water.

>Obviously one of Koch's drones is reading the net for him:

Obviously, so here's a message: if you really want to improve the wealth and stature of your company, then stop your litigious ways, and start spending your money on improving the quality and variety of your product, instead of wasting it on idiotic lawsuits.

Cheers,
Jim

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>
Subject: Re: Proposed Standards for Pub Crawling

Richard Childers suggests using the phone book instead of the HBD to find brewpubs when travelling. While this is a good idea, in my experience you get a lot information from the HBD than you would ever get from a phone book.

- 1) You get personal feedback on the qualities of the various establishments. This was critical for me on a recent trip to the Left Coast, as it let me skip a couple of places I might otherwise have wasted time on.
- 2) You can find out before you get there what the options are. This is important when you're trying to squeeze a little pubbing into a business trip.
- 3) You may get offers of pub-crawling companions. I spent a pleasant Saturday evening in the company of a fellow HBDer and friends that would have otherwise been spent in solitary contemplation of the bottom of a glass (well, several glasses, actually).
- 4) You may find out about possibilities outside the "phone book" area. Again, on my trip to Berkeley, I got info on pubs from SF (and south) to Mendocino and Hopland, as well as in the Berkeley-Oakland area.
- 5) Phone books are published once a year, brewpubs seem to come and go faster than that sometimes.

That said, I don't want everyone to take this as a "green light" to flood the HBD with requests. If you know you'll be going somewhere in the near future, you can watch the HBD for suggestions (there was a nice review of some SF-and-south pubs in today's issue), and you can scan the archives (see the HBD header for information on how to get stuff from the archives). Tom Kaltenbach's thread program (in the archives, for PC and Unix) makes it really easy to scan back issues for a particular topic.

Also, when responding to a request for brewpub information, please send personal mail. If the requestor receives good stuff, he or she can then summarize it to the list. This will do more than "banning" requests to keep the S/N ratio high. After all, a request is usually about 1 or 2 lines long, and doesn't take up much space (barring page-long signature files).

Subject: useful info

a little quasi-flame action... hold on to your heat sinks:

<ignition>

In direct response to Mr. Childers complaint about individuals asking the HBD about recommended brewpubs in a given area they are bound for...

Maybe I don't understand the purpose for the existence of the HBD but let me give you my best guess:

The HBD is a forum within which individuals can share information, ask questions and give advice on ANY home-brew related practice or issue.

I feel sorry for Mr. Childers in that he finds it necessary to attempt to "lower the noise level" by insinuating that questions relative to recommended brew-pubs are superfluous. I personally have asked the big "question" before and I received a wealth of information relative to the greater bay area brew-pubs. On my trip, I gained tons of insight as to the practices and semi-secrets observed by different brewers, not to mention just the sheer joy of the experience of visiting those brew-pubs that others in the HBD have recommended. This is supposed to be fun, right?

Why not attempt to use some advice from fellow HBDers to allow a higher percentage of great-pubs-visited rather than wasting time through trial-and-error?

Furthermore, "what's a phone book? duhhh, I don't know how to use one, duhh"

Come on, Mr Childers, are you serious? Do you really think this? This is a

rather sad commentary on your perception of the real world, isn't it? .. . And

if you are so tired and bored of people asking perfectly legitimate questions, perhaps you need to take some time off for a little r&r. (Unless you're being sarcastic, in which case... never mind, but your posting seemed quite serious).

I usually don't become involved with these sorts of flameish rebuttles but I think that Mr. Childers is just plain wrong on this one and he needs to understand that his perception of the usefulness of the HBD may not correlate well with that of others!

<extinguished with directed apologies to those anti-flamers out there>

There now, with that said,

I'll be heading to Austin, TX in the near future and I'd really appreciate any input on the best places (brew-pubs or good taverns) to visit. If you don't wish to belabor the HBD with your response than please feel free to email me directly. By the way, Celis is my first and foremost target and if any of you have visited there already, it would be great to hear from you.

happy brewpub hopping & learning, Todd ;^)

From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)
Subject: Re: ...Pub Crawlinghomebrew@hpfcmi.fc.hp.com

I agree with Richard Chillers that there is too much noise on the HBD concerning questions like "Where do I go in city X for a good beer?". He suggested that everyone consult the local phone book. While this is a good last resort, there are some other, far superior, choices.

First, there are a couple of books:

1. A book by Pat Baker called something like "A Guide to Pubs". (Cost: about \$4.00) It is an older book that came out before much of the recent revival in brewpubs.

2. Books by Steve Johnson called "On Tap" (~\$15) and "The On Tap Companion" (~\$10), published by the World Beer Review people. These are great books, with a separate page for each brewpub listing info about what kind of place it is (e.g. kind of food, kind of music, atmosphere, list of beers served). The Companion book was put out a year or so after the first book, because there were so many new brewpubs. Maybe they'll put out another one soon.

All of these are available from the AHA, and probably from your favorite homebrew mailorder place. I've heard that there is a similar book put out by CAMRA for British pubs (check old HBDS for more info).

Then, there is a pretty extensive list that is available by anon ftp from sierra.stanford.edu (the archive for the HBD). Once connected, the file is in "/pub/homebrew/publist.Z". The list was put together by John R. Mellby (jmellby@iluvatar.dseg.ti.com) and is quite complete. It contains listings by *country*, state, and city. The U.S. has the most listings, but there are a surprising number of entries from around the rest of the world. I usually just print out the pages corresponding to the part of the world my upcoming trip will take me to.

I am not related to anybody mentioned, but I must admit to being very grateful to them for making my travels that much more enjoyable.

]May I suggest an alternative.
[alternatives deleted]

Since the Internet is seen by many as the source where all information resides (or can be accessed quickly), it's easy for people to think that any information can be gathered with an email message. But doing so costs time and energy from the person who has to look the stuff up, which doesn't always seem fair.

Therefore, for hard copy and then for electronic copy, in a very rough best-to-worst order, the following are all good ways to learn where brewpubs are (relevant to the U.S. and Canada especially):

- 1> Phonebooks. Your community library has many shelf-feet of phone-books from every major city in the U.S. and Canada. If the city you need isn't represented, there is always (destination area code) 555-1212 for information. (I've found that some large corporations also have libraries and/or a massive collection of phonebooks, with at least one directory for every city in which a branch office resides).
- 2> Other books. There is at least one brewpub guide available, although the title and author's name escapes me now. There is also Michael Jackson's Pocket Guide to Beer, which might not be definitive about brewpubs in the U.S. (after all, the latest edition is 2 years old), but there are enough listed to start on, and it is fun to read. In Britain, there is the CAMRA guide.
- 3> Magazines. There are titles for beer drinkers and brewpub operators, both of which have reviews and announcements of recent openings. Ask your local newsstand for All About Beer, The Celebrator (for the west coast), or others.
- 4> The online brewpubs directory, archived and sometimes posted on alt.beer. Somebody is compiling a list of brewpubs in the U.S. and Canada, and is soliciting additions and comments. I'm sorry that i can't provide access data; ask on alt.beer. (since i don't travel, i don't keep close taps, er, tabs on listings about other places).
- 5> alt.beer. Technically speaking, this is the newsgroup in which questions about brewpubs belong, but a lot of sites have restricted or no access to alt. groups. (between you, me, and the other x0,000 readers, i think the noise level on alt.beer is awful high; keep a killfile handy).
- 6> Other mailing lists. Some email mailing lists are dedicated to beer-related activities in regional areas; ask around.
- 7> rec.crafts.brewing. Not the appropriate newsgroup, but close if one doesn't have access to alt.beer, the advantage here being that a reader can simply list out article headers and decide on what to read from it.

- 8> rec.food.drink. A somewhat appropriate newsgroup, and ignore the folks who tell you to take your post to alt.beer.
- 9> The Homebrew Digest. Heck, i just skim past the requests i see, with minimal time wasted. If the Earnest Seeker were to keep his question down to a couple lines, it would be even easier to skip past for those who wouldn't be able to help. Those who can help don't need to know the circumstances of the visit, they only need when and where the Seeker will be.

Those who reply to a question about finding brewpubs ought to do so by email; a cluster of well-meaning souls can thin the content of the HBD (and newsgroups) by posting narrowly specific information. On the other hand, i enjoy reading reviews and comments on brewpubs in trip reports, because they have information useful to a broader variety of readers, and are fun to read.

<gee, this ought to be in the FAQ.>

>It's getting tired and boring....

Amen! Although the questions are harmless, it's the answers that are tedious and should be restricted to email.

> (4)go home and _then_ tell everyone about it.

Even then, I would suggest it be limited to the quality of the beer. There are other fora for ambience and food discussions.

While I am at it, we had dinner at the Berghoff in Chicago last week and tasted their Weisbier and Porter.

Never having tasted Weisbier before, I can only say it was interesting but I have no idea why it is so popular with homebrewers. There was nothing at all memorable about it.

The Porter tasted a bit heavy and strong for a Porter, but what do I know? Again, nothing memorable other than being able to get something besides Bud at a restaraunt.

>From: rxh6@po.CWRU.Edu (Randall Holt)

>This is the first winter I've brewed in, and I'm a little disappointed to find that my basement hovers at a steady 52-55 degrees F.

I think you are in too much of a hurry. That is just about the ideal temperature for all-purpose brewing.

I would suggest that you just make sure you have an adequate starter volume and allow 24 to 48 hrs for fermentation to get underway. By heating up the wort you do nothing to improve the quality of the beer.

>Can anyone think of major disadvantages other than monopolizing the utility sink all winter long?

I can't think of a good reason to do it.

>I'll let you know how it turns out.

My guess is, it will be the best ale you ever made.

Subject: yeast culturing

Well, I'll probably be reposting this 'cus it'll be in the Christmas eve digest and I'd assume a few folks won't see it.

In any event, I have been receiving responses on yeast culturing from a variety of people (THANKS!) but no one ever mentioned culturing from the 'sludge' at the bottom of the primary or secondary. If you can use the dregs of 2 or 3 bottles to culture, it seems to me that it would be much easier to simply save the sludge from a primary and use it several ounces at a time to start a culture.

That way you'd be getting first generation yeast when you needed it, without having to worry about drinking several bottles just to get your raw material (not that I find that a hardship.)

No one has mentioned this, so I'm wondering...is this valid?

Subject: Pub Crawls and phonebooks

"The HBD is a forum within which individuals can share information, ask questions and give advice on ANY home-brew related practice or issue."

We agree.

"I feel sorry for Mr. Childers ..."

Call me Richard, if it doesn't blunt the edge of your Bic-sized flame.

" ... in that he finds it necessary to attempt to "lower the noise level" ..."

Try, 'raise the quality'.

" ...by insinuating that questions relative to recommended brew-pubs are superfluous. I personally have asked the big "question" before ..."

In other words, you are taking this personally and are not free of bias.

"Why not attempt to use some advice from fellow HBDers to allow a higher percentage of great-pubs-visited rather than wasting time through trial-and-error?"

Because trial-and-error is how the people whom you are asking got their experience.

"Come on, Mr Childers, are you serious? Do you really think this? This is a rather sad commentary on your perception of the real world, isn't it?"

Maybe. It might be holiday stress, and all my fault, entirely. I am ready to deal with that possibility, and thank all those whom advised me to relax.

It might be all the geniuses getting ready to go visit their friends and, eager to impress them with a superficial knowledge of their locale, demand this information from a world-wide audience.

"... if you are so tired and bored of people asking perfectly legitimate questions ..."

I don't believe it's been established yet that these are legitimate.

"I'll be heading to Austin, TX in the near future and I'd really appreciate any input on the best places (brew-pubs or good taverns) to visit."

When I get questions like this I pull out the phone book and look up the addresses and phone numbers. Why can't you ?

just get a

I'd like to make a couple points about what Tom has said.

In fact, the pH of your water is not terribly important. If you have soft water, the pH could be anywhere, but since there is nothing in the water to buffer it, even a small amount of an acid substance will acidify the water. On the other hand, if you have a substantial amount of carbonates, this will give a mild alkalinity to the water and buffer it strongly. In this case, the acid formed by the grist and any free calcium may not be enough to overcome the buffering. Even if it is overcome, when you lauter, you are removing most of the acidity with the wort. If you sparge with more of this alkaline, buffered water, whatever acidity remains will be rapidly overcome.

It is the pH of the mash, both during mashing and lautering, that is important. This is because, during mashing, the diastatic enzymes work best in an acid environment; and while lautering, tannins are more easily released from the grain husks in an alkaline environment.

Some have recommended acidifying sparge water with acid. This is not necessary if your water is not buffered with carbonates. My experience with Los Angeles water, at about 120ppm hardness, most of it not from carbonates, was that I could sparge with as much as half a gallon of (untreated) water per pound of grist and the outflow would never rise above pH 5.8.

Another point is that dark malts, crystal and roasted, are all more acidic than pale malt. If you are making a dark beer, the mash will be more acidic, and will tend to stay more acidic. Historically, dark beers come from places with high carbonate water (London, Dublin, Munich...).

> ALL of the water you use for brewing should be boiled before use. If you fill

There is no need to boil all your water before you brew. If your water comes with a lot of chlorine, an activated charcoal filter will remove it. You need only boil and decant your water if you have a lot of carbonates. If this is the case, another technique to lower the carbonate concentration (along with everything else) is to cut your tap water with distilled water.

> This is all covered in great detail in Dave Miller's The Complete Handbook of Homebrewing. I recommend this book most highly. There's enough theory to

So, the bottom line is, contact your water supplier and get an analysis (they will send it to you for free, generally). Measure the pH of your

mash after doughing in, and while sparging. I agree, Miller's book is a great source of information. If you're on a well or other private source and don't want to pay for testing, read Noonan's article in the conference transcripts two years back.

>The beer appeared to have developed a small amount of carbonation already (!?!), and foamed slightly with every bottle I filled. Considering the batch was still pretty cold from being in the fridge (about 40F)

I'm not sure this is all that unusual. Of times an ale (especially if the gravity is still relatively high) with seem to be lightly carbonated in the carboy. Now add to this that the beer was cold, increassing it's ability to hold carbonation. As you rack and fill the bottles the liquid will warm and the carbonation it used to be able to hold comes out of the solution. Does this sound plausible? Unless your talking huge amounts of carbonation coming out I wouldn't start throwing out those bottles yet.

> my best guess was that the temperature was too low...conceived of
> using a fish-aquarium heater to keep the temp up and steady at 62-65F.

I've got that exact situation, and came up with the same solution! I bought a fully submersible aquarium heater-- it looks like a big test tube with a stopper in one end. I drilled a 1" diameter hole in the side of my plastic primary (above the waterline), and feed the heater and it's cord through the hole. I threaded the cord through a rubber stopper and sealed it with aquarium grade silicone glue, so the whole thing is air tight.

Now, when I make ales in the winter, I dial the temp to exactly 65F and brew away. I think a big advantage is the constant temperature-- My 5 gallon batches don't have the thermal inertia of brewery's 5,000 tank, and this keeps the temp dead-on. Within 3 days I'm to within a point or two of the final gravity, and rack to an unheated secondary for conditioning.

I store the primary full of sterilizing solution with the heater floating around in it, so its always sterile when I'm ready to use it. Just a warning: unplug the heater before racking. It will overheat and shatter it if is not submerged. Don't ask me how I know...

> No one has mentioned this, so I'm wondering...is this valid?

Of course it is! I use this method all the time. Right after racking, just pour the sludge into several small sterilized bottles, put an airlock on them, and stick them in the fridge. They ought to keep for several weeks. I find that using the muck from the secondary to be a little better because you don't have all the trub in the sediment; it's mostly flocculated yeast.

In fact, this method is one of the few ways for homebrewers to achieve truly optimal pitching rates (besides being very economical). I posted an article about this in digest #1036 ("All grain tips, yeast pitching amount") a few days ago, but I'll recap the important part:

"Most references recommend a minimum pitching rate of 10 million yeast cells per milli-liter of wort, plus another 1 million cells/ml for every 0.004 gravity increase above 1.040. ...The 10...15 million cells/ml rate is easily achieved by adding 5 ml of thick yeast slurry per liter of wort."

In English(US)/homebrewer units, this desired pitching rate works out to about 2/3 fl. oz. per gallon, or 3-1/3 fl. oz. per 5 gallons. Getting this much slurry from a starter culture is difficult, but in the bottom of every secondary you have enough to start a lot of beers.

You'll also find that pitching this much yeast drastically reduces your lag times. Just use your nose to determine whether the yeast is good, and if it smells at all off, pitch it in the garbage, not your beer.

Subject: Restricted Brewing/Koch/Pub-crawling/Berghoff/commercial beers/
Richard

Ahmed B. M. Shuraim asked about making beer from non-alcoholic beer.

My dad had to work in the UAE for a few months and new of a few people at "the compound" who would make their own beer. I believe this was illegal, but I think the authorities allowed malt extract to be mailed into the country, I'm not sure. I agree with Ed that alcoholizing "near beer" as we call it here will work, but won't taste very good and I too disapprove of breaking the law.

Jim writes:

>>Obviously one of Koch's drones is reading the net for him:

>

> Obviously, so here's a message: if you really want to improve the
>wealth and stature of your company, then stop your litigious ways, and
>start spending your money on improving the quality and variety of your
>product, instead of wasting it on idiotic lawsuits.

It will take some time for him to get the message. I heard Koch on a radio program here in Chicago and he was on his way to climb some mountain in South America. He plans to leave a bottle of SA on top of the highest peak in the Western Hemisphere (if I remember correctly).

However, I agree with Chuck, Jim and the person who Jim is quoting. I, personally, am glad to see a beer with some flavor making headway in the US mass market, but I am 100% against Mr. Koch's lawsuits, deceptive advertising and misuse of the appellation "Lambic." I will boycott BBC's beers.

I support the continued use of the HBD for finding out about good beer places in "city X" if the response is via direct email. I have gone through the trouble of discovering the good and the bad places here in the Chicago Metro area and would gladly share this info with anyone who asks. I agree that a two line request is a small price to pay in the HBD for the vast amount of data that can be shared off-line.

Michael writes:

>I agree with Richard Chillers that there is too much noise on the HBD

These books are almost out-of-date as they roll off the presses. It's not that they are bad, but they are often very incomplete. Also, there are a many great beer-drinking places, some that carry 10, 20... even 500 great beers and these would not be in the book unless they brew their own.

I agree, but the Berghoff is a poor example of the pub-brewer's art. Their beers are under-flavored and are brewed with the Budweiser drinker too much in mind. Of course it's a matter of taste, but I feel their Porter is too light-bodied even for a Porter (more like an American Dark Lager) and although I have not tried their Weiss for almost a year, I must agree that it was lacking in character -- not a good example.

Jack-- you should gauge your feelings about styles more by Goose Island's brews -- they are much better examples of the style.

> you get hooked on hombrewing, you won't care anymore.

I was driven to homebrew because I could not find Bitter in the U.S.

Subsequently, homebrewing has gotten me to try many more styles than I had been used to. I welcome the increased number of better beers available commercially and drink perhaps one good commercial beer (e.g. Anchor Porter, SN Celebrator, Orval, St. Sixtus, Westmalle...) for every homebrew I drink. Besides giving me ideas for new homebrew recipes, they are a reality-check.

Richard writes:

I doubt it. Most are probably people on business trips who have a few hours to kill in a strange town. Richard-- your request to ban "Pubs in town X" questions has generated more wasted bandwidth (this post included) than six months of "Pubs in town X" questions.

>
>"I'll be heading to Austin, TX in the near future and I'd really appreciate
> any input on the best places (brew-pubs or good taverns) to visit."
>

>addresses and phone numbers. Why can't you ?

The Chicago yellow pages has four pages of taverns listed, about 7 per column-inch. Four pages with 171 total column-inches, means 1197 taverns.

Having not been to most, I have no idea which are good and which are bad. This does not include the suburbs, nor is there a listing for Goose Island, IMHO, the best brewpub in Chicago or the suburbs. As I mentioned above, I feel that asking for this kind of info is valid, and as Jack said, should be answered off-line.

Re:EARLY CARBONATION?

I'm afraid I lost name of the person asking the question. Carbonation in the fermenter is usually a sign of too much back-pressure in the airlock. If you use a blowoff tube, don't put too much water in the catch-vessel and don't overfill your bubbler airlocks. I agree with Walt that the level of carbonation is probably not a big problem unless your airlock system has clogged partway through fermentation and dissolved 2 or 3 or 10(!!!)

volumes of CO2 into your beer. If it has, just unclog and let the beer de-gas before priming and bottling.

Happy Holidays.

Al.

P.S. You won't hear from me for a few weeks -- I'm not boycotting the HBD, I'm just on honeymoon Part 2. See ya!

From: walter@lamar.ColoState.EDU (Brian J Walter (Brewing Chemist))
Subject: Sam Adams Already Boycotted

Howdy!

I too support the boycott of Sam Adams, and also support Chuck. It is truly sad to see a micro taking such a stance. In a business so volatile as the micro/brewpub one we all need to stand together, homebrewers included. It seems the BBC thinks otherwise, and is seeming like the BudMillCoors people, trying to run smaller breweries out of business, instead of welcoming the diversity.

I have been boycotting Sam Adams for some six months now anyways, due to their advertising. They seem to put everybody down in promoting the "Best Beer In America", and I think that is the wrong way to go. Tell me how good your brew is Jim, don't tell me how bad everyone else's is. And by the way, how is their beer the best in America? According to the GABF results, their stock ale is the best altbier,

and

their dunkelweiss is second best, but what of the Boston lager they so proudly tout? Are you listening BBC kronies? Down with BudMillCoorAdams.

Good Day, and thanks for listening.

Hiya, Jack, old buddy... I still have that video, and... now living in Portland, am showing it to a whole new breed of (would be) brewers. ;)

What happened here is that most likely Todd replied to Richard's (can I call him Dick? Rich? Rick?) submission in 2 ways: a reply to Richard directly, and a cc: to the digest, or vice versa. In any case, direct internet mail takes about 10 seconds to 10 minutes in any normal situation, so Richard got the reply, and was able to respond with another cc: to the digest in less than the 24 hour period that mail gets queued... (As a matter of fact, there's almost 6 hours difference between the two submissions, taking EST and PST into consideration) In any case, much like
I'm doing to you right now. You'll see this later on today, bright and

early, under the Xmas tree, while everyone else will get it stamped '26
Dec' and if they're lucky 'nuff to have home net access or cursed enough
to
have to work, read it on Saturday morning. ;)

I'd like to take this chance to say (since I'm wasting bandwidth
already)... Hope you are having/had a good one, and you're truly a fun
bunch to listen to every day. :)

Subject: % alcohol by weight vs. by volume

Ok, I've had my silly post in the digest today, this one's serious. I know some chemist out there has the answer at the tip of his/her CRC, but I haven't got one around here.

How do I compute %alcohol by weigh in terms of %alcohol by volume. I know it is a function of what type of beer I'm talking about, doppelbock being usually much denser than others, but hey, the figure of %alcohol in water would be just fine for an approximation.

Salvator (in OR) is 6% by weight. 1- does the percentage change state to state? 2- what is that by volume?

before
priming and bottling.

I seem to always be on the wrong side of the curve. Several weeks ago,
it
occured to me that if I put more water in my fermentation lock, it would
give
me a head start on carbonation at kegging time. I use the long, S-
shaped
glass ones on the secondary and although I have no way of measuring the
pressure of a three inch colmun of water, there is enough CO2 in the
beer to
make it plesantly drinkable.

Baderbrau does their entire secondary fermentation under pressure and I
presume many brewers do the same. I therefore concluded that the only
reason
homebrewers do not do it was because of the problems of glass
fermenters.

>P.S. You won't hear from me for a few weeks -- I'm not boycotting the
HBD,
I'm just on honeymoon Part 2. See ya!

That's too bad because I was planning on bringing a collection of
samples of
WGB to the next meeting of CBS. You may wish to re-schedule your
honeymoon
to avoid missing such an historical opportunity.

Has the video create a cult out there yet? Most groups get together
and dress real funny, shout out the lines on que, and pour a glass
of homebrew over their heads at each SANFU. The real sign of an
ARF groupy is to know them ALL. There are even a few words purposely
misspelled in the subtitles just to make it fun.

>What happened here is that most likely Todd replied to Richard's (can I call him Dick? Rich? Rick?) submission in 2 ways: a reply to Richard directly, and a cc: to the digest, or vice versa.

This has been a bad year for my conspiracies theories. Seems pretty simple but I was just having fun anyway and as you see, I learn fast.

Reading all these indignant opinions reminds me of the time Ken Pavechevich, the maker of Baderbrau, came to talk with my homebrewing club last spring. We shouldn't forget that in general the megabrewers are even slimier than Jim Koch is. Ken told us stories of the not-so-licit tactics employed by Miller, in attempting to hamper his success in the market. Among other things, he heard reports from bar owners that [thugs] from Miller had offered free kegs if they dropped Baderbrau! He also told an iffier story about Miller trucks blocking the way of one of his trucks, making him seem unreliable to his customers. . . . I don't know if the megas are this nasty to all micros: Baderbrau in particular comes in packages that might be more appealing to your average Beer Drinker. (The labels are shiny, without a lot of words, and the name even sounds vaguely like a cheap American beer. I don't think the word `pilsener' even appears.) (I'm only reporting Ken's `rumors' because they're hearsay, hence legally useless, right?)

Anyway, I can imagine what a hard time the BBC is having holding what ever ground they've gained in spite of the megabreweries' megastupid marketing techniques (that work! -- pitiful) and other slimy, anything-for-a-profit-so-long-as-you're-SURE-we-won't-get-caught methods. With this in mind, I do (when in a good mood) have a quantum (not more) of sympathy for Jim Koch. Sam Adams beers are a major force in the current American Beer Enlightenment. In this day and age, Koch would not have been as successful as he is without using pushy, sleazeball Big Business strategies. If Koch is getting a cozy sandwich feeling between the megas and the micros, he might as well focus his efforts below as well as above, no matter how meek the offending microbrewery might be. Any good capitalist (in the narrow sense of `effective') would tell you that. (Whether the Boston Beer Works is actually a threat to the Boston Beer Company is very questionable.)

Before everyone jumps on me, I should point out that I'm happy to boycott the BBC along with every other Big Business I comfortably can! Sam Adams doesn't even taste that great anyway, except on tap.

Well, I hope everyone got lots of presents. I'm going to go read my new copy of Michael Jackson's New World of Beer.

Cheers,
Jake.

From: joseph@joebloe.maple-shade.nj.us (Joseph Nathan Hall)  
Subject: Majority Ale (Old British Beers...)

There was a thread a while ago in the digest about 21-year-old beer. I missed the start of it. Is this a reference to "Majority Ale" as described in Old British Beers and How to Make Them?

What an extravagance--20 lbs or so of grain for about 2 US gallons of brew (once the recipe is resized).

I just found some more Thomas Hardy's Ale Vintage Sampler Packs. Even better, they are last year's! That 1989 Thomas Hardy is pretty good stuff ....

From: rwinters@nhqvax.hq.nasa.gov (Rob Winters)  
Subject: flames, boycotts, and chemistry lessons

Ed Hitchcock <ECH@ac.dal.ca> writes:  
>I disagree with Richard Childers. If I go somewhere, I do not want to  
>check out every pub in the town, and the locals frequently drink swill,  
so  
>they are not a good source of information. A two line request for good  
pubs or  
>microbreweries does not tie up the net, nor use up a lot of space in the  
HBD.  
>As long as replies are mailed, what's the problem?

Amen, Ed! Yes, Richard, we all know how to use a phone book. When people  
ask about places to visit in a city not their own, they are looking for  
recommendations from locals, not listings of places out of the yellow  
pages. What good are they? And what is that crap about people "having to"  
respond? You certainly don't. In fact, I don't WANT a bunch of addresses  
of places you don't know about. I want \*recommendations\* and \*warnings\*  
of places you \*do\* know about. Just give a couple of names. When I get  
there I'll use THE PHONE BOOK to get the numbers and addresses.

As for the queries and responses taking up too much of the digests...  
Well, there a lot of other things I'd like to read about less than  
discussions of brewpubs in Denver or Dallas or wherever:

lawsuits  
lawyers  
boycotts  
trademarks  
product marketing  
the \*business\* of brewing  
fine details of organic chemistry  
autoclaves  
...

Why are we picking and arguing like a bunch of old ladies about pub  
recommendations when this kind of stuff goes on ad nauseum? Clearly,  
this is no longer my forum, and I'm outta here. Call me if you guys  
get to be fun to drink with again. I'm much more likely to visit a  
brewpub than countersue Boston Beer, brew hectolitre batches, culture  
yeast, or autoclave \*anything\*. Not that these aren't noble pursuits,  
but I \*have\* a life \*and\* a career, and I don't need another. Thanks  
for all the good info. It's been fun, mostly.

Are we lawyers? Are we protecting trademarks? Are we busting monopolies?  
Are we professional chemists and microbiologists? Are we professional  
brewers? I thought this forum was for HOME brewers and BEER enthusiasts.

How many recipes have been in the last 10 digests? 1? 2? Is anybody  
brewing out there? I'm tempted to start my own digest. What'll I call  
it? How about the HOME-BREWERS-WHO-DON'T-TAKE-THEMSELVES-TOO-SERIOUSLY  
digest? That should keep it under 32K!

Happy New Year! I'll drink a beer for you guys!

Rob

P.S. Send those flames via e-mail. I'm dropping this puppy right NOW!  
(Richard: Please note that you don't HAVE TO flame me. It's

just a suggestion. The phone book won't be needed, either.)

The impact of a 3" column of water on pressure is negligible. One atmosphere (14.7 psi) is a column of water ~33 feet high (Torricelli discovered atmospheric pressure when he tried to pump water higher than this in one stage), so you increased the pressure by .0076 atmosphere or .11 psi. Compare this with reports of (I recall) 15-30 psi for carbonation in kegs. I doubt it takes this much to /keep/ carbonation in a keg or bottle---does anyone around here know enough about CO2 solubility vs temperature to estimate what [partial] pressure is necessary to keep, e. g., 2 volumes of CO2 dissolved in beer at room temperature?.

This doesn't mean your beer didn't carbonate; it's a lot harder to mistake carbonation than it is to mistake low levels of alcohol. But, as several msgs have pointed out, only the excess CO2 over what dissolves comes out the fermentation lock, so all but the greenest wort has some dissolved CO2 in it; the additional effect of your .11 psi vs a typical (gueseimate) .03-.05 psi can't be much.

Date: Tue, 29 Dec 92 09:29:01 -0500  
From: zentner@ecn.purdue.edu (Mike Zentner)  
Subject: Axbridge flaming of past...

Well, I SURE hope this is brewing related enough to please the digest self-appointed police.

Last year I got one of those brew-in-a-bag axbridge deals. I looked at it and made the obligatory, "wow, this is neat," oohs and aahs (although by that time I was into partial mashing). Not being incredibly excited about brewing it, I finally got around to it so that the thing was ready by Christmas Eve. I boiled my water and used recultured Wyeast Whitbread ale. I ran the water through a wort chiller and made about 3/4 quart of yeast starter which was pitched at high krausen.

In contrast to some of the results reported here earlier on this thing, the brew actually is not bad tasting at all. And it's actually kind of neat to have this bag in my garage, constantly cold and ready for the spurious decision to have a beer (I'm not into kegging, but now I see why people like it).

Anyhow, if any of you end up with one of these things this year, it can make an OK beer as long as you don't follow the directions :-).

Date: Tue, 29 Dec 1992 09:40:59 +0600  
From: mgx@solid.ssd.ornl.gov  
Subject: random musings

Here are some random thoughts I dreamed up this holiday season:

1. Could someone who was familiar with the discussion of the importance of trub removal before primary fermentation post me a summary of the conclusions?

I remember glancing at the discussion as it was going on but not paying a whole lot of attention. If someone could point me to the HBD Issue numbers that are appropriate that would probably get me going.

2. Has anyone given any thought to modifying an Atlas (Marcato) Pasta machine to grinding grain? Having just received one for my birthday the second thought

I had was that this thing would be great for grinding grain. This machine has

6 inch wide, adjustable (in steps) rollers, is hand cranked and cheap: Around

\$35-45 in the discount stores around here. It appears that all you would have to

do is take it apart and have your friendly machinist score the rollers for you then

reassemble. Voila ... your very own adjustable roller mill for under 50 bucks!

Maybe I should market them ..... Galloway Adjustable Roller Mill .... it's gotta good ring to it ....

3. A friend of mine (Hi Darrell!) made a batch of wheat beer from 100% wheat malt,

Ireks I think, anyway has anyone tried this? Is this a real style? I can only recall

mixtures of malted wheat and barley (50/50, 60/40, etc.).

What is this stuff

gonna taste like?

4. Did anyone/everyone see the plug for Beers Across America in the December issue

of Bon Apetit? It was in the column related to wines and liquors.

Thats all from the wasteland.....

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Is lactic acid ok to put in finished beer?

Can lactic acid be used in finished beer to produce a tart flavor? Recent posts have discussed using it for dropping the ph of sparge water, and one report discussed the use of a lactobacillus to drop the overall ph of Celis White beer (the beer is subsequently pasteurized and re-innoculated

with the original yeast for bottle conditioning).

I've been thinking of both white beers and Belgian-style red/brown beers that have a fruity tartness, and it occurred to me to try adding the acid. I'd prefer this to the Papazian method for souring beer, as the latter method is less controllable and might introduce other, undesirable flavors.

I'd therefore be most grateful for any comments on the following:

- 1) Is adding lactic acid to beer at, say, bottling time a safe practice? (I'm a historian, and admit to knowing nothing about chemicals)
- 2) Is adding lactic acid likely to produce a desirable effect? If so, in what quantity?
- 3) Has anybody tried this yet? How 'bout the Papazian method?

Please send any responses to me directly by e-mail, and if there is a sufficient quantity of information I'll post the compiled results.  
Thanks  
very much for your help!

From: raudins@galt.b11.ingr.com (Glenn Raudins)  
Subject: WARNING: Supplier knows ALL!

I would like to share an experience I had with a brewing supply shop over the holidays:

I visited a supply shop in Bedford, Ohio (across from Tim Lally Chevy). Dropping by, I noticed that the proprietor didn't take notice of me entering his store. (Not normal for brewing stores in my book.) I asked if he carried his grain uncrushed. Low and behold, he became God-Emperor brewer on the spot. He told me there was no reason to crush my own. He proceeded to state that the micro-brewer that taught me to brew didn't know diddly. I won't even quote his attacks. All I can sat is that I have never felt such contempt for a member of the brewing community in my life. I noticed that he was wearing a sweatshirt that said, Society of Northeast Ohio Brewers (I believe). If he is a member of this organization, I pity the members, if not, if I were a member I would ask him not wear it any more.

The reason I relay this is that people that were with me, now, have a poor impression of brewers. I feel people like this do a large dis-service to the hobby/"way of life".

I would like to urge you not to frequent this shop but I won't. I will just pass this message along as a warning.

From: blossomf@ttown.apci.com (Karl F. Bloss)  
Subject: Good brewpubs in ????

I don't want to beat this topic into the ground, and perhaps this is already being done, but why not compile a listing of \*good\* brewpubs in the archives. Then, people can be directed there first; if the city they're looking for is not there, then go to the HBD. I had asked about Boston and Pittsburgh and received oodles of great info from people who seemed willing to give it. I had a much better time there because of it, so I don't think these posts seeking brewpub info should be abrogated entirely. (IMHO)

From: roman@tix.timeplex.com (Daniel Roman)  
Subject: Carbonation in a fermenter?

Chip Hitchcock writes:

> or bottle---does anyone around here know enough about CO2 solubility vs  
> temperature to estimate what [partial] pressure is necessary to keep,  
e.g.,  
> 2 volumes of CO2 dissolved in beer at room temperature?.

According to my handy Volumes of CO2 in beer chart (ftp'able from sierra.stanford.edu), at 60 degrees F it takes 15 PSI to give you 2 volumes of CO2. At 35 degrees F it takes 5 PSI. 2 volumes of CO2 is at the low end of carbonation. You're not going to get acceptable levels of carbonation using an airlock of any kind, you need a pressure vessel (which a glass carboy is not) with some type of gas metering device. I like the soda keg approach with a pressure gauge attached. If the pressure gets too high you can always vent some off manually. I have no idea what an adjustable pressure relief valve would cost. I've found when kegging and carbonating beer in soda kegs I don't have to worry about, I just relax and let the yeast do it's stuff without intervention. What started this thread anyway? :-)

Oh yeah, in a recent digest someone asked the relationship between volume vs weight of alcohol, the ratio is 1.25 and has little to do with beer style. Alcohol weighs the same and takes up the same volume no matter what kind of beer you put it in. :-)

From: parsons1@husc.harvard.edu  
Subject: Adjuncts

I have brewed a batch of mead to which I added two oz. ginger (steep 15 min), and the taste is imperceptible. I have more recently brewed a winter warmer with three oz. ginger (steep 1 min), and the taste is overpowering. Who can tell me how much grated ginger to add to a batch so that it tastes good?

I read Saml. Childers' piece "Every Man his own Brewer" (ca. 1650), which discusses the use of more adjuncts than any modern book I have read. He even tells you how many whole eggs to put in your barrels in order to pre-serve the beer while it is being shipped to India. His book does not, how-ever, tell you what quantity of each herb to add. Occasionally, proportions such as the 'modicum' or the 'fistful' are suggested, but that is not very helpful. Has anyone done a lot of experimenting with adjuncts? It's not too late to brew a funky porter for the spring.

Subject: more random thoughts

One more to go with the four above:

I've managed to acquire somewhat limited access to a bio lab with the associated microscopes and ph meters etc. I am curious as to what beer/wine/other fermented products should look like under 100-500 X magnification. Can I see yeast at this level? What about bacteria and other nasties? Also, what are appropriate ph's for unfermented wort and finished beer/wine/mead/etc.??? Any thoughts along these lines would be greatly appreciated.

Subject: Hot-side Aeration / Laaglander high FG experiment

My wife bought me all six episodes of the "Beer Hunter" on video tape (what a wife!). Both of us have had fun watching them especially since we are planning a trip to Bavaria this summer.

During Micheal's visit to a lambic brewery in Belgium, they showed the hot wort coming out into cooling boxes. These boxes had screens on the bottom that allowed the wort to fall through and splash about cooling the wort. The first thing that I thought of was "Wow, that's a lot of hot-side aeration". The technique runs counter to the article on aeration in the latest Zymurgy. Then again, the same brewery used wild yeasts and other loosely controlled processes.

In general after watching the Beer Hunter, I was struck by two main observations. Europeans (at least the ones in the show) appreciate their beer and beer is of an artform higher than the belching retired sports stars swilling cheap chemical slurries that are portrayed in America (or all of the beer=sex implications).

The second was that most of these brewers aren't nearly as anal about sanitation around the fermenting wort as I am. Maybe its due to the extremely high amount of yeast that must be growing in 5000 liters of beer. Guys were sticking there heads in lagering tanks, walking above open fermentation vessels, etc.

Now onto my second topic, that of my high FG with Laaglander dried malt extract.

I posted a few weeks ago about a batch that finished at 1030. Briefly, I used 8 lbs Laaglander and Wyeast 1056 (plus hops). The OG was 1063.

I was reluctant to bottle at 1030 so I have done the following with little success. (actions listed in order).

- tried several times to rouse the yeast by turning the carboy
- added a new bulged packet of Wyeast 1056 (ouch, \$4 down).
- Racked again and re-oxygenated  
(by this time, my batch turned into an experiment in high FG)
- Added yeast nutrients (hydrated in cooled boiled water)
- Add amylase enzyme (hydrated in cooled boiled water)

At this point, the SG was 1028 to 1029, so the effect of all this was negligble. Plus, 3 weeks passed from my first attempt to my last - so I wasn't rushing it.

Last night I threw in some Saaz hops to at least give a hoppy aroma to an already hoppy brew that may turn out undrinkable.

After this experiment, what is my final analysis?

- 1) I will NEVER use all dried malt extract again.
- 2) My problems may have been exacerbated by a lack of cold-side aeration. (This was my 8th extract batch and the first that did not finish correctly - and I use approximately the same technique.)
- 3) Move to all grain this winter to avoid low nutrient batches. Plus

I will then be doing full boils (lack of carmelization) and I will use a wort chiller (enabling better cold-side aeration).

Sorry to go on for so long. Many people responded to my original post about high FG asking for a summary - so here you are.

One last thing - let's stop all this useless arguing over non brewing issues. This USED to be far better than rec.crafts.brewing and its really been slipping.

From: cole%nevis6.hepnet@Lbl.Gov  
Subject: Stuck Ferment, temperature, Co2 in beer

Hello all. I thought I would describe my experience with a batch of Pumpkin ale I started in November which combines many topics under discussion recently here in the HBD. I wanted to make it for the holidays but started late because I was very busy.

Crude recipe:

2 small pumpkins (sorry no weight - roughly 6" diameter)  
2# pale malt (US 6-row)  
1# crystal malt

Pressure cooked pumpkin till mushy (8 min under full pressure I think). Step mashed with protein rest for 45 min, starch conversion step at approx 152 degrees f, 1-1/2 hours for complete conversion. Sparged.

Added water to bring total volume to approx 6 gallons, added:

5# light malt extract, boiling hops, some cinnamon, etc...

Boiled for 60 minutes, added finishing hops, chilled, racked to carboy, pitched 1/2 liter starter culture of Wyeast European ale. Final volume 5 gal. Original gravity 1.060 (+/- .002).

Lag time 8-10 hours.

24 hours after pitching the fermentation was going like gangbusters. Very little blowoff but I have never seen such an active ferment in my previous 10 batches. This activity continued for 4 days until the weekend during which I was away. Over the weekend the temperature outside dropped 30-40 degrees and the temperature inside my apartment dropped from 65-66 to 58-60 degrees. When I came home and checked the beer it looked like the yeast had flocculated en mass. There was dried yeast all over the carboy, up the blowoff tube (this for a batch that hadn't really been blowing off) and absolutely no activity whatsoever. I racked to secondary and after several days there was still no activity. I then raised my apartment thermostat to 64 degrees and after several more days saw some minimal signs of activity. The first gravity reading after racking was 1.032 and after another week and a half, the gravity had only dropped to 1.027.

At this point, I started to worry and tried adding some oak chips (boiled 20 minutes to remove the oak flavor) per the suggestion in one of the recent digests. This seemed to increase the activity, (I'm not talking about the initial precipitation of Co2 out of solution, but the activity a day after adding the oak chips), but after another week or so the gravity had only dropped to 1.022.

As a last resort, I made a starter from the dregs of three bottles of bitter I had made using the Wyeast Whitbread strain, pitched this into the ale and left for the holidays. When I returned two days ago I was gratified to see substantial activity (i.e. Co2 bubbles rising) and though I haven't yet checked the gravity, it appears that the new yeast is now finishing the ferment.

I suspect the flocculation of the yeast was caused by the drop in temperature. The fact that the second yeast addition re-started

fermentation suggests that the flocculation was so efficient that there was just not enough yeast to do the job, though this seems a little hard to believe. If I remember correctly, Whitbread is more attenuative than the European Ale, but I can't believe the European ale yeast would quit above 1.020, and certainly not slow down so much at 1.032. Given that the mash was done at a fairly low temperature, I would expect the beer to be more fermentable than average so I would expect a FG of 1.010 or so. However, I have no idea what the enzymes in malt do with pumpkin starch.

Morals: Beware of sudden temperature changes. I wonder how many of the stuck ferments reported in this digest are caused by such rapid changes in inside temp.

Watch that fermentation temps. for ale yeasts do not drop too low. I was surprised by a comment by Jack S. the other day which said that 55-58 is a typical temperature range. Maybe for lagers, but not for ale yeasts.

Beware of using Co2 bubbles to gauge activity. The addition of the oak chips seemed to indicate an increase in activity, but I bet they simply caused more of the yeast-produced co2 to come out of solution. I imagine that if I had waited long enough after racking (sans chips) the slow activity would have eventually saturated the the co2 capacity of the liquid and would have shown the same activity level as with chips.

REMEMBER that CO2 will only come out of the beer when the liquid has been saturated or when precipitated by racking, addition of hops etc...

Homebrew provides a useful source of yeast in an emergency. I feel stupid for not trying this sooner. Of course, there's the worry about contamination, but with a difficult batch, what the h\*ll.

The above morals will probably be obvious to the more experienced brewers, but hopefully they will be useful to somebody out there. I will let everyone know how this batch turns out when it's done. If it is worth it, I will post the real recipe. Sorry for the long post. Happy New Year to all.

Brian Cole

>Are we lawyers? Are we protecting trademarks? Are we busting  
>monopolies? Are we professional chemists and microbiologists?  
>Are we professional brewers? I thought this forum was for HOME  
>brewers and BEER enthusiasts. How many recipes have been in the  
>last 10 digests?

Gee, the holidays sure are hard on some people... For recipes, Rob, I would suggest that you try downloading Cat's Meow 2. I found more recipes there than I could use in a lifetime of brewing. Meanwhile, though I am a cheap sonofabitch and brew all of my batches in a Rubbermaid (c) picnic cooler, I have learned a thing or two from the "professional chemists and microbiologists" who inhabit this net. Thanks to Tom Leith and Jack Schmidling, I now know how to compute my extraction rates. The thread on sparging, passed through many hands, has been immensely helpful. Bob Jones' stout \*is\* drinkable after only a week (though I suspect it will get better) but the jury is still out on Todd Enders' "perfect brew" (which is to say I have been too lazy to figure out the PH of my sparge-water, but I did try recirculating it and the extraction rate was superior to my previous tries). And, thanks to Rob Thomas, I have begun to experiment with multiple-mashing techniques and have found that some version of this old solution may be perfect for my cheap set-up and slovenly ways. Yeah, I do not understand half of the science, but I do learn something, in my simple way (some of us know more Chinese than microbiology). Meanwhile, my guests and I have enjoyed drinking up all of my "experiments." You can't always get what you want here, but sometimes you get what you need. (Hmmm. That's catchy, I should write a Christmas song.)

You are right about Childers' posting, but don't let it drive you away. The holiday season will pass... Meanwhile, if you ever find yourself in Bloomington, Indiana, I can recommend only one place to drink. C'mon over.

- --Steve, ((sorry, no pretty pictures))

From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: pondering small-brewery tactics (it ain't that bad!)

Jacob Galley <gal2@midway.uchicago.edu> writes about "Koch's sleaze in perspective". He relates some dark tales told by a Baderbrau person, then:

> Anyway, I can imagine what a hard time the BBC is having holding what  
> ever ground they've gained in spite of the megabreweries' megastupid  
> marketing techniques (that work! -- pitiful)...

No apologies for what the large brewers do...after all, they advertise in a

way that reaches the mass market, and it's not too hard to see what works,

whether you're selling beer, burgers, perfume, or cars. Fine, but...

> ...With this in mind, I do (when in a good mood) have a quantum  
> (not more) of sympathy for Jim Koch. Sam Adams beers are a major force  
> in the current American Beer Enlightenment. In this day and age, Koch  
> would not have been as successful as he is without using pushy,  
> sleazeball Big Business strategies...

Let us agree that Koch is succeeding, but let us consider whether his techniques are really necessary.

Let's think from a different angle. What's the most successful small (non-mega) brewery, long-term? Easy: Anchor. What's the character of their advertising, and how much do they advertise? Easy again: to a first approximation, they don't advertise. Why not? They don't need to; they can't meet the demand as it is.

OK, how about another one of the long-term successes in small breweries: Sierra Nevada? Again, almost no advertising; they don't need it.

The stable of either of these is far more idiosyncratic in taste than BBC.

But hold on! If it takes major marketing to get people to buy a beer with the amount of taste in (say) Samuel Adams Boston Lager, compared to the mega-breweries (admittedly a significant difference), how can Anchor's Liberty Ale, or Sierra Nevada's Celebration possibly stand a chance of selling? Yet they do.

Hypothesis: flavor\*advertising is a constant.

Opinion: Koch may not be as bad as the megas, but he provides no model for a good micro.

- - - - -

Oh, while I'm at it...Mike Fetzner asks:

Subject: re: % alcohol by weight vs. by volume

> How do I compute %alcohol by weigh in terms of %alcohol by volume...

I'll add a second question, namely "how do I remember this on the fly, after n beers, when I'm trying to [discuss/write down] a point?"

Remember that alcohol is lighter than water. (mnemonic: alcohol will burn;

it's a lighter fluid:-) The magic number is 0.8, or 4/5: Alcohol is about

4/5 the density of water; therefore %wt is about 4/5 %vol.

So, given Mike's example of 6%wt, that would be roughly 7.5% volume.

End of HOMEBREW Digest #1044, 12/30/92

\*\*\*\*\*

-----

Date: Wed, 30 Dec 92 05:50:58 EST  
From: BOKENKAM@ucs.indiana.edu  
Subject: Ginger!

In HBD 1044, Jed (parsonsl@husc.harvard.edu) the homebrewing, harpsichording, classicist (now he would be fun to drink with!) asks:

>I have brewed a batch of mead to which I added two oz. ginger  
>(steep 15 min), and the taste is imperceptible. I have more  
>recently brewed a winter warmer with three oz. ginger (steep 1  
>min), and the taste is overpowering. Who can tell me how much  
>grated ginger to add to a batch so that it tastes good?

At last, at last! Something I know something about. I do a lot of Chinese cooking and do know my way around the rhizome of the *Zingiber officinale*: As you discovered, no measurement will be truly helpful. I suspect that you used stale ginger in the first instance and fresh in the second. You want to purchase ginger that is hard and heavy (full of moisture). The stale stuff will be wrinkled and light. Those rhizomes that seem the most fibrous where they have been cut are the hottest. If you do not plan to use it right away, wrap the ginger securely in plastic and freeze it. This stratagem is not good for some Chinese dishes, but you want the juices anyway so not to worry. When you add it to your boiling wort, thinly-cut slices should leach out in a minute or so. For five gallons of mead, I would try 2 oz. of the fresh, hot stuff for starters (but I like hot stuff) and adjust subsequent batches according to your taste.

It may be that similar considerations--i.e. the differing freshness/availability/extraction variants for each spice and herb--which lead "...his own Brewer" to resort to such imprecise measurements. Why not try a few and post your findings? Good luck.

BTW (grin), someone, I forget who, asked recently about brewpubs in Indianapolis (second in "wasteland-hood" only to ORNL). I would appreciate a cc: if anyone here has knowledge of such. Thanks.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: advice wanted re kit

A non-brewing friend has presented me with a "Superbrew Gold: Barleywine" kit by Edme. The proportions appear plausible for barleywine (1.8 kg and no added sugar to make 12 pints), although I note they actually admit using sugar and caramel in the "extract"; the instructions are the usual ridiculous (hot water to thin, then cold).

\* Has anyone tried this kit?

\* Does anyone have any suggestions for making plausible barleywine from it? I'm not even sure whether barleywine should have finishing hops, and any flavor/aroma this kit might have had is going away in a one-hour boil.

\* has anyone tried using just Edme yeast for barleywine? I can always rouse the yeast if that will help, and I'm certainly going to aerate the hell out of the cooled wort, but I don't know whether I'll need champagne yeast to finish.

\*\*\* Resending note of 11/24/92 09:03

I've recently read comments soliciting more recepies. This barleywine, which I've recently named "blind squirrel barleywine" took a first place at the California State comps at Stern grove, SF this fall, and just recently won the AHA's first-ever barleywine comp. I call it blind suqirrel because, it's the first brew I've ever done which has won anything.... which proves only that even a blind squirrel sometimes finds the achorn :)

Cheers.Jackjdsaws1@pb1.pacbell.com

\*\*\* Reply to note of 11/23/92 15:41

OK - as far as I can recall from the extensive records I've kept:)

Batch size: 5 gal.

Extract:6 lbs. Williams light austrailian syrup

5 lbs. Williams light austrailian dry

Grain: 1 lb. 10-L crystalsteeped

1 lb. 40-L crystal steeped

Hops: 3 oz Chinook pellets aa%13 (60 min)

1/2 oz CFJ-90 pellets aa%9 (5 min)

1/2 oz CFJ-90 " " (dry-hopped in 2ndary)

Water 1 tsp gypsum at start of boil

1 tsp irish moss (30 min)

Yeast: 14 g. Whitbread dry

Primary fermentation - glass for 5 days at 65'

2ndary fermentation - glass for 16 days at 65'

Bottled: June 15, 1991

Note: Wort was boiled in 4 gal. pot (3 1/2 volume) with 2 gal. water added

to primary fermenter.

| There's a light at the end of the tunnel.. |  
| If it gets any brighter, get off the tracks. |

In the last HBD was this:  
From: raudins@galt.bll.ingr.com (Glenn Raudins)  
Subject: WARNING: Supplier knows ALL!

I would like to share an experience I had with a brewing supply shop over the holidays:

I visited a supply shop in Bedford, Ohio (across from Tim Lally Chevy). Dropping by, I noticed that the proprietor didn't take notice of me entering his store. (Not normal for brewing stores in my book.) I asked if he carried his grain uncrushed. Low and behold, he became God-Emperor...

and additional details.

Glenn; you'r lucky to have escaped so easily! this guy is bad news, and if you won't advise against visiting this fellow I will. Both times I left his store so angry that I almost quit the sport "If this is what homebrewers are like..."

I know of two good suppliers in the area, one is Wines Inc, in north Akron. They have a huge selection with lots of grains and equipment. I'm sure they have an 800 number but I don't have it here.

The other guy is on the East side of Cleveland (suburban) on Mayfield road; he sells HB supplies out of his liquor store (the name is Warehouse Liquors, it's in the yellow pages), and he is the most agreeable fellow ever. Thus far he has a rather basic selection, but he will special order anything you want; I got a bag of grain for \$1 more than if I'd driven to Akron.

The other \*major\* favor this guy does for homebrewers is that he handles empty bar bottles and sells them for the deposits. I left there last time with 5 cases of 16 oz refillables for \$6. I really recommend assisting this fellow's business, since he seems to be the only source for HB supplies except for the god-king-emperor in Bedford.

... and no, I don't get a cut back

> processes.

Well, yes, spontaneous fermentation is an irreducible attribute of lambik brewing. But the cooling tun ("bac refroidissoire") you mention isn't intended to cool by splashing, per se. The idea is to maximize the surface:volume ratio as the microbiota-rich breezes play across the wort. The process really isn't as "loosely controlled" as it appears; the celebrated spider webs are there specifically to mediate the development of acetic acid character by keeping down the population of fruit flies, known acetobacter vectors. It's just a different approach. Ideally such a tun would be filled as quietly as practicable, but none of them I've seen are like that; they all just slosh it right in there. It strikes me as odd too, especially in a beer that will have years in the barrel for the effects of oxidation to come into full flower. But that's how they do it.

> In general after watching the Beer Hunter, I was struck by two main

Much as I'd like to feel that's true, Steve, I can't help recalling that something like 76% of Belgium's total production is swill the average Bud drinker wouldn't find unfamiliar ...

> above open fermentation vessels, etc.

As I recall, the lagering vessel footage was in the section on Steinbier -- good footage! In order for a biological contaminant to gain much ground during lagering, it must be hop-tolerant, alcohol-tolerant, able to operate anaerobically at temperatures just above freezing, and must have a taste for the complex sugars the yeast has left behind. I don't think they're running much of a risk, especially if they plan to pasteurize or sterile-filter the bottled beer. With the open fermentors (presumably in the British section) I assume the key is that they'll serve the beer pretty quickly, before the damage is noticeable.

M. Jackson has done a great thing for us with those tapes.

Subject: How to use flaked barley?

Happy New Year, almost!

I am gearing up to brew the Guinness Draught clone published here a few issues ago, and am wondering how to use the flaked barley. From the recipe it seems that the flaked barley is steeped with the specialty grains, but when I was at the store getting the barley, I flipped through Terry Foster's Porter book, and he says that flaked barley needs to be mashed along with some pale malt. Is this absolutely necessary? ie will it be a waste of barley to simply steep it? The specialty grains I will use are roasted barley and black patent. It is an extract recipe with John Bull light syrup.

Thanks for any and all insight.  
Dan.

Subject: Rob Winters' beginner's questions

Rob writes:

>Why d'yer think my wort didn't make it to the sg that the kit predicted?  
<Too low a temp or not enough time processing the crystal malt, perhaps?  
<Do these kits (or specific ingredients) have a shelf life that I should  
be  
<concerned with?

I think you're on the right track about the crystal; probably not enough  
time  
extracting all of its sugar. I wouldn't worry about shelf life, at least  
as  
it pertains to OG.

>Why did this batch not seem to want to ferment out? Temperature? The air  
>temp was 72degF, if my heat pump is working. Not enough oxygen at the  
start?  
>Should I have ignored the kit instructions and waited for zero acitivity?

The temperature is fine; I would suspect a lack of oxygen at the start. I  
would also have waited a bit longer but I don't think you'll have any  
bombs  
at 1.017. Just to be safe you might consider refridgerating the bottles.

>Why did my ending sg come out above the kit's prediction? Will too high  
a  
>temp processing the crystal malt result in unfermentable sugars? Was it  
>just plain not done yet?

Crystal malt is intended to add unfermentable sugars. This is related to  
your last question.

>I also have questions about storage and shelf life. How should homebrew  
be  
>stored? Is the basement floor good enough, or should it be refrigerated?

it  
>good, or is it time to wash the bottles for another batch? I didn't see  
>any mention of these issues in Papazian's book or the kits' directions.

Basement temperatures should be sufficient, but then I've never seen a  
year  
old homebrew. Mine must be crawling out of the crawl space 'cause  
they're  
usually gone in 3-4 months. I certainly wouldn't pitch those porters  
until I  
gave them a good tasting. Do you need some help?

>There seems to be some debate going on about head space at the  
>moment. I realize that excessive head space will mean excessive oxygen  
>which will tend to spoil the brew. Won't insufficient head space result  
in  
>broken bottles, because there's nothing to compress as the beer primes?

I've been told about a 1-1.5 in. head space is ideal. Too much is  
supposed to  
result is under carbonation because there is not enough sugar to fill the

space with CO2. I don't know what too little head space would do.

Hoppy New Beer!!!

Date: Tue, 31 Dec 91 10:14:18 CST  
From: kerl@cmack.b11.ingr.com (Dan Kerl)  
Subject: Oxidation of wort HBD#792

The key words here are "oxidation" versus "oxygen"

Oxidation means that some substance in the wort (usually hop oils) has chemically combined with atomic oxygen in some fashion. This process also occurs when iron rusts, wood burns or cooking oil becomes rancid. This atomic oxygen has a great affinity for electrons that are part of other molecules in the wort.

In order for the yeast cells in the wort to reproduce, oxygen must be present (so the yeast cells can 'oxidize' things in the wort as they see fit). Note that this is molecular diatomic oxygen (like the stuff you breathe). Since the oxygen is 'combined with itself', it is not combined chemically with any of the substances in the wort, just dissolved in the wort. Boiling will cause this dissolved gas to leave. Since oxygen must be present for oxidation to occur (discounting other reactive substances in the wort like chlorine), relatively little of it will show up during the actual boil.

Since oxygen is so reactive chemically, SOME of this molecular oxygen will 'break apart' to chemically combine with other substances. This process is what we call oxidation.

The rate at which most chemical reactions proceed varies exponentially with temperature. This is why it's beneficial to get the wort temperature down as quickly as possible following boiling. Introducing oxygen to the wort WHILE STILL HOT will greatly increase the levels of oxidized hop oils in the wort. It also means that there will be less molecular oxygen available for the yeast to use for their aerobic reproductive phase.

So it appears that a conflict exists. Oxygen needs to be kept away from the wort to stop oxidation of wort components. Oxygen needs to be added to the wort because the yeast cells need it to build up their population. The variable that we have control of in the process is temperature. Adding oxygen to the wort when cold accomplishes two things:

1. It exponentially reduces the chances that a molecule of the oxygen will become involved in an oxidizing reaction in the wort.
2. More molecular oxygen will stay dissolved the wort, allowing the yeast to build up a working population more quickly.

The best compromise that anyone appears to have come up with is:

- a. Keep as much oxygen as possible away from the wort while it is hot.
- b. Cool the wort as quickly as possible, still keeping oxygen away.
- c. Add oxygen (aerate) to the wort only when it reaches pitching temp.
- d. Pitch yeast as soon after this as possible.
- e. A yeast starter would probably help, since more active cells would be introduced to the wort. These would scavenge the molecular oxygen from the wort more quickly, reducing the number of molecules available to contribute to the oxidation process.

From: KENYON%MOE.ERE-NET.COM@pucc.PRINCETON.EDU  
Subject: Oxidation of hot wort?

Happy New Cheers All,

In the last few months there has been much (much) discussion about  
oxidation. I recall  
several comments to the effect that aerating the wort by turbulently  
dumping it into  
the primary while still hot (ie, just off the boil) will result in  
oxidized beer, while  
aerating cold wort will provide oxygen necessary for the yeast to make  
like androgynous  
bunny rabbits and ..... Anyways, what gives here? As the wort cools,  
does the  
oxygen come out of solution leaving the wort cold, lonely, and tainted?

As a Mechanical Engineer ("If you can't see it, it doesn't exist"), I  
could probably be  
pacified enough to fall asleep tonight if someone just tells me that PV=  
nRT, pat  
s me on  
the head and says "go play in the sandbox, now".

Serious though, I do find this a bit puzzling, so if some kind soul could  
email me a  
bit more info as to why this is so, I would muchly appreciate it!

Merry Holidays  
-Chuck-

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: oxygen timing, active starters

Hey gang, Happy New Year's!

In HBD #791, mm@lectroid.sw.stratus.com (Michael Mahler) sez:

> In Papazzian's New Joys of Homebrewing, he says that you  
> should oxinate the bijeebers outa the wort so the yeast has plenty  
> of oxidation to munch on and here y'all are saying that  
> this is really bad.

The question is WHEN is oxidation good. The answer is ONLY after the wort has been cooled and the yeast has just been pitched or is about to be pitched. AT ANY OTHER TIME, it's bad. Hot wort will oxidize readily if you splash it around and will be highly susceptible to staling later. The same with beer during or after fermentation. A stronger-flavored beer will mask the effects of oxidation, as will drinking it before it ages long enough to show the effects of oxidation (the reaction is slow at room temperature or below).

and "John Cotterill" <johnc@hprpcd.rose.hp.com> asks about yeast starters....

>About a week and a half ago, I made up a yeast starter from wort and the  
>contents of a Wyeast liquid yeast package. The fermentation of the  
>starter  
>finished 2-3 days later. It has now been over 10 days (total from  
>pitching)  
>and I still have not been able to find the time to start my brew. I  
>doubt  
>if I will be able to do it before this weekend. How long can starters  
>sit  
>around? I will put the starter in the refrig. tonight (its been in the  
>kitchen  
>at about 65 deg F). Should I make a new one for this weekend?

The Zymurgy Yeast Special Issue (Vol. 12 No. 4, 1989) has an article that basically directs you to prepare another starter, wait for that one to begin actively fermenting, and \*then\* pitch into your batch. The point of starters is to add a large amount of \*active\* yeast. If this starter goes dormant, then make another, etc., etc. It seems to me that you could increase the volume of subsequent starters so as to attain a higher cell count, which would reduce the lag time after pitching.

I don't have the issue in front of me, but if my memory serves me correctly, then I remember a series of pictures, one of a frothing Erlenmeyer flask starter with the caption "appropriate for pitching" and one of an inactive starter with the admonition to "make a new starter".

By the way, in something of a 'rebuttal' (:-) to those who advocate using your glass carboy for a starter container, I recommend these flasks for the sole reason that they are made of Pyrex [TM] and can be placed directly on your stovetop. You can therefore boil your starter solution right in the vessel it is going to ferment in. Can't get much more sterile than that! Of course, since you have to cool the wort before you add the yeast, be prepared for a lengthy cooldown; Pyrex doesn't transfer heat very well.

Yours in the Suds,

STEVE

Date: Tue, 31 Dec 91 12:59:33 PST  
From: Donald Oconnor <oconnor@chemistry.UCSC.EDU>  
Subject: St. Patricks of Texas and sign off

I received many replies regarding my posting of my wife's homebrew supply in Austin. I'm leaving for Austin in about 30 minutes so here's the info again (I won't have email there.)

St. Patrick's of Texas Brewers Supply  
12911 Staton Drive  
Austin, Texas 78725  
512-832-9045

I apologize to anyone offended by this ad. My wife had a shop here in Santa Cruz for the past 10 months and I avoided making any reference to it on the HBD. WHOOPS the zip is 78727. I regard the HBD as a source of

information so a simple statement about the location or availability of a shop or supplies is fine regardless of who posts it. I and most everyone

else only object to some of the incessant dribble such as we saw from ole'

you know who.

Anyway, my wife Lynne runs the shop out of our home. We have 3 small boys so

the business has been wonderful for her because it permits her to stay home

with the kids and do something she enjoys very much. She does do mail order

so if you are in that area of the country, just request a catalog.

I also received many reponses regarding the Dr. John 'keep this crap to yourself' business. Dr. John was a really good sport and sent an apology once he realized that Lynne O'Connor was my wife. My wife and I took no offense to his first letter because we knew he simply didn't make the connection. The statement "she promised to sleep with me if I posted this" would have been neither appropriate nor humorous if it had not been about my wife. Dr. John was simply the butt of a practical joke and he was good natured about it when he found out. So thanks to everyone who sent a personal note and Happy New Year to all.

-----

Date: Tue, 31 Dec 1991 16:11 EST  
From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: starters and lag times

I'm still a relative beginner (Batch #10 is in the fermenter now), but last night I looked over my notes, and I would like to make a few comments about lag times. The first three batches were made with dry yeast in the summer; all three took off explosively within about 3 hours. Beginning with Batch #4 and Autumn, I switched to Wyeast. I had heard that most people had 12-24 hour lags, so I was careful to always make a starter. Three times I made pint starters, three times the starter was somewhere between 1 and 2 quarts, and once, inspired by Father Barleywine, I pitched onto the dregs of a previous batch. The pint starters were made by boiling a little less than three cups water with 3-4 tablespoons of dried malt extract (DME). After accounting for boil off, I think I ended up with about a pint (U.S.), give or take some. As for the quarts, I first made a pint starter, then boiled some DME with about quart and a half of water. After boil off, I always ended up with something less than a half gallon, but more than a quart.

Although there may have been slight variations in temperatures, after pitching I would leave the fermenter at room temperature for a little while, and then move it down to a basement in the mid-60s. Also, the yeast strain was fairly balanced across conditions: American Lager (pint/quart), London Ale (pint/quart), Irish Ale (pint/dregs), and British Ale (quart only). Consequently, I believe that my results are due primarily to starter size, rather than other factors (though other factors obviously had at least some influence).

Anyway, the results are as follows: The pint starters all began active fermentation in about a day. Twelve to 18 hours for the lager yeast, and 20 to 24 hours for the two ale yeasts. These numbers are consistent with what others have reported in the HBD. The quart starters, naturally, produced active fermentation in a smaller time span. What was amazing was how much smaller. The naive guess is that with around twice as much starter, you would have half the lag time. Wrong! Exponential growth or something must be going on because in all cases I got a lag of about 3 to 5 hours. The British Ale, which I pitched last night and moved to a 62 degree basement after room temp

for one hour, had visible fermentation in under 2 hours and was blowing  
stuff  
out of the blow off hose at 2 hours and 45 minutes. What's really  
amazing is  
that the one time I pitched onto the dregs, it still took 3 hours for  
really  
active fermentation.

The upshot is this: If you're worried about long lag times, it really  
does  
pay to build up a starter to somewhere between a quarter- and a half-  
gallon.  
What's more, going much bigger probably won't make too much of a  
difference.

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: Redox, Redux

In HOMEBREW Digest #792, Michael Mahler asked:

> In Papazzian's New Joys of Homebrewing, he says that you  
> should oxinate the bijeebers outa the wort so the yeast has plenty  
> of oxidation to munch on and here y'all are saying that  
> this is really bad. [...]  
>  
> So what's the poopoo?

First let's define terms: Aeration is the dissolution of air into the wort/beer. There is one point in the brewing process where that is desirable to the point of being critical. Oxidation is a chemical change that can be aggravated by aeration. I can't think of any brewing context where it's desirable.

Generally it's a good thing to keep the air introduced into the beer to a minimum, except JUST before pitching the yeast. Yeast can operate either aerobically or anaerobically; in their aerobic phase they respire, and reproduce like crazed weasels. In their anaerobic phase they ferment. Giving them the opportunity to "jump start" their colony is one of the best things we can do toward making good beer, PROVIDED the wort is COOL, when aerated!! If it's hot, the class of compounds in the wort called melanoidins are likely to become oxidized, and as they seem to have a role in mediating the oxidation of alcohols to aldehydes, that means trouble (with a capital "T") down the road. Similarly, if you splash the beer around while bottling, that oxygen you've introduced will be available to "help out" with that same reaction, over time.

So in short, put plenty of air in the wort just before you pitch, but not at any other time.

Date: Tue, 31 Dec 91 13:19:20 PST  
From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: More on Oxidation

Thomas Manteufel writes :

>> Like many other beginning-to-intermediate brewers, I steep my  
>>crystal malt at 170F for half an hour, and then pour this through a  
strainer  
>>into the brew kettle.

To which JaH responds :

>One of the things that happens during boiling is that it drives off  
dissolved  
>oxygen. I don't think that you will get oxidation reactions to a  
significant  
>degree from pouring a partial mash through a strainer. Also since this  
is only  
>a portion of the wort any effect will be diluted.

While it's true that boiling drives off oxygen, Thomas was refering to  
oxidation occurring after steeping his grains, not boiling his wort.  
This solution wasn't boiled, and is not free of oxygen. Furthermore,  
all the splashing and pouring thru a strainer will re-introduce oxygen.  
I would encourage brewers to avoid splashing hot wort, regardless of  
whether it is the dense first runnings from an all grain mash, or a weak  
crystal malt "tea".

You may still be OK because of the dilution that Jay mentioned, but on  
the  
other hand a grain bag is a pretty small investment to make to avoid  
splashing.

Dr. Lewis @ UC Davis tells an interesting tale along these lines. It may  
not  
be entirely true, but what the hell, it makes for a good story.....

The brew kettles at AB have a pipe running vertically along their insides  
to deliver Budwort to the bottom of the kettles without splashing. A few  
years back, one of the large Japanese breweries contracted with AB to  
brew  
Bud in Japan. Much to their dismay, they found that Japanese Bud was  
coming  
out darker in color (God forbid!) than desired. The beer police in St.  
Louis  
astutely asked the Japanese brewers if they had tampered with the afore  
mentioned wort delivery pipe. It seems that in their relentless pusuit of  
streamlined production efficiency, the Japanese decided that the pipes  
made  
the kettles harder to clean, and promptly removed them. They were  
instructed  
to promptly replace them, and the infamous bland consistency was  
maintained.

Hoppy Brew Year,

Subject: In Search of Spigotry

My turn to ask one: Up until now, I've been using a lauter tun fashioned from a 29qt plastic wastebasket, a drum tap, a false bottom made from the last 1.5" of a discarded soap pail, and a jellymaker's straining cloth. It's worked just great, with only two small snags: 1) The wastebasket only lasts about a year before developing cracks around where the tap's installed, necessitating replacement, and 2) I can't find that kind of wastebasket any more. Oh well, I'd been thinking about fashioning an insulated tun, anyway. My dear wife gave me an insulated water cooler for Christmas, but I'll be DAMNED if I'll stand there holding that <CENSORED> button in for the whole sparge! Anybody have any ideas where I might find a suitable tap? The drum taps I've always used are just too big for the hole in the cooler, and enlarging that seems a dubious proposition, at best. Suggestions?

By the way, this is the "alpha test" at posting directly from my home machine, so if it comes out looking bizarre, you'll at least know why ..

> third week.

> Any ideas? Thanks.

I have seen this effect before. I think it is not related to the size of the vessel but to the amount of headspace in the vessel. I think when you fill the vessel to the neck you remove the trapped air (oxygen) used by the yeast during the first stage of fermentation. This limits the total population to a value lower than optimum and the fermentation takes longer.

This is only my opinion, I have no proof other than shining a flashlight thru the fermenting wort (glass fermenter) to gauge it's opaqueness as a measure of yeast count. Ok guys, rip this one apart! :-)

Cheers!

From: wslack!wrs@mv (Bill Slack)  
Subject: Mash tun spigots

Martin Lodahl asks about a better spigot for his mashing cooler:

The best solution I found was to go to a RV store (Winnebagos, etc.) and get a plastic tap of the right diameter. Take your old one with you. You may need to use the existing nut and washer since they tend to sell bare taps. But the one I found fits my 5 gallon Igloo and 64 quart Igloo perfectly and works fine. RV stores have lots of plastic items because they resist travel vibration better than metal in some cases.

Happy New Year everyone!

Subject: Comments on Beer Hunter Comments

As Mike Zentner as Al Korz have observed, Michael Jackson was clearly not preaching to the converted in the "Beer Hunter." For the uninitiated, particularly in the US market, the series is a great introduction to the wide variety of beer styles. It is also a nice travelogue, which is probably why he was able to get it produced and broadcast.

While I agree with some of the criticism appearing here, the "Beer Hunter" is still worth watching, and buying, I might add. Why not simply tape it? Good question, Jack. The reason is that the Discovery Channel is a commercial operation. If you want to tape the series, you have to edit out the commercials. If you're taping as you're watching, this means you have to SIT through the commercials. The first runnings (har har) of the series were post-midnight Central Time. Sitting through all the ads for 900 party lines was far worse than watching the "fluffy" parts of the series (with suitable background music from Copeland or Dvorak or whoever).

And that's not all. The Discovery Channel also falls prey to the three most miserable words -- Edited For Television. Before the series was televised, I was able to see a pre-screening courtesy of a journalist friend. When I then taped and viewed the series off Discovery (yeah, Jack, I thought of that, too), I realized that many scenes I had remembered were missing. No doubt Discovery did some editing to fit it into its half-hour time slot. I broke down, ordered the tapes, and got the scenes back. So, if you cough up the dough and buy "Beer Hunter," you can be confident in the knowledge that you'll get more footage for your bucks.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: oxidation

- > a. Keep as much oxygen as possible away from the wort while it is hot.
- > b. Cool the wort as quickly as possible, still keeping oxygen away.
- > c. Add oxygen (aerate) to the wort only when it reaches pitching temp.
- > d. Pitch yeast as soon after this as possible.
- > e. A yeast starter would probably help, since more active cells would be introduced to the wort. These would scavenge the molecular oxygen from the wort more quickly, reducing the number of molecules available to contribute to the oxidation process.

I agree with all these points (except for possibly d - I wait until I've siphoned the wort off the hot break when using a quick starting yeast - read whitbread).

- > As the wort cools, does the oxygen come out of solution leaving the wort cold, lonely, and tainted?

No, but the wort loses O<sub>2</sub> when it boils, so the wort needs to be re-oxygenated.

My question is the following: Consider the popular extract boiling setup, where you boil 3 or so gallons of wort, and then dump the whole thing (while hot) through a strainer to remove the hops and foreign particles into a funnel and finally, into a carboy with around 2 gal. of cold water in it (containing a lot of O<sub>2</sub>, unless you boiled it first). Will this oxidize the wort? Does the oxidation occur while the wort passes through the strainer and funnel, or only when the hot wort hits the surface of the water in the carboy, and foams up? Will the hot wort mixing with the cold oxygenated water oxidize the wort, or is this only a result of the inadvertent splashing that takes place? (i.e. should I boil the water in the carboy?) Should I cool the wort with a chiller down to 150F or so and then proceed as usual? Should I make 5 gal. and cool it all down to 80F?

Subject: Slug Bait

I'm posting this question for a friend:

-----  
-----

I don't make home brew, but I will readily drink any that my colleagues at work will give me. There are about a dozen people in my building that do, and most subscribe to HBD. One HBD'er, Ron Jolly, gave me some Christmas Ale that I thought was really good, but unfortunately, my wife wasted one of the bottles by putting it out in our garden of strawberry bushes to kill slugs (This was several weeks back). I had told her that she could have a LITTLE of the beer to do that with, but I meant AFTER I had drunk most of it. She took that to mean she could pop open a bottle and take some off the top, and when the bottle sat in the Fridge for a day or two, it kind of went flat.

My question is this: What is it about beer that attracts slugs, and what is it about beer that kills them?

There are no insinuations here about beer-drinkers belonging to the molluscae family, or anything. I'm just really curious. Incidentally, I have outlawed the use of home-brew for slug bait at the house now, so if my wife wants to kill slugs, I'll go get a Miller pony.

Thanks,

Gary B.

Subject: cidery beer

Help, help! Will someone come to the aid of a beginning (8 batches) extract brewer? I remember reading something about "cidery" off-flavors in beer, either probably in Papazian or in this digest, but I can't remember. Anyway, I just brewed up a batch of beer that had a decidedly cidery (can you say that?) aroma after fermentation was complete. I've never had this problem before, but I did two things differently with this batch: (1) perhaps inspired by the adventures of Father Barleywine and his disciples, I decided just for fun to re-pitch some yeast from my previous batch; (2) I didn't have the time to bottle this batch until after it had been fermenting for over a month.

So, the questions are:

- does one suspect infection to be the cause of "cider"? (In this case I would probably suspect my re-pitching to be the source and be more careful [but not worry, of course] next time if I try it again)
- does beer get "Yucky" if you let it sit too long before bottling?
- does the "cidery" aroma go away? (I went ahead and bottled, optimistically)

I'd appreciate any thoughts on my dilemma.

Jonathan

Grumpy responds to my response to Thom M...

>While it's true that boiling drives off oxygen, Thomas was refering to  
>oxidation occurring after steeping his grains, not boiling his wort.  
>This solution wasn't boiled, and is not free of oxygen. Furthermore,  
>all the splashing and pouring thru a strainer will re-introduce oxygen.  
>I would encourage brewers to avoid splashing hot wort, regardless of  
>whether it is the dense first runnings from an all grain mash, or a weak  
>crystal malt "tea".

He was doing a partial mash with grains. This preceeds the boil, so  
working  
under the assumption that the results of this partial mash get recombined  
with  
the wort and then boiled (that's how I've always done it, how bout you  
Thom??)  
then any oxygen introduced here will get boiled off...

If you don't boil the result of steeping your grains, what do you do with  
it????  
I've never heard of anyone just doing a partial mash without boiling the  
results, since this stuff never gets to 180F (typical sterilization  
temps)  
you'd run a real risk of introducing contamination if you took these  
partial  
mash results and combined them with post boil wort.

Hi folks,

This is a little early, but I'll forget it if I don't post it now. If you're not from the Milwaukee area, and don't plan to be there in April, then ignore this please.

"The first Annual International Beer Tasting will be held Saturday evening, April 4 at Mayfair Mall. A fund raiser for the Channel 10/36 Friends, the event is co-chaired by Bev Greenberg and Howard Bornstein. Beer from around the world and U.S. micro-breweries will be featured, as well as food items and live music."

This is from the FINE TUNING magazine, put out by the Milwaukee WI public television stations. They list a phone number for viewer services as 414-278-1415. If they don't know what's going on they should be able to forward you to someone who does. I am not associated with these stations (heck, I've never even been to Wisconsin :) Drinking good beer and supporting Public Television. Life can't get better than this! :)

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Melanoidins and Oxidation

There have been a couple of postings lately suggesting that hop oils were the only component in wort that is susceptible to oxidation, and therefore unhopped wort is not. Only Martin Lodahl, bless him, pointed out that wort melanoidins are vulnerable, which is consistent with the discussion of oxidation found in George Fix's book.

Well brewers, hold on to your hats because melanoidins come from malt! Yes, that's right, malty solutions can be oxidized even with no hops present. Melanoidins are a result of the chemical marriage of proteins to carbohydrates, a process usually called "carmelization". They may taste sweet, but are definitely nonfermentable. Melanoidins are formed during the kilning of malt, and are especially prevalent in crystal malts.

This is why crystal can add residual sweetness to beer. Darker beers tend to have higher melanoidin content, and are therefore more easily bruised.

For a much more detailed look at the oxidation process, see GF's book, which I believe is titled Principles\_of\_Brewing\_Science.

Cheers,  
CR

Subject: oxygenating wort

Martin Lodahl writes:

> So in short, put plenty of air in the wort just before you pitch,  
> but not at any other time.

To be pedantic, it is okay to also add oxygen after you pitch. There is a period of several hours that it is okay to introduce oxygen into the wort. However, it is somewhat tricky in that the yeast won't transition to the anaerobic phase as long as oxygen is present.

In practice, the easiest and best behavior for a homebrewer is to do as Martin says.

Subject: pale ale idea

I plan to make a pale ale soon, and i would like some advise on my all grain recipe.

I want a full-bodied, malty pale with a bit of fruityness. I have heard that some WYEAST product produces a butterscutch ester. Will this be a giid idea, .... if not which yeasts produce a fruity flavor (a la newcastle).

I have heard of using brown sugar for newcastle or bass style ales. However, will not molasses be a good way to develop that character? If so... how much molasses should i try?

Should i develop body with cara-pils, malto dextrin, or crystal? Should i use a combination of these? I immagine my hopping rate will depend on these body agents... i.e. more hops if i am using a bunch of crystal ... to balance the sweetness.

Victory malt.... said to impart a biscuit like flavor. Does this sound good for a fruity bass-like pale ale? Fruity molasses biscuits sound yummy to me.

From: abirenbo@isis.cs.du.edu (Aaron Birenboim)  
Subject: mash procedure for the picnic-cooler mash tun

After reading Russ Pencin's mash procedure inspired by Dr. Lewis, i am thinking of a new mash procedure for myself. My problem is that i sue a picnic cooler mash/lauder tun, and mashing out at 170F will be tricky, i cannot just turn up my heat source

Following is my proposed procedure, along with some questions, please let me know what you think.

~~~~~

1) Strike dry grain with enough 160F water to bring mash to 153F. Stir and let rest until conversion.

Q: if i am using a mess o adjunct (barley flakes, roast barley, wheat, malted wheat, oats...) can i really get by without a protein rest???

2) Add specialty grains

3) Mash out. I cannot just add boiling water here, since it would take too much water to bring all that mash up to 170F.

I propose to drain off a gallon or how ever much it takes of liquor, bring it to a boil, and syphon it back in to raise mash temp to 170F. I will determine the quantity by experiment.

Q: Is this a good idea? I figger that decoction mashers boil part of the mash, so maybe i can get away with boiling some liquor???

QQ: Is turbid liquor OK? I won't boil long, so i hope so. I could recycle a bit of liquor and boil only clear stuff, but that would be a pain in the butt, and carry a risk of hot wort oxidation as i pout the turbid liquor back onto the grain bed. I'd like to take this risk only at the sparge if possible.

Note: syphoning liquor with the picnic cooler mash/lauder tun is real easy. Just drain liquor through a tube in to kettle. boil. Drain another few cc's into kettle. Then lift kettle above mash-tun to syphon liquor back into tun for mash-out. very little aeriatiion danger.

3) Allow mash to sit at 170F for about 10 min.

4) Recycle wort until clear, then drain into boiler until liquor drips slowly.

5) syphon 170F water (~4 gal) into mash tun. stir vigorously. then recycle run-off until clear again.

6) drain remaining liquid from lauder tun until it starts to drip, then begin the boil.

> enlarging that seems a dubious proposition, at best. Suggestions?

I converted an insulated Igloo cooler last year and successfully hooked
up a
standard drum tap. I enlarged the hole after removing the <CENSORED>
button
tap by doing some careful reaming with a power drill. The hole is not
threaded,
so just ream it gradually until the drum tap can get through. Make sure
the fit
is tight. Tighten well, using the usual rubber washer and plastic nut.
You
can remove it, clean it, and replace it at will.

It may seem dubious -- certainly not the height of brewing geekitude --
but this
sucker has survived some 20 brews without leaking or any other problem.

Subject: keg questions

I must be getting serious about this hobby because I've decided to shell out the money for a keging system. I went back through all my old HBDs and read the stuff on keging that I had foolishly ignored the first time through. Unfortunately, I've still got a few questions, so here goes:

First, on the difference between pin-lock and ball-lock. I know that one means Coke and one means Pepsi. Other than this, is there a major difference?

Both Foxx and Alternative Beverages will supply either, and there doesn't seem to be a cost difference. Is one trickier than the other? Easier? More difficult to replace or get parts for? Better? Worse? Other than the fact that I prefer Coke to Pepsi, I don't have any basis for choosing between them.

Second, I haven't (yet) gotten a second fridge--although I've been scanning the want ads (got to have something to lager in, right?). Consequently, I'm looking towards one of those cooler gadgets that cools the beer in-line. Alt. Bev. doesn't sell them, and Foxx wants (yowch!) \$137.50 (U.S.) for a one-tapper and \$177.29 for a two-tapper. Obviously, I will be building my own. I mean, geez, it's just a cheap cooler, a tap, and something for heat transfer. My two references on on building one are a piece by Jim Carroll in the gadgets special issue of zymurgy, and an article by Teri Fahrendorf in the Fall 1991 issue. Jim uses copper, which seems to me to be easiest and cheapest, but Teri says to use stainless steel because copper will "react with beer and cause oxidation if it sits in the coils" (p. 39). Now...there will rarely be a day that I don't drink some homebrew, but certainly the beer will be sitting around overnight, and I'll be dadgummed if I'm going to clean the lines every night. OTOH, stainless steel is probably harder to work with and more expensive to boot. So what's the deal? Will the beer really react with the copper? Also, I've heard about aluminum plates or something. Is this an alternative I'm missing? What should I do?

Finally, I'm thinking of getting a counter-pressure bottle filler. Foxx sells the counter-pressure bottle filler for \$21.75, but I don't think this comes with the appropriate tubing, which is another \$12.25. Again, this sounds kind of pricey to me. In the Summer 1991 issue of zymurgy, Dan Fink has an article

about counter-pressure transfer, but this is keg-to-keg, rather than keg-to-bottle. It looks easy enough and cheap enough to build on your own, but what should I do to modify it so that it will fill bottles instead of kegs?

Well, thanks. If there's anything else you think a new kegger should know about, let me know.

later,
- --frank

Subject: o2,spree

Bob D., who came back from skiing with 100 lbs. of grain (which is better than 100 lbs. of pain), said, pedantically (?), that it is ok to add oxygen for a number of hours after pitching. In fact, there was an article in Zymurgy last year (?) that indicated that the ferment will go better if more O2 is added at about 8 hours after pitching. My guess is that at that time most of the O2 has been used up for yeast reproduction, but the colony has not yet reached its optimum number of cells. A question I have is what will happen to those cells that have already gone anaerobic? Will they go back to aerobic activity?

Ok, I finally got to go beer-hunting in Boston (btw, what are the episodes of the Beer Hunter; I seem to be missing one). Commonwealth for a bitter and a Winter Warmer. Excellent. The WW had a flavor/aroma of maple tree flowers after a spring rain (!). The closest thing to nectar-beer I've experienced. My guess is maple syrup *and* honey were used, and perhaps something like an aromatic cascade hop, ala Sierra Nevada Pale Ale. Then to the Sunset Bar and Grill. Go there. It's beer heaven. 41 taps. 200+ bottles. Anchor Xmas Ale on tap. Ginger, spices, yum. Sam Adams cream stout on tap. Coffee, chocolate, creamy, yum. Dab Alt on tap. Can you say malt? Is the only way to get that German malt flavor to use genuine German malt (Vienna?). I'd really like to try to make a similar brew. BTW, if you do go to the Sunset, watch out for the cellar Worts (and BFDers). Finished the day with Guinness and Harpoon ale at the Plough and Stars. A very successful hunt, I'd say!

> Stir and let rest until conversion.
>

That will take 13 lbs of water (over a gallon and a half) for each pound of grain. Here's the algebra.

Let g be pounds of grain at 60F
Let w be pounds of water at 160F

$$\begin{aligned}60g + 160w &= (g + w) * 153 \\60g + 160w &= 153g + 153w \\7w &= 93g \\w &= 93/7 \text{ g ie. about } 13 \frac{1}{2} \text{ pounds}\end{aligned}$$

I find that a strike temp of about 180 is good, requiring a quart of water per pound of grain.

From: bliss@csrd.uiuc.edu (Brian Bliss)
Subject: cider / bass ale

Cidery flavor is typically caused by using too much corn sugar (though I doubt that I the problem in your your case, Johnathon). It does disappear over time. A gave a friend of mine a few samples of my first batches, and hae gave some of them back to me recently (after about 8 months). They had definitely improved from cidery & cloudy to crystal clear & excellent!

Someone wanted to try a bass ale - here is a recipe for what was meant to be a stronger belgian ale, but that was back in the days when I was getting shitty extraction rate (I still am - but now I adjust for it :-), so multiply the grain weights by 2/3 to 3/4 (or 1/2, means it's too strong for bass) if you get better efficiency:

10 lb pale ale malt
3 lb munich malt
2 lb wheat malt
1 lb brown sugar
weast german ale yeast (recultured)
42 g hallerau leaf 75 min
20 g fuggle pellets 75 min
17 g hallertau leaf 45 min
14 g fuggle pellets 45 min
7 g hallertau leaf (finish)

It was a little stronger than bass, and a little hoppier until it aged a month or two. OG 1.065, GF 1.021, fermented room temp. For bass, use 1 lb brown sugar, for Old Peculiar, use 1.5-2 lb. For Belgian Ale - heck if I know.

Subject: Hangovers

Happy '92 HDers! Some of you may remember that there was a little thread a while back on hangovers and how to best minimize them (short of not over-indulging). We all know the value of water to counter dehydration. I mentioned the possible contribution of B-vitamins and the sugar fructose and a few other readers mentioned the need for potassium rich foods like bananas or tomatoes. The following is a report from LONGEVITY , Jan. 1992, pg. 16. (I admit that this magazine has alot of hokey stuff in it but occasionally something shows up which catches my attention).

Lethal Hangovers Genuine Relief (?)
(I added the "?" - Mike)

No one says a hangover is lethal, but the ills you suffer after a New Year's Eve celebration or another night on the town can make you feel like you've lopped years off your life. Now, biochemist David Blass, Ph.D., technical director of Blass AG, a New Jersey-based biotech company, believes he has invented a cure for this all too-common condition.

While one of the hangover pill's chief ingredients is an analgesic like aspirin or ibuprofen, for simple pain relief, what makes the pill more effective than plain aspirin, Blass explains, is three ingredients known to help the body cope with alcohol. One is niacinamide (part of the vitamin B complex), which helps the liver metabolize alcohol. The other two are fructose, which helps carry niacinamide to the brain, and potassium, an electrolyte that heavy drinking can flush out of the body.

.....

The article then goes on to describe a poorly controlled study in which volunteers (who got free cocktails!!) were either given the "cure" pill or a pill with less niacinamide in it. Those with Dr. Blass' pill said they felt better. One glaring ommision is any comparison to those who took no pill or subjects who took analgesic only (in various doses). Furthermore I am suspect of the objectivity of Blass AG to test a product of their own which has such obvious marketability. Furthermore, what's the point in using fructose to help "carry niacinamide to the brain" when niacinamide is needed in the liver? Nonetheless, the information was interesting and leaves me with the impression that nobody knows completely what is going on physiologically or

biochemically during a hangover.

Subject: Fermentation and surface area.

A few issues ago, Chris Shenton wondered why a brew in a full 5 gallon carboy fermented at a different rate than one in a not-full 7 gallon one.

I recall George Fox mentioning, maybe a month or so ago, that a study done in the late 1940's showed that surface area bore a significant, (I think it was significant), relationship to fermentation rate and quality. I seem to remember he said th at a larger surface area, up to a point, was a good thing. This would imply that a carboy that is not filled beyond the point where the neck begins to narrow would produce a better quality fermentation.

George, could you comment on this?

If it is true that a not-full carboy produces better fermentation, then those who believe in the blowoff method are faced with some dilemmas.

Subject: sending furrin currency

In a private communication, John DeCarlo pointed out the difficulties involved in joining CAMRA because membership payment must be done in Pounds Sterling. There are two ways to send foreign currencies in the mail. Most major banks will sell you an International Money Order in just about any popular currency, but will probably add a service charge. The easiest thing though, is to send your credit card number and a signed authorization, for example:

I authorize CAMRA to charge fourteen pounds
to my GoofyCharge account #1234567890.

Signed, Elmer Fudd

Credit cards generally get an excellent exchange rate, something to keep in mind when travelling overseas.

Anybody know of CAMRA-like organizations on the continent? I am especially interested in joining Dutch or Belgian beer societies.

Subject: Mashing questions/answers

Randy@rdr.com asked some questions in #792, which I tried to answer via e-mail. My mail bounced back today, and this was the content:

> The two books I'm referring to are Papizan's "Complete Joy of
> Homebrewing" and Dave Line's "Brewing Beers Like the Ones You Buy".

A really good source for mashing information and far more detailed technique than Papazian (for mashing) is Miller's "The Complete Handbook of Home Brewing."

I don't have a copy with me, but I'll try to answer your questions as best as I can from memory and from my two, count 'em, two all-grain batches. Of course, this is after 6 years of extract based brewing.

> 1) In Line's book, his procedure for a step mash suggests doing the
> "protein rest" or first stage at 55C (131F), but Papaizan suggests
> 50C (122F). Who's right? Does it really matter?

Miller says that a 131 F rest will tend to produce more protease enzymes, so that your larger protien molecules get broken into smaller ones. Result? Less chill haze, more mouth-feel and head retention. He also says that he never did a side-by-side 122/131 comparison, so he's not sure if the homebrewer would notice the difference. My first batch was an altbier with german 2-row, and I used 131 F. I also used Irish Moss, and the beer came out quite clear.

> 2) The recipe I'm using from Line's book (for a light pilsner, a
> Heinekin clone), he calls for 5.5 lbs of "lager malt". What kind of
> malt is this? 2-row or 6-row? Unmodified, modified, or highly
> modified?

Lager malt is a color definition only. Line was British, and in both the UK and Germany they only have 2-row, as, I believe, 6-row is a north american species. All brewing malt should be highly modified. Undermodified malt is usually a mistake. You can tell by chewing a grain. The test (according to Miller is "chewy/steely". Chewy, edible malt is well modified. Undermodified will chew like gravel. The "base" malts you'll use will usually be either "lager" malt or "pale" malt. Use the pale for english style single temp mashes, lager for everything else.

> 3) In Papaizan's book, he says that 2-row barley has a LOWER enzyme
> content than 6-row. But in my catalogue for the Home Brewery, they

> tell me that 2-row barley has HIGHER enzyme content than 6-row.
> Line's book didn't mention it. What's the deal?

Miller agrees with Papazian, though he also says that 2-row American Klages (and no, I have no idea if "Klages" is a brand-name or a subspecies) approaches the enzymatic power of 6-row. American breweries like to use 6-row because the high-enzyme content makes it easy to mash adjunct starches. Me, I use all-malt, so I never worry about enzyme content. 6-row is more difficult to crush than 2-row due to the large amount of husk material, and it makes for a more tannic/harsh taste than 2-row (according to Miller).

> 4) In the same recipe in Line's book, he calls for 14oz. of "flaked
> rice". My local home brew shop has rice extract solids. How much of
> this extract would correspond to 14oz of flaked rice? (I understand
> that the rice solids go into the boil while the flaked rice goes into
> the mash). How about using regular white rice or rice grits?

I would boil your white rice to "gelatinize" it, as these brewing books recommend, and then use it. I have no idea how much would be needed to match a Line recipe. And you'll want to add it to the mash in order to convert the starch to sugar, with whatever enzymatic barley (6-row or 2-row Klages) you've chosen.

> 5) For the second stage of the mash (the actual starch conversion),
> I've heard of times anywhere from 15 minutes to 1.5 hours. I
> understand that this can change depending on what kind of beer you
> make and what temperature you mash at, but what's a good rule of
> thumb? What's the usefulness of using tincture of iodine to test for
> starch conversion?

It varies, yes it does. The test is **very** useful, so you can determine when conversion is complete. Miller doesn't bother with the test, he just mashes for 90 minutes. I have better things to do with my time, and the test works **great**.

What, no sparging questions? That's where I've had all my questions.

Find Miller's book. I think its a great book for those who are just about to jump into mashing. Papazian is easier to read but doesn't go into as great a depth as I think one needs to understand what's happening when going all-grain. I like and use both books.

From: larryba@microsoft.com
Subject: Re: Nuevo Kegger, misc.

CR Saikley sez that melanoidins are a combination of proteins and carbo's. If that is true, then it is unlikely that the enzymes in Malt will break them down into simpler sugars. If my guess is correct, then it is moot whether you mash your specialty malts or dump them in near the end of the mash. You will still get the body and sweetness. Any comment/controversy over this? What do commercial brewers do? Anyone know?

Jay Hersh, and others, have indicated that melanoidins are a major source of the "malt" smell/taste. If that is true, and emperically it seems to be: munich and vienna malts or high kilned malts seem to have more "malt" flavor, then using Cara-Pils shouldn't really add much to the maltiness of a beer. Instead use low L crystal. Heck, crystal is really the same as cara-pils - just the degree of carmelization is modified. My most recent batch of Pale Ale had a good helping of 16L crystal (HB carastan to be exact) and it seems very nice. Sweetness and malty without that carmel taste overpowering things. I used to use a lot of 70L xtal. Now I am moving more towards low L xtal + chocolate and a little 40 or 70L for color.

For the fellow kegging: the only advantage to pin lock, that I have seen, is that every so often some 3.5gal cornelius kegs are surplused. Since I have all firestones (pin lock) I have been reluctant to pick up some small ball lock kegs. However, Foxx sells pin and ball lock nipples for both style kegs so it is really only an additional \$11 or so to convert either style to the other. Beware, however that only Firestone pin or ball lock nipples will fit on Firestone kegs and vs. However the Quick Disconnects are compatible across lines. Now, if I could get some used cornelius kegs for \$5... Another consideration: Firestones tend to be squater and shorter. Sometimes that is an issue when trying to shoehorn kegs into a refer.

Also, for the kegger - forget a counter pressure filler. What a waste of time/\$. Use a 10" piece of hose (tygon) attached to your tap. Drop the keg pressure to 3-4lb and fill away keeping the end of the tubing below the surface of the beer. If you are doing Ale, cool your keg to around 40-50f first. You can fill you bottles up in about 20sec with minimal/no foaming. It is low tech but it works very, very well. You might have to adjust the keg pressure for best results. An advantage of a little foaming is that the head space is guarenteed to have no O2.

An interesting observation: Even when I fill a bottle with well conditioned beer, storing it seems to make the carbonation even better. Anyone else notice this?

>whole thing (while hot) through a strainer to remove the hops and
>foreign particles into a funnel and finally, into a carboy with
>around 2 gal. of cold water in it (containing a lot of O2, unless
>you boiled it first). Will this oxidize the wort?

The answer here is a big yes... Chilling the wort before aerating it on
the way
into the fermenter is a key step...., this 212F post-boil wort *will*
oxidize, often causing a visible color change, as some people have noted.

In way of a little additional comment on Thom M's question about possibly
oxidizing the results of a partial mash by straining, I wanted to point
out
that many European Breweries, notably Pilsener Urquell among them, use a
system
where the sweet wort that goes from the mash tun into the boiling tank
is drained from the mash tun via a number of spigots. The brewer controls
the
flow rate out of the mash tun by the number of spigots opened. These
spigots
run the sweet wort into a trough, where it collects and then flows into
the boiling tank. I have seen this in operation. Yes the sweet wort gets
aerated here, on it's way from the mash tun to the boiling tank. PU does
a
triple decoction, so this happens 3 times, yet there wasn't a hint of
oxidation
in the fresh Pilsener Urquell.

I think perhaps too much worrying is being done here. The temperature of
post boil wort is typically 40F higher than the sparge temps Thom cited,
The rate of the oxidation reaction is temperature dependent, so I think
at the
lower temperature of sparging it is sufficiently slower that the amount
of oxidation components produced are not critical before this liquid
reaches
the boil, and of course as I had mentioned this volume is diluted into
the
full wort volume.

A couple of people had responded to me on this, so I hope this provides
both a commercial reference point as for why I don't think it's critical,
and a reasonable homebrewing reference point for my beliefs. And yes as
CR
points out none of this has to do with presence/absence of hops, I don't
think
I ever stated this, but perhaps some read this into my reply.

>Bob Devine
>[who just came back from a skiing vacation with 100 pounds of grain...]

OK Bob, I give up, how do you ski with 100 pounds of grain?? Does the grain get it's own skis?? Or is the challenge to ski while holding it??

Not really. You can sort of force a ball-lock fitting
onto the wrong spigot if you're strong enough and it's drunk
out (this is handy for artificial carbonation, but not
absolutely necessary). Since I buy my kegs used, I just went
for whatever I could get a steady supply of.

> every
> night.

You'll run out of ice, too, and you have to refill the
damned thing every night. The beer that sits inside gets too
cold, and the beer that hasn't got in yet is too warm. Here's
what I do: I store a freshly-brewed batch in five gallon kegs,
then transfer into a three gallon keg (two of which fit in
the fridge without displacing too much of the other contents)
as soon as I'm ready to dispense. The three gallon kegs are
hard to find, so I only need to have two this way. Two brews
on tap, and I didn't have to shell out (or find room) for a
dedicated fridge.

When I take some to a party, I just yank it out of the
fridge and take it along (I give each keg a shot of CO2 once
in a while to keep the pressure up, so I don't have to keep a
CO2 line hooked up all the time, even when the kegs leave the
fridge).

> Finally, I'm thinking of getting a counter-pressure bottle filler. Foxx
> sells
> the counter-pressure bottle filler for \$21.75, but I don't think this

I've got one you can have for five bucks.

The Foxx setup is junk. You could do better in your garage, and it wouldn't cost as much. DeFalco's sells one I've heard good things about (713 523-8154) but it costs more, and frankly I haven't had much use for bottles lately, so I haven't bought one.

>Should I cool the wort with a chiller down to 150F or so and then
>proceed as usual? Should I make 5 gal. and cool it all down to 80F?

You have several options (listed in order of preference, IMHO):

1. Build or buy a chiller, make 5 gallons, chill down to 80F, aerate, pitch.

Note that when you do a full boil, not only are you safer sanitation-wise, but also you get better boiling hop utilization (see the Hop issue of Zymurgy for more info on hop utilization). Also, the chiller will give you a better cold break than option 3. The down side is that you need a big kettle and you need a chiller.

2. Build or buy a chiller, pre-boil and chill 3 gallons of water, make up 2 gallons of wort, chill down to 80F, aerate both, mix, pitch.

The advantage here is you can get by with a 3.5 gallon kettle. Again, the chiller will give you a better cold break than option 3. The down side is, you need to be careful to keep two containers of 80F liquid sanitary instead of one, you need a chiller and you get less hop utilization.

3. Pre-boil and chill 4 gallons of water in the fridge, put one in the freezer 8 hours before brewing, make up 1.5 gallons of wort, gently pour the gallon from the freezer into the kettle, gently add another from the fridge (now you should be pretty close to 80F), aerate as you pour into

the fermenter, top up with cooled pre-boiled water (aerating also),
pitch.

The advantage here is you don't need a big kettle or a chiller. The
down side is worse hop utilization, you don't get much of a cold break
and you increase your chances of picking-up an infection as you increase
the number of containers you use.

I started with the "popular" method, later moved up to option 3, and then
finally switched to option 1. Each step was a significant increase in
final product quality.

Subject: Re: More on Oxidation

>>I would encourage brewers to avoid splashing hot wort, regardless of
>>whether it is the dense first runnings from an all grain mash, or a
weak
>>crystal malt "tea".

>He was doing a partial mash with grains. This precedes the boil, so
working
>under the assumption that the results of this partial mash get
recombined with
>the wort and then boiled (that's how I've always done it, how bout you
Thom??)
>then any oxygen introduced here will get boiled off...

The question seems to be how long will it take for the undesirable
oxidation
effect to take effect. If oxygen introduced to hot work immediately has
a
reaction with components of that wort than reboiling will not correct the
problem. However, if said oxidation effect take 5 to 10 minutes than
hope-
fully prompt boiling of the combined wort will drive off the oxygen before
it
oxidizes the wort.

Can anyone comment of the time it takes for these undesirable oxidation
effects.

Subject: Re: Diacetyl (aka butterscotch)

aaron asks:

>I want a full-bodied, malty pale with a bit of fruityness.
>I have heard that some WYEAST product produces a butterscotch ester.
>Will this be a giid idea, if not which yeasts produce a fruity
>flavor (a la newcastle).

The butterscotch flavor is not from an ester, but from a chemical compound called diacetyl and you are correct in that some yeasts are more prone to making diacetyl than others. According to Wyeast Labs, their London Ale yeast (#1028) has a "slight diacetyl production." Yeast produces more diacetyl when it is oxygen deficient, but too little oxygen and you could get stuck fermentation, so you need to be careful. Yeast also breaks down diacetyl, so to leave more in your beer, you can force your yeast our of suspension with finings in the secondary (Isinglass or Gelatin will work for sure and maybe even Polyclar), but again, too much and you won't have enough yeast to carbonate. Brewing is easy, but perfecting a recipe is difficult unless you are very lucky and get close the first time around.

I'll leave it to others to comment on the brown sugar, molasses (I've also read Demerara Sugar is used, which I recently found in Canada and bought 3 kg, but haven't tried yet) and various malts, since I haven't worked much with these in association with trying to duplicate Newcastle or Bass.

Subject: re: Oxidation of wort

In HOMEBREW Digest #793, kerl@cmack.bll.ingr.com (Dan Kerl) writes, in a nice discussion about wort oxidation:

>The rate at which most chemical reactions proceed varies exponentially
>with temperature.

More correctly, the rate varies exponentially with the negative of the inverse of the temperature.* Assuming that the chemical reaction involved has an activation energy of 1 electron Volt (a guesstimate; anyone know what the real number is?), then in cooling from 200 F to 70 F I calculate that the reaction rate will decrease by a factor of about *2300*. Which is a large amount! Moral of the story - cool your wort before you aerate it (and pitch immediately afterwards).

I apologize if this is too technical for this forum, but it is interesting to see how much benefit one gets from cooling the wort.

From: Robb Holmes <RHOLMES@uga.cc.uga.edu>
Subject: historical homebrew

There have been some recent items about historical homebrew recipes, and I thought this might be of interest to some. If it has been covered in the past, I apologize.

Around 1975 or 76, the first time I got interested in brewing, I bought a can of the mysterious Blue Ribbon Malt Syrup. The label invited me to write to Premier Malt Products for a recipe booklet, and I did. A few weeks later it arrived: a well-produced, four-color print job with recipes for using malt syrup in cakes, cookies, biscuits and the like, but not a word about beer. The closest thing was a back-page recipe for malt vinegar.

In another week or so, a plain brown envelope with no return address appeared in the mail. Inside were two mimeographed sheets of beer recipes.

Below is the text from one of those sheets, front and back, in approximately the original format. As much as possible, the spelling, punctuation and capitalization are as in the original. I've used the single-quote (') to represent the degree symbol from the original. I'll post the text from the other sheet later, unless there's a unanimous flame-judgment that it's of no interest to contemporary brewers.

BE YOUR OWN BREW MASTER

It's simple - It's smart - It's thrifty too!

Making home brew is an ancient art, that dates back to 6000 B.C. when the Babylonians and later the Egyptians made beer from barley. In that historic era, the brew was frequently used as a medicine with spices and certain bitter herbs added a hint of HOPS to come.

In the early days of our Country, George Washington, Samuel Adams, Thomas Jefferson, James Madison and Patric Henry and many other famous colonists brewed their own beer by the relatively crude methods available then. Today with Hop Flavored Malt Syrup on sale at many grocery stores, the process of making home brew beverage is a simple matter.

R E C I P E
1st Stage:

Dissolve 1-3/4 lbs. of sugar and the entire contents of a can of Hop Flavored Malt Syrup in 6 quarts of hot water and stir until thoroughly dissolved. Pour 14 quarts of cold water into a crock which has been scoured with ARM & HAMMER SAL SODA and rinsed thoroughly with clear water.

Add the hot solution of water, malt and sugar. The temperature of the total mixture should be about 65°F. Dissolve a cake of compressed or dehydrated yeast in a small quantity of luke warm water (about 8 oz. of 75'

water) and add to the crock. Stir thoroughly - then cover crock with a clean cloth and allow the liquid to ferment 4 or 5 days. Skim off the foam

at the end of the first and second days. The fermentation process is completed when no more gas bubbles appear.

2nd Stage:

Siphon the beer into 12 oz. bottles which have been thoroughly washed and rinsed. Before siphoning the beer place a scant 1/2 teaspoon of sugar into each clean bottle, then cap and allow to remain at a temperature of 60 to 70 degrees for about 7 to 10 days. The brew can now be cooled and consumed.

THINGS TO REMEMBER:

Cleanliness of all utensils, including bottles, siphon hose, crowns and crock is essential for good results. Wash everything in a hot solution of sal soda or everyday detergent before and after each batch. For convenience it is suggested that a 7 or 9 gallon crock be used and thereby avoid messy foaming-over.

GOOD BREWING TO YOU AND PROSIT!

- -----
and, on the back:

Many consumer failures can be averted by using a "starter."
A starter consists of:

- 1 Package or cake of yeast
- 2 oz. sugar
- 1 pint of water (room temperature - 72°F.)

Let starter stand for about 3 to 4 hours then mix into fermenting crock container (sic) 3/4 lbs. sugar, can of malt and 5 gallons of room temperature water.

- -----
the second sheet will follow in a future posting.

Subject: Mashes & Spigots

Aaron Birenboim asks about pale ales, fruitiness, what not:

I would strongly recommend steering away from sugar, etc. for a beginning brew and stick to a nice, all-malt recipe. You can arrive at the desired fruitiness by choosing a good yeast and plenty of tasty hops. If you can get British ale malt, use that, along with .5 to 1 pound of British crystal malt. Maybe toss in 2 oz. of flaked barley for a good head; you can also throw in a pound or so of CaraPils (stay away from malto dextrin; you're an all-grain brewer now!). For five gallons, you probably want to have a total of 9 pounds of malt. Try hopping with 3/4-1 oz. of high alpha early in the boil and throw in something tasty (1 oz or so) like Fuggles, Goldings, Willamettes or Cascades at the end of the boil. Save the molasses and brown sugar and whatnot for experiments; same, IMO, for toasted malts in a pale ale. The WYeast British ale has a very nice fruity quality; the American Ale (aka Chico, aka Sierra Nevada) is clean and crisp.

With a camp cooler, it's not really necessary to raise the mash temperature to 165F; since the bed hasn't been disturbed since strike temperature was reached, you don't need to have a lauter rest; just run your sparge temperature at 170 and you shouldn't have any trouble with the mash breaking down your dextrins. You can also try something along the lines of George Fix's suggestions and add the crystal and dextrine malt at the strike temperature rest (if you're using British ale malt, though, you don't even need any protein rest: just go in at 150-156 and hold it until the iodine test sez to sparge).

On spigots: my camp cooler mash tun has a copper tube that protrudes from the grain bed and out through the cooler drain hole; it fits very snugly and doesn't leak. On the outside, a plastic hose fits snugly on the copper and a simple plastic valve controls the flow. Purty simple.

On slugs: Here in Orygon we feed our slugs beer to make 'em big and tuff. Anyway, I put out some Imperial stout to protect the tomatoes; as far as I can tell, the slugs ate the plants and washed them down with the stout.

On oxygen: Y'know, I'm just as careful as the next guy, and just as skeptical of people who say several hundred years of brewing knowledge is irrelevant and too much work. But... I really think there's entirely too much hysteria here about oxydizing wort. The only damaged beers I've encountered have been clearly attributable to mishandling at racking and bottling. Some British breweries *deliberately* oxygenate the hot wort to darken the beer. So let's stop worrying new brewers about oxygen in the sparge water and what all. Really. If you've got a problem with you beer, then starting backtracking and checking everything out. Otherwise, give yourself a break!

Jonathan Knight: Cidery beer is virtually always a result of there being too much sugar (as opposed to malt) in the beer recipe. It's not impossible that your problem is related to repitching; it's not the repitching that's the problem, though, but some failure in your procedure. When the beer is

ready to drink, you can better judge the problem. Lots of times
unfinished
beer can seem a little weird; when the final product is tasted, you may
well forget there was ever a problem.

Subject: Lurking no more...

Greetings Homebrewers,

Although I have been an avid reader of the HBD and R.C.B for a long time, I have not yet used up my share of bandwidth. With 5 extract and 7 all grain batches of homebrew under my belt I feel that it's time I released a video. :-)

Seriously, I have some thoughts to share and some questions to ask. Some background/credibility: I'm a grad student in phys. chem. (4th and last year) who has adopted Dave Miller's book as canon in my kitchen brew house. So I use a stepped infusion mash and sparge in the double 5 gal. bucket Miller describes. Since switching to all grain I can't imagine going back to extract due to the amazing improvement in my beer(YMMV). People who have a bad preconception of "homebrew" due to past tastes have been amazed at the all grain brews I've fed them. This leads to my first question. In a recent tasting at the Heart of the Valley Homebrewers club meeting I was able to correctly identify via blind tasting all the extract brews. What was I tasting; it's something I describe as a "tang". There was no difference in the brewers relative experience as a function of brewing method.

Next question is concerning adjuncts in all grain brewing. The local food coop here in Corvallis has in bulk flaked oats, rye, and wheat. These flaked grains have the same appearance as the flaked barley I used in my dry stout but are less than half the cost. Does the identifier 'flaked' imply that the starch in the grain has been gelatinized or do I have to pre-cook them before adding them to the mash? Also concerning whole grains, do I have to pre-cook unmalted, crushed wheat and rye before mashing.

On the last trip down from Seattle (post New Years, very blurry) my wife and I stopped off at Hart Brewing in Kalama, WA. Had a 1/2 hour tour hosted by the head brewer, Clay Birebom(sp?) none other than the Barleywine class winner at the Nat. HB contest the same year that Darryl Richman won. The Pyramid Ales brewed there are quite good IMHO and are worth a taste if you're in the PNW. Well I think I've taken up enough space, thank's in advance for any and all help. P.S. Any Willamette Valley HBDers or even those east of the Cascades (Florian) give me a yell if you're in the area.

Subject: Pressure cooker...

Well, I finally broke down, did the necessary homework, and bought a pressure cooker. This will make preparing bulk yeast starters easier, and will be VERY handy when I start to culture yeast. The wife also has some designs on it 8')

In case you are interested...It is a Presto 22 Quart Pressure Canner and Cooker Number 0178004 (Service Merchandise number 01780NP). It cost me \$79.97, which I consider amazing, since this is capable of holding seven quart Mason jars at a time. The two Quart "pot roast on the stove" model was the same price. I found mine in Nashua, NH, but it appears to be a standard SM item.

So - one more reason to spend money and buy more equipment for the ultimate hobby. I am doing up some starters now, and will have a porter in the carboy before you can say "undisciplined wastrel".

Cheers...Gary

Subject: Klages, Beer Hunter

To: Homebrew Digest
Fm: Jack Schmidling

Subj: Klages Conversion

There has been a lot of discussion on the virtues of Klages malt and the following is my experience with my first Klages batch, mashed this weekend.

My previous 7, all-grain brews have been made with 6 row and two different two row, barley types. I have used everything from the most complicated, partial decoction to straight infusion. The iodine test has always indicated incomplete conversion and I concluded that, as long as the beer is good and the yield is acceptable, I would just not worry about the iodine test.

This weekend I brewed up a batch using Klages from Minnesota Malting (.55/lb) and using a two step infusion, I achieved a neutral iodine test after 60 min at 155 degs. I did not test it before the hour, so I have no idea when conversion was complete.

The process was 9 lbs malt and 4 gal doughin at 110 degs, followed by 60 min at 155 and 15 min at 175.

This is of course, anecdotal and a sample of one but all science has to start somewhere.

From: stevie@spss.com
Subject: Comments on Beer Hunter Comments

>Why not simply tape it? Good question, Jack. The reason is that the Discovery Channel is a commercial operation. If you want to tape the series, you have to edit out the commercials.

That is a mighty strange bit of logic. The vast majority of the taping I do is so that I can zipp through the commercials later and not have to put up with them.

> If you're taping as you're watching, this means you have to SIT through the commercials.

I am utterly baffled as to why anyone would do that unless one were a pirate and selling copies.

> The first runnings (har har) of the series were post-midnight
Central Time. Sitting through all the ads for 900 party lines was far
worse
than watching the "fluffy" parts of the series (with suitable background
music
from Copeland or Dvorak or whoever).

I thought that was the reason someone invented VCR's.

> I broke down, ordered the tapes, and got the scenes back. So, if you
cough
up the dough and buy "Beer Hunter," you can be confident in the
knowledge
that you'll get more footage for your bucks.

Far be it for me to suggest that people stop buying video tapes but I
could
never understand why people buy stuff that is broadcast and free. If
nothing
else, the broadcast quality and first generation copy is/can be, far
superior
to the copy you would purchase.

From: "Dr. Full-Time" <enders@plains.NoDak.edu>
Subject: Starters and thoughts on bittering hops

With all the talk about when to pitch starters, I'd like to add my own data point to the discussion. What I almost always do is pitch the slurry after the starter has fermented out (or almost so). While it is true that the dormant yeast cells have to wake up and start reproducing, I feel the sheer number of cells you dump into the wort wins out here. Fermentation is usually up and running within 6-8 hours (from a 500 ml starter). Also, I can taste the "beer" I decant from the starter, giving me a check on the health of the starter (one less thing to worry about :-).

However, I do feel that exactly when to pitch depends somewhat on the yeast strain involved. Vigorous yeasts like Whitbread can stand up to waiting till the starter ferments out. On the other hand, Sierra Nevada (cultured from the bottle) seems to be a little slow getting started again. My most recent batch (01/01/91) pitched with SN took about 16 hours to get up and running, so the pitch at high krausen crowd may have something here.

Another thought I had whilst brewing this last batch: Is there **really** any difference in which variety you use for bittering hops? I mean, after 45-60 minutes in the boil, I doubt there are many aromatic compounds left, and as for flavour, I can't say for sure, but it seems to me that it doesn't make a bit of difference. What I've been doing is using whatever medium to high alpha hop I have on hand. Also, it seems to be a waste of good Halertauer, Tetnanger, Saaz, etc., to use them for bittering. Then again, I suppose you **could** taste the difference if you used 3 oz. of 3% alpha Halertauer for bittering :-)! What say, folks?

From: zentner@ecn.purdue.edu (Mike Zentner)
Subject: cleaning copper tubing

Back when this came about, I think I was the main advocate of cleaning. My batch of tubing had a pretty bad case of "grease" inside, to the point where, when I let water (cold or hot) drain out of it, the leaving the last few drops to fall on the counter. Silvery specs appeared to be floating on these water drops, but this was really small pools of grease/oil. So, to tell how much, if at all, your tubing needs cleaning, take a Q-tip dipped in propanol or ethanol and stick it in the end of your tubing, swishing it around. If it comes out black, then you know you've got more than copper on the worst side of your tubing.

Here's the bad news...If you've already built your chiller, it will be very difficult to clean. Here's a list of things I tried running through mine (a list of things that did not complete the job): many flushes with cold and boiling water (more than 10) combined with dishsoap, then bleach, alcohol, and, in desperation, Lysol. No amount of running anything through it would stop the grease "particulates" from dropping out. The Q-tip still came out black (have to stick it in a little farther each time you test).

Finally, I took the thing out in the back yard, uncoiled it, and with much work and undiluted dishsoap, I was able to snake a stiff wire through all 30 or so feet of it (coming from both ends and hooking in the middle eventually). All the scraping, twisting, and pushing the wire combined with the dishsoap really loosened a tube full of black gunk. To one end of the wire, I hooked a very strong string and pulled it through. To wash out the soap, I hooked the whole thing to a garden hose and ran water through for a while. Then, to get the last of the crud out, I hooked cotton balls on the string, soaked them in alcohol, and pulled them through. At the other end of the tube, I replaced the cotton and worked my way back and forth several more times. It was finally clean!

Anyhow, the lesson learned was to clean the tubing BEFORE you use it if it is dirty, because no amount of rinsing will get the stuff off completely, just like your dishes don't wash themselves without either severe agitation by your hands or a water jet (which you can't produce inside of tubing).

What to use for sanitizers? Try an experiment. Cut off 1 inch pieces of tubing and soak each of them in 1 of your proposed sanitizers, using one in plain water as a control. When I did this with water, bleach, and B-Brite, I came to the conclusion that plain water caused the least deterioration. I usually boil 2 gallons worth of water to run through the chiller prior to the wort, and this seems to have worked fine so far (run the boiling water through before you've filled the other side of the chiller with cooling water). Of course, should anyone use this method, it's important to note that when you're done brewing for the night or day, you're not done until you run lots of hot water through the chiller to get out any remaining sugars, and then work it around in a circle to drain it and prevent mold.

Sorry for the length, but this was a real pain when it happened to me and if it can save someone else the aggravation, I think it's worth it. Granted, the fouling of my tubing may have been a

severe case, but it is very worth checking.

Subject: homebrew in Sweden

I'm not sure about Sweden, but in Norway (when I was there 12 years ago, anyway), it was definitely illegal to brew your own. Not that this stopped people from doing it (although more of the people I knew distilled their own, also illegal), but I would be surprised if there were good sources of HB supplies and equipment to be found. I do remember ads in the subway for a malt extract that said (in translation) "It is forbidden to brew beer from [brand] malt extract." Sort of like the situation here during prohibition. ("If you were to take this can of malt extract, mix it with so much water and sugar and add yeast, you would get an illegal beverage. So don't do it.")

Hi HBDers - Dave asked about cleaning up after boiloers:

to clean up old boiloer stuff, you can wet it down, sprinkle baking soda thickly on it to make a paste, and let it sit (making the water you wet it with as hot as possible helps). You should be able to just wipe it off, if you let it sit about 30 minutes. You may need to do it more than once if the stuff is really crusted on. This also works well on barbeque grills and oven spills.

>into the boiling tank is drained from the mash tun via a number
>of spigots.

This arrangement of spigots is called a "grant". Anchor uses one in their system. I once inquired as to the reason for this step in the brewing and was told by the brewer on duty (Mike Lee, if I remember correctly) that it was "traditional, it came with the brewery" and he knew of no specific advantage to it. Nor was he aware of any problem with oxidation. He also told me it could be by-passed and was when they made Old Foghorn. I'll be over there later this week and ask again.

Subject: Is boiling (water) really n

Is boiling (water) really necessary?
In HbD#795 (Subject: Re: oxidation) Al Korz <korz@ihlpl.att.com> implies that any cold water that is to be combined with bitter wort in the fermenter should be boiled. Is this really necessary, or will plain old tap water do?

I can think of only a couple reasons why it would be a must.

1 - Your water is from a shallow well and rich in microflora. In this case I wouldn't even want to drink it, never mind brew with it. In this case boiling has an obvious advantage.

2 - Your water is high in temporary hardness. Boiling the water would remove some of the minerals that might give your brew an off-flavor.

3 - Your water is chlorinated or flourinated beyond an acceptable level (whatever that may be.) In this case boiling would drive off these ions.

Now if your water does not fall into one of these three categories, I would say that boiling is a waste of time and energy. Please let me know if anyone has an other viewpoint. (like nobody does?, Right!;-)

From: "Knight,Jonathan" <KNIGHTJ%GRIN1.bitnet@CUNYVM.CUNY.EDU>
Subject: an in-cider's view

Many thanks to those who responded to me via e-mail and in "print" about my problem with off-flavor. I have concluded that the cideriness of my beer is due to the fact that, having been too lazy/broke to pick up a carboy for secondary fermentation, I've been single-stage brewing in my beginner's bucket, and THAT's where the beer sat for a month. (Obviously there's a moral to be drawn here for the beginner, or maybe several)

Interestingly, enough, I finally went out and picked up a carboy just before I sat down to read my mail. At any rate, assuming this is a correct analysis of my problem, it shouldn't trouble me again since I use only extract, and yeast hasn't been a problem for me. And,

I'm VERY glad to hear that the odor will probably go away after long enough in the bottle. See - you really shouldn't worry, right?

Subject: Re: altbier

>We may have to finish it off with some champagne yeast. It's probably
>worth trying, since the beer is still very sweet but has a good taste.

I can't see that yeast nutrient, as Ken suggested, could do anything for
this all-malt brew.

I observe that this same thing happened when we brewed the hi-test
Christmas ale at Ken's. That started at 1.090 or 1.080, I forget, but is
the closest thing to this batch at 1.078. Perhaps this slow fermentation
is simply a characteristic of high-gravity ales.

Options:

- 1) We could throw in some yeast nutrient. Can't hurt.
- 2) We could pitch some liquid yeast; Wyeast 1007 German ale, which has
proven itself up to the high-gravity Christmas ale. Perhaps the
dry yeasts aren't sufficiently alcohol-tolerant.
- 3) We could do nothing for a couple of weeks and see if the gravity
changes.
- 4) We could rouse the yeast cake. I'm dubious, because this risks
infection and oxidation, plus there's not that much cake to rouse.

I suggest #3. It's the easiest.

Modern american 2 row is almost equivalent to traditional 6-row in enzymatic power.

Most american lager malts are fully modified. English malts are over-modified. Continental malts, i believe, are under modified. The protein rest is needed mainly for the latter. I do protein rests with Klages mainly as a sort of dough-in. I like seeing 15 min conversion when I step to 155. If you are adding a lot of unmalted barley or oats (for a stout) then a protein rest might be needed. I have made perfectly fine stouts w/o the protein rest and they cleared just fine.

Conversion rates are dependent upon temp and calcium/pH. Apparently you can fiddle with these variables to get differing rates of extract and various qualities of the beer. High efficiency doesn't always equate to high quality. I usually go for efficiency. In short, about a gram of gypsum/gal of water (assuming you carbonate levels are low) should make for rip-snorting conversions. I believe a tbls is about 5 grams.

Rice syrup would be the converted rice (starch -> sugar). Since you can expect to get around .030 pt/lb/gal from flaked rice and around .040pt/lb/gal from syrup, i would guess that 10-11oz of syrup would be equivalent to 14oz of flakes. Cooked, mashed rice added to the mash would be equivalent to using flaked rice. Flaked anything is pre-cooked by passing the grain through heated rollers. You need to pre-cook it to gelatinze the starch (make it soluble in water). Malted grain is a little different in that the growing plant releases enzymes that break down the kernel structures and release the starch.

I was pretty nervous when I did my first all grain beer. Don't. Things are much more flexible than most authors will imply. You may not get the exact same beer they did, but you will still be pleased with your results.

Oh, use iodine. Why piss away an extra hour if everything is done in 20 minutes? Do the starch test just after the step to see what a positive reaction looks like. After conversion there should be little or no color change (no black granules). You might get a few if you let it sit around - that is the iodine reacting with the cellulose particles from the husks. An hour at 155 is roughly 2x overkill in my experience if you have sufficient calcium (above). Another test is to simply taste your wort every 10 minutes or so. When it is very sweet and smooth, you are done.

Cheers!

point
>where the neck begins to narrow would produce a better quality
>fermentation.

Could it be the height-to-cross-sectional area aspect ratio and not
necessarily the surface area? Maybe it has something to do with the
depth
of the fermenting wort? The extreme example of this is Samuel Smith's
Old
Tadcaster Brewery, which uses very squat, long and wide fermenters
made from slate. They use open fermentation. I've read that this
configuration is used to create a large amount of diacetyl, which is what
they want. However, I don't think the diacetyl production is an issue
here.

>George, could you comment on this?

Yes. George wrote:

> 1.Geometry- In the late 1940's deClerck studied fermenter shapes and
>concluded (for a long list of reasons) that it is desirable that the

its
>depth.

What are some of the "long list of reasons" that deClerck suggests
are most important, George? Where can I get a copy of deClerck's
book? I've read its out of print.

>If it is true that a not-full carboy produces better fermentation, then
>those who believe in the blowoff method are faced with some dilemas.

Having been a long-standing proponent of the blow-off method, I obviously
have a vested interest in deClerck's findings and Dan's suggestion of a
dilema. On the other hand, I'm very happy with the flavor of my beers
and
their fermentation times are reasonable, so why worry? I don't use a
starter for my Wyeast, get active fermentation in 12 to 36 hours,
depending
on the yeast type, and have not had an infection in over four years (some
beers sitting in the fridge, on-tap for over 9 months - no problem). The
last infection I had, I could safely attribute to the dry yeast I used
back
then. My challenge still stands: if you think blow-off is a waste, I
dare you to drink a glass of blow-off. I hope this doesn't sound too

antagonistic. I don't mean it to. It's a friendly challenge and I'm always open to be proved wrong, as long as I learn something in the process.
Comments?

Subject: racking

Greetings,

I am new to brewing and could use some guidance regarding racking. I have read two books so far to help me in my extract endeavours. Millers is relatively rack-happy compared to Papazians (those are the two big two books in my library).

Specifically, how important is it to rack your beer off the trub during primary fermentation as advocated by miller? what are the dangers besides infection?

When exactly should you rack to a secondary fermenter and why?

Thanks,

-Alan

Subject: Casks

A while back, someone (sorry) asked about what kind of cask they should buy: plain, charred or paraffin-coated. Yesterday, while studying for the BJCP exam next Sunday, I ran across what the Prazdroj Brewery uses to make Pilsner Urquell. According to Jackson in "The New World Guide to Beer," they use "pitch-coated oak fermentors" which are periodically sent back to the coopers for re-pitching when it becomes necessary. There's a bit more detail, but this is all I can remember now. Jackson's Beer Hunter video shows the coopers at work. I don't believe the voice-over gave any detail in the video, or recall how much could be learned from watching the coopers, but I wouldn't completely rule it out.

Now, what can we learn from this? Apparently, the oak does not make significant contact with the Pilsner Urquell, so all of you adding oak chips to your Pils, may want to reconsider. Pitch-coated was not one of your options, but you may be able, with sufficient research (call some coopers), to coat the casks yourself.

Just one correction. It's incorrect to say "tend to produce more
protease enzymes." All the enzymes you will ever get to use are in the
grain when you begin. You can add enzymes you purchase separately. I'm
sure what you meant was something on the order of "activate."

According to Papazian's New CJoHB, at temperatures ideally between 113F
and 122F, one type of proteolytic enzyme cuts long proteins in to amino
acids, which can subsequently be used by your yeast. Between 122F and
140F, other proteolytic enzymes break the long proteins into shorter
proteins (I'm borrowing from Miller on this) which contribute, as Josh
said, to mouth-feel and head-retention. If you leave the long proteins
around, that will contribute to chill haze, which is partly why you would
like to cut them up.

>> 2) The recipe I'm using from Line's book (for a light pilsner, a

Undermodified
>will chew like gravel. The "base" malts you'll use will usually be
either
>"lager" malt or "pale" malt. Use the pale for english style single temp
>mashes, lager for everything else.

I disagree again. Brewing malt can be 2-row or 6-row AND highly-
modified
or under-modified. Lager malt is less-modified than British pale malt.
Undermodified malt has more starch available for conversion to sugars
and more complex (long) proteins, but less amino acids. It requires a
protein rest. Fully-modified malt, aka, British pale malt, has less

starch available for conversion to sugars, less complex proteins and more amino acids. With pale malt, you can skip the protein rest and do a simple infusion mash.

In the rest of Josh's post, I concur, but also cannot provide a documented conversion rate from "flaked rice" to "gelatinized white rice." Papazian, however says that flaked rice is simply "moistened" and "passed through rollers" which gelatinizes them. Later, he says that white rice needs to be cooked at least 30 minutes to gelatinize. Based on this, I would intuitively say that you should substitute 1:1 dry white rice to flaked rice and then make sure to gelatinize it before adding to the mash.

>get the slurry off the bottom when pitching is not a very good idea.

I have to agree, but not for the reason you state, Bryan. The amount of dissolved CO2 in wort at high krauesen is not very great, not compared to finished beer, at least. But dissolved CO2 really is immaterial when pitching your starter. The reason I feel that you shouldn't shake your starter (if it's really at high krauesen) is because the slurry is trub (hot break, cold break and dead yeast). If you've waited too long and high krauesen is over, then your slurry contains some dormant yeast but intuitively, I feel not enough to bother with -- again don't shake. If you've waited *way* too long, and your starter has cleared, then shake it up, and pour it into a new starter. At high krauesen, there's nothing you really want in the slurry -- what you want is either on top or in suspension.

!!
!!!!!!!!!!!!

I would like to thank Bob Jones for posting the recipe for his holiday ale. I have drank several bottles of the stuff and it is great! There is one problem, Bob's water is very, very soft and if your brewing water has even moderate calcium hardness you should back off on the amount of hops that you use. nuff said

On the subject of bottle fillers. It has been my experience over many years of homebrewing that what works best is counter-pressure bottle filling from kegs. The C-P fillers make it possible to purge the empty bottle of normal atmosphere and pressure it with either CO2 or nitrogen. Doing this can eliminate a lot of worry about oxydation. There are several adds in zymurgy's classifieds for counter-pressure bottle fillers at reasonable prices. I have one of the HIGH TECH bottlers it cost 49.95 and is by far the cleanest and easiest to use C-P filler I've seen.

I am in the process of converting my draft beer system at home to nitrogen /CO2 from straight CO2. The mix is 85/15 this is a standard gas mix available from welding supply places. The advantage in this is the your beer will not absorb the nitrogen as it would the CO2 possibly altering the mouthfeel and flavour/bouquet profile of your beer.

I have come up with a device that will make a soda keg beheive like the new guinness cans. It is very simple ,easy to install and remove and you can make it your self. Cost is about 3-5 bucks worth of SS and 15 minutes on a lathe (or bribe a machinist, they usually take beer). If anyone is interested Email Bob Jones and I will give him a DXF file with a nice drawing on it. Most any CAD system should be able decipher the DXF for you. Plus they are easy to transmit (I think?).

A bit of info for those of you who subscribe to Zymurgy mag. and do not recieve the Beverage People news from GFSR. It seems that the special issue on beer styles has some errors(besides Paddy Giffens picture). The munich helles article contains some gross mis-information. Byron Burch claims to have written and submitted it as a sort of joke, after mailing it in he says that he called the AHA editor to inform them of the nature of the article in question. But many months later it appeared in the '91 special issue, errors and all, and the best part is the author credited is CP. So read this article about helles for its humorous value and not its brewing advice.

SOUR MASH

I've had great success with sour mash beers. I have used several different yeasts with the sour mash including Chico ale yeast, Chimay reculture, and S. Delbruki they all worked great. I haven't tried a lager yeast yet but am planning to make one. So as to be useful I'll describe my mashing (sour) technique.

First I'll explain, I do my sour mashes as two separate mashes, one soured and one straight. The sour mash is 80% wheat the rest 2-row klages. This is mashed in with 32 oz. water per pound of grain, strike temp. is 180F this should be stable at 158-160F. I do this part of the mash in a picnic cooler with some duct tape around the lid to minimize heat loss. I start the mash the evening of the day before I intend to brew. The mash time is usually 12 to 14 hours.

On brew day I do a normal straight infusion mash with a high percentage of 2-row klages usually a one hour mash.

And now to the good part! Go, and open the lid of the cooler that has the 14 hour old mash in it. If the smell makes you want to vomit, it is done and its OK (the colour may be a little grey too). Take the soured mash and the straight mash and mix them together in your lauter vessel. Then do a mash out at 170F and hold it for 15 min. Sparge your brew length, then boil down to size and gravity desired. Hop as you wish. If you ferment in clear glass the wort may appear somewhat grey in colour, this will clear by itself. I've made high, medium, and low gravity beers with method and they have all turned out pale, clear and very tasty. The flavour is difficult to describe but as digusting as the process is the resulting beer taste is well worth it.

Note: I also have done a alcohol removed sour mash spiced with coriander and CFJ90 hops as my contribution to responsible yet flavourful drinking. If anyone wants the recipe let me know.

AND SOUR MASHING IS NOT A PART OF LAMBIC BREWING (to avoid confusion)

From: Tom Bower <bower@hprnlme1.rose.hp.com>
Subject: Mash/Lauter Tun Construction

Being more of an ale than a lager fan, and wishing to enter the ranks of all-grain homebrewers, I've been trying to accumulate the necessary equip-ment to do single-temperature infusion mashes (and sparges) in an insulated container.

I'd like to hear from the net on mash/lauter tun construction. Assuming some kind of picnic/water cooler to be adapted for this use, I've got some questions:

+Which shape works better (and why?) - Cylindrical (water jug) or rectangular? What size works well assuming perhaps some barleywines as worst-case mash quantities, 5-gallon recipes in general? Any other good things to use besides insulated ice chests & water coolers?

+What is the ideal arrangement for straining out the runnings? I've heard people describe slotted copper tubing, plastic bucket-bottoms with holes drilled or slots melted through with a hot knife, with or without the use of grain bags. If I could construct the ideal false bottom, what would the average size and geometry of the openings be, and what % of open area overall would there be? I'm thinking of getting some stainless steel screen/mesh. What are the consequences of the openings being too small? Too large? Too infrequent? How about the amount of space under the false bottom? Is there a type of construction that makes a grain bag unnecessary, or would it just be easier to make an over-permeable false bottom and rely on the grain bag for the straining effect?

What say ye? Feel free to reply here or via e-mail, if there's interest I will summarize & post.

Subject: Spargin blues.....

Awhile ago I surveyed the all-grain brewers. The purpose of this survey was to determine why 'you brew the way you brew'. The results, (posted), ran the gamut from mysticism to economic necessity. Agreement was nearly unanimous, however, that the final brew tasted better. Thus I was motivated to invest in the equipment and give it a try.

After about 7 batches, a few observations.....

I like it. It's fun. I think the beer is tastier. I doubt I'll go back. I bought 55 lbs. of Munton and Fison 2-row pale for \$.65/lb. For less than \$10.00 one can make 5 gals of top quality all malt brew. Neat !

I try and do things simple. I use a single temp infusion mash with a cooler. I boil in a 33 qt porcelain on junk metal boiler. Wort chiller is a coil of 1/4 i.d. copper tubing inside my cooler filled with snow (when available)

Things usually go fine, with one possible exception..... Yeah you guessed... Sparging is the downside of all-grain brewing. I can usually get a decently clear flow, and decent extract rate, but it's a pain, and this leads to a question.

Why not just drain the sweet liquid from the mashing vessel, through a couple layers of cheesecloth, and into the boiler..... once. No recycling! Then run the necessary amount of 170-180 F water through the same grain bed and cheesecloth, (again just once), to make 6 gals.... and be done with it. It'd take minutes, rather than 1-2 hours.

I'll probably try this anyway in my next batch (call it an experiment) but I'd be truly interested in the opinion of the HBD'rs. Has anyone tried this, or something similar? Would you expect the grain bed to be a better filter bed? Would you expect the extract rate to suffer?

I have tried both a 'double bucket' and a grain bag approach to sparging. I like the grain bag better, but mine (I guess) is too fine, and get's clogged. I find the double bucket too time consuming and I don't like the extra items to clean. Am still waiting for a better sparging system

Jim White

The new auxiliary Wort chiller arrived on New Year's Day, but so far....
it's
bust. When I needed it cold, it was about 40 F and raining.

> That will take 13 lbs of water (over a gallon and a half) for each
> pound of grain. Here's the algebra.

> Let g be pounds of grain at 60F
> Let w be pounds of water at 160F

> $60g + 160w = (g + w) * 153$
> $60g + 160w = 153g + 153w$
> $7w = 93g$
> $w = 93/7 g$ ie. about 13 1/2 pounds

John, does this set of equations take into account the difference in
specific heat between the two substances, or would that be significant?
Most texts I've seen (particularly Noonan) seem to indicate that the
malt has a higher specific heat than the water, which (and I'm sure the
physics-prone amongst us will let me know) would mean that another
coefficient has to be added in, one that I think would result in an even
higher weight of water having to be added.

I too am curious about the necessity of boiling tap water. Dave Miller treats it as a must, so as to kill any bacteria, drive off any chlorine (he claims that even small amounts of chlorine can lead to horrible phenolic (medicinal) flavors), and to precipitate ions. Yet other books treat it as optional if they consider it at all. Anybody have any good evidence that it does or doesn't matter?

I am very interested in trying this technique after sampling many
Flanders Brown
and Lambic beers while traveling through Belgium. I love the tart (but
very
pleasant) sourness of these brews. I have a few questions on your
procedure:

First, is the 80% wheat that you use malted? I assume that it is since
the
barley malt is only 20% and that would not seem to provide enough enzyme
activity to convert all that wheat.

I believe that someone else here recently had bad luck (Aaron, I believe)
attempting a sour mash. Do you think that the natural beasties on the
wheat
malt somehow are more well suited to sour mashing than those on barley
malt?
Does anyone know if the type of bacteria contained on the two differ to
any
degree? Another possibility is the local environment where the sour mash
is
done, unfortunately I live quite close to where Aaron made his attempt..
.

Finally, is the sourness produced by your method similar to that in say a
Flanders Brown Ale?

Thanks, can't wait to give this a try!

Dave

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Sour Mashing
Subject: Hot side aeration of wort (George Fix)

Several years ago I used an ill-conceived horizontal mashing system where hot wort was transferred via a "pump" from the mash tun to the brew kettle, and after the boil through a wort chiller into the fermenter. The system was pretty to look at as well as being easy to use. There was, however, considerable "hot side" aeration during the transfer. The beers produced did not display "cardboardy", "papery", "woody", and/or "vinegary" flavor tones one usually associates with oxidation, so I concluded that hot side aeration was not an important issue.

This was also a time that beer competitions started to appear, and I entered as many as could be managed. What was particularly frustrating was the vast discrepancy between my evaluation of my beers and that of the judges. Some of the beers did ok pointwise, but concurrence over their strong and weak points were rare. I concluded at the time that some of the judges were full of . . .

It was only in background research for my book on brewing science did I come across the "oxidation without molecular oxygen" phenomena that I discussed in an earlier post. I promptly reconfigured my brewing system with a goal of minimizing hot side aeration. It is impossible to completely avoid some of it, but I was able to affect substantial reductions. The difference in the performance of the resulting beers was astounding. Even those consumed at home seem to have a more rounded and smoother finish.

There is a good deal more to life and homebrewing than how well our beers do in competitions. Moreover, some beer styles are more susceptible to these effects than others. Ironically, the less malt, hops and color, then the less this issue is relevant. (It is a myth that lighter beers are harder to make than heavier beers, particularly with respect to flavor stability!) Yet all and all, I strongly feel that minimizing hot side aeration is a goal well worth considering.

I am aware of some commercial beers that have been produced with considerable hot side aeration. One is Bateman's XXX, where hot side aeration is used to darken the beer. At the brewery, Bateman's ales are sensational, and even those I tasted in London were very good. In the US, on the other hand, I find

them almost undrinkable. Last week we tasted some which according to a decoding scheme given to me by Paul Farnsworth indicated that they were only eight weeks old. They had a hard astringent finish that overpowered the desirable fruity/hoppy tones in the ale. This was totally unlike the ones I tasted in England which had a nice malt finish.

What may come as a complete surprise to folks in California is that Anchor's products suffer from the same problem. I have yet to get a Anchor Steam or Liberty Ale in Texas that comes close to doing justice to these great brews. Moreover, the versions we get are not that old. This is in striking contrast to Sierra Nevada's ales which always have an excellent malt flavor (not to mention the Cascades!) even when they are several months old. The fact that SN's ales are bottle conditioned helps, but I feel there is more to it than that. If you ever get the chance, compare the brewhouse procedures in detail at Anchor and Chico. The latter, in my opinion, comes close to the ideal, while the latter, as noted in other posts, use "splashing grant" similar to the one at Pilsner Urquell.

Russ: When you visit Anchor this weekend ask Mark Carpender about this matter. I have talked to him in the past about this issue, but I would be interested in his current views. I know the tradition of steam beer brewing means a great deal to everyone at Anchor, and that is why we all have such a fond regard for everything associated with this operation. However, if they bypass the grant for Foghorn, why not for Liberty Ale and their Porter as well?

Subject: Blowoff

korz@ihlpl.att.com writes:

>Having been a long-standing proponent of the blow-off method, I obviously have a vested interest in deClerck's findings and Dan's suggestion of a dilemma. On the other hand, I'm very happy with the flavor of my beers and their fermentation times are reasonable, so why worry? I don't use a starter for my Wyeast, get active fermentation in 12 to 36 hours, depending on the yeast type, and have not had an infection in over four years (some beers sitting in the fridge, on-tap for over 9 months - no problem). The last infection I had, I could safely attribute to the dry yeast I used back then. My challenge still stands: if you think blow-off is a waste, I dare you to drink a glass of blow-off. I hope this doesn't sound too antagonistic. I don't mean it to. It's a friendly challenge and I'm always open to be proved wrong, as long as I learn something in the process.
Comments?

Of course. A better test would be to brew two identical batches, blowoff one and not the other. See if you can taste the difference (I doubt it). Using your logic, would you drink a glass of yeast slurry? I wouldn't, but then it doesn't hurt things to be there, does it? (this assumes you rack off of it, etc. etc.). Has anyone done a side-by-side like this? BTW, I don't mean to be antagonistic (remember the Rat's *ss Stout?) either, but I would like to know. Al, you're happy with your beer fermented with the blowoff method; I'm happy with mine fermented without it. That's all. Some year I may try this experiment. Until then, Just Brew It.

Subject: Demise of Klages, and 2 row color malts

I was chatting with the head of one of the larger Northwest
microbreweries
recently about the available US malts.
The following unconfirmed facts, opinions and questions are offered FYI:

1)

It appears that AB (the major consumer of Klages 2-row in the US by far)
intends to replace Klages with Harrington (sic) in the long term.
The economics of the brewing-barley / malting industry would tend to
indicate that Klages would then quickly disappear from the market.

Does anybody here know anything about the relative brewing
characteristics
of Harrington?

2)

This same discussion bemoaned the lack of 2-row crystal malted in the US.
Great Western Malting in Vancouver WA had the proper equipment
to make it, but all the people that knew how to operate it have
retired.

In the recent past,
a potential alternative malt supplier someplace in the Northwest
with plans to rectify this situation
died before it could deliver any malt.

Briess seems to have had this business all to itself for a while,
probably helped by the fact that the huge breweries only use the
dark malts in tiny amounts for color adjustments, and fear any possible
flavor contribution.
Is Briess going to have a lock on US-made crystal forever?

Subject: Re: Bittering Hops, racking and wheat beers

>From: "Dr. Full-Time"
>Subject: Starters and thoughts on bittering hops

While all the references imply that any hop would be sufficient for bittering (the aroma is driven out after 20-30 minutes) in my past experience even a 45 minute boil with chinook hops (alpha ~ 13%) will give the beer a distinctive aroma and flavor. Perhaps this isn't so true with lower alpha hops or "noble" hops, which have fewer resins and perhaps less aroma potential?

Although I have not done controlled experiments, I go ahead and use the highest alpha hop in my refer for at least half the base (boil) bittering units. Usually the colored malts and aroma hops cover the residual flavors. For light pilsners and wheat ales I use the same or similar hops for the bittering as I do for aroma.

>From: Alan Mayman
>Subject: racking

I avoid racking wherever possible. Lately I have been racking to a secondary when making lagers and when dry hopping ales. Jeeze, if I am going to dump in 2oz of hops, fresh from the field, why worry about a bug or two? the beers seem fine. Try it either way. The beers will be fine. If you are just starting brewing, take the easiest approach. Complicate things after a couple of batches are under your belt.

Review some of the old HBD on Father Barley Wine's yeast cake technique: no racking involved at all. he just lets the fermented out beer sit on the cake until the previous batch has been consumed (sometimes for months!). Then he racks to his keg and dump the new wort on the previous yeast cake. I tried it a couple of times when making a series of ales or lagers - it worked just fine for me. Now that I am using a wider variety of yeasts and beer styles it is not practical to reuse the yeast cake.

>From: Jon Binkley
>Subject: All Grain Weizen

I made several wheat ales ranging from 1:5 to 1:1 wheat to 2 row pale malt (klages). In all cases the mashing and sparging was pretty much routine. I think the 1:1 was a little slower than usual, but still cleared and sparged in less than an hour.

I think a thing that really gums up sparging is the quality of the crush. I have had all klages mashes sparge very slowly when I over ground the grain in a corona mill (lots of flour). I am at a loss to describe a proper crush. The grain should be mostly like course sand with big chunks of husk (preferable whole, but split).

Good luck!

Thanks to the fellow on sour mashing technique. Sounds interesting!

I have an anecdote relating to this question. One of my experiments which
was designed to (hypothetically) reduce oxidation was to fill my
fermenter
with CO₂ after siphoning the wort into it. The result was that after 2
days
the beer never did start fermenting. I had to open up the airlock and
introduce oxygen (air) and new yeast (which probably wasn't necessary)
in order to get fermentation going. There was plenty of splashing during
siphoning so I figured that the wort would be aerated and all I would do
is
reduce oxidation on the surface but it didn't seem to work that way.
Oxygen
on the surface seems to be important too.

Subject: Boil Overs Be Gone!
Full-Name: "John Cotterill"

Last night I brewed up a batch of pale ale. For the first time since the discussion several months ago on boil-overs, I remembered to skim off the pre boil scum on top of the wort. For the first time, I had no boil-overs!

Not even a hint. Needless to say I was impressed. The scum has a great creamy character to it. Does anyone know if pulling this stuff off the wort causes any taste or head retention change?

>
>1 - Your water is from a shallow well and rich in microflora. In this case I
>wouldn't even want to drink it, never mind brew with it. In this case boiling
>has an obvious advantage.

Your water need not be from a shallow well to be rich in microflora, but the general rule is: "if your water tastes bad, beer made from it will too."

>2 - Your water is high in temporary hardness. Boiling the water would remove
>some of the minerals that might give your brew an off-flavor.

Yes, I agree, but would like to add (simply for completeness) that removing
excessive hardness is more important than just for flavor if you are doing
all-grain.

>3 - Your water is chlorinated or flourinated beyond an acceptable level
>(whatever that may be.) In this case boiling would drive off these ions.

Agreed. Chicago water is what I get and it tastes neutral to me, however,
visitors from Europe and Alberta have noted a chlorine smell/taste, which,
obviously, I have learned to ignore. This goes for any water flavor, so we should all be wary of this.

>Now if your water does not fall into one of these three catagoies, I would say
>that boiling is a waste of time and energy. Please let me know if anyone has
>an other viewpoint. (like nobody does?, Right!;-)

I feel that my water could probably be used straight out of the tap, but still boil all my water. Why? Because there may be minor amounts of microflora which (in the long run) could spoil my beer and because I know I have both flourine and chlorine in my water and would rather boil them out. I'd simply rather be safe than sorry. That's my own, personal, case.

My posting, however, goes out to people all over the world and their water could have any and all the problems you described. Bearing this in mind, and since that post was primarily about chilling to pitching temperature,

I chose to write for the worst-case scenario. In general, Chris, I agree with you.

Yes, your original thermostat. You simply need to calibrate it with a thermometer. Granted, it will probably have a larger detent (the hysteresis -- the 1 or 2 degrees between on and off) than a more expensive thermostat, like the Hunter. My Hunter Energy Monitor (\$24.95 at Builder's Square) has a manual mode which basically means "ON all the time."

I just put the thing on manual and use the refrigerator thermostat when I
want
to go lower than 40 deg. Not a bad deal for \$20 at Home Depot. It gets
pretty cold here in the Southern California desert during the winter and
I
notice that my refrigerator doesn't need to run since I keep it in the
garage.
I haven't brewed that much in the winter, but I might want to get a
heater to
put in the 'fridge or put it inside the house.

Larry Barello says:

Subject: it's storytime!

Hey now all you hbd'ers-

I want you to curl up in the warm glow of your terminals with a frothy mug of winter warmer, 'cause Uncle Davey is gonna tell you a scary story.

Once upon a time not too long ago (last week in fact), a friend of Uncle Davey's decided to brew an Irish Stout from an ingredient kit he got from Santa. The brewer, known as Oz to all that know him, did the batch and put it in a shiny glass carboy to let the yeasties have their fun. Oz went to bed around midnight a few nights later and slipped into a wonderful doze.

At around 1 AM Oz was awakened by some sort of explosion, the sort that rattles the windows in the house. The next sound that Oz heard was his dad, Mr. Oz, who was shouting at Oz to "get his ass downstairs 'cause his beer blew up." "Uh oh," said Oz, "it sounds like I'm in big trouble."

When Oz arrived at the brewery downstairs he found that the shiny carboy, which had previously been holding his happy yeasties, was now in about a zillion pieces. In fact, one piece was propelled upward so hard that it blew a hole in the ceiling of the brewery. Oz was right, he was in big trouble, for the ceiling of the brewery also happened to be the floor of Mr. and Mrs. Oz' bedroom. Uh oh. Although the hole didn't go through the ceiling, it was enough to scare the living bejeezus out of Mr. and Mrs. Oz. When Oz finally found his blow off tube, it was dirty and blocked with hop pellet residue. Oz was amazed how a little gunk could cause such a big boom. So were Mr. and Mrs. Oz.

The end of the story finds us with two things: One- a shop-vac full of Irish Stout and glass shards, and Two- a warning to all you little brewers out there who do primary fermentation in carboys (like Uncle Davey does) to remember the story of Oz and be careful with those things! Oz could have been the Late, Great Oz if he had been standing next to his little time bomb when it went off...

Subject: travels with barley? ;-)

Jay Hersh asks:

|>Bob Devine
|>[who just came back from a skiing vacation with 100 pounds of grain...
|]
|OK Bob, I give up, how do you ski with 100 pounds of grain?? Does the
grain
|get it's own skis?? Or is the challenge to ski while holding it??

Ahhhh,

Sit back all brewers,
And you will hear,
The amazing tale,
Of the skiing beer!

It happened one winter,
The sky was blue,
Everyone was thirsty,
For a barley brew.

The slopes were well packed
With freeze dried skiers,
Whose throats were parched,
For some tasty beers. [well it sorta rhymes]

But alas and alack,
For the hour grew nigh,
When all souls came,
For some beer to buy.

But none was left,
Not drop, nor flask,
In all the town,
The taps dispensed gas. [Oh, oh, getting desperate!]

An alarm was raised,
People were harried,
'Til one soon shouted
(Actually, queried):

"How do you expect us,
Tomorrow to ski
If we cannot get an,
Apres-ski brewski?" [look out! a 2 syllable rhyme!]

"Take heart", the mayor said
"Look up on the slope!"
Down came somebody,
Skiing like a dope.

Over the moguls,
Through the ski school,
Came Brew-Ski Man,
Acting like a fool.

His skis on backwards,
His shirt untucked,

One could really tell
He was truly, ah, drunk.

On his back he carried,
Two full sacks of grain,
"Are you the folks" he said
"Who have beer on the brain?"

That said, he dropped them,
(the grain, I mean),
And started in brewing,
Not stopping to clean.

The skiers gathered close
Stopping to stare,
As Brew-Ski Man brewed,
Right in the open air.

"On Plzen, On Michelob,
On Blatz, Blitz, and Bud,
Look out for the burner,
And don't step in the trub."

Out of his backpack,
Came 5 tiny men,
As ragged and scuzzy
As drunks on the mend.

In a blink of an eye,
A carboy was filled,
By the tiny helpers,
(And only half was spilled).

"Oxygenation?"
He said with a scoff,
"That's just more flavor!"
As he started to cough.

Fermentation soon began,
Not 3 minutes went by,
Before the B-S Man,
"Let's give it a try!"

Glasses were passed around
To everyone in line,
As B-S man downed the first
And pronounced it fine.

As all the skiers drank
Brew-Ski Man staggered away,
But before he left,
Here is what he said:

"Now some may drink
Miller or Corona,
But give me a homebrew,
And I'll be in nirvana!"

By the way, if anyone goes skiing at Breckenridge, stop at the Breckenridge brewpub. I spent over an hour talking to Tim, the brewmaster about their beers and the brewery. He was willing to sell me a couple of bags of American 2-row for a good price - 40 cents/lb.

Subject: malt identification

With all this talk of the level of modification of malts, the following re-post may be of some interest. By the way, to my recollection, I don't believe anyone really answered Jackie's questions.
Al.

From: <BROWN%MSUKBS.BITNET@CORNELLC.cit.cornell.edu>
Subject: modified malts again

Here's a quote from the transcript of Greg Noonan's (the decoction mash king) 1985 Hombrewer's conference talk about determining the modification of malt:

"British malt, which is commonly referred to as "well-modified," is very well sprouted to three-quarters of the full length of the grain. If you cut away the husk on the dorset side of the grain, you will see a white spear growing from three-quarters to the full length. Most of the world's brewers consider British malt overmodified. In comparison, American and continental malts are less modified, showing growth from only one-half to three-quarters of the grain. Before you start mashing, you should examine your malt. Take 20 kernels, find the more rounded, nonfurrowed, dorsal side, and cut it off or rub it away to get an idea of what the conversion is. From that, you can decide what to do. If they are well modified, you may need an infusion mash. But if they are undermodified or show a great variety of modification, then use the step infusion of decoction mashing."

I would add that the temperature-controlled mash (sometimes called upward infusion) can be substituted for the decoction mash. If you think the former is complex, read the directions for decoction mashing sometime. Does anyone out there actually do a full decoction mash a la Noonan? I hear that this guy is the lager guru -- do all you folks with lagering refridgerators go whole hog with decoction mashing? Are the advantages very noticeable?

Happy with my ales but curious,

Jackie Brown Bitnet: Brown@msukbs

Well, you're not the first to bring this up.

Here's what I see empirically - one pound of grain at ~60F added to two pounds of water at 180F yields a mash at about 155F. Using my formula above, it should be 140F. But there are many ways to account for the difference - weighing exactly one pound of grain at exactly 60F is difficult; worse, weighing exactly two pounds of water at 180F; maybe the enzyme activity is exothermal.

This does imply less than 13 pounds of 160F water would be needed for one pound of grain, but not that much less.

It seems to me that if you combine substances, the final temp is going to be an average based on mass, nothing else, unless there is chemical activity. Perhaps the physicists and chemists would like to roast me for this naive opinion?

From: gjfix@utam.uta.edu (George J Fix)
Subject: Second thoughts (George Fix)

Shortly after sending my post this morning I realized that the reason Old Foghorn is not sent through the grant is that this beer is not sparged. Thus it is unlikely that Anchor would consider a similar procedure for their other beers.

Many friends have kindly and gently suggested that I have made too much of hot wort aeration. They are absolutely right in the sense that there are bigger fish in the ocean. Nevertheless, I can not resist one final shot at the target. Can you think of many beers that have a greater flavor stability than Foghorn? Taking into account that it is a high gravity barley wine, what about the finesse of its malt flavor? Not sparging helps (although this is an expensive way to brew), however I believe its desirable features come primarily because it is not sent through that #&#% grant.

JaH and JF: I promise there will be no more about this!

Actually, melanoidins are the result of a combination of carbo's and
amino acids, not proteins as I originally posted.

At any rate, it's conceivable that malt enzymes could still bring changes
in crystal malt's melanoidins. If you began with a melanoidin consisting
of an amino acid and a complex carbo, you may end up with an amino acid
and a simple sugar. Is this the case, or are the starches transformed
into
other components which aren't broken down by malt enzymes??? Anybody
know???

Homebrewing isn't illegal in Norway today, and I don't think it was
illegal

twelve years ago. I remember seeing homebrew kits in the stores when I
was
a little kid.

What is illegal, however, is the Norwegian version of "Moonshine".

I made a few batches of this with a friend, with a kit (including a crude
distillation device) which we bought from an obscure mail order firm. It
is not illegal to possess the equipment to make this liquor, but if you
are

caught in the act (e.g. if the whole sheebang explodes) you're in deep
shit... The Norwegian Moonshine, unlike the American, is not whiskey.
The goal is to get it as tasteless as possible, so that you can mix it
with

any cheap extract, and it will pass for liquor bought at the government's
"Wine Monopoly"... It usually gets a very easily detectable crappy taste
which immediately gives it away, but if you have good equipment and
filter

the stuff enough times, you can get liquor that only chemists can tell
from the real thing...

Btw, another Norwegian prohibition is the one against advertising for
alcoholic beverages. This always gets the imagination running around
Christmas time, when the christmas brews are launched along with X-mas
soda

pop. All over the place, posters announce, "X-mas soda pop is here!",
with

the same typeface as is used on the X-mas beer label... And nobody *
really*

believes that it is the breweries' non-alcoholic brands that go so well
with

the food in the commercials... There are a lot of these hidden messages
in

the breweries' commercials...

Subject: Starters

In reply to Dr. Full-Time (Todd Enders) who says:

>With all the talk about when to pitch starters, I'd like to
>add my own data point to the discussion. What I almost always
>do is pitch the slurry after the starter has fermented out (or
>almost so). While it is true that the dormant yeast cells have
>to wake up and start reproducing, I feel the sheer number of cells
>you dump into the wort wins out here.

But there is only going to be a negligible change in the number of yeast
cells
after aerobic respiration ceases since this is when the bulk of
reproduction
occurs, due to the fact that aerobic respiration releases 12 times as
much
energy as anaerobic respiration, energy which goes towards reproduction.
So you don't really get any increase in the number of yeast cells by
waiting
till fermentation finishes, though you do get yeast in a less active
state.

Thanks Russ, I'll pass that along to Jim Fitzgerald, who was dying to find out about what they were used for (we did) though we never learned the name in English (or German for that matter).

Good to have someone who can just pop over to the Anchor brewery. While Sam Adams is very nice to us, their equipment (Bill Newman's old setup) is old hat to me as I 'd toured it in Albany before Newman's stopped brewing draft there and went 100% contract and sold it off to Jim Koch.

Keiran,

Hello again, I can no longer reach you directly these days.
Anyway what do you mean by "efficient lagering--say around 32 degrees f?"

I do my lager yeast ferments in the high 40s, and then just turn the
hunter
to the "on" position letting the fridge's thermostat keep the beer at
~35F after kegging for the aging period. Take some advice from someone
who has
frozen a Cornelius Keg solid, don't go below 35F. This is a fine
temperature
for cold aging, but not too close so you'll freeze the keg.

Subject: Metal brew

Hi folks,

I have a batch of nut brown ale bottled and aged a little more than a week, and it currently has a very metallic taste, and little or no body. I used a can of nut brown extract that I got as a Christmas present, no adjuncts, boiled with an ounce of Cascade hops, and finished with half an ounce of Northern Brewers (it's all I had at the time). The fermentation went well, and I bottled after 4 days (primed with corn sugar). The brew cleared up fairly rapidly (1-2 days), but has not developed much carbonation at all. What could have gone wrong here? Even if I oxidized or contaminated the heck out my wort, I can't imagine how it could end up tasting like the inside of a rusty tin can (which it does). If I didn't know better, I'd say that I had left out half of the extract, and had boiled my wort in a cheap aluminum pot, but I used my trusty stainless steel stock pot, sanitized everything with a bleach solution and rinsed well, etc., etc., as usual. The fermentation seemed to go well, although Any ideas? Bad water, bad extract, bad yeast? I'd appreciate any pointers before I try another batch.

Subject: Cleaning copper, sparging

Mike sez:

>Back when this came about, I think I was the main advocate of
>cleaning. My batch of tubing had a pretty bad case of "grease"
>inside, to the point where, when I let water (cold or hot) drain
>out of it, the leaving the last few drops to fall on the counter.
>Silvery specs appeared to be floating on these water drops, but
>this was really small pools of grease/oil.

I felt it worth pointing out that this is indeed an extreme case. I'm not sure where Mike bought his copper but the tubing I buy from the local plumbing supply never has anything remotely similar to the stuff Mike describes.

>contortions related to cleaning the copper deleted<

..an admiral tale of perseverance, Mike!

>It's important to note that when you're done brewing for the night or
>day, you're not done until you run lots of hot water through the
>chiller to get out any remaining sugars, and then work it around in
>a circle to drain it and prevent mold.

I usually follow this procedure with a quick siphon of my clorox solution and store dry. The little bit of clorox will help insure sterilization but it's not enough to cause any appreciable corrosion. In fact I used to store my chillers with a clorox solution inside them from one brewing session to the next and the chiller held up fine.

When I pull out my chiller for the next session, I boil up about a gallon of water and siphon it through the dry chiller to insure sterilization prior to taking the wort through it.

Jim asks:

>Why not just drain the sweet liquid from the mashing vessel, through a
>couple layers of chessecloth, and into the boiler..... once. No re-
>cycling!
>Then run the necessary amount of 170-180 F water through the same grain
>bed
>and cheesecloth, (again just once), to make 6 gals.... and be done with
>it.
>It'd take minutes, rather than 1-2 hours.

I'm all with you on this one, Jim. I usually re-cycle once just to set the grain bed. Then I drain the lauter tun completely to get the thickest runnings out of there. After that, I run a normal sparge until 6 gallons are collected. 45 minutes. No reason to take 1-2 hours.

Cheers!

Subject: Striketemp,Camra, Klages, Diacytl

Someone posted calculations for the amount of water to get to a specific strike temperature. YOU forgot to include the specific heat of the malt, and water. Although I forget the exact formula, and values, it is needed if you rare going to do this. A friend and I tried to set up a spread sheet so we could do infusion mashes directly by calculations This included measuring the specific heat of malt in a calorimeter (thermos). Off we went brewing, and although the first step was OK, subsequent steps always required corrections. After several experiments, and careful checking of our caluculations and formulas, we concluded that the specific heat of the malt must change as it is mashed. THIS makes sense given the dramatic change in the malt, but still makes us unsure on where the heat goes as the specific heat changes. I'll see if I can dig up our formula (out of the CRC handbook), and the values we measured for specific heat of dry malt. If you are only going to do a single step, it should work OK.

Joining CAMRA with Pounds Sterling? Why not join Camra Canada? Then you could pay in Loonies Bronze? I don't know the address, I'll see if I can get it? Also you can write a check in any currency. All you have to do is mark the currency on the cheque. At least I can at my bank. NOTE: they do charge a service charge for clearing a cheque in a foreign currency.

What is Klages Malt. I bought a kilo the other day, and can't find any info on what it is?

Butterscotch flavor, and Diacytl: YOU can increase diacytl in you beer two ways
Low oxygen wort at pitching will tend to cause the yeast to produce more diacytl. Boiling all your water will cause low low oxygen wort.
Most yeasts create diacytl as an intermediate fermentation product, and later re-metabolize it, If you strip the yeast out early in the fermentation, by cold shocking it, or adding finings before racking to secondary. you will preserve this diacytl. Although the subsequent fermentations will go a little slower, You won't have problems with carbonation. At least I never have. I have been using these methods to produce buttery english ales ala Samuel Smith for years.

Bill Crick Brewius, Ergo Nonum ThermoDynamics! I brew, Therefore I don't need no stinking Thermodynamics!

Subject: Specific heat of Grain

Here is an example of the spread sheet for calculating infusion step mash water additions.

For the first single step mash, the formula is
 $Mnw = (Tf - Ts)(SHg * Mg + HCTun) / (Tnw - Tf) * SHw$

Where Mnw is mass of water to add kg (1 litre= 1 kg)
Tf is desired final temp C
Ts is original grain temp C
SHg is specific heat of grain joules/kg C
Mg is mass of grain kg
SHw is specific heat of water Joules/kg C
Tnw is temp of water to be added C
HCTun is heat capacity of mash tun (ignore. Preheat tun)
NOTE:all are metric SI units. "what is that in real gallons?"
4183.33 Specific heat of water
2130.00 Specific heat of grain -3629.79

Protien Rest Step3.93

26.67 Enter grain temperature 80.00 F
65.56 Enter Water temperature 150.00 F

Enter the desired protien rest temperature 122.00 F 50.00 C

Enter the weight of the grain in pounds 11.50 lb 5.22 kg

ADD 3.93 L of water to the grain for the protein rest

Conversion Process First conversion step
 $Mnw = (Tf - Ts)(SHg * Mg + SHwMow + HCTun) / (Tnw - Tf) * SHw$

What is the new mash temperature? 122.00 F 50.00

Enter the desired conversion temperature 153.00 F 67.22

Enter the step water temperature 210.00 F 98.89

ADD 4.06 L of water to the grain for the protein rest

Second Conversion Step and so on.....

Subject: Mead, Nutrients, Germany

Greetings all,

Got some questions for ya's. First, I've tried to make a mead. I pretty much followed Papazians new appendix on making mead. My 3 Gallon batch had:

5 kilos Imker honig (trans: 11 lbs beekeeper honey)
48 oz red Raspberries
1/2 tsp Irish Moss
Champagne Yeast in starter of
1/2 cup Corn Sugar
1 tsp Yeast Nutrient
1 cup H2O

I boiled the honey in 1 gallon H2O, turned off the heat, added the raspberries, let steep for about 30 minutes, then dumped all into a plastic primary and brought total volume to 3 gallons. OG was (eek!) 1.142!! So, I pitched the yeast the next morning and let it go. Last night, (5 days later) I racked to a glass secondary w/ an addition couple tsps. of nutrient dissolved in a cup of H2O, grav = 1.080.

Now for the problem. This stuff smelled like baby larks bladders boiled in ox bile. I mean it was downright NASTY smellin'. I couldn't bring myself to even attempt tasting it. I asked my wife (who normally doesn't like homebrews) to help describe the smell. Funny part is, she couldn't smell anything but a slight raspberry odor. She promptly drank my sample and proclaimed "Yum, Fruit Punch with a kick!!," and left. I was amazed. Has this ever happened to anyone else? Am I having some sort of olefactory hallucination?

Second, the yeast nutrient I got is labeled DiAmmonium Phoshate, but w/o any instructions. So how much should I use for, oh, say a mead? Would this have some have any affect on my naseI imagination??

In HBD #796, Jim Grady ask about homebrew distributers in Germany:

Yeah Jim, I'm in Germany. I'm sorry to report that I haven't found any distributers, nor have I confirmed the legality of homebrewing. I'll be taking a tour the the BBK (Bavarian Brewery of Kaiserslautern) on 29 Jan, so I may have more info then. I'll be sure to post a review...

Auf Wiedersehen,
Johnny B.

Subject: Boiling water

Jeff Rickel asked:

> I too am curious about the necessity of boiling tap water. Dave Miller
> treats it as a must, so as to kill any bacteria, drive off any chlorine
> (he claims that even small amounts of chlorine can lead to horrible
> phenolic (medicinal) flavors), and to precipitate ions. Yet other
> books treat it as optional if they consider it at all. Anybody have
> any good evidence that it does or doesn't matter?

How about good evidence that it does... to the tune of about 13 gallons
of
beer and mead? We started brewing about this time last year, and made
three decent batches of beer in a couple of months. We never bothered
boiling all our water, using cold tap water to top off our extract
brews. No problem.

As spring set in, we brewed a pale ale. It was very nice when we bottled
it, by far our best effort, so we quickly followed it up with another
batch
and, while we were cooking, a batch of mead. About 2 weeks later, we
noticed a slight plastic flavor and smell to our beer, which within a
week
or two became so strong that the beer was undrinkable. Chlorophenols,
we figured. Had to toss about three gallons of that wonderful elixir.

Then when it came time to bottle the pale ale and mead we'd just brewed,
we
found the same stench already developed. Scratch ten more gallons.

Our reasoning was that the spring had brought with it a bacteria bloom,
and
the water treatment plant had countered by upping the chlorine levels. As
a result, our beers suddenly contained much more chlorine and, perhaps,
some new bacteria; a good recipe for chlorophenols. It's worth noting
that our second and third batches, brewed before our first plastic pale
ale, never developed this problem even after more than 9 months had
passed
in the bottle.

We now religiously boil our water (we even have it blessed! 8-) and have
not had a recurrence of this tragedy.

> From: Dave Coombs <coombs@bashful.cup.hp.com>
> Subject: Re: cleaning copper tubing
>
> This is the same sort of copper tubing that's used in plumbing, right?
> And we drink the water that travels through it to the faucet. So what
> is commonly done when installing copper plumbing to ensure clean
> water?

To my knowledge, nothing... but then again, there's a lot of difference
between what's acceptable for household water and beer. Your water
doesn't
require sanitized conditions, so little bacteria-harboring pockets of
grease wouldn't matter. Grease/oil that may be insoluble in tap water

might be more soluble in hot wort. You don't expect a glass of water to maintain a nice head. You don't fuss with water for hours, store it for weeks, then bottle it in individual 12-oz bottles and give it to friends.

From: des@swindon.swindon.ingr.com (Desmond Mottram)
Subject: Re: Boiling tap water

I boil our local tap water because it is FULL of bicarbonate, which buffers mash pH. I get a heaped teaspoonful of scum, sediment and precipitate after a 15 minute boil. The amount of precipitate varies with the length of boil and I have found it is possible to overdo it, resulting in a mash pH which is too low. Now I just boil for 5 minutes and no more.

Incidentally, another interesting experiment worth trying is to taste a series samples taken throught the brewing process. Taste a bit of wort every half hour during mash and boil, and then each day for the first week of fermentation. and weekly thereafter. It's instructive and fasinating to discover just how the character of your brew shifts as it passes though its various stages. It shows you just when and in what way the important changes occur; where you are wasting time with an unnecessary wait; when you may be spoiling the flavour by underdoing or overdoing something. Your tastebuds will reveal things no amount of technical apparatus can show. It was a surprise to me, for example, just how much sparging washes out the flavour of the wort (one day I MUST try fermenting a full strength batch, WOW!!!).

From: man@kato.att.com
Subject: Re: boil-over preventer

In HBD 797, Dave Ballard says:

<Hey now all you physicists- I got this thing in my stocking this year
<that is supposed to prevent boil-overs (all kinds, not just beer).
<It's a glass disk, about 4" in diameter, with about a 1" lip around
<it. It kinda looks like big coaster.

<I haven't used it yet but my mom put one in a pot of spuds on xmas. It
<didn't seem to work too well 'cause there was soon spud foam oozing
<all over the stove.

<My question is this: why should I expect this to work and if it did
<work, what does it do?

<iko-
<dab

I got one of these as a gift a few years ago and posted a question about
it back then. Mine didn't claim to prevent boil-overs, only that it would
automatically stir the contents. As such, it works on low viscosity
liquids
like wort, but not heavy sauces. I used it when I made batches on my
electric
stove and it prevented the wort from being scorched every time. It did
not
produce enough of a stirring motion to prevent a boilover, but it was
useful
for overcoming the effects of electric stove hot-spots.

Since I started brewing outside with a King Kooker rocket engine, the
baffle
on the unit seems to prevent hot spots on the kettle and the pyrex
ashtray is
no longer being used.

From: abirenbo@rigel.hac.com (Aaron Birenboim)
Subject: sour mash

I'd like to share my sour mashing experiences with the list, so others will not repeat my mistakes.

I used papazian's method of cooling the mash to 130F, and adding some cracked malt.

My first attempt did not sour at all for about 12 hours. At that time, i mucked about in it, and uncovered it. The next morning, it had a white film, and smelled like rotting corn. I covered it with saran wrap, and let it continue. It got really nasty, and rancid. the rotting corn smell made you retch. I dumped it. In retrospect, it might have been fine.

I have seen conflicting opinions on this question: ARE THE SOURING BACTERIA AEROBIC? If not, cover the mash, if so, leave it uncovered.

BTW: I was using wheat malt from great fermentations, and pale 2-row from Minnesota malting. I think the mash was 2# wheat malt, 5# pale, 1# barley flakes.

with the same mash, i tried again. this time i added some acidopholis capsules, and covered. the capsules were from barley malt culture (great for us lactose sensitive people) obtained at the health food store. This time i covered the mash. After two days the mash pH dropped to about 3.4, and it smelled only slightly rancid. I boiled 90 min. The finished product is sharply acidic, but with a hint of remaining rancid flavor. I think that this Lactobacillus Acidopholis contributes this rancid character which is not driven off in the boil.

How will sulphur levels effect the souring? How much sulpher does Minnesota malting use? Not only did the first mash smell sulphery, but the second mash gave me hints of sulpher too. On the second mash, i goofed and charred a bit of malt. This scorching produced not just your usual burning food smell, but definite sulpher overtones. In fact, the sulpher smell was stronger than the burnt food smell. Does all scorched malt produce this smell? (this was the first time i schorched malt)

Bob Jones : could you ask Micah Millspaw how much of the mash he soured, and how much he did regular? with that information i can try M. Millspaw's technique outlined in HBD 796.

Aaron (I'm gonna emulate berliner weisse even if it kills me)
Birenboim

P.S. Anybody know where I can get a buttermilk starter culture? Martin Lohdal tasted a nice Berliner Weisse emulation made by pitching buttermilk starter with the yeast. I's sure like to avoid that stinky sour mash!

Subject: Grant

>>...many European Breweries, notably Pilsener Urquell among them,
>>use a system where the sweet wort that goes from the mash tun
>>into the boiling tank is drained from the mash tun via a number
>>of spigots.

>This arrangement of spigots is called a "grant". Anchor uses one in
their
>system.

As I understand it the grant serves two purposes:

1 It provides a handy place to grab a sample during run-off to determine
clarity.

2 It allows the brewer to balance the flow of wort during run-off.
I think if the flow is uneven there is a risk of part of the mash
compacting
and getting stuck, causing a loss in efficiency.

At Boulder Beer I recall that they have a series of pipes, each with a
valve
and a gauge.

A friend of mine peeked behind the grant at Anchor and said that all
the taps were connected to the same pipe.

Subject: RE: Boiling Tap Water
To: SMTP%"homebrew@hpfcmi.fc.hp.com"

Ok. If I do decide that I want to boil my tap water to rid it of chlorine, bacteria, etc. how long should I boil it? I would suppose that it would be long enough to rid the water of the nasty stuff, but not so long that any minerals in the water become concentrated too much from the reduced volume. What would therefore be the acceptable range?

Subject: boilin' and blowin'

John asks:

>Last night I brewed up a batch of pale ale. For the first time since
the
>discussion several months ago on boil-overs, I remembered to skim off
the
>pre boil scum on top of the wort. For the first time, I had no boil-
overs!
>Not even a hint. Needless to say I was impressed. The scum has a great
>creamy character to it. Does anyone know if pulling this stuff off the
>wort causes any taste or head retention change?

I've been skimming the pre-boil scum for years and I've detected no
taste or head retention change. In fact, if you taste the stuff,
you'll find it to be quite astringent--another reason I'm happy to have
it out of there.

And Dave warns:

>When Oz arrived at the brewery downstairs he found that the shiny
carboy,
>which had previously been holding his happy yeasties, was now in about a
>zillion pieces.

Looks like it's time to post my usual warning about blowing off
through siphon hose. *****DON'T DO IT***** It's dangerous. If you're
blowing off using a right-side up carboy, use the 1" ID siphon hose.
For those interested in the upside-down system, the BrewCap uses 1/2"
hose and we've found that to be as small as you can go and still be
safe. No one's ever blown a carboy with the BrewCap.

And lastly, some feedback for you guys who rely on word-wrap on your
terminals. All words past the first line just run right off the
screen here. I'd sure like to know what you're saying!!

Cheers and beers!

>blocked with hop pellet residue. Oz was amazed how a little gunk
>could cause such a big boom. So were Mr. and Mrs. Oz.

By any chance, was Oz's blowoff tube a simple 3/8" siphon hose?
I haven't read Papazian's New CJoHB, but in the first issue he
recommended a regular siphon hose for a blowoff tube. I had a
similar misfortune as Oz, but luckily only my stopper blew. There
was beer dripping from the ceiling in the aftermath and only 2 of 5
gallons left in the carboy. Since then I switched to a 5/8" OD --
1/2" ID hose and have had no problems. You can even use a 1.125"
hose right in the neck of the carboy (no stopper).

I checked the Troubleshooting issue of Zymurgy and found nothing that
you could have done wrong in the table or the section on Metallic taste.
It could be your water, but as I wrote recently, if you're used to the
taste of the water, you shouldn't be that sensitive to that taste in the
beer. Get a water analysis and check the Iron content. The
Troubleshooting
issue did, however, mention that two constituents (1-octen-3-One and
1,5-Octadien-2-one) have the source "Lipids from malt or brewing adjuncts
such as rice, corn, etc." This would be the fault of the extract
manufacturer.
What brand was it? Maybe other Digesters have had problems with this
extract?

From: korz@ihlpl.att.com
Subject: Samuel Smith's CORRECTION

Recently, I posted a discussion of fermenter dimensions in which I said that the shape (actually, the shallowness) of the fermenters used by Samuel Smith's Tadcaster Brewery causes an increase in the production of diacetyl. I had read this somewhere a while ago and I'm not sure if the dimensions of the fermenter have anything to do with diacetyl production.

Yesterday, I received my copy of Terry Foster's "Pale Ale" from the AHA. I immediately checked the fermenters used in Tadcaster and sure enough, nothing is mentioned about dimensions. I hope Terry forgives me for quoting one paragraph, but I'm certain that any serious Pale Ale brewer will eventually buy this book anyway - -- I love it! Here's what Terry writes on pp. 20-21:

" Yorkshire brewers in another important pale ale brewing center, Tadcaster, had a different type of yeast and developed their own technique for handling it. This was the Yorkshire Stone Square System. It is a circulating system like the Burton Union System, but with a very different purpose. Circulation in the Unions is designed to achieve good separation of a poor-settling yeast from the beer. The Yorkshire brewers had a highly flocculent yeast which would rapidly settle out, giving poor attenuation in traditional "rounds." So the Stone Square circulation system was designed to continually rouse the fermenting wort, keeping the yeast in suspension until full attenuation had been achieved. A side effect of using such yeasts is that the beer may have high levels of diacetyl; the resulting "butterscotch" flavor is often an accepted characteristic of beers brewed in this way. Incidentally, in the British homebrewing revival of the 1960's and 70's, such rousing was mistakenly assumed to be essential for all yeasts and recipes often recommended rousing the wort twice daily. Not only is this usually unnecessary, it is also an excellent way of starting bacterial infections!"

In the associated picture of the "Slate tanks of the Yorkshire Stone Square system," the tanks appear to be about 8' by 8' and (if the brewer in the picture is not on a ladder) about 4' high.

Subject: boil-over preventer (response to Dave Ballard)

Hey now all you physicists- I got this thing in my stocking this year that is supposed to prevent boil-overs (all kinds, not just beer).

[...snip...]

It didn't seem to work too well 'cause there was soon spud foam oozing all over the stove.

Dave, as I understand it, these disks don't **prevent** boilovers, they just clank around on the bottom of the pan to warn the cook that a boil is eminent.

I always understood these things "worked" by making a hellatious noise
that tells you when the pot is just starting to boil (clatter clatter).
Then you come running and turn down the heat or dump in cold water or
whatever. Do the instructions give any clue about this? I can't think
of any reason why a glass disk would inhibit foaming.

Subject: Blowoff and Bombs

As I've stated in this forum before, I use a 7-gallon carboy and fermentation lock as my primary fermenter. I don't worry about blowoff or blowoff hoses or the associated problems with plugged hoses, because of the considerable gap between my 5 gallons of wort and the top of the carboy.

Well, Dave Ballard's little fairy tale got me to thinking (sometimes I needs a jump start). If, during high krausen, my wort scum did actually rise enough to find its way into the f-lock (and somehow plugging it), I'd be in deep doo-doo like our buddy Oz was.

Now, since deep doo-doo is not the desired effect, I have a question:

CO₂ is heavier than O₂ right? So, if I was to put my stopper (with f-lock, or blowoff hose for that matter) on a bit loosely, and pressure did find a way to build up, the stopper would simply fly off. In the normal case, where this did not happen, O₂ would not find its way into my carboy, would it? (OK, I lied - two questions). Assuming all this is true, even if the stopper took a trip toward the ceiling, CO₂ would still blanket the brew and protect it.

For safety sake, I'll use a very light touch on my next batch, unless someone comes up with a good reason against. Comments?

George Fix writes:

> Several years ago I used an ill-conceived horizontal mashing system
where
> hot wort was transferred via a "pump" from the mash tun to the brew
kettle,

since I'm considering making a recirculating infusion mash system with a
pump to transfer to the boiler: should I be concerned? How did you
redesign? Just a simple gravity feed or was there more to it than that?
The basic ideas of my design are below. Any comments are appreciated.

Vessels: 1/2 of a stainless steel drum, ~27.5 gallons with a false
bottom

(perf. stainless 30% open, 1/8" holes) resting on a stainless
angle iron X. 1/2" stainless steel nipple mig welded 1"
up from the base of the vessel (affectionately known as
the mash-tun from hell -- currently sitting in my hallway)
(probably) two 15.5gal kegs welded one on top of the other.
(cut the top off one, the bottom off the other, step a lip
into one and weld. 1/2" nipple in the bottom from transfer
both in and out. I have yet to make this one.

The mash tun (1/2 drum) will have a pump attached to its nipple. This
will pump to a set of valves which either directs the flow through a tube
flash heater or to the boiler nipple. If the flow is through the heater
it is then directed to a set of nipples up the side of the drum. Only
one of these will be open. This will allow the recirculation to occur at
the highest level possible without going over the top of the mash. These
nipples will be on the opposite side of the vessel so flow must be across
the
grain. I do plan to do a lot of stirring to distribute the heat. Heater
control will be via a little bit of techie wizardry -- a microcomputer
which will control both flow as well as clip the AC to the heater.

The boiler, two kegs welded together, will have at least one hot water
heater affixed to the bottom a la a *big* BrewHeat. Yes, I know some
people believe this will lead to scorching, but I havn't had such a
problem
with the BrewHeat & I believe with care this will not really effect
things
much, if at all. The input/output to/from the boiler will be through the
single nipple in the bottom. A valve will be attached to allow input
from
the mash tun pump or output to a cooler and eventually an output keg
(gravity fed).

Well, yet another screwed up batch from the Serious Live Rabbits Brewery.
...

Some friends and I attempted a 4-gallon version of "Quick Mead" from the Cat's Meow recipe book, using 7 pounds of honey and increasing spices and such accordingly. I boiled the honeywort for maybe 20 minutes to kill

anything that may have been living in the honey; the reason we did this batch was to use up some old, crystallized honey that we had lying around.

I made a yeast started and pitched it when it started to foam. Nine days later, there is NO activity. None. Nada. I haven't checked S.G., but the stuff doesn't smell fermented, and there's no yeast sediment in the bottom.

So, how did I screw up? Is Edme ale yeast not suitable for honey? Am I just too impatient? Is crystallized honey chemically changed into something unfermentable? Help save this poor carboy of sugar water, pleeeeeeeze....

oh, p.s.: 2 pounds of the honey used was fresh and normal, so you'd think that SOMETHING would happen....

Subject: JSP Grainmill review - very long!

Disclaimer - I am not connected to JSProductions in any way. I am merely a customer. I have not received, nor do I expect to receive, any compensation for the following review of the JSP GRAINMILL.

My intention is to take Jack's original description of the GRAINMILL and describe my experience with the unit. I am evidently the first real customer for this unit, which sorta surprises me. My overall impression of the GRAINMILL is that it is that it beats a Corona Grinder hands-down in every respect except esthetics, and with slight re-work will be totally indispensable to this 2 batch-a-month all-grain brewer.
.....

```
jsp> Anyone who uses whole grains quickly realizes that [...] unsuited
for milling
>malt [....] They pulverize or shred the husks, which severely limits
the
quality of the
>filter bed when sparging [....]nothing else is available that fits the
budget of
>even the affluent home brewer. [...] It is a genuine roller mill.
>It crushes malt, leaving ALL of the husk in tact and a minimum of flour.
>Not one grain can get through it without being properly milled. It does
>exactly what a malt mill is supposed to do.
```

Jack's right-on here. The Corona works, but the husks are shredded. The GRAINMILL, on the other hand, really does "implode" the grain. When the rollers spacing is properly set, the husks are cleanly split into two pieces and the kernel is broken into several (read, more than 6) little granules about the size of coarse table salt. The roller spacing can be set via an ecentric on the idler, however, it turned out that the optimum setting exactly coresponded to natural resting point of the ecentric, any closer spacing than this causes the motor to stall with every type of grain I tried.

```
jsp> The mill consists of two, 12" long rollers, 1.5" in diameter. The
rollers have
>meshing teeth running their entire length. In cross section, they look
like
fine
>toothed gears. However, the rollers are spaced about .025" apart so
the
teeth do
>not actually mesh. Their purpose is to pull the grain through the
rollers. The
>spacing assures that the grain will only be crushed enough to expose
the
>contents without tearing the hulls or unduly compacting the malt.
```

Exactly as advertised. My unit did have the addition of the eccentric for

adjustment, but this proved to be all but useless due to the extremely low power of the motor. My first test was to crush 1 lb. of Edme Pale Ale Malt. This malt is rather 'soft', so I expected no problems. Well the problem was that I had "cranked" the eccentric, and the motor stalled. I released the eccentric, letting it find its natural resting point, and re-tightened it. I proceeded to crush the pound of grain in about 20 seconds. I examined the crush and found what seemed to be some un-crushed kernels. I picked a couple of these up and found that indeed they were crushed but the husk had not been separated. Bearly pressing on one of these kernels caused the husk to fall away, leaving about 6 granules of starch in my palm. So as a test, I counted 100 kernels of Edme (anal, ain't I) and ran them through the mill. I then counted the "un-broken" kernels, there were eight. Again, they were crushed just not husked. At this point I'm pretty happy with the product on 'soft' grains. I retested it on 80L English Crystal. This grain is slightly harder than Edme, maybe firmer is a better word. 100 kernels, zero (!) un-husked pieces - and the most beautiful crush I have ever seen - perfect husks and thousands of little "crystals" everywhere. Final test was 100 kernels of CaraPils malt. Now this stuff is unbelievably hard - more like rock than malt.

The rollers stalled on the first kernel. I proceeded to hand crank the kernels through the mill (a very easy task with the 10 inch pulley) and inspected the crush - 28 un-husked and un-crushed kernels. I ran this crush through again - resulting in another 'perfect' crush - no stalling, perfect husks, and thousands of pretty little 'cara-pills crystals'.

jsp>One of the rollers is driven by a 1/30 HP electric motor or a hand crank, depending on the model. The motor drives the roller through a set of reduction pullies at a speed of about 140 RPM. In the hand cranked model, the crank turns the roller directly. The second roller is driven by the first, through a rubber friction ring. The motor driven unit is designed to stall in the event of unwitting attempts to mill fingers. It will smart but not much more. The assembly is mounted on a plywood base, 16 inches square. It is intended to sit on a table, with the business end hanging over the edge.

This should say "one of the rollers is 'bearly' driven by an under-powered motor". If I had it to do over again, I'd buy the hand crank unit and spend the extra money on a 1/4 horse motor and pulleys. The asthetics of the unit

leave alot to be desired. Externally, the whole thing looks like something out of junior-high woodshop. The hopper is made from press-board mounted on two triangles of 'fake-wood'. There is no exit chute for the grains, so they tend to 'implode' in a pretty wide area around the bottom of the unit. The hopper suffers from 'lack-of-slope' and capacity. I plan to replace it immediately with a "sheet metal / pop-rivet" hopper with high slope and 5 lb. capacity. Which leads me to suggest that you try to buy just the roller/casting assembly and save Jack the work. While the outside looks very amatuerish, the roller assembly is absolutely top-quality. The castings are cast aluminum with pressed bearings at roller contact points. The rollers are a sight to behold - exactly what Jack described - like little gears - but they don't mesh. I hope Jack will consider just selling the business part of the mill and let the buyer decide to do the finish work.

jsp>Operation consists of slowly pouring the grain into a hopper and catching the milled product in a pan or bucket underneath. It takes less than a minute to mill a pound of grain with either the motor or hand crank. The motor driven model could be made to work much faster but I was more concerned about safety than speed. Slowly is the key phrase here! If the slope of the hopper were higher and the motor were stronger the unit would have no problem milling 5 lbs in 3 minutes max. I understand Jack's concern for safety - but it kinda feels like the helmet law, the seat belt law, the warning label on alcohol, etc.... Just sell me the parts with a disclaimer that this unit is sold as a paper-weight, the seller accepts no responsibility for any other application.

jsp>The product that emerges looks like a picture out of a text book on brewing. >This is normally only obtainable through a series of rollers whose spacing gets progressively closer. By using the toothed rollers, we are able to achieve the same results in one step. Again, exactly as advertised. The Edme crush was an absolute dream crush - perfect in every way. With a larger hopper, an exit chute, and 1/4 hp motor this unit will challenge any roller mill I seen, and I've seen a dozen and used 3.

jsp>the price is \$200 plus shipping. The hand-cranked model is \$100. >[...] he who hesitates, may be lost. I believe I got what I paid for. Obviously, alot of labor intensive

construction went into my unit, but I would have liked to do the labor
(of
love) myself - of course, I will any way. My recommendation is order the
motorized one if you are not mechanically inclined, oeder the hand crank
one if
you can get an in-expensive 1/4 hp motor, pulleys and belt cheaply, or,
if you
are a fanatic like me, try to talk Jack into just selling the business
part of
the unit and flesh it out yourself. But the bottom-line is order one if
you
and/or your friends currently grind more than 20 pounds of grain a month
- you
won't be sorry.

Hi folks,

A friend wants to know some things about hops. This may have been asked recently, but my memory is bad (age and all :)

- 1) If you make beer without hops, what do you get?
- 2) When were hops first used, and what did they use before then?
- 3) Why did someone decide to use hops?

I'd look in the Zymurgy hops issue, but I don't have it yet (but I have a birthday coming up in a few months... :)

I just received a sale flyer from Superior Products. They are a discount foodservice equipment supplier, and they have, among other things, Vollrath stainless steel 'stock pots' on sale (catalog says sale ends Feb 7, 1992).

>From the catalog:

Stainless Steel Stock Pots by Vollrath

Made of 18.8 _stainless_ for greater resistance to pitting and corrosion, plus heat conductive base to save energy. Flat covers allow stacking to save space. *In Stock.

\$List \$SPECIAL

7-L-100	7-1/2 qt.	4 lbs	77.00	43.00
7-L-103	11-1/2 qt.	6 lbs	83.00	46.00
7-L-105	16 qt.	6 lbs	108.00	59.00
7-L-107	20 qt.	8-1/2 lbs	121.00	65.00
7-L-129	24 qt.	9 lbs	130.00	70.00
7-L-130	38-1/2 qt.	13 lbs	172.00	90.00
7-L-492	60 qt.	15 lbs	255.00	130.00

Covers:

7-L-123	For 7-1/2 qt.	15.00	9.90
7-L-125	For 11-1/2 qt.	19.00	12.40
7-L-127	For 16,20,24 qt.	29.00	18.40
7-L-136	For 38-1/2 qt.	38.00	22.00
7-L-494	For 60 qt.	39.00	23.00

They also have other goodies like restaurant-quality beer glasses and mugs, and lots of draft beer equipment and plumbing. There is a 'stainless steel beer chiller' which is used to chill beer inline on its way to the draft arm which could be used as a wort chiller. They also have CO2 tanks and regulators, etc.

Superior Products can be reached at (800)328-9800; their catalog is free.

I am in no way affiliated with Superior Products, I am just a happy customer who thought he'd pass some info along. Bottoms up!

Subject: re: Samuel Smith's CORRECTION

I just want to point out that korz's observations on the Yorkshire slate squares are a bit misleading (but that's certainly not his fault). It's true that the vessel you see in Foster's book is about 4 feet high, and full of foam right to the lip. What you don't realize is that that vessel is entirely full of yeast.

There is a second vessel lying directly underneath, with a hole in the center between them. The lower cube is filled with wort and as the fermentation progresses, the yeast flocculates out in the upper square--sort of a giant blow off system, but with a 3 foot tube instead of 1 1/8".

I don't know what Sam Smith's used to do before pumps, but when I took the tour, there was a fellow walking around with a portable pump, and he would throw a pickup tube into the bottom fermenter and spray some of the yeast back into the beer. (Yes, "spray", and it clearly was taking up air on its way back in; I'd be proud to get that kind of aeration going into the primary. On the other hand, the amount wasn't very much compared to the volume of beer in the fermenter, so perhaps it doesn't matter.)

BTW, if you get to England, it's definitely worth taking the tour, although my experience was that I couldn't understand a single word the guides said. The tours occur occassionally, so you need to call ahead. They are conducted in the evening and begin in The White Horse and Angel pub next door--ah if that were only my local.

Subject: ss ferment

I just racked a light lager to secondary last night. I dry-hopped it with an oz. of Saaz. It's actually gonna be more of a steam beer (TM) since it's been fermenting at about 50 degF. Anyway, the important info is that the primary was done **in the brewpot**. I cooked it up, chilled it with an immersion chiller, pitched, covered, and moved it to the cool room. It was a Rapids 10 gal. pot. It worked great. The cover is loose enough to allow CO2 out. One odd thing is that the brewpot is now as clean as it has ever been. There were minor scorch marks on the bottom, from the 2 gas flames I use to cook with, but now the bottom is absolutely clean. Hmmm. The pot itself cleaned **very** easily. Obviously, if you're concerned about racking off the cold break, this is not for you. But it's quick and easy. We'll see how the beer turns out. Recommended, so far.

Subject: Radioactive isotopes used in breweries

On the news last night there was a piece about low-level radioactive waste disposal. The usual sources of this waste were mentioned; medical and nuclear power plants. But also mentioned were breweries that apparently used radioactive isotopes for measuring the level of beer in bottles. Does anyone know how this method works? Are isotopes mixed into the beer and then detected when it reaches a specified height in bottle or is beer bombarded and detectors sense some change when the bottle is filled?

Is there a different isotope for ale and lager?

Subject: re: boil-over preventer

I used to have one of these gadgets (it broke).

I never observed that is was much good at preventing boilovers involving foaming liquids (cooking spaghetti, hardboiled eggs that crack, etc.). However, it seemed to be effective at preventing boilovers caused by superheated water (where the liquid temperature goes above boiling without generating steam). This happens to me when I try to boil water in a clean glass pot (one of those Whistler-brand things), which I used to make tea. The pot would just sit there on the burner and do nothing - until you bumped it or dropped a teabag into it, whereupon it would eject half of its contents on whatever happened to be close.

It appeared that this glass disc would provide nucleation sites for steam bubbles to form, limiting the liquid temperaure in the pot to the boiling point. It doesn't quite make sense that a smooth glass disc would provide more nucleation sites than the smooth glass walls of the pot, but this is what I've observed.

Subject: cleaning copper

I'm surprised that no one has mentioned this, since I got it from this list, and it works great - use a dilute vinegar solution to remove the grease from copper tubing. I boiled my immersion chiller in a vinegar solution, and it came out shiny. You could probably run the solution through the tubing if you were making a counter-flow chiller. It really works great. Use about so much vinegar in about that much water ;-)

Subject: Northwestern malt -- Weiss vs. Weizen?

I made a batch of something wheatish using one bag of Northwestern Wheat extract and one bag of N'Western Amber malt extract. I used the dregs from a friend's wheat beer to culture up some yeast--I think he used WYeast of some sort. It turned out pretty good, although not at all weissen like--at least it didn't have any clove taste or smell. It just tasted like a good beer. Kind of ale-like even.

Would anyone care to explain briefly and clearly the difference between Weiss beer and Weizen? That's one distinction I've never figured out.

Thanks.

Danny

Yes! It's a high-quality extract, and the bag-in-box is handy, easy to use and lightweight. Bill McKinless of The Home Brewery's new retail shop in Teaneck, N.J., recommended it to me for an Oktoberfest, and I was pleased.

For what it's worth, The Home Brewery has shifted their contract for production of Yellow Dog Amber from Alexander's to Northwestern, and the old Dawg is coming out in bag-in-box now.

I posted this a couple of days back, but it never appeared. Sorry if it eventually shows up twice.

>From Russ Wigglesworth :

>This arrangement of spigots is called a "grant". Anchor uses one in their
>system. I once inquired as to the reason for this step in the brewing
>and was
>told by the brewer on duty (Mike Lee, if I remember correctly) that it
>was
>"traditional, it came with the brewery" and he knew of no specific
>advantage to
>it. Nor was he aware of any problem with oxidation. He also told me it
>could
>be by-passed and was when they made Old Foghorn. I'll be over there
>later this
>week and ask again.

I had a similar exchange with Bruce Joseph, another brewer at Anchor. When I asked him about the purpose of their grant, he shrugged and said, "Hell if I know", or something to that effect. Then he grabbed a glass, filled it with some of the sweet wort that was passing thru the grant and gave it to me while mumbling something about those pesky homebrewers with their endless stream of questions.

The only real use for a grant that I've ever heard of is that it makes it easy to asses the color and clarity of the runoff.

Subject: Re: Metal brew / Boiling water

Concerning my metal brew problem:

Joe Palladino suggested that I might have used too little extract in my wort. Although this seems a very possible cause of the kind of taste I've gotten, the can was a double-sized one, which I forgot to mention in my original post.

Al Korz answers:

> What brand was it? Maybe other Digesters have had problems with this
> extract?

Good question. I left the label back in Massachusetts, and it was mistakenly thrown away. I can't remember the brand name, but I hope to venture to my local homebrew shop to try to find it, since I remember what the label looked like.

Concerning the water boiling issue:

Bill Thacker writes:

> About 2 weeks later, we
> noticed a slight plastic flavor and smell to our beer, which within a
week
> or two became so strong that the beer was undrinkable.

I've had the same problem with the water in Schenectady, and have boiled tap water used for brewing ever since. I blamed the chlorine levels, which seem pretty high by my taste.

>when you fill the vessel to the neck you remove the trapped air (oxygen)
>used by the yeast during the first stage of fermentation. This limits
>the total population to a value lower than optimum and the fermentation
>takes longer.

The reasoning seems sound, and it is true that oxygen-deficient wort will cause your yeast to have trouble reproducing, but 2 gallons of air sitting on top of your 5 gallons of wort are not going to enter the wort unless you shake. I think the rate that the air will dissolve into the wort, if it simply sits quietly, is very slow and aeration during the filling of the carboy would be several orders of magnitude more than aeration from the air sitting quietly. Comments?

Subject: Recirculating mash & blowoff

To : M. Sharp

I tried your idea on a recirculating mash tun, al la R. Morris/Zymurgy. I screwed around with it for about a year, and had BAD luck. The problem most likely is with the mash tun geometry. Too tall a mash tun will cause too much grain compaction therefore slowing the flow thereby burning or overheating the liquid. You are trying to maximize two things in nature that naturally oppose. Also there is a problem with just how much heat or energy you can get from household voltage. You can get much more energy from a burner of any sort. The electronics is the easy part the fluid mechanics can kill you. Be forewarned!

To : N. Pyle

I also had a carboy spew about 80% of its contents on the ceiling years ago.

Your idea of a loose fitting f-lock may not save you because the fermenting beer/foam will slowly seal/glue the stopper very well before the pressure builds up enough to blow. I'm sure the pressure we are talking about here is very low.

I don't know a lot about melanoidins (maybe there's something about
them in George Fix's "Principles of Brewing Science" book -- I haven't
checked yet -- I hope there is), but from what I've read recently, they
are somehow associated with the level of caramelization of the sugars
in the mash/wort. If this is true, maybe the fact that PU is generally
pretty pale and doesn't have a lot of melanoidins is why the grain
doesn't cause oxidation problems. Comments?

Maybe the reason PU is not REALLY pale is due to the oxidation and maybe
the "cardboard smell/flavor" is from hop oxidation (there aren't any hops
in the mash). Comments?

Wouldn't there be less oxidation in the case of PU's triple decoction
than in aerating an entire batch of (our) beer at 200F because:

1. the temperature would be lower (120F to 168F),
2. only part of the mash is taken and not the whole thing, and
3. that part of the mash gets boiled only a few minutes later and
the dissolved air gets boiled out (this goes back to someone's question
of how long does it take for the oxidation to take place... at say, 150F?)
)?

Comments?

Subject: pH Pen Review

Subject: pH Pen ReviewTime:2:44 PMDate:1/9/92
Hardware Review

Litmustik pH Pen
Model PHH-1X
\$44.00 + \$2.95 S&H
Omega Engineering, Inc.
PO Box 4047
Stamford, CT 06907
1-800-826-6342

I have been interested in purchasing a digital pH tester ever since I checked the pH of my first batch with test papers and found them nearly impossible to read with any accuracy. Until recently the cost of these devices has been in the neighborhood of \$80. About a year ago I began noticing advertising for units in the \$40 range so I waited to see what reviews surfaced prior to buying one. So far I have yet to find such a review, except in the sales material of several retailers. I had occasion to purchase a couple of dial thermometers from Omega in order to complete my 1/2 barrel system this Fall. I noticed that they sold a pH pen for \$44 I suppose I was feeling extravagant when I placed the order for the thermometers and tacked on the pen as well as some buffer solution for calibrating the unit.

I was a little dismayed when the pen arrived. Now bear in mind that I have no experience with such devices so what may be obvious and expected by frequent users was not so with me. The advertising copy had stated the pen had a range of 32 to 122 degrees F. It does, however it needs to be calibrated at the same temperature that the sample will be read at so, either I had to heat the buffer or cool the sample. Not a big deal, I chose to cool the mash sample to room temp. The sales literature also stated "single point calibration" with a range of 0-14 and an accuracy of +/- .2 pH. Foolishly I thought that meant that you calibrate it at 7 and it figures out the 0-14 range. Not so... The specifications which come with the pen are more specific adding "+/- 3 pH units from standardization point". This means you need to calibrate the pen with a standard buffer solution close to the range (within 3 points) which you intend

to measure. Again, this is not a large problem, but I would have liked to know it ahead of time. Standard solutions are available at 4 and 7 pH. Not exactly ideal for brewers who are looking for 5.0 - 5.5 pH. I am investigating making my own standard solution by mixing portions of the standards.

The other characteristic of this device which I was unaware of when I purchased it is the fact that you must keep the probe moist. This isn't a problem for me as I tend to brew at least once a month and usually more. The instructions suggest immersion in tap water once a week for improved performance. The cap has bit of felt in it to assist with the task, however this is one more bit of maintenance which makes the pen risky for casual brewers.

So after all that, how does it work? Quite well. I was very happy to be able to read a pH of 5.7 after mash-in and 5.3 after an addition of gypsum. I suspect though that I don't really need this toy. If I could find a nice set of pH papers which would be readable once immersed in a stout or porter mash I would do as well. Yet I could make the argument that the pen will pay for itself by my not needing to replace my supply of papers as they run out. At current prices, that ought to be in about 200 batches...

One last comment. Along with the pen came an advertisement for a "NEW!" model PHH-2X pen with "ATC" (Automatic Temp Correction?, Auto Touch Calibration?) and improved Accuracy & Range for \$49.50 + S&H. Hmmm...

Hi there,
Mead takes longer to ferment than beer, but some activity should be noticeable.
Your fermentation lock should be bubbling every minute or 5.

Our local brewery (Elm City, New Haven CT) boils all their water, and told me to do the same. We have lots of bacteria and they just throw in more chlorine (we don't have so much chlorine that it's a major taste factor in plain water or tea). I think they said boil for about 20 minutes or so, but don't quote me on that.

(Kinny, is this more readable? This is using hard returns instead of word wrap.
I too have problems with some posts running off the edge, although I think it's people with word wrap who go beyond column 80 that bug my machine, such as it is.)

Subject: Hot Wort Aeration

George F> JaH and JF: I promise there will be no more about this!

No need to make such promises. It is interesting to note your experiences,
I think many people will also find them interesting. My comments were based on an observation of what is done commercially, a little knowledge of the temperature relationship to the speed of the reaction (ie it occurs slower at sparging temps than boil temps), and only minor direct experience.

I certainly couldn't argue that PU has any kind of stability. The bottles i carried home had shown noticeable flavor changes in only weeks despite being stored cold. I wouldn't dare to attribute this to their use of a splash grant, but perhaps the casualty you suggest merits concern.

I think some research and/or discussion with some commercial brewers could shed some light here. If I had the time I'd hit the library, but I'm very busy these days.

I think you have the wrong picture. The mash tun is ~1.5' high with a diameter of 2'. I don't expect to use it at anything near its capacity. If anything I thought this would be a bit on the short side. The boiler is the tall skinny vessel. I couldn't see any reason why it couldn't be (& kegs are cheap too).

FWIW, the boiler (made of two kegs welded one on top of the other) won't be used at capacity either. Since my targetted batch size will be about 15.5 gallons (the oak casks I use are 15gal) post boil, I wanted enough room for the initial wort (figuring a 4-6 hour boil -- traditional for lambics) as well as a little room left over for the inevitable attempt at boil over.

> Also there is a problem with just how much heat
> or energy you can get from household voltage.

Yes, I'm somewhat concerned about this. I'm going to have to experiment. The area in which I brew has a 40A 220V line. I'll just keep adding more water heater elements to the boiler until I can get ~18-20gal to boil. I don't have any delusions about doing this quickly. Current plan is to wire the heaters to run at 110 so I don't go scorching everything during the boil. I'm not sure if I'll wind up running them at 110 or 220. Time will tell.

> You can get much more energy from a burner of any sort.
Quite true, however I believe my landlord would be quite upset when I ran this in my apartment. Not to mention there is the problem of not melting through the flooring and the in-flow/out-flow of air. I've worked out numerous burner designs, but having to run ducting through the apartment as well as the noise of a burner running full blast has lead me to scrap the idea. Then there is the general danger of a 200KBTU burner running in a 10x12 room...

Trivia question for the physically capable: Hot water heater elements are sold with ratings like 9KW. Does anyone know how I'd go about figuring the BTU output (assuming that its running full blast for an hour)? I'm sure I could figure it out if I dug out Halliday&Resnick, but someone out there must know...

Jack! Get a clue! I've never seen such an utter waste of bandwidth. Please do a quick reality check and realize that these postings were made quite a while ago. I'd rather not read your tirades that time forgot.

As far as using this as a tool to redeem yourself in the eyes of HBD and for besmirching those that opposed/offended you, it just makes you look like a fool. (said in a moderate, instructional, matter of fact voice, NOT a beligerant, ranting, attacking one).

ARF -- his grain mill

FWIW, I did like the review of your grain mill. sounds like an interesting unit. Did you make the supporting castings yourself or were they left-overs from something else? I've wound up going the route of welded plates due to casting costs. Did you wind up using stainless for the rollers or some form of tool steel? I've been thinking about a tool steel approach but I'm somewhat worried about someone trying to clean the unit (mine) by popping it in the dishwasher. Perhaps I just need a big sticker on the side that says 'Dont even think about getting this wet.'

I've never seen these used for beer bottling, but the technique is probably to pass the bottle through a "gage." On one side of the bottle is a chunk of radioactive isotope as a radiation source; on the other side is a detector. The radiation is attenuated (i.e. partly blocked/absorbed) as it passes through the beer, so if the radiation level "dims" far enough you know there is beer between the source and detector; and thus that the bottle is full to the height of the detector.

Similar methods are used for things like measuring the thickness of paper or coming off a mill.

From: tony@spss.com (Tony Babinec)
Subject: chicago brewpubs, bars, stores (semi-long)

Here are some Chicago area brewpubs and bars.

The Goose Island Brewery is at 1800 N. Clybourn, which is north of North and west of Halsted. On tap are a Kolsch (the only one in America?), a Pilsner, and a Pale Ale (very good, with slight biscuit and diacetyl notes). You'll also find seasonals and specialties. Recently, they've had an IPA. There's ample parking nearby. You can also eat there, the food's pretty good. I'll plug it again: if you're in town on the first Thursday of the month, there's an informal homebrew get-together too!

The Berghoff Brewery is on west Ontario past Orleans and the expressway ramp. Recently, they've featured a light (dort), a dark (American dark), Octoberfest, as well as several ales (amber ale, porter, stout). You can also get Berghoff beer at the Berghoff restaurant in The Loop. Go to the standup bar on ground level.

The Weinkellar is in Berwyn, and therefore not accessible to downtown stayers without a car. Take the Eisenhower to Austin, exit and go south to Roosevelt Road, then go west on Roosevelt for a mile or two. It's on the south side of the street. Their own beers on tap include an amber ale, several wheat beers (filtered Weizen, hefe-Weizen, and Berliner Weiss), and I don't remember what else. Some of their specialty beers (Doppelbock, Octoberfest) have been very good. They also have hundreds of brands of beers for sale in the bar and an adjacent store. It's an interesting ethnic neighborhood bar.

Tap and Growler is on Jackson, two blocks west of Halsted, in the old Greektown neighborhood. They get Chicago Stadium traffic (Da Bulls, Blackhawks) coming and going. The neighborhood is definitely "urban," so don't wander off too far in any direction. T&G got a bad reputation a few years ago for, shall I say, indifference to the quality of its beer, but appears to be making amends. On tap recently were an Irish ale and a stout. *Chicago-area homebrewers and beer aficionados note*: the 1992 Chicago Beer Society membership meeting will be at Tap and Growler on Sunday, February 2, early afternoon.

Sam's Liquors on North Avenue just west of Halsted has a great selection of U.S. and imported beers, not to mention wine, single malt scotch, etc. Stock up!

Quencher's, at Fullerton and Western, has 15-20 taps and a couple hundred brands of beer in the cooler. Those of you on the coasts (especially Pacific) are used to this, but we're only just beginning to see the many-taps phenomenon here.

An old German neighborhood, roughly at Lincoln and Damen, has a number of German bars, including Lashett's, Riese's, and Von Stuke's (I'm not sure about any of those spellings). You'll find multiple beers on tap at any of these, plus get a sense of what Chicago and dozens of other cities must have been like years ago.

Chicago and area micro beers to look for include:

Chicago Brewing Co.--Legacy Lager (won European Pilsner category at 1991 Gr. Am. Beer Fest), Legacy Red Ale, and seasonals (Heartland Weiss is the only one so far, and probably the best bottled

American-made German Weizen I've tasted, with some of that "clove" character).

Baderbrau, a dark-ish pilsner.

Kalamazoo Brewery beers, including Bell's Beer, Bell's Amber, a good porter, a very good Third Coast Old Ale, and others.

(Larry Bell does multiple homebrew-size mashes to fill his fermenter, and in the end bottles or kegs it!)

Capital Brewery (Madison, Wisconsin) beers.

Subject: Water Treatments

When making water treatments to try and match typical brewing styles, what water should one treat. This concern mostly is for grain brewers. I usually treat only the mash strike water, but then a sparge with twice as much untreated water. Is it adequate to only try and duplicate the mash environment or should we try and duplicate the water in sparge? Did anyone know of a common source for calcium chloride, like at the grocery store.

>
> Carl
>

The problem I can see here is over-lautering of some grain and/or possible under-lautering of some of the rest. The ideal lautering system will wash all the grain with equal amounts of water so that the leaching of sugars is optimal everywhere. It would also have a filtering system that let all dissolved solids through and left all undissolved solids behind. Normally we use the grain itself for this which is why we require a 'sufficient' bed. If you have a good enough mesh screen to do the filtering then it would be better to have a short wide lauter tun along with some way to deliver water evenly distributed over the surface. I'm pretty unhappy with my current lauter tun (two plastic food buckets) so I'm thinking about building a new one.

My guess is that the volume of air above the fermenting brew is less important than the surface area. I would agree that little new oxygen would enter the wort once it starts to ferment but the much of the yeast could still have contact with air at the surface (remember the little snorkelers?). This is especially true as the beer starts to circulate due to bubbles forming below. Since a CO₂ layer gets built up on the surface fairly quickly then "head space" as in height of air above the surface is probably not important. Once again short and fat beats tall and skinny :-)

> appeared in the '91 special issue, errors and all, and the best part is
> the author credited is CP. So read this article about Helles for its
> humorous value and not its brewing advice.

I am the author of that article (that's me, Charlie Papazian). I wrote
it and
believe that it is accurate. It is based on information and observations
I got
when in Germany. I also consulted with German brewmasters and
Weihenstephan
Graduates. The point about Munich having hard water is a superficially
correct
observation. But just because a city's water is hard that does not mean
breweries will use it untreated. In fact for light lagers such as Helles
and
even Weissbiers (the lighter ones, especially) they DO treat their water
in a
way to reduce the hardness. If you were to use very hard water in a
light
delicate lager like Munich Helles the hop character would become harsher
on the
palate. The same principal applies when brewing Pils. Brewers in Munich
brew
Pils, but they don't use the water right "out of the tap." For many
reasons.

Brewing Munich Dunkels, dark beers, with hard water is another story
and is
more steeped in tradition. The darker malts help acidify the liquor to
begin
with, etc. etc.

The claims that "errors" were brought to editors attention and we did
not
reply, are baffling to us.

The lesson here, I believe, is that you can't take water data at face
value.

You have to research and see how the water is used and treated.

Hope this clarifies this issue. I can be reached on Compuserve mail
at
72210,2754 until Monday the 13th of January, when I'll be out of town for
a few
weeks. I'm going in search of the oldest brewery in the Americas

> when the bottle is filled?

I've heard of using radioisotopes for detecting levels of fluids, cracks in bottles, etc. The isotope emits particles that are picked up by a detector on the other side of the sample. Somehow they figure out if everything's OK. It's like using an X-ray except that it can penetrate metal. The isotopes are absolutely not mixed with the beer. (They'd only do that if they wanted to figure out who was drinking their beer -- we'd all have to walk by their detectors :-). My guess is that this technique is used only for statistical sampling; not every can is tested.

> Is there a different isotope for ale and lager?

Nope. (There might be a different isotope (or isotope density) for Real Beer (tm) as opposed to American mass-brew, though :-)

Another use of radioactive isotopes is neutron bombardment of a sample for sterilization purposes. The neutrons kill all life in whatever it is you bombard, so it'll "live" forever (in its lifeless form, of course :-).

Subject: glass, crystal, toasted

I planned on making a batch this weekend, but since my Wyeast was anxious to get at my great tasting beer wort, I decided to go at it after work last night. There are a couple points of interest I'd like to share.

Be it the "power of suggestion", or just fate, all the recent sharing of glass carboy disasters got to me. As I was lifting a carboy full of sterilant to my deep sink, a thought of the "Oz Incident" came to me, and I mentally said "I should be very cautious with this". At that very instant, slip! A mere 2 or 3 inches drop to the edge of the metal deep sink was followed by an angry crash of glass and splashing chlorinated water. Man, if you want to empty a carboy quickly, this works :-). Luckily, I suffered only a very minor cut on my thumb. I donned a pair of leather gardening gloves to clean up the extremely sharp shards, and noticed that the gloves, while not only protecting my hands from cuts, also provide a very "sticky" grip on the wet glass. I'll definitely wear them while handling carboys from now on. I've been looking at kegging equipment for a while now, and this incident will speed up my buying decision. I plan to use 5 gallon soda kegs for fermenting, racking, and serving. This is outlined in an issue of Zymurgy (not sure which), and seems like a simple, safe, and efficient method.

A few digests back, someone discussed the damages crystal malts suffer at mash temperatures. This intrigued me, and I gave it a try in last night's brew. I rested all but the crystal at 155F, did an iodine test which showed no remaining starch, and then added the crystal and began the raise to 170F. An iodine test after the crystal addition also showed no starch. Could this mean that there is very little/no convertible starch in crystal malt? I believe Miller recommends mashing it to extract the remaining starch and the full goodness of it. What about other specialty malts? For instance, do the sugars in chocolate malt need only be steeped, as in extract brewing, or are there benefits of giving them a full mash?

After having the smell of toasted pale malt described to me with utter excitement, I was encouraged to give this a try also in last night's brew. I put .5# Klages on a cookie sheet in the oven at 350F for 15 minutes. I rested this at 155F with the rest of the mash, but would this possibly be better just steeped like the crystal too?

cheers and thanks,
bob

Subject: Radioactive isotopes and breweries

Peter Karp writes:

>On the news last night there was a piece about low-level radioactive waste disposal. The usual sources of this waste were mentioned; medical and nuclear power plants. But also mentioned were breweries that apparently used radioactive isotopes for measuring the level of beer in bottles. >Does anyone know how this method works? Are isotopes mixed into the beer and then detected when it reaches a specified height in bottle or is beer bombarded and detectors sense some change when the bottle is filled?

First of all, to gain a little credence, let me state that I hold a Ph.D. in Nuclear Engineering. Secondly, let me add the caveat that radiation gauges were not my specialty, although I do know more about them than 99% of the people you would meet on the street. I don't know anything in particular about how breweries use radioisotopes. What follows is purely an educated guess.

A common way to use radiation to determine the level of something is called a "transmission gauge". Basically, the idea is to have a source of radiation (a small amount of a radioisotope) on one side of something and a detector on the other side. The detector measures the amount of radiation that gets through the material, which is a function of how much material is there. If you put a transmission gauge at a certain desired fill level on a bottle of beer, the difference between transmitting radiation through a little glass and air (if the fill is low) and transmitting radiation through a little glass and some beer (if the fill level is high) could determine whether or not the fill was above the level of the gauge. Here's a diagram:

Another common radiation gauge is called a "backscatter gauge". It uses a similar principle to the transmission gauge, except the detector is on the same side of the sample as the source. The detector is shielded from the source so that no direct radiation is detected. The radiation that is detected has gone from the source into the sample and backscattered to the detector. The amount that backscatters (and sometimes the energy of the radiation) is a function of how much "stuff" is in the sample, so this method could be used to detect fill levels also.

I just now looked all this up in a text of mine ("Radioisotope Measurement Applications in Engineering", Gardner and Ely) and on page 331 there is a diagram similar to the one I've drawn above, except that there are multiple gauges so that some accuracy in the measurement of the liquid level is obtained. They generally use gamma rays generated by a Co-60 source.

Radiation gauges are used in all sorts of places that you might not expect: measuring paper thickness in a mill, measuring water content in soil or concrete, oil-well logging, and measuring thicknesses, liquid heights and densities of anything. An medical X-ray is a type of radiation gauge (source on one side, transmitted photons detected on the other side).

But I also wanted to directly answer your questions...

>Does anyone know how this method works?

See above.

>Are isotopes mixed into the beer and then detected when it reaches a specified height in bottle?

No, I'm *sure* that no isotopes would be mixed in with the beer. We have more to worry about with the chemicals they're putting in :)

> or is beer bombarded and detectors sense some change when the bottle is filled?

Yes, this is much closer to the truth. The more I think about it, the best analog that people would be familiar with is a medical X-ray. Note that exposing beer to gamma rays does not harm the beer.

>Is there a different isotope for ale and lager?

No. As far as the gauge is concerned, beer is mostly water. There would be little difference between the transmission of radiation through ale and lager. Remember, the gauge works on the principle of detecting the difference in radiation transmission between beer and air (or CO2).

I hope that I have answered all of your questions. There is just so much bad information being spread by the media on scientific matters that I felt obliged to respond to your query before it I saw it in the papers :)

I also live in a high chlorinated water zone.

I find that my Amtek whole house carbon filter in conjunction with my Amtek (don't know the model but it's also sold at Sears) undersink "double barrel" carbon/sediment filter leaves me with pristine water.

You really shouldn't need to boil city/chlorinated water.

I'm a happy Amtek customer, nothing more filter wise.

Date: Fri, 10 Jan 92 14:13 CST
From: korz@ihlpl.att.com
Subject: Weisse vs. Weizen

As I've noted before, I'm studying for the BJCP exam this sunday and a question like this may cause a core dump of information, so if I write too much, excuse me. I should be back to normal on Monday.

Weisse means "white" in German whereas weizen is "wheat." Both refer to beers are made from a mixture of wheat malt and barley malt with top-fermenting yeast. There are two distinct styles of wheat beers in Germany. In the north, a style called "Berliner Weisse" is made from a lower percentage of wheat malt than the Bavarian style of wheat beer (I don't remember the exact percentage), has a low level of alcohol (around 3% v/v) and is characterized by a lactic sourness. Often the beer is served with essence of woodruff which turns the beer green or (I believe) raspberry syrup which turns the beer red. It is a refreshing drink and thus often associated primarily with summer. The Bavarian (southern) style is usually called Weizen and is made from at least 50% wheat, has a level of alcohol just over 5% v/v and is characterized by a tart (not lactic), fruity palate with clove overtones which (contrary to Papazian who blames the yeast and the wheat) I believe come just from the yeast (S. Delbrucki (sp?)). Paulaner, Ayinger, Spaten and others from Munich call their wheat beers Weisse, though. In a related note, Hefe means "yeast" and Hefe-Weizen is wheat beer with yeast in the bottle. Alas, the yeast added to the bottle is usually a lager yeast due to better flocculation, so culturing it won't give you a Weizen yeast. There are also Dunkelweizen (dark) and Weizenbock (a weizen in bock strength sometimes served as a Christmas beer).

I brewed a Dunkel Weizen using 100% wheat malt (Ireks) and used Wyeast's Wheat yeast, but did not get a clove character. I know that Weihestephan #308 is recommended by Miller for that clove character (although it's an Alt yeast) and that Munton & Fison Ale yeast produces a lot (too much for my liking) of 4-vinyl-guaiacol if fermented at 68F, which gives a clove-like flavor.

To summarize (which is what Danny wanted in the first place):

Weisse and Weizen both mean it's a wheat beer, but if it's name also includes Berliner, it should have a lactic sourness, whereas if its, Bavarian, it should have clove overtones and no lactic sourness.

Sorry,
Al.

From: Arthur Delano <ajd@itl.itd.umich.edu>
Subject: storytime (fermenter blowups)

dab@pyuxe.cc.bellcore.com (dave ballard) writes about a gift of Irish Stout kit that blows up his glass fermenter.

Perhaps Oz had jammed the cork on too tightly. Coincidentally, a friend of mine (hi, Tim) emailed me around the same time as this message was posted, saying that his first batch of homebrew (also a Christmas present)

blew the stopper/blowoff hose and sprayed the ceiling of his bedroom with hops. Fortunately, the carboy didn't blow up so he cleaned up and re-attached an airlock; it seems to be doing well now. I would guess that

if the friction of the stopper can keep it in place while the natural strength of the glass jar cannot keep itself together, the stopper probably

was in too tightly. (IMU(unedicated)O) More coincidentally, I noticed that

one of my current batches of beer was building up a great head in the glass

but not going up the blowoff tube. I took the stopper off and noticed that

its underside was coated with pellet hop goop, so I guessed that the tube was stopped; a q-tip solved that problem.

A long-range solution to the problem would be to use larger hose; plastic

tubing comes in diameters large enough to fit the mouth of the carboy alone. I can't see something that large getting stuck unless you're brewing

with grain stalks (:->).

I have a somewhat related question. Has anybody had beer bottles explode?

When I first moved out here, there was considerable protest by a roomie who was afraid of blow-ups. I was able to mollify him by saying that none

of my batches (all of two) had exploded. Under what sort of conditions would a bottle explode? Does anybody know what PSI the contents would have

to be at (roughly, I know, because bottles come in all sorts of configurations) for the bottle to explode?

Thanks, AjD

Subject: Sour Mash Answers

!!
!!
Following submitted by Micah Millspaw. I'm just the old conduit.
!!
!!

GENERAL ANSWERS TO SOUR MASH QUESTIONS

DAVE- and many others ask :

Yes it is malted wheat . The 20% barley malt is american grown 2-row klages, it has an ubundance of enzymes for starch conversion (plus there is a lot of time available). The wheat seems to present a more interesting flavour profile IMHO. As for the sour mash contaminating your brewing environment, I've not had a problem with it.

There are a lot of questions coming in so here goes.
I sour 1/2 (one half) of the mash, the high % wheat half the other is straight infusion.
Aluminum foil has nothing to do with sour mashing technique, CP is awfully vague about this and most other topics. I do how ever make a effort to minimize heat loss by using a ice chest and sealing the lid with duct tape.
If it smells rotten is OK.
The bacteria at work are for the most part aerobic.
If it looks bad its OK.
After 14 hours no matter how bad you think you screwed up, its OK just see the thing thru, it is worth it. Good Luck. Prost.

SOUR MASH RECIPE (this one is good)
10gallons
5# 2-row klagesmash @ 158F for 14 hours
10# wheat malt

10# 2-row klages infusion mash @ 155F 1.5 hours
2# wheat malt

2oz centennial hops 12 alpha
1/2oz coriander freshly crushed half in each fermenter
OG 15 BFG 2 B
combine mashes for mash out @ 170F 15 min. sparge @ 170F
75 min. boil, after cooled split into two carboys, pitch a Chimay reculture into one and a chico ale yeast into the other, add 1/4 oz freshly crushed coriander to each. After 7 days fermentation blend the two batches together in a larger vessel ferment 7 days more kegged with 1/4 cup corn sugar per 5 gallons. Counter pressure bottled after 2 weeks.

=====

As I noted before this mashing technique is not a part of lambic or sour brown production. Although you could use it. The lambic's flavour/aroma is a result of a unique fermentation process involving a host of yeasts and bacteria, I recommend J.X. Guinard's Lambic book for more info. It is unfortunate that articles in Zymurgy writen by CP lead people to beleive that sour mashing is a part of lambic, perhaps he could read Guinards book after all isn't he the publisher!

=====

=

THIS IS NOT A SOUR MASH BEER RECIPE. PLEASE DO NOT BE CONFUSED

Dave asked about Flanders or sour brown ales, so here we go.

Making a sour brown type beer is somewhat easier than a lambic. So here is my recipe for an excellent sour brown kreik beer.

5 gallons
10# 2-row klages
15# wheat malt
2# chocolate malt
1/4oz styrian goldings
2oz cluster hops
OG 1070 FG1020
single temp. infusion mash @165F for 1.5 hours
prise de mousse (S. bayanus) and Pediococcus D. in the fermenter
7 day primary/14 day secondary
kegged with 16oz cherry concentrate (68 brix) and Brettenomyces culture.

Subject: New Brewer

Hi! I'm going to try my first batch hopefully sometime within the next week. I've been digesting vast amounts of information from HBD and R.C.B, and have learned a lot so far. Anyway, my question at present is: Would it be a good idea for me to build a simple immersion chiller, cool the wort to the 70F range, and then allow the wort to splash around a bit (pass through the air) on transfer to the fermenter to be aerated/oxygenated and make the yeast happy, and not be worried about oxidation?

That's my question for now....

Thanks in advance

Subject: Historical Homebrew (no. 2)

This is the second posting containing beer recipes that I received in 1975 or 1976, presumably from the makers of Blue Ribbon malt syrup. The first installment appeared in Homebrew Digest # 795, and one more remains to be published after this. Please note that this recipe is posted here for purposes of historical interest only. It is not a recommended recipe. The format of the original has been followed faithfully, except that I have not attempted to indicate where underlining occurred in the original, and the single quote character (') stands in for the degree symbol. I am aware of two spelling errors, which are reproduced from the original. Any others must be mine.

INGREDIENTS FOR A FIVE TO SIX GALLON BATCH

1 can Hop-Flavored Malt Syrup -6 Gallon Crock or Plastic Container
(Light, Pale Dry, Dark or Extra Pale) Bottle Capper
3 or 4 lbs. Sugar Good Crown Caps
1 Yeast cake or Vierka Lager Yeast Bottles (clean)

Dissolve malt syrup and sugar in 2 quarts of hot water. When dissolved pour into crock and add about 18 to 20 quarts of cold water. Mix yeast in a cup of lukewarm water (70°F.) and with a wooden spoon gently stir into the malt and sugar mixture. Cover with a clean cloth and allow to ferment at room temperature (about 68° to 70°). Skim off the foam for the first three days. The fermentation process is completed when no more gas bubbles appear (about the 4th or 5th day). If tester or hydrometer is used, bottle at the red line, being certain it is down in the surface. Gelatin may be used to settle the yeast. Dissolve two small envelopes of Knox Gelatin in hot water. Pour the gelatin over the top of brew in crock about a day before you plan to bottle or when tester is around 1/2%.

Bottling: After bottles have been thoroughly washed put a scant 1/2 teaspoon of sugar in bottle and fill to within an inch and a half from the top. Cap, then tip upside down once and store upright in a warm place (70-75 degrees).

Storing and Handling: Store bottles in an upright position (not on side) to allow beer to age. The sediment and yeast will settle to bottom and the beer will become golden clear. In a couple of weeks the beer should be aged sufficiently to drink. To cool beer, place bottles in an upright position in the

refrigerator. When handling the bottled beer it is essential they remain in an upright position. This will allow the sediment to remain on the bottom and not be disturbed.

To Serve: Open cold bottle of beer and pour into a pitcher or glass that is large enough to hold contents of bottle. Pour slowly and avoid sloshing the beer in the bottle. When the sediment starts to flow to the neck opening stop pouring.

Things to Watch:

1. If beer is cloudy or tastes gritty you have disturbed the sediment by shaking it up or pouring too fast.
2. If beer tastes "flat" you either bottled it too late or did not allow it to "age" long enough.
3. If beer tends to foam up or tastes "airy" you bottled it too soon.

Wash crock in plain water, never use soap, detergents or soap pads. A Chore

Girl pad should be used to remove brown ring. By having a large container -

6, 8, 10 or 12 gallons, you can increase the recipe proportionately and it will avoid foaming over. Soak bottle caps in warm water to soften cork lining before bottling for easier and firmer capping.

GOOD LUCK!

Subject: copper

Dave Coombs writes:

>This is the same sort of copper tubing that's used in plumbing, right?
>And we drink the water that travels through it to the faucet. So what
>is commonly done when installing copper plumbing to ensure clean
>water?

Yes, it is the same copper sometimes used for plumbing -- ridgid tubing is more common. Clorine is reccomended -- often required -- for cleaning out new plumbing -- one of the things this does is clear the pipes of any residual flux.

Subject: Homebrew Malt Qualities

Last night, I took my first Beer Judge Certification Program class, which is being taught by Fred Scheer of the Frankenmuth Brewery. During a discussion of ingredients, Fred talked about malts that are available to him and compared them with malts that are made available to home brewers. He said that most malters will modify malts for home brewers way beyond what they would do for commercial brewers. His explanation is that every home brewer uses a slightly different procedure, rests may be too long or too short, and that homebrewers are concerned with high extraction rates. The commercial brewers are able to adjust procedures to match differences in batches of malt, whereas homebrewers may not be able to do so. This came up during a discussion of diacytl production due to the level of the amino acid valine (sp?).

He asked us, "How many of you have called your malt supplier and asked for an analysis?" He said that this is very difficult for homebrewers to get, as they don't buy malts in commercial quantities.

I mentioned that I'd just obtained a general analysis of various malt types (thanks, Russ), and he said, "Your supply will vary, you should get an analysis with every batch." He suggested that we as homebrewers demand this information be included with every batch of grain. If we begin to demand this information, our retailers will ask our wholesalers, who will ask the malt houses, who will eventually supply it due to consumer demand. Then, along with our Alpha Acid analysis on every bag of hops, we'll get a malt analysis on every bag of malt.

Of course, we'll need to build HCU (Homebrew Color Units) and HDU (Homebrew Diastatic Units) and other HxU numbers into all our recipes.

This is going to be an interesting class!

Subject: How to put caffeine and anise in beer?

I'm sorry if this idea offends anyone too much, but this brew I'm planning has a special purpose. I am planning to make a Sleepout Caffeinated Doppelbock. Sleepout is a weekend in the Spring when all us nutty undergrads here at the University of Chicago "sleep" out on the quads the night before the first day that we're allowed to make registration appointments. The earlier you arrive, the earlier you can register for next year's classes, and the less the chance of the classes you want/need being filled by the time you get there. So understand, I need a drink that will intoxicate me and my friends, but "won't slow us down" as some marketroids might put it.

Does anyone have any ideas about how to add caffeine to beer? I don't want any coffee flavoring -- not in a doppelbock. Would pills be okay? Do I have to be careful of heating the caffeine too much?

I'm also toying with the idea of adding a hint of anise or fennel flavor, but I realize that aniseed is fairly oily, and don't want to jeopardize the head. Can someone suggest a method of adding flavor without oils?

I plan on pitching trappist yeast. If this works out, I'll post the recipe. Thanks in advance!

Subject: Natural History Magazine Hops article

I've fallen dreadfully behind in my HBD reading so excuse the repetition if this has been mentioned already.

The January issue of Natural History had a nice article on Hops in the regular feature 'A Matter of Taste' by Raymond Sokolov who writes about food from around the world.

He visited the Willamette Valley and describes the various steps in the production of hops. He describes one of the hazards in the early days of hops processing -- 'drowning' in the deep chambers where the dried hops were stored before baling. What a way to go.

He refers to Papazian's 'New Complete Joy of Homebrewing' regarding the role of hops in beer -- bittering, aroma, head retention, flavor characteristics of different strains, etc, and makes a small plug for homebrewing to any reader interested in learning firsthand about the role of hops in beer.

He confesses his primary interest is consuming hops themselves -- the tender spring shoots, which apparently are a delicacy in Belgium, eaten like asparagus. No one in Oregon who he met had ever eaten hop shoots but it was suggested that the shoots should probably be earthed over to keep them sweet and tender.

He included two recipes: Creamed Hops from 'The Belgian Cookbook' (Atheneum, 1970)

2lbs hop shoots, simmered 10 minutes, heavy cream and butter for the sauce, topped with poached eggs, salt and pepper to taste;
and Hop Sprout Salad from 'Bavarian Cooking' (Kochbuch-Verlag, Munich, 1983)

2lbs sprouts, boiled, and drained, marinated in a vinaigrette for an hour or so.

I don't recall seeing any mention of eating hop shoots in the digest. Anyone ever tried 'em?

First of, STOP THE BUBBLE MACHINE.

I am being inundated with mail, including warnings from Rob, about those two articles at the end of the last HBD. Kindly note that they are dated October and I had nothing to do with reposting them. I will offer no public comment on how or why they were reposted but rest assured, THAT is not my way of making points.

>From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: why boil H2O?

>Second, my water has chlorine in it. Not a lot, but enough to smell/taste and enough to combine with chemicals found in grains to produce nasty, possibly carcinogenic things like chloramines (?). Jack S., our resident amine-phobe ;-), can fill you in on that concern.

In this case it is trihalomethanes. They are a product of the reaction between chlorine and organics found naturally in just about any water in the world. They are highly carcinogenic and represent a serious health hazard that no one wants to talk about. It is entirely possible that the majority of human cancers are a direct result of chlorination of drinking water.

The problem is that politicians would be held responsible for epidemics of cholera or other water born diseases but finger pointing is ineffective with a disease that takes 30 years to show itself, so they just make believe it isn't there.

The problem is surfacing in the soft drink industry in California. Additional chlorine is added just before bottling to assure shelf life and the trihalomethane level is causing concern. It looks as though they are going to voluntarily modify the process to avoid bringing publicity to the issue. The soft drink industry just does not need an "alar affair". That's not to say that pop is good for you, they just don't want you to know how bad it is.

The good news is that trihalomethanes are very volatile and evaporate quickly when water is boiled. So, by boiling water, you get rid of the thm, in

addition to the chlorine, that would be available to make more tmh if
left
in. I have been boiling all my drinking water for years and my new 10
gal SS
pot has raised the process to a new dimension.

What turned me off, before I knew about thm were the grotesque
vegetables
that used to grow around my swimming pool. Where ever the garden was
in
range of water splashed from the pool, the vegies exhibited cancer-like
growth. That was enough evidence at the time and further information
confirms my early suspicions.

>of the vessel but to the amount of headspace in the vessel. I think
>when you fill the vessel to the neck you remove the trapped air (oxygen)
>used by the yeast during the first stage of fermentation. This limits
>the total population to a value lower than optimum and the fermentation
>takes longer.

korz> The reasoning seems sound, and it is true that oxygen-deficient
wort
korz> will cause your yeast to have trouble reproducing, but 2 gallons of
korz> air sitting on top of your 5 gallons of wort are not going to enter
korz> the wort unless you shake. I think the rate that the air will
dissolve
korz> into the wort, if it simply sits quietly, is very slow and aeration
korz> during the filling of the carboy would be several orders of
magnitude
korz> more than aeration from the air sitting quietly. Comments?

I now remember (I haven't been home for a few weeks) another difference
in
the two fermenters. The 7 gallon had an airlock, while the 5 used a 1"
blowoff hose into a jar with about 3 inches of water. Could the larger
back
pressure from the latter inhibit fermentation?

Subject: Chlorine removal, and re: moribund metheglin

First, thanks to those who replied to my question concerning the metheglin that wouldn't ferment. I added 4 tsp. of yeast energizer, and within 2 hours the stuff was bubbling away. Moral: whatever "yeast energizer" is, use it when making mead!

Concerning chlorine in your water: I had a conversation with the water chemist at our treatment plant about chlorine in our water, since I have had what I suspect are massive chlorophenol problems with my brew so far. He suggested that rather than boiling all my water, which takes lots of time and gas, I should just leave a carboy full of tap water out in the sun for a couple of hours. This, he claims, will drive off most of the chlorine if the carboy is loosely covered. One must exercise caution to keep the neighborhood cats out of your carboy, but otherwise this method seems to work well....

Also, for those who have high levels of bacteria, with or without chlorine, or for those who simply wish to be anal about sterilization, he suggested using ultraviolet light rather than boiling, for energy conservation purposes. They use a 254 nm wavelength blacklight in the lab to kill everything dead; he suggests surrounding a carboy of water and the proper blacklight with aluminum foil and leaving overnight. Another option is a gadget which is listed in the Cole-Parmer catalog; it's a UV water sterilizer which works on demand. They come in 1 or 2 gal/min flow capacities and a range of power requirements, and range in price from \$340 to \$500. Or if you are adventurous and want to build your own, replacement lamps for this gadget are \$32. None of these are cheap, but they may be worth it to you in time reduction or peace of mind....

Subject: Brew it at Home, a Review.

I received a copy of Jack Schmidling's "Brew it at Home" last Thursday, and thought I'd post a review. I am aware that this video has been the object of a lot of flack, but it does deserve a review nonetheless. Since I am virtually blind, I was especially interested to see (hear) how well this product could be used by the visually impaired to get them started in homebrewing. The AHA videos, while very fine, are so visually oriented that they are useless to one like me.

My wife watched the video with me, she has been my assistant in most of my brewing, and thought that the video effects and, especially, the closeups of the yeast and the timelaps work was very good.

I had observed from some of his postings that Jack has good powers of description. Beings as I can't see, I am very sensitive to this. These powers are employed in the video as well. I tried to imagine that I had never heard of brewing beer at home before and listened with an ear to how good the descriptions were. They were excellent. Never mind that I might disagree with Jack on some technical points of brewing for the beginner, the description could get anyone with a fourth grade education started, while not talking down to a grad student. I thought the tack of starting with root beer and moving to beer was good.

I was very happy with the lack of "patter" conversation during the actual brewing stages. Only the essential information was given. It was clear and understandable. There are moments of silence while things are being, I assume, stirred, etc., but that's all right. I prefer that to a useless patter that is so common among the television chefs and chefettes.

My wife was disappointed that Jack didn't go into the mashing process, but I told her that this was a subject for a future video. I feel that that Jack delivered on what he said the video was for. It would be just fine to help anyone get started in brewing. It would be most helpful for a visually impaired person getting started. He does explain some things that I had to figure out for myself since not all postings in the digest are complete primers on brewing. My first batches were rather haphazard, but they worked. While I never used sugar in a batch as Jack recommends, I still think if a person follows his suggestions, they will not be unhappy with the results.

There are some areas for technical improvement, but I'll not deal with those since this is not a professional audio-video forum.

I do recall that there was one complaint that Jack didn't mention the AHA in the video. This is not a problem, so far as I am concerned. While he may well have done so, he surely is under no obligation to give them, nor anyone else free advertising.

(Comments, thoughts, or flames to me directly!)

>From my audio only perspective, this is a good video and I can recommend
it
with no reservations.

Subject: What Yeast for high OG beer?

Yesterday, as an experiment, I started to ferment a brew made from unsparged wort. This is British style beer made with pale and crystal malt.

I mashed more grain than usual (with more water) so that I could run off a couple of gallons of neat wort before sparging the rest as normal. I boiled the neat stuff with hops separately, racked it, cooled it, racked it again and then kicked it off with a good beer yeast.

I knew it was going to be strong but hoped the yeast would cope. However, the OG turned out to be 1084! This, I'm pretty sure, will kill the yeast before it gets anywhere near finished. I've heard that a wine yeast can finish the job off but have no idea what to try. I don't have access in the

UK to the strains I've seen mentioned in HBD, but my local homebrew shop does have a large range of wine yeasts, conforming to different wine styles and grape varieties. Is this a good idea and can anyone suggest what type of yeast to go for? Can anyone offer experiences with brewing high gravity beers please?

Thanks,

From: jmiller@anubis.network.com (Jeff J. Miller)
Subject: Long Tall Lauter Tun

Since getting my large brewery set up I have been having lots of problems with good sparge techniques. The brewing vessel is an old piece of dairy equipment that is tall with a diameter of 26". It has an inverted dome on the bottom that drains out a spigot. It came with a 6" grate that would fit over this drain.

So... because of the large number of grains that I use, I would try to sparge out of the pot through the small grate. Because of the slopping sides of the inverted dome this mostly didn't work. I often get stuck sparges and it is a REAL hassle pulling the spent grains out. Since this pot is also used for the boil I also take a real hit on time and heat loss as I have to wait for all the wort to drain out, clean the pot, and then start up again.

Well... keep visiting those junkyards because this weekend I think I found the solution. I found a stainless screen bucket that looks like it was once used as a filter for some sort of large laundry drying machine. The bucket is heavily reinforced with 1/4" steel and has a bar across the top that will work good as a handle. The bucket itself is 18" across and 3' high with a slight dome on the bottom.

The one thing that I have been thinking about is possibly creating a tube that with lots of water outlets drilled into it that can be placed in the middle of the bucket to force the sparge from the center out over the entire height of the bucket. Any comments?

Subject: Re: Homebrew Digest #800 (January 13, 1992)

Beer making news I'm just bottling my first batch. Thinking about dosing it with a tablespoon of honey per five gallons to see what it will do,
but I don't know if it's the wise thing to do, and it's too early to relax
and have a homebrew ...

--*--

I noticed, in the last Digest, a repost of an old article by Jack Schmidling.
It looked like it had come from him ... and so I flamed him, privately.

Jack told me he hadn't done it ... which suggests that one of his enemies
-
um, enemies - did it. He seems to have quite a few, and they apparently do
not object to stooping to the level of dirtying HBD with their abusive
and
amoral tactics. I don't see why Jack would fart in his own pew, as it
were.
This is a major source of pleasure to him ... as to the rest of us.

As it so happens, only a day or so ago I commented to one of JS's enemies
on
the net that they were making themselves look incredibly bad with their
ways,
and that whatever differences I'd had with Jack, I'd never been
threatened -
which I have been, for addressing this other group of people. I pointed
out
that Jack was a solid contributor to Home Brewer's Digest. Then this
occurs.
It makes me wonder.

While I can't comment publically on whom this might be, since I'd be
beset by
a pack of lawyers drooling to profiteer from controversy and the
possibility
of a libel suit, I guess I can privately request the records from HDB HQ,
to
try and see where this message came from, if not Jack Schmidling, and if
any
person explicitly requests a copy of the email I sent, referred to in the
previous paragraph, I'll probably honor that request. I'd like to find
out
who thinks this is an acceptable tactic to practice ... otherwise, it
will
just happen again. And the mail header should show the relay systems ...
and
the relay systems can verify the header's contents. Or not, as
appropriate.

--*--

After all, if you're not Jack Schmidling's enemy ... you must be his friend.

Right ? So much for the Land of the Brave and the Home of the Free.

From: martin@daw_302.hf.intel.com (martin wilde)
Subject: When to Pitch?

I recently read somewhere that most commercial brewers have their yeast in the fermenter (the hungry beasties ready to go) prior to filling it with cooled wort. They say the beasties start working as soon as the fermenter starts filling.

I have been using this procedure (put the yeast starter in the fermenter before filling with chilled wort) for some time now. I have heard rumors that the little beasties (the yeast) would take longer to start re-production since they are "buried" under the weight of the wort and it is harder to make their way to the top.

any comments...

Thanks martin

From: Bob.Mastors@Central.Sun.COM
Subject: re: faucet adapter

A little while ago I asked for any experiences people have had with the William's faucet adapter and quick disconnect system.

There was general agreement about how well it worked.

It leaks a little but not enough to bother anyone.

It is easy to snap connectors on and off the adapter.

Everyone who responded liked it.

So I bought the faucet adapter and the connection for my bottle washer. I like it. Its easy to use. It does not leak (yet). It appears to be very well constructed.

As one person noted:

> One thing you should be aware of is that it does not provide any aeration to
> the stream of water.

Indeed it does not. But I actually like it better without the aeration. I wonder why its considered a feature.

A different person pointed out that the snap on plastic garden hose adapters could be used. I use these on my outside faucets and they work great. The William's system looks cooler though.

Bob

>
> ...
> Another use of radioactive isotopes is neutron bombardment of a
> sample for sterilization purposes. The neutrons kill all life in
> whatever it is you bombard, so it'll "live" forever (in its lifeless
> form, of course :-).

First off, thanks to Michael Hall for the authoritative response to your question! It's always nice to have an appropriate scientist on the mailing list when a topic such as this comes up! :-)! Second, I hope I am the first to point out my error in the above: I don't think neutron bombardment is actually used to sterilize foods; it may be used to sterilize other things, but the sterilization plant I read about in this morning's paper used Cobalt-60 as a source of gamma rays (electrons, not neutrons) to kill bacteria and prolong the shelf life of fruits and vegetables. And any food not sealed won't "live forever", of course. Bacteria will still grow on them; I was thinking only of those space food paks hermetically sealed in foil. Sorry for the earlier misinformation.

In other news, my first batch is conditioning right now. I had a sample of it last night (after four days) and it's quite flat. Did I put in the wrong amount of conditioning sugar? Or is the carbonation level expected to rise much between day 4 and 7-10? I made this batch from the first recipe in the New Brewer's Handbook (John Bull light malt extract, dextrose, Cascade hops pellets). Thanks!

From: korz@ihlpl.att.com
Subject: Treating Sparge Water + BJCP exam

Bob Jones asks if treating sparge water is necessary. Noonan, Miller and (I think) Papazian all agree that sparge water should be treated. The reason being that too alkaline a sparge will extract astringency out of your grains. I read this to mean that if your tapwater is not alkaline then it's okay to use it "straight."
Al.

P.S. I "survived" the BJCP exam with only a sore writing hand and a fried brain. The questions are very broad, like: "Discuss and distinguish beer styles X, Y and Z." and "Describe and distinguish three methods of process-A." I took it mainly so I can judge at competitions and learn more in *that* way AND to try to do my part towards making competitions better (I had read that there was a shortage of judges). Plus, with the level of quality that homebrew has achieved, I'll bet that some of the best beers in the world will only be available at the Regionals and at the Nationals and I may just be lucky enough to drink one of them!

I use a special handle that fits on the neck of a 5 gallon carboy
(I don't know about other sizes). It is metal, coated with orange
plastic, and attaches with machine screw and wingnut. I only have one
and move it from one carboy to another (I have yet to find a need to
carry two carboys at once). I believe I got it at Lil' Olde Winemaking
Shoppe (708-557-2523).

>are there benefits of giving them a full mash?

It is my understanding that, well-made crystal malt will contain little starch. The benefits of crystal malt are: its characteristic caramel flavor, it adds caramel color, it adds body, and it increases head retention. It has no active enzymes. For body and head retention without caramel color or flavor, dextrine malt (Cara-pils (tm)) can be used instead. In a person communication around 9 months ago, I asked George Fix about mashing crystal malt. The debate at the time in the HBD was about whether dextrans or proteins give a beer body. By the time I figured it all out, I forgot to post it to the HBD. Here's an edited version of our discussion:

Dr. Fix--

Recently, a question came up in the Homebrew Digest regarding mashing Crystal Malt as per Dave Miller's book (p. 54 - USING SPECIAL MALTS). A debate came up as to whether mashing the Crystal Malt will break down the complex carbohydrates (unfermentable ones) we are seeking by adding Crystal Malt into simple sugars and lose the body, heading, etc. gained by using Crystal Malt.

I decided to check in your book, Principles of Brewing Science (which I have just started reading) and could find lots of info on the enzymes, but could not find which types of carbohydrates are found in Crystal Malt. Do you have this data? I imagine that there are a wide variety of long sugar chains which would probably be mostly converted to fermentables by the enzymes during mashing. Am I correct? The little bit of starch left in the Crystal Malt is probably best left unconverted and the grains simply steeped at 170F or so and then sparged along with the mashed grains, right?
Al.

George Fix's response:

I feel it is best to mash crystal grains in the same way pale malt is mashed. This will indeed break down high molecular weight proteins down into small and medium weight proteins, however these make positive contributions to a beer's body, foam, and flavors. The same is true of the high molecular weight proteins. The latter, on the other hand, tend to be unstable. They will fall out of solution in both fermentation and

aging, as well as being only partially solvable in finished beer. I have found this effect to be quite important in amber and dark beers. In beers which use only a small fraction of color grains it probably doesn't matter whether they are mashed or not.
George Fix

Then I asked:

Prof. Fix--
Thank you for your response. I can tell that you are another believer in the body==protein-content theory. Is there any experimental proof of this? Can a low-protein/high-dextrin beer have a lot of body also? But this is another issue.

My main concern remains unanswered, namely: "Doesn't mashing crystal malt break the unfermentable sugars down into fermentable ones, thereby resulting in the fermenting away of the unfermentables that we seek by adding crystal malt in the first place?"
Al.

Dr. Fix replied:

Both unfermentable dextrans (alpha-glucans) and proteins contribute to a beer's body. Of the two, viscosity measurements show that proteins are more important. This can be directly verified in small volume brewing experiments. Try a normally mashed all malt beer as the control. Then do a "diat" version with a long and extended low temperature mash. The finished beer will have almost the same protein spectrum, but much less alpha-glucans. It will be stronger in alcohol content but thinner in body. This illustrates the effect of dextrans. Next do a third brew where, say, 15% of the malt is replaced with a dextrin corn starch. The latter has no proteins and approximately the same carbohydrate structure as crystal malt. Compare the three test brews taking their different alcohol content into account. A point I forgot to mention in my last message is that the main reason I use crystal malt is for color and for its special flavoring. Mashing crystal malt is the best way I know to get both. Other procedures that have been put forward --e.g., boiling-- tend to extract husk constituents that I find unpleasant in finished beer.

Subject: Re: Oxidation

Well, this is the way I have always looked at it. Feel free to correct me if I am wrong.

oxidation - chemical reaction in which oxygen and some other compound react to form an oxygen containing compound. Thus, the oxygen is not easily available to be used in the aerobic processes of the yeast and forms unwanted compounds in the beer. This is bad in brewing.

aeration - a physical process by which oxygen is dissolved in a liquid, but does not react with any other component. Thus, the oxygen is still free and available for aerobic reactions by the yeasties. This is good in brewing.

Am I missing something here or does this sort of explain why you want lots of oxygen in your beer but oxidation is a no-no?

Subject: pH Pen

Thanks for the review of the pH pen, Russ. Now maybe I'll know how to use the damn thing ;-) A couple of things I wanted to add.

>Standard solutions are available at 4 and 7 pH. Not exactly
>ideal for brewers who are looking for 5.0 - 5.5 pH. I am investigating
making
>my own standard solution by mixing portions of the standards.

I don't think this will work. The standards are buffers, which means that if small amounts of other stuff gets dumped in, the pH will remain unchanged.

This is why they are useful as standards. Compare this to say, distilled water.

It has pH of 7, but the addition of small amounts of nearly anything will cause

a change in the pH. You may be able to mix the two standards and get something

with the appropriate pH, but it will lack the stability of the standards.

>Yet I could make the argument that the pen will pay for
>itself by my not needing to replace my supply of papers as they run out.
At

>current prices, that ought to be in about 200 batches...

I bought one of these from Edmund Scientific a couple of years back. It lasted only about 7-8 months (15 or so batches) before it died, even though

I followed all of the maintenance instructions. It's a cute addition to the

brewery, but I haven't felt a need to replace it.

Subject: Chiller,alcohol.weight.vs.

Chiller,alcohol.weight.vs.voulume
I have a question on the best way to use a chiller in extract brewing. I recently built a counter-flow chiller [thanks to Mike Zentner for the plans] and used it for the first time yesterday. This is my procedure:

Boil 3 gallons of tap water and run the boiling water through the chiller, with no counterflow, in order to sanitize it. I save the output for later use (yes thanks to the HbD advice I received, I now boil all my water. Thanks.)

Do my regular extract boil, this produces about 2.5 gallons of concentrated wort.

Run the wort through the chiller to cool it and send the output to an empty, sanitized carboy.

Top up the carboy with the now room temp (or there about) water that I had boiled before.

Aerate the wort in the carboy and pitch my starter.

Rack to a secondary, when fermentation begins to subside (2-4 days).

Now, how do the rest of you do it, or what would you recommend that I change?

Second question:

Do hydrometers indicate potential alcohol content by weight or volume? And is there a way to convert one to the other?

Subject: yeast bank questions

Well, I've finally purchased one of these yeast bank deals for long term storage of my yeastie boys. The kit came with a bottle of blue liquid called "Freeze Shield" (glycerin?). Anyway, what you do is make a starter, divert some to a small test tube, pour in the Freeze Shield, shake it up, and freeze. So far, so good. But when you're ready to wake up the yeasties, you thaw, and dump it into a new starter. The directions don't say explicitly, but it sure seems like you're supposed to dump the whole thing--Freeze Shield and all-- into the starter wort. Assuming I'm correct, what will this stuff do to my brew???? I don't know much chemistry, but this Freeze Shield junk is not something I would have added on my own. Will it make a difference, or is there some way I'm supposed to separate it from the yeast?

Thanks,

Subject: Lots of questions about brewing

First I'd like to say thanks to everyone (Stephen Russell, Joshua Grosse, and others) that gave me the excellent information to help me with my first all-grain mash. I haven't actually done it yet (it's hard to find the time) but I feel much better prepared than before.

Anyhow I have some more questions.

1) What is a good off the shelf beer to "steal" a good lager yeast from? A local beer shop here in Reston, VA has an excellent (IMHO) selection of fresh beers imported from all over. However, I've heard that some breweries actually filter out their brewing yeast then pitch a special "conditioning yeast" at bottling time, and others that pitch more than one strain of yeast (Sierra Nevada perhaps?).

2) Can someone provide me the phone # and/or address of Zymurgy so's I can get a subscription?

3) About a year ago I acquired one of those old-fashioned Anheiser Bush "Golden Gate" kegs (just to cover myself, I didn't steal it, a friend found it in the attic of a house he bought -- and let me tell you, a few ounces of Budweiser sloshing around an empty keg sitting in an attic for a year or two produces quite a smell when opened :- (). Anyhow this is one of the older kegs with the wooden "bung" in the side and tap fittings at the top middle and bottom side. This is the very same keg that is pictured in Papaizan's Complete Joy of HB (the first one) in his kegging appendix. ANYHOW (the point at last) I would like to acquire the tap hardware for this keg; this would consist of a pump (for the top hole) and a "picnic style" tap and hose with the corrent connector (for the bottom hole), and am interested in hearing of any suppliers for such hardware.

4) Lastly, I'm looking for a recipe for an all-grain honey/ginger lager. I checked in the cat's meow and didn't find anything I liked. Anyone?

Thanks in advance!

Subject: Munching hops

In HBD #801 Paul Ford asks:

> I don't recall seeing any mention of eating hop shoots in the digest.
> Anyone ever tried 'em?

I heard about eating hops from some other source and tried to harvest some from my hop plants last spring. Unfortunately I didn't have a clue as to when to harvest. I waited till the shoots were almost 6 or 8 inches in length above the ground and then harvested. The shoots were still green but they were rather tough. They also had an almost thorny nature about them on the stems.

Anyway, since I didn't have any idea as to how to prepare them, I steamed them and was going to eat them like asparagus. The end result wasn't all that good but I think the problem was created by improper harvesting rather than the hop or the preparation. I'm going to try again this spring only I'll harvest sooner. Thanks for the recipes.

BTW: I was eating tatenger.

Subject: Warm Beer

First off, after nearly a week in our new house I finally had a chance to brew last night. Now its starting to feel like home!

Now to my question: yesterday a friend and I stopped in at a local store which reputedly has a large selection of imported and micro-brewed beers. That reputation seemed justified, as there was quite a large selection, albeit pricier than I'd seen elsewhere. What caught my eye was the selection of Sierra Nevada brews, including their Pale Ale, Stout, and Celebration Ale. I'd been keeping my eye out for the Pale Ale both to taste and as a source of yeast to culture, but I was quite surprised to see
lots of these beers stacked out on the floor, right next to the Bud! Of course, my own brews were often stored at room temperature, but never for too long.

Is there any reason to expect these beers to be less suitable for consumption or yeast culturing? I wasn't able to find any date code on the bottles (is there one?) so I don't know how old they may be.

Thanks,

Tom

Subject: Re: Carbonating in SS Kegs

>From what I've read on the HBD, most keggers seem to naturally carbonate their beer. What you're describing (with the shaking, etc) sounds like artificially carbonating the beer, which is what I've done.

With the grand total of one (1) soda keg (lots o' bottles, though) of homebrew under my belt, artificially carbonating worked fine. I followed the advice of Ron Downer (Brewhaus in Knoxville, TN) and after chilling for 12 hours, I looked up the pressure to use on a chart he gave of CO2 volumes at a given temp. Cranked up the pressure, sat on the floor with the keg between my feet, and shook for 15 minutes while listening to the CO2 go into solution. It was a breeze (and actually I didn't hear anything go into solution the last 5 minutes). The beer was the weakest homebrews I ever made, 1.8KG Ironmaster Canadian kit with 1/2lb Clover honey (the MiCoBud crowd loved it) which I thought would be one of the hardest to carbonate. Hardest part was knowing how long to wait for the head to go down before venting the excess pressure out the gas port - sure glad I had that towel handy :-)

BTW, Ron has a quick disconnect on his CO2 with both a gas and a liquid connector on the ends. When carbonating, he hooks up to the liquid and bubbles the CO2 through. I took the cheaper/lazy approach.

From: larryba@microsoft.com
Subject: Re: Trihalomethanes and brewing water

If boiling supply water will drive off residual Cl and the reaction product, then boiling the wort should do the same, right? If so, then why bother boiling the supply water?

I have noticed that hot water from my tap usually comes out effervescent and never smells chlorinated, unlike the cold water which sometimes smells chlorinated - Usually near the end of summer when supplies are low.

Two things: the effervescent water is caused by the dissolved gasses coming out. That probably explains why there is no Chlorine smell. The water usually clears within 3-5 minutes. Also, perhaps, the dissolved chlorine is coming out in the tank and reacting with the sacrificial anode? Anyone know?

I have heard that using Hot tap water is bad for brewing. However, it looks to me that using hot tap water is the way to go since it gives you much of the advantages of boiling w/o the time involved.

BTW I do all grain and full wort boils. I avoid bleach whenever possible, using boiling water for sanitization (except for the glass carboys...). In essence I am boiling all my water eventually, although not specifically to drive off nasty chemicals.

Comments, Suggestions or Data Points?

[re 5 gallon batch in 7 gallon carboy fermenting in one week,
while the one in the 5 gallon carboy is in its third week]

I personally wonder about aeration of wort in these cases. The only time I fermented in a 5 gallon carboy with blow-off I had to be much more careful in filling the carboy, resulting in much less aeration (with highly visible foaming and the like) than when I poured into the 7 gallon carboy. I have foam that takes an hour or more to subside just from pouring the cool wort into the 7 gallon carboy. I don't see how you could get that effect in a 5 gallon carboy.

Microwave Sanitizer
After reading James Smith's post on using UV light to sanitize water, I've decided to ask about something that I've been wondering about for a while. Wouldn't a microwave make an effective equipment sanitizer? Of course I know that there are size limitations, like your carboy surely wouldn't fit. But for quickly sanitizing your turkey-baster/wine-theif, thermometer, fermentation-lock, etc., it might just work very well. I would guess that the 'wave would cook the beejezus out of any little buggers on your stuff without even heating up your delicate plastic equipment (at least not much). What's the consensus?

>pressure from the latter inhibit fermentation?

Ahhh! I think I might have the answer. Wheat beer, right? Top
fermenting
yeast, right? The 5 gallon carboy used the blowoff method, so it blew-
off a
lot of the yeast that would have dropped back into the beer when the
krauesen fell. Maybe that is a significant amount of yeast and thus,
fermentation subsequently went slower? I would be interested in the
difference in flavor of the two "batches." I had noticed longer
fermentation
times since I switched to the blowoff method, but I had attributed
that to the heavier gravity beers I started making at the time and the
switch to Wyeast, also around the same time (I used to use M&F and Edme
which have both been hailed as explosive fermenters in the HBD).

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Byron and Charlie (George Fix)

It is sometimes a good thing when two accomplished brewers get into a brew ha-ha, because interesting things on the technical side tend to shake out of such spats. Moreover, bruised egos are quick to heal.

The dispute in question is between Byron Burch and Charley Papazian. At issue is Byron's eccentric Munich Helles formulation. In effect, Byron is recommending that highly alkaline water be used for this pale beer. When I first saw Byron's analysis in the GF newsletter in early Dec.,

I promptly called him to get more information. What emerged was more questions than answers. Also based on test brews started at that time it has become clear that there are some interesting issues that go well beyond a particular recipe and indeed a particular beer style.

Gerald Stoker has asked me to give a presentation at the Homebrew Festival in S. California in April. If I ever emerge from the current fog about the above issues, then I will talk about them. In particular, any input from others about pale beers (ale or lager) brewed with highly alkaline water (say with alkalinity of 200 mg/l or more) would be welcome. In order to directly compare them with those I am preparing, some or all of the following would be of interest:

1. Yield (e.g., weight of grains, volume of brew, and starting gravity achieved)
2. pH at the end of the mash
3. pH of the last runnings from the sparge
4. final pH of the chilled wort
5. amount of water used in the mash as well the sparge
6. type of mash system used (infusion or decoction)

Also of interest would be your evaluation of the malt character as well as the hop character of the beers. What is desired here is not a data base to establish general scientific results, but one that directly pertains to homebrew. I would of course acknowledge the source of any data used in a public presentation or publication, both of which would be confined to a not for profit situation like the Homebrew Festival or publications like HBD and Zymurgy.

Subject: pure water

Date: 14-Jan-92 Time: 12:54 PM Msg: EXT02642

Hi folks,

Water Purity:

Jack S. mentions Trihalomethanes as one poison class that results from interaction of Chlorine and water and other substances found in water. I don't know if Dioxin is a Trihalomethane, but it is one common name people should recognize (remember Love Canal?). It comes from Chlorinated water too.

James Smith mentions alternatives for getting rid of chlorine such as letting your water sit out overnight for evaporation or in the sun for UV destruction of the bad compounds. We used to let our fish water sit out overnight to evaporate, and none of the fish died (unlike what happens usually if you put goldie in with tap water). There was an interesting segment of 60 minutes, or 20/20 or one of those shows on alternative water use, and one part was on UV water purification. Almost everything (and they put some really icky stuff in) got broken down into H2O, CO2 or some other safe compound.

Wayward Posts:

I subscribe to another digest (SCA) and we often have posts recycle. I think sometimes some machine gets backed up somewhere, waits a few months, then spits out some old posts. I noticed that they were old posts and figured that had happened. It is absolutely incredible to me that someone would take annoyance with Jack that far, to make it look like he was still on about things like back in October. Besides, if someone wanted to make him look bad, wouldn't they make the header show a recent post date? Do not attribute to malice what can be attributed to computer error.

Subject: info on the yeast bank

Yow, lots of requests about the yeast bank. Where did I get it, how much, what does it come with, etc. Rather than responding individually, I'll post this summary instead.

I got it from Alternative Beverages in North Carolina. There number is 1-800-365-BREW. You can ask for a catalog (free), or if you only want to order the yeast bank, the order number is Y-BANK. It costs \$5.95 (US) plus UPS shipping for 1.5 lbs from North Carolina to you. Extra culture tubes and Freeze shield are available. The order numbers and costs are, respectively, CUL-TUBE, \$0.50, .1 lbs, and FRE, \$1.75, .3 lbs.

The \$5.95 kit comes with the following: 5 culture tubes, 4 oz. of Freeze Shield, a storage container, an eye dropper, and directions. The storage container is nothing but a 1-quart generic plastic storage container with a sticker saying "Yeast Bank" stuck to it. You can get the container at most grocery stores. When I saw it, I realized I already owned 7 or 8 of them (I use them for storing soups, stock, broths, gumbos, etc., in my freezer)--although mine, of course, don't say "Yeast Bank" :-)

The directions say that they (the autorhs) have successfully kept yeast for over 1 year. One cool thing about the tubes is that they come pre-sterilized in plastic wrapping, so you can open them and use them immediately without separately sanitizing them.

Hope this helps,
- --frank (a satisfied customer)

Subject: Getting Hoppy

More Hops Talk:

Hop cones (strobili) make a nice smoking substitute. The smoke the smoke smells like cannabis because it is. Some people report a mild effect. Hops (*Humulus lupulus* L.) is a member of the Cannabaceae family. Maybe if hops had been bred for smoking instead of beer making, they would cost \$900 a pound, be grown under lights in basements and be the source of much discussion, but the beer would be great.

Subject: Re: Long Tall Lauter Tun

I've been doing 15 gallon step infusion mashes in my clothes washer:
use warm wash (protein rest) and hot rinse (starch conversion)
selections; I turn up my water heater the night before to get the
higher temperatures I need.

The agitation insures that all the temperature distribution is even
(like the AutoMash). The final rinse and spin gives me a fantastic
sparge due to the grain bed compaction and the fine spray of hot water
over the grain. The wort is pumped out the output hose right into my
boiler. Simple, easy, and less expensive than AutoMash; it does a good
job on clothes, too.

Subject: Easy Label Glue!

Milk. That's right, the stuff you get from squeezed cows. Pour a small amount onto a plate, and dip the back of your plain paper label into the milk.

Stick it on your bottle, press in place with your fingers, and presto! It dries and stays stuck to the bottle, and any milk that got on the front of the

label dries clear. I got this little tip from another member of the Ann Arbor

Brewer's Guild at one of the meetings, but I didn't have a need to try it until last night when I was packaging up some gift bottles. I used 1/2%, but

I doubt that it would matter much.

Also, in honor of the "Hail to Ale" AHA club competition next month, I've included a little stanza to my signature (just for today) that you might enjoy.

Subject: Unholy carbonation (coors story)

Does anyone have any thoughts on "natural" (yeast-fart) carbonation vs. "artificial" (from a cylinder) carbonation? I hear a lot of marketing hype about the "fine, tiny bubbles" introduced by natural carbonation. Does this imply that artificial carbonation puts huge wonking bubbles into the brew? I've got a carbonation system, and haven't noticed much a difference in quality or taste.

- ----

On my way to the Anchor tour this winter, my mother told me a story about a clause in the union contracts of Coors brewery employees in the mid 1960's.

Apparently, for each employee at the brewery, 5 gallons of brew had to be on tap in the lunchroom. Each employee was allowed 4 beer breaks a day. How did they get any work done?? (A brewer at the Anchor told me that the rules there was "no beer until you've worked 4 hours...")

Bottoms up, heads down!

Subject: Air Infusion System

I have been thinking of ways to build an Air Injection System
for my "garage" brewery.

Since doing the "lambada" with 5 gallons of wort is not the
most exciting thing (my wife gets a chuckle), I thought there
must be a better way. I know the commercial breweries inject
oxygen into to the lines carrying the chilled wort to the
fermenters, but bottled oxygen is expensive.

So here is my idea...

The only problem I can think of is how to I get "clean" air
into the air pump?

Thanks, martin

From: djt2@po.CWRU.Edu (Dennis J. Templeton)
Subject: Freezing yeast cultures

In response to a recent posting about freezing yeast cultures, I'm posting the methods that we use in our research lab for freezing and recovering yeast. I have used similar methods for a while to culture ale yeast (1028) and I don't see why it should not work for nearly all organisms of importance to brewing. Translating the methods from the lab to the kitchen is another issue, and has been dealt with occasionally here.

We grow yeast in a rich medium, that can be substituted in the brewery with a simple wort: 1-2 tablespoons DME in a cup of water. In the lab we autoclave to sterilize the medium; in the kitchen I have found that making the wort up in mason jars with lids works well; I boil the jars and all in a covered kettle (better still a pressure cooker) for 45 minutes.

To freeze your favorite culture, make up two different jars with medium: 1 with DME in water, the other with DME in water:Glycerine (glycerol) 4:1 (i.e. 20% glycerol in water) Sterilize both. Inoculate the water culture with your best culture source; ideally, this will be a single colony from a petri dish (another topic altogether) using a sterile loop (or a long thin wire heat sterilized). Grow the culture for a few days at room temp, until it is distinctly cloudy. I don't worry about excluding air, since the culture is nearly absolutely sterile. If your inoculum is less certain (i.e. the dregs from your last bottle) there is a chance that you'll have other beasties in with your yeasties.

When the culture is dense, but before it's sat around too long (i.e. it is as healthy as it can be) pour the glycerol medium into the culture bottle, and mix. I dispense this into sterile vials using a sterile pipette.

Now, what to do in the kitchen. For sterile vials, I would recommend small glass vials, maybe 1/2 ounce with black bakelite caps. These can be sterilized in the oven (try one first) maybe 400 degrees F for an hour. Any small jar that seals well and can be heated should be ok. You might be able to boil them to sterilize, but this seems awkward. For a sterile pipette, you could boil a medicine dropper. Pharmacies sell these for giving medicine to kids, and they should be boilable. Fill the vials about half way.

Now, we store our cultures in the lab in an ultra-low freezer; -80 degrees C. I have kept these cultures at -20 (my home freezer) with good results,

but the liquid doesn't seem to freeze reliably. My 6 month old cultures have ice at the top and a brown liquid layer at the bottom, where most of the yeast are.

To use the culture, you CAN just dump it into the starter, since the glycerol (10% of 1/2 ounce (15 ml)) is less than a half teaspoon (1.5 ml).

Better, though, is to simply take a small innoculum from the vial. Take the vial out of the freezer and warm it until it just starts to thaw. Sterilize your loop (or wire) on the stove, and while hot, stick it down the side of the vial, to the bottom where the yeasties are. Then either streak your loop onto an agar petri dish for colonies, or dip it into a sterile jar of medium (wort) for your starter culture. Put the vial back into the freezer. This way, a few vials should last eons, as long as the vials are not fully thawed each time. I don't know the lifetime of the yeast in a kitchen freezer, but it is indefinite in the lab freezer.

Microbiologists know the advantages of working from single colonies, in that rare mutations are removed from the culture at the beginning of each experiment. I would highly recommend for those who maintain your own cultures learning how to streak for single colonies. I may offer suggestions for this in the future if it seems useful.

good luck-- dennis

Just a few comments of a non commercial nature.

> This should say "one of the rollers is 'bearly' driven by an under-powered motor". If I had it to do over again, I'd buy the hand crank unit and spend the extra money on a 1/4 horse motor and pulleys.

I hooked it up to a 1/2 HP motor from my belt sander and it scared the hell out of me. If one got his finger in, it MIGHT stop at the shoulder, but I doubt it.

I have chosen a different approach. Another set of pullies and another belt reduces the speed to about 70 RPM and increased the torque just enough to do the job with the "under-powered motor". It also eliminates the splatter of grain.

> The asthetics of the unit leave alot to be desired. Externally, the whole thing looks like something out of junior-high woodshop.

An artist I aint.

>The hopper is made from press-board mounted on two triangles of 'fake-wood'.

The "fake-wood" is not a cheap substitute for wood but a rather expensive but eco-friendly substitute for plastic. It is made from recycled milk bottles.

>There is no exit chute for the grains, so they tend to 'implode' in a pretty wide area around the bottom of the unit.

Speed reduction solves this problem.

> The hopper suffers from 'lack-of-slope' and capacity.

I took the cue and widened the slot on the bottom to eliminate grain jamming but now fingers can get in and I had to add a safety screen.

>I hope Jack will consider just selling the business part of the mill and let the buyer decide to do the finish work.

I have given this a great deal of thought but come up with no solution to the product liability problem.

>I understand Jack's concern for safety - but it kinda feels like the helmet law, the seat belt law, the warning label on alcohol, etc.... Just sell me the parts with a disclaimer that this unit is sold as a paper-weight, the seller accepts no responsibility for any other application.

Let me tell the story of the farmer and the ladder manufacturer and you will understand the dilemma.....

Once upon a time there was a farmer who was painting his barn. It was a very cold day in Northern Wisconsin and said farmer could see no reason not to set his nice new ladder in a frozen cow pie and lean it against the barn. Well, as the sun came out and warmed up the pie, the ladder slipped and the farmer fell and injured himself.

The farmer successfully sued the ladder manufacturer for \$80,000 because there was no warning on the ladder about frozen cow pies.

I saw this story on 60 Min and the ladder in question was almost totally covered with warnings because of previous, idiotic lawsuits. That is was America is all about and I am not about to risk my cosy life over a grain mill.

From: Mike Sharp <msharp@cs.ulowell.edu>

>ARF -- ??why??

Still more bubbles.

>FWIW, I did like the review of your grain mill. sounds like an interesting unit. Did you make the supporting castings yourself or were they left-overs from something else?

All of the castings are custom designs, sand cast by me. I use my brew kettle burner as a foundry furnace. Or was it the other way around?

>Did you wind up using stainless for the rollers or some form of tool steel?

The rollers are aluminum. Yeh I know, Alshaimers from the aluminum flaking off into my malt. Even I can be practical sometimes.

BTW, I tried making pasta with it. Forget it!

From: korz@ihlpl.att.com
Subject: Re: crystal + BODY

>It is my understanding that, well-made crystal malt will contain little

starch. The benefits of crystal malt are: its characteristic caramel flavor, it adds caramel color, it adds body, and it increases head retention. It has no active enzymes.

I think you missed the most basic reason for using crystal malt. All of the above can be achieved through other means but only crystal malt can be dumped into a simple extract brew and boiled for a few minutes to add the (some?) character of "fresh" malt.

What makes crystal malt unique is that it is essentially mashed during the kilning process. Other malts are bone dry before going into the kiln but crystal goes in at about 50% moisture content and is held at low temps until bone dry, then elevated to finish temp. The pseudo mashing occurs while the moist grain is in the low temp range.

I learned this by accident at the local home brew shop. When I tasted his malt, I discovered that only the crystal tastes like the stuff I make and demonstrate in my video. A little research pointed to the fact that by putting the grain in the oven when "dry to the touch", I was making crystal malt.

This also happens to be the most efficient method of producing nitrosamines and even the hardliners like Breis, make crystal malt by the indirect process. That is, by kilning it in such a way that it is never exposed to the combustion products of a gas flame. This also led me to stop making malt in my kitchen oven.

Subject: Freeeze Shield

Frank Tutzauer asks about reviving yeast from the freezer :

>But when you're ready to wake up the yeasties, you thaw, and
>dump it into a new starter. The directions don't say explicitly, but it
sure
>seems like you're supposed to dump the whole thing--Freeze Shield and
all--
>into the starter wort.

I don't have a yeast bank, so I'm speculating here, but I tend to agree with Frank. You probably don't want to dump antifreeze into your beer. One way around this is to :

1. Make up a small starter from the frozen sample, antifreeze and all.
2. When your starter is active, "plate it out" to isolate single cells. (A tight sphincter is essential here!)
3. Identify a healthy culture on your plate, and inoculate a small starter with that.
4. Successively pitch starter into larger batches until you have enough to pitch into a full batch.

This will not only assure that you've gotten rid of the antifreeze, but building the starter from a single cell will help ensure the viability of your starter.

Cheers,
CR

From: Douglas Allen Luce <dl2p+@andrew.cmu.edu>
Subject: Anchor -- Nierra Sevada Porter/Bigfoot

Hello all!

This Christmas I did the Anchor Tour; (I had made the reservations a month and a half in advance, and am told I just made it in!) highly recommended to all!

I also noticed the grant, and asked the tour guide what it was for; he said it pretty much wasn't used, but could be used for determining when (or if) a particular part of the lautering bed had been spent, and the grains should be shuffled around to increase the efficiency of the sparge. When I was there, it was kicking up quite a bit of foam.

Across the hall from the fermenting vessels was a setup to cool and aerate the wort, and (I think) some device to separate out the trub. I remember the guide saying something about swirling wort; there was a cannister about 8 feet tall, maybe 8 feet in diameter that was being gestured to during the description. Is this supposed to work similarly to swirling the wort around in the brewpot?

At the end of the tour, the guide made sure that all the participants were offered a sample of all the varieties on tap (Weiss, Steam, Liberty, Porter, Christmas '91, and Foghorn, wow!). Good thing I wasn't driving! Fat chance I can get kegs of a good barleywine like Foghorn in Pittsburgh (unless we see a Budweiser release...nah, they've already got King Cobra "good buzz fast" malt liquor.) I gave a little bit of thought as to how one might get a half-barrel to the airport check-in counter.

- - -

I did, however, smuggle back a couple of bottles of Sierra Nevada. One was a porter, from which I captured the yeasties and now have them slaving away on a nice thick porter of my own. (Aside: what does one get when they dry-hop a porter?? Is this a recommended procedure?)

The other bottle was the Bigfoot ale. Does anyone know anything about what yeast is in this thing? Is it different from the Pale Ale strain? Would it be suitable for a high-gravity brew or barleywine?

Bottoms up, heads down!

Subject: Sterilization using radiation

I hope this doesn't stray too far from the beer topic, but there were some additional questions about sterilization using radiation. There are several items on the market that are sterilized using gamma radiation. Some that I can think of include "Top Shelf" (a kind of "frozen" dinner that doesn't need to be refrigerated) and those cardboard juice containers that come with their own straw. I don't know if they do this to beer, but it is certainly plausible (and, in my opinion, preferable to pasteurization).

There seems also to be some confusion about what the different types of radiation are. Here is a table of the most common forms of radiation:

Common name	"What it is"	Mass (AMUs)	Charge
alpha particles	helium nuclei (2 protons + 2 neutrons)	4	+2
beta particles	electrons	.0005	-1
gamma rays	photons (electromagnetic radiation)	0	0
neutrons	neutrons	1	0
X-rays	photons (electromagnetic radiation)	0	0

For sterilization, gamma radiation is most commonly used. This is because alphas and betas wouldn't go very far into the sample (because they're charged), neutrons might activate the sample (make it radioactive itself), and X-rays would not be strong enough. The only difference between an X-ray, a gamma ray, visible light, and radio waves is the wavelength (and therefore the energy). Somebody just chose a certain wavelength range and gave it a name.

As far as how the sterilization using gamma rays actually works, I don't really know. My guess is that the radiation causes random screw-ups in the DNA of the bacteria, and hence prevents the replication necessary for reproduction. Is there a biologist/radiation specialist on this list?

We now continue with the brewing discussion, already in progress...

Subject: "chlorine" and boiling

Larryba@microsoft.com writes:

> I have noticed that hot water from my tap usually comes out
effervescent and
> never smells chlorinated, unlike the cold water which sometimes smells
> chlorinated - Usually near the end of summer when supplies are low.

May be that your water supply uses chloramine for disinfection, as mine does. This doesn't smell like chlorine, but some of its breakdown products do. According to the chemist I talked to at the local water plant, it takes 3-4 days for the breakdown to occur, and it is usually helped along by nitrifying bacteria in the water mains. It only happens when the temperature is warm (above 14C in the pipe), and so is usually evident in late summer and fall, and then only if you live far from the plant in "pipe distance", as I do.

No doubt the effervescence in your hot water is due to gasses coming out of solution. Whether the chloramine is among these gasses, I don't know. I boil all my brewing water now (since talking to the chemist). Who knows what those nitrifying bacteria might do to my wort, not to mention the chloramine.

"Relief" may be on the way, though, but at a cost. The paper reported recently that new federal regulations will probably require the Ann Arbor water treatment facility to switch to ozone for disinfection. This will make the water bill go up by 25-30%, but will mean that there won't be "any" chlorine in the water (and fewer bacteria, too).

Subject: weizen/weisse

I was doing my bedtime beer reading last night, and here's what Jackson's New World Guide says.

In south Germany, Weisse and Weizen are used interchangeably, although Jackson's column heading refers to the south German style as Weizen. This is the style most of us are likely to be familiar with: 50-60% wheat malt, relatively low hopping, use of *sacchromyces delbruckii*.

In north Germany, notably Berlin and Bremen, the Berliner Weisse style (and never Weizen to my knowledge) is a low-gravity (low 1030s), sour wheat beer, very lightly hopped, and fermented with *lactobacillus delbruckii* (that Delbruck got around!).

Subject: hop shoots as delicacy

As I understand it, hop shoots as food are served for only a very limited time during the year, namely the time when the hops are just sprouting. As the very young hop shoots are beginning to grow, they will force their way out of the hop mound. Until they really get going, they are very small and white rather than green. To cultivate hops for eating, throw a bit of dirt on the young sprouts to keep them white. After they've grown some and turned green, they're tough and "thorny."

Subject: Re: 1" i.d. tubing

Hello all. I have a few questions about culturing yeast.

I was reading Papazian and understand about getting the sterile wort in the bottles. However, then he says to dump some pure yeast culture in the first bottle. I assume he means wyeast. However, do you dump it all in one bottle, or do you put a little in all bottles. It seems to me that you would put a little in all bottles, so it can multiply and you would have 12 bottles full of cultured yeast.

But back to his method. If you put it all in one bottle, he seems to imply that you then dump the first bottle in the second and so on. That makes no sense to me. Bottles are only so big.

I am sure I am missreading him, and I plan to go buy millers book friday to see what he has to say. But could you please explain the procedure to me. I understand about getting the sterile wort, but what do you do after that.

Thanks for the help on this and everything. I hope I get net access when I start working.

Frosty

ps. speaking of that, does anyone know anything about public user unix access in chicago? that is where I will be working...thanks!

>

> Bottoms up, heads down!
>

> douglas luce
>

While I don't know about the 60's, Coors is now and has been (for many years, at least) a non-union operation. But they do have beer on tap in the lunchroom. I've seen it on tours. The tour guides say the policy is that anyone not operating machinery (lift trucks, bottling machines, etc.) is free to drink the beer. But if you get drunk, you loose your job. The guides say that has never been a problem.

All in all, I think Coors is a really good company, even if I don't like all of their products. If only they would make Winterfest all year long.

...

Of course, I'm biased! Coors sends excess steam from the brewery over here to heat many of the campus buildings.

>The other bottle was the Bigfoot ale. Does anyone know anything about
>what yeast is in this thing? Is it different from the Pale Ale
>strain? Would it be suitable for a high-gravity brew or barleywine?

>From what I have read, the yeast added to make the Bigfoot Ale is the
same as that added to make the Pale Ale. I choose the wierd phrasing
because of what I read about the repitching at SN (Zymurgy Styles
issue?).

Sierra Nevada repitches their yeast from batch to batch. They do not
harvest yeast fom the Bigfoot Ale, however, because the high alcohol
content makes it likely that the yeast will have mutated.

So, the yeast in the Bigfoot bottle is descended from the Pale Ale
yeast, but may not be identicle.

You still have to aerate your wort. So assuming you have plenty of
turbulence when you siphon into the fermenter then the yeast won't
get burried and you shouldn't have to worry.

In Digest #802, Tony Babinec asks:

> Does anyone have information from Wyeast or anywhere else about the
> two newest yeasts in the line, namely, "Belgian" ale and "California"
> lager? They are supposed to be arriving in the homebrew shops soon.

St. Patrick's of Texas already has them listed in their catalog.
(Remember
Don O'Connor's posting re: the nice lady that runs the place sleeping
with him
if he posted her address?) Well, I thought the posting was quite
humorous and
I have a soft spot for someone (in this case, Don's wife Lynne) who runs
a
business out of their home in order to be with their children. So, I
called
and got a catalog from her. Her price for WYeast is \$3.90 each. From her
catalog:

Belgian Ale #1214

California Lager #2112

Her number is (512) 832-9045.

I have no affiliation with St. Patrick's. I **will** be a customer soon.

I'm not sure about the glass that is used for carboys but i believe that window glass removes a significant amount of UV. Putting a black light outside if a carboy may not be doing much. You might be better off putting the light in the lid of a wide mouth container (hopefully not plastic but stainless). I heard glass absorbs the UV and that is why UV EPROMS have a piece of quartz over the window and not glass.

Subject: Priming with Malt

After brewing several batches of reasonably good beer, I have noticed a strange aftertaste which diminishes over time. When I taste the beer immediately before bottling and carbonation it is fantastic. However, the finished product never tastes even close. My sanitation could not be better short of an autoclave. I have been priming these extract brews with corn sugar could this be the problem. How does one prime with malt? I would like to boil up some dried extract and add it to the unprimed beer before bottling. Papazian mentions krausening with unfermented wort, but I would rather just use malt instead of sugar. Any suggestions on how much malt extract to use would be appreciated.

When I brewed in Massachusetts I never had this problem with an identical setup and procedure. So maybe the problem is Chicago water and not the use of sugar, but then again the beer tastes great before bottling. I am getting frustrated because prior to bottling I think I have made an ambrosia of the gods, but after priming in the bottle the taste alters considerably for the worse, although still much better than Bud etc. What is happening here? Anyone else have a similar problem. How was it solved? Help!!!

Thanks in Advance,
Caitrin

I've been stewing about this top/bottom fermenting thing ever since Micah
mentioned it several weeks ago. I remember reading in one of the brewing
tomes (Noonan? or was it Miller?) that top fermenting = ale and bottom
fermenting = lager is not strictly true. Several strains of ale yeast
available to the home brewer are bottom fermenters. I don't remember if
it
was stated that there are any top fermenting lager strains. Does anybody
else
remember this or do I need to go and dredge up a reference?

Subject: Sierra Yeast

There have been a couple of questions about Nierra Sevada lately :

From: quinnt@turing.med.ge.com (Tom Quinn 5-4291)

>I'd been keeping my eye out for the Pale Ale both to
>taste and as a source of yeast to culture, but I was quite surprised to
see
>_lots_ of these beers stacked out on the floor, right next to the Bud!

Storing Sierra right next to Bud is clearly undesirable, but you may be
OK
anyway. :-0 :-) Oh yeah, warm storage isn't ideal either.

A seldom mentioned advantage of making starter cultures is that one has
the
opportunity to do quality control checks (yummm) along the way. First of
all,
smell and taste the Sierra. Second, taste it again. Third.....

If you find anything off, don't bother making a culture from it. Hold out
for a fresher source. (Fire up those flame throwers!) Yeah, I live in the
SF area, so that's easy for me to say. There are probably folks out there
who will maintain that you can get a perfectly viable yeast from a beer
that
is light struck, oxidized, etc.... This is probably OK if you are willing
to streak the yeast on a petri dish and isolate a healthy colony. If
however,
you simply plan to dump the dregs into sterile wort, your best bet is to
get hold of a clean, fresh tasting sample.

Once you've made your starter and it's ready to pitch, smell and taste
it.
It may be bready, yeasty or overly sweet, but above all it should be
clean.
If you detect any defects, don't use it. If it tastes fine, then it's
probably OK to pitch, even if it was stacked next to cases of Bud.

>I wasn't able to find any date code on the
>bottles (is there one?) so I don't know how old they may be.

I believe that Sierra uses notches on the label to encode the date. There
are no months written there, but the key to the code has been published.
Zymurgy?? I met some Wort Processors at the 1990 AHA convention in
Oakland
who had this little card that deciphered the date when properly aligned
with the label. Maybe JaH knows of this.

From: Douglas Allen Luce <dl2p+@andrew.cmu.edu>

>I did, however, smuggle back a couple of bottles of Sierra Nevada.

[snip snip]

>The other bottle was the Bigfoot ale. Does anyone know anything about
>what yeast is in this thing? Is it different from the Pale Ale
>strain? Would it be suitable for a high-gravity brew or barleywine?

I've heard that Sierra uses the same yeast for all of their products. Since Bigfoot is pretty serious stuff, it's safe to say that Sierra yeast works well for barleywines. You're better off getting your yeast from a Pale Ale though. It will be healthier because the higher levels of alcohol in Bigfoot are more toxic to yeast. It will also be fresher because Bigfoot requires a longer maturation period than Pale Ale. Living at the bottom of a bottle of Bigfoot is difficult, even if you happen to be a yeast cell :-)

> but
> they may be worth it to you in time reduction or peace of mind....

Holy Moly! That's a good chunk of change for a UV sterilizer. If you want
to
experiment with UV sterilization there's a lot cheaper route to go. UV
sterilizers are used by aquarist types to kill parasites. Here are some
selected prices from "That Fish Place", a mail order outfit that I do
business
with:

Aquanetics 30 watt inline UV sterilizer	94.89
Hawaiian Marine 30 watt inline sterilizer	199.89
30 watt UV replacement bulb	25.49

Sorry, I don't know the flow rates these sterilizers will support but you
can
be sure they're less than 1 gal/min. You could probably do 5 gallons in
an
hour or two but that's a purely random guess on my part.

Subject: Radiation Sterilization

That was a nice writeup on radiation by Mike Hall in hbd #802. I would like to add something about the use of microwaves that has been questioned occasionally. Microwaves will not sterilize wort or equipment. The microwave ovens can sterilize or pasteurize by heating its contents to an appropriate temperature but the microwaves themselves have a small or no effect on killing microorganisms. I say that not because I'm a microbiologist or a nuclear physicist but because I use a microwave oven periodically for warming bread dough to make it rise. It heats the dough very evenly and can really speed up the rising provided that you do not heat the dough too much. My conclusion from this is that the yeast is not dying; it is actually thriving.

I have not, however, gone so far as to heat my yeast starter solution in the microwave oven because I am afraid of the microwaves causing mutations in the beer yeast. Perhaps a microbiologist can respond as to whether this paranoia of mine is justified. Mutations of bread yeast would not bother me because they are there only to produce CO2.

Sterilization in a microwave is practical provided that there is sufficient water and not very much metal inside. I've heard that if you violate either of these two rules you run the risk of destroying the klystron. I have a friend, though, who has put many different kinds of things in his microwave such as foil and light bulbs (no cats though) and his still works.

The temperatures required for sterilization are: 250 F for steam sterilization and 300 F for dry sterilization. Pasteurization temperature is typically 150 F which would kill all yeast and most (99% ?) bacteria. These temperatures should apply inside a microwave oven also.

Subject: Re: fermentation times vs vessel size

Date: Thu, 9 Jan 92 15:03 CST
From: korz@ihlpl.att.com

The reasoning seems sound, and it is true that oxygen-deficient wort will cause your yeast to have trouble reproducing, but 2 gallons of air sitting on top of your 5 gallons of wort are not going to enter the wort unless you shake. I think the rate that the air will dissolve into the wort, if it simply sits quietly, is very slow and aeration during the filling of the carboy would be several orders of magnitude more than aeration from the air sitting quietly. Comments?
Al.

Al's comments are very true. A great deal of air will dissolve into wort if it's surface is disturbed or agitated, and very little if it is not.

I found out about this when I was researching aeration techniques for my aquariums. Basically what was said is that if the surface of the water is disturbed, air will be dissolved into the water. So I experimented by rigging up a water pump with a tube on the pumps outlet. I pierced the tube every 3"-4" (approx 1/8" dia hole) over the length of the tube. Placing the tube under water, orienting it so that the pumps output just barely disturbed the surface. None of the fishies that I put in the tank suffered from O2 starvation (this was 2 years ago). I have now converted all my tanks to using this method. It's quieter (can't here it from a few feet away), simpler, and seems to aerate the water more efficiently than those d*mn air pumps!

Oops! Sorry for excess detail - but seeing as how wort is mostly water.

I just racked a light lager to secondary last night. I dry-hopped it with an oz. of Saaz. It's actually gonna be more of a steam beer (TM), since it's been fermenting at about 50 degF. Anyway, the important info is that the primary was done *in the brewpot*. I cooked it up, chilled it with an immersion chiller, pitched, covered, and moved it to the cool room. It was a Rapids 10 gal. pot. It worked great. The cover is loose enough to allow CO2 out. One odd thing is that the brewpot is now as clean as it has ever been. There were minor scorch marks on the bottom, from the 2 gas flames I use to cook with, but now the bottom is absolutely clean. Hmmm. The pot itself cleaned *very* easily. Obviously, if you're concerned about racking off the cold break, this is not for you. But it's quick and easy. We'll see how the beer turns out. Recommended, so far.

I've been doing this for about a year now. It works great, and has freed up my old fermenter for use as a carboy. I can now brew approx twice as often as I used to.

Subject: oldest brewery

Date: 14 Jan 1992 8:08 EST
From: dab@pyuxe.cc.bellcore.com (dave ballard)

Charlie P. mentioned in his posting that he was going off in search of "the oldest brewery in the americas." Anyone have any idea what that may be? I think that Jackson's book says that Yeungling (sp), in Pottstown, PA, is the oldest in the US. I assume that "the americas" means both continents. Which do you think has the older brewing history, north or south america?

On a recent trip to New Hampshire, I tried "Frank Jones Indian Pale Ale". The Frank Jones Brewry (Portsmouth, Maine) claimed to be the oldest brewry in the US (I have forgotten the date they were established). The brewry closed their doors during prohibition, and reopened a few years ago. They claim that the recipes they are using are the original, authentic recipes used when established, or was it when they closed their doors? Good Indian Pale.

I vote for south america; Inca, Myan (sp), et al.

Subject: Re: yeast nutrient

Micah Millspaw writes:

>The urine smell/taste in your mead is a result
>of the yeast nutrient. Don't use the ammonia salt type nutrients for
>meads. Their use and appearance in recipes is the fault of CP. The
>smell/taste will go away in a year or so.

I just checked TCJoHB and TNCJoHB and nowhere does Charlie mention ammonia salt nutrients for meads. In the 1st edition, he simply says "3 teaspoons of yeast nutrient" in the one mead recipe listed, the "Barkshack Gingermead." In the 2nd edition, there are three recipes for mead and in the two new ones it says "1/4 oz. yeast extract" which he describes as the "guts" of yeast cells. The "Barkshack Gingermead" recipe now recommends that you add either the yeast nutrient or the yeast extract.

Now... I don't know about either of these nutrients, or whether the only variety of yeast nutrient is the ammonia salt type, but I just wanted to clear this up. I disagree with some of the things that Charlie has written, but I disagree a lot more with Miller. By the way, as I read Miller, I marked things with which I disagree. Maybe I'll post a couple for debate someday.
Al.

Subject: Random thoughts on carboy handles, grain mill rollers

Someone, I don't remember who, and it was a long time ago, posted the suggestion to use a plastic milk crate to hold the carboy. I have a plastic milk crate and it does work well. The carboy is a little smaller than the crate, so there is room to slid my fingers into the handles. The weight of the full carboy rests on its base, and doesn't hang from the neck like it would from a handle. The plastic absorbs some of the shock when I set it down on a hard cement floor. Legal cheapo milk crates may be purchasd for a few bucks. Illegal ones are cheaper. To be fair, carboy handles may be better when holding a full wet carboy sideways to dump out the sanitizing water. I can rest the carboy on the side of the laundry tub (still in the handy crate) when I empty it, so supporting it is no problem.

All this talk of knurling and scoring grain mill rollers to grab the grain has me wondering: Why not coat the rollers with some sort of rubber, like a stick-on sheet, or hot dipping, to grip the grain. If the rubber is thin enough, or hard enough, the grain should get crushed just fine. Has anyone ever done this? Or is a silly idea for some reason I haven't thought of?

Subject: RIMS Temperature Controller?

I have been using a RIMS unit (a la R. Morris) for a while with good results.

I built the temperature controller he used per his diagram posted on Compuserve, and could not get it to work. (Yes, I checked and quadruple-checked the wiring, and replaced parts, and all that) I suspect device parametric differences, such as drive current, etc.

In any case, it doesn't work. I have a 100K NTC thermistor encapsulated and positioned in the wort flow. I have plotted the resistance curve and presently read the resistance to determine temperature, while turning on the heating element to get to the desired temperature. This hasn't been so bad, because once you get the mash to the desired temperature, it tends to stay there for a while, and it still beats the stir/scorch/cuss/scramble method.

I still would like to have real temperature control though. Does anybody have a tried and true temperature controller circuit which would work for something like this?

I'm in the process of upgrading the system by using a "mash tun from hell" similar to the one described in the digest some time ago in place of the cooler. If there is any interest, I'll post some of my construction details and/or experiences.

Cheers,
Alan Gerhardt

literature says you can go 6-7 generations, but out of fear of mutations, etc., I have always stopped at 3. Since I usually prepare about 10-15 tubes at a time, my \$3.50 pouch of Wyeast goes a long way, and each tube ends up costing me 25-30 cents, mostly because of the cost of the solution.

Cheers,
Alan Gerhardt

Subject: Additives, Travel, and Banana Esters

Greetings,

Lately, fragments of postings have dealt with the use of chemicals to foster Yeast colonies. Would someone please address this topic in detail, comparing and contrasting the various Yeast Nutrients, Yeast Energizers, and Brewing salts?

I flew from Rochester, NY to Minneapolis, MN a couple of weeks ago with a full case of home brew. It fit neatly under my seat. I had no trouble bringing it past the security inspection point. I had only one mishap, the straps of the duffle bag which contained the case tore off while I was boarding in Rochester so when I switched planes in Detroit I ended up walking a fair piece with the bag cradled in my arms like a newborn baby...

Sipping a bottle of my brew the other day, I noticed a hint of banana. I wonder if somehow esters were formed. Being something of a novice, I don't doubt that my lousy technique is at fault. Does anyone know which parameter(s) the beer considered when deciding to ester or not to ester?

Cheers,

Steven J. Boege

Subject: New Yeast Strains (fwd)

In today's Digest, you ask if anyone has information about two new WYeast strains. What, specifically, do you want to know?

I've brewed with the Belgian strain, as a sort of Beta site for WYeast. Haven't talked with Dave about my results yet, but I will say that if you use it, I would strongly recommend holding the fermentation temperature down below 60F. (This on advice of Martin Lodahl.) I kept it at 65F and resulting beer was VERY estery; this is in line with Martin's experience with Chimay yeast. Luckily, my wife loves all that fruit, but it's not what I had in mind.

On the positive side, it took a 1.072 wort down to 1.012 in about a week, maybe less. It has taken quite a while to clear in the bottle; or anyway, longer than I'm used to with Sierra ale yeast.

The "California lager" yeast is a genuine, st**m b**r yeast. If that's the kind of beer you're interested in, this is probably your best choice.

If I learn anything more, I'll post. I believe the yeasts are in the stores now; there was a considerable delay because the package manufacturer failed to deliver on time.

From: KENYON@MOE.ERE-NET.COM
Subject: Doubling batch size after Primary in SS Boiling Pot.

Hey all, I've got a hyperthetical question for ya' ...

Suppose you had a SS pot capable of boiling and fermenting 10 gallons of wort.

S'pose also, that what you really wanted was 15 gallons of beer.

Presuming that we designed our 10 gallon batch to have an OG 1.5 times higher than our 15 gallon would have been (wiollhaven!?), is it possible to add the extra 5 gallons of water (boiled of course!) after primary fermentation without adversely affecting the finished product?

A few subquestions on this subject:

- 1) Would it be best to aerate the extra 5 gallons of water and carefully rack the wort onto it for secondary fermentation? Or would the oxygen added during this "secondary" aeration tend to oxidize the beer?
- 2) Will the ensuing secondary fermentation be vigorous or turbulent enough to thoroughly mix the beer and ensure a good blending of the various flavoring and aromatic components?
- 3) Has anybody tried this and with what results?

I don't know if this is a good idea. You had better be sure you've
sanitized the grain -- steam maybe? A common source of bacterial
infection is grinding the grain in the same room you fill the fermenter.
The grain dust carries a lot of bacteria.

Subject: Re: weizen/weisse -- beer lore

Tony Babinec says that Jackson's Book says:

>>In south Germany, Weisse and Weizen are used interchangeably, although
>>Jackson's column heading refers to the south German style as Weizen.

With all due respect to the esteemed Mr. Jackson, I beg to differ:
In southern Germany (Bavaria or better, Bayern), use of the term Weisse
anywhere but on the label is rare. The people ("Volksmund") do not refer
to their Weissbier as Weisse or as Weissbier: they call it Weizen. If
you ask for a Weisse in Nuernberg or Munich you'll get a funny look. If
you ask for Weizen, they'll ask "Hefe oder Kristall?" meaning with or
without yeast. Real Weizen drinkers drink Hefeweizen, carefully pouring
it by putting the bottle completely into the glass holding both at a 30'
angle (from the table) and allowing the foam to be sucked into the
bottle.

The bottle is slowly pulled from the glass keeping the mouth 1-2cm from
the level of the beer as the glass is raised to vertical. This does take
practice, and is best tried for the first time outside or over a sink.
A small amount of head left in the bottle is allowed to 'condense' back
into beer, and then is swirled around to pick up the yeast -- this is
then

poured into the glass, causing what is locally known as 'the snowstorm
effect'. Living in Bavaria is living in Beer Heaven. There are lots
of different Weizens to try many of which are wonderful (Erdinger is
excellent, Schneider is good, Kitzmann and Tucher are nothing to write
home about).

My 2pf worth.

Subject: Sour Foghorn?

I had some Anchor Foghorn on draft the other night in Pasadena and it tasted quite tart, not too unlike some of the Belgian styles, but not what I expected. When I've had it on tap in DC (where I live) I don't recall any tartness at all, but heavy, rich, sweet, alcoholic elixer.

I complained to our waitron who told me ``It's supposed to taste like that.''

So, what's the scoop: does Foghorn lose it's tartness on its travels to the East, or was this keg contaminated?

> !Correct me if I'm wrong (like it had to be said), but
> isn't Morton's Lite salt (or sumpsing like that) made
> with Calcium chloride instead of Sodium Chloride??

Morton's lite salt is made from potassium chloride (along with some sodium chloride; I believe it's a 50%/50% blend). Potassium is directly underneath sodium in the periodic table: it has the same valence, similar properties, etc. Calcium is next to potassium; it has an extra electron in its outer shell (8-8-2 vs. 8-8-1), so it combines with two chlorine atoms to form CaCl₂.

>The Frank Jones Brewry (Portsmouth, Maine)claimed to be the oldest brewery
>in the US (I have forgotten the date they were established). The brewery
>closed their doors during prohibition, and reopened a few years ago. They
>claim that the recipes they are using are the original, authentic recipes
>used when established, or was it when they closed their doors? Good
>Indian Pale.

To correct a few minor nits:

The beer is actually called Frank Jones Portsmouth Ale, and it is in the style
of an India Pale Ale. The Frank Jones Brewery in Portsmouth, New Hampshire,
not Maine, isn't yet on-line, so its beers are still being contract brewed at
Catamount Brewing Company in White River Junction, Vermont.

I've never heard of Frank Jones claiming to have been the oldest U.S. brewery,
but he did claim to be the world's largest, though it's thought that he was
using a bit of license making that claim. The original brewery did take up
much real estate in Portsmouth around the turn of the century, and Jones had a
brewery in Boston at one point too.

The current Frank Jones brewery is owned by partners Don Jones and Lee Ann
Lombardi. Don is a relative of Frank's, great-grandson I think.

There are presently two Frank Jones beers: Portsmouth Ale is a hoppy, bitter
India Pale Ale, and Frank Jones Special Reserve is a high-gravity, high-alcohol,
delicious ale that is similar in style to Sierra Nevada Pale Ale. The Special
Reserve is currently only available in NH state liquor stores, due to arcane
state regulations regarding the alcohol content of beer in NH. Normally
beer
is sold in supermarkets and variety stores in NH.

Frank Jones Ale is available on tap in several locations around
Portsmouth,
and one of them, The Rusty Hammer, has many pieces of original Frank Jones
breweriana. Check it out if in the area, and look for the brewery to open soon.
And get some Special Reserve, it's a winner!

The oldest (established) brewery in America? I think it's Molson, which dates back to 1786?

Subject: Re: Clorination... Seattle water

Just an FYI for all out there responding to my query about chlorine and hot tap water. Seattle water is surface run off from protected mountain valleys. There is little treatment other than settling ponds, a coarse filter and CL2 injection at the main intake and at each reservoir.

I believe that about ten years ago Seattle started treating the water with a little lime to protect the water pipes in older houses (a little coating of lime to prevent corrosion and leaching of lead). The net result is very soft water with just a tad of calcium carbonate hardness (20ppm or so).

>
>CR

That was the problem that most disturbed me about one of those pH pens.
The
probe part of the instrument is not replaceable, but pH probes do wear
out.
I built a pH meter which uses a Digital Volt Meter (DVM) for the readout,
and use a low cost (\$35) pH probe I bought from Cole-Parmer. The
accuracy
is much better, and all I replace is the probe, not the entire
instrument.
pH probes are perishable and there is not much that can be done about it.

[dave ballard asks about 1" tubing]

>Hey now-
>
>I need help locating 1" i.d. plastic tubing.

I got mine from the local ACE Hardware store. I don't think home
improvement
places would carry the large stuff.

[Tom Quinn asks about date coding on Sierra Nevada]

>What caught my eye was the selection of Sierra Nevada brews, including
>their Pale Ale, Stout, and Celebration Ale. [...]
>
>[...] I wasn't able to find any date code on the
>bottles (is there one?) [...]
>
>Thanks,
>
>Tom

The date code is in little notches on the edge of the label. The wide
notch is an index, with last digit of the year, day and month encoded.
Check the homebrew archives. I have a little card I carry in my wallet
so that I can check the date codes of Sierra Nevada.

[martin wilde talks about an air infusion systems]

>I have been thinking of ways to build an Air Injection System

>for my "garage" brewery.
>
>[diagram of aquarium pump]
>
>The only problem I can think of is how to I get "clean" air
>into the air pump?
>
>Thanks, martin

I am going to use this method on my next batch. I found an item that is similar to an airstone, but is a smooth porous ceramic tube with rubber end grommets. This will fit perfectly on the end of a 2 ft. piece of 10mm. glass tubing. The plastic tubing connects the air pump to the glass tubing. Both tubing and diffuser are easy to sanitize with boiling water. I am not going to worry (!) about the bacteria that may be present. I think that the amount present would be small. I thought of enclosing the air pump in a small box with a quartz UV tube that I have, but I am not sure I want to blow ozone through my beer either. (Talk about oxidized beer) You can buy filters from Cole-Parmer that will filter the bacteria from the air, but I didn't want to spend over \$100 for a package of 100 filters. Maybe we could split the package 20 ways?

On the subject of UV lamps for sterilization, does anyone have any reference books that deal with exposure time and penetration of UV radiation at 254nm? I checked a local electrical distributor and I can get a 15 watt, 18 inch germicidal tube (\$22) that will fit my undercounter light in the kitchen. I want to use this for area sterilization while I am doing my yeast culturing. I know this wavelength UV will burn skin and eyes, so I WILL be wearing protective clothing and eyewear.

Tanker Ale is the name of the beer Perry is describing, if that will help
anyone
answer Perry's question. I've drunk Tanker Ale on three occasions, and
have
always been very impressed by the amount of fresh grain aroma in it.
Actually,
the one Perry tried on Saturday may have been a little old, because it
was less
impressive than the other two I've had. Still good though.

If anyone knows how Boulder Brewing Company does it, I'd like to hear.
Curiously, when I see printed mention of BBC's products, Tanker Ale is
never
mentioned.

It only took me about an hour to put a bizzilion holes in the bottom of
one of those buckets. The problem is that you generally drill from the
bottom and that little plastic curley-cues are left on the other side
which, in this case, is the inside of the bucket. The curley-cues tend to
partly block the holes. I took a single-edged razor blade and trimmed
them off. Melting holes (or slots) is another alternative which might
make globs but no curley-cues. I bet it's a lot slower though since
you'll
have to heat the knife for each hole/slot. With a power drill it's just
bzzzzzt, bzzzzzt, bzzzzzt, ...

Subject: Re: Trihalomethanes and brewing water

>If boiling supply water will drive off residual Cl and the reaction product, then boiling the wort should do the same, right? If so, then why bother boiling the supply water?

Good question. I guess the only answer I can think of is, why make new poison just because you think it will go away? That's not a very good answer

but that's because it was a very good question. I simply applied what makes

sense for drinking water to brewing without thinking it through.

>I have noticed that hot water from my tap usually comes out effervescent and never smells chlorinated, unlike the cold water which sometimes smells chlorinated - Usually near the end of summer when supplies are low.

I noticed something else about hot tap water and did some experiments that convinced me that using cold water is a MOMILY. Fill a glass with hot tap water and one with cold and let them sit over night then taste them in the morning. In the case of Chicago water at least, the cold water usually has a very unpleasant taste after sitting out.

I found this by accident because I frequently noted that water served by restaurants around Chicago had a very foreign taste. When I noted the same taste at restaurants IN Chicago, the scientist in me came out because I drink Chicago water at home and it never tastes that way, until I tasted some that was left out over night.

Although I now boil my water to get more miles out of my nifty SS brewpot, I had been just keeping several pitchers out for for drinking water. I fill them from the hot water tap and generally sit for 24 hours before drinking.

This does indeed get rid of the chlorine and other volatiles, just takes longer than boiling.

Subject: Pitching Wort ONTO Yeast

>You still have to aerate your wort. So assuming you have plenty of turbulence when you siphon into the fermenter then the yeast won't get burried and you shouldn't have to worry.

I have found a very simple way to aerate wort. I tap the chilled wort one gallon at a time and glug this into the fermenter after giving it a few shakes. The amount of aeration one gets this way is considerable.

From: caitrin lynch <lyn6@midway.uchicago.edu>
Subject: Priming with Malt

>After brewing several batches of reasonably good beer, I have noticed a strange aftertaste which diminishes over time.

When you prime with malt you will find the opposite situation. After you add the malt solution, the beer takes on a raw malt taste that goes away with time.

>How does one prime with malt?

Boil about a cup in a little water and use just like sugar.

According to a recent posting though, sugar won the taste test between malt and sugar.

>When I brewed in Massachusetts I never had this problem with an identical setup and procedure. So maybe the problem is Chicago water and not the use of sugar, but then again the beer tastes great before bottling.

> I am getting frustrated because prior to bottling I think I have made an ambrosia of the gods, but after priming in the bottle the taste alters considerably for the worse, although still much better than Bud etc. What is

happening here? Anyone else have a similar problem. How was it solved?
Help!!!

My very similar problem went away when I started using Edme yeast.

> Anyway, the important info is that the primary was done *in the
brewpot*.
I cooked it up, chilled it with an immersion chiller, pitched, covered,
and
moved it to the cool room.

> It was a Rapids 10 gal. pot.

I thought I was in untested waters when I fermented my last batch in my
Rapids. As you said, it is a dream and having a spiggot on the bottom,
no
more syphoning. However, I was stuck with storing the wort until the
"brewpot/fermentor was empty and cleaned out. Enough of a pain to cause
me
to decide to go back to the old plastic fermentor.

>I've been doing this for about a year now. It works great, and has
freed up
my old fermenter for use as a carboy. I can now brew approx twice as
often
as I used to.

The question left is, is this extract beer or all grain? As there is
considerably more and different residues from all grain, I am still
reluctant
to try fermenting on the boil crud till someone claims success.

From: Arun Welch <welch@cis.ohio-state.edu>
Subject: Re: Microwave Sanitizer

While this has been discussed to death, here's one more data point. It is possible to sanitize stuff in a microwave, but only at low pressure. Essentially, the gases turn to plasma, which does a very good job of killing off everything in the container. Practical applications of this technology for medical sanitation are expected to be a year or two out, unfortunately. It has the added benefit of not getting too hot, so you can sanitize some of that plastic tubing, etc. :-).

Subject: Unmalted rye in brewing

Greetings,

As I write this I'm roasting a pound of unmalted rye in my oven (375' F, 35 min. so far). The idea is to make the following take off on a stout.

- 7 lb. 2 row Klages
- 1 lb. carastan
- 1 lb. roasted unmalted rye
- 1 lb. flaked rye

The procedure will include a 30 min. protein rest and a 60 min sacc. rest at appropriate temperatures and the right hopping for a semi-dry stout. My main question is, has anyone done this and if so is it good? Also if anyone has experience roasting grain, unmalted or not, I'd love to hear about it. I'm just tired of paying up to 5X what our friendly HB store owners are paying for grain. Yes I buy my 2 row in bulk and the carastan too (\$0.30 and \$0.37/lb.) but I don't use enough of the dark grains to justify 50 lb bags (I only wish). If there is interest in this and if I get some good roasting info I will gladly summarize in this august journal.

Thanking you in advance,
Glenn Tinseth

I'd say as far as the wine-theif, fermentation lock, etc go this should
work
but probably wouldn't be easy. You probably have to heat enough that the
actual equipment gets hot. I don't think that the bacteria or yeast would
have enough polar molecules (like water) to absorb much microwave so
you'd have to rely on the heat from the surfaces to kill them. (To
clarify,
they may be 99% water but they have a very small cross-section.) In this
case
you might as well put them in the oven. Bleach is probably the quickest
and
most reliable. Since I obviously don't know a heck of a lot about it I'll
move
on to what I do know and the main reason for the post:

DON'T PUT YOUR THERMOMETER IN THE MICROWAVE
DON'T PUT YOUR HYDROMETER IN THE MICROWAVE

Both contain metal. If you don't already know how metal reacts in a

There are all kinds of epoxies available. There are formulations available that don't become brittle and some that are approved for food containers. Sorry I can't recommend a specific brand. Read the labels carefully and check around.

You can improve the bond by sanding around the crack to roughen it up so the epoxy will have more to hold onto. Most epoxies don't bond well to smooth surfaces. Also, covering the crack with some sort of strong synthetic cloth that you can permeate with epoxy will make the patch much stronger, and more flexible.

Food grade epoxies can be very handy for building homebrew equipment. Be sure you give them plenty of time to cure so they lose all their volatile constituents before using them.

Good luck.

Subject: Yeast is Yeast

There was a farmer who had a horse that had a very long mane. Every morning the farmer would go out and plow his fields and everything was fine until one day a flock of birds flew over and built a nest in the horse's mane. This was bad enough, however, the birds would tweet and tweet all morning so that the farmer could not get his plowing done! One day while the farmer was in town he ran into Gus, the local know-it-all. "Gus", the farmer said, "this flock of birds have built their nest in my horse's mane and all morning they tweet and tweet and I can't get my plowing done! What should I do?". "I've got the perfect solution", said Gus, "go home and put some yeast into the horse's mane and all your troubles will be over!". "Yeast!", the farmer exclaimed, "what good will that do?". "Just try it", said Gus! So the farmer went home and put some yeast into the horse's mane. Next morning the nest was gone, the birds were gone, and no more incessant tweeting! The farmer was overjoyed! The next time he was in town and ran into Gus, he asked Gus how did he know that putting yeast in my horse's mane would get rid of the birds, the nest, and the tweeting? Gus replied: "Yeast is yeast, and nest is nest, and never the mane shall tweet!".

From: Greg Beary <gbeary@advtech.uswest.com>
Subject: Botulism

While laying awake last night, I started to worry. I have a batch of Montmellick (sp?) Stout in my secondary. My worry concerns the state of one of the cans I used to make it.

I purchased one can roughly +year ago. A second can came my way via England, where my brother bought it for me in a British Home Brew shop. I had asked that he bring back a few bottle conditioned beers, so that I could "steal" their yeast. He unfortunately got the message confused. The woman in the store sold him "this great product that produced stout just like Guinness". He was rather disappointed when I told him it was the same brand I normally use (though in a different outer packaging).

Anyway, I decided rather than use one can of extract and one can or bag of malt extract, I'd use two cans of extract (one US, one Brit). The problem was that when I went to open the US one (about 14 months sitting on my shelf) it was a bit swollen. The ends of the can bulged out. When I opened it, it gave off a bit of pressure, but smelled normal. I figured at the time, what the heck I'll be boiling it real well, it can't do any harm. So, I prepared as normal, racked onto the trub left from a Brown Ale (done with "stolen" Sierra Nevada yeast) and left it to ferment. I had chilled it very well, down to about 45F, and I wasn't suprised that it took a day to come to temp and get fermenting. Anyway, three weeks later everything looks to have gone normally.

My real question is if anyone else has had problems with Extract cans swelling? Also, while laying awake, I thought that I remembered reading somewhere that Botulism is a toxin. That is, if you have a can with the big "B", you can boil the contents and kill the critters that manufacture "B", but that doesn't remove what they have already produced.

Why this didn't occur to me when I was brewing, I have no idea. Perhaps I was working too hard at not worrying.

Anyone have any insight on this issue?

Thanks,
Greg

>I wonder if somehow esters were formed. Being something of a novice, I
don't
>doubt that my lousy technique is at fault. Does anyone know which
parameter(s)
>the beer considered when deciding to ester or not to ester?

Esters are produced by your yeast. There are primarily three factors
that
affect ester production: the strain of yeast, the fermentation
temperature,
and the pitching rate. Some yeasts are more likely than others to
produce
esters (try a bottle of St. Louis Gueze -- WOW! -- unfortunately it is
filtered -- RATS!). Red Star Yeast is widely known to produce banana
esters. Higher fermentation temperatures increase the production of
esters
and higher pitching rates increase ester production. In the
Troubleshooting
Issue of Zymurgy, David Logsdon also mentions that high-gravity beers
generally
have more esters, but I have not found this correlation in my beers.

One other related piece of info, the Troubleshooting Guide notes that
in time, esters tend to be converted to higher (fusel) alcohols and give
the beer a solvent-like flavor. I have not noticed this in my beers.

Jack responds to Caitrin:

>>How does one prime with malt?

>

>Boil about a cup in a little water and use just like sugar.

>

>According to a recent posting though, sugar won the taste test between malt

>and sugar.

Not exactly. Dextrose (corn sugar) is 100% fermentable but malt extract is only 75-80% fermentable (by weight). Therefore, if you are happy with your carbonation when using 3/4 cup dextrose, which weighs 4.5 oz, just weigh out 5.4 to 5.7 oz of dry malt extract, boil that and prime. Since each brand of malt extract has a different fermentable/unfermentable profile, you will have to experiment a little and adjust accordingly.

From: Curt Freeman <curtf@hpwart.wal.hp.com>
Subject: B-Brite longevity
Full-Name: Curt Freeman

On occasion, I have kept a quantity of B-Brite solution around and used it at a later date. Recently I was told that B-Brite solutions are not like Metabisulfite solutions; they should be used immediately and then discarded. However, the person who told me this was the same person who sells me it. Is B-Brite a free oxygen scavenger or something that loses effectiveness over time. I can verify that old B-Brite solutions remain effective cleaners, etc, but maybe they don't remain effective sterilants.

On another issue: the swirling technique of aiding separation of trub from wort should result in something like:

```
| |
| * | * |
| **A ** |
| ***** |
| ***** ***** |
| * B *** *** B * |
| ***** |
```

Brew pot

So where is the high concentration of trub supposed to be, in A or B? "Trolling" around the pot with my siphon wand didn't provide an obvious answer. Guess I have to work on my swirling.

To be fair, carboy handles may be better when holding a full wet carboy
sideways to dump out the sanitizing water. I can rest the carboy on the
side of the laundry tub (still in the handy crate) when I empty it, so
supporting it is no problem.

>

One idea that springs to mind here is to weave some rope around the
carboy
neck and down through the holes in the milk crate. Say, 3/16" sisal
would
keep even a full carboy steady in the crate when emptying. I would also
use cutouts from an old tire to brace the carboy in the crate, so that it
doesn't slide around. I will make one of these setups the next time I
find
a milk crate, as my carboy scares me every time I pick it up full. Thanks
for the good idea, folks!

With two milk crates per carboy, you can set up a little stand that
makes draining carboys a breeze and frees you up to do other things
while they're draining. It works like this :

Cut a diamond shaped hole in the bottom of one crate. Make the hole
sufficiently large so that enough of the carboy's neck fits in to
make it stable, but small enough that the entire carboy doesn't slip
through. It should like something like this, but square instead of
rectangular.

Stack the cut crate on top of the uncut crate, bottoms down. You can
then invert the carboy and place it inside the upper crate, where it
will happily glug away until empty. The conservation conscious can place
the stack inside a drum, and collect the water for later use.

Subject: Bottling vs. Kegging question

From: "The Rider" <mfetzer@ucsd.edu>
Date sent: 17-JAN-1992 19:44:57 CUT

As many of you know, it takes a while for beer to carbonate in bottles. After about a week or so, there's enough CO2 to make it drinkable, but the taste is just not quite right yet. I have personally found that our beers are at their peak 6 weeks or more after bottling, and some that were unaccepttable after 2 weeks were great after 6. These are mostly india pale ales I'm talking about, usually partial mashes.

Enter a friend with a story of Hales brewery, in Kirkland WA. They brew in large vats, that are completely open to the air. They rely soley on CO2 to keep nasties out of their beer. To do that, you have to of course pitch a large amount of yeast. So, after a batch has fermented 3 or 4 days (I forget which, seems like it was 3!) they skim the floating yeast off the top, pitch it into a new batch of beer and off it goes. Now, they immediately cold filter the first batch, and keg it! It goes out to breweries on a truck the same day, and is drunk within a week. Excellent beer.

So my friend decides to try the kegging at home, and he claims it works. He does a two stage ferment, still, but then he kegs and can drink it immediatly. No weird taste that takes 6 weeks to go away. What gives?

Is it the conditioning in the bottle? The yeast thats suspended in the process? Why does everyone say beer needs to age several weeks?

Take care,

Mike

From: gjfix@utam.uta.edu (George J Fix)
Subject: Bottling vs. Kegging question
Subject: Foghorn (George Fix)

Chris Sheldon mentions tasting a tart Foghorn on draft, and asks about the origin of this flavor. This is not a normal characteristic of this beer, and is likely due to an infection (possibly lactos). Given Anchor's standards and rigorous microbiological tests, it is likely that the infection was picked up in the beer lines of the establishment where the beer was served. This does not happen that often, but it unfortunately does sometimes.

This type of flavor defect is totally different from the ones I described in an earlier post. The latter were found in bottled beer, purchased and consumed thousands of miles from the brewery. I believe (perhaps incorrectly) that they are due to indirect oxidation originating in the brewhouse procedures used by Anchor.

Subject: Random thoughts on carboy handles, grain mill rollers

Date: Thu, 16 Jan 92 08:01:08 CST
From: tomm@pet.med.ge.com (Thomas Manteufel 5-4257)

All this talk of knurling and scoring grain mill rollers to grab the grain has me wondering: Why not coat the rollers with some sort of rubber, like a stick-on sheet, or hot dipping, to grip the grain. If the rubber is thin enough, or hard enough, the grain should get crushed just fine. Has anyone ever done this? Or is a silly idea for some reason I haven't thought of?

It is much more cost effective to knurl or score the rollers. Rubber compounds hard enough to do the job are expensive, difficult to apply, and expensive to apply. I would hate to try to apply sheet stock to any roller; cutting the length would be very difficult at its easiest.

Subject: CO2 volumes/temp/pressure chart for kegging.

Folks were curious about the chart I got for finding the pressure to use to artificially carbonate beer. I entered it in and it can be anon. FTP'ed from cs.utk.edu in the /pub/key/ directory as co2-chart. The chart is approx. 154 char wide by 44 lines long of text. It was printed from the program co2-volume.c that's also in the directory. It has the original data so you can modify it's printing to get a different layout. Please let me know if you catch typos, the relationships are fairly linear.

From: Robb Holmes <RHOLMES@uga.cc.uga.edu>
Subject: Ale Atlanta beer ratings

The Atlanta Journal-Constitution, in its Thursday, January 16, 1992 edition, published an article (in the food section) on beer ratings by a local club called Ale Atlanta. The article says the club has about 30 members, with about 20 attending most tasting sessions. According to the article, 101 beers were considered, divided into 12 categories. In each category a winner and runner-up was selected, or two runners-up if the 2nd and 3rd place finishers were separated by only one point.

Here are their ratings. I won't reproduce the comments that accompanied all the first-place winners, but will provide them on request.

Amber: Wild Boar, John Courage Amber
Ale: Pete's Wicked Ale, Whitbread
Import Pilsner: Tsingtao, Pacifico Clara
Import Dark: Spaten Dark, Augusteiner Maximator, San Miguel Dark
Wheat: Paulaner, Hacker-Pschorr
Dry: Pete's Pacific, Iron City
Light (low calorie): Watney's London, Iron City
Specialty: Samuel Adams Cranberry Lambic, Lindeman's Framboise,
Lindeman's Kriek
Non-alcoholic: Coors Cutter, Kalibur
Special Ale: Young's Special London, Young's Ram Rod
Stout & Porter: Mackeson, Sam Smith's Imperial
Domestic Pilsner: Samuel Adams Boston Lager, Cold Spring Export

More than an entire page of newspaper was devoted to beer-related items (getting ready for the superbowl), but there was only one mention of homebrewing. One of the homebrewers, it was said, "knew what to look for -- or smell for. /He/ is a home brewer who experiments with his own recipes."

Subject: sterile aerator, fixing keg

Regarding the aquarium pump to aerate wort. A local company sells a "beer machine", whose main claim to fame is that they aerate the wort, which causes endless wonderful things to happen blah blah
blah..... Their aerator is an aquarium pump. They use a little 1" diameter filter holder (which is also very extra special..... Looks like typical lab supply stuff), which holds an extra special blah blah
blah filter disk which I suspect is a standard 1um, or 1/2um filter paper. This filters out the nasty biological stuff from the air. You should be able to get a filter holder, and filter papers from any good lab supply, or medical lab supply house. Check your yellow pages, or call your local hospital lab, and ask them where you might be able to get some.

Regarding patching your plastic keg? Depends what it is made from. If polyethylene, which is likely, it can be thermally welded (melted). If it is ABS, or polyvinyl chloride (unlikely for a pressure vessel as they are too brittle) then solvent based repairs are possible.

How to get it fixed? One possibility is locate someone who fixes sailboards, which are commonly made from these materials. Contact local sailboard shops, they may be able to point you to help. Chance of success is pretty good. Note: Don't mention that it is a pressure vessel!!! IF you do, then the guy

will likely refuse to fix it if he has half a brain due to possible liability (ain't 'Merica Wunnerful?) problems. Also note that Windsurfer brand boards are polyethene which is what I believe both my plastic kegs are/were made from.

Subject: Plate Streaking

How to streak a yeast sample to isolate single colonies
This needs to be done on a petri plate, thus the reason why most homebrewers don't bother with it. Should you have access to them, make the usual malt extract culture media and add 1.5 or 2.0 grams of agar per 100 ml of culture media. Of course, autoclave the media and plates. Pour the plates. Allow to cool and solidify. Now, in your mind divide the plate into thirds like a pie. Get your inoculating loop and flame it. Allow it to cool and dip into your favorite yeast sample. Run the inoculated loop in a zig zag manner over one third of the plate. Flame the loop again. DO NOT reinoculate it, that means don't put it back into your yeast sample. Instead streak the second third of the plate by running the cooled loop through one or two streaks made in the first third. Flame the loop and do the same to the final third by picking up cells from the second third. Your goal is to streak out fewer and fewer cells each time. Now when these cells begin to grow, the streak in the final third will only have cells growing every so often rather than a smear of cells as in the first and second thirds. Now you have a colony of cells produced from a single cell all with exactly similar genetic properties. A good source to consult on the above procedure is any laboratory manual to microbiology, which you can find in any academic library, or write me.

NA HOMEBREW

Everytime I mention NA beer, people give me funny looks and ask questions like, "why would anyone want to do that to homebrew?"

Having been a victim of my hobby some years ago, I drank nothing but Kingsbury for almost 10 years. The thought of going back to that is all the motivation I need. I have been limiting myself to one 16 oz glass of beer, per day for a couple of years and I no longer consider myself a recovering alcoholic.

However, making beer is so much fun and homebrew tastes so good that rather than cheat, I have been experimenting with making NA homebrew.

Y'all will no doubt remember when I started asking questions about measuring alcohol in beer. That was about the time I started. I have made six batches and think the process works well enough to publish.

So far, I have only produced one gallon batches but I have 7 gals clearing now, that will be my first full scale batch, five gallons of which will be kegged for NA on draft. Here is the process.....

.....

When you have your next batch ready to bottle, syphon off one gallon before priming. Put this in a kettle with (2) tablespoons of sugar and bring the temp up to 170 F with the lid off. Let it cool, uncovered until the temp gets below 150 F. Then cover it and cool it to room temp as quickly as possible. I put it in a sink with running water.

When room temp, add 1/8 tsp Champaign yeast. I have been using Red Star. Let it sit for a while to dissolve and disperse, then stir well with a sanitized spoon.

Pour the brew into your favorite bottles and cap. I always include at least one plastic bottle to monitor carbonation. When the plastic bottle is hard, refrigerate them all. This usually takes no more than a few days at room

temp. I have no idea how long this stuff will keep in or out of the
fridge
but time will tell.

What does it taste like? You'll have to try it yourself to find out.

Just for drill, I took an early version down to a Chicago Beer Club
meeting
and had it judged blind. I then gave them a bottle of the beer it was
made
from as a comparison.

What did the judges have to say:

In general, "lousy beer" but they could not tell the difference between
the
original and the NA nor had they the slightest clue, that one had no
alcohol.

Unfortunately, that batch was the one I have previously described as
clovey
(they said bananas) and you can't make bad beer, good by taking out the
alcohol.

I was toying with the idea of sending NA as my entry in the Usenet
Brewoff
Challenge just for fun but decided that it was too much trouble for a
practical joke.

js

P.S. Had two bottles with pizza last night and noted the clovey taste
again.
They were from two different batches. As the original beer does not
exhibit
this bonus, I attribute it to the Red Star champaign yeast. I think it
is
now safe to roundly condemn ALL Red Star yeast. On the next batch I
will
re-inoculate with EDME which is what I am using in the original
fermentation.

Subject: That Looney-Tune Noonan

Well, I've finally finished reading Noonan. Wow. Lots more biochem than I expected. Also, his writing style is terse and what I can only describe as "dogmatic"--but still, there's lots of good stuff in the book. I do have one question, however. At several points, he says that beer samples should be "black." For example, on p. 200, he talks about post-kraeusen beer, and says, "Remove a sample glassful, agitate it, and examine it. The beer at this point should be clear, bright, and black." What does he mean, black beer? Maybe if your brewing a stout or something, but I think he means it in a different sense here. Anybody know what he's talking about? I'm sure clue-free.

Subject: Now that's a hot break (also agar,canning wort)

I've finally gotten around to canning some wort, basically following the procedure outlined by Rog Leistad in Yeast Culturing for the Homebrewer (G.W. Kent, 1983). When I brought the jars out of the pressure cooker, there was the most tremendous hot break I had ever seen--like an inch of crud at the bottom of the jars. I'm assuming that this is normal and that I should decant off of the break before using. If not, let me know.

Also, about this agar stuff. In most Chinese grocery stores, they sell a product called agar, or sometimes agar-agar. It's some kind of seaweed something or other that comes dried in long, thin, white, almost colorless strips. When you rehydrate it, it turns gelatinous and is used in salads, aspics, jellies, and stuff like that. It tastes pretty flavorless. I also understand that you can get agar powder that works similarly, but I've never used it, so I can't describe it like the other stuff, which I have used. Well anyway: Is this the same thing as the agar in all the yeast culturing literature? Can I use it, or do I need some fancy schmancy biochemical-rated USP UL super-special agar? The Chinese agar is food quality (you eat it afterall), and Leistad processes at 15 psi for 15 minutes anyway. And I'm sure it's a darn sight cheaper than getting it from a lab supply house. So, whaddya think?

Subject: Historical Homebrew (part 3)

This is the third and final installment of traditional "Prohibition Pilsner" recipes received anonymously, presumably from the makers of Blue Ribbon malt syrup, in the mid-1970's. Previous installments of Historical

Homebrew appeared in Homebrew Digest # 795 and # 800. This is posted here

purely for historical interest, and not as a recommended recipe, although the techniques called for here seem to be much closer to currently recommended procedures for beginning brewers, than in the earlier historical postings. The format of the original is retained as much as possible.

If anyone is interested in having the original copy of these recipes for a

collection of beer memorabilia, please contact me by E-mail.

- -----

FOR 5 GALLONS -- One can hop flavored malt syrup-- 3/4 pound granulated sugar -- one cake compressed* yeast. Dissolve syrup and sugar in boiling hot water -- pour into cold water to make five gallons -- allow to further cool for two hours, then add one cake yeast. Cover crock or other fermenting vessel with clean cloth. Keep in a cool, dark place. Watch carefully and when bubbles of gas cease coming to surface fermentation has been completed and liquor should be quite clear (approximately four days).

Now siphon off clear liquid to another clean crock, leaving the thick sediment behind. To the liquor in the second crock add 1/4 pound granulated sugar and stir until dissolved. Fill into bottle by siphoning or pouring. Cap and immediately store in a cool dark place. The beverage will be ready for use when clear -- requires one to two weeks.

One crock can be eliminated if the liquid is siphoned directly into the bottles from the fermented crock. In this case, place 1/2 teaspoon sugar in each pint or one teaspoon in each quart bottle. Best consistent results can be obtained if a five gallon bottle is used instead of a crock for the fermenting vessel, using a water seal. All vessels and tubing should be entirely clear and sanitary before use. A 2-3% warm lye solution is an excellent one for the purpose. Rinse with water after the use of lye solution. Use of Hydrometer is not necessary if the above directions are followed. The specific gravity at the time of bottling will however, be 1.012 - 1.016.

*or Dehydrated Vierka Lager Yeast.

From: tony@spss.com (Tony Babinec)
Subject: kegging, bottling, conditioning

In HBD #805, Michael Fetzer relates his experiences with kegging versus bottling and the resulting conditioning of the beer.

In my humble experience, here's what has worked for me. The beer ferments for a week in primary. Rack into secondary and let it sit for another week. By racking to secondary, you are removing the beer from most of the yeast, and also, whatever yeast you transfer will mostly settle out via gravity. When ready to keg, I've not bothered to use finings. I've just kegged. Following Byron Burch's suggestion, don't prime while kegging, but instead use only co2. The beer can be consumed 3 days after kegging, and is suitably carbonated. Follow the temperature/pressure chart for kegging mentioned in previous HBDS, and also found in Burch's article (Beer & Brewing, vol. 9?).

So, with roughly a 14-17 day turnaround, you can have beer, which is not the case if you bottle. However, I would argue that for higher gravity or highly hopped/multiple hopped beers, you'll get some flavor change for some time, unless you drink all the kegged beer fast! Depending on the style, young beer has unmistakable hop flavors that recede with time. "Conditioning" means more than "carbonating." For normal gravity beers, brewed for present use, we're emulating what the Brits do with real ale. It's hard to beat a good draft beer taste. In any event, kegged beer kept under pressure, under co2, and refrigerated, stays good!

As for bottling, it takes time for carbonation to occur, and while young in the bottle, yeast in suspension will affect flavor and clarity. But, beer in bottles also conditions, again especially if highly hopped and/or high gravity.

From: nnieuwej@pooh.bowdoin.edu
Subject: How much, oh lord?

In october I brewed a two gallon batch of beer which I hoped would have a cranberry flavor and the deep red hue I've heard so much about. I used 3.3 lbs of amber extract, 1.5 lbs of crushed cranberries, and (I think) 2 oz cascade hops. Now 3 months later the beer has neither cranberry flavor nor color. The predominant (but not overwhelming) flavor is a (not entirely unpleasant) tang; there is little or no beer flavor and the tang is certainly not identifiable as cranberry.

Last week I brewed a two gallon batch which was intended to have a hint of garlic. I used one BIG bulb of garlic with the cloves peeled and crushed with the flat edge of a knife (not minced). I thought this would give a nice full garlic flavor without the harshness that comes with minced garlic. Last night I racked it from the primary to the secondary and there was no trace of garlic flavor or aroma.

What's up? Is my sense of proportion that far off?

-Nils

From: gjfix@utamat.uta.edu (George J Fix)
Subject: How much, oh lord?
Subject: Multi-strain yeasts (George Fix)

Two of the three strains in the Whitbread culture are definitely *Saccaromyces cerevisiae*. Both are "mutants" in the sense they are nonfloculent. One is a fast starting strain that is quite sensitive to ethanol, over say 2.5% by weight. The other is a slow starting strain that is tolerant of ethanol. Typically the first strain gets things started, but becomes dormant around the midpoint of the fermentation. But this is exactly the point where the second strain becomes active.

The third strain is a nonsaccharomyces yeast. It for example will not ferment glucose. It, however, is a strong flocculator and takes the other two strains to the bottom of the fermenter at the end of the ferment. It is my belief that the Whitbread "lager" yeast is exactly the same as the Whitbread "ale" yeast. I conjecture that the former is taken through several generations at progressively lower temperatures before drying and packaging.

I like this yeast especially for British style ales, and the way the three strains work together is rather elegant. However, isolating the individual strains is not a trivial matter as Mike Lelivelt correctly pointed out in HBD#805. There are morphological differences between the nonsaccharomyces strain and the other two, and this can be used to isolate the former in ways suggested by Mike. The results can be checked by staining
(I use Rhodamine B) in conjunction with microscopic examination at 200X. Sometimes I go up to 1000X using immersion oil, but this is rarely necessary.

Isolating the other two is a different matter altogether. Currently the following procedure is used. The yeast is pitched with an unhopped malt extract solution (S.G.=1.020). Once the fermentation starts, yeast is skimmed from the top and streaked out on a petri dish. This typically a mixture of Nos. 1 and 3. Then more yeast is added to a malt extract solution, this time one spiked with sterile beer giving a total alcohol content of 3-3.5% by wt. The ferment should be slow to start indicating that No. 1 is dormant. Once the ferment starts, yeast is skimmed from the top and streaked onto a petri dish. This hopefully is a mixture of No. 2 and No. 3. The latter is then separated from Nos. 1 and 2 by the methods cited above.

To use for brewing, the three strains are propagated by the classic "Hansen procedure" nicely described in Paul Farnsworth's Zymurgy article. Here one uses three petri dishes, one containing each of Nos. 1 to 3.

There is no guarantee that this procedure actually isolates Nos. 1 and 2. I am not aware of any reliable procedure for checking this. However, in practical terms the performance of the yeast has been normal. One additional bonus is that this is also a good way to "clean up" the yeast. Virtually all packets

of Whitbread yeast have some level of infection. Usually it is low enough
so
finished beer flavors are not affected, but sometimes this is not the
case.
Paul Farnsworth told me that he found unacceptable levels of infection (
over
one cell per 1000 yeast cells) in one out of four samples in his study
reported in Zymurgy.

Subject: Multi Strain cultures; Chinese agar; Streaking for single colonies

Mike Levielt writes:

According to Fix's article on Wild Yeast in Zymurgy's Yeast Issue, Whitbread culture (1098) consists on three strains of yeast. In the same issue Burch in "Yeast and Beer Styles" says 3056 is composed of two strains. Does anyone know of other Wyeast cultures being multi-strain in nature? I ask because these strains are incompatable with the isolation techniques presented above. A friend (Hi Veg) isolated both species of the 3056 culture due to differences in colony morphology. This techniques cannot be applied to 1098 culture as all three are Saccaromyces cerevisiae derivatives and possess similar colony morphology. Please don't tell me to run protein gels, I'm already anal enough. My current solution is just not to attempt to isolate. Come on big brains, any answers?

Mike: I've been struggling with this same problem, and someone (Martin?) suggested picking 8-10 individual colonies into 500 ml cultures of DME, fermenting them, then TASTING to distinguish them... certainly NOT what you'd do in the lab, but more relevant to homebrew. You might not get ALL of the strains that comprise a culture, but should get all of the major ones...

Protein gels would be interesting too...

And in response to the question about agar-agar in chinese food stores, YES by all means use this stuff; I had suggested health-food stores, but many of them don't have it.

About pouring plates at home, Mike suggested autoclaving, and that is what we do in the lab, but I think that boiling the wort in a saucepan should be good enough. Solution: 2 cups water, 4 TBSP DME, 1 gm agar (about 1 tsp powdered) and boil covered for 40 minutes or so.

Get petri dishes if you can, try the highschool micro lab, a local hospital, or your doctors office lab. Homebrew shops ought to carry these.

A fair price is \$5 for a sleeve of 20 sterile plastic dishes.

I've been looking around the house for a substitute and have eyed the margarine tubs that are about 4 inches around. While I haven't tried it, these look to be usable, and the polypropylene ones (marked PP on the bottom by the recycle lable) should be boilable. I would use a boilable plastic medicine dropper (for giving kids medicine, from a pharmacy for a couple of bucks) to fill these things from the saucepan. Since sterility might not be perfect, don't make more than you intend to use in a few days. fill the cups a half-inch deep, and let harden.

Mike's method for streaking is fine. My way is to imagine the plate as a clock face. The first streak is a light drop of culture, drawn from 11:00

to 1:00. heat the loop, then draw through the first from 1200 to 3:00, heat the loop, then draw a couple of streaks through the second streak, i.e. 200 to 500 and 300 to 400. Heat the loop again, the last streak is a bunch of squiggles through the third streaks, zig zagging through the unstreaked part of the plate to cover it. The whole point here is to reduce the number of organisms being carried along with the loop to the center part of the plate. The first and second streaks will be too dense and will be solid growth, hopefully the last streak will give you 20 or so well-separated colonies. Practice a couple of times.

Let the plates grow a couple of days at room temperature or slightly warmer. Colonies on a plate should be viable for a month or more in the fridge, but since sterility of a boiled margarine tub might not be perfect, I'd pick individual colonies into sterile wort for freezing before letting the plates sit around long. I posted this method a while ago, write me if you want a copy.

Mike brings up an important point; with some cultures you may not WANT a homogeneous (i.e. single) strain. I would appreciate someone who knows the strain characteristics of popular cultures posting that info here.

good luck,

dennis

From: Dan Feldman <Feldman@GODZILLA.SCH.Symbolics.COM>
Subject: ss ferment

To: Homebrew Digest
Fm: Jack Schmidling <arf@ddsw1.mcs.com>

From: Dan Feldman <Feldman@GODZILLA.SCH.Symbolics.COM>
Subject: ss ferment

Anyway, the important info is that the primary was done *in the brewpot*.

I cooked it up, chilled it with an immersion chiller, pitched, covered, and moved it to the cool room.

I've been doing this for about a year now. It works great, and has freed up my old fermenter for use as a carboy. I can now brew approx twice as often as I used to.

The question left is, is this extract beer or all grain? As there is considerably more and different residues from all grain, I am still reluctant to try fermenting on the boil crud till someone claims success.

I made a big mistake when I read the original message (sorry, I don't remember who sent the original message, my machine crashed and the data was lost). I hope this will clarify my process.

I'm an all grain brewer. While the wort is boiling, I clean thoroughly rinse and sterilize my mash-tun. When the wort is done boiling, I siphon it through a reverse flow wort chiller, into my mash-tun (I keep the output end of the chiller 4"-8" away from the bottom of the mash-tun and surface of the cooled wort; this provides aeration for the yeast), being careful not to pick up any residue from the bottom of the pot. I then pitch with an active culture, and cover the mash-tun/fermenter with a plastic bag.

After re-reading the original posting, I must agree with Jack. I will not ferment any of my brews on the boil residues. I feel that fermenting on the boil residues will cause more harm than good (for the beer that is).

Dan

Subject: Botulism

> Also, while laying awake, I thought
> that I remembered reading somewhere that Botulism is a toxin.
> That is, if you have a can with the big "B", you can boil the
> contents and kill the critters that manufacture "B", but that
> doesn't remove what they have already produced.

Your recollection is semi-correct, I believe. What I recall, from my high-school microbiology class lo these many years ago, is as follows:

Botulism is an illness... an intoxication, technically... caused by a toxin released by a species of bacteria (*Clostridium botulinum*). The symptoms include blurred vision, difficulty in swallowing and breathing, paralysis, and death. The toxin is extremely powerful... weight for weight it's one of the most powerful poisons known.

The *C. botulinum* bacterium is widely distributed. It forms resting-stage "spores" which are relatively heat-resistant... boiling water is not sufficient to kill them, but pressure-canning is (when properly done). Improperly-canned home vegetables and fruits are perhaps the commonest source of botulism.

C. botulinum grows and reproduces under conditions of low oxygen concentrations and low acidity. It cannot grow if exposed to air, nor in acid conditions (which is why citric acid or vinegar is often added to vegetables prior to canning). Tomatoes used to be considered safe, because of their high acid levels... but modern hybrid-cultivar tomatoes are often bred to have lower acid levels, and tomatoes are now considered unsuitable for unpressurized canning.

Although the *C. botulinum* organism is resistant to heat, the toxin it releases is not. Heating canned vegetables to boiling, and keeping them at that temperature for a sufficiently-long time (I believe 20 minutes is sufficient but I can't swear to this) will denature the toxin. For this reason, I've read that health authorities recommend that all home-canned vegetables be boiled before serving. Cooks should NOT taste the vegetables "right out of the can" to "see if they're OK"; dangerous levels of the toxin cannot be detected by taste, and even two or three toxin-contaminated green beans can be enough to cause the cook to become quite ill.

I believe that it is generally recommended that ANY can or jar which shows signs of possible bacterial growth... an odd odor or color, bubbles where there should't be any, swelling of the can lid, or an outrush of gas when opened... be disposed of immediately without tasting.

So... what this seems to add up to, with respect to your batch of brew, is that you're probably safe from botulism if you boiled the mixture well and didn't allow any of the unboiled extract to get into the secondary.

However, there are other classes of bacterial poisoning to consider. Staphylococcal food poisoning is much more common than botulism... it's the type which is responsible for most "bad potato salad" illness [I think it's staphylococci which are responsible, rather than streptococci, but it's been 20 years since I took that class...]. The staph bacteria grow at room temperature and normal oxygen levels.

Although they can be killed by cooking, the toxin that they release is heat-resistant, and (I believe) can cause illness even if the spoiled food is cooked before eating. Staph food poisoning is not, I believe, terribly dangerous to healthy adults... it's rarely fatal... but it is thoroughly unpleasant!

If people write to you and say "Yes, extract containers do swell up over time, it's normal and nothing to worry about", then don't worry. If you don't get reports of that sort, then you do have reason suspect that your can may have been contaminated by some type of microbe... and prudence would suggest that discarding the entire lot would be the safest thing to do.

Subject: NA beer

I believe someone posted an article on how the big brewers make NA beer. Whoever it was, could maybe add more to (read, correct) this post. What I recall from that post is that there are four methods used to make non-alcoholic beer: 1) evaporating the alcohol away from regular beer, 2) using a special yeast that makes very little alcohol, 3) killing a regular yeast before it creates much alcohol and 4) osmosis. I would like to think that the osmosis method would make the best-tasting NA beer and, from what I recall, it was used by the brewers that I thought made the best NA beer, Kaliber and I forget name of the other. Unfortunately, the osmosis method is also the most expensive, but Jack has proven to be resourceful and has the ability to manufacture, so I think he may have a chance to build the proper device.

By the way, my reason for NA is different: I love beer and I love to sailboard -- unfortunately to replace the fluids lost during a hot summer day of sailboarding, one would have to drink about 12 beers. I don't know about you, but I can't sail too well after 12 beers.

Subject: aeration

Mr. Schmidling writes:

>I have found a very simple way to aerate wort. I tap the
>chilled wort one gallon at a time and glug this into the
>fermenter after giving it a few shakes. The amount of
>aeration one gets this way is considerable.

My two cents:

My best aeration/fermentation results occur when I prepare a one-pint starter three or four days in advance, chill the wort to 70F (or so) in the kettle, and aerate by siphoning from the kettle and allowing the wort to free-fall from the top of a seven-gallon carboy, then pitch the starter. I get vigorous fermentation in four to twelve hours, rack to secondary in four days, and bottle in seven.

brew and enjoy

Subject: Toffee notes

There is an elusive 'toffee' character in some bitters which I have been trying to duplicate for some time. Crystal malt is sometimes reputed to give this character, but, for my needs, it doesn't fit the bill; it just makes a brown ale style brew. Logically, we know that toffee is made from caramelised sugar and so caramel colouring could be the answer, but this doesn't seem to work either; it's not smooth enough. All of which leads me to be considering three other options :

a) The brewers are using special sugars or in-house caramels which are not generally available. (One example being black invert sugar which MJ claims goes into some brown ales). Golden syrup in fact does partly what I want, but the quantity required is ideologically unsound and thins the brew out too much.

(b) The toffee character derives from boiler conditions. Which leads me to wonder about the advisability of pressure cooking some of the wort. In misguided days of yore when I made invert sugar at home, a concentrated solution was always said to be necessary. So maybe pressure cooking the first high gravity runnings from the mash could be the answer ?

(c) The toffee character is a fermentation by-product (possibly a ketone, a la diacetyl). So maybe this aspect could be encouraged (yeast selection ? inhibiting later stages of the ferment ?)

Subject: Malt Extract Questions, plus

I am somewhat new to the digest, but I think it is a great thing you have here!

I have a few areas where I could use some help, So please beer with me (oops).

I have been reading thru the archives here (thanks to tom fitz.) and have not seen much in mentioning the various extracts available. I have been brewing with extract for over a year (MF, Bull, American Eagle). I have recently solicited info for Breiss, Premier malts. The info they give is fair. I am looking for experience in use. (i know you guys/gals prefer all-grain, but i have my reasons (i won't have room for the extra equipment, or the the time for a while)).

So a few questions for the brew masses:

Has any one used either of these malts or others?
How do/did they stack up to Munton/Fison, Bull, others?
What beers did you brew?
Did you do a partial mash?
Any finings used?
How was the outcome?
Any other comments you have?

I am primarily intrested in a Golden/Blonde Ale, do these styles relate to the cream style?? I don't see much info regarding golden/blonde ales in Zymurgy or any other brew books. Any pointers to refer. material would be greatful.

On yeast/nutrients:

Has anyone used Siebel's Dry Ale Yeast 1 (Whitbred strain??) or the product they call YEASTX (a nutrient added to the kettle)?

Thanx in advance, keep on brewin'(to the BATF limit of course)

 From: agerhardt@ttsi.lonestar.org (Alan Gerhardt)
 Subject: RIMS/MashTun Details

I got several requests in response to my last posting, so for what it's worth, here's some details of my setup. I have used the RIMS unit itself for several months, and it works great except for the temperature controller, and just finished my new mash tun.

I just tried out my new mash tun this weekend, and it works great.

I built my mash tun by getting a 15.5 gal keg, using a metal cutting blade in a circular saw to cut the top off at the top seam where the handle ring is welded on. As it turns out, the groove at that weld tends to guide the blade, so it is easy to get a straight cut. Be sure and use safety glasses, however, because sparks and metal bits will be flying. Make sure you follow all the normal safety tips for working with kegs as well.

I then drilled a drain hole in the bottom, and used a brass "cooler drain" fitting. The fitting has a nut and a gasket, which gives a good seal, and is threaded on the inside as well. I then attached the required pipe/fittings to connect the drain to my RIMS unit.

I used a water heater jacket as insulation by cutting it in approx thirds, and wrapping three layers around the keg and securing it with duct tape.

For a false bottom, used a piece of 3/8" copper tubing formed in a circle to fit the bottom of the keg, and soldered a straight piece as an extra support across the center. Picture an international "NO xxx" symbol and thats what it looks like. A piece of stainless screen rests on top. I also soldered a 1/2" copper coupling to one side of the inside of the copper ring into which I stick a vertical piece of copper tube as a vent stack which sticks above the grain bed. This limits the compaction of the grain bed by the suction from the RIMS pump. If you're not using a RIMS, then you don't need the vent stack, and you have a conventional mash/lauter tun.

My plumbing is set up as follows:

x

drain
w/valve

On the next installment, I will describe the construction of my
RIMS unit, which is patterned after the original Rodney Morris unit.

Cheers,
Alan

Subject: re: publicly traded breweries

Chuck, I'd like to supply you with the info you're looking for, but alas, I don't have it. CAMRA has a trading club for UK breweries. However, I believe that they are losing their collective shirts right now. (I seem to recall reading that the fund is worth 89% of its original investment.)

My former motorcycle dealer was a home brewer. Unless someone else was buying, however, he only bought Bud. To show his support of A-B, he bought a single share in order to frame and hang up. This was a number of years ago, and in the 70s, A-B stock value rose enough that they split 3 for 1. A-B has ever since been trying to get him to turn in his share certificate for a new one for three shares, but he doesn't feel the need to do that.

Subject: Wort Chillers

Hi all. I have a question. (Imagine that huh?)

I am still an extract brewer, and when I sparge to my fermenter, I do it via papazian (ie. into cold water) I do not run it through a wort chiller. It does take a certain amount of time to strain the hops and such. Does this small amount of time make a difference. What is the big advantage to using a wort chiller.

I know that in all grain brewing, temperature considerations are very important, but is this also true with extract?

Lastly, if someone has some good ideas for making a wort chiller, I would love to see them (via email is fine). I read a little about it in Miller and Papazian.

Thanks for the time,
Frosty

Subject: re THM

richard@pegasus.com (Richard Foulk) says (referencing Miller's CHHB):
> He also says that chloroform is another name for THM.

IFF Miller says that, he blows much of his credibility as a chemist. THM ("trihalomethane[s]") is a generic term including fluoroform (very rare)

,
chloroform, bromoform, and iodoform. (Fluorine, chlorine, bromine, and iodine are all halogens(*); -form is an old suffix meaning a molecule consisting 3 of the named halogen and one hydrogen all attached to one carbon.) THM also includes all permutations of the above (e.g., 2 chlorine + 1 each bromine, hydrogen, carbon).

Most of the THM in [typical] water is probably chloroform, but the analysis doesn't distinguish---THM's are similar enough chemically that distinguishing at low levels is (a) difficult and (b) unnecessary---you don't particularly want /any/ of them in your water.

(*)My memory of the bottom of the periodic table is fuzzy---I think the heaviest halogen is astatine, which is radioactive and /very/ rare.

Actually, the previous quote doesn't help Miller look good either:

> ``I draw my brewing and sparge water
> from the hot water tap at about 150°F; at this temperature, chloroform
> boils and chlorine gasses out in a few minutes.''

65C sounds a little low for the boiling point of chloroform, but I don't have a reference with me. However, the boiling point of a pure liquid has nothing to do with the temperature to which you have to heat a mixture in which that liquid is the lowest-boiling compound in order to drive off the last bit of it. At any temperature, vapor from water with a few ppm of chloroform in it will be mostly water---the concentration of chloroform will be higher in the vapor than in the underlying liquid, but not much. I wouldn't even bet on boiling to remove the last few ppm, as it's an asymptotic process---the lower the concentration, the less you can get out.

From: rich@bedford.progress.COM (Rich Lenihan)
Subject: Yeast Starters / Faucet Adapters

2 questions:

Yeast Starters: I've recently started using liquid yeast (Wyeast) and while I'm sold on their value for brewing, I've twice had trouble getting the yeast started. In each instance, I popped the seal, the package swelled within 24 hours and then I added the yeast to my prepared starters (once a dilute dextrose solution, once a dilute wort solution). Both times the yeast died in the starter. Is there a *simple* sure-fire no-miss method for preparing yeast starters. Note that I don't currently have access to an auto-clave or pressure cooker.

Faucet Adapters: I recently purchased an immersion chiller and was very excited about using it the first time. Tested it out at home and it worked fine. Brewing time: different story. Somehow, in my haste or excitement, I managed to strip the threads on my faucet adapter. So, not only couldn't I get the hose to the chiller in straight, I can no longer get the aerator back in place. My wife is not too thrilled (nor would my landlord be if he knew). I figure a trip to the hardware store and some \$ will fix the faucet. What I'd like in the future is some sort of adapter that would allow me to put the hose onto the faucet without removing the aerator. Ideally, this device would allow the hose to snap onto the faucet without screwing. Does anyone know of such a gizmo?

Thanks,

Subject: Coriander

Danny Breiden asks about crushing coriander.

Ray Spangler (who should know) says that your 2-3 year old coriander will be OK to use (R,DW,HAH). Crush it slightly (just run it through the grain mill like your malt). A Half to one teaspoon in the boil is normally quite enough. Dry-"hopping" (dry-seeding) with it is at least three times more effective per unit quantity used. Coriander should be used very sparingly -- just enough to give a slight twist to the brew. When you drink it, you should not be able to recognize the flavor, unless you know what you are tasting for. It should just be "some kind of slightly unusual twist" to the brew. Note that this is extremely effective in a sour mash beer.

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)
Subject: Are Eckhardt's formulae correct?

WARNING: HIGHLY NERDLY QUESTION IMMINENT!!

Ok, you were warned...:-)

In Fred Eckhardt's book, The Essentials of Beer Style, he quotes the following formulae on p. 29:

$$(1) AE = RE + .46(ALC)$$

and on p. 31:

$$(2) ALC = .4167(OG - AE)$$

where:

ALC = weight percent alcohol (3.5% goes in as 3.5)
AE = apparent extract, in degrees Plato, which is just the final gravity
RE = real extract, in degrees Plato, which is the final gravity of the
'wort' you'd get if you boiled off the alcohol
OG = original gravity, in degrees Plato

with degrees Plato = $.25(G - 1)$, G = specific gravity in g/cc,
and the density of alcohol = .796 g/cc at 60F.

I attempted to derive these, using reasonable (IMHO) approximations and taking it as only to first-order. Although the relationships I got were similar, the numbers weren't. If anyone else has done this, did you get Eckhardt's numbers? Anyone else interested in trying?

Please e-mail to me directly; I am sure this is not of general interest.

Yes, I know, I have nothing better to do with my time 8-)

Yours in Nerdly Bliss and Heavenly Suds,

STEVE

>richard@pegasus.com (Richard Foulk) says (referencing Miller's CHHB):
>> He also says that chloroform is another name for THM.

>IFF Miller says that, he blows much of his credibility as a chemist.

As a matter of fact he doesn't say that, he says that chloroform is a THM, and that the water analysis doesn't distinguish between THM's.

I guess Miller's credibility as a chemist remains intact (although he has never claimed to be one, he's just a guy that likes to homebrew). Perhaps you should read the book rather than speculating about it.

On another Miller topic, the brewpub of which he is brewmaster has recently opened in St. Louis, after a considerable amount of effort expended by Dave on getting Missouri's laws changed. We previously had a three tier system here which forbade brewers from retailing their wares, there is now a clause exempting producers of less than 2000 bbls per year (I think that figure is about right). Homebrewing is still illegal in Missouri though.

Subject: blow-off

Greetings & Salutations,

Thanks to all who have shared thier knowledge!

For my next question :) I would like to enquire about blow off tubes.

In Mr. Millers book he views the act as wastefull and possibly unsanitary (where the tube may provide a path for bacteria to travel back into one's fermenter). However we also have Mr. Papazian, a proponent of the blow off method, who states the process removes fusel oils (?) and other unsavory gack from your bubbling brew.

In my vast experience (3 batches!) I have found that not so much gack (or spooage-gack as we say `round here) comes out of my blow-tube to make the process prohibitively wastefull, so that leaves the possible route for infection as a possible detractor to this method.

What if I just put the end of my blow tube in a container that has some bleach water or something in it, wouldnt that prohibit any nasties from cruising up by tube (so to speak)?.

Also, what about the contents of the stuff being blown out? Is it truly that detrimental to the finished product?

Thanks for the help

- Alan

Subject: Test re:Wetting Grain to reduce flour

Carl West asks about getting flour when crushing grain.

I was wondering the same thing as I was crushing grain this past weekend. So I tried a couple tests. Well, I never finished that PhD in rocket science, so this experiment was qualitative only. I crushed a cup of grain in a variety of ways (wetted, not wetted, adjusting roller spacing), then sifted the results through a kitchen strainer. The sifted stuff was then collected and dissolved in a glass of hot water.

The larger husk pieces float, the malt makes the water cloudy & sinks, and the smaller husks tend to sink. It's easy enough to visually compare the different crushing methods. The gist of it was expected: much less flour and husks and when grain was wetted.

I've got a master's degree in (kitchen) science,

Subject: Unglazed containers

I've been saving St. Sebastiaan Crock Ale 75cl bottles, in anticipation of using them for an Abbey Ale. They are made of some kind of ceramic material (talk about being anal about light-struck prevention!). This weekend, I noticed that the bottles are only glazed on the OUTSIDE. I've heard of people getting botulism from unglazed pottery (they even suspect that some civilizations died-out because of this) but the acidity of the beer in the bottle would keep the botulism bacteria from taking hold. However, from a sanitation point of view (lactobacillus, etc.) isn't the unglazed inside an invitation for problems? Am I making more of this than I should? It seems to me that the semi-porous surface of the inside of the bottle is equivalent to the "scratched plastic fermentor" problem. Am I missing something? Maybe if I baked the bottles? Maybe if I found some pottery expert to glaze the insides? Al.

I'm the one who keeps posting about using a hot knife instead of a
drill. I've done both and I'm completely sold on the hot knife.
You can pierce three or four hole each time you heat the knife.
(I used a propane torch to heat it.) It takes much less than an hour.
One reason for doing it is do eliminate the curlicues. You can
pierce holes for a sparge bucket using a hot pin or nail. Try it
and flame me if you don't like it.

> auto-clave or pressure cooker.

Two questions: 1) what were the temperatures of the yeast packet and the starter, and 2) did you aerate the starter? If the temperature difference between the packet and the starter is significant (I don't know really, say, 10 or 20 degrees) then you could shock the yeast. You won't kill them all, but you could kill enough to look as if you did. If you don't aerate the starter, you won't get a large increase in yeast population and could have a really long lag before the starter begins to look active. To make a starter, I simply boil up a 1018 wort (1 oz of DME in 16 oz of water) and simmer for 10 minutes. Then I cover the pot so the steam sanitizes the lid and stick the pot in the fridge till it cools. I aerate the wort as I pour it into the starter bottle and then jiggle the starter bottle to aerate some more.

> Does anyone know of such a gizmo?

What you need is a combination quick-disconnect/aerator. There are two types of faucet quick disconnects available, for use on washing machines, dishwashers, etc. The part screwed on to the faucet has kind of a narrow outlet on one type, and does not have a built in aerator. The other type looks very much like a Pepsi ball-lock disconnect, and is used to provide aeration when used as a faucet. When the other end of the QD is attached, it pushes the aeration screen out of the way.

You can get these at building supply shops, hardware stores, plumbing suppliers. They cost about \$8 for both halves. One half has faucet-pitch threads (the aerator half), and the other end has male hose threads (the QD half). I have a 6 foot washing machine hose with two female QDs on either end. My sink faucet has a male QD end, and so does the inlet of my wort chiller. My jet bottle washer has a female QD on it. I can snap the bottle washer on and off the faucet in a jiffy, connect my wort chiller in two jiffys, or use just the hose to clean buckets, or fill buckets for tropical fish maintenance. I've even gone so far (too far?) as to build a device out of various pieces of plumbing that quick connects to the faucet and allows me to spray water through my beer dispensing hose to clean it after I've drawn just a pint or two from a keg. I love my QDs!

Subject: Re: Trub Separation

Tom Quinn asks what people do with the trub/hops stuff left on the bottom of his SS brew pot after whirlpooling and racking the wort off.

I used to simply toss the stuff. Recently I purchased a fine nylon hops bag (something from Crosby & Baker at my local HB shop). I strain the trub through the bag, bottle the wort in qt mason jars and process (boil) for 30 minutes. I use the recovered wort for krausening and starters, etc. I usually recover 1.5- 2 qt of wort this way. BTW I use pellet hops.

Drew Lawson writes about Mineral Content in Hot H2O:

>The water you get from your hot water tap may be significantly
different in
>mineral content from that you get from the cold. The problem in this
case is
>that the iron level may be significantly elevated. Of course, this
depends on
>the construction of your heater, as well as its age.

Another item that can be elevated in hot water is lead. In older systems
lead bearing solder was used and significant amounts can be leached into
the
tap water. I have seen several health advisories to this effect.

Rich Lenihan writes about Faucet Adapters:

>Ideally, this device would allow the hose to snap onto the faucet
without
>screwing. Does anyone know of such a gizmo?

I have a quick disconnect from an old portable dishwasher, the faucet
end can
be purchased at most hardware stores, I use junked dishwasher parts
although I
supposed you could buy new ones from an appliance repair place.

Subject: DMS and light Lagers

About two months ago I posted a request for hints on reducing the DMS smell in a German Pilsner I made. I finally made a second batch and tried the tips I received. I didn't change malts for this experiment. The big one (actually the only one) was to keep the kettle uncovered while chilling down the wort (Counter flow chiller). This was to allow maximum evaporation of DMS precursors.

I made some other changes as well: I used Wyeast Bohemian Lager yeast instead of Whitbread Lager, Sazz instead of Tettnanger hops and krausened with 1 qt of gyle rather than force carbonate.

Well, after a week of carbonating at 48f (no lager period), the beer had a sulfery, buttery nose. Actually it wasn't too unpleasant. After another 4 days of conditioning the sulphery notes seem to have dissapeared and the buttery nose (diacetyl) is much reduced. I actually like the softness that trace amounts of Diacetyl gives to the beer.

It appears that the DMS smell is no longer a problem. It was either the yeast or the uncovered kettle that did the trick.

I received my copy of "Continental Pilsners" by Dave Miller. Interestingly he mentions low fermentation temperatures (48f being low) as a source of DMS smell. Appearently warmer ferments (55f) allow the yeast to reduce/use the DMS. So, here is one reference telling me that I need to ferment warmer to get a "clean" lager!

This is the first time I have used Sazz hops. They have a nice clean bitterness. I am sorry I didn't dry hop with them. Miller thinks that is the only way to go. Well, there is the next version to be made with continental malts - and dry hopping.

>bubbling brew.

This is still a subject of some controversy. Kinney Baughman and I have corresponded on this subject, with both of us recalling a study done, possibly at UC Davis, to which we can't find a reference.

As you can see with Miller and Papazian, people believe different things. However, it does seem that you can brew really good beer either way, so while blow-off may or may not be harmful/beneficial, the exact benefits/harms are not well known.

Blow-off is not a common technique among commercial brewers, but their techniques are different enough from homebrewing techniques that this comparison may not be useful.

If I had to try and say something relatively unbiased in conclusion, I would say that if you don't use a secondary fermenter, you may well benefit from having stuff removed during blow-off. OTOH, if you rack to a secondary fermenter shortly after high krausen, you are leaving behind a fair amount of trub in the primary, thereby avoiding any need for blow-off.

Anyone know if there are any statistics on award-winners and percentage of those who use blow-off?

From: Steve Anthony <steveo@Think.COM>
Subject: Interesting Experience

I brewed up a dopplebok a couple of weeks ago and had an interesting experience. I'm working my way up to all-grain (I do partial grain now) and had made use of some new equipment. When I was done, I had about 3.5g of wort and added that to 1.5g of water. My method todate has been to let this settle overnight, and then siphon the beer off the settled trub and then pitch the yeast. I've found that this has led to a minimum of sediment in the finished product. However, my brews have had some infection problems in the past few batches, so I've avoided the plastic pails I was using and just pitched directly into the carboy that had the beer, trub and all. I had waited until the beer was about 70F before pitching, and there was a good 2-3" of trub at the bottom of the carboy.

After three days, nothing. Relaxing, I looked at my logs from the previous batch, where I used the same yeast (WYeast, Bavarian Lager). It had taken 3 days for that to show signs of activity. So I waited. After 5 days, still nothing. Now, worried, I reasoned that I had a bottom fermenting yeast that was down there in the trub looking for things to eat and not finding anything. So I got a siphon tube, sanitized it and stirred the muck up. Two days later, it was off and running. It's still (1 week later) going crazy! The 2-3" of trub has been blown up into suspension by the activity of the yeast. It is absolutely amazing to watch.

So I think I solved the immediate problem; this batch. But the longer term problem remains. How to avoid getting the trub in the carboy. How do you netbrewers deal with this? I was thinking of a 6g carboy, adjusting the recipe to fill it and then after the trub had settled, siphon to a 5g and pitch, but there must be a cheaper and easier way. Ideas?

Subject: Grain Mill Discovery!!!!

- ----- Original Message -----

While registering with my bride to be at the mall this weekend I accidentally discovered a grain mill for kitchen use that operates using three serrated stainless steel cylinders - just like the big guys!! This manufacturer also makes pasta makers. So forget trying to destroy your pasta machine. The name of this product is:

The Marcato Marga Mulino Grain Crusher/Grain Mill. Of course it's obviously made in Italy. I asked the store clerk if this was a new product and he said that no, they've always been able to order it along with all the other pasta equipment but just never ordered it. He also said that they have sold several already.

Here's the info that I can remember about it. First the price is \$69.00. I haven't bought one yet, I'm waiting to see if I get it for a wedding present. If I don't get one, I will buy one for sure!

It has three settings:

- 1) for crushing grain into flour
- 2) for crushing grain into flakes with some flour
- 3) for crushing grain to just expose the inside with no flour created

It even mentioned all the different types of grains you could use and of course barley was mentioned.

From my memory, the unit stands about 6-7 inches high, about 5 inches square. It was made of chromed steel and came with a low hopper of about 2 inches in height - this will require a minor modification to increase the height. The three rollers beneath the hopper are very strong and of course have many gripping grooves. Two rollers are on top, side by side and the third rests beneath these two. Their distance is controlled by an adjustable knob on the side of the unit. And lastly this device comes with a hand crank.

I WANT ONE, I WANT ONE!!!!!!

By the way, the store that I found this in is called Table Talk here in Tucson and carries everthing you could ever think of for the kitchen. When I finally aquire this luxury unit I'll post more info on it.

Subject: Eisbock?

Date: Wed, 22 Jan 92 21:16:47 -0700
From: David Suda <suda@barley.Colorado.EDU>

My brewing partner has committed us to brewing an eisbock.

How are you going to freeze it? Stuff a carboy in a freezer? or bottle
- -- sans caps? -- then freeze? If the latter, you should probably top
off each bottle since you'll lose some to the ice.

Our current plan is to start with a dopplebock (OG ~1.080) and then put
it through the "ice" process. Is it possible to carbonate the beer,
freeze
it, and then bottle the results with an acceptable carbonation level?

Why carbonate first? Sure, I've had my fair share of ``ice cold beer''
which froze upon uncapping, so that will work. Seems unnecessary tho.

If any of you have experience with or references to this process, I'd
appreciate your help. Also, are there any commercial examples
available in
the US?

I believe EKV-28 (Germany) is an Eisbock. If I remember correctly, the
28 is the initial gravity in degrees plato. (It may be Samiclaus,
though; I don't have the book here). Check Jackson's world guide to
beer: he talks a little about it there.

Let us know how it comes out!

Subject: Re: blow-off

When I do use a blowoff method I normally put the end of my tube in just plain old water. Once your blowing away I don't think that there is much threat of anything crawling back up the tube. One thing to consider is that if the temp of the wort in the fermenter is not completely cooled to room temp when you put on the tube, then the cooling wort will contract and suck water (or air if your not in water) back up the tube. (once fermentation starts this is not problem). Before swithing to a 1" tube and a wort chiller, I actually had water sucked all the way back into the fermenter. I'd hate to think that I might suck bleach back into there. If your really worried about infection try putting the hose in water with a shot of vodka.

Subject: Cheap Soda Kegs
Full-Name: "John Cotterill"

I was looking for this information during the thread on kegging and artificial carbonation, but could not find it. Well last night I did. Here is a source of cheap used kegs. I bought a bunch last year. They were all in very good shape and held pressure. They were ball lock Spartan Cornelius type kegs. They were \$25.00 each (I don't know if that price is still current). Hope this helps some of you get into kegging.

Subject: Re: Old Carboys

Funny someone else should ask that question.

A couple of months ago I too received an old carboy that had dirt in it (but no scratches). I first tried to use a strong ammonia and then bleach solution on this. The bleach solution succeeded in getting the dirt out, but I saw two rust stains on the bottom of the thing once the dirt was clear.

After posting to the net, I went out to Grossman's and bought some HCl (I can't remember the brand name of this stuff but have it at home if you want to know). After a day of soaking the carboy in an acid-water solution (not very diluted), the rust stains disappeared.

Already I have used the carboy as a secondary for some cider and everything came out OK.

"Well, the shuttle, Discovery, lifted off this morning (Wednesday), and I heard on the radio that one of their main projects is to do experiments on plant growth and small-animal behavior. What I want to know is this: If you fermented in a free-fall spherical fermenter, how would you tell the bottom fermenting yeast from the top fermenting yeast."

Perhaps by using a rotating still ? Or, better yet, by introducing minute amounts of turbulence to the already complex fluid dynamics of the solution with a magnetic stirrer, you might evenly distribute the yeast throughout and make the gravity-derived categories obsolete and irrelevant, as they brew things undreamed of by us earth-bound mortals ...

I can just see it ... "Atmospheric Ambrosia", 'bottled' in a bubble of soft and non-reactive polymer, with a disposable one-way valve to squirt contents into one's mouth ... made in huge, Sun-warmed vats in fixed orbit ...

--*--

On a (slightly) more serious subject ... does anyone know anything about making root beer ? It takes sasparilla, that much I think I'm sure of. Does one treat the root like one does grain ? Do conventional brewing yeasts work ? Does anyone have any references to articles or literature ?

>What if I just put the end of my blow tube in a container that has some
>bleach water or something in it, wouldnt that prohibit any nasties from
>cruising up by tube (so to speak)?.

Being one of the more vocal proponents of the blow-off method, I felt a responsibility to respond. I feel that the chances of nasties traveling back up the blow-off tube are virtually nil. I can't imagine how they would propel themselves the three or so feet from the blow-off collection vessel to the carboy. I use a blow-off tube during the first week or so, sometimes using bleach in the blow-off collection vessel and other times not, and then switch to an airlock. Note, that I use a 1/2" ID, 3/4" OD hose since the explosion, four years ago. If you want to stay completely worry-free and bleach in the collection vessel will help you do that, then by all means use bleach. I have yet to notice a difference.

>Also, what about the contents of the stuff being blown out? Is it truly
>that detrimental to the finished product?

My information on this from Papazian so I can't add to what you've read. I noticed a slight improvement in flavor when I switched to blow-off (six years ago), at which time I was specifically researching how different ingredients and procedures affected my beer and thus made an effort to only change one aspect of my process at a time. It was quite a while ago (and many, many beers ago) so I can't recall the exact flavor qualities that were affected -- only that they were significant enough to decide to not go back to non-blow-off again.

Subject: PUMPING BEER.

I'm doing some mental designing for a medium sized basement brewery. I want to use a pump of some sort to move beer or wort from one vessel to another. A peristaltic pump is out of the question because of cost. I've been looking at the Little Giant SC series magnetic drive pumps.

They are not NSC or FDA or USP approved for food grade materials, but I'm not sure that should bother me. The actual liquid contact time would be on the order of milliseconds. The materials that the liquid would come in contact with are: A polypropylene impeller, some Aluminum impregnated ceramic and a couple of O rings. I figure that, since it is rated for saltwater aquaria, the O rings should be pretty inert. I'm not worried about the momentary contact with the polypropylene, but I am concerned about the ceramic and Aluminum stuff. Should I be concerned? Should I be concerned about things I've said I wasn't?

This pump does 470 gallons per hour and costs \$119 from "That Fish Place," so would be a pretty good deal if it's useable.

Am I nuts? Thoughts?

 From: agerhardt@ttsi.lonestar.org (Alan Gerhardt)
 Subject: RIMS Part 2

As promised, here's a description of my RIMS unit. I started with the R. Morris basic design and adapted it as needed.

I think Rodney deserves a lot of credit for coming up a practical homebrewer's implementation of this idea. His methods sure gave me a headstart.

I wanted the unit to be able to do at least a 10 gal batch size, which for me usually equates to 16-20 lbs of grain, so I chose a 5KW heating element from WW Grainger. It is a very low heat density element which is advertised to be able to even run dry. It is a very long element, which has in a "U" shape, and folded over to be about 19" long. It cost about \$20, but has turned out to be a very good investment, in that I have seen no evidence of excessive heating (which would kill the enzymes) or scorching. With this element, I get about 1.75-2 degrees/min temperature boost with 18 lbs of grain and about 7-8 gal of water.

I used a length of 1.5" (about 21") copper pipe as an element housing, with a cap for each end, and assorted fittings to connect things up.

The inlet and outlet pipes are .5" copper. I drilled holes in the 1.5" tube for the inlet and outlets (a tight fit is better), and soldered them in.

The trickiest part was the mounting of the heating element. Rodney used a 1" threaded pipe to copper pipe adaptor. Since the adaptor narrows down too much to allow the element I chose to fit through, I cut off the threaded portion, in effect making a copper nut. I soldered the nut outside of the cap (with hole drilled in it), and the element just screws into the end of the pipe. The supplied gasket makes a water tight seal. The element is easily removed for inspection/cleaning,

although cleaning is seldom required if a clean water rinse and recirculation is performed after use.

I put the thermistor inside of a .125" copper tube, and sealed it in epoxy, being careful not to short it out. The tube is inserted through the stopper so that it sticks into the fluid flow.

The Radio Shack thermometer Rodney used is no longer available, so I didn't put that through the stopper too. I use an external digital thermometer instead.

I put the whole thing into a wood case, with the inlet and outlet tubes sticking out through drilled holes. I connect to the unit using plastic tubing and band clamps.

I built a pump speed control per Rodney's design and it works fine.

I have not been able to get his temperature controller to work yet, and am currently using a toggle switch instead.

As he recommended, I used a GFI outlet inside my box, from which I get all power. That is in my opinion, a very wise investment.

I set the whole system up on two Workmates, one for the RIMS unit, and the other for the mash tun. The whole thing disassembles and stores so I have my garage back when done.

Observations:

- (1) At full flow, the outlet stream will sometimes generate a LOT of foam in the mash tun if not properly directed.
- (2) Sparging is a snap now. I just add as much water as my mash tun will hold, raise to 165-170 degrees, and recirculate for about 30 minutes. My efficiency is typically 30-31/lb/gal, for 6 row malt (Stew's Brew malt), just short of Miller's numbers. For larger quantities of malt (not as much room for more water), I plan to drain/replace the sparge water as required.
- (3) A proper grain grind is just as important as always.
- (4) The wort runs incredibly clear by the time you are sparging, and no husks or other particles make it into the boiling kettle.
- (5) If you are contemplating building a RIMS, don't scrimp on the pump or the heating element.
- (6) You have to be crazy or an obsessive tinkerer to go to this much trouble.

I hope this helps somebody !

Cheers,
Alan

Subject: Shipping beer/Eisbock

1. On shipping beer: While waiting in line to pick up a package at the Lafayette, IN UPS office, I persused the info they have hanging on their walls. There I noticed that they refuse to ship "wine or liquor."

I noticed that they did not specifically mention beer. But, I am not at all surprised that people would catch flak about trying to ship beer. Evidently, what you have to do is lie. The standard line I hear is that you tell them you are shipping non-perishable food in glass. If pressed, I would tell them it is beans canned in mason jars.

Or strawberry preserves. Since UPS is a private company, you can lie all you want to and all you have to worry about is reckoning with your

God (if you have one and if It doesn't want you to lie). I'd never pull such a lie with the USPS. I get nervous around gov'ment organizations--even if they are pseudo-private.

2. On Eisbock: I am not an authority, but I read in this forum a long time ago that distillation of alcoholic beverages is strictly illegal.

Freezing alcoholic beverages and removing the water is a form of distillation. I tend to believe that the BATF would not condone these activities if they knew about them. Just a thought.

Subject: Shipping Beer Across the Northern Border

In HD809 John Freeman brings up the question of how to ship beer. I wish to extend that query into what is likely to be a more complicated issue. A friend in California wishes to set up a FedEx beer-exchange with me in Ontario, Canada. He will send me some mighty fine US microbrewery products and I will reciprocate with some of our local beauties. Judging from past posts in HD on the issue of shipping we have decided to avoid both the postal system and UPS, and have chosen FedEx as a likely deliverer. My questions are as follows:

- 1) Should the package contents be revealed or should we just say "bottles, but they are double boxed and well padded."?
- 2) Have any HD readers shipped beer successfully by this or any other method across the US/Canada border?
- 3) Is there any other advice to extend our way?

This is a thread which has been on HD in the past but was never resolved. Some detailed replies to both John and myself would be much appreciated. Replies to me can be direct e-mail if you wish. Take care.

Subject: Shipping Beer Across the Northern Border

Guy McConnell asks in HBD#809 about the use of oak chips in IPA's.

I have never understood why people (presumably in search of an authentic taste) put oak chips into IPA's. As Terry Foster points out in 'Pale Ale', English oak doesn't impart any flavour to beer, American oak does but it wasn't used for transporting IPA. Type of wood aside, I think that the barrels were often lined with pitch.

Andy

From: darrylri@microsoft.com
Subject: re: shipping homebrew

Although there is no explicit regulation against shipping alcohol by UPS (it is illegal via the post), they can and will turn you down on their own authority. I have never had a problem shipping beer, because I don't call it that. I tell them that the contents are "Perishable Food". This is an official category of items for the UPS, and saying so probably gladdens the heart of the clerk I meet at the counter.

They will not insure such items, so you can't get any money if your case reaches its destination wet inside. I have never been pressed for more detail, but if I am, I will state that I'm sending canned food.

Another way to deal with this is to take your package to a Mailboxes, Etc. (or any other PO Box type of outfit) and pay for their pickup service. Since they are completely clueless, and the UPS fellow will be in a hurry to pick it up, you probably won't have any difficulties as long as there aren't big black words on the outside saying BEER.

Perhaps someday the AHA will win an official ruling from UPS, but we're small and they're in a hurry.

From: martin@daw_302.hf.intel.com (martin wilde)
Subject: Re: PUMPING BEER

I just recently purchased a pump for pumping beer. It was a Teel pump. The specifics are as follows:

- a chemical magnetic drive pump.
- designed for sanitary conditions.
- pumps fruit juices (beer should have no problems!!!).
- ph range of 5-9.
- temperature range of 32-180 degrees.
- gravity feed (will not pull a column unless primed).

I payed about \$60 for this pump (wholesale). It is quiet and does the job.

I also checked out the following:

Little Giant Pump Co. PN #2-MD-SC ord PN #1-MD-SC

Look in the yellow pages for a pump dealer. My experience with aquarium stores are that they markup alot. There are lots of chemical pumps out there. I settled on the Teel (Grainger Dealer) because it was cheaper and its pumping rate was about 3-5 gallons per minute instead of 8-12 (wow suck that pot of brew up in < 1 minute!!!).

The size of the pump is small (5" x 6" x 7").

I hope this helps.

Subject: Re: Shipping Beer

The recent Zymurgy (Winter 1991) contains information about how to ship beer (alcohol) using UPS.

It is not illegal to ship alcoholic products for judging purposes. It is best to not tell the bozo behind the desk what is in the package. Just label it as "Food in Glass". Just like any other organization not all the people know all the rules. IF THE PERSON STILL WANTS TO KNOW MORE, JUST GO TO ANOTHER PLACE. My experience has been the little "satellite" places which ship UPS don't really care much what is in the package. They just go through the motion of asking since they are required too. I guy looked at my "Food in Glass" statement and said okay... He probably knew there in there by the address I was shipping it to.

In HBD #809 Chris Shenton (css@boa.CCSF.Caltech.EDU) writes:

> How are you going to freeze it? Stuff a carboy in a freezer? or bottle
> - -- sans caps? -- then freeze? If the latter, you should probably top
> off each bottle since you'll lose some to the ice.

I think the easiest method would be to rack to a bottling bucket (I don't like the idea of freezing in glass), freeze it, and then rack to a keg for force carbonation. Forced carbonation is needed since the high alcohol content would kill off any beer yeast. The problem is that I don't have a keging system, but might be able to borrow one.

> > Is it possible to carbonate the beer, freeze it, and then bottle the
> results with an acceptable carbonation level?
>
> Why carbonate first? Sure, I've had my fair share of ``ice cold beer''
> which froze upon uncapping, so that will work. Seems unnecessary tho.

If I can't get access to a keg, the options are to carbonate before "icing" the beer or else repitch with an alcohol tolerant strain of wine or champagne yeast.

> I believe EKU-28 (Germany) is an Eisbock.

Although Jackson used to claim EKU-28 was an eisbock, I think he now says it is not. Is EKU-28 still available in the US? I haven't seen it in a couple years.

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>
Subject: Art's Brewing, Sourdough Cultures, Long Digests

Ken Dobson mentioned legal status of brewing around the country:
Just so you know, homebrewing is still illegal in Utah, and probably will
be for a very long time. This despite the existence of 3 homebrew supply
shop I know of in UT.

Which reminds me...

John Cotterill mentioned buying inexpensive kegs from Art's Brewing, in
SLC. That was a one time deal, since he managed to get a great price for
many kegs (1 1/2 yrs ago?). I'm pretty certain that his price is back up
to the "market" price, now.

__Sourdough__

Last night, my girlfriend and I attended a class offered by the city's
school system, on making your own sourdough bread. REALLY interesting to
me, and to many homebrewers, I'm sure. (I'm quite certain I was the only
brewer in the class; the others looked to be Mormon housewives ;-)
The thing I'm concerned (not worried) about is keeping wild yeast in the
brewery. Since much effort is expended keeping wild yeast OUT of my
beer,
am I asking for trouble by culturing wild yeast for my bread? Has
anybody
had this problem?

====Concerning the length of the Digest====

As a result of recently learning that the digest is limited in length, a
few things have occurred to me.

1. If you submit a post and it doesn't show up the next day, RDWHAHB.
That
digest was probably filled to its 50k limit, and so your post will show
up
the next day. Two posts just clog the digest with redundant material,
and
probably pushes somebody else's post back to another day.
2. Try to limit the length of your posts. Again, lengthy posts make the
digests approach the 50k limit, thus causing other posts to be delayed.
There's no need to include lengthy quotations from previous posts; just
include the relevant facts. Besides, we've all read it before. Also,
some
people have pretty long "tags" (is that the name of the long thing at the
end
of each letter with your name, favorite quote, disclaimer, and operating
system preference? ;-)
Maybe these can be trimmed down a little?

I don't mean to be a stick-in-the-mud, but the distribution of the HBD
has
grown and continues to grow, so we've all got to start assuming some
societal
responsibilities. (I know, this post is pretty damn long...)

Cheers,
Chuck

Subject: RIMS unit, only computer controlled

All this talk about the RIMS units make me want to talk about our setup.

..
Ours is very similar to the one recently described, however pumps can be purchased through surplus houses(JerryCo) from time to time... look around, you'll find one eventually.

But, the nifty part about our system is that it is CPU controlled. Take one of the versions of the 68hc11(16 bit motorola part), the one with the built in parallel i/o port and the built in A/D converter. Then get the 1millivolt per degree F temperature sensors and attache to A/D converter. Connect the parallel port to a DC/AC controller(+5v makes the AC go on), and control the Hot water heater elements in the path of the wort pump. Connect the built in serial port the the hc11 to a dumb terminal, or PC, the write nifty user inteface SW(just a matter of software!) , and voila, CPU controlled step masher, mash-outer, and sparger. Gives the brewer the chance to wash bottles (of the previous batch) uninterrupted.....,

>
> ***Just what is the status of legalization across the country???*
>
> Has this question been addressed in prior issues of HBD? We would
really like
> to be disseminating correct information to the Georgia Legislature when
we tell
> them that we are one of only 3 states firmly rooted in the '20s.

Well Ken, I just got off of the phone with the enforcement office of
the
Alabama Beverage Control Board here in Huntsville. The gentleman I
talked to
said that "there is no law specifically covering homebrewed beer in
Alabama".
He said that winemaking is legal but your are "supposed to have your own
grapes
and stuff". He said "as long as you don't try to sell it or give it to
minors,
no one will bother you about it (homebrewing)". So, it is neither legal
nor
illegal in Alabama, according to this source. On the surface, that
seemed to
be a pretty good situation to me but, the more I think about it, the more
it
worries me. All it would take is one zealous group and we could suddenly
find
it illegal here.

Subject: pre-crushed grains and basil beer

How long would one want to keep pre-crushed grains around, assuming they are sealed pretty well (not necessarily air-tight) in a cool, dry environment?

What is the problem with old pre-crushed grain, is the yield simply lower, or do bad flavors (or some other catastrophe) develop?
What is the best way to store pre-crushed grain?

If you were going to make a basil beer, how would you add the basil? would you:

1. throw some into the boiling wort?
2. steep some in hot non-boiling water, strain, and add the result to the primary fermentation?
3. throw some into the primary (or secondary); i.e. like dry-hopping?
(would you need to sterilize somehow?)
- or 4. some other ingenious method?

Any ideas on how much you would add to a 5 gallon batch?

Thanks. - Bryan

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: Schmidling's NA beer

I asked Jack how he was sure his procedure produced NA beer, and got the following info, which I've annotated.

>I forgot the numbers but you would be amazed at the volume reduction just
>bringing up to 170 and letting it cool. It is on the order of a cup or more.
>That's about 4 times the volume of the alcohol in the beer so I think it is
>safe to say, it's gone.

* 1 cup per gallon is 6.25%; by volume, typical homebrew is 4-6% alcohol.

(All US commercial figures are in weight%, which is lower; the traditional weak "3.2 beer" is 4% by volume.)

* The composition of a vapor is governed by the concentrations and vapor pressures of the components of the underlying liquid. At 170F (76.7C), vapor pressure is 310 mmHg for water and 711 mmHg for ethanol, which means that the vapor should have ~2.3x as much ethanol as the beer---e.g., it will be ~10-15%v/v ethanol.

>As I am currently a very light drinker, I can vouch for the fact from my
>personal reaction that, this is NA beer. I get a considerable buzz from
>a glass of normal beer but zero from this stuff.

There is certainly a psychological as well as a physiological component in the "buzz" from alcohol, but I don't know how significant it is. It may be true that "the proper measure of mankind is man", but you can't substitute "beer" for "mankind"---I wouldn't trust subjective measurements.

>I am not quite sure why I started using Champaign yeast but it clearly is
>unnecessary. I use it for soft drinks because it is supposed to impart little
>or no flavor of its own and I happened to have some on hand when I started the
>NA project.

You should have included this info---if you want to be a momily-buster, don't spread any of your own....

> It also occurred to me that one should not have to prime the beer
>because the alcohol which originally limited the fermentation is gone but that
>doesn't seem to be the way it works. I got no fermentation without sugar.

Not surprising; most fermentations poop out not because of high alcohol but because the sugars the yeast can ferment are gone. You might get more gas

by using a less-]attenuative[yeast in the primary and a more-]
attenuative[
one in the bottle (where]attenuative[refers to the # of types of sugar
it
will digest, not to the alcohol level it tolerates), but this is chancy.
You could also try repitching a bit of the yeast slurry (heating to 170F
probably wipes out any suspended yeast) instead of using fresh
yeast---especially if you were trying to hold down the cost.

>The next batch I am going to carbonate in a keg. It will be interesting
to
>see how that turns out.
>
> js

Subject: Eisbocks and the law (who cares?)

David Suda and Chris Shenton have been chatting a bit about eisbocks. As I have been following the other threads regarding the various legalization efforts, I seem to recall that any type of home distillation of alcoholic beverages is illegal by Federal law (hence the "revenoors" of the Prohibition days). To my knowledge, this has never been changed. Since it is freeze distillation which makes an eisbock an eisbock, it's probably illegal. (Don't worry, I'm relaxing...)

Would that make an eisbock category at a sanctioned contest a case where the AHA is inviting and condoning an illegal activity?

(I don't know why I thought this question up, but it is Friday afternoon, and I'm in a rather philisophical mood...time fer another 'un, I guess)

Subject: sassafras extract for root beer

For those of you who are still looking for extracts of roots to try and brew a 'real' rootbeer, here's something you might try to use...

Pappy's Sassafras
Concentrate
Instant Tea

12 oz. 355 ml

Contents: filtered water, extractives of sassafras (safrole free), and natural flavors, caramel coloring, potassium sorbate as a preservative. Very low sodium. No caffeine.

Made by: H & K Products, Inc.
Columbus Grove, OH 45830

"Refreshing As Spring ... All Year 'round"

This is sold in a glass bottle and is meant to be added to hot or cold water and made into a tea ... add as much as you like, and sugar, YUM! Actually, I have had it cold, and it tastes like weak root beer - a hint of the wild cherry mintiness comes through.

Btw, I don't know where you DO get this. I got mine at the NHD store in Middletown, RI, in their close-out bargain basement for a buck. Call the company, maybe...

Subject: Oldest brewery

There was some speculation here recently about Charlie P's visit to the "oldest brewery in the Americas." An article appeared in the local paper a few days ago that might hold the clue. A Vermonter named Alan Eames recently returned from a similar quest, down in southern Peru. He was in the "sacred valley" area, not far from Machu Picchu. A brief quote from the article:

"He aimed to examine a beer prized by the Incas The lifeblood of their society was a corn beer called 'chicha,' brewed for 10,000 years -
- still brewed, in fact -- by women of the remote Quechua Indian tribes."

This would be my guess for C.P.'s whereabouts, and a very likely candidate for oldest brewery in the Americas.

I agree with John's advice wholeheartedly. However, the major reason that I use a blow-off tube is not because I don't use a secondary, but because of the fear of gook getting spewed all over my kitchen when my airlock gets blown off by CO2 pressure during the first few days of fermentation. Is there an alternative method for avoiding this that I am unaware of?

cracking.
>
> We do, we did, it did. Scratch one carboy.

I wasn't going to comment on this thread, but this response forces me to.
We've autlcaved carboys many times. Never has one cracked. This is
opposed to the experience of some friends, who decided to boil their wort
in the autoclave. That carboy *did* crack, scratch 5 gals of beer. *
BUT*
I am certain that it's all a function of the individual carboy (no
imperfections, please) and also, you probably have to use the slow vent
cycle... As I said, 2 carboys of mine have been through the autoclave
half
a dozent times (we usually find it's too much of a hassle to take them to
the lab) but they're all quite healty...

Take care,

From: Bob_Konigsberg@3mail.3com.com
Subject: Eisbock

A couple of notes here. I've got a book on Cider making which discusses both freezing and distillation.

1) Freezing for the purpose of concentrating the alcohol is in fact illegal, most folks know that.

2) What is more interesting is the books discussion of problems with freezing. Although their discussion is limited to cider, it will apply here. One of the things that proper distillation does is to separate out stuff called heads (substances more volatile than alcohol), and tails, (substances less volatile than alcohol), both of which are generally undesirable side products of fermentation. The problem is that by separating out the water alone by freezing, it concentrates these substances (fusel alcohols, etc.) in the remaining beer, as well as the alcohol, and may make it taste worse. By way of example, hard cider concentrated in this fashion is called "cider oil". Draw your own conclusion.

3) Another item discussed is that if you are going to do this, don't use a high gravity brew to start with. Apparently (as an extreme case), high alcohol cider (substitute beer), is a little too resistant to freezing to enable good separation. I'll try to remember to look up in the book any general guidelines that apply for those who wish to try it.

From: sherwood@adobe.com

Subject: sparging

I have been thinking about switching from extract to all-grain. There is a limit to the number of vessels I would like to purchase, namely one (a fellow brewer uses a 20-gal SS pot with a SS screen held off of the bottom an inch with a valve below; this should make both a good mashing/boiling vessel)

I also do not want to buy another burner. How to provide sparge water is thus my problem. Dave and I got to talking, and he said that his water heater will get up to 150F -- if it got to 160F he would use that. Nifty idea -- no sparge vessel needed, no extra burner, and you have pressurized hot water that can be piped (er, hosed) anywhere. I like it. I know small hot water heaters (like for mobile homes) are not particularly expensive.

So, has anybody tried this? If the best we can do is 150F, would that still work reasonably (not ideally, maybe, but reasonably?)?. Alternatively, we could replace the thermostat if higher-temp ones are available. Anybody know if they are?

So many questions; so few answers....

Thanks much,
Geoff Sherwood

Subject: Culture equipment

Occasionally the question of where to buy culture equipment comes up on the net and the recurring problem is that most supply companies will only sell to "authorized" labs (sheesh!). I've found a company that encourages sales to individuals, using mastercard or visa payment instead of a university P.O. The company is Cole/Parmer, and I'm looking at their 1992-1993 Plasticware catalog. Their number is 1-800-323-4340. Their prices are about the same as the other scientific supply houses. They'll probably be more willing to send you the catalog if you use some bogus company name when you call.

This catalog has petri dishes, culture tubes, plastic tanks, tubing, and valves that might come in handy. They also have a hand-held pH meter for \$43 that's cheaper than my homebrew supplier.

And, no, I do not own stock in this company.

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Culture equipment
Subject: Wyeast Cultures (George Fix)

Mike Lelivelt in HBD#810 asks about yeast cultures at Wyeast. I have not had practical experience with all of them, but this is what I do know.

The Whitbread dried culture is made in England, and distributed in the US by Siebels of Chicago. This is where Wyeast got their stock culture, although they now keep it on slants, or at least this was the case as of a few years ago when I last talked to Fred. Remarkably, slant systems can be effectively used even for multi-strain cultures, and this is but one of a long list of reasons why it is such a practical system for yeast maintenance.

The other ale culture which I have had some practical experience is the Chico or American Ale culture. I believe it is the same as Siebels BRY-96, which in turn is the production yeast at SN. It is most certainly a pure single strain. I find it makes excellent ales in the moderate gravity range (say up to 13.5 deg or 1.054). Whitbread, on the other hand, makes excellent high gravity ales. No.2 in this three strain culture is an incredible fermenter.

I am familiar with four of their lager yeast. I conjecture that the Bavarian strain is the same as W34-70. The strain 2308 is the same as W308, better known to some as Wisenheimer. Both are pure strains. W34-70 is widely used in Germany today and makes excellent lager beer. It tends to be sensitive to high trub levels. Also, it tends to be somewhat of a slow starter when first pitched, however it gets much better in this regard when it is reused.

The Bohemian strain is reported to be from Pilsen. It is dramatically different (and better) than the "Saaz pitching yeast" available from ATCC in Rockville, Md. The latter is also from Pilsen, and is a very strong ester producer. Darryl Richman brought back yeast from Pilsen from which two strains were isolated. One called strain W is very close to the culture at ATCC, and does not make good beer. The other, called strain D, produced some of the finest lager beer that I have ever made. It is less fruity than the Wyeast culture and produces rounded, soft continental flavors. It is less sulfury than W34-70, but a tad fruitier. I believe it is different from the strain at Wyeast. Check with Darryl if interested.

The American Pilsner strain is reported to be AB's production yeast. It

produces apple like flavors found to some degree in all AB products. The culture from Wyeast, however, can have on occasion very strong apple flavors.

These will diminish to some extent with aging, nevertheless measured acetaldehyde levels are always well above what is normally thought of as acceptable. It is my belief (totally without proof) that the Wyeast culture (unlike AB's production yeast) is a multi-strain culture.

>

I disagree. The (alleged) benefits of blowoff are the removal of higher (fusel) alcohols and (from my own observations) some hop oils. Some brewers swear by the blowoff method, others consider it a waste of beer -- I used to be in the former camp, but I'm trying to be objective and plan to do a few experiments to see if I can tell the difference.

>I agree with John's advice wholeheartedly. However, the major
>reason that I use a blow-off tube is not because I don't use a
>secondary, but because of the fear of gook getting spewed all over
>my kitchen when my airlock gets blown off by CO2 pressure during the
>first few days of fermentation. Is there an alternative method for
>avoiding this that I am unaware of?

The most common way is to use an oversized primary. I know that 6 and 7 gallon glass carboys are available and although I don't recommend using plastic fermenters, there are 11 gallon plastic food-grade buckets available.

On a related note, Friday I brewed up a Cherry Stout. I miscalculated my and brewed up about 5.5 gallons. I put 5 in a glass carboy and 0.5 in a gallon jug. Since there are whole cherries in this batch, and I could not split them accurately (in the proper proportions) between the carboy and jug, this will not be a good test for blowoff versus non-blowoff. Back to my point. I put two 3.3 lb cans of John Bull dark unhopped extract, 1.5 lbs of DME, 1 lb of Crystal and some non-fermentable grains in this batch, which is not really a high OG: not including the cherry solids (no way of knowing how much sugar they add to the wort) the OG for 5.5 gallons was 1054. Oh yeah, I also steeped 2 oz of flaked barley while the wort went from 125F to 165F. Pitched Wyeast #1084 - Irish Ale yeast. The blowoff was incredible! This morning (monday) the kraeusen has fallen, the total blowoff was about

a half of a gallon. The point I'm trying to make here is that I suspect that even a 7 gallon carboy would have needed a blowoff hose. I can't even imagine how much blowoff there would be in a 1112 OG beer like EKU 28

Kulminator! Have any of you really-high-gravity beer brewers successfully

brewed without blowoff? Chuck-- have you? Oops again -- I failed to mention the ferment is being done at 66F.

From: Conn Copas <C.V.Copas@loughborough.ac.uk>
Subject: Yeast and head retention

I've been combing the literature (and the archives) on factors which affect head retention, and one thing which is conventionally neglected is yeast strain. On the other hand, I've seen some brands which advertise this as a plus, and it accords with my experience. So what might be the mechanism? Obviously, we need to rule out factors which are only indirectly related to the strain, such as degree of attenuation, rapidity of bottle conditioning, preferred working temperature, etc. I'm thinking more in terms of fermentation or maturation by-products. Any ideas ?

Re dried yeast, I saw a recent claim that top fermenters survive the drying process less successfully than bottom fermenters. The result being that dried ale yeast tends to contain a high proportion of spores, as opposed to dormant cells (presumably), which makes for an inferior ferment in some fashion which escapes me and for which I would welcome an explanation. Thus, so-called dried ale yeast may in fact more closely resemble lager yeast. I'm wondering if this is an alternate explanation for why dried yeasts are so attenuative; it's not just because they are inherently vigorous, but because they are biased towards a particular strain. Ideas ?

From: trwagner@unixpop.ucs.indiana.edu
Subject: Axbridge Beer Kit

Howdy all brewers.

Last October, I was milling through my local liquor store in search of George Killian's Red (now THAT's a great beer!!) However, much to my disappointment, Indiana does not distribute Killians at all! (damn). I spotted a beer kit called Axbridge Beer Micro Brewery. I thought it was a cool thing. I gave it a glance a few times when I returned but left without the kit due to its price. (I still wanted one though, even if it did cost \$39.95)

The kit is basically a sealed plastic bag inside a synthetic woven bag on the outside. At the bottom of the plastic bag, sticking through the outside one, is a spout. At the top is a plastic cap with a valve. All you do is add about 60 oz of HOT water to the mix *inside* the bag, add another 340 oz of cold water, toss on the brewers yeast that is included with the kit, cap the bag, and wait for about 21 days. (of course, I will wait about 28 days).

The cap with the valve is supposed to keep the pressure inside the bag and add co2 throughout the process. It is an English Ale and is supposed to clear after 20 or so days.

I purchased and finished setting up the kit on Saturday the 25th of January. When finished, I will release a result for those interested.

My question is this. Has anyone else out there tried a micro brewery like this (or this exact one), know of a BETTER price, know if these kits can be purchased mail order, or if they can be re-used?

Thanks

Subject: New on hbd, high-gravity brew

This is my 1st submission to the digest, though I have received it for quite a while through CompuServe's Beer forum.

I brewed a high-gravity bock last weekend, and wonder what I can do to get as complete a fermentation as possible. My SG reading was 1.136, part of which I think is attributable to some trub in my sample, but it still is chock full of fermentables. I pitched Wyeast London Ale, cause it's what I had.

How well will that yeast do, and should I attempt to rouse it when fermentation slows/stops? Should I add another strain later in fermentation? If so, what? In the interest of general information, here is my recipe:

8 lbs pale malt
1 lb Vienna malt
.5 lb chocolate malt
2.5 lbs dark extract syrup
2.5 lbs light DME
1 oz Chinook 12.5% alpha boil
1 oz Hallertau finish

Grains mashed in a RIMS. Extracts added to boil. Forgot my Irish Moss <slap>. I'd like to get the gravity as low as possible, I mean I don't expect 1.009 or anything but I sure don't want to see it stop at 1.070 or similar. Thank you thank you thank you.

and

I feel that there isn't a problem with leaving the beer on the trub for
a short while, say, a few weeks. You can reduce your trub by cooling in
your kettle (the added advantage of being able to aerate as you pour into
the primary without fear of oxidation (as long as the wort is under 80F)
)
thus getting your cold break in the kettle rather than the primary. This
implies an immersion chiller. If you use a counterflow chiller, you get

the same benefit but you need to cool as you transfer and then rack off the cold break. Cooling your wort quickly gives the additional benefit of reducing DMS in your beer, which is produced while your wort cools from boiling to 140F. Shortening that period of time will reduce how much DMS gets created. Since you mentioned Lager yeast, I assume you will be fermenting for a long while at cooler temperatures. That's when I think you need to worry about getting the wort off the trub. I suggest that you get an immersion wort chiller, siphon the cooled wort off the cold break into a 6 gallon carboy, then after three weeks rack off the trub into a 5 gallon carboy. I know you mentioned "cheaper and easier" and I suggested a more expensive, more difficult way. Sorry. Well, on second thought, if you cooled your wort in the kettle, by say, putting it in a tub of icewater, that would be cheaper than a chiller. I think you've described the easiest way, though, so I'm afraid I can't help you there.

[stuff deleted]

>This pump does 470 gallons per hour and costs \$119 from "That Fish
Place,"
> so would be a pretty good deal if it's useable.

I've been thinking the same for a while -- a pump would make siphoning
obsolete and sanitation easier. However Dan, you mentioned that a
peristaltic
pump is out of the question because of cost, but the Coleman-Palmer
catalog
has peristaltic pump heads for \$80. Drive motors begin (I think) at
\$125,
but there are a lot of \$20 motors out there. If you're willing to spend
\$119, I think you should be able to put together a peristaltic pump. I'm
not familiar with the Little Giant SC, but one very important
characteristic
of the kind of pump we both are looking for is: SELF-PRIMING! If the
pump
you get is not self-priming, then we're back to square one -- siphoning.

Subject: PH readings

Greetings,

Is there a better (and also cheap) way to determine the PH of your grist than with typical PH papers? I take a reading and for the life of me I can determine the PH with any kind of accuracy. Do other people has this problem or should I consult an eye doctor?

Shifting Gears, I tried "Samual Smiths 'Pure Brewed Lager Beer'" over the weekend since it was the first time I've heard of it. Since the Oatmeal Stout is one of my favorites, I thought the lager deserved a try. I must say that it was exceptionally smooth with a nice bitter kick at the end. Unfortunately, I won't be drinking a lot of them, though, as they are \$11 a six here in Chicago.

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)
Subject: When to add lactose?

I have read that certain sweet stouts (i.e. Mackeson's) add lactose (milk sugar) at both boiling and bottling. What I am wondering is, if lactose is really unfermentable by beer yeast, why should it matter when it is added? Does it react in some way during fermentation that I am not aware of, or at least change in flavor profile?

FYI, our club (the Ithaca Brewers' Union of Ithaca, NY) is having a Stout and Porter competition for St. Patrick's Day. Only 2 bottles and \$4 per entry required. 5 categories, 3 prizes in each category. If anyone is interested, send me e-mail directly and I'll send you information.

Cheers,

Subject: Ph Ranges

martin wilde) found a machine for PUMPING BEER:

>I just recently purchased a pump for pumping beer. It was a Teel
>pump. The specifics are as follows:

>- a chemical magnetic drive pump.
good.

>- designed for sanitary conditions.
good.

>- pumps fruit juices (beer should have no problems!!!).
not an issue.

>- ph range of 5-9.

HUH? My understanding is that beer has a ph lower than 5.0 Wort is
in the low 5's, and fermented beer is more acidic. My guess is the
dissolved CO2 acidifies the beer.

>- temperature range of 32-180 degrees.
good.

>- gravity feed (will not pull a column unless primed).

I'm not sure what graviry feed means. I can start a siphon, and the
beer moves by gravity feed!

The capacity of the pump seems a little high, but should be useable. Most
pumps I've seen are either much to fast (tens of gallons per minute) of
much too slow (liters per hour). I'd like a pump in the 0.5-1 gallon per
minute range.

I'm not sure what makes these pumps (any pump), but I'd be worries about
oxidatation. If an impeller spins around, pushing the beer, I'd think
it would oxidise the beer. Any comments?

>I recently moved into a house with a septic tank. After reading up a bit
>on the way septic tanks work, I became concerned that dumping the chlorinated
>water I use to sanitize will disrupt the workings of my septic system. Is
>this a real problem or am I worrying overly (I'm getting a homebrew to relax
>with right now)?

I also live in a house w/ a septic tank, and I was advised not to use bleach
in cleaning the bathroom, because the bleach running down the drain would
kill all the little septics :-). As for chlorinated water, I would guess
it would be a function of what the percentage of water you are introducing
into the tank is (as compared to the tank's capacity), and what the concentration of chlorine is in the solution. My gut feeling is that I would advise against it.

My solution to this problem would probably not be apropos to you, as I live
in the fairly rural area of Alabama that surrounds Huntsville, and my neighbors have not said anything to me when I dump my toxins into the drainage ditch at the edge of my back yard :-). I have not noticed any dead
birds or two-headed squirrels in the area, so I don't think it is affecting
the enviroment that adversely, but that may or may not be socially acceptable in your neck of the woods.

If worse comes to worst, I can't remember the exact amount, but I believe
it would cost less than a 100 bucks to have your ceptic tank drained and
have them re-introduce the bacteria into the system. The builder of our
house advised that you do that every 4 or 5 years, anyway.

Subject: Whitbread,ss spigot

I've got a data point in support of G.Fix's assertion that the #2 Whitbread strain is a good fermenter. I made a strong ale (mistakenly, but that's not important) that had an OG of at least 1.060 and might have been over 1.100, depending on my extraction rate. The initial (first 1-2 weeks) of ferment were slow. Then, without any prompting from me, the ferment just took off, almost making another krausen head. It's been more than a month, and it's still fermenting strongly. I took a taste after about 2 weeks, and didn't like it: strong solvent/cloves/vinous flavor/aroma. If I remember correctly, that is characteristic of the #1 strain. Correct me if I'm wrong. Since then, the aroma has mellowed/sweetened considerably. I would expect the flavor to have similarly improved, although it may still need some aging. It was intended to be an Oatmeal Stout, btw, but it turned into an Imperial Oatmeal Stout. New category anyone?

I'm also looking for advice as to adding a spigot to a stainless steel brewpot. According to the person with the MIG welder, the spigot has to be the same steel as the pot. True? And if so, where to find a ss spigot?

Russ

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>
Subject: Teel Pumps

The Teel magnetic drive pump is a gravity feed pump, which means that the fluid must get to the pump on its own - the pump does not suck. This makes it suitable for setups where the pot or tun from which you are pumping has a bottom spigot. It won't work in the situation where you want to just drop the hose into the pot and start pumping. Another way of describing this pump is that it is not self-priming. The capacity of the pump is not really a problem, because you can put an inexpensive motor speed controller on it and slow down the pump. Oxidation should not be a problem - the pump body and impeller should not contain any air....

Subject: Malt mill (ala JS)

Well, folks, I did it. I sent my money off to JS and bought one of his bottom of the line (non-adjustable, hand cranked) malt mills. As was mentioned in the review several weeks ago, the aesthetics are kind of home-shop. However, in a nano-brewery where lots of the stuff is built out of plastic buckets and hacked up kegs, it looks right at home. The important part is the roller assembly, and that is a gem. It is very simple, but that does not mean it would be simple to build. I actually have all of the tools needed to do the job, (well, I don't have a foundry, but the parts Jack casts could as easily be fabricated from thick aluminum plate) but the time it would take me would be just too much. For \$100, I'm willing to let Jack do it. Besides, he did the research - if I built my own, I'd probably have to do it a couple of times before I got it right.

So how does it work? In a word, great. I ran several kinds of grain through it, and they all got a great crush. It is quick and easy. If what you want is Williams-Sonoma yuppie glitz, this mill will not make you happy. If you want a mill that is pretty much optimized for the small scale brew, this is your machine. IMHO the price is fair, and I don't feel ripped off at all. BTW, Williams-Sonoma has, among all the yuppie glitz, some very nice 3 liter canning jars for \$6 apiece that are great for storing specialty grains, etc.

I have no connections with Jack other than reading his posts (and yes I was pretty pissed last fall too :-)) and buying his mill. I'm glad he's making them.....

following this thread on how UPS is refusing to ship alcohol because it is company policy or whatever. This is garbage. Every month I receive two bottles of wine and two six packs of beer from UPS (Taste of California and Beer Across America). UPS is the most inconsistent organization in the world. Supposedly, they have a signature for everything they deliver, but I come home from work all the time to find things left on my porch in broad daylight. Sometimes the boxes contain very expensive things (software, china etc). The first time I got my shipment of wine from Taste of California, they made a really big deal out of getting an adult signature because the package contained alcohol. We called up and asked if we could leave one of those yellow slips with our signature on it and they said "Oh no, you'll have to sign in person for packages containing alcohol." So we went into UPS, signed and got our wine. Well, the very next month, I come home from work and what do I find on my porch but two bottles of wine delivered from UPS WITHOUT my signature. Oh well, same much for company policy. The bottom line is that they will ship alcoholic beverages, but who knows what you have to go through to get them to do it. I think the easiest thing is to lie and tell them it's something else and avoid the hassle altogether.

From: loc@bostech.com

Subject: Wyeast Package Problems

With reference to the various experiences people are having with Wyeast packages, I noticed something new on the package. Yes, it is a bit strange but I do read packages. (8^) The new Wyeast packages contain new instructions on them. I understand that these new instructions are specifically intended to prevent the seam from failing. I noticed these new guidelines on a package of Danish lager I just used.

The instructions now say to place one hand across the bottom seam of the package, holding it closed, while the other hand is used to just rupture the inner yeast packet.

>From what I can gather from my sources, Wyeast fills the package from the bottom and this is the seam that is the most prone to failure. (I've had seams go before, but can't remember which one right now)

DISCLAIMER the following statement is pure conjecture and has no base in fact. With that said, I suspect that the Wyeast people are working to solve the failing seam problem, but it is a harder problem than meets the eye.

So check out the next Wyeast package you get that has a 1992 date on it and read how the directions have changed. If I learn any more, I will post the info.

Subject: AHA Nationals.. told you so...

AHEM... not being one to pat myself on the back and say I told you so :-
) , but
long time readers of the HBD will recall a discussion held several years
ago
calling for the creation of a tiered competition system where winners
judged at a
local or regional site would then be forwarded on to the National Round
finals.

At the time of the discussion the AHA competition was smaller, but there
were also a lot fewer judges. I think back then (late 87 or 88) the
AHA just did not have confidence in anyone outside of Boulder to take
these responsibilities. While much controversy raged around this issue
(and some of us let our AHA memberships lapse over it...) time has
vindicated
those championing such a system.

Now if the AHA would only actually let it's members have some real
representation, say like having an elected Board of Advisors who actually
had
some authority to make policy over certain non-publishing issues (such as
judging and competition policy) I'd be really happy. Still in all they
have
been a lot more responsive in the last few years accepting suggestions
such
as moving the conference around...

Subject: Botul-oops!

After being notified privately that my recent post on the heat-lability of the botulism toxin was in error (and particularly offensive to boot), I resorted to re-checking my facts (which should have been my first move).

Facts:

- 1) The botulism toxin is quite unstable in boiling liquids; a 10 minute boil should thoroughly inactivate it.
- 2) Boiling does not kill the organism's spores; this requires at least pressure-cooker temps.
- 3) I think Jack S. was right on this one. (Argh that hurts!)

There are bacterial toxins that are resistant to boiling (or pressure cookers) Staph toxin is one; this was the source of my error.

My thanks to my tutors (especially Jim W.) and my apologies for the waste of bandwidth.

Subject: PSI/Temp chart for force carbonation

I have the above mentioned chart in my hot little hands right now. In the past, I have force-carbonated mostly by luck, but I figured this chart would take the guesswork out of it. Well, I have a question. There is no mention of time anywhere. I went back through old digests and found no mention there either. If I want 2.4 Volumes in my beer, I can put it under 14PSI @ 46F. But how long will it take? Obviously, it isn't instantaneous, but when it does reach 2.4 Vols., will it stay there and not take anymore CO2 into solution ? My guess is no, but I'm a programmer, not a cellar-master. So, what am I missing ?

Subject: Re: sanitizing agents

John Rodin writes:

I recently moved into a house with a septic tank. After reading up a bit on the way septic tanks work, I became concerned that dumping the chlorinated water I use to sanitize will disrupt the workings of my septic system. Is this a real problem or am I worrying overly (I'm getting a homebrew to relax with right now)?

My brother-in-law and part-time brew partner designs and builds septic systems. Since I recently acquired my first septic system I asked him about the effects that homebrewing might have on it. He felt that the small amount of chlorine involved (approx 2 ounces per five gallons to sanitize) would have no effect on the system's workings. In fact, he thought the yeast slurry which would be sent down would be an excellent treatment to keep the system healthy and functioning well (I guess he meant decomposition-wise). He couldn't comment on the environmental impact of the bleach.

Subject: Schmidling's NA beer

> I asked Jack how he was sure his procedure produced NA beer, and got the following info, which I've annotated.

I find it a bit strange that you would ask me questions in private mail and them respond with edited, out of context sound bites, in public.

>>I for got the numbers but you would be amazed at the volume reduction just
>>bringing up to 170 and letting it cool. It is on the order of a cup or
>>more. That's about 4 times the volume of the alcohol in the beer so I think
>>it is safe to say, it's gone.

> * 1 cup per gallon is 6.25%; by volume, typical homebrew is 4-6% alcohol.

(All US commercial figures are in weight%, which is lower; the traditional weak "3.2 beer" is 4% by volume.)

* The composition of a vapor is governed by the concentrations and vapor pressures of the components of the underlying liquid. At 170F (76.7C), vapor pressure is 310 mmHg for water and 711 mmHg for ethanol, which means that the vapor should have ~2.3x as much ethanol as the beer---e.g., it will be ~10-15%v/v ethanol.

All that is fascinating and elegant but, sheds not the slightest bit of light on whether it is or is it not, "safe to say, it's gone"?

>>I am not quite sure why I started using Champaign yeast but it clearly is unnecessary. I use it for soft drinks because it is supposed to impart little or no flavor of its own and I happened to have some on hand when I started the NA project.

>You should have included this info---if you want to be a momily-buster, don't spread any of your own....

Yes Mom, but I was just passing on a recipe that works and all of my reasons for everything in it would be a waste of bandwidth. Furthermore, you know how sensitive I am. Why did you ask the question in private and then scold

me in public. Are you trying to stimulate another temper tantrum?

>I see in the last HBD that ol' Jack S. has advanced from being simply the world's greatest brewer to being authority on community water supplies and medicine too.

>Nay nay, I say.

>Dear Jack; you cannot destroy the botulism toxin with a pressure cooker.

>You are out of your league on this one.

>dennis (M.D. Ph.D.)

Not sure what "league" I am supposed to be in but if you are really an M.D., you provide an excellent reminder of why most intelligent people have little confidence in doctors.

The following is from: Bacteriology, F W Tanner.....

"The toxin formed by Clostridium botulinum is one of the most active poisons known. A small amount will cause death. Some fatal cases have been reported where a little liquor left on the tongue from tastina a portion of a bean pod caused death with typical symptoms. Experiments have shown that this toxin is quite susceptible to heat and destroyed by boiling for a few minutes."
"

This information is so basic that even moms routinely demonstrate a far higher level of understanding than yours. Mom are advised to boil home canned foods for a few minutes before eating or tasting.

The next time I need a doctor, I will make a point of checking out his "poetic license".

Subject: sparging

>How to provide sparge water is thus my problem. Dave and I got to talking, and he said that his water heater will get up to 150F -- if it got to 160F he would use that.

I posted an article recently on the effects of sparging with boiling water and never got a single reaction and have suspected it got eaten. If you read my article on sparging temp, you will probably be disinclined to try to use water that cold. It is fairly easy to keep a kettle of water boiling for sparging if you are doing it at the proper rate. If you are using your

kettle as a mash tun, move it off the burner on to a stool for sparging.
You
now have the burner available for heating sparge water. If you put a
spigot
on the kettle used for boiling, the process becomes automatic. If not,
just
dip it out with a soup ladle. Every time you take out a ladle, replace
it
with a ladle full of tap water.

The ideal solution is two kettles. I started with an enamel 32 qt and a
coffee pot. I now use the enamel pot for mashing and a ten gal ss pot
for
sparge water which is then available for boiling when sparging is
complete.

Subject: Be wary of CAMRA Canada

A few weeks back someone (I forget who) suggested joining CAMRA Canada rather than sending off a credit card authorization to CAMRA (UK) for 14 pounds. This may make sense for any digest readers living in North America, but I would suggest you be wary of CAMRA Canada. I sent them a cheque for Cdn\$18 in September 1990 and have not received a thing from them; no "What's Brewing", no "thank you for joining CAMRA Canada", no nothing except for the fact that my cheque cleared the bank shortly after I mailed it in.

I have written several letters to them to try and figure out what happened and why I haven't received ANYTHING from them, but they won't even do me the courtesy of replying to my letters. So I've basically kissed my \$18 goodbye.

This leaves me feeling somewhat awkward. On the one hand, I do endorse many of the aims of CAMRA, but on the other hand I have the feeling that I've been taken by a bunch of swift-talking con artists who have fed into my emotions on the subject of big-brewery commercial beer.

All this, of course, IMHO.

Subject: RS lager

I guess one man's clean is another man's dirt, or something like that. Chip H. took exception to my "clarification" of Red Star lager yeast as "clean". Ok, so it's full of contaminants. Agreed. But the *yeast* itself will ferment cleanly, as demonstrated by your single-cell tasting. This is in contrast to Red Star ale (also full of contaminants, I would guess), the *yeast* of which has a "dirty" ferment. My point was that I would never use Red Star ale; it's lousy and there are a lot of other choices, but I do use Red Star lager. I've found Vierka to be worse (when I could get it to ferment at all), liquid is expensive and not always available, and my lagers are not light, so I don't notice the fermentation flaws. Liquid or single-cell yeasts are definitely better, especially for lighter lagers, but still I submit that Red Star lager yeast is ok, not great, not lousy, but just plain ok. Ok?

Subject: How I force carbonate (long)

In HBD #812, Mark Nevar says:

> I have the above mentioned chart in my hot little hands right now.
> In the past, I have force-carbonated mostly by luck, but I figured
> this chart would take the guesswork out of it. Well, I have a question.
> There is no mention of time anywhere.

I've been fielding a lot of E-mail about technique, so I think a summary is in order. Please note, I've only got two keggings under my belt (well, over my belt these days...), so please don't hesitate to point out errors in my technique. My source is Ron Downer of Brewhaus in Knoxville (and I had to call him up at the Firehouse my first time keggering to get the answer to time :-)

The way I do it is that I keg my beer, put up ~10psi to set the seals, and toss it in the fridge overnight to chill. Ron says 6 hours is his minimum. I pull the soda keg into the middle of the floor, hook up my CO2 and crank it up to the pressure the chart gives me. I think shake the heck out of the keg (and contents). This causes the solution to mix up and increases the surface area available for the CO2 to go into solution. My technique is to shake hard for 2 minutes, rest for 30 seconds, and start up in another direction. This is typically for a total of 15 minutes. You'll hear the CO2 going into solution at first. When you stop hearing that, start listening to your regulator and you'll hear more CO2 being added to the system. After a while, additional shaking doesn't cause a pressure drop as the CO2 going into solution has maximized. I keep shaking for a few minutes more to be sure. It is usually a comic sight in my kitchen when I carbonate: I sit on the floor with the keg between my feet - imagine rowing...

Then, I put the keg back in the fridge and wait 45min. to 1hr for the head to go down and vent off some of the excess pressure and get back down some lower, but not atmospheric, pressure (have a towel ready and no, I didn't wait my first time and blew foam). I hook up the CO2 tank at dispensing pressure and bring out the first few glasses. If it's over carbonated, bleed down, shake to bring it out of solution, and then try carbonating again at a lower CO2 pressure. If undercarbonated, do the carbonation dance again at a little higher pressure. I noticed that going from 17psi to 20psi made a BIG difference.

> Obviously, it isn't instantaneous, but when it does reach
> 2.4 Vols., will it stay there and not take anymore CO2 into
> solution? My guess is no, but I'm a programmer, not a
> cellar-master.

Using my BS knowledge of Chem E., from an engineering perspective it actually will stay there. The solution is at an equilibrium for that given composition, temp, and pressure. The main time-problem is the permeation of the CO2 across the gas-liquid boundary. Just think of how slow sugar spread across the top of your coffee goes into solution as opposed to stirring it up. The partial pressure differential is what drives the CO2 into solution. Hence my carbonation dance in the kitchen to stir the solution up.

I'll stop now as I'm embarrassed about how much Chem E. I've

forgotten. I'm sure others carbonate just fine without shaking,
but it doesn't take long and I can use the exercise.

From: tony@spss.com (Tony Babinec)
Subject: how long does it take to force-carbonate a keg?

In HBD #812, Mark Never has determined his pressure and temperature from the chart, but wonders how long to force-carbonate.

In my experience, 3-5 minutes should work. Sanitize your keg and rack the beer to it. Secure the keg. Vent the keg. Attach the OUT fitting to the CO2 line. Attach the CO2 line to the OUT pin on the keg. Start with the regulator screw turned out, that is, with no pressure. Open the lines and tighten the screw to send some gas in. Stop the gas. Vent the keg. Do this relatively quickly 4 or 5 times to purge the headspace of air. Now, you're ready to carbonate in earnest. Open the gas line and set the pressure to the desired value. You should hear some vigorous bubbling as the gas enters the keg and the beer. The fun part is this: shake and roll the keg around as you're pressurizing. Over the course of time, the pressure inside the keg will go up, and CO2 will enter the keg less forcefully. However, shaking and rolling the keg seems to let more CO2 in. After 3-5 minutes, you will tire of this, and little CO2 will be going into the keg anyway. You're done.

Subject: CO2 & Kegging

I recently got back into kegging after I had a bad experience several years ago. Low carb or all foam problems were the norm. I have been trying force carbonating a few kegs and natural carbonating others by sealing prior to the end of fermentation or priming. The results are not all in yet. My question is what do you long time keggers perceive as the difference (if any) in the mouth feel or head retention, etc between methods? Does the CO2 bind up differently in the beer if it is not injected via a stone? I could imagine the CO2 grabbing on in big pieces rather than small pieces with natural carbonation. The bottom line would be whether one could tell or taste the difference. I know BUDMILOB is force carbonated and the head goes flat very fast, but it don't have any body to support a head anyway!

flat very fast, but it don't have any body to support a head anyway!

Subject: Beer Delivery

While reading through some recent posts about getting UPS to accept beer for shipment I thought of another question. Surely there are a few locations that receive a lot of UPS-shipped beer, like the Anchor Brewery in SF, which as I recall donates cooler space for brews sent for the regional AHA judging. At that point it seems likely that the UPS driver knows what he's delivering in such large quantities, and so must the UPS area office.

I seem to recall that Russ W. mentioned in his 'how to pack beer' article in Zymurgy that he worked at Anchor receiving these beer shipments. If you're still out there, Russ, has there ever been any difficulties at the receiving end? Do the UPS (and other) delivery persons know what's going on around competition time?

Anybody else had any experience receiving lots of beer shipments?

Subject: re NA beer

I sent you a private message because I didn't think the procedure would work but wanted to get any facts you'd left out before calling you on it in public and seeing any remaining facts go up in flames.

I included your entire message, even the signature line. If you don't remember what you've been saying, maybe you've had too much of your "NA" homebrew.

Actually, the numbers I gave shed a great deal of light on your implausible claims, starting with a quantitative demonstration that you don't even know how much alcohol was in your beer before you treated it (unless you left out another fact and have been brewing //really// weak beer...). I'm not foolish enough to say flat-out that you haven't produced

a NA beer without seeing an independent assay; this digest is a running demonstration of the differences between practical results and theory, however solidly-founded (and the theory behind distilling is /very/ solid).

However, it's certainly not safe to say the alcohol is gone from your beer; in fact, it's damned unlikely that your procedure will have much effect on alcohol level.

On a more general level: I recall a msg 1-2 days after arf's saying that

a west-coast group had produced NA beers via boiling. Does anyone have anything---procedures, volume losses, assay results---to substantiate this?

The formula I was working with (see below) indicate that the ethanol/water ratio goes /down/ as the temperature goes up, suggesting that low-pressure distillation would work somewhat better. Does anyone /know/ how the commercial breweries do it?

Formula for vapor pressure, from Lang's Handbook (courtesy a friend and sometime brewer who is closer to still practicing chemistry than I am):

$$\log_{10}(P) = A - B/(C+T)$$

P is the vapor pressure in mm of Hg and T is the temperature in degrees Centigrade.

For water: A=8.107 B=1750.3 C=235 (0-60 Centigrade)
A=7.967 B=1668.2 C=228 (60-150 Centigrade)

Ethanol: A=8.045 B=1554.3 C=222.6

This gives a vapor pressure ratio of 2.51 at 10C, 2.30 at 75C, and 2.22 at 100C. (Don't ask me for an explanation of the disjunction for water. I /think/ these numbers are empirical fits to known data points.)

 Subject: Stainless Coupling

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

> I'm also looking for advice as to adding a spigot to a stainless steel
 >brewpot. According to the person with the MIG welder, the spigot has to
 >be the same steel as the pot. True? And if so, where to find a ss
 spigot?

I've talked to a four professional welders, and they all agree that only
 stainless should be welded to stainless. I'm not a metallurgist, so I
 defer
 to those with practical experience.

However, there is an easier and cheaper solution than getting a stainless
 spigot. Get a threaded stainless coupling. For the benefit of those who
 aren't familiar with plumbing lingo, a coupling is a cylinder with
 threads
 on the inside. (Which makes it female, as opposed to a nipple, which is
 male - go figure.) Weld the coupling to the stainless, and then screw
 your
 spigot of choice into the coupling. A ball valve works well here. You can
 then put a 90 degree elbow into the other side of the coupling (inside
 the
 boiler), and screw it in such that the open end of the elbow points down.
 This will have the effect of lowering the drain hole and will allow you
 to
 drain more from the boiler, which may be desirable.

Another embellishment is to get some stainless mesh, fashion a filter
 screen
 out of it, and attach it to your elbow. (That's the elbow inside the
 boiler,
 not the elbow on you arm, silly.) This will help keep the spooge in the
 kettle and out of the carboy. It will also help prevent whole hops from
 plugging the spigot. If your spigot is already as low as you want it, bag
 the elbow and screw a nipple into your coupling. Then affix the screen to
 your nipple instead of your elbow. (Getting pretty pretty graphic here!)

It should look something like this :

Russ Gelinias writes:

> I'm also looking for advice as to adding a spigot to a stainless steel
> brewpot. According to the person with the MIG welder, the spigot has to
> be the same steel as the pot. True? And if so, where to find a ss
spigot?

You can find stainless steel valves at a plumbing supply shop, but you'll
pay dearly. Last I checked, a 1/2" ss valve, not full-bore, was on the
order
of \$25.

However, the valve doesn't need to be stainless, it's what gets welded to
the ss
pot that needs to be stainless. Typically, that would be a nipple, which
is a
short length of pipe threaded at both ends. Since most plumbing ball
valves
I've seen have female pipe threads at both ends, a nipple with male pipe
threads
is perfect. I recently paid \$3.40 for a 3"x1/2" NPT stainless nipple. I
then
bought a 1/2" full-bore brass ball valve for \$4.50. The body of the
valve is
brass, but the actual ball is stainless. BTW, in a full-bore valve, the
actual
hole through the ball is 1/2". If you don't get full-bore, the hole is
more
like 5/16".

If you want to attach something to the nipple inside the vessel, for a
collection pipe or whatever, it would either have to have a FPT end to
attach
to the nipple's MPT, or if the something had a MPT end, you'd need a
stainless
union to connect the something to the nipple. Optionally, get a longer
nipple
and put most of it inside the vessel.

BTW Russ, I got my stainless nipples from a former friend in the plumbing
supply
business in the southern NH area. I recommend you try elsewhere. ;^)

From: Bob Jones <BJONES@NOVA.llnl.gov>
Subject: Sanitizing with Bleach

After a recent discussion with a friend about sanitizing with bleach I decided to but pencil to paper and thought I would post my results. The concentration of bleach required to sanitize something is on the order of 50-300 ppm for a 30 minute contact time. These concentrations come from Micheal Lewis (50ppm) and a Microbiologist (300ppm) friend who works for Clorox. A concentration of 65ppm can be obtained with 1/2t in a 5gal carboy of water. 2T of bleach gives 780ppm in 5 gals of water. Assume you use 2t of bleach and you drain the carboy and leave 1t of residue. If you then refill the carboy with 5 gals of beer you are diluting the residue

by a factor of 3855. Therefore the 780 ppm residue will be diluted to .2ppm in the refilled carboy of beer. The 1t of residue seems about what

I get for a hasty dump. Now consider other concentrations and their resultant residue/dilution factors.

Bleach added	Concentration in 5 gal water	Residue in final Beer
1/2t	65ppm	.017ppm
1T	390ppm	.1ppm
2T	780ppm	.2ppm
1/2C	3120ppm	.8ppm
1C	6240ppm	1.6ppm

The moral here is that more isn't better! If you want to reduce your input of known bad players, keep your bleach solution to a realistic level. I would go for a little overkill and use 1T in 5 gals. This should also prolong the life of your SS kegs too. All this assumes you keep your equipment clean and you are doing a 30 min soak.

Subject: Wyeast seams

The old 1.75 fl.oz. packages used to have three seams of one kind, a sort of fine-machined 1/2 inch seal, and one of a different kind, a sort of corrugated 3/4 inch to 1 inch seal. The new ones are the opposite. I've never had a package burst, but just from looking at the packages, I feel that the fine-machined seams would never burst (I think the foil would fail first!) and the corrugated ones looked suspect. Therefore, it seems to me that this new package is a step in the wrong direction. On the other hand, the people at Wyeast have GREAT products and I doubt they would goof something like this up. Can someone who knows David Logsdon personally or professionally ask him about the change in packaging? I'm curious.
Al.

Subject: Slow starting yeast.

Ok, after two days my Red Star (never again) yeast did NOTHING. I then acquired some more dry yeast from a friend (no brand marking on the package), and two MORE days later, after a little stirring it is finally bubbling through the lock. My question is, is it likely that my brew has become infected durring the long waiting period? Also, could such an infection cause any un-tasteable/-smellable (i.e. undetectable) poisons, like the big B, or anything like that?

Thanks,

-Ken

>better beer (besides -- most bars frown on bringing in your own homebrew).

This is so, so true... My friends and I like to go to the local "good beer" store and buy 1 or 2 racks of a mixture (Sam Smith, Sam Adams, Anchor, etc.) and the tab usually comes to 11-12 bucks a rack. That comes to roughly 2 dollars a beer. Compare that to a Budilobiken at the local dives for 2 to 3 bucks and you have a deal. If something is worth drinking, it's worth paying a little more for. And most of these bars can keep their "atmosphere".

Subject: BBK Tour, HBD #812

Hello Folks,

Yesterday (29 Jan 92) I took a tour of the Bavarian Brewery
Kaiserslautern
in Kaiserslautern, Germany. The brewery has been in existence for over
170 years, and still conforms to the German purity law (Reinheitsgebot?)

Unfortunately, the brewmaster didn't speak English and our tour guide's
German, while passable, didn't include a lot of beermaking words we're so
familiar with, such as trub and wort, etc., so I think a lot was lost in
the
translation. But anyway, they process 4000 Hectoliters every four hours
in
their boilers (Big huge copper kettle things..). After converting the
barley
to wort, they boil it for 2 hours, then cool it for two hours, then it's
off
to the lagering tanks where it ferments for 6-8 weeks at under 0'
Celcius.
(At least I THINK that's what the sign said...)

After Lagering, the beer passes thru a series of filters (cold
filtered..)
and then on to the bottling room. This was the Neat part. They are set
up
to go from returnables -> final product all in one room. They were
process-
ing 36,000 0.33 liter bottles per hour when we were there, and could
process
40,000 0.5 liter bottles when set for such. They also had a new keg
process-
ing for 60 Hectoliter per hour using the 'new' british kegs, as opposed
to the
more conventional barrel types. The Brewmaster said these were easier to
clean
and replace than the others, but it took an initial investment of 1
million
Marks to convert the plant, so there aren't many in Germany.

Unfortunately, there was some misunderstanding about the tour, so we
didn't
get any samples... They make a Weizen, an Alt, Pils, Lite, Bock, und
others.
I've tried them elsewhere, and they're nothing to rave about.

By the way, BBK is also known to the local GI's as Bad Brewery
Kaiserslautern, so you can make your own assumptions.

Also Could someone mail me a copy of digest #812? mine got lost in
the
ether...

Thanks

Johnny B.

Subject: Drinking Water

With all the discussion on boiling water, I began to wonder if a person couldn't use store bought distilled water or drinking water instead. Sure it would cost a minimal amount of cash, but to me it would be worth it. Also, how about the difference between soft and hard water? If the former was not appropriate, I am looking for suggestions on speeding up this boiling process, such as boiling ahead and freezing in milk jugs, etc. I have heard some approaches, but I was wondering what others do. I am sorry if these questions have been discussed, I am just a lowly new subscriber.

Subject: Coffee in beer

In Digest #813, jpj asks:

> Greetings, HB's...
>
> I'm sure this question's been asked before -somewhere-, but I'll
> ask it anyways -- I'm interested in introducing coffee flavor into
> my next batch of stout. Can I get away with using instant coffee?
> Should I just add it to the boil, or the secondary? Are there certain
> brands of instant that I should avoid?
> Should I just avoid instant coffee altogether and use real coffee?

I brewed a stout with coffee *and* chocolate back in mid-December and it turned out very tasty. Here's the recipe:

Mocha Java Stout
or
(Three Passions Stout)
5 Gallons

7 pounds Glenbrew Irish Stout Kit
1/4 pound (1 cup) Flaked Barley
1/8 pound (1/2 cup) Black Patent Malt
1/2 ounce Fuggles hop pellets (bittering - 60 min)
1/2 ounce Fuggles hop pellets (flavoring - 10 min)
4 ounces Ghirardelli unsweetened chocolate
2 cups Brewed Coffee (Monte Sano blend)
1 package WYeast #1084 Irish Stout Yeast
3/4 cup Corn sugar (bottling)

Brew coffee using 2 scoops coffee to 12 oz. cold water.

Steep flaked barley and cracked black patent for 45 minutes. Bring 1.5 gallons water to a boil in brewpot, sparge in grains, and add extract and boiling hops. Boil for 50 minutes. Add chocolate and flavoring hops and boil for 10 more minutes. Remove from heat and carefully stir in coffee. Cool and pour into fermenter containing 3 gallons cold (pre-boiled) water. Pitch yeast. Rack to secondary when vigorous fermentation subsides. Bottle with 3/4 cup corn sugar.

The "Monte Sano blend" coffee is a mild coffee (sorry I can't remember exactly which coffees are blended to make this) that I buy locally in a coffee store. I wanted something mild for the first attempt so as not to overdo it. This beer turned out wonderfully black and the chocolate and coffee come out nicely in the aroma and flavor. In spite of the oils in the chocolate, it has a rich, creamy head that stays with it until the bottom of the glass. The low hopping rate is due to the fact that both the coffee and the chocolate add to

the bitterness and I wanted their aromas to dominate this beer. It has been well received by all who have tried it. I called it "Three Passions Stout" because three of my favorite tastes (from the world of food and beverages anyway) are chocolate, coffee, and stout - not necessarily in that order. I have set aside two six-packs of this to see how well it ages (if I can leave it alone, that is).

An all-to-familiar occurrence. They took my money and ran two years in a row. I received one copy of their newsletter in two years of membership at \$18 per year. They haven't returned the queries I left on their answering machine (yes, I even resorted to long distance calls to check for a pulse). I would not recommend CAMRA Canada membership to anyone. However, CABA (Canadian Amateur Brewers Association) is excellent and growing in leaps and bounds. Homebrewers always do it up with style ;-)

Subject: Beer Across America

Since I have recieved a lot of requests for info on Beer Across America (I mentioned it in my UPS post), I figured I would post the info here so everyone could benefit from it.

Beer Across America is a Microbrewery of the Month Club. Once a month you get a shipment of two six packs from two breweries around the country. Last months selections were:

D.L. Geary Brewing Company's Pale Ale
Mass. Bay Brewing Company's Harpoon Golden Lager

This was my first shipment so I can't comment as to the quality of the beers they send you, but these first two were very good. The only thing I don't like about the club is that if you find a beer you really like, you can't order more. You do get information and addresses of the Breweries so I guess you could call them and find out where they distribute. Anyway, the newsletter I got tells me to pass on information about this club to anyone that is interested so here it is:

Beer Across America
150 Hilltop Ave.
Barrington, IL 60010-3402

Subject: Coffee in beer.

Just a quick question, has anyone out there ever put coffee in their beer? How was it? Last week I was brewing a batch of stout and in a moment of insanity threw in a half a pound of fresh ground coffee. I love good stout and good coffee so I figured they must go together. The problem I have is that there seems to be some wierd stuff floating on top of the beer (it is done fermenting and will be bottled this weekend), but I can't see it real clearly through the dirty side of the carboy. It seems like it may be some residue from the coffee grounds even though I strained them out before putting the wort into the carboy. The stuff floating on top doesn't look like the nasty mold I had a few batches ago, so I hope it is just something to do with the coffee. Anyone out there had any experience with coffee beers that could answer some of these questions?

>

I hope too many of you don't get bored by this thread, but I have been wrestling with the benefits of blowoff lately (especially as I've been watching 0.5 out of 5.5 gallons of \$40 cherry stout foam into my blowoff vessel) and I think the debate is healthy.

I don't know how much fusel alcohols are produced by Wyeast Ale yeasts fermenting at 66F. Maybe it's a negligible amount. Maybe the dry yeasts I used to use before switching to the blowoff method were the culprits. Obviously, this concerns me enough to merit running some tests. I'll try contacting The Siebel Institute and see how much chemical analysis would cost. (I already have a bet with my grandfather that my beer is safe to drink -- if it is, he pays the analysis costs, if not, I do -- maybe this is an opportunity to kill two birds with one stone.)

Well, I just got off the phone with J. E. Siebels & Sons and found out about prices of analysis. A taste profile costs \$58/sample. A complete beer analysis (taste + computer + chemical analysis) costs \$175, but does not include the ASBC Higher Alcohols and Esters Test which is \$95/sample. This test provides levels of Ethyl Alcohol, Isopropyl Alcohol, Isobutynol, Iso-amyl-acetate, Iso-amyl Alcohol, Amyl Alcohol, Ethyl Acetate and Propynol. Having these tests done is not in my budget at this time, but being an engineer, I like the quantativeness of these tests and that they would settle this matter once and for all. Wouldn't they? Comments?

Subject: pre-crushed grains and basil beer

I sent this before, but don't think it got through.--

How long would one want to keep pre-crushed grains around, assuming they are sealed pretty well (not necessarily air-tight) in a cool, dry environment?

What is the problem with old pre-crushed grain, is the yield simply lower, or do bad flavors (or some other catastrophe) develop?

What is the best way to store pre-crushed grain?

If you were going to make a basil beer, how would you add the basil? would you:

1. throw some into the boiling wort?
2. steep some in hot non-boiling water, strain, and add the result to the primary fermentation?
3. throw some into the primary (or secondary); i.e. like dry-hopping?
(would you need to sterilize somehow?)
- or 4. some other ingenious method?

Any ideas on how much you would add to a 5 gallon batch?
Anyone want to guess?

Thanks. - Bryan

From: eisen@kopf.HQ.Ileaf.COM (Carl West)
Subject: *Old* style homebrewing

This is the first part of a fairly long piece I've scanned in, on request I'll post the rest of it, in pieces of course.

This is from One Hundred Years of Brewing, originally published in 1903 as a supplement to The Western Brewer. Re-published in 1974 by the Arno Press which claims no copyright.

HOME BREWING IN SCOTLAND.

The following from the Scotsman [about which I know nothing more, 100 Years... has no bibliography. "Victorian Scholarship" is an oxymoron. -CW] well describes the processes of domestic brewing in vogue before the public brew-house became an established institution:

In whatever manner yeast was introduced, it was ever after preserved by constant use, being passed from one home brewer to another in ceaseless succession. If for any reason, such as scarcity of grain, there was a temporary cessation of home brewing, the yeast was enclosed in an earthenware or glass vessel and buried in peat moss till required again. Present-day peatcutters, unaware of this practice, are occasionally perplexed by finding these forgotten jars ("pigs") or bottles of yeast.

Like most old domestic arts, brewing was a long and toil-some process. A month elapsed from the time the grain for malt was put in soak till the ale was ready for drinking. Thirty-six pounds of grain made about three gallons, or " a kirn " of ale. Nine pounds more was sometimes allowed for shrinkage. The grain, which had to be full, round and unbroken in the threshing, was thoroughly winnowed and picked over. It was put into a carefully scrubbed out, scalded and aired kirn, and water poured on it till it was just covered. A rhyme couplet had it that the malt should stand

Four and twenty hours in steep,
Eight and forty hours in dreep,

but the number of hours was reversed in different parts of the country.

When the water was poured off, the top of the kirn was thickly covered with straw, which was fastened down with meshwork and bands of rushes. Two bars of wood were laid across the top of a shallow tub and the inverted kirn was set on this to " dreep." At the end of forty-eight hours the grain if good, was "cheepin'," i. e., the sprouts just appearing. If dreeped too long, the malt was dry and useless.

The "cheepin'" malt was then packed in a straw basket, covered with a thick layer of straw, and allowed to stand two or three days till it was so sprouted as to be grown together. If the grains sprouted at both ends, the malt was spoiled. When each grain had three sprouts at each end the malt was properly " come." As this germination took place quickly or

slowly, according to temperature, it had to be watched to prevent it going too far.

The malt was then spread out evenly on the barn floor, a finger-length deep, and out of any draft. It was turned every day, underside up and edges to center. This was done till the grains, on being broken, "could chalk the nail." From ten days to three weeks brought it to this stage. It was then ready for the "sweet heap."

It was piled up, covered with woolen cloth, and left so till it became so hot that a hand could scarcely bear being thrust into it, and was covered with moisture when withdrawn, or till an egg could be roasted in it. It took about three days for the malt to attain this degree of heat. During the latter hours of this period it had to be watched closely, as when it reached the proper point of "sweet" heat it had to be kiln-dried at once, otherwise it lost strength. Hence it was common to "waulk maut."

The kiln fire had to be perfectly clear and smokeless, and the drying done slowly and thoroughly. The ale was brown or pale, as the malt was "sore" or lightly dried. After drying it was rubbed, fanned and picked again to remove the dried sprouts. It could then be kept for any length of time. It was in this state that malt was bought and sold. If the brewing was to be at once proceeded with, the malt was then coarsely crushed or ground so that every third grain was left whole. If ground too fine, the wort thickened and could not run.

Subject: UPS Problems

Subject: UPS Problems Time:10:12 AM Date:1/30/92
In response to Tom Quinn's question on the 1st Round entries received at Anchor...

I have never heard of any comments originating from the UPS driver(s) when the entries arrive. I don't work at the brewery, so I have no direct contact with the UPS types there. I am sure the woman who signs for the UPS stuff would pass along any comments.

I do ship my own stuff from the same UPS office that services Anchor, and there I have had problems. I frequently use used Styrofoam boxes, perfect for a six-pack of Anchor, which I get from the pharmacy here at UCSF. Last fall I offered to ship some of the Anchor Spruce to those less fortunate around the country. I took about a dozen of the Styrofoam boxes to my local UPS drop. I claim the standard "perishable food in glass" on the manifest. This time I got the third degree from the agent. The result of which led to the insistence that she be allowed to inspect the packing. Finding bottles of beer, she told me that "we don't ship alcoholic beverages". I argued that this was not true (etc, etc) but got nowhere. I ended up taking the boxes to a third party drop where they don't take things so seriously (tho I understand that the pick up person from UPS wasn't happy about taking the boxes from them later on).

Now I put the Styrofoam boxes inside plain brown ones and lie on the manifest as to contents. I have recently seen a UPS stamp on boxes which state "Alcoholic Beverage Enclosed, Adult Signature Required" (or some such) in red ink on boxes originating from a wine club here in California. I plan to investigate the possibility of using this format for future packages. I prefer the honesty.

The AHA has been trying to get an answer on all this from the home office of UPS since last year when boxes destined for the Nationals were turned back in areas of the East Coast. I don't know the status of the discussion at present.

But the "ship to" addresses in the '92 instructions seem to indicate that deception is still the way to go (ie. NHC 92 c/o Anchor Brewing Co. rather than zymurgy/wigglesworth c/o Anchor used last year).

Subject: Sanitary Method to Start Siphons

Lately there has been a lot of talk of siphoning again. I would agree with those who discourage the "mouth start" idea. It just adds the unnecessary risk of infecting the wort with some strange bacteria. The way I do it, siphon, is what I think a very easy, and sanitary way. This was suggested to me by the owner of my local supply store. Go to a pharmacy and buy anal syringe. They are used for enemas, anyway they look kind of like this:

This big end is like the handle of a turkey baster and the small end is hard plastic tube. The tube is the perfect diameter to fit into the hose of the siphon, and the ball (other end) has enough pressure when squeezed to start the siphon easily, no matter what what angle or location your two containers are in. Mine cost about \$6.00, the only problem is that you may have to ask a sales person for help in finding one (I did, and it was a little embarrassing. But its really no big deal.) I also have tried using turkey basters but they dont seem to work as well for me. The tube has to be forced into siphon, and there isnt always enough pressure to get the siphon started.

Anyway it works well and sanitizes easy (it comes apart). I think it is well worth it and it works quite well. I hope this helps some of you people.

Happy Brewing,

Lee J. Slezak

"Date: Wed, 29 Jan 1992 13:23 PDT
From: Bob Jones <BJONES@NOVA.llnl.gov>
Subject: Sanitizing with Bleach

After a recent discussion with a friend about sanitizing with bleach I decided to but pencil to paper and thought I would post my results. The concentration of bleach required to sanitize something is on the order of 50-300 ppm for a 30 minute contact time. These concentrations come from Micheal Lewis (50ppm) and a Microbiologist (300ppm) friend who works for Clorox. A concentration of 65ppm can be obtained with 1/2t in a 5gal carboy of water. 2T of bleach gives 780ppm in 5 gals of water. Assume you use 2t of bleach and you drain the carboy and leave 1t of residue. If you then refill the carboy with 5 gals of beer you are diluting the residue by a factor of 3855. Therefore the 780 ppm residue will be diluted to .2ppm in the refilled carboy of beer. The 1t of residue seems about what I get for a hasty dump."

Being a clean freak, I like to massively overdose with bleach. I figure it also cleans out the lines when I dump it down the drain. I generally add about a quarter cup, soak everything for a day or so, then rinse until it smells clean, IE, until I can no longer detect bleach. This is pretty easy, and doesn't involve wasting much water.

I would guess that one's nose - and tongue - are more sensitive to extreme dilutions of bleach than any other instrument at hand.

I'd guess my methods work, because my batch is fizzing away happily right now in the carboy ...

This also peels off eveything organic inside the containers, and keeps 'em real clean. And the sterile food-grade tub makes a good sterile container for tubing and corks and the like.

Russ Gelinas put in a "clarification" that Red Star /ale/ yeast was bad but the /lager/ yeast was "clean". This doesn't match the ZYMURGY lab results [snip...]

To add a data point: I just brewed my best porter to date using RS Lager yeast. I've used virtually the same recipe with various dried ale yeast (including RS) and was dissatisfied with the high attenuation of all of them and the off flavors (IMHO, RS was probably the worst for off flavors and aromas). *However*, the RS lager was fairly clean and seemed to be a little less attenuating (good quality in this application).

Subject: RIMS unit plans/diagrams/whatever?..

I have read two or three articles describing modifications to a mystical creature called a RIMS unit. This intrigues me, as I need an alternate method of producing beer, due to lack of access to my household kitchen for brewing purposes 8^(...

If anyone could clue me in to the whereabouts of the original article (or whatever) that diagrams the construction of one of these, I would be most grateful.

Subject: More questions on sanitizing agents

To Bob Jones:

I found your calculations very interesting. I was wondering if your friend from Clorox gave you any indication about what concentration (in ppm) would actually disrupt the workings of a septic tank? It may be that lower concentrations would be innocuous, and I can stop making trips outside.

Subject: Update on homebrew legalization in Georgia

A while ago, I asked one and all to write a Georgia Senate committee to support homebrew legalization. Since then I have gotten several copies of letters sent and requests for updated info. The committee is scheduled to discuss the bill on Monday morning, 3 February, so it is unlikely that any more letters will get to them on time. We want to thank everyone for answering our call to action. Whatever the fate of our bill, I will post it on the Digest

Subject: AHA Structure and Regionalism

Jay Hersh talks about the AHA Nationals and the move to regional first-round judging:

>AHEM... not being one to pat myself on the back and say I told you so :
>), but
>long time readers of the HBD will recall a discussion held several years
>ago
>caling for the creation of a tiered competition system where winners
>judged at a
>local or regional site would then be forwarded on to the National Round
>finals.

Yes, I DO recall - you were one of the first public AHA bashers! That was a long time ago - before Rob started numbering these digests. You rabble-rouser!

> time has vindicated those championing such a system.

Yes, but I think that the AHA did that only because they needed to farm out some of the work; I question whether it is because of an AHA desire to make the Association more "Democratic" and more member oriented.

>Now if the AHA would only actually let it's members have some real
>representation, say like having an elected Board of Advisors...

My guess that the Board of Advisers is just a gesture to quiet the anti-AHA sentiment of people like Jay. The Board of Advisers are picked by Charlie P, and they have no role in setting AHA policy. The Board is just a few people who happen to have attended ALL the AHA conferences over the years. It may also be a scheme for the Board to deduct their conference expenses on their taxes!

I agree with Jay in saying that the AHA has improved its attitude to members, that they genuinely try to help out in whatever way they can, but they still have a way to go before becoming a true Association of Homebrewers. We need a representative board!

Subject: CAMRA Canada

Is CAMRA Canada associated with the original? One would think so. One would also hope - strongly - that those of you who have been bitten would send a note about your experiences to CAMRA in England. If you do not wish to do that, please give me permission to send them your notes about the subject from HBD.

Thanks...Gary

Subject: SLIMEMOLDS

My daughter (9), wants some more "pets". She has access to slime mold spores via the program at the local science museum and has been badgering me to help get her started. Having a degree in Biology, I have no problem with slime molds but when i looked at the introductory literature that comes with the kit (from Carolina Biological, I believe), the critters are lumped with *S. cerevesia*!!

If I were to let the new "pets" into the house, what would be the probability of infection of my wort. (I understand the "germ theory of disease" even though my last microbiology class was taken over 20 years ago: I also looked at the media that these critters are cultured on and you could use the same stuff as slants for yeast propagation.)

So am I being paranoid (or what)?

Subject: Wine via UPS - the hypocrites!

i'll second ted wagner's observation! my in-laws live on the north fork of long island, which lately has had an explosion of wineries (every time we go down for a visit, two or three new ones have popped up). some of them even make pretty good wine (the only good thing besides my wife to ever come out of long island - flames to me, please ;-)
anyway, seems like every once and a while you go buy on "wine shipping day"
and the places are lousy with UPS Trucks! next time they try to reject my beer, im going to whip out some photos of them loading cases of wine!

Subject: Re: To Blow-off or Not?

Hi, has anyone compared the volume of trub left behind when not using blow-off vs. the amount removed by blow-off and then left behind? I wonder if you end up with more volume either way. Do you really lose volume with blow-off? Just not sure.

Subject: RIMS unit plans

The original RIMS unit was designed and built by Rodney Morris and was briefly described in the Zymurgy Gadgets special issue. Detailed construction plans were published by the Maltose Falcons in their newsletter. You might try contacting the Maltose Falcons (address in the Zymurgy clubs listing) to see if you can get a copy of that issue. Mine is an Nth generation photocopy, and can't really be read when copied one more time.. :-(
