(pre-prepared and >sterilized)  
>... It's in the secondary now and appears to be perfectly normal...

>  
>Now, onto my questions:

>  
>How long can I leave them in the fridge (they're stored upside down with  
the >agar on top to alleviate moisture from dropping on the plate).

The plates should no last very long (a few weeks at best, I suspect). For longer term storage, one should make up a small (12 oz) wort in a bottle and pitch a little of your "purified" yeast into it. Make sure it has an airlock and chuck it in the fridge after it starts to get going. This should last up to 2 months or more. For more technique, see Papazian's Complete Joy...

Option two is to take a "stab". That is, use a sterile toothpick and stab a little glump of yeast (yes, that gooey half-and-half stuff) and place it in a small, preferably plastic 1 or 2 ml container of 15% glycerol. This should keep in your home freezer for several months. If you work with a -70C freezer at work, it should last almost indefinitely.

>Is there any easy way to tell how pure of a strain I got?

Try swishing the yeasty liquid around when you first put it on the plate. This (if your active cells are dilute enough) should set up single-celled colonies. Yeast will have more of a rubbery appearance (don't try to bounce it or anything) than will bacteria. It will also smell like yeast. Bacteria will stink to high heaven. If your culture is diluted and spread properly before you start growing the plate, you can pick and choose the colony you'd like to grow up.

>Is it valid to use Potato Dextrose for culturing?

Can't say I've tried it before, but if you are growing yeast with it, it sounds valid to me. I make my own plates with 15g agar and 40g malt x-tract per litre of media.

>Should I be super sterile? (ie: I have access to a class 100 clean room >in which they normally do wire-bonding onto dies.) Should I bother with >the clean room and masks/rubber gloves?

The question here is, do the class 100 clean room supervisors/owners really want potential yeast/bacterial contamination? I sure wouldn't risk the job security. All this work can be done in a clean,

draft-free room without much chance of airborne contaminants (though if you're a heavy panter, a mask might be a good idea). If you do get 'em, heck, you can still pick out and purify your colonies, right?

good luck,  
LizardArm

From: SSIEGLER@LANDO.HNS.COM  
Subject: Re: Chillers and Bernoulli (Uncle!)

Ok. As I wrote In HBD #953:

> As I understand it, as air is forced thru increasing smaller tubes  
> the rate of flow increases, and the temperature drops.  
> (etc.)

So my thinking was a little off.

Steve (steved@longs.lance.colostate.edu) answers:

>It probably would if water was an ideal gas (compressible). The  
equation  
>of interest is:  $PV = nRT$  ...  
>...This does not happen with  
>liquid water because it is essentially incompressible. Maybe freon  
>or ammonia would be a better fluid. Actually, I think someone else  
>already thought of trying those. :-)

Cush (cush@msc.edu) answers:

>It is true that when gas \*expands\* from a high pressure to a low  
pressure  
>it cools, but this is different from fluid sucked through a tube.

and,

Scott (scojam@Auto-Trol.COM), you're not wrong, Im just dumb  
(ps congrats on soloing!)

However: Frank(fmayhar@mpd.tandem.com) answers:

>But the idea of using smaller tubes is still okay, within limits. You're  
>trying to get the most efficient surface-to-volume ratio.

So, if one were to use, say 10 mini tubes (the space and throughput that,  
say, one large tube would yield) would that provide more surface area for  
cooling? Since the water would flow faster, more cool water would be in  
contact with the (copper) tube [I'm thinking here of the "Skin Effect"  
that  
is associated with wire (that electricity flows along the outside of the  
wire)]?

Maybe I should just stick to something I know about.  
[would anybody know what that is? :-)]

From: Tracy Waldon <TWALDON@macc.wisc.edu>  
Subject: Vit C, breweries, Kraeusening

On the topic of ascorbic acid (vitamin C):

I recalled reading that it was not very effective as an anti-oxidant. I went back and checked and Fix's Principles of Brewing Science discusses its use. The gist is that it might help limit certain oxidation reactions when used in large enough quantities (>300 ppm). It will not help stop other oxidation reactions. The bad news is that it may actually cause oxidation in some instances (in the presence of iron is one instance). So the question is unanswered. This seems to be the perfect opportunity for some enterprising brewer to do a little home experimentation by deliberately introducing oxygen at bottling into bottles of the same beer (preferably something light) some of which contain ascorbic acid and some of which don't. I suggest a blind taste test. I'll leave this as an exercise for someone.

On the topic of historical breweries:

John Wiehn writes:

>I've had a patron to my library ask if I could find a list of breweries of  
>Connecticut which were in existence prior to 1918 (pre-prohibition).  
Can  
>anyone help with this list???????

I thought some others might also find this book interesting.

American Breweries  
by Donald Bull  
Manfred Friedrich  
Robert Gottschalk

published by Bullworks  
P.O. Box 106  
Trumbull, CT 06611

(C) 1984

ISBN 0-9601190-6-X

There is very little detail other than the city in which the brewery was located, the name of the brewery, and the dates of operation. However it is interesting to see how common breweries were in the 19th century, and also how competitive the market was.

And now for my question:

I have decided to begin kraeusening my beer rather than using corn sugar. Noonan gives a table detailing the amount of wort to add depending upon the degree of carbonation desired. I have been unable to find anything which suggests appropriate carbonation levels for various styles of beer. If anyone knows of a source for this info please let me know. Also if you know of the formula for calculating the amount of gyle to add in order

to get the various degrees of carbonation I would be interested since Noonan's table is not terribly complete. And as we all know, the world is not linear

From: Pierre Jelenc@cunixf.cc.columbia.edu  
Subject: B-Brite

In HBD # 953, Bob Gorman asks about B-Brite ingredients.

"Sodium percarbonate" is the common name of a molecular compound of sodium carbonate and hydrogen peroxide, that for practical purposes behaves like hydrogen peroxide itself. True sodium percarbonate ( $\text{Na}_2\text{CO}_4$ ) does exist, but it is rare, and is not an industrial chemical.

Sodium silicate is used to stabilize "sodium percarbonate" (it is typically 0.6% of the total), but has no cleansing or disinfecting properties of its own.

Sodium perborate in non-chlorine Clorox is another "active oxygen" compound, this time truly the salt of a peracid.

Peracids and peroxides all act similarly, by oxidizing organic materials, especially proteins in the case of sanitizers.

Subject: "Natural Carbonation" and Siphons

RE: Two questions in yesterday's HBD:

1) I went to Anheuser-Busch's Baldwinsville Brewery last year for a tour. I think the "natural carbonation" is captured carbonation from the primary fermentation. Breweries try to cut costs at all corners, and this is one. In fact the Zip City BrewPub in NYC uses its wort chiller water for the next boil, if I'm not mistaken (Yes, Steve Russell?)

2) Siphoning: An easy way provided to me by my friend Dwight Beebe: use a funnel on the end of the siphon hose which the siphon hose will not go through. Suck on the pointed end of the funnel, and then as it is flowing, remove the funnel and place the hose in the carboy(girl). Dwight actually uses a valve type thing which attaches to the hose, but I lost the one he gave me. No need for drills, water, pumps or anything else. And your mouth doesn't touch the hose.

Flame on (god, I know its coming)

From: envkas@sn634.utica.ge.com  
Subject: manifold for cooler mashing

>To Spencer.W.Thomas@med.umich.edu,

I too use a cooler for mashing and sparging... My manifold is made of rigid 1/2 in copper tubing connected with fittings at the corners. The trick

I use is not to solder the fittings (no lead in my beer please) so that when I am done, the whole contraption can be taken apart, cleaned and stored with ease. Here is an ASCII version of the setup...

```
/ flush tube to clean out manifold before sparging
/
e--t-t-t--e   -
|   |   |   | = 1/2 in rigid copper tubes w/ slots in bottom of
cooler
|   |   |   | T = 1/2 by 3/8 t fitting
|   |   |   | e = 1/2 in elbows
|   |   |   | t = 1/2 in t fitting
|   |   |   | - = short pieces of rigid copper tubing to space long
tubes
e--t-T-t--e   -
|
| 3/8 in clear plastic drain tube thru end of cooler
```

The flush tube runs vertically up the end of the cooler and has a cap on it during the mash stage. When I am ready to start sparging, I run about a gal of 170 F H2O thru the flush tube until the run off is clear. The run off is then recycled onto the top of the cooler to filter back thru the mash.

This flush idea came from Brewing Lager Beer by G. Noonan. I adapted it to the cooler manifold concept and have been very happy with the outcome. I have also been very happy with the decoction mash techniques he describes in the book. Does anyone else have comments on the decoction method???

From: wegeng.henr801c@xerox.com  
Subject: Re: Beer Concentrate

This discussion about brewing concentrated beer is interesting. When I first started homebrewing (a few years ago), I wrote letters to several breweries (including AB, but not Coors) asking questions about their brewing process. All of the breweries replied, though some didn't give many details. AB sent me a nice brochure, which among other things mentioned that they brew concentrated beer and then add carbonated water at bottling time to both bring the beer to the desired strength and to add carbonation. The wording of the brochure indicated that they were very proud of this \*efficient\* use of their brewing facilities.

Sounds like the only real difference between AB and Coors is that Coors ships their beer to Virginia before diluting it.

Subject: carbonation, beer concentrate

In HBD 954, Michael J. Gerard writes:

>I saw an ad on TV the other day for Budweiser. In  
>the ad it claimed that bud was "naturally carbonated".

>This does not make any sense to me. If it was primed  
>there would be sediment and the bottles (or cans)  
>would require aging.

Natural carbonation can take place in a variety of ways and during different times in the process. From what I've been told at a couple of breweries, the "naturally carbonated" claim is made because the brewery captures the CO2 that is released during fermentation, compresses the gas and injects it back into the beer via a carbonating stone. Another method of achieving natural carbonation is to conduct the final portion of the fermentation in a closed pressure vessel and let the carbonation build up. Some cylindro-conical fermenters are designed to hold the pressure, and have an adjustable pressure relief valve (Micro-Mat is one brand) attached. The beer is then filtered under pressure and packaged. The latter method is used by some microbreweries I'm familiar with. This is basically "bottle conditioning" in a rather large bottle. Rather than adding priming sugar or gyle, the beer is fermented to a predetermined SG and then bunged off.

Bottles with yeast sediment are "bottle conditioned", a subset of natural carbonation, if you will.

On the subject of "Beer Concentrate" discussed previously by Jack S. and Arthur Delano: During a tour of the Hudepohl Brewery in Cincinnati, the brewer told the tour group I was in that they, like many other large breweries, employ a method of high-gravity brewing in order to get more beer from their equipment. Basically, they brew \*and\* ferment at at higher gravity and then dilute with carbonated water to finished product gravity at the time the beer is packaged. This would allow them to get, say, 1200 bbls from a 1000 bbl system. The brewer wouldn't say what the dilution level really was, tho.

>>

>>-----  
I attended Bridgewater College which is about a half hour from the Coors  
Virginia Plant. I drove by it's location many times prior to it's  
opening.  
When Coors purchased the land (located conveniently to RR lines), they  
also  
purchased a mountain. The name of that mountain was "Rocky Mountain".  
I'm  
fairly certain this wasn't hearsay. There were articles published in the  
Harrisonburg paper with this news, but I personally never verified it.  
Thus,  
the intention was that initially beer would be shipped to VA and then  
bottled  
with the long term plan being to brew in VA. And because of the "Rocky  
Mountain" in VA providing very good spring water, there'd be no problem  
with  
labeling. Any of you guys from BackDoor Brewers in Charlottesville have  
anything to add to this posting?

Date: Tue, 25 Aug 92 08:49 EDT  
From: "C. Lyons" <LYONS@adcl.adc.ray.com>  
Subject: Questions answered.

Several people answered my questions on adding ice to cool the wort to yeast pitching temperature and the use of 170F water for sparging. Thank you all!

The concern with using ice is that of sanitation. It appears that the freezer is a happy haven for free-loving bacteria. Transferring ice from the freezer to the cooling wort can be a means of introducing nasties. Suggestions were made to avoid tray ice, boil water and freeze in a sanitized closed milk container, cool wort by placing brew pot or primary in an ice bath, or use a wort chiller.

As for the use of 170F water for sparging. The general consensus is that the purpose of the sparge is to remove remaining sugars from the grains. To do this the water should be as warm/hot as possible without extracting tannins from the grain. Cold water will not dissolve the sugars to the extent of warm water, and boiling water will result in obtaining a harsh (astringent) beer flavor.

Thanks for all your comments! Since I am always looking for short cuts, it helps to have an understanding of the techniques.

From: roman@tix.timeplex.com (Daniel Roman)  
Subject: Re: Beer Concentrate

Arthur, I heard a commercial for Natural Lite (or is it Light) beer where they talked about Coors Lite (or is it Light :-)) being shipped in tankers as a concentrate to Virginia and reconstituted there with Virginia water as opposed to Rocky Mountain spring water. This radio spot was on a major New York City station August 22nd so if the spots were supposed to have been pulled prior to that it's news to them!

If I recall correctly, there was a short spot in Zymurgy as well as the New York Times before Christmas 1991. I would have to surmise that there is something to this and Coors is none too happy ;-)

Anyway, the radio spot goes on to say that since Natural Light is brewed locally and not shipped concentrated in tanker cars you should buy it because it's fresher, and by implication, a more "honest" beer.

I personally don't care what Coors does with Coors Light (I don't like Perrier either), just as long as they keep the Killians and Winter Fest in their product line!

From: Ed Hitchcock <ECH@AC.DAL.CA>  
Subject: Clean siphoning

In the last HBD Chris was looking for a method of siphoning cleanly. I believe Papazian would blame his troubles on insufficient relaxation, but to help Chris and others relax, here is a simple way to start siphoning without sucking or using motorized pumps. Items required: one two-hole bung (I have seen two-hole orange rubber carboy caps, they will do nicely); one bicycle tire pump; siphon tubing. First, take the bike pump apart and reverse the washer so that it makes a seal when pulling, rather than pushing. Then connect some siphon hose from the bike pump to one hole of the bung. Connect siphon hose to the other hole, and run it to the brew. The hose may be extended from the bung down to the bottom of the carboy to prevent splashing, or left at the level of the bung to allow splashing if siphoning cooled wort before pitching. Step three, pull on the bike pump a few times. This sucks air out of the carboy, which draws wort in through the hose. This technique also works for starting flow through a chiller. If one is over-worried about sanitation and handling the equipment, pick up some surgical gloves at the local pharmacy.

You know, it's funny, but I've only found one other supplier in  
Chicago. Since I've found it convenient to shop at IGS, I've never been  
to  
or called any other. In Elmhurst, you should find Winemakers. I don't  
know about the address, but I think it's on Elmhurst road right across  
the  
street from Who's On First, the now defunct comedey club. As far as IGS  
is  
concerned, I've been homebrewing 1 1/2 years and have only ever been out  
there once, and their stock variety has more than doubled since my first  
purchase. Call them up (800) 444 2837. They'll send you a list and sell  
you what-u-want. The fellow I've always spoken to is quite friendly (a  
rarity in this city) and lends good advice when I need it.

Happy Homebrew

From: pyle@intellistor.com (Norm Pyle)  
Subject: Re: Brewing Disaster

A couple of years ago in my brewing youth I had an interesting experience:

My own brewing disaster came in the winter here in Colorado, my second batch, I think. It too involved cooling the wort. I hadn't learned about wort chillers. I didn't even have the sense to put the cold water in my primary prior to adding the hot wort (oxidation? what's that?). Soooo, I sanitized my 7 gallon glass carboy primary and heated it up with hot water before adding the hot wort (I did know a little about thermal shock...but not enough). The hot wort was not a problem going into the carboy (fooled you, didn't I?). I then added cool water on top of the hot wort, no problem.

Well, the temp was still too high; I could tell by touch that it was over a hundred degrees F. I decided to put it outside in the cold Colorado air to cool it faster. When I was carrying it out, the hot bottom started getting to my hands (the thermal mass of the original hot wort really had the bottom of that carboy toasty). I decided I'd better put it down quickly before I dropped it and, heaven forbid, broke it. Well, the spot I chose (or got stuck with) had a small patch of snow which I didn't really pay attention to, since I was starting to get concerned with the first layer of skin on my hands. You guessed it this time, the carboy cracked from the thermal shock of the snow against the hot carboy.

Only a small bit of hot wort came out the bottom and then the contraction of the fluids inside pulled the carboy back intact! It was holding! I decided "if I'm going to lose a carboy I'm sure as h\*ll going to try and save that homebrew". Sooooo, I went and got another carboy and sanitized it, figuring on racking off most of the wort while avoiding the bottom few inches to prevent sucking up some glass shards.

Of course, as soon as I pulled the foil, or plastic wrap, off the top of the carboy the vacuum was broken. The carboy came apart and the goods were lost. And then depression set in... It was an interesting crack, though, in that the entire bottom of the carboy came off clean in a disk shape.

Moral: Use a wort chiller, OR put cold water in the carboy before adding the hot wort, OR use a plastic primary, OR use some common sense...

From: mcnally@wsl.dec.com  
Subject: re: where is Bayreuth

Just goes to show ya: as the "where is Iowa" affair demonstrated a year ago, and as my latest foray into the dimwit zone reinforces, it's real dangerous to attempt geographymanship ploys without access to a map.

Sorry Darryl.

On to beer. I've been working my way through a "Belgique" ale brewed with some "Ambre" malt I got from Liberty. At the time, I had no mill, so the crush was achieved with a marble rolling pin (see "dimwit zone" above). The crush was thus insanely uneven. The beer is not bad, but it's kinda thin; the head consists of relatively big short-lived bubbles. I suspect that the poor crush is in some way responsible, but I'm not able to rationally explain it to myself. Suggestions?

From: "Rad Equipment" <rad\_equipment@rad-mac1.ucsf.EDU>  
Subject: Siphon Starting

Subject: Siphon Starting Time:8:34 AMDate:8/25/92  
Chris Estes mentioned his concerns for starting siphons when he uses the  
"fill  
first with water" method. I frequently use this approach when racking.  
Here's  
how I do it.

I transfer from my 15 gallon fermenter to kegs with a 1/2 inch siphon.  
The cane  
is made from soft copper so it can be sanitized with boiling water. The  
tubing  
(about 5') is stored in a bleach solution between uses and rinsed in  
water  
just prior to use (about a 1/2 gallon of boiling water in a large pot  
with  
tubing submerged in it). When I have the cane in place, I take 2 large  
hemostats (about 10") and pinch off both ends of the tubing in the pot,  
trapping the solution inside, and remove the tube from the water. I pinch  
one  
end of the tube leaving enough free to mate with the cane. Hand contact  
at this  
end isn't a problem since you're only concerned with the inside at this  
end.  
Once mated, I clamp the tube to the cane with a plastic pinch clamp and  
remove  
the hemostat at that end. The other end of the tube is then lowered and  
its  
hemostat removed, starting the siphon.

> Starting siphons is a part of brewing that I WORRY about! ...

I have found a very simple solution for siphoning worries. Rubber gloves. I thoroughly clean and sanitize the siphon, put my gloves on, and dip these in a jar of sanitizing solution. Then I can pick up the siphon and manhandle it any way I want. To start the siphoning action, I jamb a sanitized pipet into the end of the siphon and suck on it. When the flow starts, the pipet is removed and the siphon's end stuck in the carboy. It doesn't take much care to ensure that nothing but sanitized parts touch the siphon.

From: tony@spss.com (Tony Babinec)  
Subject: lallemand windsor ale yeast--a data point

I picked up some of Lallemand's "Windsor" and "Nottingham" yeast at the AHA Milwaukee conference. I don't customarily use dry yeast, but I recognize that it's convenient and that many use it. I recently used Windsor to ferment a Bitter, and to all appearances, it performed well.

I first rehydrated the yeast by sprinkling it into some pre-boiled tepid water in a flask and letting it sit for 10 minutes. I then added some sterile wort and put a fermentation lock on. The yeast took off relatively quickly, say, within an hour. Meanwhile, I finished the boil, chilled the hopped wort, and combined the wort and yeast in the primary. Fermentation was complete within about 3 or 4 days at an ambient basement temperature of 68 degrees F. The wort clarified nicely. I have since racked to secondary, dry-hopped, kegged, and tasted it, and noticed nothing amiss.

This account is merely one data point. I cannot speak in any technical way to the purity of the yeast. But it seems that if the yeast is well-handled and fresh when you get it, it will produce a clean beer.

I intend to use the Nottingham yeast on a similar recipe to see whether it performs any differently.

Subject: Metal Taste and Mashing Questions

I again want to thank everyone for the help and ideas about my first all grain brews. Thanks!!!!

Now to the problems/questions, I have been using my SS soda kegs for both primary and secondary fermenters for the past year and I have been quite happy with the way they work. On the pickup tubes of my two primary kegs I have short(~1 in.) pieces of copper pipe with caps on one end. These work like the caps on siphoning tubes to keep me from picking stuff of the bottom of the kegs. I got the idea for these caps from an article in Zymurgy about transfer from keg to keg. I transferred my Blueberry Wheat beer from the primary to my secondary over the weekend, I took a sample and tasted it. It has a very bitter metal taste, I also notice this metal taste in a Blackberry Stout I made about a year ago. With the stout the taste when away in about two weeks but I used much less berries than my Blueberry wheat and of course the stout flavor could have hidden some of the metal taste. I figured I would give my wheat beer a month or so and see if the metal taste went away.

Well, last night I cleaned out the primary keg which had the wheat beer in it and when I remove the copper cap it looked like it had been etched by an acid. I had cleaned it well before putting the wheat brew in it and at that time it was smooth. I use iodophor as my sanitizer so I don't think it was etched by my sanitizing agent.

I believe the berries are the cause, what does the HBD think?

I am going to throw all my copper caps away and use a SS pickup tube with about 0.75 in cut off the bottom. This should do the same job as the caps and eliminate the question of the copper. The only problem is that all the fresh Blueberries are gone so I will have to frozen but that is the way we learn.

Ok, now about my second all grain brew. I got a stopped sparge, I tried blowing in the drain tube, it would flow again for a minute or two and then reduce down to just the smallest of flow. I poured the grain out and cleaned out my Phil's Phalse bottom, I thought the hose which comes out of the bottom was clogging before the grain bed could set. After much messing about I got it to flow again but only a trickle. I used a right angle water shut off valve like you see under sinks, so I removed the valve part from the assy. and used a wire to check for clogs. Everything was clear, so I am sure the problem was with the grain bed. I used the grain mill at my local homebrew store and I believe I got too fine a crush and this caused my mash problems. It did slow down my sparge rate from my first brew but this is not the way I wanted to do it.

So the point here if you have a poor flow rate look to the crush first and not the size of the holes in you manifold.

From: wegeng.henr801c@xerox.com  
Subject: Vinometers & Beer Making

A friend of mine (who is a home winemaker) has told me about a device called a "vinometer" which is used by winemakers to determine the amount of alcohol in their wine. I've never seen one, but apparently this is a device with a small diameter glass tube sticking out the top. The glass tube is marked with alcohol percentages. When you pour wine into the vinometer some of it goes up the tube (capillary action?), and the level of liquid in the tube tells you how much alcohol is in the wine. My friend claims that he has tested his vinometer with whiskey and other alcoholic beverages of known alcohol strength, and it's always been correct.

Has anyone ever heard of this device? Does it really work, or is my friend full of baloney? Will it work for beer? While this device would not replace my hydrometer, it sounds like it would be a useful addition to my beer making kit.

Thanks,  
/Don

From: "Joel (J.N.) Avery" <javery@x400gate.bnr.ca>  
Subject: Bubbles while siphoning / Labelling bottles

We've talked for a while about getting bubbles in the siphon hose, and ways to get rid of them, but never about what they mean. Bubbles happened to me a couple of times way back in 85 or 86 when I was a rookie. When this happened, I took it to mean that, since there still was a lot of dissolved carbon dioxide in the beer, that perhaps the beer was not ready to be racked (or bottled, depending on when the event occurred). So, like the good book says, I relaxed, and let the beer sit longer in the primary, and I never have this problem any more.

So, does the presence of bubbles in the crook of the siphoning tube (I still use the stiff J shaped tube), indicate that the beer is being racked too soon, or does it really matter? For that matter, can you actually rack beer too soon?

Labelling brews. Ever since the first batch (which was brewed with a lot of interest and excitement), I have never glued a label to a bottle of my homemade beer - I just write the batch number on the cap. This way, I find it real easy to dig up a bottle of #17 in my beer archive.

It also cuts down the bottling process, and the bottle cleanup process, as the cap just goes into the recycle bin. Well that, and perhaps the fact that the White Beaver brewing company dropped from having three employees to just one has resulting in a streamlining of the labour involved in the process (and the quality improved!).

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Bringing beer back from Europe

In HBD 953 Brian Davis (Brian%mbf.uucp.ics.uci.edu) asked for information about bringing large quantities of beer back from Europe. I replied with some of my experience, but in retrospect I felt guilty for shooting my mouth off without providing any real, hard information. Guilt is the great motivator, so I called the U.S. Customs Service here in Washington to get the scoop.

According to the folks there, people are allowed to bring back one liter free of duty or taxes. Depending on the state you are returning into (that is, where you clear customs) you may now or soon will be able to bring in a gallon instead. Beyond this you are supposed to pay a 10% duty, which is calculated at 10% of the purchase VALUE of the beer you are importing. I stress this because duty is payable on stuff you were given, as well as things you bought.

But there's a catch (isn't there always?). The Customs Service doesn't seem to care how much you bring in, as long as you pay the duty. However, the actual amount you can bring in is controlled by each state. In other words, the state where your airport is located (i.e. New York for Kennedy Airport arrivals) can sieze beer if you bring back more than they allow.

How much do they allow? Well, that's where I ran out of information. Based on the assumption that most European travelers return through Kennedy Airport, are there any HBD readers in New York who'd be willing to check on this? If you could just figure out who to contact I will be happy to do the calling, and I'm sure that this information will be of use to a good number of readers.

For more general information the Customs Service can be reached at 202-927-2095. For information on duties in particular, call 202-927-0770. The guys who know about beer appear to be Arnold Sarasky and Ed Bohannon, whose office can be reached at the second number.

Subject: RE: Hop questions

In HBD 953, Mike Schrempp wonders: Why not let hops dry on the vine?,  
and  
How come his fingers don't turn sticky?

I've been waiting out the ripening period here in Washington state. We've had some cooler weather and my hops aren't ready to pick yet. I've been bringing samples to the office. My co-workers refer to the little pile of fresh hops as my "hop altar". As the not-yet-fully ripe hops dry, they start to shed some of the lupulin powder. This is very evident if they are kept on a dark surface. The lupulins start coming loose as the hops dry out. If you let them go on the bine, the precious resin glands will be scattered by the wafting breezes.

I have a brochure on hop growing that was printed by the John I. Haas Co. It has a chart that shows the alpha content steadily rising from 4% to 8% for clusters during a two week period in August. The rate of change is straight as a line. The booklet says that ripeness and picking time is determined by testing for alpha acid content. Though the chart doesn't tell you much, I assume that alpha production levels off and then falls, with the best time to pick, just as the curve levels off.

My dad (he's 74) used to pick hops in Yakima when he was a kid. He says that his hands would be black from the hops at the end of the day. He also said that the hops made people's hands very sore, though he can't remember if it was the sticky stuff or the roughness of the bines. Some people wore gloves, but that made it harder to pick. I'll ask him more about it next time I see him.

From: "Jim Ellingson" <jimme@pi28.arc.umn.edu>  
Subject: Altbier/Oktoberfest Recipe

There was recently an inquiry about alts and Oktoberfest recipes. We are posting this recipe in response to that request. We have not yet bottled, but we felt compelled to post initial results so that others wishing to make a similar brew for Oktoberfest will have time to do so. This is an initial recipe only, and is not meant for inclusion in the Cat's Meow (should another one be created). A complete recipe with taste results will be posted at a later date.

Brewers: Cush Hamlen (cush@msc.edu) and Jim Ellingson(jimme@ahpcrc.umn.edu)

Wishing to create an Oktoberfest-style beer, but lacking facilities to lager during the summer months, we decided to try our hands at an Oktoberfest-style altbier. At racking to secondary, it shows promise, so we hereby post the following recipe for:

"ALTOBERFEST"

10 # 6-row pale malt  
1/2 # caramel malt (90L)  
1/2 # toasted malt - also called Victory malt (25L)  
1/8 # chocolate malt (350L)  
1 tsp gypsum  
1 oz. Hallertau hops (alpha = 4.5), boil 60 minutes  
1/2 oz. Tettnanger hops (alpha = 2.6), steeped 5 minutes  
1/2 oz. Tettnanger hops (alpha = 2.6), dry-hopped  
1 tsp Irish moss, last 10 minutes of boil  
Wyeast "European" yeast (#1338) in 3 cups 'starter' (SG = 1.030)

Procedure:

Use step-mash: add 2.75 gallons 130F water to achieve a 120 - 124 grist, hold 15 minutes, stirring every 5 minutes (shortened protein rest).

Add 1.4 gallons 200F water to achieve a 150F grist. Hold 5 minutes. Raise grist temperature to 158 (we used direct heat on a stove). Hold 25 minutes or until iodine test shows conversion.

Raise temperature to 170 (mash-out). Hold 15 minutes. Sparge with 5.5 gallons water, maintaining 170F grain-bed temperature.

Boil one hour. Add Irish moss for last 10 minutes of boil. Add 1/2 oz. Tettnanger hops as heat is turned off. Allow to steep for 5 minutes. Cool wort to pitching temperature (immersion chiller, 30 minutes to 70F.)

Yield: 5.5 gallons at OG = 1.052.

Pitched to starter 48 hours after breaking capsule. Pitched to wort 3 days later, long past krausen. Slow bubbles in 7 hours. Established a nice steady fermentation in 18 hours (a bubble every 15 Seconds.) Transfer to secondary and dry hop with 1/2 oz. Tettnanger after seven days. SG at racking = 1.016.

Comments:

The 1/8 # of chocolate malt gave a surprisingly dark, reddish brown color to this brew. Not too far out of character, but not quite what we had anticipated.

Fermentor was still bubbling about 1 bubble every minute, and wort was cloudy at racking time. This yeast is supposed to be a slow working yeast, so this did not concern us. The aroma of fermentation was yeasty, but quite pleasant. Tasting at racking showed a smooth brew, perhaps a bit under-hopped (by Pacific Northwest Standards. By MaltWest Standards it's fine to hoppy ]:~)!!). The dry-hopping will help balance the malt flavor. The 'Alt' character of the yeast is very apparent, and very delicious.

We plan to bottle in about two weeks, and will post a complete recipe/ comments sometime after. Too bad we have to wait until Oktober to REALLY enjoy this batch!

Cheers,  
Cush and Jim

From: Bob Devine 25-Aug-1992 1642 <devine@sfbay.enet.dec.com>  
Subject: Re: BEER CONCENTRATE

The gist of the Anheuser-Busch v. Coors lawsuit stems from the advertising that Coors does. Its claim of fresh Rocky Mountain spring water was challenged by A-B because Coors brews high-gravity batches at its Golden Colorado site and then ships the undiluted beer via refrigerated railcars to its Virginia bottling plant. A-B claims that by adding Virginia water to dilute the beer Coors is practicing false advertising.

I agree that A-B is factually right on this (even though the Coors plant is near a mountain called "Rocky Mountain" in Virginia!)

However, PLEASE don't discuss this in HBD since it ain't homebrewing!

Bob "who died and appointed me arbiter?" Devine

From: chuck@synchro.com (Chuck Cox)  
Subject: Re: Digest reader/extractor for Unix?

Stefan Karlsson asks:

```
>  
> I've seen programs for reading the digest in a nice way for  
> PC and Mac, but does someone know about such a program for Unix,  
> for example a script for sed or emacs. mp -d breaks pages  
> for printing but it would be nice being able to extract  
> a single article. Please post or email.
```

>From what I've seen on the digest, and in private email, I think the following might be of general interest to the digest even though its not strictly homebrew-related.

Here's the 'undigest' script I use. This works on my mutant, antiquated Xenix system, so you will probably have to change at least the 'execmail' line to work on any reasonable system.

```
#  
# split digest on stdin into separate messages  
#  
# usage: undigest reply_address recipient_address  
#  
# init variables  
FROM=$1  
TO=$2  
TMP="/tmp/ud.$FROM"  
# copy stdin to tmp file  
cat - > $TMP  
# split tmp file into individual article files  
csplit -s -k -f $TMP. $TMP '%^Date:%' '/^Date:/' [99] 2> /dev/null  
# mail each article to recipient  
for MSG in $TMP.??  
do  
    (echo "Reply-To: $FROM"; cat $MSG) | /usr/lib/mail/execmail -f $FROM  
$TO  
done  
# clean up  
rm $TMP*
```

Here's how its invoked from my '.elm/filter-rules' file:

```
if ( from = "homebrew" ) then execute "/usr/local/bin/undigest hbd chuck"
```

I use the Elm mailer and filter. You can accomplish the same thing with most modern mailers. Since the individual messages are mailed, you can use additional rules to filter each article. If you don't have a filter program, you can probably establish a mail alias to receive the digest and send it to the 'undigest' program. See your sysadmin for details.

Warning, ranting ahead:

You'd be amazed how much the quality and attitude of the digest improves with a little filtering to delete articles from certain authors, with certain subjects, or containing certain keywords. My filter normally removes one or two articles per digest (except during the recent promotional campaign when most articles were tossed). Yet it hasn't interfered with any threads that mattered to me.

As unmoderated mailing lists grow, the signal-to-noise ratio degrades. Thats just a fact of life. Don't worsen the problem by complaining about it to the list. Use your computer to filter out most of the noise. After all, shouldn't these #%&@\* machines do something to improve our lives?

I dry hop all the time with pellets. Simply swirl your carboy about  
twice a day to get the hops to mix with the beer. Somewhere between  
the first and second week, all of the hops will have sunk to the  
bottom and your beer will be clear. Patience! To keep from getting  
hops in your bottles, wrap a piece of sanitized cheesecloth over  
the end of the racking tube and secure with a plastic wire tie.

Jay,

I have this problem too. Can you be more specific? Did the grooves

go from one end of the roller to the other? Or just in the middle?  
How far apart did you space the grooves? Did/Can you access the  
rollers from underneath?

Is this how you did the grooves (the dashes)?

Re: Siphon bubbles

The best way to siphon from a carboy is to use a carboy cap.  
This orange cap has two openings, one for your racking tube,  
another for you to blow through. I never have siphon bubbles.  
I blow through hard enough to get a good fast flow.  
Also, if your siphon stops for some reason, it's easy to restart  
without you having to put your mouth on the siphon hose.  
Dont worry about blowing into the carboy, your breath is relatively  
sterile. In any case, I've NEVER had an infection.

If you have bubbles reform at the junction of the soft vinyl hose  
and the racking tube, you probably have an air leak. Make sure the  
hose is on securely.

-----  
Re: Coors

I would think the best way for Coors to transport would be a high  
gravity beer, already fermented. That way you have alcohol present  
to ward off bacteria and not as much beer to ship.  
Tanker cars just dont seem to clean to me.  
Just my 2 cents.

Darren

From: Brett Shorten <s05bas@cc.uow.edu.au>  
Subject: diluting boiled wort

I have a question about diluting boiled wort in order to obtain a target OG figure.

Last weekend, I followed Line's recipe for 'Guinness Extra Stout', but after boiling and chilling I ended up with 21+ litres of 1057 wort, rather than 1045 as Line suggests.

I figured to lose about 2 litres due to break material, so that leaves 19 litres. I figured that if I added 3 litres of (pre-boiled) water, I would end up with 22 litres of wort at  $19/22 * 57 = 49$ , or 1049 OG.

My question is, is the formula really this simple?

From: whg@tellabs.com  
Subject: Re: Digest reader/extractor for Unix?

I wrote a really stupid but actually quite useful little program about a year ago. I receive the HBD in the mail and write it out to a "temp" file. Then I run my "hbd" program on it and it simply scans through the temp file and inserts a unix mail heading above each digest line that starts with the string "Date:". It works something like "hbd < temp > HBD". Then I do a "mail -f HBD" and voila each digest article is its own piece of mail. You can scan the heading, go to a particular mailing, go back to an article, and save individual articles. A reply ("r" from the mail prompt) will reply directly to the sender.

Although this is a rather "low tech" solution it works great 99.9% of the time. Every once in a while an actual line of text will start with "Date" and become its own piece of mail but not often.

Following is the above C program:

```
/*  
1) save the digest to "temp"  
2) hbd < temp > HBD  
3) mail -f HBD  
*/  
  
# include <stdio.h>  
  
main()  
{  
    char dummy,line[81];  
    int i;  
  
    i = 0;  
  
    while( (dummy = getchar()) != EOF){  
if( dummy != '\n') [  
    line[i] = dummy;  
    i++;  
] else [  
    if ( (line[0] == 'D') && (line[1] == 'a')  
    && (line[2] == 't') && (line[3] == 'e') )  
  
    /* This line just signals the start of a mail article.  
    You can make the user, date and time whatever you want.  
|  
v    */  
    printf("From whg Wed May 15 04:27:24 1991 /n");  
    line[i] = '/0';

From: garti@mrg.xyplex.com (Mark R. Garti)  
Subject: liquid yeast

I recently purchased two packs of brewers choice (British Ale and London Ale). One was dated Aug the other Jul. According to the directions on the package, 1 extra day for each month past due, in addition to the first day. It continues to read that its ready after the package swells to 1 inch thick. Well at 75F i got 1 inch in about 4-5 hours not 1 day. I had to refrigerate the package as was not prepared to brew for at least another 15 hrs. What are the correct incubation instructions for these packages (or better yet what seems to work? )?

Also i just poured the contents of the package into my primarys. Both primarys had a good inch of krausen after 20 hrs. I've heard of many people making starters with the packages? How? Does this yield a faster, stronger start? Am I making any major mistakes?

Thanks,  
Mark

Jack "shared" his observations of a review of a Chicago homebrew club meeting he found in The Chicago Tribune. Nothing useful was said until the end when he added (realizing many of the brewers owned his MALTMILL):

>> What was even more peculiar was that the third picture was indeed of a  
>> MALTMILL, but it was cropped in such a way that all one could see was the  
>> hopper full of grain and the logo carefully excluded.

>> Now this normally would not bother anyone except that there was no shortage  
>> of plugs in the article for gizmos for sale and places to buy, associated  
>> with others in the article.

>> Do I detect a conspiracy?

Yes! There is a conspiracy! It's called marketing your product on the Homebrew Digest. I see no other point of your article than putting in a plug for the MALTMILL. I don't doubt it's a fine product - when I make the switch to all grain (I've been doing extracts since 1981 and make some FINE beers), I will certainly put these feelings aside and probably buy one! However, I'm tired of reading this crap on the digest. Let's get some sharing of ideas rather than sharing of advertising on the digest!!!!

When I read Charlie's prohibition on ice in TCJOHB, I assumed it was because that ordinary household ice is not very sanitary. If you took the precaution of boiling the water first and then freezing it in a covered, sanitized container, I don't see what would be wrong with dumping ice in the wort to chill it.

I read somewhere that your fridge is one of the most unsanitary places in your kitchen and I assume that your freezer isn't much better.

Anybody know why a fridge is a haven for micro-nasties?

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: Wyeast 3506

Hi All,

Some time ago there was a thread in HBD regarding the clove-like character (or lack thereof) produced by Wyeast Bavarian wheat yeast (3056? I can never remember those numbers). Some of the participants in that discussion claimed the clove character produced by this yeast was considerable, provided the beer was fermented at warmer temperatures. Last month I brewed two batches of dunkelweizen one week apart. The recipe(s):

Batch 1

-----  
5# wheat malt  
3# Munich malt  
2# 2 row pilsner malt  
1 cup black patent  
1 oz. 4.6AA Hallertaur  
Wyeast Bavarian wheat yeast

1/2 hour protein rest @~120F  
Mashed @ 153F-155F  
Mash out @ 170-175, 10 mins.  
Single hop addition, boiled hops for 60 mins.  
OG 1.048

Batch 2 differed only in the proportion of Munich to pilsner malt, i.e.,

2# Munich and 3# pilsner in batch 2. Oh yes, I also ground the wheat malt separately from the barley, on a finer setting, so batch 2 had a slightly higher OG.

The temperature in my basement was 70-74 during fermentation. Somewhat surprisingly, both batches seemed to take forever to ferment out, despite

the warm temps. I kegged batch 1 after 2 1/2 weeks, placed it in a fridge

@ 45F, and force carbonated by putting 30psi for a few days. The beer had

a lot of residual sweetness at first, it seemed like the yeast had'nt quite finished it's job. I raised the temperature to 55F (love those Hunter airstats), and after about 5 days the sweetness was all but gone. The beer had a \*very\* pronounced clove flavor, but it also had a noticeable

banana flavor as well. I suppose this was to be expected from the relatively high fermentation temperatures.

Batch 2 was very similar, I let this ferment a bit longer (3 weeks) before kegging, then placed it in the 55F fridge and allowed it to condition for 5 days before force carbonating. I just tapped this last night, this brew is quite enjoyable, though it also has considerable clove/banana flavors.

My conclusions:

1) The Wyeast Bavarian seems to take quite a while to ferment out, on

the order of 3-4 weeks. The package was date coded June 92, so it was'nt old. I had visible fermentation in both batches within 8 hours of pitching, so the yeast was reasonably vigorous.

2) Wyeast Bavarian will provide considerable cloviness if fermented above 70F, but it also seems to buy you a boatload of banana esters as well.

I've had commercial dunkelweizen exactly once, at the Portsmouth Brewery.

It too had traces of banana esters, though not as pronounced as the two batches I brewed. I admit that I don't know much about this style, perhaps someone on the net who does can tell us if the banana character is normal??

Cheers,  
Jim

Subject: Silver Solder

] From: bob@rsi.com (Bob Gorman)  
]  
] I was thinking of using the silver solder approach to adding an outlet  
] to a keg. However, I boil my wort with a 160,000 BTU propane burner.  
] Obviously I don't want to put the outlet on the bottom of the keg, but  
] rather low down on the side. So I guess my question is what's the  
melting  
] temperature of this silver solder?  
]  
] I figure the side of the keg won't get much hotter than the boiling  
wort,  
] it should be under 300F. And as long as the outlet and valve aren't in  
a  
] direct flame then there shouldn't be any concern with the solder  
melting  
] and the outlet springing a leak. Could someone who knows what they're  
] talking about please substantiate or refute this claim?  
You're right there, of course. The solder and stainless in a  
keg are both good heat conductors in contact with the boiling wort, so  
there is no temperature problem with the solder. I made a boiling keg  
about a year ago with an outlet tube on the side which was attached via  
silver solder, but I had a different problem. The silver solder is not  
very mechanically strong, and after a couple of months the wear and tear  
started a small crack in the solder which increased quite quickly with  
time. My net result was to scrap the silver solder idea and machine  
a stainless fitting which went through the original hole and sealed by  
a threaded piece on one side which tightened the fitting down on o-  
rings,  
sealing to the keg. Here goes my ascii effort:

```

      | <-----keg wall
-----|
stainless fitting-> | |o|o|-| <--- nut to seal o-rings to wall
      |-----| |----| |-----|
      | | | | / / / / / / <- threaded side of fitting
      |-----| |----| |-----|
      | |o|o|-|
      | <-----keg wall
```

where the o-ring cross sections are denoted by "o". This may not be the best idea for those who don't have access to machine something like this, but I mainly wanted to note the mechanical problems with silver solder, so that if the method is used, some other form of mechanical stability is present to prevent cracking of the solder joint.

Auf ein neues,

Tom Strasser...strasser@raj5.tn.cornell.edu...strasser@crnlmsc2.bitnet

Subject: Re: Bringing beer back from Europe

Phillip Seitz sez...

>

> What you need to do

> if you are planning to bring back a lot is call the U.S. Customs

> service and inquire about the duty on beer.

Unfortunately, doing this will only convince you that your tax dollars are being wasted on a twit subsidy program disguised as the civil service. Every time I have called customs (in the US) or an embassy (overseas) about beer, I have gotten a different, and unbelievable story. I have been told that it is illegal to bring even one bottle back. I have been told I could bring as much as I want. I have been told I must submit paperwork in triplicate. I have been told the first bottle is free, but that duty on the rest will be determined by an obscure formula based on the actual volume and alcohol content of each bottle. I have been told I could bring up to a quart of beer, and anything over that amount would be confiscated. In practice, I have never paid duty on beer, nor had any confiscated, and I usually bring about a case back every time.

The fellow who runs the Artisanales Beer store in Brussels (forgot his name) says he regularly sends cases of beer into the US. The recipient has to pick it up from customs. He didn't know if they paid duty, but they always get their beer.

> It is extremely rare taht

> returning Americans get their bags opened.

I have to strongly disagree with this statement. I have done a LOT of travelling, and I think US customs is the most intrusive and inept amongst the major nations. Back when I had short hair and travelled on a DOD passport, I would get the third-degree when entering other countries, and breeze into the US. Now that I sport a pony-tail and a civilian passport, I fly through foreign customs, but get hassled by the US.

The best place to enter the US is NYC. They are too busy to bother with trivial games. On the other hand, the customs droids in Boston seem intent on proving they are doing their job by bothering as many people as possible.

I have never been hassled about beer, but a Boston customs inspector obviously thought he was headed for a BIG promotion when he found several large bags full of a suspicious pale brown powder (malt extract) in my luggage.

I recently had this discussion with a customs inspector:

What are you bringing back?

Beer and literature.

Literature?

Yes.

What kind of literature?

Books and magazines about beer.

Magazines?

Yes.

Are these magazines pornographic?

No, they're about beer.  
Let me see them.

On the other hand, recently in Boston I had worked my way through three customs inspectors and was confronted by the fourth and final officer. The surprisingly pleasant and young inspector asked me the usual questions, then:

So what are you bringing back?

Beer.

Really? How much?

23 bottles.

Wow! I see you've been to Belgium, did you get many Belgian beers?

Yes, they're mostly Belgian.

You sure know how to travel. Welcome back to the US Mr Cox,  
I'm sure you'll enjoy your beer.

> When I asked

> the customs officer what I should do about it, he replied (and

> I quote), "Get the hell out of here." I love New York.

Yeah, this is exactly the same experience I had bringing a case through NYC customs. They seemed truly irritated that I would waste their time asking about beer.

Subject: The Novice Revisited

To all HBDers,

I would like to thank those of you who responded to my last post and got me started in the world of homebrewing. Originally I asked for some information on beer and homebrewing. First I found some great places in Manahttan to go and have a beer; some on my own and some from HBD. One place is Zip City, the only brewery in Manhattan. They are located at 3 W. 18th St. They brew 5 different types of beer, but only serve 2 on any given day. All are fresh and delicious, and is a must see/drink if you are in the area. Another place is Mc Soreley's Ale House at 15? W 7th St. They serve Mc Sorley's light and dark ale and that's it| Both worth trying. Then there is the Peculiar Pub located on Bleeker St. in Greenwich Village, and The Slaughtered Lamb on W 4th St. in the Village. The Peculiar Pub has over 200 bottled beers and 10 or so on tap, including Sierra Nevada Pale Ale. The Slaughtered Lamb is an English style pub with many English ales and a house brew called Full Moon Ale which I think is quite tasty.

I also found some good books through the HBD that I would recommend to anyone interested in homebrewing. They are The New Complete Joy of Home Brewing by Charlie Papazian, and The Complete Handbook of Home Brewing by David Miller. Both were very helpful in getting me started homebrewing. If anyone has any other suggested reading please let me know.

One thing I would like to say to any novices that might be reading HBD is that you should just go out there and start brewing. My partner and I have already brewed 3 batches: a traditional bitter, an I.P.A. and a mead :). We found the first batch so easy and enjoyable that we began brewing the next batch as soon as possible. We only had one problem that I think should be pointed out so it *\*NEVER\** happens to anyone else. We originally bought a starter kit that contains plastic buckets to ferment the beer in. The secondary or bottling bucket has a plastic spigot on it, and if it not in right your beer will leak all over the floor. I might be admitting that I'm *\*lame\** by saying this but it is worth it to prevent the loss of anymore precious homebrew. Needless to say we were heartbroken and felt as if someone had taken our baby and kicked him through the uprights for 35 yards out. We have since purchased a couple of glass carboys and will be burning our plastic bottling bucket in a voodoo bonfire.

In the near future we are planning on making a porter and marzen. If anyone has any tips, pointers and/or advice on making these styles please let me know. It would be greatly appreciated. Also I have a couple of questions on mead: We added yeast nutrient to our mead, will this speed up fermentation? How long should it take? I have never tasted mead, can anyone describe the flavor or will I just have to wait. BTW: If anyone in the Westchester, NY area (just outside of NYC) is interested in forming a homebrew club please contact me. My partner And I would be very interested in meeting some fellow homebrewers. Likewise, if there are any existing clubs in the area we would like to join. We brew in Yonkers, NY.

Thanks again for all your help and support,  
Erik Zenhausern, "Talzen Brewery"

Subject: what does 1.028 mean?

carruth@mksol.dseg.ti.com (matthew carruth) writes:

>I bottled a batch last night. The final specific gravity was 1.028.  
Does

>that mean anything. I used one "can" of extract, 3 lbs of powdered  
malt

>extract, 1oz of finishing hops, an one package of dry yeast. I added  
enough >distilled water to make 5 gal. It has fermented for 5 days.

Are you looking for a technical analysis or are you wondering if  
its ok? This SG sounds a bit high to me (provided that you've already  
been  
through primary fermentation). 1.028 is pretty normal for a batch that  
hasn't yet been pitched, so it seems that if you've not yet finished  
your  
vigorous flocculation phase (when lots and lots of foam bubbles out of  
your  
blowoff tube and the adrenalene starts to move) you're doing fine. Give  
it  
some time to blow out and to chill out. If you've already been through  
that, something's up. However, 5 days is a terribly short time for  
primary  
fermentation to subside. Feel better?

Now, as for the technical aspects of "what does 1.028 mean?",  
Specific Gravity is a scale which measures the density of a liquid. This  
is the mass per unit volume of your wort. The density of water, the  
universal solvent, is 1.000 grams per 1.000 mililiter (by definition of  
"gram").  $1/1 = 1$ . The mass units change as our solutions get heavier  
(we  
put things like salt or malt in them) or as our liquids get lighter.  
Alcohol's density is lighter than that of water, so its SG is lower - 0.  
795  
to be precise. 1 ml of ethanol has a mass of 0.795 g.  $0.795/1 = 0.795$   
g/l. Liquid butane will be even lower still.

Now in the event that we add things to a solution, the density will  
increase, depending on the density of what we're adding. Sound  
confusing?

Don't worry. Let's say we put sugar in some water. For argument's sake,  
let's call it dextrose. The total mass of the water + the total mass of  
the sugar will equal- well, I don't know what, but that doesn't matter.  
What does matter is that if you add equal masses together, you're not  
necessarily adding equal volumes. I'm sure you'll agree that the density  
of your Munton & Fison canned, undiluted, unhopped amber extract must be  
higher than that of water (try measuring out 1/4 cup of each if you don't  
believe me). The extract has lots of sugars and proteins and such to  
weigh  
it down. More mass per unit volume.

I hope this little tutorial helps to answer your query. May it  
serve to enlighten and relax you when you next do your brew.

From: Steve Kennedy <kennedy@ranger.enet.dec.com>  
Subject: Yeast in SN's bottles/Foxx Equip

In HBD #955 Russ Oertel writes about culturing yeasts from beer bottles:

>> For instance, I know that Sierra Nevada's yeast is the same as  
Wyeast's  
>> Chico Ale; so, can anyone tell me anything about the yeast used by [.  
..]

Through another homebrew forum I was told that according to Dr Martin  
Shiller  
of The Yeast Culture Kit Co., SN yeast out of the bottle is not the same  
as  
their brewing yeast. According to him, SN cold filters the beer and then  
adds  
a special conditioning yeast when they bottle. Therefore what you get  
from  
the bottle isn't what SN uses for brewing. That said, I've heard people  
have made brew using this "special conditioning yeast" with good results.

=====

In HBD #955 Jim Kirk writes about Foxx Equipment:

>> Actually they are getting into it BIG TIME. The deal is, they don't  
sell  
>> wholesale anymore except to homebrew suppliers and other beverage  
>> distribution companies.  
>>  
>> In a letter from Ford Maurer, President I quote: "We have established  
>> distributors across the country, and are looking to have complete  
>> geographical coverage of the USA and Canada."  
>>  
>> I have spoken with a representative from Foxx and was told that they  
will  
>> still sell RETAIL to anybody, but you can get better pricing from a  
>> participating homebrew supplier.

I concur with Jim's statement that Foxx is IN the retail business -- at  
least  
if my experience with them this week is any indication. The difference  
is  
that they now have retail prices for everything and homebrewers can no  
longer  
get stuff at wholesale prices. I placed an order with Foxx this week and  
the  
person I dealt with was nothing less than very helpful in helping me  
determine  
what was best for me needs. They also set-up a new account for me this  
week,  
which I'd don't think they would do if they were actively moving OUT of  
the  
retail business.

I'm not sure about the prices being better through a participating  
homebrew  
supplier, despite the fact that the source of Jim's statement is Foxx  
itself.

There's some stuff I just can't find locally and comparing Foxx's prices with those of the very few suppliers I know about in my area (MA), I still get the impression that the prices are pretty good -- even compared to other mail order places.

FYI: If you're having problems getting a catalog, my suggestion is to call up and ask to speak with someone who might be able to help you with an equipment order and that you might have some questions. I have found that sometimes the person that answers the phone isn't very helpful, but that the people who know about the equipment are extremely helpful. After I got some initial questions answered, I asked the person helping me if they could send me a catalog.

cheers,  
/steve

From: Steve Kennedy <kennedy@ranger.enet.dec.com>  
Subject: Labeling homebrew bottles

I use a method to label bottle caps (and not the bottle) which is pretty similar to those previously mentioned (but just a bit different):

I use colored adhesive 'dots' about 1/2 inch in diameter and write the beer's batch number on the label before sticking the dot on the beer cap. I alternate the color of the dot used from batch to batch (among the six colors available) so at any one time it's less likely that the same color will be used for different batches beer that are available for consumption.

And even if 2+ batches are marked with the same color, the batch number on the dot specifically identifies the beer and by that time you know which number goes with which brew.

I prefer this to just marking bottles with something like "pale ale" or "PA" or something semi-generic, because in addition to just knowing that I'm drinking a "pale ale", I can easily look up the recipe in my brewing log or have multiple beers of the same type and be able to tell them apart (at least until the cap comes off ;-)

/steve

>From: dougd@uts.amdahl.com (Douglas DeMers)  
>Subject: Extraction rate (was Re: All Grain Help)

>I've never seen it stated for all-grain brewing, but it is my understanding that the gravity readings given in Miller for example, and others are after the boil. And when Miller says something along the lines of expecting 33 points per pound of malt per gallon - I believe that is after the boil and not after the sparge. If this is incorrect, then I've got a real problem with my extraction rate.

This may come as a surprise to the mathmatically lazy, but it makes no difference. As long as all the variables are measured at the same time.

If you measure the gravity before boiling, you must use the volume before boiling. If you measure it after the boil, use the volume after the boil and be sure to include the trub left in the bottom of the kettle in the volume.

>From: bob@rsi.com (Bob Gorman)  
>I was thinking of using the silver solder approach to adding an outlet to a keg.....

I am trying to understand the problem here. Brass spigots are available with pipe fittings on them. If you are using a heavy gage kettle, all you have to do is drill and tap a hole and screw in the spigot. Brass fittings for copper tubing are available to hang anything you want on the inside. If your kettle is a lighter gage, drill a clearance hole and use a washer to take up the taper of the thread and a fiber washer on the outside will make it leak proof.

>From: "PAUL EDWARDS" <8260PE@INDINPLS.NAVY.MIL>

>On the subject of "Beer Concentrate" discussed previously by Jack S. and Arthur Delano: During a tour of the Hudepohl Brewery in Cincinnati, the brewer told the tour group I was in that they, like many other large breweries, employ a method of high-gravity brewing in order to get more beer from their equipment..... The brewer wouldn't say what the dilution level really was, tho.

I suppose he wouldn't say how high is "high-gravity". My guess is it, is what we call beer, not "concentrate".

I received a lot of mail on this topic, most of it defending, in one way or another, what the majors are doing. I find it strange that so many people (in particular, homebrewers) are willing to believe they are doing anything other than duping the public into buying a watered down product.

I re-reading the article, I note that the beer under discussion is Coors "Light" and I if anyone thinks that light is anything other than watered down "beer", I have a bridge for you. My guess is that the only difference between various types of beer is HOW MUCH WATER it is diluted with.

Finally, we all know that all they have to do to increase the gravity is to use more sugar anyway. So one wonders at the value of high gravity in the first place if all it contributes is alcohol. When we think of diluting, we think of diluting flavor. In an already flavorless product, adding water only enhances the bottom line.

>Anheuser-Busch keg and CO2 canister (for a net cost of \$20!).  
>  
>I don't have any fittings, and before i buy any, i would like  
>advice on what i need to get. While soda kegs seem to be  
>common currency among homebrewers, i don't have one and i assume  
>that the fittings are different.

Find yourself a standard keg tapper, one where the fitting  
on for the lip of the keg is connected to the pump with a  
hose. disconnect the hose from the pump, and connect to  
a pressure regulator. walla.

Actually, there exists two versions of said fitting, one for  
CO2 and one for the air pump taps. I've used the air pump  
fitting with CO2 with no problem, except that I had to replace  
the gasket on the pressure relief valve because it wasn't up  
to snuff. If you don't get all the fittings to seal tightly,  
you can always just pump up the pressure before going to bed at  
night and disconnect the lock from the tap.

- -----

O.K, I've used the above screnario before with standard ponies,  
and finally scrounged around enough to find some soda kegs  
and fittings. Can someone send me that temp/psi force carbonation  
chart that was posted many digests ago? The beer in question  
is a Scotch Ale, so I don't want too much carbonation, so  
suggestions on how much to deviate from the chart would be  
appreciated, also.

From: stevie@spss.com  
Subject: WHO IS WHO IN CHICAGO? A response.

Some comments on Jack Schmidling's comments about the recent Chicago Tribune article on homebrewing (a bit lengthy, sorry):

>"On a recent evening, club members shared 25 different beers they had brewed.  
>Chris Campanelli got raves for his deliciously rich imperial stout, a strong  
>brew that was originally exported from England to the court of Russia in the  
>1700s."

Indeed, Chris (well known to HBDers) had a great imperial stout.

>"Al Korzonas, though, had a bad night. About his bock beer, consensus among  
>club members was that it was "within style" but had several flaws, not the  
>least of which was that it smelled like home hair-perming solution."

>"His second offering smelled and tasted something like bananas. This was an  
>interesting concept, except it was a mistake, Korzonas cheerfully conceded."

If there was a "conspiracy" here, perhaps our HBD colleague Al has a case. The Tribune writer neglected to say that these were two "problem" beers that Al brought to the meeting specifically for analysis and comment. In fact, one of these was the "banana-Chimay" previously discussed here in HBD. Completely unmentioned were the other beers Al brought specifically for drinking. I personally sampled 3-4, and they were just fine, thank you.

By the way, Al won 3 1sts and 1 2nd at the Central Illinois Homebrew Competition two weeks ago. HBD may not be the Trib, Al, but congratulations.

>Among other things, this sort of confirms my opinion of the usefulness of  
>brewing "to style". It also points out the idiocy of trashing someone's  
>brewing skill based on a random tasting. It also reminds one of the old  
>adage of living in glass houses.

The great thing about homebrewing is that nobody will ever force you to brew to a style. As has often been said in HBD, if you're happy with what you're making Jack, that's great. I'll not belabor the point, but many of us want a more objective measure of our brewing ability. We value the comments and opinions of experienced brewers and judges who understand how problems in process may detract from the flavor and aroma of our beers.

When you brew to a defined style, you have a basis for comparison. You demonstrate your knowledge of brewing ingredients and process, and your ability to produce a product within understood guidelines. Clearly, if you set out to brew a Budweiser-clone light lager and it ends out looking and tasting like a Bass Ale, you've got some problems. The end result may still taste good and amaze your friends, but it ain't what you wanted to make. To paraphrase beer writer Michael Jackson, you don't go into a restaurant and order a plate of "food." We all presumably have some idea of what we want to brew before we brew it, and I'm sure it's something more definite than just "beer." This holds even if you're not brewing to a recognized style.

As to the proverbial glass houses, well, those of us who judge understand this concept more than you can possibly imagine. Most of us take great care to offer the brewer constructive criticism and support, and are quick to praise when it's warranted.

>The other thing that caught my attention was that, in spite of the fact that >just about all named in the article own MALTMILLS and the process of all >grain brewing was described in some detail, not one word was said about the >need to mill the grain.

>What was even more peculiar was that the third picture was indeed of a >MALTMILL, but it was cropped in such a way that all one could see was the >hopper full of grain and the logo carefully excluded.

>Now this normally would not bother anyone except that there was no shortage >of plugs in the article for gizmos for sale and places to buy, associated >with others in the article.

>Do I detect a conspiracy?

I hope you were being facetious, Jack. Otherwise, you are way out of line. As you have noted, almost all of the people quoted in the Tribune article were customers of yours. And one of those mentioned, Chris Nemeth, is actually going to be selling your maltmills at his new homebrew shop at Evanston First Liquors! Conspiracy?! Sure...

The evening the article appeared, I went to Ray Daniels' house to assist on a CBS judging seminar. Ray and I both mentioned that we thought you'd be thrilled to see the photo of your mill. We didn't even think about the crop-ping -- the mill was easily identifiable by anyone who either owned (not me) or had seen one.

To even raise the possibility that any of the people mentioned in the article would somehow try to systematically remove any mention of you and your mill is preposterous. If you did not ask this in jest, well, I'd say you were being incredibly paranoid. Hell, imagine what these guys would have done if they HADN'T bought your mill!

BTW, the "plugins" for other gizmos and places to buy included: Randy Mosher's "Doctor Bob Technical's Amazing Wheel of Beer" (a popular tool many of us use in recipe formulation) and "Beer Repair" (a concentrated malt/hop solution that can be squirted into an industrial beer to give it some real flavor); Chicago Indoor Garden Supply, one of the better local brewing supply shops.

The Trib writer actually began his research by visiting Chicago Indoor. Owner David Ittel and his staff directed him to the regular "First Thursday" meeting of the Chicago Beer Society, and the rest is history. Ray Daniels invited him over for his brew that Saturday, where they were joined by Randy Mosher. So, it's hardly surprising that Chicago Indoor and Randy were mentioned prominently.

Sorry for the length, folks.

From: Robert Schultz <SCHULTZ@admin1.usask.ca>  
Subject: Re: Labels

What I use for labels are the small avery labels (1/2" X 3/4").  
These come on an enveloped sized pad with 42 labels per sheet (7 X 7).  
I set up a spreadsheet with four lines per label (A1:A4) with the other  
41\*4 cells referenced to these 4 cells. I only have to fill in cells A1:  
A4

and the rest of the sheet is automatic. I use something like Helvetica  
6 pt font which allows up to 18 capital characters per line using a  
laser printer. I can place a good description and date which are easy to  
read. This is fast, easy to place on each bottle and you don't have to  
peel labels off the bottle - I haven't heard of anyone re-using caps.

Robert.

From: klumpp@casbah.acns.nwu.edu (David Klumpp)  
Subject: bottle sterilization and plug for Charlie

In response to a recent post concerning bottle sanitization, I use a technique which provides reliable results and provides great time flexibility: I bake my bottles...

When I buy used returnables from the local tavern (for the cost of deposit) I soak them in a HEAVY bleach solution >1hr to kill anything bizarre and remove labels. After rinsing exhaustively, I allow the bottles to dry. [For bottles I've already used and cleaned this way once, I simply rinse well with my jet bottle washer and allow to dry.] Once the bottles are fully dry (ca. 1 day), I take a piece of foil about 2"x2" and wrap it over the bottle mouth like a bottle Beck's. The bottles can then be stored this way until enough are accumulated for your next bottling event.

When I am ready to bake, I simply load my cold oven full of the foil-topped bottles and crank the heat to 400F. I bake about 1.5hrs. I assume the temperature will equilibrate in less than 1hr, so nasties are killed. After baking, turn off heat and open the door to allow cooling. Once cooled the bottles can then be stored until you are ready to bottle without fear of microbial invasion. Words of caution:

1. Do not remove hot bottles from the oven and place them on a cooler surface. About 5min after you do this with a bunch of bottles, you will begin to hear a symphony of cracking glass.
2. Do not pack the oven so full that some bottles touch the oven door; those touching the door will certainly crack (at least in my oven)

For those who still have not parted with the \$10 required for a jet bottle washer, buy one immediately. Charlie is right: there is no other way.

One final comment to newcomers from another (I only have 8 batches under my belt). If you haven't heard of it, Charlie Papazian's book The New Complete Joy of Homebrewing is indispensable! Although I still much, much, much to learn, I often see questions on HBD which are addressed within the first 50 pages. Not that there is anything wrong with such questions. But a quick read of the first several chapters of TNCJOH can prevent many potential problems before they become problems (such as not putting an air lock on your fermentor right after pitching). It also has many good recipes and excellent tables providing guidance on hopping rates etc.

Anyway, I hope some of this can be of use to others, and I enjoy reading the exploits of fellow brewers.

Hearty quaffing,

Dave

From: tpm%wdl158@wdl1.wdl.loral.com (Tim P McNerney)  
Subject: Using cara-pils

Seeing as how I am interested in trying new stuff in my beer, I picked up some cara-pils on my last visit to the homebrew store. Upon consulting Papazian I learned that cara-pils needed to be mashed, but that it contained no enzymes itself.

My question, then, is how do I use this stuff since I am generally an extract brewer? Possible solutions I have come up with:

Doing a partial mash using some grain which does contain enzymes. I have done partial mashes before, but I really don't have the time to go back and get some more grain. How much would I need if I were to use, say, half a pound of cara-pils?

Using DME, which I would guess (but do not know for sure) has enzymes available (thus the name).

Adding the enzymes directly. Can you go out and buy a bottle of alpha/beta amylase for use in brewing?

Just adding some malt extract, assuming it has enzymes, which I would doubt (but please correct me if it does).

Throw in a chicken beak and the heart of a cow killed at a full moon.

So which of the above are valid?

Thanks for the help.

Subject: Cooling Wort

I've been reading the digest for quite some time now and started brewing my own earlier this summer. I started with a combination of extract and grain and now have some questions regarding wort chilling before the primary.

What are the advantages of cooling the wort before the primary? I've heard (read) such things as "hot break" and "oxidation". What are these and what affect do they have on the beer? Are there any physical characteristics of these?

If cooling the wort is the way to go, would lowering the pot of hot wort into a sink full of ice water do the trick? Is the idea to get the temp down to around 65 degrees as quickly as possible?

I have been very satisfied with the quality of my homebrew so far, but a simple extra step (lowering into a cold water bath for example) that will make a difference in quality would be worth it.

Sorry for the new-B type questions, but a guy has got to learn somewhere. I sincerely hope no flames come my way!

Subject: Propane .vs Natural gas - PROs, CONs

I do my brewing indoors and plan on moving to allgrain which implies heating large volumes of water. I have been following the Cajun Cooker and other approaches for heating lots-o-water. One item that comes up is propane fuel .vs. natural gas.

Can I use propane indoors? Are there any problems with fumes from propane? Do people convert to NG out of convenience of using gas lines in the house? I would think that using propane tanks would be more convenient because you could move your cooker.

Date: Thu, 27 Aug 92 11:28 EDT

From: hjl@gummo.att.com

**Subject: Syphons**

Starting syphon: Sterilize hose. Stick enough hose in liquid to be syphoned so that a length greater than twice the distance from the surface of the liquid to the top of the container is submerged. With sterilized fingers (however), fold the hose double (above the top of container) and pinch the fold between thumb and forefinger, thus entrapping a length of air (or whatever gas was in the hose) and enough liquid to reach from the surface over the top of the container and down the outside to a point below the liquid level. Withdraw the hose from the container until the liquid level is above the top of the container. Fold and pinch the hose at the liquid level (you may release the first pinch at this point). Insert the free end of the hose into the receiving vessel. Withdraw the hose from the liquid being careful to keep the end below the surface. Bring the pinched fold down outside the container to a point below the surface of the liquid in the container. Release the pinch. The syphon will start. This process is trivially simple if the container is full but requires some dexterity if the liquid level is low. Practice with water. Play with length of submerged hose until you're comfortable. Smooth motions work best.

Regarding bubbles in syphon: Bubbles forming at junction of syphon "cane" and hose have been addressed. (Pinch the bubble and it goes away) My experience is that when bubbles form in syphon hoses used alone, they occur at the point where the hose contacts the edge of the vessel being drained. I believe this happens because the hose flattens at this spot, thereby constricting the flow, locally increasing the velocity of the liquid, and therefore, the turbulence (same flattening, albeit less, occurs at the bend in syphon "canes"). The agitation thus produced drives the carbon dioxide out of solution. To prevent this one needs to keep the hose round. A short length of garden hose (~8 inches) slipped over the syphon hose and positioned at the edge of the container stiffens the system sufficiently to avoid the problem.

From: perley@easygoer.crd.ge.com (Donald P Perley)  
Subject: Re: coors light and vinometer

What the Light ad didn't mention is that for many brands the "light" beer is just the regular beer watered down a bit (I don't know for SURE about Coors). So the "concentrated Coors light" being tanked around may in fact just be the normal Coors beer.

On vinometers:

What they measure is sort of a balance between specific gravity and surface tension. The implicit assumption is that the alcoholic fluid has been fermented dry. fine for dry wine, but for beer or sweet wine, it won't read correctly. Dry wine has a specific gravity in the range of .998 or so, while finished homebrew is often around 1.010 (and varies a lot).

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: siphoning

Hi All,

There has been considerable discussion in this forum and RCB recently regarding procedures for handling of siphon tubes, surgical gloves, etc. I'd like to relate an experience from a high school biology course.

The course instructor came in one day with a culture containing some kind of common bacteria (I can't recall which kind, this happened almost 25 years ago). She placed some of the culture on an sterile petri

dish with no growth medium, and put it aside. The next day, examination of the culture under a microscope revealed the culture was completely dead, as there was nothing in the petri dish on which it could feed. She then took another sample of living bacteria from the original, healthy culture, and placed it in the palm of her hand for one minute. She scraped the culture off her hand, and placed it on a slide. This culture was almost completely dead, there were only a few cells remaining that were left alive!

The lesson for that day was that human skin contains a natural bacteriacide that protects us from all those airborne micro-nasties that we all go to such great lengths to keep out of our beer. It's what enables

us to live in the air without being ill constantly.

DISCLAIMER:

I have absolutely no background in medical science, but I did observe this

firsthand. I have also brewed over 200 batches of beer in the past seven

years, and have never had an infection that was the result of touching siphon tubes with my hands. I even start my siphon by forming an "o-ring"

over the end of the tube with my thumb and forefinger, for the purpose of

avoiding direct contact with my mouth. Now, I would'nt recommend racking

beer after changing the oil in the family car, but I feel as long as brewers keep their hands clean, touching a siphon tube will not cause an infection. IMHO, wearing surgical gloves, etc., qualifies as excessive worry.

If there are any net.brewers with training in medicine/biology out there that know more about this than I do, perhaps they would care to comment.

Cheers,  
Jim

Subject: Re: Woodruff

From: Alan Mayman <maymanal@scvoting.fvo.osd.mil>

After sampling a May wine from a local winery I was very impressed with the flavor of Woodruf(f?). If anyone has used this herb before in mead or beer...

In Berlin people drink Berliner Weisse, a sour-tasting Weizenbier, out of glasses that could best be described (with my limited eloquence) as a half of a small fishbowl or an half-sphere ice cream sundae glass.

Into this (IMHO unpalatable) beer they introduce one of two additives:

Raspberry Syrup (red)  
or  
Woodruf Extract.

Its being neither "Hopfen" nor "Malz" would preclude its being used in German beers. I don't like the stuff, but it is "interesting".

Cheers,

From: jdg@grex.ann-arbor.mi.us (Josh Grosse)  
Subject: Easy sterile yeast transfer

Avoiding infection during yeast culturing on plates or slants is imperative. Several methods are used to reduce the chance of infection, such as:

- o working very quickly, so that plates and slants have a minimum exposure to the environment
- o making multiple plates or slants at the same time, to increase the chance of successful transfer
- o wearing a mask and/or hat
- o wiping down the work area with 200ppm chlorine.

Truly sterile transfer is not easily accomplished in the home environment without building a sterile box.

Here's a simple, cheap, easy way to build a sterile box, without needing any skill or special materials whatsoever (my requirements). The only tools required to build it are scissors and tape. This box design came from a friend who uses one to culture orchids instead of yeast, but the requirements are the same.

Ingredients:

Cardboard box  
Aluminum foil  
Plastic wrap (eg: Saran)  
Plastic dishwashing gloves (eg: Playtex)  
Spray bottle  
Chlorine

To sterilize equipment and materials going into the box, use whatever you use to sterilize slants and plates, such as:

Canning jars (eg: Mason)  
Pressure canner (15 minutes at 15 psi)

Building your sterile box:

1. Cut all four of the top flaps off the box.
2. Cut down two sides at an angle to make a work area opening, leaving a lip on the bottom, like so:

Side View Front View

3. Line the inside with aluminum foil. Leave no cardboard

exposed.

4. Tape your plastic wrap to the back of the box, so that it drapes over the opening you've cut.

When you sterilize your slants and plates, also sterilize your transfer equipment, such as loops or eyedroppers (the latter for making slants from Wyeast). Do this by sealing them in canning jars (with a little water) prior to pressure canning 'em. Also, can a plain jar of sterile water to use as a rinse.

Put on your gloves, place all equipment inside the box, and spray 200ppm chlorine onto the box walls, floor, the plastic wrap, and the exterior of all your slants, tubes, canning jars, and the gloves themselves.

Dip anything that comes in contact with your yeast samples in the sterile water to rinse off the chlorine prior to opening it.

Tada! It's not a thousand dollar sterile hood, but it beats the kitchen table and allows you to work a little more slowly..Also, if the box gets ratty from use it's real easy to make a new one.

>Ok, now about my second all grain brew. I got a stopped sparge,

>I used the grain mill at my local homebrew store and I believe I got too fine a crush and this caused my mash problems... So the point here if you have a poor flow rate look to the crush first and not the size of the holes in you manifold.

If it was a roller mill, designed for malt, it is not likely your problem.

I hate to sound like a broken record but my guess is that your mash cooled off. To resolve the question, you need to check the temp of the mash from top to bottom. The bare minimum is to take a reading of the run off.

I do not think the hole size is very important because it is the husks that do the filtering. The holes just keep the husks from clogging the spigot. What is probably happening is that your thick mash, which consists mainly of sugar and starch is turning to glue because of the temp and glogging the holes.

The solution is hotter sparge water. My system is no doubt different from yours but (in spite of all contrary advice) I use boiling water and my runoff is only around 140 to 150F but that is aparently enough to prevent glue formation.

>From: wegeng.henr801c@xerox.com

>A friend of mine (who is a home winemaker) has told me about a device called a "vinometer" which is used by winemakers to determine the amount of alcohol in their wine.... My friend claims that he has tested his vinometer with whiskey and other alcoholic beverages of known alcohol strength, and it`s always been correct.

>Has anyone ever heard of this device?

Sure. Most brew/wine shops carry them. They work very well but, unfortunately, only on dry wine and booz. They are totally useless for beer.

Mine says about 7% no matter what kind of beer I put in it, even NA.

From: Pierre Jelenc@cunixf.cc.columbia.edu  
Subject: copper; woodruff

In HBD # 956, Tom Feller is getting problems with copper in his brew. Copper is quite poisonous, and can cause severe disorders, especially colic, diarrhea, and vomiting (and that's at low doses). I would recommend using the contaminated brews as slug bait.

Copper is not such a problem at the beginning of the brewing process (copper kettle, lauter tun, chiller, etc) because yeast uses some copper for growth, and most of the rest precipitates into the trub as complexes with tannins. Once the beer has cleared, however, any additional copper will stay in solution.

Alan Mayman asked about woodruff. There was a long discussion on the subject last year in the Beer Forum on Compuserve. From a German friend, I learned that woodruff has to be gathered early, as it just flowers, for best aroma. Then last summer, while visiting my parents in France, I found out that my father has a fairly nice patch of it in the back of the garden. It is a very unprepossessing plant with round leaves, the kind one would never pay attention to, although it is said that the little white flowers are very pretty.

The aroma of woodruff is that of coumarin, and it is the basis of the green syrup that the Berliners put in their Berliner Weisse when they are not putting raspberry.

Subject: Keg fermenting

Greetings,

Our mail got held up, and I just received two HBD's today, so the following may be slightly dated....

In one of Jacks previous posts... [ sorry, can't remember the issue # ]

> Friday's Chicago Tribune had a great article on homebrewing....  
[good!]

[ ... deletia ... ]

> What was even more peculiar was that the third picture was indeed of a  
> MALTMILL, but it was cropped in such a way that all one could see was  
the

> hopper full of grain and the logo carefully excluded.

> Now this normally would not bother anyone except that there was no  
shortage

> of plugs in the article for gizmos for sale and places to buy,  
associated

> with others in the article.

> Do I detect a conspiracy?

I would suspect not a conspiracy, but whether the editor of the Tribune has a USENET account, or reads the HBD .... ;-D

Okay, now the real reason I'm here today. I was wondering if it would be possible to ferment in the primary as normal, and before the fermenting is complete rack into a 5 gal. soda keg, seal up, and let the ferment finish in there.

I realize you'd probably have to time it right, but would that not eliminate the need to prime? Would the finishing ferment provide the carbonation?  
Am

I risking death and dismemberment if I do this too soon?

Has this been beaten to death before? :->

Cheers,

Mitch

**Subject: re:bringing brew from Europe**

re: bringing beer back from Europe.

I don't know about Europe.. but I used to live in Texas about 3 years ago and would visit my friends back in Toronto on a regular basis. I had NO problem bringing back large amounts of beer! I recall one time clearing US customs at the Toronto airport and they asked the usual questions.. how long staying etc.. when I was asked if I had anything to declare... I simply unzipped my hockey bag I had to carry my junk onto the plane and showed the customs guy the 24 king cans of Molson Export I had. He just looked at it and said " I guess it's real hot in Texas" and stamped my passport! (mmm...memories of the Shiner Brewery... Shiner Texas.. just outside of Austin)..

Subject: RE: Bringing beer back, igloo cooler

Hi All,

In HBD#957, Chuck Cox writes:

>>It is extremely rare taht  
>>returning Americans get their bags opened.

>I have to strongly disagree with this statement.

I have to go along with Chuck on this one, I have traveled extensively in Europe, Mexico, and the Carribbean, always on a civilian passport. I have always breezed through customs when entering another country, the only times I was ever searched was re-entering my own country. Chuck is also correct that Boston is horrible. I was searched there because I was carrying a single bottle of gin through for a travelling companion. You get one bottle duty free, so I had'nt put it down on the declaration form. I was detained for 20 minutes while they searched through three suitcases full of dirty laundry. Poetic justice, I suppose.

Another horrible re-entry point is at the Mexican border at San Ysidro. The pinheads down there think that if you're young, male, and carrying a bag then you are obviously smuggling drugs. Our tax dollars at work. \*SIGH\*

Sorry for turning this into soc.politics or alt.drugs, gang, I did actually have a brewing related question. I recently aquired an Igloo 10 gallon round cooler, which I'd like to use for both mashing and sparging. The problem is the spigot is one of those push button types. I had planned to remove the spigot, bore out the hole with a hole saw, and replace it with the plastic tap from my existing lauter tun. A friend advised me that it's difficult to reseal these coolers once the original spigot is removed. He suggested I cut the end off the original spigot and replace it with a small threaded brass faucet. The problem is it's not obvious where to make the cut. The push button portion meets with the spout where the liquid comes out, I would have to cut it absolutely flush with the outer wall of the cooler to get a round hole. Anywhere else along the spigot, and the hole would be oblong, and would'nt take a threaded tap without leaking.

Anyone else done this? (Kevin, I know you're out there). Any advice would be appreciated.

Thanks,  
Jim

Cheers,  
Jim

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Baking bottles

Recently an HBD reader inquired about sanitizing bottles, and one respondent described his process for heat sanitizing. In summary, this consisted of cleaning the bottles, covering them with a 2" x 2" aluminum foil "cap", and then baking them for 1.5 hours at 400 degrees.

I use an identical procedure, with the exception that I bake at 200 degrees for about half an hour. To be exact, I fill the oven and close it, turn on the heat, and turn it off after half an hour. As I understand it, sanitizing requires 170 degree heat, with a contact time of about 15 minutes. 200 at 20 minutes or so therefore already has a fudge factor built in. I've never had a problem with a contaminated bottle.

I might also add that sanitizing with the aluminum cap on means you can leave the bottle unfilled for some time without losing your sanitary state. I'm too nervous to let my baked bottles sit for weeks, but I have done bottles the day before bottling. This is particularly convenient when you'll be bottling at someone else's house--you can show up with two cases ready to go. (Note: remove the aluminum foil before bottling!)

My thanks to the infamous Mr. Pete, brew-devil of the great Northwest, for suggesting this technique.

Last thoughts: I can fit a case of bottles into my oven. At 200 you can remove the bottles relatively quickly, and they don't take too long to cool--I've baked my bottles, set them out, and bottled within about 45 minutes.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Re: Cooling Wort

Why chill your wort before the primary?

In no particular order:

1. You can pitch sooner. (Reduces infection risk.)
2. You can do a full-volume boil (helps with hop utilization -- you can use less hops, and reduces caramelization). Note that with all-grain brewing you have to do a full-volume boil.
3. You get the "cold break" in the kettle (if you use an immersion chiller) instead of in the fermenter. Reduces trub volume in the fermenter and generally makes for a cleaner ferment (IMHO).
4. You have less risk of oxidation when transferring the wort from the kettle to the fermenter. In fact, you can aerate during the transfer or immediately after (or before, I suppose). At a minimum, oxidation will darken your wort. It can also lead to off-flavors (Note to potential flammers: I said "It CAN ...", not "It WILL").
5. I pitch the yeast into the brew kettle while the trub is settling. This way it (presumably) gets to use some of the nice proteinaceous material in the "break", but it doesn't sit on it throughout the whole fermentation.
6. You don't risk cracking your carboy with hot wort.

results.  
>  
>

I thought I needed to clarify this since I am the network access for  
Dr. Schiller. I just got off the phone with martin and we cleared up  
this confusion. We had a discussion a while back about different  
breweries that ferment with one yeast and condition with another. The  
obvious ones that come to mind are Bavarian HefeWeizens (top fermented  
with a single cell culture from Weinhenstephan that produces Banana  
esters and copious anoumts of phenolics due to the production of  
4-vinyl guaiacol, filtered and repitched with a flocculant lager  
strain) and Belgium Ales (fermented with almost any mix of strains and  
often conditioned with another strain). Somehow this concept got  
confused with the process that Sierra Nevada employs. Sierra brews  
all of thier excellent ales with the same strain, an ale yeast that  
apparently originated from Narragansett (sp?). After primary  
fermentation is complete, the beer is filtered (I believe they sterile  
filter) and force carbonated in the bright beer tank. The carbonation  
level is above 2 atmospheres (about 90+% of the final carbonation).  
After this stage, the beer is primed with about 4 pounds of the SAME  
ale yeast per 200 BBls. This is an incredibly small amount of yeast  
for bottle conditioning and would not work well without the previous  
force carbonation of the product. This yeast then produces the final  
carbonation level desired. This method has numerous advantages over  
traditional krausening in that the initial product filtering helps  
to maintain quality control (remove any fermentation affected yeast  
cells, provide a sterile environment) possible fermentation modified  
stage allows the brewery to only add a minute amount of yeast (ever  
noticed how little yeast sediment is in a Sierra product?)

Hope this helps clear up the confusion. Look for an upcoming post  
So, the yeast many of us culture from the Sierra bottles is actually  
the same yeast as that used in the fermentation, just healthier.  
Dont forget to culture up 1 liter for all five gallon starters.

on my Counterflow, parallel-chiller from hell!

From: Lester Paul Diamond <ld0h+@andrew.cmu.edu>  
Subject: First Timer Question

I started my first brew on Tuesday night. I think I did everything right so far. By Wednesday morning my airlock was bubbling away. The thing is that by Friday morning the bubbling appears to have stopped. It may be bubbling slowing, but I didn't stand around to check. There may be nothing wrong, but I've never been down this path before, so I'm not sure. Any advice or reassurances would be appreciated.

Also, I'll be bottling next week, and I'm a bit concerned about sanitizing the bottles. I was going to use Chlorox in a large barrel and soak the bottle for a short time, then take them out and empty them. After that I was thinking of running them through a rinse and dry cycle in my dishwasher. Would this be OK? What if I just rinsed the bottles by hand and allowed them to drain upside down for a while?

Thanks in advance. I'm excited about this first round.

Lester

Subject: Airstat in a freezer?

I have an unused chest-type freezer that would be perfect for fermentation if I could control the temperature. Years ago I rigged it up with a "cold room" thermostat to keep quantities of beer cool for parties, and it worked well enough, but the temp. varied quite a bit. ( I rigged up 2 muffin fans in a platform on the floor of the freezer to keep the air circulating on the theory that very chilly air would collect at the lower levels.) I have heard "Hunter Airstat" mentioned on the HBD: how closely will it regulate temp. in such a freezer?? Does anyone have experience in this area? Also, where can I get said Airstat device, if it is recommended?? Thx -gk

Subject: Re: Using Cara-pils

Tim McNerney writes:

>Seeing as how I am interested in trying new stuff in my beer, I picked  
up  
>some cara-pils on my last visit to the homebrew store. Upon consulting  
>Papazian I learned that cara-pils needed to be mashed, but that it  
>contained no enzymes itself.

I don't believe that cara-pils malt has to be mashed. Cara-pils (dextrin  
malt)  
is produced in much the same way as crystal malt, but kilned at a much  
lower  
temperature so as to impart little or no color. The process used to  
produce  
crystal and dextrin malt essentially "mashes" the grain in the husk. The  
malt  
is held at a temperature near the upper limit of the saccharification  
range in  
a 100% humidity environment for a period of time and then kilned. Thus,  
the  
starches in the grain are converted primarily to dextrans which is  
exactly what  
we want in order to add body, head retention, a little residual  
sweetness, etc.  
to our beer.

A while back there was quite a debate in this forum as to whether these  
dextrans  
will be converted to simpler sugars during mashing and whether or not  
mashing  
negates the effect we are trying to achieve by adding them in the first  
place.  
As always many of us have our own opinions on this topic...

As for throwing in a chicken beak and the heart of a cow killed at a full  
moon  
along with the Cara-pils, I always do this. Doesn't everyone? ;^)

>conditioning yeast when they bottle. Therefore what you get from  
>the bottle isn't what SN uses for brewing. That said, I've heard  
>people have made brew using this "special conditioning yeast" with  
>good results.

This is partially correct. I have it from Steve Harrison at the brewery  
that  
they do filter their Pale Ale and then introduce yeast for culturing in  
the  
bottle. The yeast which is used is a washed version of the same yeast  
used to  
ferment the ale in the first place. So, while it isn't the exact yeast  
which  
fermented that particular batch, it is the same yeast strain.

As long as we're talking SN yeast, Steve also told me that they do not  
re-use  
the yeast which goes into Bigfoot or Celebration Ale. They use the same  
yeast  
as for the Pale Ale but find that after the yeast gets through the higher  
alcohol fermentations of the other two products it mutates and behaves  
"very  
strangely". The yeast is dumped after these seasonal beers are brewed.

This discussion was prompted when I tried to brew a Celebration clone  
using  
yeast from 3 bottles of last years' Celebration Ale. The yeast behaved  
like  
lager yeast in that it never formed the typical SN pancake, nor much of  
any  
foam on the surface of the primary. The beer came out fine, but I  
wouldn't do  
it again because of the unpredictability of the yeast. Other brewers I  
have  
spoken with have had similar experiences when trying to culture from  
Bigfoot  
bottles.

I use SN yeast (from bottles) for all of my ales and have never had a  
problem.  
I take the dregs from 3 bottles and put them into a 1200 ml wort at about  
1.035  
with 1/8 teaspoon of nutrient. The starter is ready for use in 4 - 5  
days. My  
10 gallon primaries take off within 6 hours.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: RE: Propane/NG indoors

In HBD 579, Steve Anatasi asks about relative merits and safety of propane vs natural gas. For indoor use, **good ventilation** is very important. In a closed space, a burner can snarfle up a lot of the oxygen and replace it with CO2 and (to a much lesser extent) carbon monoxide. This doesn't bother the beer, but it might make you ill. Assuming the burners are working properly, there isn't much difference in the exhaust gasses from the two fuels.

There is a considerable difference in safety, if you have a gas leak. Propane is heavier than air, tends to flow and pool like invisible gasoline. Propane also has a much wider explosive mixture % with air. If you are going to use propane indoors, test all your gas joints with soap solution to be sure they are leak-free.

Another Great Moment in Brewing History: I once had an exciting adventure with an indoor propane leak. A supply hose for a burner on a bench-top developed a leak. My spark lighter ran out of flint after I had opened the tank valve. I turned the gas off at the burner, but this left the leaky hose still going. Because I had opened the valve without lighting the gas, there was some gas odor. I walked across the room, got a new flint and went back to the burner. I opened the burner valve and WHOOOMMMP!!

Suddenly I had the entire benchtop aflame, with the flames spilling off the edge of the counter like a Niagra Falls of fire. As the fire hit the floor, it flashed the pool of propane that had collected around my feet. It was all over in the blink of an eye (now missing eyebrows). I was VERY surprised. I was very lucky that I hadn't dithered any longer getting the flint for the lighter.

Propane does not need to be enclosed in order to be explosive. A friend of mine once watched his boss get tossed twenty feet by a propane explosion in an open storage nook on the outside of a building.

All these horror stories aside, many homes and trailers use propane for heat and cooking. I have two burners that I use for brewing. Propane is less expensive to get started with, is more expensive per BTU. NG costs less to use and more to install. Use good ventilation and test for leaks.

Paul de Armond -- Coor's Rocky Mt. VA sounds like intent to deceive....

David Klumpp outlines his method of sanitizing bottles in the oven. I  
have been  
using a similar approach.

I use Anchor bottles and clean them as they empty, then soak them  
overnight in  
a mild bleach solution just prior to bottling. I then rinse with a jet-  
washer  
and hot tap water. Differing from Dave, I heat the rinsed, but still wet,  
bottles to 350 degrees and hold for 30 minutes. I figure the steam action  
produced helps a bit. I then allow the bottles to cool slowly to prevent  
cracking. I bottle as soon as the bottles are cool enough to handle. I  
warn you  
that I don't bottle too often. Perhaps a batch of barleywine and a  
holiday  
batch each year. Nevertheless, barleywine from 2 years ago is still clean  
and  
beast-free.

Subject: labelling

Well, everybody else has posted their labelling strategy; might as well join the fun. I used the dots like several other posters, white ones mostly (cause they didn't have colored ones in my earlier bottling days). I would take a date stamp and stamp the bottling date on all of them, then write enough description above and below the date to identify it. M/F Amber, HT was a common one (Munton & Fison Amber, Halletauer hops). Sure, it took a few minutes to write out 50 of these, but really not very long. When I was at max production I was about 7 batches ahead, drinking 5 or 6 of them at once. I would never have kept a cryptic batch number straight, but a simple 'IH Bitter' (Iron Horse Bitter), 'Georgie Brown Ale' or whatever meant I -- and my guests -- always knew what we were getting.

From: JKL <JLAWRENCE@UH01.Colorado.EDU>  
Subject: Hartford Brewery, Bock Beer

Recently I was on vacation in southern RI and managed to make a side trip to Hartford and The Hartford Brewery (on Pearl St., I believe). My husband, 2 small children and I arrived about 2:30 pm on a Tuesday, and the place was virtually deserted. The service was mediocre, at best, even with only 1 other customer.

Also, I didn't even like the beer! It's very possible that my tastes are too pedestrian, and the beers offered a bit exotic. Has anyone out there tried these three (I got a sampler) and could tell me what it is that I tasted that I didn't like? For you hopheads, I think they were all VERY strongly hopped . . .

Kolsch OG 1.038 very hoppy, golden color  
Pitbull Golden OG 1.042 even more hoppy, golden  
Bacchus Ale OG 1.062 dark brown, carmelized flavor,  
slightly sweet, burned(?)

All 3 were moderately carbonated, and all seemed to me to have an unpleasant bitter aftertaste. They were brewing an IPA that day, but I couldn't wait around for it to be ready ;-).

Thanks to all those who sent me suggestions for breweries in that area.  
Sorry this is the only one I got to.

From the Longmont (Colorado) Daily Times-Call, L.M. Boyd's column:

Q. Why is a goat always used as a symbol for Bock beer?  
A. Bock is the German word for goat. It was only in March that the Germans made that bock beer, and according to the old astrological tables, March was the goat month.

From: Bruce Hoylman <bruce@advtech.uswest.com>  
Subject: Re: Ice to cool wort

I've done on the order of a dozen or so mostly extract brews with, getting fancier and fancier with adjuncts as I begin to understand the process. A co-worker who got me interested in brewing showed me how he cooled the wort by dumping it into a food-grade plastic primary that was filled with ~10lbs of ice. Nothing special ... just ice one can purchase at the grocery store! He's always done it that way, and that's the way I've done it too. I've not had *\*any\** problems with this process to date, and I've really put some interesting beers together in the process. I find that the ice brings the wort done to temperature VERY quickly.

I don't plan on changing my methods of wort chilling at this point. Maybe if I get more into all-grain brews (which I have ambitions of doing once I get bored with extracts) I'll change, but I'm more than satisfied with my current process and what comes out, namely a brew that I can call my own and one that is superior to most that can be purchased over the counter.

Just my 2 bits worth.

Peace.

From: bob@rsi.com (Bob Gorman)  
Subject: Re: B-Brite

In HBD #953, Bob Gorman asks about B-Brite vs. non-chlorine bleach.

To which Pierre Jelenc replies;

> "Sodium percarbonate" is the common name of a molecular compound of  
> sodium carbonate and hydrogen peroxide, that for practical purposes  
> behaves like hydrogen peroxide itself.  
>  
> Sodium perborate in non-chlorine Clorox is another "active oxygen"  
> compound, this time truly the salt of a peracid.  
>  
> Peracids and peroxides all act similarly, by oxidizing organic  
materials,  
> especially proteins in the case of sanitizers.

Ok, that was great! Now let's see if we can put this into practical terms. I could therefore assume;

- 1) That non-chlorine bleach could be used in place of B-Brite as a cleaning agent.
- 2) That non-chlorine bleach could be used in place of B-Brite as a sanitizing agent.

Does this make sense?

Can anyone offer more insight into the wonders of B-Brite vs. non-chlorine bleach?

Thanks,

Newsgroups: rec.crafts.brewing  
Subject: Importing of plant species  
Summary: how do i find out if this is legal?  
Expires:  
Sender:  
Followup-To:  
Distribution:  
Organization: Hughes Aircraft Colorado Engineering Labs  
Keywords:

This is a bit off the subject, but i do not know where to go. My mother just returned from Peru, and at my request brought back some of their odd corn varieties. One of which is a special corn they grow to ferment, which has large kernels. I am thinking about planting some next spring, and emulating their recipe, which unfortunately is sketchy.

- 1) soak and drain the corn
- 2) re-fill with water
- 3) cook for a while
- 4) add honey
- 5) let ferment spontaneously

Well... i do not want to introduce some kind of incredibly nasty weed to the continent, so how can i find out if this is OK?

Also... for you o-chem, bio-chem gurus:

can corn be converted by boiling, or do i need a warm temp rest like barley.

Do you think that there may have been a germination period between the soaking and the cooking?

My mom's friend will return to peru for x-mas. At that time he can get me some of the famed "chicha morada" purple corn, that they use there for making a yummy cool-aid like drink. Just boil the whole purple corn cobs for a while, and add sugar. (use the corn like tea bags) I have had this chicha morada in LA, and it was quite good. I also hear that there is a fermented chicha morada beverage, which i will try to emulate. The only think i know about chicha morada is from the article that somebody posted here or to HBD about a guy who went into the indian territories of peru. i think it was published in outside or something.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: When to measure SG and what to include?

In HBD #957, Jack talks about when to measure SG and sez:

>...If you measure it after the boil, use the volume after the boil and  
>be sure to include the trub left in the bottom of the kettle in the  
volume.

Any other opinions? I've always done what Jack says, but I'm never  
sure if it's right. Specifically:

- the trub is in solution before the cold break and in suspension  
after, right?
- stuff in suspension doesn't affect SG readings, right? (E.g.  
throwing wood chips or marbles into wort wouldn't change the  
hydrometer reading.)
- Does stuff in suspension take up more room than stuff in solution?
- If the answer to the last one is 'yes', then doesn't it mean  
that pre-boil SG is different from post-boil SG, whether you  
include the trub volume or not?

Only wondering. Wish I remembered more of my pchem.

Cheers,  
Rob  
(bradley@adx.adelphi.edu)

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Cajun Cooker Enclosure

Sometime back, Phil Miller asked :

>How long can I expect a standard tank of propane to last if I use  
>a Cajun Cooker type burner to heat my wort for boiling (i.e., rocket  
>blast mode to bring 5-6 gallons to a boil and then idle mode to  
>maintain a vigorous boil for 1 1/2 hours)?

About two years ago, Kinney Baughman introduced me to the Cajun Cooker/  
Bunsen Burner from Hell. In the intervening time I've worked out a way to  
get more mileage out of my propane tank. It was a bit of a project, but  
I enjoyed it.

The first time I used it, I was brewing outside on a windy day. When  
Alexandra peered out of a second story window, she was shocked to see the  
entire garden shimmering from the heat. Being a master of the obvious, I  
deduced that too much heat was going into the garden, and not enough into  
the beer. At the end of the brew day, my just filled 20 lb propane tank  
was  
75-80% consumed.

I decided to try to improve my efficiency, and seeking inspiration took a  
quick look at industrial boiler designs. A common design for high  
efficiency  
entails enclosing the kettle in an outer jacket, and putting the flame  
between the two. Further enhancements include adding intake vents at the  
bottom, directing the intake gasses thru the center of the flame and not  
around it, and providing an exhaust vent at the top. So I went to my  
friendly  
neighborhood homebrew supply shop (Oak Barrel in Berkeley) to get one of  
these.

What I came home with was an empty 55 gallon drum - malt extract of  
course.

>From this, I fashioned an enclosure with the afore mentioned vents and  
manifolds, added holes for a gas line in and a wort line out, and  
installed a  
door for easy access to the inside. The entire boiler assembly, kettle  
(Bud  
keg), burner, support/manifold, rests inside the 55 gallon drum.

Overall, I'm very happy with the results. The flames are protected from  
the  
elements, and heat transfer is greatly improved (ie the garden no longer  
shimmers). I now get 4-5 brew sessions (heat mash water, heat sparge  
water,  
1 1/2 hour boil) on a single fill. As an added benefit, some of the jet  
engine  
noise is muffled.

One of these days I'll get around to modifying those 45 gallon double  
jacketed  
tanks in my back yard.

Cheers,  
CR

From: stevel@chs.com (7226 Lacroix)  
Subject: Sanitizing Bottles..

My method for what it's worth...I wash out my bottles immediately after pouring the contents into my glass (except the ones I scrounge from the recycle bins around my house). Next, I throw them in with all the other dishes currently in the dishwasher and wash them before storing. When it's time to bottle, I bring them out, shoot them with a bottle washer (read invaluable tool). I run my dishwasher empty and about half way through the cycle, open the door and dump a little household bleach in it to clean the inside. Next I load the bottles into it and run it. Again about half way through the cycle, I open the door and dump a little bleach in. Finally, I let the heating element dry the bottles. I don't open the dishwasher until I'm ready to fill the first bottle. I've got a fairly efficient bottling system (and a good brew partner), IMHO, and from dishwasher to capper is a snap...so the bottom line is I've never had any problems with infection since I started using this technique. This may not be for everybody (like people living in water restricted areas, but slight modifications might work) but it seems to work for me.

Now a question...  
Why in the H am I getting low hydrometer readings on extract brews?? Am I just \*lame\* or what?? (no I haven't ruled out that possibility). The instructions that came with the meter are pretty simple, but the OG always seems to be low. The info in Line's BB of B (those formulas on page 149, I think) seem to produce the expected OGs, but who knows. I check the meter in 60F H2O and it is fine...I read a recent posting about problem readings so this isn't just my imagination (but then again the 60's were...). Any thoughts?Thanks in advance for any opinions or enlightenment.

From: CHUCKM@CSG3.Prime.COM  
Subject: sanitation and questions

Hi everyone...

I have a couple of questions and a few thoughts (about brewing)

1. What is the difference between aeration and oxydation?
2. Re: Sanitation.... How do the breweries handle this? Do they ever get bad batches that they must dump or do they have some magic way of salvaging....

Some brewers use open fermenters (Anchor, Pilsner Urquell, etc). Why don't they have sanitary problems. I would never think of fermenting in the open, but Pilsner Urquell does it in caves with no apparent problems.... Any comments?

3. How is alpha acid content measured and Can I easily do it at home for my home grown hops. Will the AA content of homegrown hops vary significantly from the published ranges for a given species.

Thanks in advance....

From: andre vignos <andre@Think.COM>  
Subject: recipe wanted

The last time I was in germany, the 1986 oktoberfest, I stopped up in Bamberg Germany to pick up a friend who was stationed there. We stayed a couple nights in the area and sampled some quality brew. There was one type that I absolutely loved but I have never seen any bottled form of it, much less a brewpub that serves it. It is served with a thin lemon slice in a pilsner glass and is a wheat beer known as "crystalweissen". Being german I understand what the name means(doesn't take a genius). What I was wondering was, does any body have a recipe for said beer?

From: Joe Rolfe <jdr@wang.com>  
Subject: Bring Back Beer from Afar

hi all

one method a friend in Canada uses - very well to boot - is to declare all bottles as Yeast Samples - for lab purposes, not for consumption.

to really do this you have to remove the labels (relabel with coded - home brew type to keep them identifiable) and add the yeast sample not for human consumption lab crap.

this friend makes trips to/from the US/Canada and Europe amongst others and has never had any trouble. i would investigate the exact rule that allows this type of duty free transfer - to expunge it upon the customs people.

if you seem to know what your talking about they leave you alone...

just another data point

Date: Mon, 31 Aug 92 15:05:27 EDT  
From: avalon!jm@siemens.siemens.com (Jeff Mizener)  
Subject: Oktoberfest, priming & siphoning

First, travel question:

When is Oktoberfest (the one in Munich)?

Other stuff:

I've had the bubbles-form-at-the-intersection-of-the-racking-tube-and-siphon-hose blues for some time now. I have used tiny hose clamps, cable ties (Ty-Wraps) and heavy twist ties to try to get a seal. The cable tie works well but costs a cable tie per batch. Does anyone have a reusable solution? We seem to have a lot of chemists out there... I know that the problem is caused by a siphon hose that's slightly too large, caused by what we in industry politely call "production tolerances". The tiny hose clamps work pretty well if you put them where the racking tube is \_straight\_. Any suggestions?

When people bulk prime, they add (something sweet) to the beer in the fermenter. Then they presumably stir it up. Which causes all sorts of gunk to be stirred up from the bottom. Do we all solve this problem by racking first to another container? (Primary > secondary > priming vessel?) Or what?

Neat idea for starting siphons: At my local homebrew dealer I saw a little pump humming away attached to a tube that went down inside a little 'mini carboy' (a gallon jug) to a thing with thousands of tiny holes in it out of which were streaming tiny bubbles. In the middle of the tube was a small disk-shaped thingy. In response to my question, it was explained that this thingy was a filter and the whole assembly was used to oxygenate beer during the early stages of fermentation. The filter keeps the nasties out. Cool. Now we use an orange carboy cap connected to the filter to the pump (a simple aquarium pump they said). Through the other hole goes the racking tube into the beer, with the siphon hose at the other end. An on-off switch controls the pump.

Overkill, right? I thought so. Sorry.

Cheers,

Subject: wooden kegs

The recent postings on old brewing techniques piqued my curiosity about the possible use of wooden kegs. Naturally, these were all that were available to earlier brewers. Wineries use them (old bourbon kegs sometimes) to age red wines for that oaky taste. Does anyone use wooden kegs to store beer? Would there be some taste advantage to doing so? How would you make them clean enough to use? I've read in books lamenting this century's loss of old-time country living in Britain sorrowful remarks that no one uses wood anymore only aluminium which (it is claimed) gives the beer a lifeless quality.

>WILL settle out. At that point, more sugar isn't the answer.  
>You may need additional YEAST. But again, the best solution is  
>to bottle after 7-14 days (take a hydrometer reading to know  
>when to bottle).

As with all these discussions, your brewing environment comes  
into play. I routinely leave my brew in the secondary for weeks  
and months (I have a porter in the secondary that has been there  
since April). As the proud father of a 27-month old and a 4  
month old, plus having other duties around the house, bottling  
may take a back seat to other activities. So, I keep plenty of  
secondaries around.

Anyway, I have never had a carbonation problem no matter how long  
I left it in the secondary, but then my basement never gets below  
55 and is mostly around 60 in the winter and 68-70 in the summer.  
If I put some bottles in the refrigerator too soon, then they  
won't be fully carbonated.

So, do what works for you, but try to isolate the important  
variables in your environment (is priming sugar being left in the  
sludge of your bottling bucket, are you storing bottles in the  
fridge, are the caps on tight, etc.?) and only worry about the  
right ones. I no longer worry about some aspects, but my dusty,  
moldy, mildewy basement requires that I not skip any sanitizing  
steps while I am racking down there.

That is what I use (actually, nowadays, I just buy the little  
white dots and write on them a two or three letter code).  
However, this works poorly when you have guests trying many  
different styles (say at a homebrew club meeting, or a party at  
your house), because once the caps come off, it becomes difficult  
to tell what is in each of those dozen bottles on the counter.

The basic concern with using ice is that it may be highly  
contaminated. There is often quite a bit of bacteria in a home  
freezer, not to mention the possibility of picking up strange  
tastes or smells.

I always boil up some water, put it in heavy plastic and cover,  
then cool then freeze. Result, sanitized ice you can use safely  
to cool your wort.

Subject: Extract quality

Well, I expect I am asking a lot, but it cannot hurt to try.

I am currently an extract brewer and have been buying whatever the brewstore I am shopping at carries in bulk, since it is both cheaper and I can get whatever quantity I want. I would like to try some other extracts, but I have a difficult time in what amounts to about double what I pay for bulk extract without knowing whether it would be better (or even as good).

So, what I was wondering was whether anyone had ever made a (semi)comprehensive survey of extract (kits) that are available, rating quality of beer made, characteristics of the extract, average price and whatnot (basically a Consumer's Report article on malt extracts).

Barring that, what extracts have you used that you like/dislike?

From: chuck@synchro.com (Chuck Cox)  
Subject: mashing in a jacket (and tie)

While I am trying to get some stainless false-bottoms for the AcoustiMash, I am also formulating the first recipe. I will be brewing a 10 gallon stout, probably around 1060 OG. I know its not exactly traditional, but its based on a recipe I really like.

In planning the mash, I ran into an interesting question involving heat loss when mashing-in. We know that you generally heat your mash water about 18 deg F over your initial mash temperature to accomodate the relatively cool grain. This assumes you are using an insulated mash tun.

The AcoustiMash has a substantial (>20gal) thermostatically heated water jacket surrounding the two tuns. The mash water comes from this jacket. Tests, extrapolation, and some wild guesses suggest that when full of water, I can expect about 1 degree F temperature rise per minute from the 1.5kW heater. Since the system heats much faster than it cools, it would be better to under-shoot than over-shoot the initial temperature.

My gut feeling is that I should simply set the thermostat for the initial mash temperature, and stir the mash well for a few minutes. I think the system has so much thermal mass that the grain won't have any serious effect on the equilibrium temperature. Theoretically, any minor cooling would be quickly handled by the heater.

Any comments?

From: bgros@sensitivity.berkeley.edu (Bryan Gros)  
Subject: SG temp. adjustments

Can anyone give me the adjustments to SG readings at different temperatures? I guess this scale is pretty non-linear?

I was trying to measure the gravity of my spargings last weekend and wasn't sure how much to adjust for the temperature. The measurements were interesting however.

After the sparge I got a reading of the wort of about 54. This would be at around 150F. I was shooting for about 75 (Christmas beer), so I ran to the store and got some bulk extract syrup. I figured I'd worry about where I lost my efficiency later, and added three pounds of syrup. The man at the store figured one pound of syrup would raise the gravity of 5 gallons of wort by 7 points. My gravity measurement after the boil and after the added syrup, and after cooling to 60F was 92! (for 3.5 to 4 gallons of wort). So I guess I didn't need to add the syrup after all. And my efficiency is not as bad as I thought. I gotta get rid of this electric stove though...

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: a different kind of fermentation

Hi ya'll. Well, I finally (after 3 weeks :-0 ) racked my steam beer. After tasting and taking a s.g., it is clear that the fermentation has not proceeded the way it usually does. Nothing really to worry about, but I thought I'd ask for your ideas about what you think is going on.

First, the recipe: I used 6 lbs of light dried malt extract, some crystal, some pale malt, 1 oz of 6.5 Northern Brewers for 50 min, 1 oz for 1 min, (I estimated about 30 or so International Bittering Units) and Wyeast 2035 (American Lager). It's a recipe I have made many times before. I ferment anywhere from the high 50s to the low 70s depending on time of year. It usually finishes anywhere from 1.008 to about 1.015, and is one of my favorite beers to brew.

After racking, I tasted the sample. Very good, but too sweet. A hydrometer reading confirmed: 1.022, higher than I expected after three weeks (although I once bottled at 1.028--fermentation definitely over--and it was my best batch ever. I had more hops that time, though.)

O.k. Differences in procedure between this batch and others of the same ilk.

1. The yeast had been frozen with glycerin. Usually, I make a starter from the package, or from bottle dregs. This is the first time I've ever used the glycerin. The yeast had (I guess) settled to the bottom. I poured off most of the glycerin and used the test tube dregs to make my starter. I don't know whether or not there was yeast suspended in the discarded glycerin. This time the starter smelled and tasted "woody"--usually it smells and tastes like sour apples.

2. I used Laaglander dried malt extract. Usually I use Munton & Fison.

3. This was the second batch I made using my new wort chiller. So I had a full boil (instead of three gallons), and I had a MUCH bigger cold break. Since I'm still learning about the chiller, I ended up with a lot more trub in the fermenter than usual. (No way I expected that much, so I didn't give it long enough to settle--and then I was too lazy to rack.)

4. I let it go three weeks in the primary. Usually, I rack after about four days, or if I'm lazy, let it go two weeks and then bottle.

There was a very vigorous ferment, but without as much blowoff or krausen as usual. Although what stuck to the shoulders of the carboy was denser than usual. For the first few days, the "woody" smell, rather than the "sour apples" smell emanated from the carboy. The beer has not cleared as well as usual (but jeez with all that trub, it's to be expected. The little orange thingy on the racking tube wasn't even big enough to clear the trub/yeast!)

So I'm interested in your opinions on why the gravity is still so high. My guesses are:

1. The freezer/glycerin mutated, degraded, or otherwise affected the yeast.
2. The heat knocked out the yeast. It IS a lager yeast, afterall, and I suppose there might have been a day or two up above 75F, but most of the time the temp was 68-73.
3. Laaglander is a lot less fermentable than M&F.
4. The quantity of trub and length of time spent on the trub adversely affected fermentation.

Right now, I'm leaning to a combination of 1 and 3. Since the starter smelled and tasted differently, the yeast was obviously somehow different. Also, I bet the extract is less fermentable, although I have no experience with Laaglander, so I don't know.

Anyway, my current plan is to let it go another week in the secondary. The sweetness doesn't bother me that much, because I can always doctor it up with a little isomerized hop extract before bottling. I suppose I could pitch some more yeast, but right now I'm inclined to RDWHAHB. On the other hand, I AM curious as to what you folks think is going on here. Like the one guy's sig file says, when I stop learning, bury me.

Subject: keg priming

Well, the folks on R.C.B couldn't help me with this, so I'll ask here.  
(Actually, I would have asked here first, but I didn't have my  
digest address handy.)

We all know that when naturally carbonating a Cornelius keg, you  
decrease the amount of priming sugar--like down to 1/3 of a cup,  
rather than the usual 3/4 c. for bottles. My question is this: Why?  
My reasoning is that five gallons of beer is five gallons of beer,  
and the 5-6 psi you use for sealing the seals and dispensing the  
beer shouldn't make that much difference. Does it? Or is there  
some other reason?

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: Re: Marcato Marga Mullino

Darren asks about how I modified the roller

Yes basically the grooves ran from one of the roller to the other along the long axis of the roller, as Darren accurately depicted.

I only put 4 grooves into 1 of the 2 top rollers. These grooves were placed at right angles (i.e. evenly distributed) about the roller. I considered using as many as 8, but things seemed to work well with only 4 so I stopped there. I think if you added too many then you would reduce the surface area without grooves, which does the crushing. The crush occurs between the top 2 rollers and the third (bottom) roller.

I disassembled the unit to put the grooves on, but by popping off the plastic hopper up top the rollers are directly accessible (it is made to pop off without breaking...) and you can just pick one of the 2 top rollers and score it right in place with the unit bolted to a bench. Score a groove, rotate the rollers 90 degrees, score a groove and repeat.....

From: SLK6P@CC.USU.EDU  
Subject: Bacteria on the Hands

There was a note in the last HBD about the use of hands on siphon tubes, and the bacteria on them. I don't recall who it was but he described his science teacher's growth experiment.

The claim that makes me cringe is that of "hands having a natural bacteriocide". There is some truth to this, but it is a bit off and potentially dangerously misleading.

FYI: There are two major classes of microorganisms found on hands (skin)  
Resident= the normal flora of the hands (bacteria, yeasts, fungi, - these are generally harmless, and difficult to remove.) Transient= "passing" microbes often picked up from other surfaces. Are generally easier to remove and can be potentially pathogenic (depending on the type/source). There is some truth to the "natural bacteriocide" in that the resident microbes can actually serve some protection from transients by outcompeting them for nutrients and even producing inhibitory metabolites.

The real problem here: is that transients come off easily. That can mean into your beer or on your siphon tubes. If you eat a salmonella covered chicken sandwich, then dip your hands in your brew, you're asking for trouble. In the same respect, picking your nose, scratching your butt, petting your dog- can result in similar transfer of "bad bugs".

My suggestion: Don't be paranoid, be sensible. Wash your hands thoroughly before contacting your beer/beer implements. Dipping them into your chlorine solution wouldn't hurt either (unless it's REALLY strong!). If you are worried (first, don't be...) then use a scrub brush, and wash down several times. Use common sense and sanitary practice. Don't change the baby's diaper as you bottle your beer. But do not believe that your hands are naturally sterile and "protected" from picking up bacteria. You are a jungle of microorganisms. From your hair to your toe nails You contain a plethora of bugs you probably don't want in your beer. (this does include your breath btw. Just as you wouldn't want to sneeze into a carboy, its best to avoid puffing in your beer too.) If you don't believe me- get a plate of rich medium and stick your finger on it. Then count the number of colors/shapes/sizes of growth which appear in a week. It's impressive.

Another note: For culturing yeasts. I would highly recommend the use of flame ( a good time for flaming...) on such things as inoculating loops, test tubes etc. Rinsing them with chlorine is not always a good idea.  
1. You don't want chlorine solutions contacting the yeast culture.  
2. Chlorine can damage inoculating loop metal, and other metals...etc.  
Besides for ~ \$10-15 you can get a small propane torch and tank of gas to

sterilize utensils/glassware. Alternatively- dipping into EtOH, then burning the EtOH will effectively sterilize many surfaces. (Esp glass rods). Gas flames are a common piece of equipment in any micro lab. The sterile box sounded like an easy thing to create. I just use the desk in my bedroom sprayed down w/lysol and wiped with EtOH. It is away from the bathroom/kitchen "cultures" of wild bugs. It is also a good

idea to turn of fans, close windows, or doors to minimize movement of air.  
A small propane burner takes up less space, and a good room probably do more for me than a sterile hood would (I have several at work/school- but feel comfortable with a careful technique, decent space, and some common sense)

Enuf bantering. Hell- just Brew! John Wyllie SLK6P@cc.usu.edu

From: hiroki@limerick.cbs.umn.edu (Hiroki Morizono)  
Subject: Hydrogen peroxide to sanitize stuff.

I've been using peroxide (the kind you get in the drugstore, not the 30% stuff you can get in a lab) to sanitize my goodies lately, but I haven't read anywhere about it--I just clean out my bottles with water and a scrubber, then pour some peroxide into one, and shake, pour it out into the next, till I have enough for a batch. Then I just drain the excess, and put the bottles in a warm--not hot--oven till they dry. Probably breaks all the H<sub>2</sub>O<sub>2</sub> into H<sub>2</sub>O as well. I wipe out my fermenter with a Kimwipe or paper towel soaked in fresh peroxide, and then rinse with boiling water. Gloves are important :-) ratty clothes are good too.

I was wondering if anyone else does this--It's a lot easier than rinsing out bleach.

From: cestes@argos5.DNET.NASA.GOV (Chris Estes)  
Subject: Halifax/Yeast Collaboration

Hi all...

I've got two questions for the collective wisdom:

- 1) I'm going to be in Halifax, Nova Scotia in a few weeks. Are there any points of beer interest there?
  
- 2) Regarding the use of multiple strains of yeast... I'm planning on doing a barleywine soon and would like opinions on a strategy I've used before with good results. I previously made a barleywine using 12+ lbs of extract (syrup and grain combination). I was shooting for a high alcohol content, but with a traditional ale flavor. I pitched Whitbred ale yeast and let it ferment (actively) for 4-5 days. As this began to calm down I pitched champagne yeast (supposedly alcohol tolerant) to finish the job. My reasoning was thus: My normal ale yeast would make the beer taste like my usual ale, and the champagne yeast would further raise the alcohol level without affecting the taste TOO much. Am I wasting my time with such a procedure? Am I doing anything wrong? Is my reasoning (based purely on conjecture) anywhere close to reality? etc., etc., etc...

Well, we all know where Bayreuth is by now, don't we? Now if I could just figure out where Munich is.....:-)

The original posting about Maisel's products asked about the six-pointed star that occurs on the label of their Dampfbier. I don't believe that the question was answered.

On page 13 of Michael Jackson's "The New World Guide to Beer" there is a picture of an engraving of a brewer whose head is surrounded by a six-pointed star. According to Jackson, the star is the symbol for alchemy and was frequently used by brewers. Certainly, it must have seemed magical to the average man that a brewer could take grain and turn it into ale.

From: man@kato.att.com

Subject: Jokes, efficiency revisited, Chore-Boy, cold break, Bev-Con kegs

In Hombrew Digest 959, Jack Schmidling says:

>I think I had enough fun with this just to let it drop.

Then, why didn't you let it drop? You just had to get the last word in, didn't you ?

>Suffice it to say  
>that I took my lumps from my Milwaukee beer and thank those who defended it  
>and grin at those who trashed it.

>And yes, "conspiracy" is a fun trigger word and all I can say from the  
>reaction is that it was either a lousy joke or a totally ineffective  
>conspiracy... take your pick.

Come on, Jack. Your article about the "conspiracy" was not taken as a joke by this reader, nor by the others who I correspond with off-line. Whenever you get effectively proven wrong in this forum, you call foul, say "let it drop", and then say it was only a joke. Only this time, you left out the "I guess I need to use more smiley faces in my posts" part.

Now for something new, revisited: Yield

For a while now, I've been using points/lb/gallon. I realize this works best with a single grain type, but it can be adapted to mixed grain. Anyway, recently, Russ Gelinas said to use the theoretical maximums found in literature or (what he uses) the Brew Recipe Formulator. Now, I have this tool, but I hadn't used it yet. So I looked up Pale Ale Malt. It says 1.036. Is this the theoretical maximum ? Not according to Terry Foster in his Porter book, which I just reread. He says (talking about Pale Ale Malt and Klages, loosely paraphrased) "the best a homebrewer can hope to do is 36 points/lb/gallon, which is 80% of the theoretical maximum." This make the maximum 45. So, where are you people getting your maximums from ? I used the numbers in the BRF for my Porter and I get 96.6% efficiency. If I assume the numbers in there are really 80% of maximum, then I get 77.3% efficiency.

This brings up the discussion of efficiency claims by people on the digest. When you say: "I let my sparge go 90 minutes one time and I got 90% efficiency. WOW!", is that 90% of the theoretical maximum or is it 90% of the implied homebrewers maximum ?

For the record, my brew was a modified Redcoat's Revenge Porter:

For 13 gallons (US):  
20.75 lb Pale Lager Malt  
11b 60L Crystal  
11b Cara-Pils  
1.2 lb Chocolate  
5oz Black  
2.25 oz Chinnok 12.6 AAU 80 min  
1oz Cascade10 min  
.75 oz Kent Goldingsteep  
WYeast American Ale  
OG 1.062

I had a 2.5 hour sparge (remember the brew length)

I want to thank Kinney for his Chore-Boy/grain bag filter idea that I first read about, oh, 3 years ago. I tried it this time and there is no looking back. Using this method, there is no need to change your efficiency calculations to claim lost wort in the bottom of the brew kettle. You get every drop. Absolutely amazing.

Now 2 questions. I began using a counterflow chiller 3 batches ago. The last two, I chilled into my mash tun to allow racking off of the cold break a few hours later. When I racked it, there was no break material. My wort out temp is 62F. How long does it take for the cold break to precipitate out ? I will add that I rack by opening the ball valve on the bottom of my mash tun. I realize it is possible that the break runs into the fermenter along with the wort, but something should be there. If it takes longer, then claims for immersion chillers having the advantage of racking off the cold break are probably over stated.

Question 2: When I chilled my recent porter, my wort was oxegynated by liberal splashing. This caused much foam to appear that tasted extremely bitter. What is this stuff? Should it be allowed in the fermenter ?

I've got something else to add: Bev-Con International sells new and used soda kegs. Right. Big news. But they sell 3 gal kegs for 29.50 and 10 gal kegs for 36.50. All plus shipping and \$4 COD. They come with relief valves. I bought one of each. Good stuff.

Well, I've rambled on enough.

From: Jon Binkley <binkley@beagle.Colorado.EDU>  
Subject: oxidation vs. aeration, open fermentation

CHUCKM@CSG3.Prime.COM wrote:

>What is the difference between aeration and oxydation?

Oxidation is a chemical reaction wherein one molecule loses electrons to another molecule. The former molecule is "oxidized" the latter molecule is "reduced." Frequently, the molecule causing the oxidation is oxygen itself; e.g. the oxygen gets reduced at the expense of your precious beer molecules, which get oxidized, and your beer tastes lousy as a result. For our concerns, oxidation happens when very hot wort is overexposed to oxygen, or when fermented-out beer is exposed to too much oxygen before botteling.

Aeration is the process of introducing dissolved oxygen into a solution; i.e., it's a mixing, not a chemical reaction. You WANT to aerate your wort after it has cooled down. If you do it while it's hot, oxidation is promoted. Aerated wort helps the yeast get off to a good start; they need an aerobic growth phase to build their numbers before they go into anaerobic fermentation.

>Some brewers use open fermenters (Anchor, Pilsner Urquell, etc). Why >don't they have sanitary problems. I would never think of fermenting >in the open, but Pilsner Urquell does it in caves with no apparent >problems.... Any comments?

It's a numbers game. The brewers add a huge number of active yeast cells which get off to a quick start. There's no question that molds, bacteria, wild yeast, etc. fall into open fermentation tanks; but they are simply overwhelmed by the  $10^6$  to  $10^9$  fold excess of the desired yeast cells. After the beer is fermented out the alcohol suppresses most microbial growth.

Another seeming paradox of open fermentation which confused me for quite some time is: given fermentation is an ANAerobic process, how can it take place in an open, aerobic environment? The answer is that our clever friends the yeast only turn on their mitochondria when they really need to. In a sugar rich environment (like unfermented wort) the yeast get all the energy they need from anerobic glycolysis (a.k.a. alcoholic fermentation). The beasts do a quick molecular cost/benefit analysis and decide that while aerobic respiration is possible, the extra energy obtained from it isn't worth the cost of building more mitochondria to do the dirty work. In a low sugar, aerobic environment, glycolysis alone won't provide sufficient energy and they fire up the ol' Krebs cycle. This applies to the "cell growth and maintenance" phase of the yeast cell cycle. When the yeast are in their heavy-duty reproduction phase, like right after you pitch them, they need the extra energy and so go into aerobic respiration, even at high sugar levels, until they reach a limiting cell density.

Smart critters, huh? And you thought they just stupidly plodded along and made beer at your bidding!

Sam Smith's still casks their beer in wood. They even employ  
coopers at their brewery to construct said casks. As for sanitation,  
they just scrub 'em out really good. As with all British  
"real ale" their cask conditioned products are intended to  
be consumed quickly- i.e., within weeks of keggings- so while  
the casks are probably infected the beer disappears too quickly  
for it to be a problem.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: "For a couple of pins," says Troll, and grins ...

Long ago and far away (12 years ago in England, to be precise)  
I worked for a while pulling pints in a pub. It was a  
Wadsworth's house. I recall we usually got 6X in kilderkins and  
Old Timer (seasonal) in firkins. If memory serves me correctly:

1 pin = 4.5 imperial gal. (=5.4 US gal, approx. 20.4 litres)  
1 firkin = 2 pins  
1 kilderkin = 2 firkins  
1 barrel = 2 kilderkins  
1 hogshead = 2 barrels

Any mistakes here? Does the sequence continue?

Cheers,  
Rob

From: "CBER::MRGATE::/"A1::RIDGELY/"@CBER.CBER.FDA.GOV  
Subject: Scottish Ale Recipe

From: NAME: Bill Ridgely  
FUNC: HFB-300  
TEL: FTS 402-1336 <RIDGELY@A1@CBER>  
To: SMTP%"HOMEBREW@HPFCMI.FC.HP.COM"@MRGATE@WPC

This is in reply to Mike Gauland's posting of last week requesting a recipe for Scottish Ale. One of my all-too-numerous passions is for single malt Scotch whisky, and I belong to the Washington, DC organization called Cuideagh O Corn O Uisgebeathe (loosely, the Society of Tasters of Whisky). Most the meetings are dedicated to the fruits of the pot still, but once each year, we set aside a day for lighter fare and taste the Ales of Scotland.

This partial-mash recipe is specially brewed for the occasion. It represents a "missing link" in what is actually a broad range of ales produced in Scotland, from the relatively low-alcohol 60 shilling (60/-) "Light" (with an O.G. of 1.030 - 1.034) to the traditional, full-bodied 90 shilling "Wee Heavy" (with an O.G. of 1.070 and above). In between these extremes are the 70/- "Heavy" (at O.G. 1.035-1.039) and the 80/- "Export" (at 1.040 - 1.052).

Unfortunatly, no commercial beers of Scottish origin are available in the U.S. (at this time, anyway) in the 60/- and 70/- strength. Belhaven is the only one available at the 80/-. The 90/-'s, are fairly well represented by the old standard, McEwan's, as well as McAndrews (a somewhat paler version), and what I believe is still the most expensive beer available in the U.S., Traquair House, which retails for about \$9 per 10 oz bottle (Cases can be had for a bit over \$100 if your dealer is in a good mood).

To my knowledge, there is no beer produced in Scotland in the gravity range of 1.055 - 1.070, so I made my own to 1.060 and called it "Wee Export". It uses traditional black malt for color and a bit of brown sugar to boost the sweetness (per the style). Also, the mash was conducted at a somewhat higher temperature to bring out unfermentable sugars, and the yeast had a relatively lower attenuation than some of the other standard ale yeasts on the market.

The beer ages well and is still wonderfully drinkable after a full year in the bottle. Slainte!

Subject: Scottish Ale Recipe

OLD BEULAH WEE EXPORT  
(An 85/- Scotch Ale)

Ingredients for 5 Gal:

2 lb 2-row Klages Barley Malt  
1/2 lb 60-L Crystal Malt  
1/4 lb Black Patent Malt  
1/4 lb Flaked Barley  
5 lb Amber Malt Extract Syrup (I use American Classic brand)  
1 lb Dark Brown Sugar  
1 oz Northern Brewer Hop Pellets (6.5% AA)  
2 oz Fuggles Hop Pellets (4.5% AA)  
3 tsp Gypsum  
1/4 tsp Irish Moss  
Wyeast #1028 London Ale Yeast (In 1 qt sterile wort starter)  
3/4 cup Corn Sugar (For bottling)

Step Mash (Temps in Degrees F)

Crush grains and add to 3 qts water (with gypsum dissolved) at 130.  
Maintain mash temperature at 125 for 30 min (protein rest). Add 3 qts of boiling water to mash and maintain temperature at 158 for 1 hour (saccharification rest). Drain wort and sparge grains with 5 qts water at 170.

Boil

Add to the wort in the brewpot the malt extract and brown sugar. Bring to a boil. After 30 min. of boil, add 1/2 oz of Northern Brewer hops and 1/2 oz of Fuggles hops. After 15 more minutes, add an additional 1/2 oz of each hop. Boil for a total of 1 1/2 hours. Ten minutes before the end of the boil, add the Irish moss. Five minutes before the end of the boil, add 1 oz of Fuggles hops (for aroma).

Fermentation

Cool the wort with a wort chiller and add to the primary fermenter with sufficient water to make 5 gallons. Pitch yeast when temp of wort is below 75. Ferment at 65 for 5 days. Rack to secondary and ferment for 15 more days at 65. Bulk prime with corn sugar before bottling.

OG - 1.060  
FG - 1.015  
Alcohol - 6.0% vol (4.8% wt)

Subject: Christmas Ales - need a recipe

I would like to start a spiced Christmas Ale pretty soon and am looking for a recipe that approximates Sam Smiths Winterfest (I think that's the right name, anyway).

I would prefer an all grain recipe, and something that is fairly light on the cloves and ginger.

Also, will this mellow out properly in time for November/December drinking, or am I behind the power curve?

thanks in advance,

Jay

Subject: Chuckm's Questions

In HOMEBREW Digest #959, CHUCKM asked:

> 1. What is the difference between aeration and oxydation?

Aeration is the process of dissolving air into a solution (wort, in this context). It is not a chemical change. Oxidation, on the other hand, is a chemical change. Aeration is required if you need to increase the population of yeast in the ferment, as we all do, unless you're pitching massive gobs of yeast. Oxidation, on the other hand, is worth avoiding.

The specific compounds that can be the most troublesome are the melanoidins, pigments produced in the malting and mashing processes. They tend to mediate the oxidation of alcohols into aldehydes, so it's in our best interests to have them in the reduced state. If the wort is cool or cold, it can be aerated without oxidizing the melanoidins. If it's hot ...

The best treatment of the subject that I've seen is in George Fix's "Principles of Brewing Science", which, I believe, should be on every homebrewer's bookshelf.

> 2. Re: Sanitation.... How do the breweries handle this? Do they ever  
> get bad batches that they must dump or do they have some magic way  
> of salvaging....

Sure, it happens. The Big Guys constantly sample the unfinished beer, and all have thresholds for a variety of biological contaminants, beyond which the beer is sewerred. If the infection is less severe but still detectable, the beer is blended to dilute the defect below sensory thresholds.

> Some brewers use open fermenters (Anchor, Pilsner Urquell, etc).  
Why  
> don't they have sanitary problems. I would never think of fermenting  
> in the open, but Pilsner Urquell does it in caves with no apparent  
> problems.... Any comments?

Sure. Anchor has all their fermentors in rooms fed by positive-pressure, sterile-filtered air. Not much is likely to go wrong there. Concerning the many breweries using open fermentors without such precautions, consider this: hop tolerance is not all that common among microbiota. If the resident critters are not hop tolerant they may fall in the wort, but they'll die micro-screaming. If they make no contribution at all, the brewer will see no reason to go to closed fermentation. In some cases, the contribution they make can actually be positive, and there are quite a few Belgian breweries that specifically exploit the environmental biota.

> 3. How is alpha acid content measured and Can I easily do it at home  
for  
> my home grown hops.

The "Readers' Digest" answer is no, you can't do it. Anyone who comes up with a really excellent way to do this that doesn't require a home-grower's entire crop will have the undying gratitude of thousands. Well, maybe dozens. Well, maybe you and I and a couple

of others ...

> Will the AA content of homegrown hops vary significantly  
> from the published ranges for a given species.

You can take that to the bank. In most cases, it will be much higher in your homegrown hops than in the commercial equivalents. The most experienced hop grower in our club says it will be twice as high, but his hops are so outstanding that I suspect him of trafficking with Dark Powers ...

Subject: Crystalweiss, Oktoberfest, and Priming

In HOMEBREW Digest #959, inquiring minds wanted to know! :-)

andre vignos <andre@Think.COM> asks:

>Subject: recipe wanted

>

>

>The last time I was in germany, the 1986 oktoberfest, I stopped up in  
>Bamberg Germany to pick up a friend who was stationed there. We stayed a  
>couple nights in the area and sampled some quality brew. There was one  
>type

>that I absolutely loved but I have never seen any bottled form of it,  
much

>less a brewpub that serves it. It is served with a thin lemon slice in a  
>pilsner glass and is a wheat beer known as "crystalweissen". Being  
german I

>understand what the name means(doesn't take a genius). What I was  
wondering

>was, does any body have a recipe for said beer?

I'm truly amazed that the brew you mentioned was not Schlenkerla Rauch-  
bier. Kristallweizen (or "crystalweissen") is just your standard  
clarified

Bavarian wheat beer, "kristall" referring to the crystal-clarity of the  
pure golden (usually) brew, and there are plenty of examples of those in  
Bavaria, especially southern Bavaria and (of course) Munich. Franconian  
examples also are numerous, including Tucher, EKV, and Wurzbürger  
Hofbrau.

Part of the secret is the wheat/barley proportion in the malt - the wheat  
gives the beer that distinct tangy flavour - but the real secret lies in  
the yeast. You can use any of a number of extract-based or full-mash  
recipes to make a good, basic pale-golden wort, and after cooling, pitch  
with the S. delbrueckii yeast. Wyeast #3056 is a mixture of a more  
common

top-fermenting strain with S. delbrueckii, and the results will vary a  
bit,

but you can come close by using moderately elevated fermenting  
temperatures

(especially during the primary) to get all those esters and phenolics  
forming. By the way, it is not at all inappropriate to refer to these  
beers as "deliberately infected" - but this is deliberate in the same way  
that Berliner Weisse is deliberately infected with Lactobacillus. The  
end

result is unique flavour, and deliberately encouraging the beer to form  
flavouring compounds you may normally try to avoid.

See Dave Miller's latest book - among the many recipes for all the  
world's

beer styles, he gives both extract-based and full-mash recipes for a  
good,

estery Bavarian-style wheat beer. Whether you want to clarify / filter  
it

to obtain a true "kristallweissen" is entirely up to you!

avalon!jm@siemens.siemens.com (Jeff Mizener) asks:

>Subject: Oktoberfest, priming & siphoning  
>  
>First, travel question:  
>  
> When is Oktoberfest (the one in Munich)?

Oktoberfest ENDS on the first Sunday in October, and begins two weeks before that. That puts it at September 20 to October 4 this year.

>When people bulk prime, they add (something sweet) to the beer in the >fermenter. Then they presumably stir it up. Which causes all sorts >of gunk to be stirred up from the bottom. Do we all solve this problem >by racking first to another container? (Primary > secondary > priming vessel?)  
>Or what?

Primary > secondary > priming vessel is indeed the answer, and although we are usually trying to avoid oxidatation, judicious and careful racking of the fermented wort into a priming vessel is useful, and not at all a bad idea. While the beer is siphoning out of the secondary (a carboy in my case), one can slowly add the sterile ('cause it was just boiled :=) priming solution to the wort as it fills the priming bucket, obtaining (usually) a reasonably even distribution of the priming sugar into the almost-beer.

This assumes bottling, of course, and I make the assumption here that there is no CO2-based equipment lying around, which changes the rules a bit, especially if you have a kegging operation.

See y'all in a couple of weeks - I'm off to Central Europe for history, culture, and a lot of mighty fine beer-drinking! U Fleku, here I come! :-)

From: sherpa2!BMOORE.ELDEC@mailsrv2@sunup.West.Sun.COM (BMOORE)  
Subject: RE: Propane Tanks

Another note regarding propane cookers and tanks:

NEVER, NEVER store your propane tank inside your house. When finished brewing, banish the tank to the porch, patio or the flower beds! Propane tank valves contain an overpressure relief pop-off valve. This valve will vent propane if the tank is relatively full of liquid (which is incompressible) and it gets too hot (the liquid expands). If such venting occurs indoors, vapors can collect in a low spot and need only a source of ignition before...KABOOM!  
By the way, the same advice applies to car trunks... If you get your tank filled, throw it in the trunk and leave the car parked in the sun, overpressure venting can occur... with the same results!

Happy Brewing!  
Barry Moore

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: Another brewing mishap

Talking about brewing mishaps? Stand back and gimme some room!

Once upon a time i was making some yeast starters. Pretty simple process. Make some wort, fill up some mason jars and boil in a water bath. A real no-brainer. At that particular time my setup was spread out. I would prep the masons in the kitchen and at the same time boil the wort in the basement. When ready, I would bring the wort upstairs into the kitchen to fill the masons. The basement stairs are positioned such that they come up from the basement and meet a landing with the back door, so you can literally walk up the stairs and straight out the back door.

On that fateful day as I was carrying the four gallons of boiling wort up the stairs, I was thinking to myself "Boy it sure would be a mess if I dropped this pot". No sooner, I stumbled near the top of the stairs, dropping the you-know-what on the landing.

It's interesting how the mind works in life-threatening situations. Everything seems to move in slow motion. Its as if the brain can't believe the mess that the body has gotten the two into so the brain decides to slow down the visual images as some form of mental denial.

I watched the pot hit the floor and dump out in slow motion. The pot spilled in such a way as to release the wort in one mass. As this Wave of Wort moved away from me and crested towards the back door, I thought to myself "If I open it, they will come". Roughly translated, if the back door is open the wort should proceed to flow out the door into the backyard, saving me much cleanup. The back door was already open but the storm door wasn't. So I quickly vaulted over the Wave of Wort, fully expecting to land face-to-face with the storm door and simultaneously hitting the door latch so as to have my momentum push the door open thereby allowing the door, myself and the Wave to pass through the doorway in said order.

As I landed at the storm door and hit the latch, it became apparent that the storm door was locked. My momentum was such as to carry me not through the doorway as expected but smack into the storm door. Thus, having formally introduced my face to the storm door, I proceeded to unlock and open the storm door, exit the house and remove myself to higher ground.

Yet to my shock and horror the doorsill was too high for the Wave of Wort to pass over so with somewhat weaker force yet equal determination the Wave reversed course and proceeded towards the basement stairs. It is at this point that I admitted defeat, realizing that some higher force was at work against me. I watched with remorse as the wort flowed down the stairs, cascading from step to step like some perverse Slinky. I cursed all within earshot. I even cursed my old nemesis Sister Sharon, my Catholic grade school principle.

Only a quart or so reached the drain near the bottom of the stairs. The rest of the wort had coated the stairs and the workshelves under the stairs. The dry cat food in the dish on the floor near the steps was no longer dry.

Damage assessment after the flood was painful. For tripping UP the stairs I received a gouge on the shin and a black-and-blue big toe. For

kissing the storm door I received a bloody nose and one pair of bent eyeglasses. For ineptitude I lost one can of extract. For General Principle I received one wasted afternoon.

chris campanelli

FOLLOW-UP: This occurred in winter. Come spring, the ants not only found what dried wort I had missed during cleanup but proceeded to tell all their friends within a five mile radius. It got so bad we had to call a professional exterminator. The house stank from insecticide for a week. Needless to say, ALL brewing related activities have been banished to the garage. :(

From: Richard Hargan <HARGAN@UMDD.UMD.EDU>  
Subject: Brewing disasters

Well, not exactly a disaster - a major embarrassment.

I had been dating a woman for a few weeks and introduced her to the wonderful world of homebrew. Having recently finished a batch (my 13th, I think), I left a case over at her condo.

When I dropped by for dinner one evening, I found her in the kitchen with a worried look on her face and a mug of beer on the counter.

"I don't think I poured it right", she said. (I had explained to her that bottle conditioned beer required care in decanting).

"It tastes .... funny".

So, I poured a glass. I took a sip. Not bad, but then there was the aftertaste. Ah yes, the aftertaste.

You know the taste that is left in your mouth after heaving your guts up? This batch of beer had duplicated it.

We promptly dubbed it Bimbleman's ("When you want a beer real bad, we've got a real bad beer"), and fed the remainder to Mr. Sink.

Surprisingly, this experience did not turn her off to either homebrew or me, and we wound up married and brewing together. It did convince me to take sanitation more seriously in my brewing.

So, there was a happy ending.

Rich Hargan (hargan@umdd.umd.edu)

Date: 02 Sep 1992 10:01:35 -0400 (EDT)  
From: Frank Tutzauer <COMFRANK%UBVMS.bitnet@CUNYVM.CUNY.EDU>  
Subject: Brewing mishap

Last July, some friends and I (there were six of us) attended the Winterhawk Bluegrass Festival in the Berkshire mountains. We were miles from civilization and it was to be three days of fun and sun and some really great music. I had also just bought my first Cornelius kegging system, and this trip was to be its inaugural run. Having never kegged before, I didn't really know what I was doing (I still don't know what I'm doing), but I figured what the hell I'll fake it.

When we got to the top of the mountain, all of my friends oohed and ahed at the shiny copper coils in the jockey box. They were suitably impressed by the sophisticated dials and gadgets, and awed by the industrial-looking tanks and containers.

Much to my amazement, the kegging system and jockey box worked far better than I had expected. Except for one detail. I had used a hose barb to attach the fittings on the keg to a vinyl hose which ran into the jockey box. Well, let me tell you it wasn't sufficient. A day or two after we arrived, we were all sitting around under our tarp, enjoying some Winterhawk Amber. We had just finished a wonderful lunch. Someone was playing guitar. The afternoon was beautiful. Bliss....

And then, PFFFSSSHHHHHHOOOO!

A geyser of beer spewed straight up, and out, and seemingly everywhere. I jumped up and began cranking on the valve to the CO2 canister. It took me a second to realize that this was futile, of course. There was plenty of pressure in the keg to keep that beer spewing and spraying and oh my God what do I do now I'm getting soaked any ideas what now somebody help and then by a miracle I thought to disconnect the out fitting from the keg and the volcano stopped.

Of course everybody just roared with laughter, thinking this event was oh so funny. According to one of my friends, the best part was that once the beer geyser erupted, I evidently jumped up and shouted, "Yee ha," before diving into the fountain.

What had happened was the hose barb had come loose. I had thought to bring some hose clamps, so once I figured out the problem it was easy to fix. And we still had plenty of brew left, so it wasn't a total disaster. But now we were all beer-sticky. Our hair was sticky, our clothes were sticky. The ceiling of our tarp, the guitar, the keg, our supplies, everything--sticky, sticky, sticky.

But the music was good.

Subject: ne head

Heard about Quayle Ale? It has no head.

Same with my alt. The recipe included 5 lbs. munich, 2 lbs. pale, and 1 lb. wheat malt. I did an one-step infusion mash. Would a protein rest have helped with head retention?

Had an odd ferment with my latest, a porter. Used the slurry from the primary of the above alt, OG of the two were similar. Yeast was Wyeast German Ale (1007?). With the alt, there was a \*thick\* krausen, and much blowoff. The krausen stayed a good 4" thick for a week, with much obvious ferment activity in the carboy. With the porter, the krausen peaked at 2", no blow-off, and went down after 2 days. I thought I had a stuck ferment, but it had actually fermented down to 1.016 (from ~1.040) in those 2 days. What gives? Did the yeast adapt that quickly to my environment?

From: c\_vandev@hwking.cca.cr.rockwell.com (Craig Vandeventer)  
Subject: Brewing Disasters

Well, since someone out there wants to hear tales of horror, here is mine:

It all began way way way back in the early 1980s when I was a grunt engineer working for Boeing in Seattle. I was just starting out in the home brewing hobby when the Boeing Winemaking/HomeBrewing club was to hold an auction of wine making and beer making supplies at one of their meetings. I thought this would be a great opportunity to pick up one of those great big jars they show in "Better Beer and How to Brew It"(carboy). Well, it just so happened that there was one there. It was an older carboy with smoked blue glass. The auctioneer claimed that it was an antique carboy. So I ended up bidding the highest for the antique carboy(~\$30) and proudly carted it home. Boy, was I proud of that carboy. It was just the most beautiful carboy any home brewer could ever have.

My first brewing experience with God's carboy would have to wait since my wife and I packed up and moved to Cedar Rapids, Iowa. We rented a small 3 bedroom house with very light colored carpet(nice forshadowing, huh?). After a few months of getting adjusted to the less stressful lifestyle in Iowa I got the itch to brew a batch of beer. After a few hours of brewing and beer drinking I got everything into the carboy. I pitched the yeast and put an airlock on. I placed this beautiful carboy in the spare bedroom that we rarely entered(used it as a storage room).

The next morning, full of anticipation, I went into the spare bedroom to check on my creation. The airlock was flowing with goop and the goop was running down the side of the carboy onto the nice carpet. I quickly grabbed some newspapers and placed the carboy on top of the papers. The carpet had sustained minor staining but the papers covered that up so the wife couldn't see it to bitch at me about it. So now I thought maybe I should take the airlock off and clean it and then put it back on, but I would have to do that over and over until the goop stops coming out of the carboy(what the hell is a blowoff system, anyway?). I decided to leave that airlock on until the goop stopped flowing. I would replace it then.

So now I closed the door to the spare bedroom. It wasn't until 3 days later

that I remembered to check on how the brew was doing. Thinking I was going to replace the goopy airlock I went and grabbed a spare, filled it, and headed off to the spare bedroom. I opened the door to find that the carboy that was sitting on some newspapers 3 days ago was no longer there. Instead of a lovely carboy filled with fermenting beer there were shards of glass everywhere. God's carboy had turned into the carboy from hell.

Evidently, the air lock got glogged and would not let any CO2 to escape. But those little yeasties didn't care and happily munched away until BOOOM!! Not only was the nice light colored carpet a deep shade of brown, the walls had brown specks on them, the ceiling had brown specks on it, furniture had brown specks on it, EVERYTHING had brown crap on it! Several boxes of our belongings were ruined because the boxes help soak up the brown crap(sweet wort outside of proper containment vessels is defined as crap).

Well, after cleaning out the spare bedroom of everything I gave Stanley Steamer Carpet Cleaner a call. They came out and cleaned the carpet. After a few days the carpet turned a light shade of brown. Stanley Steamer came back out and cleaned it again for free since they didn't get it clean the first time. Once again the carpet turned a lighter shade of brown(tan). Stanley Steamer refused to clean the carpet again without me paying for it. We no longer live at that house and the owners never said anything about how one of the bedrooms has a darker carpet than the rest.

This story is why I never brew any more 5 gallon batches in 5 gallon carboys.

Subject: Badbrau

In the Chicago area last March, the Baterbrau brewery recalled/cancelled their spring batches of beer. As it turns out, the Elmhurst water works, supplier of B'brau's water, discovered intolerable levels of radium in the water supply. Residents were warned and instructed to take necessary precautions, and restaraunt businesses (beverage suppliers) were warned to correct/prevent problems that would resurface in their products. Coincidentally, this past summer has, from what I hear from hop growers, been a bit harsh on our well-loved flowers of the vine. The radium problem has since been solved, and all danger has, to my knowledge, passed. It does, however, strike me as amusing that such experienced brewers as these (the Baterbraumeisters) would experiment with alpha and beta rays as a substitute for alpha and beta acid resins!

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Mixed yeasts, bitter foam, assorted hop info

In HBD 960, Chris Estes asks about using ale and champagne yeasts for a barley wine. My friend, Perry Mills, has been using champagne yeast with ale yeast for several years with good results. His beers are extremely interesting in that he violates most of the current taboos and gets very good beer for his efforts. He uses large amounts of corn sugar (up to 1/2 of the fermentables), boils his specialty grains for hours after grinding them in a blender, gets very low hop utilization, and skims the foam off of his open fermenter. All of these things have been condemned in print. The most interesting part is that his beers do not have the "cidery" taste supposed to result from using lots of sugar. Most of his high-gravity beers are in a dry porter/stout style. His technique is extremely methodical and evolved as a way of improving his brews.

At any rate, he uses repitched yeast, Munton and Fison dry ale yeast and Red Star Champagne, all pitched together. As I recall, OG ~1.110 FG ~1.010. Very dry beer, with light body and roast malty tones. The primary is in a plastic garbage can, batch size is usually 10 gal. Perry skims the foam until no more is produced. I think this may remove some of the harsher flavors and higher alcohols. Perry insists that the ash that falls off his cigar when skimming is crucial to the success of the beer.

Then the beer is racked into 5 gal carboys. The secondary fermentation can take up to six months. My guess is that the ale yeasts reproduce faster than the champagne, and so are responsible for the primary fermentation, then the champagne just keeps chugging along.

For more than a year, I badgered Perry about his ingredients and methods, then I got some sense, tasted the beer and shut up. We now agree that if everyone made the same beer, the world would be a boring place.

Mark Nevar in HBD 960 asks about the bitter foam on his Redcoat's Revenge Porter. The bittering principles in hops, alpha-acids, are not very soluble in wort. Only a small portion gets isomerized and goes into solution, the rest falls out of solution with the trub and other precipitates. The bittering principles that are not in solution ride around on the CO2 bubbles. Blowoff foam and the scum that forms a ring at the top of open fermenters has a lot of these insoluble bitter resins in them. I've done some comparison brews between bucket and blowoff primaries. My impression is that the blowoff is slightly less bitter and has a smoother taste.

Carboys that have been used for blowoff primaries always have a lot of brown crud stuck to the top and neck. I've found that clear ammonia, 1 cup / 5 gal water gets it right off. Throwing a cup of cold water into the brewpot will stop a boilover in its tracks.

I really liked Chris Campanelli's disaster story. Another Great Moment in Brewing.

From: Greg.Winters@EBay.Sun.COM (Greg Winters)  
Subject: RE; Multiple yeast strains (was Halifax/Yeast Collaboration)

Chris Estes writes about using multiple strains (ale & champagne) for a extract barley wine -

Chris, I think you are on the right track. I also made one similar using wyeast Belgian ale yeast and champagne yeast. I might suggest that you give liqued yeast a try and this particular one provided great flavor. Just don't let the temp get to high. Here is my recipe -

DATE: 2/7/92

NAME: Breakfast Barleywine

INGREDIENTS:

14 lbs. Alexanders Pale Malt Extract  
2 oz. Black malt  
1 lb. Golden Brown Sugar  
1 lb. Honey  
2 1/2 oz. Hallertau N.B. plugs (7.5%) 90 minute boil  
3 1/2 oz. Fuggles plugs (4.2%) 90 minute boil  
1/2 oz. Fuggles plugs (4.2%) dry hop for 1 week  
3 tsp. Gypsum  
Wyeast Belgian Ale  
Vintner's Choice Champagne Yeast

BREWING NOTES:

OG: 1098  
SG: 1024

PRIMARY FERMENTAION TIME: 1 week TEMP: 63  
Very vigourous primary fermentation that took off within 12 hours.

SECONDARY FERMENTATION TIME: 5 weeksTEMP: 66  
Racked off trub and pitched liquid champagne yeast. Not much activity, the belgian must have done the trick. Still, there is some minor activity.

TASTING NOTES:

3/18/92 - Upon bottling, it is already delicious.

9/2/92 - Well I only have two left and probably should have let it age out  
for another six months, but it just wasn't meant to be...  
This was by far the best strong ale I have ever made. Color and taste is out of this world. I also found that it seems to fair better bottled  
in champagne bottles for some reason. Much smoother carbonation. Only problem is I have to find someone to split it with!

Luckily I have another batch going.

Take Care, Greg

Subject: a brew from hell

hi all,

well some of the stories of troubled brewing sessions got me thinking, heres one that could have been worse but.....

i was readying to brew up a good size batch, doing the calculations for hops, extract (yes i still am a lowly extract brewer), yeast amounts, boil evaporation etc.....

well started to bring the water to boil (lots), water was getting pretty warm as i began to dump in the extract, shit - forgot to put the hop screen in the outlet valve... major problem run off from the kettle would be forever without it... sunk the screen on a couple of copper wires, lined er up and wacked it into place with my trusty charismatic OAR. Great start dumping the extract, gas heat off, leave eletric running, a big can of syrup added. usually after adding i check the SG just to ensure i am on track (which i did) drawing off the sample, putting the hydrometer in - damn the hyrometer hit the bottom of the test jar an cracked the bottom. great i am nowhere near the sg i need, i'll not even be able to test the pre ferment...lets use the holder of the hydro jar wrong it melted the damn thing.... o well. add the dry extract as calculated and boil.....

hops added boiled all is well - so i only broke the hydro jar. set up the counter flow chiller, connect up the hoses to the fermenter, sanitize, flush, ready to go. start the yeast (dry type) in warm water. whirlpool, add irish moss - wait 30 min..... feed wort thru the chiller, check output temp -- oh no my yeast starter is foaming out the top of the jar, quickly run over to shake the foam back down, i feel something warm on my back side, well it is not warm any more, it is hot - really hot, i hear splashing, lots of splashing holy shit, oh no - i kick the pump/hose and it busted off the hot wort output nipple. wort hot wort spurting up from the pump hitting the ceiling, the back of my jeans. quick pump off valve closed - what a f\*\*\*\*\* mess 4 gallons of wort all over the floor. yeast foam all over the sink. relax, don't worry i don't think so....

i had another pump and cleaned up the mess all was well, actually the  
beer  
turned out to be not bad considering, .... my beer from hell - batch  
number 3  
got some other fermenters (glass carboy) added raspberry, blueberry and  
dry  
hopped another (4 different beers from hell). The BFD'ers liked them  
too!

so there is my story of disaster

>Subject: Cajun Cooker Enclosure

Aside from the renters and homesteaders, I have a hard time understanding the propane business.

What happens when you hook one of these things to natural gas? I presume they have an air/gas mixture adjustment... no?

>From: SLK6P@CC.USU.EDU

>Another note: For culturing yeasts. I would highly recommend the use of flame ( a good time for flaming...) on such things as inoculating loops, test tubes etc....\$10-15 you can get a small propane torch and tank of gas to sterilize utensils/glassware.

It may not be very elegant but a BIC lighter is probably as cost effective as one can get.

>Gas flames are a common piece of equipment in any micro lab.

I have often wondered about the "proper" method of flaming. It would seem that just passing through a flame would kill anything on the tool but on the other hand, the tool is a heat sink and the critter might not even get hot.

So to make sure, I heat the loop cherry red and the glass rod till I know it is hot. The problem is, if you then poke it into the yeast to transfer it, the yeast gets fried unless you let it cool. While cooling, it is in the unsterile air and one never really knows when it is cool.

So, the question, at last... is just passing through the flame sufficient?

And finally, I am getting about 3 quarts of juice from ten lbs of apples with

my crude crusher/press. Does anyone know what I would get if I invested  
a couple hun into a real one?

From: William Boyle (CCAC-LAD) <wboyle@PICA.ARMY.MIL>  
Subject: How dumb can I be?

OK I'll tell you how dumb I can really be. I ferment in a 5 gal water bottle with a 3/8" blow off tube (dumb). I use a 1 foot piece of copper tubing bent into a "J" with the long end in the stopper and a tube connected to the other end going into a bucket of water. I set this on my kitchen counter which is about three feet from the dinner table.

One morning I was eating breakfast before I left for work, with a batch bubbling away (yes it was bubbling, I checked it when I first got up). Sometime after I checked it, bits of hop pellets began to collect in the tube. The next thing I knew the stopper blew out spewing wort and stuff all over my kitchen and me. The carboy looked like a fountain. I picked up the stopper and tried to put it back on, which is like trying to screw a nozzle on a garden hose which has water flowing, this did not work. So I figured the tube was clogged, so I removed the copper tube and tried to put just the stopper in the carboy, now this is like getting the nozzle on the hose and opening it up, the foaming mess then shot up in a higher fountain hitting the ceiling. By this time I was wet and sticky (which can be fun :-), but I was not having fun) and the stuff was still foaming. I ended up waiting for the wort to stop foaming before I was able to put on an airlock, By this time I had lost (actually I did not lose it I knew exactly where it was :)) about two gallons of wort :-).

I know this is not as bad as breaking a foot or breaking your face but it still was no fun, especially since my wife did not find this humorous.

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: BRF malt ratings

The malt ratings in BRF are 100%, i.e. theoretical maximums. If you came up with an efficiency of 96.6% I think you might want to recheck your measurements. Imprecise malt weights and/or wort volumes can drastically alter an efficiency as can gravity readings at temps other than 60F. I'm open to rebuttal but I seriously doubt any homebrewer can achieve an efficiency of 90% or better. I'm in no way a great brewer but I have been brewing for six years. I can only achieve the upper 80's and that's with preground malt, rigorous pH control, slow sparging and the like.

As for what Terry Foster states about malt ratings, six different authors will give you six different answers. I pulled out a lot of hair trying to get a comprehensive list of malt ratings. Believe me, I understand your confusion. For a more definitive source I would suggest Doctor Bob's Amazing Wheel of Beer. Not only are the malt ratings more trustworthy but the Wheel is a fiendishly ingenious tool of its own right. The values in BRF are not written in stone. You have an editing option. Your's is the final word.

One of the problems with this whole rating system is that we are dealing with an agricultural product. Barley is susceptible to seasonality. Although malting companies hit the mark consistently, malt gravity contributions may vary from time to time.

The only source of information that I truly trust is the malting company. I usually buy malt in bulk. I contact the malting company and ask them what the current rating is for the malt in question. Malting companies perform laboratory analysis on every batch of malt that goes out. The information they provide is painstakingly accurate. If I buy a 50 lb bag of malt tomorrow, I'm not going to trust the malt rating that some self-proclaimed yahoo printed in a book 8 years ago.

Subject: Extract Madness

First, I'd like to thank everybody who offered help with my "Siphon Woes" problem. I haven't racked anything else since then, but I'll let y'all know how it goes.

I have a few questions about extracts because I like to brew in 3 gallon batches, so I end up playing with recipes a lot. I realize that the answer to them is probably "It depends", but I'd appreciate any wisdom you might like to offer me.

- 1) If you were going to make amber extract out of light extract plus specialty grains, how would you do it?
- 2) Same question, but making dark out of light extract.
- 3) I was told that liquid extract is typically less fermentable than dry extract. In other words, given two identical batches, with the same starting gravity, one made with liquid extract would have a higher final gravity than one made with dry extract. Is this true? [Note: I'm not talking about the fact that liquid extract contains water and therefore contains less fermentables than dry extract on a pound for pound basis. The person who told me this was talking about the proportion of fermentable/unfermentable sugars for each type of extract.]
- 4) If you had an all-grain recipe that called for, say, 8 pounds of 2-row malt, and you wanted to use light dry extract instead, how much would you use?

Thanks,  
chris

From: STROUD <STROUD%GAIA@leia.polaroid.com>  
Subject: B-Brite/Bleach

B Gorman asks whether non-chlorine bleach could be used instead of B-Brite to clean and sanitize.

It probably could, except that every package of non-chlorine bleach that I've ever seen in a grocery store has "fragrance" as an ingredient. If you want to make a batch of "Perfumey" Pale Ale, go for it.

\*\*\*\*\*

In HBD #959, C.V.Copas@lut.ac.uk asks:

>Is this suggesting that chlorine degrades with time, even in a sealed  
>container?

Actually, it's hypochlorite, not chlorine, in bleach that degrades with time. I used to use Chlorox as a reagent in grad school. We always titrated it before use. Fresh bleach would always be about 5.25% NaOCl (sodium hypochlorite), as is listed on the bottle, but this value would slowly decrease upon storage. Older bottles (~1 year old) often would be down in the 3.5-4% range.

Incidentally, sodium hypochlorite in bleach is produced commercially by the electrolysis of cold, dilute aqueous sodium chloride solutions under conditions where the sodium hydroxide and chlorine can mix.

-----  
The net reaction is:

The sodium hypochlorite produced is unstable at elevated temperatures and undergoes autooxidation-reduction to form halides and halates:

From: gummitch@techbook.com (Jeff Frane)  
Subject: Brewing Disaster #1

My net connection has been busted for almost two weeks, so I missed the call for brewing "mishaps". I've certainly had my share of those, but the worts (oops!) was early this summer. I'd spent most of the day putting together a six gallon batch of stout from a recipe which worked beautifully before. We were headed toward an OG of 1070, with four or five kinds of malt, three kinds of hops and much spousal anticipation. At the end of the boil, I hooked up the siphon hose to the wort chiller, clamped off the far end and stirred up a great whirlpool.

I had some reason for doing a little research upstairs, digging in a brewing text, during the 20 minute rest. When I wandered down to the basement, though, I was dismayed by an unexpected splashing sound. Running across the room I was in time to watch the last pint or so disappearing through the wort chiller, down the outside of the carboy and down the floor drain!!!!!!!!!! Naturally, I calmly cleaned up the mess, quietly put all my equipment away and returned upstairs to the bosom of my family. Any blood-curdling screams and loud slamming of metal reported by my neighbors is a lie!

As many times as I've struggled to get a syphon started, or lost one in the middle of an operation, I've never had one volunteer before.

Now I never leave the brewery unattended -- for anything.

From: JOE@syd.deg.CSIRO.AU  
Subject: homebrewing horror story

Date sent: 3-SEP-1992 09:07:48

Well, I hate to tell on myself but after Norm Pyle's request for more horror stories and Chris Campanelli's awesome blow-by-blow.....here's a true story:

I was going to brew the best all-grain pale ale Boulder had ever seen. I got my Corona set PERFECT, no flour just husks. The dough-in, protein rest, and mash went exceedingly well. The pH's and temps were great. All that remained between me and homebrew nirvana was a simple sparge and boil! The sparge started great, sweet clear wort, high gravity, awesome extract rates. Patting myself on the back I decided to call it "Attention to Details Ale". I was collecting the last two gallons of twelve, to add to the first ten that were starting to boil on my electric stove nearby, when IT happened. BLAM (and I mean BLAM) the whole kitchen was bathed in this very eerie ultraviolet/blue light and accompanied by a VERY loud POP. This brought me to my senses, and brought my wife running (thinking she'd finally become a REAL homebrew widow). I rushed to the stove and thought "huh, better not grab my lovely 15 gallon stainless pot right now, or I could get fried". So I ran to the other room, turned off all the circuit breakers I could find and came back to face a real problem. I grabbed the pot and hefted it off the stove (not an easy feat with 10+ gallons of boiling wort inside). As I stood there holding it, my wife said "better take it outside it's leaking like hell". I went into the denial stage here, saying "no it can't be leaking, this is my 15 gallon stainless pot!" The burning sensation on my feet finally convinced me to take it outside. There I was rapidly moving from denial to anger to sorrow. Ten gallons of my best-ever wort, sitting in my 15 gallon stockpot, with a 1/4" hole in the bottom, slowly pooling up and freezing to my patio (it was about 0F outside). Believe it or not there is still a happy ending.

My wife came out to console the unconsolable. Despite my protesting she convinced me that all was not lost. Dumping my grain from its plastic bin, we saved most of the beer, boiled it in four smaller batches in my enamel pot and renamed it "Sparky's Disaster Ale". It was by all accounts, remarkable. The

handy guys at the local SS welding place fixed the hole in my pot, I  
built a  
cajun-cooker-clone, and relaced the defective electrical coil.

Moral: Be oh so careful about overloading your electric stove, those  
little  
buggers just don't hold up too well to 70+lbs. And don't ever give up!

Relaxing and wishing I had a Sparky's right now, Joe

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: flour catcher

If you use a Corona grain mill, as I do, you cannot avoid getting some flour along with your cracked grains. Too much flour can lead to a stuck sparge. A good way to get rid of the flour is to put the grains in a big paper bag as you grind them. Pour the grains from the bag into the mash-tun, and much of the flour stays behind in the bag.

From: tighe@kc.camb.inmet.com (Michael Tighe)  
Subject: Brewing Mishaps - my tale...

This sorry tale involves an experimental batch of mead I made several years ago...

I had made two different batches, one with nutmeg and cinnamon and another with lemon-peel and ginger and as is usually the case when I bottle, there was this "left-over" liquid on the bottom of my primary fermentation vessel. (Luckily in those days I was brewing in one-gallon experimental jugs!)

Well, not wanting to waste anything, I mixed up the dregs from both batches and bottled them. My assumption was that it would taste lousy, but I was curious as to what it would be like. In those days, I bottled in 16-oz Coca-Cola bottles - you know the kind - I've used them to hammer nails into a two-by-four when the hammer was too far away from where I was. I believed them to be indestructible. (Foolish man...).

I had two bottles of this "dregs-brew", and had brought them with me to my girl-friend's apartment for the weekend along with several bottles of the "good stuff", and placed it on the bureau in the front hall. In the early days, my mead had this annoying habit (notice I said HAD - I don't HAVE this problem any more!:) of going off (i.e., exploding :) at dawn. Most explosions occurred around 6:00 am or thereabouts, with annoying regularity. This batch (the "dregs") decided to follow suit, and early on a Saturday Morning there was this "BOOM" from the front hall followed by the fearful sound of glass skittering on wood.

Quickly apprising the situation (having been woken from a sound sleep), I refused to let my girlfriend out of the bedroom, and utilizing standard bomb squad techniques, I grabbed a towel and quickly contained the second bottle of "dregs", the one which had NOT yet gone BOOM. I rushed to the kitchen and then stood there over the kitchen sink - now what do I do? This is when the term "glass grenade" really starts to become meaningful and fearful. Utilizing my great wisdom, I popped the top off of the towel-wrapped 16-oz Coke bottle filled with "dregs" and heard "POW" as I tried to aim the bottle's contents down the drain. Problem was that the spray emptied the bottle all over the ceiling, countertops, walls and cabinets of the kitchen before I could turn the bottle mouth-down to the drain. (It is this experience which convinced me to open any suspicious bottle out-of-doors!)

The original bottle's explosion had broken the mirror on the antique bureau, sent shards of the Coke bottle across the living room (we found pieces under the piano weeks later), stripped the finish off the bureau top and leaked through the top onto my girlfriend's nicest silk gloves and hankies in the top drawer. She did forgive me, but it took a while!

Moral of the story: Don't bottle dregs - its not worth the risk! :-)

Subject: Oak chips in IPA?

Super Dave writes:

> I was planning on using some Oak chips I got from a brew supply shop >  
> for an IPA. I read somewhere where I should toast them...

Actually, how you prepare the oak chips may be a mute point. Terry Foster (Pale Ale, The Book) claims that English oak is different than American oak (and French oak, I think) in that English oaken barrels don't impart any flavor to the beer that's stored in them. Apparently, we Americans, used to the characteristics of our oaken casks, just assumed that English IPA which had been sitting in a wooden cask must have some oak flavor. So, Terry's point is that if you're trying to brew an authentic IPA, don't add any oak chips.

Of course, that's not to say that you can't add oak chips to beer just for the fun of it. Just don't do it to be 'true to style'.

Anybody need a bag of oak chips, never used? I'll let mine go real cheap... ;-) )

Subject: Re: Oak Chips

Dave asked about oak chips in an IPA. The William's Brewing catalog which sells oak chips suggests the following:

Rinse with water and steam for 20 min. in a vegetable cooker or toast for 20 min at 350 F for a "crisper oak character". Add the chips to the fermenter, and leave in contact with the beer for at least 8 days. Use from 2-5 oz for a 5 gal batch.

I used William's chips in one batch. I used about 3 oz. and toasted them for sanitation. The result was a very oaky beer (too much oak). If I used oak again I would not use more than 2 oz. and I would steam them instead of toasting.

Subject: Beer Sampling/Yeast culturing Event!

Brewfest/Yeast culturing. An evening of fun and fungus.

The other night some fellow brewers and beer unthusiasts joined me for an evening of sampling several "exotic" brews (in Utah terms that is) for the sake of comparison (quaffage) and to attempt culturing all of the culturable yeasts. We had stuffed squash from the garden, and watched Michael Jackson Beer Hunter Videos (well, we saw a bit of Jack's video too for kicks). It sure was inspiring to see the Lambic brewing system. Talk about "Not Worrying" to an extreme! The image of spider webs all around the casks haunts my mind. When I saw fruit flies hovering around my DunkelWeiss as I racked to the secondary the other night, I decided to savor the spider who has placed his home next to my brewing space in the basement.

Here's what we "sampled":

- \*\* Guinness \*\* Bass
- \*\* Anchor Steam \* Black Hook Porter
- \*\* Celebrator\* St Pauli Girl (dark)
- \*\* Red Tail \* John Bull
- \*\* Portland Ale \* Caribe
- \*\* Chimay

The next night- with refreshed palates, Toot and I dipped into some even MORE exotic brews:

- \*\* Samichlaus\* Wicked Ale
- \*\* Corsendonk\*\* Thomas Hardys Ale

I had a collection of malt agar plates. We poured the sediments onto them after carefully dispensing the beer into our little sampling glasses.

Boy- even a small glass (when you have many of them!) can sure put you under the table. Good thing I just had to fall into bed, not go anywhere! Beer sure makes my girlfriend frisky! Whew...

So- with a fair bit of followup culturing (restreaking for single colonies, then transferring to agar slants) I should have quite a stock of viable yeasts. I wonder how much overlap there might actually be in terms of which strains are really which? Might any of them actually be the same as any Wyeast cultures? This is probably going to drive me to freezing some cultures.

I'm also wondering which brews actually had culturable yeasts, and which just had sediments, and which plates now just have a layer of yummy beer on their surface. Any input? The ones with two \*\* are ones I'm pretty sure -> quite sure are culturable (\*\*\*) means they are already growing!).

Just thought I'd share this enjoyable experience with you folks.

"Beer is a part of our phfood, an important part of our daily phfood intake"

From: Bob\_Konigsberg@3mail.3com.com  
Subject: Assorted Comments

Jack Schmidling asked (or was he reprinting another's question) about hooking up a cajun cooker to natural gas. It can be done, but the BTU's of propane are much higher, and he's not going to get as much heat out of it. Jack, I also use mine outside, having had one boil over in the garage (my wife was not appreciative). One safety note for all, I noticed that the tripod legs could tip over the cooker in a direction between the legs, and since I've got little ones (curious too), I bought a 3/4" X 2' diameter plywood circle, varnished it thoroughly (3 coats), flattened and bent over (in a vise) the last 1.5" of the tripod legs for the cooker and drilled holes and then screwed the legs to the plywood disk. The cooker is \*much\* more stable now, and I'm not as worried.

Concerning flaming, according to a friend (who ought to know), flaming consists of just passing the loop through a flame, not heating it red hot.

I don't have any brewing disasters of my own (just a boil over or two), but I do have a question. My latest batch (a brown ale) is not bad, but has a noticeably metallic taste. Here's the particulars for this 10 gallon batch.

12 lbs. Alexander's Light LME  
6 lbs. Alexander's Dark LME  
8 oz. Chocolate Malt (steeped, NOT boiled)  
1 lb. Crystal Malt 40L  
4 oz. cascade @ 5.3% AA (boiling)  
2 oz cascade (finishing in last 5 minutes)  
Wyeast Irish Ale Yeast built into a 1 qt. starter 3 days before.

S.G. 1.054  
F.G. 1.024 (calculations say about 4% alcohol)

Wort was chilled in a counterflow chiller and fermented with a blowout tube. Lag time was less than 8 hours (I was asleep and not watching).

It tastes pretty good except for the mettalic flavor. By this I mean, I'd like to get rid of the metallic part, but I'll drink it anyway.

Has anyone else had a similar problem, and if so, to what did you attribute the problem?

BobK

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>  
Subject: Whirlpools & siphoning

Jeff Frane (gummitch@techbook.com) recounts as part of a disaster story:

> At the end of the boil, I hooked up the siphon hose to the wort  
chiller,  
> clamped off the far end and stirred up a great whirlpool.  
> I had some reason for doing a little research upstairs, digging in a  
> brewing text, during the 20 minute rest.

I've tried the "make a whirlpool and siphon off the side of the pot"  
technique for racking after the boil, but I found it difficult to  
stir vigorously and start the siphon at the same time, and my siphon  
(copper tubing with slots in the bottom) still clogged with (fresh) hops.

Jeff's comment suggests that whirlpooling (to coin a word) and siphoning  
don't have to be done simultaneously: you can stir up the whirlpool to  
concentrate the solids in the center, let them settle, and then siphon.  
If so, do you still need some kind of filter to keep solids out of your  
wort?

From: James S Durham <js\_durham@pnlg.pnl.gov>  
Subject: Two brewing disasters

Back in the good old days, when I had only about three batches of beer under my belt (literally), I had a brewing experience that convinced me to use a coleman stove in the garage. I had just bought a new home, and I was all set to watch the world series and brew my favorite stout (recipe posted sometime last week) as my first batch of beer in the new house. Well, the first disaster to occur that day did not affect me personally, but they cancelled the baseball game for the San Francisco earthquake.

I did not have the full complement of brewing equipment that I now have. I brewed a 1.5 gallon extract recipe in a three gallon pot, just as I always had. I was tired of fighting with the swelling that occurs just as the wort starts to boil, so I thought "I'll just let it boil over and use a stainless steel mixing bowl to catch the overflow." What a good idea! As the wort was heating to boil, I decided to warm the mixing bowl on another burner so that the overflow would stay hot. Since just about every house in town has electric stoves (electricity is VERY cheap here), my stove was no exception. I placed the mixing bowl on one burner and anxiously awaited the boil. Soon, however, I noticed that the mixing bowl was glowing red, so I quickly turned down the heat to low and inspected the bowl. Sure enough, I changed the properties of the steel in the bottom of the bowl. Oh great, my wife (who doesn't like my beer) will kill me. So I set the mixing bowl down on a cold burner. Meanwhile, the wort approached boiling and the foam was rising in the brewpot.

Just as the foam was approaching the top of the brewpot, I lifted the pot up to move it over the mixing bowl. I failed to notice that this stove had a ventilation hood over it where the stove in the old house didn't. I hit the hood with the brewpot, and a small amount (about two cups of wort landed on the red-hot burner that had just been vacated by the brewpot. This started a small fire on the burner. I quickly set the brewpot (now cooled slightly so it was no longer in jeopardy of overflowing) onto the only available burner on the stove (the mixing bowl covered two cold burners. Unfortunately, the only available burner was heating on low. As I was dousing the flames on the cooking burner, I glanced up just in time to see Mt. Wort erupt like Vesuvius. The wort flowed into the burner, down the little air vent that leads to the oven, into that inaccessible area that houses the wiring for the burners below the burners, across the counter and onto the lily-white sculptured-pile rug that some madman had installed in the kitchen.

Needless to say, I didn't have to worry about my wife becoming upset about the mixing bowl. I (as brewer) was banished to the garage forever, which greatly facilitated my brewing anyway. It's a good thing I brew and allow primary fermentation to occur in the garage now, because it minimized the effect of having a cherry from a cherry stout recipe clog the airlock during primary fermentation this summer. The airlock exploded (thank goodness not the carboy) and cherries went everywhere! BTW, the volcano beer that I described above turned out to be one of my best brews, but I don't think I want to repeat the recipe exactly.

From: Chris McDermott <mcdermott@draper.com>  
Subject: Re- Baderbrau (Radium)

Re: Baderbrau (Radium)

Since I am not a nuclear physicist, I'm sure someone will correct me if I am wrong....

I think that what the Elmhurst water was contaminated with was probably Randon gas and not Radium. As I understand it, Randon is a decay product of Radium which is in turn a decay product of Uranium. Radon contamination of ground water is VERY common in areas that have a bedrock structure that is composed mainly of granite. This is because trace amounts of Uranium in granite rock decay eventually into Radon and since Radon is a gas it can dissolve in the ground water. And because it is soluble it can reach fairly high concentration levels. Fortunately, Radon has a very short half-life and quickly decays into non-radioactive products.

The way the "Radium problem" was most likely solved was to let the water stand in some sort of holding pond for a few days before distributing it. The Baderbrau could also have been "made safe" simply by letting it sit in the bottles for a while.

A similar method is used in a very popular spring water from Maine. The aquifer that feeds this "spring" is the same one that my parents' artesian well taps into a few miles away. Since we found out about the problem about 15 years ago, we would let the water sit in the refrigerator for at least a day before drinking it.

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Malt flames from Micah Millspaw

I thought that I'd let you all know about a horrible brewing experience that I had recently. I made bad beer! and not just a little bit of it either, a total of 45 gallons of bad beer. This disaster took place in 15 gallon increments, and at the first incident I blamed the yeast (even though I had proofed it myself). So I changed yeasts and brewed again, same problem ( the defect was massive amounts of DMS) I've been using the same wort chiller for several years with no trouble. So slow cooling wasn't the problem. And so to rule out some horrible bacterial infection as a source, I re-etched my SS fermenters with acid. So I went really anal about sanitation, got some known good yeast from a local brewery and tried again. Still more DMS. Then began the search for a common element and I found it, it was the pale malt. For years now I have been using pale malt from Great Western malting, but my source for it recently went away and so I bought some Breiss malt. I should have thought of blaming the malt sooner but it seemed to unlikely. I stopped trying to brew and located a new source for Great Western malt. Then I did some tests. With the same yeast that was used in the high DMS beer (last made) I made some test batches, I mashed a pound of breiss, boiled for an hour, cooled it and pitched the yeast, then did the same with the Great Western malt. Within 2 days the DMS smell from the Breiss was overwhelming, the Great Western was okay. This satisfied me that the malt was the problem and I'll never use Breiss again. I've got some good beer fermenting now, made from Great Western malt. Since this problem occurred I talked to many other brewers both home and commercial and they all said, don't use this malt (Breiss). I thought that I'd pass this on to you HBDers because it sucks to make bad beer and its even worse not to know why.

From: "Regan Fulton" <fulton@molbio.cbs.umn.edu>  
Subject: Wood Chips

I used wood chips recently and found they gave a very nice aged character to the brew. I followed Charlie's India Pale Ale recipe very closely, as I remember--though I don't have my notes with me. I also toasted my grains for that one, so I can't say whether the wood alone contributed to the very pleasing character, but I do think of it as my best so far. This was a full-bodied ale with high alcohol content and real hint of wood. I steamed the chips in a collander for about five minutes prior to adding to the brew pot--I'm a sanitation freak in addition to being a hop head. Finally, I found the wood chips at Cellarcraft (Minneapolis). Cheers.

Subject: oxidation and porters

I got only one response to my question about SG and temp. relations.  
And I don't have a postscript printer, so that didn't help much.  
Maybe I can get something out of a chem. book.

With the talk about oxidation, it is said that shaking COOL wort  
is good--leads to aeration which yeast like. Then it is said  
that shaking beer (before bottling) is bad--leads to oxidation  
which taste buds don't like. So what is the difference in the  
two settings? Why is unfermented cooled wort not as susceptible  
to oxidation?

And sorry if it was discussed recently, but what is the reviews  
of Terry Foster's book on Porters?

From: card@apollo.hp.com  
Subject: yeast.starters

I decided to finally write this down rather than stumbling through my brew books every 4 months or so, when it's time to make starters.

BTW, since the bottles and are now sealed and the wort "sterilized", I presume you can just store them "in a cool dark place" rather than refrigerating.

Also, if anyone has had bad experiences with just adding the yeast to the starter bottles and re-sealing without an air-lock, until time to pitch, I'd appreciate any feedback.

Thanks and happy brewing,

/Mal Card

YEAST STARTER PROCEDURE  
-----

Read Miller's "Brewing the World's Great Beers", page 33-35

Material:

- \* Eight 1 quart canning jars ##
- \* Eight NEW covers (rings and lids)
- \* 3/4ths lb dry malt (~1.5 cups)
- \* 1/4 oz hops (I used Hallertau pellets)
- \* stainless 1.5 gallon boiler
- \* ceramic, or stainless boiler (16 quart)

Procedure:

1. clean the jars and covers (i don't think boiling is necessary). Ideally you could boil the jars and lids as described on the canning bottle box. The jars should probably be left in hot water until ready to use for thermal shock reasons.
2. Boil ~ 1 gallon water uncovered for 15 minutes
3. Turn off burner and add dry malt and hops
4. Bring to a boil
5. boil wort for 15 minutes
6. turn off boiler and let the wort settle for 15 minutes or so.
7. while this is cooling, fill the ceramic boiler about 1/3 full. bring to boil
8. Stir wort to evenly distribute the hops and transfer hot wort into bottles (half full) and then loosely cover

9. place the 8 jars into the ceramic pot with water ~ 1" from the top of jars.

10. bring to a low boil and simmer for 30 minutes

11. with tongs carefully remove the jars and finger tighten the lids

12. let cool overnight on wooden surface (keep out of draft)

## note: Miller "specifies" pint bottles but I've found if you use 1 quart bottles, you can add the yeast directly into the bottle since there is now adequate head room. This has worked successfully for me for about 6 batches but I'd be interested to hear if anyone has had problems with this. IE. exploding bottles.

IN ANY CASE, ONCE THE YEAST HAS BEEN ADDED, CARE SHOULD BE TAKEN, AND IF THE LID SWELLS, SIMPLY RELEASE THE PRESSURE WITH A QUARTER TURN OF THE COVER AND RETIGHTEN.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: corn/distasters/open\_fermenters/traquiar\_house

> can corn be converted by boiling, or do i need a warm  
> temp rest like barley.

corn is just like barley in that it can be malted, which produces amylase enzymes (don't know how corn differs from barley in the amounts of different types of amylase produced, though), it must be boiled or processed before being used as an adjunct, and conversion must take place in the presence of amylase at ~150F, etc. I'd like to taste an american pilsner made with malted corn (but let somebody else do all the work :-)

-----  
On brewing disasters:

How about 15 lbs honey & 7 lbs blueberries, put into a 6 gallon fermenter? I decided that my friend's basement would make a cooler environment in which to ferment this beast, so I carried the entire thing down 2 flights of stairs, drove across town, keeping it from tipping over with my right hand, hoping that the police wouldn't decide to stop me and inspect/infect the content of the fermenter, got to my friends house, opened the basement door, carried the carboy down another flight of stairs, and ever so gently sent the fermenter down on the concrete ledge. All I heard was a slight "clink", and didn't notice that the carboy was becoming lighter by the second. I could have saved a gallon or two and put it in jugs, but I was so disgusted I just threw the whole damn thing (about 2 gallons was left in the fermenter by the time I tipped it over to stop the flow) out in the dumpster and proceeded with the cleaning up process.

Fortunately, there was no carpet on the floor, and a drain nearby.

Unfortunately, the drain was 90% clogged.

Fortunately, It wasn't my house.

The ants loved it.

>>problems.... Any comments?

>  
>It's a numbers game. The brewers add a huge number of active yeast  
>cells which get off to a quick start. There's no question that  
>molds, bacteria, wild yeast, etc. fall into open fermentation  
>tanks; but they are simply overwhelmed by the 10<sup>6</sup> to 10<sup>9</sup> fold  
>excess of the desired yeast cells. After the beer is fermented  
>out the alcohol suppresses most microbial growth.

A Zymurgy article last year stated that when PU brews, they split the batch in 3 parts. They monitor these closely, and if one batch starts to develop a mild infection [as long as it's not too early in the fermentation cycle, I would assume]

they quickly bottle it, mixing it with the other 2 batches,  
which brings the off-flavors below the taste threshold level.

Subject: Flame Loops, Not Your Fellow Homebrewers!

Jack S. Writes:

>I have often wondered about the "proper" method of flaming. It would seem  
>that just passing through a flame would kill anything on the tool but on the  
>other hand, the tool is a heat sink and the critter might not even get hot.

>So to make sure, I heat the loop cherry red and the glass rod till I know it  
>is hot. The problem is, if you then poke it into the yeast to transfer it,  
>the yeast gets fried unless you let it cool. While cooling, it is in the  
>unsterile air and one never really knows when it is cool.

>So, the question, at last... is just passing through the flame sufficient?

When streaking bacteria I always get the loop red-hot. If I'm coming from an agar plate I just jam the hot loop into an unoccupied portion of the agar; this cools it off quickly and keeps the loop sterile.

If I'm coming from a liquid culture I stick the hot loop right in the culture; sure some of the bugs get fried, but since you're dealing with billions of them (or hundreds of millions in the case of yeast) you get more than enough live ones in your loopful.

From: ithaca!amber!phoebe@uunet.UU.NET (P. Couch)  
Subject: Re: Hops and disasters

I have finally harvested the hops and got 1 lb dry weight out off the cascade, 0 out of the Willamette, 4 oz off the the Nugget and 0 out of the Mt Hood, all of them 5 months old. The Willamette has this weird bug that wilts all the leaves from the root up, the leaves turned brown and papery, but they don't fall off. None of the other hops had the problem. The first batch of dry hops have now been used in the Cascading Hopping Spider AltBier, not that using Cascade is true to style of an Alt, and most of the spiders are removed from the cones. I will post the results when the beer is ready. As for brewing horror stories, none of mine could top what's out there. All the damage were confined to the kitchen and storage area in the basement. The funniest one is the probably the ballistic air-lock. It hit the ceiling and spewed all over the place. The last one was when I brewed with my brewpartner a couple days ago at my house and it was Laurel and Hardy time. I started brewing after work, and of course we decided to do 2 batches at once, fools! so at 9pm, we started sparging, at 10 pm, we started to brew, after painstaking working out the recipes we added the hops to the wrong batch, and at midnight, we put in the finishing hops in the revised recipe. At that time, we realized that we forgot to add munich malt to one of the mashes. We then carried a full 5g pot to the basement and use the chiller. So there was a trail of hot beer all over the kitchen and down the basement. The chiller attachment doesn't hook up tightly on the washer hose so there was a small fountain and one of us had to keep a hand on it to stop in from spraying. When it was done, we realized that we forgot to add Irish moss, so we went back upstairs and added it to the second batch. We then repeat the last process at ~1am with the second batch. It was then time to put stuff in the fermenters, my partner for some reasons decided to pour the stuff into the carboy with a funnel, I wanted to use a hose, but he insisted on pouring, so I let him (We both wanted very much just to finish the hell up and go the sleep), halfway down, the filter of the funnel got clogged, after some more struggle and losing pints of beer to the floor and some trub into the carboy, we got all the beer into the carboys at 2 something am. At this point, my partner decided to drive home cos he had an early meeting the next day. So I had to mop up the floor, and of course the mop broke. Well, anyway stuff got cleaned up the next day, and the beer is bubbling, and the next morning, I realized that we forgot to take an sg reading. We are not normally this dingbatty, but we just moved brew location and had too many home brew with our deep dish pizza.

From: Lester Paul Diamond <ld0h+@andrew.cmu.edu>  
Subject: Second-timer's question

Well, my first batch, a nut brown ale, is bottled. The flavor seemed to be fine going into the bottles, though it was a bit sweet. I suspect that it has to do with the corn sugar I put into the wort with the dry malt.

I immediately started another batch. This is an export ale. I wanted it fairly hoppy, so I boiled the wort longer, about 45 minutes, and left out the corn sugar. I'm not inclined to use the sugar again at any rate given what I've been reading.

My question is, how soon should I start seeing bubbling through the airlock? Last time it began within 12 hours. This time it hasn't started after that much time. I know I'm being a bit anal retentive, but I checked before I came into work and just thought I'd ask. One think I did differently this time was to just throw the yeast on the top on the wort without stirring it in. Last time I stirred it in.

If it doesn't start bubbling away what can I do to move it along?

Thanks in advance. You all have been very helpful to me a couple times in the past. This is an easy one, I know.

Lester

From: "C. Lyons" <LYONS@adcl.adc.ray.com>  
Subject: Hydrometer reading as a function of temperature

Someone a little while back asked about hydrometer readings as a function of temperature. The brochure that came with my hydrometer had the following correction table (add correction to reading):

Temp in deg. F    Spec. Grav. Correction  
-----

50	-0.5
600.0	
701.0	
772.0	
843.0	
955.0	
1057.0	

Example: A measured specific gravity of 1.035 at 84F translates to a corrected (relative to 60F) specific gravity of 1.038.

I plotted the above data and fit it to a third order polynomial. The fit was quite good (R=0.99994).

corr. =  $6.66365 - 0.34722 * T + 0.00474726 * T^2 - 1.3431775E-5 * T^3$

With this equation one can write a short program that takes the measured specific gravity, and temperature, and outputs the relative specific gravity at 60F.

... Hope this helps,

From: YATROU@INRS-TELECOM.UQUEBEC.CA (Paul Yatrou)  
Subject: Wyeast Belgian Ale (how not to prepare a starter)

Hello all,

last week the cooler weather started to set in and I decided to make my first batch in over four months. I chose a Belgian dubbel recipe (pg. 122 "Belgian Ale", Pierre Rajotte, all-grain), cracked the grain Friday night, and promptly realized I hadn't prepared any yeast! I pulled out an 8 month old Wyeast Belgian Ale packet out of the fridge and popped it. Now, 8 months old, let's see. .. that should take about one week before it would be ready, and I wanted to brew the next day. Hmmm..

So on Saturday I mashed, sparged, boiled, and cooled without any mishaps and by 3PM it was time to pitch. The packet hadn't budged at all. I decided to wait till night time. At 9PM I started fretting about the "unprotected" 5 gallons of wort sitting in my closet and pitched the far-from-ready Wyeast.

On Sunday morning I rushed to the closet and ... nothing. Sunday night, NOTHING! Monday morning ... de nada. I started to worry a little, and thought of throwing in some dry Whitbred ale yeast, but it was time to go into work.

After work, as I was climbing up the stairs to the apartment I heard the distinctly heavenly sound "glub ... glub ... glub". I rushed in and, low and behold, there was a party in my carboy.

It's been fermenting wildly all week long now. The closet smells like a giant Chiquita, there's still a thick krausen, and I'm a happy camper. I seem to recall a thread on HBD about 2 months ago about the characteristics of the Belgian Ale Wyeast, namely banana esters, drawn out but active primary fermentation, preference to lower temperatures (below 65F if possible).

So, I guess the jist of all this is: RDWHAHB, have confidence in your brewing technique, and trust your Wyeast (even if it's old)!! Of course, I'm not affiliated with Wyeast etc..., I'm just a happy camper.

Paul Yatrou.

From: Alexander R Mitchell <ARMITC01@ULKYVM.LOUISVILLE.EDU>  
Subject: Dry Yeast starters / brewing disasters

Prog/Analyst II C & T  
Phone: (502)588-5626

Dry yeast question:

Could dry yeast be re-constituted in plain water and then add up to 5 or 6% of alcohol to kill bacterial and (hopefully not alcohol resistant) wild/mutant yeast? If one added a hop pellet or two to an ounce of 100 proof (50%) vodka, would that make the some hop oils water soluble? The vodka/hops mixture could then be added to a pint of re-constituted yeast-water.

Brewing disasters:

I was using the Charlie P. 3/8 diameter blowoff system in a two room apartment and after a couple of batches my luck ran out. Of course the hop bits clogged the blowoff tube. Fortunately I had shoved the carboy in a corner behind one of those poppasson <-sp? (looks like a satellite dish) chairs. There were dried hop bits all over that corner of the room. Lucky for me the hop bits (not to be confused with naughty bits - for you Flying Circus fans) washed off the walls and the ceiling was one of those bumpy ones that a can of white spray paint took care of. the big round pad from the chair became a dog pad for a friend's pet. The carpet required Mr Stanley Steamer's attention. Also I had set bamboo chair frame outside and the ants cleaned it for me :-)

The second disaster was terrible! A new girlfriend came over for dinner and was quite impressed with my homebrew until she opened her second bottle. It was a beer geyser and blew foam all over her sun dress because she tried to close the swingtop cap and ended up directing the spray at herself. I, being a southern gentleman, helped her out of her wet sticky clothes and into the shower ;-)  
Like I said, it was a horrible experience.

From: pmiller@mmm.com  
Subject: To stir or not to stir...

Hi everyone,

I tried mailing the following question to Micah Millspaw (c/o Bob Jones) but it bounced. I've decided to post it to the HBD because I think it would be of general interest.

Before I get to the question though...

1) I'm going to be including some information that I got from Micah in an e-mail message. If I'm breaking some cardinal netiquette rule about including information from a private e-mail in a public posting then I'll take my lumps and apologize. In my defense, I want to point out that I have good intentions (I'm trying to clarify a point, not criticize) and that most of this information has been posted to the HBD anyway and it wouldn't take a rocket scientist to deduce the rest...

2) If, after reading this post, you have strong opinions about Micah's mashing technique, you may want to verify that I've described his procedure accurately before you post your scathing critique. Humble pie tastes terrible...

Those disclaimers out of the way, on to the questions (finally!):

Micah uses an underlet system for his mash which he described to me like so:

```
Underlet tubing ----> |
[ | ]
[ | ] <---- Mash tun
[ | ]
[ | ]
[ | ]
[== =====] <---- False bottom
[_| _____]
```

Micah has said that he adds hot water in different amounts to achieve a step infusion mash. He's also pointed out the importance of not stirring the mash (I think he quote George Fix here as saying that a lot of real breweries get into trouble by stirring their mash needlessly or something along those lines.)

OK, question #1: Why is stirring the mash unacceptable? Miller's book (Dave's -- I haven't written one yet ;-) describes in excruciating detail just how to stir the mash while heating the pot on the stove to boost temperatures and it's pretty obvious that Jack's EasyMash system would require stirring, too.

Now, the thought that comes to mind is that after a certain point, (e.g., 5 minutes before you begin sparging) stirring may disturb the grains and put a lot of flour into suspension. It makes sense that you may not want to mess around in the mash just before you try to establish the grain bed. But certainly you have to stir mash when you first mash-in, right? So at what point should you stop mucking around in the mash or am I completely missing the point?

Question #2: I did some back of the envelope calculations (Quick! Can anybody guess what my undergraduate major was?! ;-)) and I figured that for 8 lbs of grain and 8 quarts of water at 155 F, I'd need to add about 5 quarts of boiling water to bring the mash to 170 F for sparging. If I don't stir the mash, won't the hot water extract tannins from the husks that it contacts? Or does the heat diffuse quickly enough that this isn't a problem? Or, should I be using more water at a lower temperature to bring the mash to 170 F? How thin can you get the mash before you run into problems?

Question #3: Assuming that stirring the mash is bad, why use an underlet system to add the hot water to the bottom of the mash (rather than, say, dumping the hot water on the top of the mash)? Is it because the grains are heavier than the water and therefore water that's poured on top of the grains just sits on top whereas water that's added to the bottom of the mash ends up percolating through the grains from the bottom up?

Please, please, somebody straighten this out for me. I'm hopelessly confused. Thanks!

>two settings? Why is unfermented cooled wort not as susceptible  
>to oxidation?

The difference is in what the yeast are about to do. In the former case the yeast are about to go into a massive, aerobic growth spurt, consuming any oxygen they happen to come across. You want to give them lots of it to come across.

In the latter case, the yeast are going to quickly consume the relatively small amount of priming sugar you add and then settle out; they'll use up some oxygen doing this, but they're not guaranteed to use it all, especially if it get's vigorously aerated.

I actually feel that the "Conventional Wisdom" overstates the risk of oxidation at priming, but I don't want to risk my beer with experimentation and it's not too difficult to avoid aeration during priming. There's no question, however, that vigorous aeration helps the yeast get off to a good start after pitching.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Specific gravity of hot stuff

Bryan Gros will have some very heavy christmas beer. SG will always read lower when things are hotter. This is due to the fact that things expand when hot. More volume, same mass = less density. This size/temperature relationship is linear, as long as you don't have a solid/liquid/gas phase change. Charlie Papazian on p.26 of The Complete Joy of Homebrewing (1984) says that SG drops .002-.003 for each 10 degrees F above 60F. My hydrometer has a correction factor printed on it. This should be close enough for horseshoes and handgrenades. FWIW the beer I brewed Wednesday had an apparent SG of ~1.030 @ 200F and a real SG of 1.051 at 60F. The coefficient of expansion may vary with the amount of sugars in solution, so it wouldn't hurt to check this out.

Does anyone have a table of coefficients of expansion for worts of different gravities? Since gravities vary by 100% (more or less) this could have a substantial effect, or maybe not....

Date: Fri, 4 Sep 1992 08:43:30 -0700 (PDT)  
From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Sparge times and extraction

There has been some discussion of the relation between sparge time and yield. This week I did two test batches to calibrate the alpha % of my recent hop harvest. I made two identical batches, same grain, same grind, same everything, except the sparge times. I use a Gott cylindrical cooler with a vegetable steamer and mesh "press bag" to hold the grains. For batch B, I would drain ~.5 gal from the cooler, add more sparge water, then wait five minutes.

BatchA B  
Sparge time 15 min.45 min.  
Gallons in carboy 4.5 4.75  
SG 1.045 1.051

As you can see, there was better yield from the slower sparge. In both cases, the grains had no sweet taste afterwards. I think that 15 minutes is too fast, and that you can go too fast or too slow. It is going to require more experiments to settle the issue conclusively, but I'll relax and take a break while sparging in the future.

=====  
Nothing Fancy Test Batch Ale

8#Munton and Fison pale ale malt  
.25#40L Crystal malt

mash with 2 gal @ 152F for 90 min. Sparge with 6 gal. 1 tsp gypsum in water.

2 oz. Homegrown hops (A=Willamette B=Cascade) 90 min.  
(added after foam subsides)  
1/2 tsp Irish moss 15 min.  
1 oz. Homegrown hops 10 min.

Cool to 70F with immersion chiller.  
Pour wort into spigoted bucket with vegetable steamer to catch hops. Let settle 20 min then drain into carboy.  
Pitch 1 pk Edme ale yeast.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Isomerizing lupulin powder?

When I was packing my recent hop harvest I kept sheets of newsprint under the drying screens to catch the yellow resin that falls off the hops during handling. I now have a vacuum sealed bag with 1/2 ounce of the orange lupulin resin powder. I would be very interested in isomerizing this for post-fermentation bittering (repairing underhopped beer.)

Does anyone have an article or reference on how this is done? All I know is that there are two processes: one uses sodium or potassium hydroxide, is quick and can overconvert into non-bitter isomers; the other uses sodium carbonate and is slower and less likely to damage the bittering.

Any help would be greatly appreciated.

Date: Fri, 4 Sep 92 11:25 EDT  
From: "C. Lyons" <LYONS@adcl.adc.ray.com>  
Subject: Follow-up on SG vs Temp.

Following up on the specific gravity of water as a function of temperature.... The earlier equation was based on data for 50F-to-105F. Since the equation was from a polynomial fit, it should not be trusted for predicting SG outside this temperature range. The data below was obtained using the "Handbook of Chemistry and Physics (CRC)", and is valid for a temperature range between 0 and 212F.

Temp (C)	Temp (F)	Density	Correction relative to 59F
0	32	0.99987	-0.74
3.98	39.16	1.00000	-0.87
5	41	0.99999	-0.86
10	50	0.99973	-0.6
15	59	0.99913	0
18	64.4	0.99862	0.51
20	68	0.99823	0.9
25	77	0.99707	2.06
30	86	0.99567	3.46
35	95	0.99406	5.07
38	100.4	0.99299	6.14
40	104	0.99224	6.89
45	113	0.99025	8.88
50	122	0.98807	11.06
55	131	0.98573	13.4
60	140	0.98324	15.89
65	149	0.98059	18.54
70	158	0.97781	21.32
75	167	0.97489	24.24
80	176	0.97183	27.3
85	185	0.96865	30.48
90	194	0.96534	33.79
95	203	0.96192	37.21
100	212	0.95838	40.75

The correction term was computed relative to 15C (59F). It may be easily calculated relative to any temperature. A third order polynomial fit to this data was also very good ( $R^2 = 0.999969$ ):

$$\text{Correction}(@59F) = 1.313454 - 0.132674 * T + 2.057793e-3 * T^2 - 2.627634e-6 * T^3$$

where T is in degrees F.

This equation should be good for the entire temperature range of interest :-)

... hope this helps,

From: eurquhar@sfu.ca  
Subject: For the adventurous: Chicha, corn beer of the Andes

First, before you even think of planting corn from what plant quarantine would call a "briefcase introduction" consider the disease epidemic (blight, root rot, virus etc.) which would result from infected corn and the huge losses which would result to the American corn crop.

Second, I found a recipe and method for chicha recently in "The Art of South American Cooking" by Felipe Rojas-Lomabardi (excellent chef and native Peruvian) published recently by Harper Collins 1991 (ISBN 0-06-016425-5).

#### Chicha de Jora

1 pound jora (germinated and then sun dried whole corn, sort of like corn malt)

8 allspice berries or cloves

2 cups dense packed dark brown sugar

Lemon wedges for service

(1 tsp. dried Yeast for the less adventurous, use your favourite)

1. Grind jora until partially crushed.
2. Put all ingredients except sugar in stainless steel pot with 8 qts. cold water. Stir and soak for 1 hour.
3. Place over med. heat and bring to the boil. Lower heat and simmer gently for 4 1/2 hours. Stir regularly to keep from sticking. If a lot of liquid evaporates add some more water. You want 3 to 4 qts total mixture at the end.
4. Remove and let sit undisturbed for 1 hour.
5. Strain mixture using a stainless steel strainer into glass container through a double layer of good cheesecloth. Twist the separated mass to extract all the liquid and discard. Add sugar and DON'T STIR.
6. Cover with a piece of cloth. Pitch yeast into mixture here.
7. Let sit in dark draft free warm spot for 5-8 days. If all goes well it will ferment. The longer it sits the thicker and more potent it gets.

Sounds like the andean version of lambic.

#### JORA (corn malt)

the author said that the preferred type in ecuador is from yellow corn where in Peru both yellow and purple corn are used.

Soak whole yellow corn 1-2 days in cool water. Line a baking tray with several sheets of paper and cover with a double layer of cheesecloth. Spray with water until all is soaked. Drain water and then cover with double cheesecloth. Keep moist but not wet until corn is sprouted about 8-10 days (sounds like an awfully long time so use your best judgement). Dry in sun until thoroughly dry, several hot days but take in at night. Will keep indefinitely in dark, cool and dry place in airtight container.

Well gang there it is. Haven't made it as I just got the book out of the library which by the way itself is fantastic. I'm going to give it a try someday but first some corn malt.

Have fun,

From: eurquhar@sfu.ca

Subject: Yeast culturing

The method we use to sterilize instruments for subculturing is to dip them in 95% ethyl alcohol (for research it's tax free) but methyl alcohol will work and then burn off the alcohol in a bunsen flame. Dip as

much of the instrument as possible into the alcohol. Do this a couple of times and believe me they're sterile. Then touch the hot loop or probe to the new sterile plate or a clear spot on your culture plate to cool it.

If

the culture has no contamination this should cause no problem as generally

only pure cultures are used.

It is common practice to roll ends of test-tubes and flasks through the flame slowly to dry them off and kill any bacteria which may have fallen

on the neck.

May the culture be yours,

From: chuck@synchro.com (Chuck Cox)  
Subject: Electric Corona

In order to take full advantage of the AcoustiMash (the false-bottoms are being laser-cut now), I am going to electrify my Corona grain mill. I've got a big, powerful variable speed drill that will be perfect.

I re-read the article in the all-grain issue of Zymurgy, but that is really only a half-design since it just leaves the electric drill sticking out in space. I'd like a self-supporting system, so I don't have to hold the drill the whole time. I'm considering using a second sawhorse, or perhaps doing something creative with a 90 degree drive.

I'd appreciate pointers to more useful articles, or ideas that you have seen work.

Once the mill is electified, how fast can I run it before something bad happens? What are the symptoms of a too-fast grind?

On an only slightly related note:

Has anyone ever overloaded a cajun cooker type gas burner? I've got one of the smaller ones. I've had no problem with 10 gallon batches, but a 15 gallon keg might be too much. I'm going to have some extensions welded on to hold the half-barrel kettle, and I'm wondering if I should reinforce the legs too, the three legs are made from what looks like 1/2" iron bar.

<Story about bad beer, DMS, and Briess malt deleted>

I have had the exact same DMS problem with Briess malt also. I believe the problem stems from their direct firing of the malt. This produces excess nitrosamines, so in order to keep within federal regs for nitrosamines, they add sulphur to their malt - thus creating the DMS problems.

Needless to say, I don't use Briess anymore...

>Another seeming paradox of open fermentation which confused me for quite some time is: given fermentation is an ANaerobic process, how can it take place in an open, aerobic environment?

Would not the fact that a blanket of CO2 over the beer make it an anerobic environment?

.....

Well, I just had my first taste of meade and I did it the easy way.. I drank someone else's.

One of the neat things about this forum is the ease with which one can make friends (and deals) with people with a common interest. I recently swapped a video and a bottle of beer and a small nip of 1971 brandy with John Wyllie for two bottles of his pampered meade.

He sent me a bottle each of cyser and methaglin. The methaglin is too young to try yet but the cyser was from Nov 91 so we popped the cork with a Chinese dinner.

I, of course am not a certified judge, nor do I have any ribbons so I wouldn't dare use any of those fancy words. I will just describe the experience in words us Joe sixpaxes understand.

The cyser was crystal clear and the cork popped right out with little help. It was bubbly and efervescent like a fine champagne.

Probably the most interesting thing about it was the aroma. I have never smelled a drink quite like this. It was like walking through a meadow in full bloom. Not the pukey sweet smell when you jam your nose into a carnation but sort of like a funeral parlor at 20 paces.

We were looking for something that tasted like honey and it did not, so therein lay the only disappointment.

What it did taste like, escapes my humble vocabulary but it was dry and mild and resembled a good champagne. The first glass went well with the food. As the alcohol content was higher than I care for, I drank only one glass. My wife finished the bottle and dragged me off to the bedroom. As an

aphrodisiac, it gets the gold.

In summing up, I would call it an amazing champagne taste-alike considering that it contains no grapes. I used to make champagne with grape juice concentrates and was only moderately satisfied with the results. This cyser is indistinguishable from good champagne.

I doubt that the gods on Olympus drank this stuff but I now have a better idea of what is was they did drink.

Neat stuff, John. Thanks for sharing it with us.

> concentrate the solids in the center, let them settle, and then siphon.  
> If so, do you still need some kind of filter to keep solids out of your  
> wort?

>  
As far as I can tell, whirlpooling only really works if you give it a  
little time to settle: usually about 15-20 minutes works fine in a 10  
gallon batch. I start the whirlpool with a long-handled spoon, trying  
not to splash the wort anymore than necessary. When I draw the wort  
off, I get a dramatic cone of hops, especially if I use (as I usually  
do) pellets.

The trick, I think, is the take-up attachment for the wortchiller siphon  
hose. I have a copper tube of the same diameter which runs around the  
inner circumference of the kettle. The bottom of the loop (the part  
touching the bottom of the kettle) has scores of teeny-tiny holes  
drilled in it (I used the smallest bit I could get for my Dremel  
Mototool drill). Needless to say, the end of the copper tube has been  
hammered closed, so the wort has to be drawn through the little holes.  
These holes are small enough that loose hops never clog them, and if the  
whirlpool has been done properly, pelletized hops almost never do.  
\_Sometimes\_, it's necessary to give it a gentle jiggle if the outflow  
has dropped noticeably -- this usually clears the holes completely.

I tend to use pelletized hops because they sop up less wort.

You might want to try sifting out the flour for other uses.

This is from One Hundred Years of Brewing, originally published  
in 1903 as a supplement to The Western Brewer. Re-published in  
1974 by the Arno Press which claims no copyright.

#### HOME BREWING IN SCOTLAND.

The following from the Scotsman  
[about which I know nothing more, 100 Years... has no  
bibliography. "Victorian Scholarship" is an oxymoron. -CW]  
well describes the  
processes of domestic brewing in vogue before the  
public brew-house became an established institution:

.  
.  
.  
[much stuff about malting and preparing of vats deleted]

.  
.  
Some of the malt was then put through a sieve. The part  
that sifted out was called " smeddum "--which word Burns  
takes occasion to use metaphorically. It was kneaded up into  
tiny bannocks, baked on a griddle and eaten. If when baked  
the smeddum inside the crust was in taste and appearance  
like a thick dark syrup, the malt was good and strong. If not  
syrupy, the malt was poor. These smeddum bannocks were  
rather tasty, and the entire household judged it necessary to  
pronounce on the malt.

.  
.  
[the rest of the brewing process deleted, if you're interested,  
check out the digests circa Jan 28 1992]

From: Bob\_Konigsberg@3mail.3com.com  
Subject: Oops - Correction

I stand corrected on the point of flaming the inoculating loop.

It should be heated red hot, and then chilled in a vacant spot in the agar. Once it's cool, then use it to draw out yeast. The reference to a "casual" flaming is to the neck of the tube/bottle prior to opening it.

Sorry for the misinformation.

Subject: Re: Jack-free forum

Dear Stone Skin--

>Then here's more mail for ya.  
> that's fine. I was wondering about the statement. I don't  
>plan to discuss him (much) anyway. Just curious. So how are people  
>being indoctrinated to this forum? brew on. I take harshness with  
>a pound of sugar anyway. Call me Stone Skin.....JDW  
>

Indoctrinated? If you mean how do they know the rules, they are  
displayed  
at the top of each issue of the Brewer's Forum. I used to take harshness  
with a grain of (Epsom) salt, but that was in netnews, not in this  
private  
digest that I co-founded.

When beginners start to fear posting -- even I began to second-guess my  
questions, it's time to do something about it. I've been a contributor  
since the HBDs inception in 1987 and the mood was always friendly -- look  
at some of the back issues. No one had an axe to grind or a pet peave  
over  
which to stab someone in the back. We were all friends, even when the  
numbers  
got up to 4000 digest members.

Then came Jack Schmiddingling. He introduced hatred and intolerance to the  
HBD  
and caused the mood of the digest to change. Suddenly, posters who were  
silently sitting in the wings listening about beer, started jumping in  
with  
"lame" comments. Any idiot with one or two poorly-made beers can make  
someone feel bad (and themselves "important") by calling them "lame" or  
humiliating them. That's not the spirit that I want to be a part of. If  
you'll notice, I haven't posted anything to the HBD in a while -- instead  
I  
send private mail -- it gets to the person faster and they won't get  
bowled  
-over if in tomorrow's digest someone calls them lame.

It's much harder to answer a simple beginner's question without making  
them  
feel stupid. I've always gone out of my way to answer "stupid" questions  
in  
a way that doesn't make the person feel dumb. I'll say "Oh, that's what  
I  
thought too, but then I read that..." Some will not take the effort to  
be  
nice. They may be too busy or just lazy, but I can't blame them. There  
are people, though, who try to make themselves self-important at the cost  
of  
others. Those people should have their fingernails pulled out in slow  
motion.

Sorry. I got carried away. The bottom line is, that its not that hard  
to  
be nice, and its \*especially\* important to be nice to beginners. I  
recall

when I didn't know anything and in fact read Charlie's book twice before  
I  
had the courage to try my first batch, even though all the ingredients  
and  
equipment was sitting there ready to go. If someone blasted my beer or  
technique back then, I may not have brewed a second batch. I don't want  
that to happen to anyone -- the more homebrewer's the happier.

Al.

P.S.

I feel that these are very important points and that my feelings on this  
subject should be known by the HBD membership, so I'm Cc'ing the HBD.

From: cestes@argos5.DNET.NASA.GOV (Chris Estes)  
Subject: Keg Conditioning/Larger behavior

Hi all...

Well, I've got another two things for the collective wisdom to comment on...

1 - I've just tried my first keg batch - a light ale of 6.6lbs extract, 1.5 lbs misc. grains, etc. When I first tapped it, almost all that came out was foam. This quickly subsided into beer with very little carbonation in it. The head was great! But I want some more carbonation. It sat for two weeks at room temp; I thought that should be enuf. Anyway, it tastes fine, except for the lack of co2. Now, I've increased the pressure up to 30psi and shook it vigorously a few times a day, and its getting more carbonation in it (more yeast bite too :-). Any suggestions on how to avoid under-carbonating a keg in the future?

2 - I always make ales, but bought larger yeast by mistake the other day. What the hell... I'll give it a go. I suppose this brew should be something like Anchor Steam (yeah, in my wildest dreams!). The stuff fermented very actively in my primary; emitting a foul sulphur smell. When I racked it to the secondary 5 days later, all activity has seemed to stop. The ferm. lock has not bubbled and shows no signs of a pressure difference. Any words re the care of larger yeasts for an ale brewer?

As always, thanks for the input

-Chris Estes-

Subject: My first batch of lager beer

Greetings, all,

I have been brewing all-grain ales for almost three years now. The recent blessing manifested in a FREE REFRIGERATOR gives me, at long last, the capacity to brew lager beers. There is one problem, though, that of course I have never brewed lagers before. I read Miller's chapters on lager, but, as usual, those made me feel more miserable and depressed than able to brew. Thus, I beseech the lager brewers of this community to offer me some advice. First, though, let me present my first recipe and brewing schedule:

For 5 gal. of doppelbock:

6 lbs Dutch dried extract  
4 lbs Pilsener malt  
2 lbs Munich malt  
1 lb German crystal  
1 lb Chocolate

1 1/2 oz Hallertau (60)  
3/4 oz Hallertau (30)  
1/2 oz Hallertau (15)  
1/4 oz Hallertau (5)

Wyeast bavarian lager yeast

8 qts water to strike heat 140F  
protein rest @ 122 for 30 min  
starch conversion 1/2 hr at 153, then 1/2 hr at 149  
mash out @ 169  
sparge with 4 gals.  
Boil 60 min

I plan to have a primary fermentation in a 6-gal carboy, then a secondary in a 5-gal carboy fitted with a Brewcap, and then to bottle.

My questions are, what temperatures should I shoot for for the various steps in fermentation? Should I raise the temp a little after secondary fermentation to help eliminate diacetyl (according to Miller's suggestion)?

Is it even necessary to execute primary fermentation below basement temp (65 F)? Will my bottles get primed at 55F, or will the yeast just go to sleep?

I should be overjoyed at any help. If you have a response which you feel is too pedantic for posting, please send it anyway to me.

Thank you!

Subject: Baderbrau & Radium

Pavichevich Brewing Company is the proud makers of Baderbrau and is located in Elmhurst. In May, Elmhurst switched over to Lake Michigan water. Prior to that the water source was ground wells. The ground wells had high levels of Radium. And yes, thats Radium, not Radon. I live in the town next to Elmhurst and we had the same problems. We too switched over to Lake Michigan water but up to that point we received the following disclaimer every three months:

" . . . The Village of Villa Park Public Water Supply wishes to advise its customers that the Maximum Allowable Concentration (the maximum amount allowed in drinking water) for radium has been exceeded in samples collected during the past year. The MAC for radium as designated by the Illinois Pollution Control Board is 5 pico curies per liter of water. Quarterly samples taken over the past year indicate the average level to be 8 pico curies per liter. A portion of the radium which is ingested remains in the bone. The radiation which is given off from the radium, because of its high energy, causes damage to the surrounding tissue. A dose of SpCi/l may result in the development of bone cancer in a very small portion of the population . . ."

Beer anyone?

This spring Lake Michigan water came to Dupage county so this is all a moot point. Needless to say, I'm REAL happy about getting Lake water but I'll certainly miss those glowing reviews from the beer judges. One added benefit is that Lake Michigan water is great for brewing. All the right ions in the proper concentration. Now if I can only figure out how to get rid of the high levels of PCB's.

From: walter@lamar.ColoState.EDU (Brewing Chemist)  
Subject: Brewing Experience

Howdy Fellow Brewers,

You guys had to bring it up didn't you. I thought back through my two years of brewing experience, and had never really had a disaster. Sure there were about three exploded bottles, and some beer that spoiled over the hot summer in my second story apartment, but nothing really major. Then you guys start talking about such things, and like magic, it happened to me.

Last Friday night I was leisurely cleaning up my equipment, getting it ready to brew my peach weizen and the mead I had planned for the weekend. I was mostly done, when I decided to rack my pumpkin ale to a secondary to help it clear, as I was planning on bottling this weekend also. Anyway, I was fermenting my pumpkin ale in a glass fermenter given to me by a fellow homebrewer. The reason I received this carboy was that it had a crack in the neck from pouring hot wort in it. Mitch had the right idea in throwing it out, but the male instinct in me would not let him throw it out. I said "I'll take that. It'll be good for racking into at bottling time." And this is what I did with it, until last week. I used it as a primary because my other glass carboy was full, and my plastic carboy was dirty. I know I should have cleaned the plastic carboy, but I didn't. Anyway, my pumpkin ale is now in the flawed glass carboy, and I am carrying it across the room so I can rack to the secondary. I am careful of the neck, and have one hand under the carboy supporting the weight, and the other wrapped around the side for balance. The carboy started slipping so I adjusted the underneath hand, and out of instinct grabbed the top of the carboy with my right hand to steady it. When I did this I knocked the top clean off at the crack, and cut my index finger at the same time. Luckily the carboy was just above the table I was taking it too at the time, so it did not crash to the floor, but rather just fell a couple inches to the table. Having no bandaids in the house, I had to make due with cheese cloth and scotch tape. The cut wasn't too deep, just painful. But, it still could have been worse.

Live long and prosper,

Chuck Cox asks:

> Once the mill is electified, how fast can I run it before something  
> bad happens? What are the symptoms of a too-fast grind?

One of our local club members did some extensive experimenting with an electric drill attached to a Corona (after gettting the plates adjusted to his liking).

The result of his research was that anything faster than one crank per second gave unacceptable results (too much flour). A cheap adapter from the local hardware store stabilized his drill at 60 rpm and he is now a very happy camper who makes some pretty terrific beer.

From: Carlo Fusco <G1400023@NICHEL.LAURENTIAN.CA>  
Subject: Beginner Hop Question

Hello,

As a beginner who is just starting to experiment with his brew, I have a few questions. I am an extract brewer and have just finished Charlie's book. (I now know there is more to brewing beer than following the instructions on the tin of syrup) The first thing I did was to stop using corn sugar and use dry malt extract. Also, I am now starting to use hops.

1) I added hops to my last brew for the first time. I did not want the hassel of sparging the leaves so I improvised. I boiled the hops in a small pot of water for 30 minutes. (I used pellets) I then used a coffee filter to add the hop water to my boiling wort. I stirred it in and transfered it to a open primary. Is this an acceptable way to add the bittering qualities of hops to my brew? Or, am I missing something really important by not boiling them in my wort?

2) My last batch of beer is undercarbonated. I used 1 cup of corn sugar to prime 5 gallons. It has been sitting at room temp. for 2 weeks now and still the problem persists. I think it is because I did not leave a large enough air space in the bottle. If I pour out some of the beer and recap the bottles and leave them for another week, will carbination increase? If I do this will the risk of contamination greatly increase? Will there still be enough sugar and active yeast in the bottle to further increase carbination?

Thanks for any advice you can give.  
Carlo Fusco  
g1400023@nickel.laurentian.ca

P.S. I am posting these questions because I really need help and because of the plea not to blast beginners in the last digest.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Stirring, Lupulin, Flour

To: Homebrew Digest  
Fm: Jack Schmidling

>From: pmiller@mmm.com

>OK, question #1: Why is stirring the mash unacceptable?...

>Please, please, somebody straighten this out for me. I'm hopelessly confused. Thanks!

Your confusion results from the not-so-obvious fact that there are a great many "unacceptable" ways of doing things that work just fine. This is one technology with few absolutes and this forum and others like it are great ways of finding out what works for OTHERS. It is up to you to find what works best for you.

Another tip I learned here that has since worked well for ME is called "cutting the mash". To maximize extraction, I had been stirring it thoroughly AFTER drawing the first 5 gals and letting it settle again before finishing the sparge. By using a long, thin knife to cut down almost to the bottom, occasionally during the sparge, I eliminated this extra delay. I cut from the outside/in like spokes in a wheel and a few circles in the middle after every gallon or so. This assures that all the mash is exposed to the sparge water and does not affect the filter bed.

>From: Paul dArmond <paulf@henson.cc.wvu.edu>  
>Subject: Isomerizing lupulin powder?

<When I was packing my recent hop harvest I kept sheets of newsprint under the drying screens to catch the yellow resin that falls off the hops during handling. I now have a vacuum sealed bag with 1/2 ounce of the orange lupulin resin powder.

Don't know nut'n bout isomerizing but unless you processed "tons" of hops, I would think 1/2 oz of lupulin was a significant proportion of the lupulin originally harvested. Seems to me you would want to return it to the dried hops to get its true yield.

>From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
>Subject: re: flour catcher

>If you use a Corona grain mill, as I do, you cannot avoid getting some  
>flour along with your cracked grains. Too much flour can lead to a  
stuck  
>sparge.

I hate to downplay the importance of having a proper roller mill but according to Noonan, flour should not EXCEED 10% of the total crushed malt.

He defines flour as the stuff that will pass through a 100 mesh screen. That's a lot of flour.

It is important to understand that there is a step in the process that is intended to deal with the flour and is known as "doughing in". This is the thorough mixing of the malt with a small amount of warm water prior to commencing the actual mash. If properly mixed and wetted, the flour virtually dissolves and will be held in suspension when the rest of the water is added and becomes the first to convert because it is so readily available to the enzyme-rich water.

If your process does not include "doughing in", you should either figure out a way of working it into your process or get rid of the flour.

I have been preaching about water temperature being the main cause of "set" mashes but it just occurred to me that I have never seen the term "doughin" used by anyone but me in this forum. If this means that the plastic bucket gang is not "doughing in", it could be worth looking into.

From: "C. Lyons" <LYONS@adcl.adc.ray.com>  
Subject: Frank Jones Tour & Dry Hopping

I visited the Frank Jones Brewery in Portsmouth NH last Saturday. They have tours at 11AM and 2PM every Saturday. The guide offers the guests samples prior to the tour. Kind of fun tasting the product ahead of time.

You may bring your drink with you as you tour the brewery. After the tour ... more samples :-). They only have two products available, with a third to come out next month. Their golden ale is a pilsner, and not much to speak of. Their portsmouth ale is a india pale ale, and is quite good. Their pale ale uses three types of grain: 2-row pale ale, crystal, and carpils. The tour guide (Shawn(sp?)) explained that the carpils are used to give the beer its extra body. All grain is mashed together. The mash consists of a single infusion, 145F for 45 to 60 minutes, with a test for conversion after 45 minutes. Two types of hops are used, Fuggles

and Challengers. A 55/45 ratio of Fuggles/Challengers is used for bittering, and Challenger is used for finishing. The wort is boiled for 90 minutes. The first 30 minutes is treated as a sanitation stage with no hops added. The bittering hops are added 30 minutes into the boil. After 90 minutes the boil is stopped and the finishing hops are added (steep). The reason the tour guide gave for not using Fuggles as finishing

hops was because it would give the beer a grassy character. He had the group smell the hops, and the Fuggles had a flowery aroma, but did smell green. The Challenger hops were not as aromatic, but seemed more refined, without the green fragrance.

This brings me to my question, when I dry hop I've noticed a green (or grassy) flavor. In the past I've used Kent Goldening and Cascades to dry hop. In all cases the grassy flavor from dry hopping was quite pronounced. I've cut back from 10z, to 0.5oz, to 0.25oz. I haven't had a chance to taste the last batch with 0.25oz, but I'm hoping to make the taste less dominating. Does anyone have any recommendations of An alternative hop that would be smoother? Or is this the flavor that people seek when they dry hop?

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: "Sterile enough"

I've recently been discussion yeast culture with my wife, who cultures E. Coli almost daily (she's a molecular biologist). She feels that many of us are being overly paranoid about infection -- she rarely flames her tubes, etc, nor does she feel that a "sterile box" is necessary. A fellow in her lab has a term: "sterile enough".

Now there is a question as to whether we have good reason to want a greater degree of sterility (if it indeed has degrees), because of factors such as

- \* Beer wort is (initially) a very attractive medium for lots of nasty things to grow in. (As opposed to specialized culture media?)
- \* Yeast in beer grows for a much longer period than the typical "plate culture" in a lab.

It's kind of funny -- I'm running around paranoid about infection and she's much more casual. Familiarity breeds contempt?

From: Jon Binkley <binkley@beagle.Colorado.EDU>  
Subject: Aerobic vs. Anaerobic

Sometime last week I wrote:

>>Another seeming paradox of open fermentation which confused me  
>>for quite some time is: given fermentation is an ANaerobic  
>>process, how can it take place in an open, aerobic environment?

In Digest #963, Jack S. asked:

>Would not the fact that a blanket of CO2 over the beer make it an  
>anerobic  
>environment?

While the CO2 level would be too high for you or I to breathe, I'm pretty sure that there would be too much oxygen exchange for it to be formally called anaerobic; labs working with obligate anaerobic bugs go to some pretty extreme measures to keep ANY O2 out of their systems.

At least one brewery which employs open fermentation, Samuel Smiths, not only ferments in open tanks but actively aerates the wort throughout primary fermentation. They have what looks like a fountain head in the middle of each of their big slate tanks and periodically pump the fermenting beer through it. Seeing this was what got me perplexed in the first place- all my biochem profs and textbooks said that alcoholic fermentation was an obligate anaerobic process. Luckily for us, the yeast don't listen to them.

>

I haven't bought a Bud keg in many years, but I have one from a previous life. It is technically known as a Golden gate keg. Mine has two fittings, one on the top and one on the side near the bottom. My brother made a special tool to remove the valves, which is no more than a flat plate welded to a handle. The flat plate is the right width to fit into the slot of the fitting.

Subject: Corsendonk

After seeing the brand name Corsendonk mentioned here in the digest, and seeing it in a store, I bought a bottle. I'm glad that's all I bought. Perhaps I got a bad bottle, but it tasted infected. Mind you, I've never had a Belgian beer before, so I don't know if they are supposed to taste this way. But, when my beer has tasted like this, I poured it out. I didn't know I should have been selling it for \$3 per bottle.

From: walter@lamar.ColoState.EDU (Brewing Chemist)  
Subject: Skimmin the Skum

Howdy Folks,

I started a batch of mead the other day. While looking for recipes, techniques, etc., I came across Byron Burch's recipe for his "Alberta Frost" mead which won him best of show last June. In his recipe he said that you should skim the scumk that forms on the top of the honey during the boil. And, I believe that I have seen this advice at least one other time.

My question is, why? I do remember talk of skimming wort when boiling to prevent boilover. Is this the reason in mead?

From: mcnally@wsl.dec.com  
Subject: re: dough-in

If you're doing a single-step mash by heating water and adding the grain to the water, the dough-in step is a pain. I've had success in breaking up flour by using a big wire whisk vigorously for a couple of minutes after dumping the dry grain into the mash water.

> primary. Is this an acceptable way to add the bittering qualities of hops to  
> my brew? Or, am I missing something really important by not boiling them in  
> my wort?

I've never tried this particular technique. The only serious objection I can think of is that the hop bittering efficiency is strongly dependent on the volume of the boiling liquid (at least, according to some learned reprints a friend gave me, which I don't have at hand). Apparently the hop acids et al. reach equilibrium quickly, and 2 oz. of 4% alpha acid hops produce \*much\* more bitterness in a five-gallon boil than in a two-gallon boil. But I don't know...you're performing a grand experiment now, so let us all know how it comes out.

By the way, sparging the hop pellets or even flowers isn't really that bad. When I use a bucket for my primary, I fit the top with an elasticized disk of fine nylon mesh I got from the local homebrew store. I pour the wort through the mesh...that's that. When fermenting in a carboy, I siphon the wort in, and since hops generally float I haven't had any trouble there, either. By the time I get down to the bottom of the pot, I can just pour the last gallon or so through a mesh-lined funnel by hand.

If your local shop doesn't carry any hop-straining cheesecloth or nylon gadgets, let me know and I'll dig up a mail-order address. The gadgets are really really cheap and helpful.

> and active yeast in the bottle to further increase carbination?

Personally, I \*never\* mess with the bottles after bottling, because it's at

bottling that I most often cause infections. One cup in five gallons is more than adequate; in fact, I've had over-carbonated beer using one cup and lately I've been cutting back to 3/4 cup. Air space may not be the issue: even one or two finger's worth of space is adequate. (You didn't fill the bottles right up to the lip, did you?) Most likely you have some slow-working yeast there. Give it another week, since I've had beer that has taken three to four weeks to carbonate properly.

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: Dry ice

As you may recall, I recently asked the readership for advice regarding the use of ascorbic acid for the purpose of preventing (or repairing) damage to a finished beer due to oxidation at bottling time. Judging from the low number of responses (2), I guess not too many people bother with it. This is a very relaxed crowd, who obviously don't worry too much about oxidation.

But, I can't help it- I've got this mead that's been sitting in my carboy for nearly a year now, and I don't want to take any chances. I happened to read my summer edition of Zymurgy the other day, and in it, Charlie P. advocates the use of dry ice. It's such a simple concept! Just take a chunk of dry ice, and put it in the bottom of your bottling bucket, and allow it to "melt" (actually, sublime.) As the CO2 changes from solid to gas, it will displace the air in the container, and, since it is somewhat heavier than air, it will (hopefully) stay there.

This, then, is my solution. I will throw a chunk of dry ice into my bucket before racking, allow it to fully sublime, rack and bottle my mead, and then cap with SmartCaps to absorb any O2 that may have made its way into the bottles in the mean time.

But, now that I think about it, I wonder if the dry ice might be full of contaminants and nasties. Any thoughts on that?

Trying to relax,  
Chuck

Subject: Big Bad Wold

To: Homebrew Digest  
Fm: Jack Schmidling

>As a beginner who is just starting to experiment with his brew, I have a few questions.

I would normally assume that the Digest would be flooded with answers but in light of the recent remarks about a "Jack Free Forum" and today's limited entries, we may be all that is left. So here goes....

>1) I added hops to my last brew for the first time.

I remember the first batch I made with real hops. It was the first time I ever smelled the stuff and really got hooked on that smell. The hopped extract is a rather poor substitute.

> I did not want the hassel of sparging the leaves so I improvised. I boiled the hops in a small pot of water for 30 minutes. (I used pellets) I then used a coffee filter to add the hop water to my boiling wort.

I am affraid what you did is not much of an improvement on what they do in hopped extract. They basically add "hops extract" to the malt extract. A

much better approach would be to add pellets directly to the wort and boil it for the full time. You can use Kinney's copper scrubber around a syphon or my system of a short roll of window screen pinched off at the end.

I suspect a copper scrubber stuffed in a funnel would also make an acceptable filter.

I will let the experts fill in the details but a whole bunch of chemistry takes place while the hops boils in the wort and it just does not occure when done separately.

>2) My last batch of beer is undercarbonated. I used 1 cup of corn sugar to prime 5 gallons. It has been sitting at room temp. for 2 weeks now and still the problem persists. I think it is because I did not leave a large enough air space in the bottle.

The head space has little or nothing to do with carbonation level. There are

a number of possible causes/solutions to you problem:

Time.... give it a few more weeks before you condemn it. The is particularly true in cold weather.

Incompletely rinsed bottle. If any bleach was left in the bottles, it would kill the yeast. However, you said under- not un- carbonated so I doubt this is the problem.

There are other possibilities but I would bet it will improve with time.

If not, try adding a little more sugar to a few bottles just to see what happens. BTW, when I was using bottles, I always bottled several samples in plastic pop bottles just to monitor the carbonation. When they get hard, you know they are carbonated without having to open them.

>P.S. I am posting these questions because I really need help and because of the plea not to blast beginners in the last digest.

Well, now you know that, the Big Bad Wolf is a myth. His teeth are sharp but he only bites in self-defence.

Subject: Stout Recipe ???

Hi everyone...

Will wonders never cease??? Whilst at a local watering hole (serving a decent variety of beers: Roratonga Rodeo in Arlington, VA) this weekend, I discovered that my sweetie does indeed have a taste for beer, heretofore unknown to either of us. What struck a happy chord upon her palate was a particular variety of stout, a very sweet stout. We discovered two which she enjoyed: Watney's Cream Stout and Dragon Stout from Jamaica. I've had a few stouts in my time, but these were sweet; like they had sugar added or something.

Can anyone suggest an extract based recipe for such a beer?

Thanks,

-Chris Estes-

A solution to cooling that people have recommended to me (including my wife the microbiologist) is to use cooled sterile water. Of course this water doesn't remain sterile very long once exposed to air, but presumably you are organized and not spending forever transferring with the loop.

As others have mentioned, the unused part of your plate works as well.

>that shaking beer (before bottling) is bad--leads to oxidation  
>which taste buds don't like. So what is the difference in the  
>two settings? Why is unfermented cooled wort not as susceptible  
>to oxidation?

Roughly speaking, there are two basic processes in action as far  
as oxygen is concerned in brewing:

- 1) Yeast will use dissolved oxygen in the wort to reproduce.  
Lack of dissolved oxygen can cause poor fermentation. An  
article in \_zymurgy\_ claimed that this is the biggest problem  
for beginning homebrewers.
- 2) Oxidizing reactions will occur for certain molecules in wort,  
causing new molecules that adversely affect the taste, can  
darken the wort, and probably a handful of other things.  
Believe me, you don't want to hurt your beer any more than you  
have to. :-)

\*Plus\*, the 2) processes occur \*much\* faster at high temperatures  
than low ones. I know someone posted some numbers on this in the  
HBD, though I couldn't find it with my limited data base at work.  
Anyway, the molecules will oxidize at least several orders of  
magnitude faster at boiling temperatures than at 60F. So, even  
though you risk causing 2) when you aerate for 1), if you do it  
just before or shortly after you pitch the yeast, and the wort is  
cool, the dissolved oxygen should be used by the yeast and not  
cause perceptible levels of oxidation.

Hmmm. I sincerely doubt that lack of head space (air space) in  
the bottle is the problem. I leave about 1/4" to 1/8" in my  
bottles, as a rule, with no carbonation problems at all.  
Even those I overfill leaving no head space carbonate just fine.

Perhaps there is some other factor in the process you used to  
bottle (sometimes a problem mixing in the sugar syrup causes some  
bottles to be undercarbonated and others to be overcarbonated)  
that is affecting carbonation. Room temperature is at least 70F,  
right? What kind of carbonation level do you have now? Are you  
sure the bottle caps were crimped tightly? Does it have a good  
head but poor carbonation or good carbonation but no head?

Before you consider rebottling, check the rest of the  
process. Anyway, I always tell people that if you can ask the  
right questions, you are more than halfway to the solution  
<grin>.

Date: 8 Sep 92 11:13:00 -0700  
From: BELLAGIO\_DAVID@Tandem.COM  
Subject: How much fresh hops to use?

I recently brewed a batch of IPA with some fresh Cascade hops I received from a friend. These were just recently harvested. They sure looked great. Not like the ones I get at the brew store all packaged up. BTW, I did not use my Oak Chips as I didn't want to possibly make an overly woody beer and as people pointed out, traditional IPA does not have an Oak barrel flavor. So, now I have a few questions:

- 1) Is there a way to determine the AAU from the hops I have? I assume there is now way, but, the most potent Cascade hops I have seen in the store are around 7.8% AAU. Is there a maximum AAU for each type of hops or could any hop type be at any AAU level?
- 2) Are pellet hops fresher than the whole hops purchased at brew stores? One book I have read states that they are, but the store I go to always pushes their whole hops claiming that they are fresh. Maybe they just want to move their inventory.

Super Dave

From: CW06GST <CW06GST@SJUMUSIC.bitnet@CUNYVM.CUNY.EDU>  
Subject: NOVICE QUESTIONS

Hello All,

I hate to do this but...about a week and a half ago I posted an article under the title "The Novice Revisited". The day after I sent in the article my node @SJUVM was shut down and consequently I was not able to receive any mail.

In that post I asked a few questions and if anyone answered them I appreciate it but I was not able to read them. I will repost a summary of the questions and ask that if you answered them in the first place that you resend them to me at CW06GST@SJUVM. Of course all are welcome to comment, suggest, flame or do whatever you want as I am not easily offended. I will post a summary of answers if it is warranted.

1. Can anyone suggest some good reading material other than Papazian or Miller? Preferably something entertaining as well as informative.

2. Please send suggestions, comments, tips, recipes, advice on the following styles of beer: Porter, Stout and Marzan. I will soon have access to a refridgerator and would like to try making lager beer. Unfortunately I am only able to brew extract beers presently, so please post accordingly.

3. I recently tried to make a mead and would like to know how long it takes to ferment. When I went to the homebrew supply store they told me to add 1 pkg. of yeast for every gallon of mead. It was a wine yeast that looked and smelled like ground up mushrooms. I also added a package of yeast nutrient. After about 12 hours very vigorous activity began and the fermentation lock blew of 3 times. It has been about 2 weeks now and there is still a lot of activity in the fermenter. Also, what can I expect the finished product to taste like? I have never tasted mead.

4. Finally, if there are any brewclubs in the lower Westchester, NYC area, my partner and I would be interested in joining; if there are other brewers in this part of New York who are interested in forming a brewclub please let me know.

Thanks to everyone for this wonderful forum.  
Erik Zenhausern CW06GST@SJUVM

Date: Tue, 8 Sep 92 10:18:54 PDT  
From: hartman@varian.varian.com (John Hartman)  
Subject: re: DMS and Briess Malt/Gears for Motorized Mill

I too am speaking up to say that I have had a recent DMS experience and I use Briess malt. I couldn't figure what might have caused this as nothing unusual occurred during the process. It simply smelled mightily of cooked corn. It's an experience you do not want to have. I had to throw that 10 gal. batch out, which was quite a disappointment. I wish I could say for sure that the problem was the malt, but I can't since apparently an infection can cause high levels of DMS. Micah's test sounds pretty conclusive though. Way back in digest 765, 11-21-91, Jack Schmidling pointed out that in the direct firing process the grain is "sulphured". The grain is sprayed with sulphur as a means of reducing the nitrosamines to a level below the FDA limit of 10ppb. Maybe they forgot to wash the sulphur off after the process or they used too much sulphur. Who knows. Perhaps the Briess people know. At any rate does anyone have a reasonably priced California source for Great Western Malts? If you do, please speak up.

On a different topic, I plan on motorizing my grain mill. I have a 1700 rpm, 1/4 HP motor which I'd like to use. I'll be attaching it to the mill with what I guess you'd call pulley wheels and a radiator belt. I don't know who sells these pulleys though. Does anyone have a vendor for such pulleys, or at least an idea of what type of vendor sells them?

Thanks in advance,  
John

From: chuck@synchro.com (Chuck Cox)  
Subject: Re: Electric Corona

Thanks for all the useful suggestions about electrifying my Corona.

Here's what I did:

I made a small sawhorse with the cross-beam sticking out 8" or so on one end. I Added a 4"x4" shelf on the side of the long end. When the Corona is mounted on this shelf, it is parallel to the beam and discharges over the end. I made a simple drill mount with some scrap 2x4 which bolts to the handle bolt hole on the drill. Using empty bleach bottles, I fabricated a larger hopper and a discharge guard. I attached some flexible ducting to make a discharge chute that empties into a small barrel.

Looking down at the empty chassis:

```
----- legs
 / /
 / /
cross-beam
  +---+ +---+ /
  |   | +---+ |   | /
+-----+-----+-----+-----+
+-----+-----+-----+-----+
|   |   |   | ++ |   |
+---+ +---+ / +---+
  /
  / /
 / drill mount bracket
 /
mill mount shelf
```

Looking at the side:

```
drill mount bolt
 /
 / bit of wood to help support drill
+-----+ /
| o   ++ /
+-----+
|
+-----+-----+-----+-----+
+---+ |   |   |   |
+---+-----+-----+-----+ |---+
|   |   |   |
|   +-----+
|   +-----+
 / |   |   |
 / +---+ +---+
 /
bit of wood to help support shelf
```

With everything attached:

```
+-----+
| | ----- extra hopper (approx 5 lb capacity)
```

```

| |
 / /
 +-----+
 | | corona w/ large hopper
discharge| | /
chute// / / big variable speed drill
 / / - / / /
 / / - - - / / /-----+ /
 / / / -+ | |====< ++
 / / // -+ / - - - / / - - - +
 // // + - + + | / - /
 // - - - + | | +-----+-----+-----+
 // + - + - + | | | | | |
 // + + + + + = - | |-----+ | - - +
 | | | | | | | | | |
 +-----+
 | | | | | | | | | |
 | | | | | | | | | |
 +-----+
 | | | | | | | | | |
 +-----+
 +-----+ +-----+ +-----+

```

Its not quite as unbalanced as it looks. The drill is fairly heavy, and the sawhorse extends far enough back to act as a counter-balance. I have only tested it with small amounts of grain. I hope to have my new brewery finished this week, then I'll run about 20 lbs through it.

From: Richard.Goldstein@EBay.Sun.COM (Richard Goldstein)  
Subject: Conducting the boil and beer color

OK homebrew fans--

I have two questions, and I believe that they are at least partially related.

1) What is the proper way to conduct a boil (for an all-grain brew)? Dave Miller talks about a strong, vigorous boil for at least the first 30 min to help the protein coagulation. And homebrewing companions have talked about a roiling boil to get the most out of the hops. But do I really want that full-strength of a boil for the whole boil?

The reason I am wondering is that I seem to be boiling off more than most of the books/recipes assume. If I sparge to 6.5 gals, I can easily boil away 1.5 gals rather than 1.0 gals that are usually assumed. I'm not using a blast furnace or anything, just a plain old gas stove. Beside leaving me with less finished product, we now go to question #2...

2) How do I make a light colored beer? This may sound funny, but I haven't really been able to get a pale (straw colored?) brew. I'm talking about beers made with 2 row Klages malt, and maybe an adjunct like Vienna malt. I realize that my full-blast boils are caramelizing my wort, and that is difficult to avoid to a certain extent. But what do you folks do to create light colored beers?

Are there any other dangers/defects/flaws I should be aware of due to vigorous boiling?

Thanks for your input.

Date: Wed, 9 Sep 92 11:20:22 MET  
From: dejonge@geof.ruu.nl (Marc de Jonge)  
Subject: Conducting the boil and beer color

In HBD 965 Richard Goldstein asks:

>1) What is the proper way to conduct a boil (for an all-grain brew)?

>..

>The reason I am wondering is that I seem to be boiling off more than  
>most of the books/recipes assume. If I sparge to 6.5 gals, I can easily  
>boil away 1.5 gals rather than 1.0 gals that are usually assumed.

and:

>2) How do I make a light colored beer?

and he suggests these problems may be related.

Well, I'm not sure about the relation (apart from caramelization) but  
I use a somewhat different method for mashing, if I'm brewing light  
(coloured) beers, which seems to solve both problems:

In my experience using more (up to an extra gallon) water for the mash  
produces a lighter wort (after boiling to the desired gravity) and  
it gives you a larger wort volume before boiling.  
I prefer using more mash water to more sparge water to avoid  
extracting nasty flavours from the husks.

I hope this is of some help.

I'm not certain, but I seem to remember that ascorbic acid only really  
works with wine... I can't remember the refernce to this, as all my  
brew books are in a different continent.

>This, then, is my solution. I will throw a chunk of dry ice into my  
bucket  
>before racking, allow it to fully sublime, rack and bottle my mead, and  
>then cap with SmartCaps to absorb any O2 thay may have made its way into  
>the bottles in the mean time.

>But, now that I think about it, I wonder if the dry ice might be full of  
>contaminants and nasties. Any thoughts on that?

Sounds like a good idea, and I doubt you have to worry about any  
contaminants in dry ice, as the extremes in temperature and pressure  
in making the dry ice probably would kill anything...

Before everybody flames away about what I have to say here, let me stress that my methods work for me personally, and may not work for other people. Also, I don't know anything about yeast culturing; I am talking about simple brewing here.

I have been following the discussion about clever ways to start a siphon without touching, and ways to sterilize bottles (soak in bleach, followed by a dishwasher cycle with baking at the end, etc.). In my opinion, a lot of people are worrying way too much.

I rinse my bottles with hot water after use and before bottling, using a bottle washer. I suck on the hose to start siphoning. Everything works just fine for me. I have not had any infections since my first few batches.

From: Paul Matulonis <paulm@sci.ccny.cuny.edu>  
Subject: Stout recipe

Chris Estes (cestes@argos5.dnet.nasa.gov) asked for a stout recipe that is extract based. The following is a batch I 'krudged' up (as I found I lacked the proper ingredients to dupe the stout I was aiming for); it turns out to be MUCH better than the stuff I was looking to duplicate.

Grains were crushed and steeped in a bag in a pot with about a gallon of H2O for about a half hour. The total volume of the boil was about 3 gallons. "Big pints" refers to Fischer beer bottles which are about 22 oz.

I still have about three bottles left of this stuff and it still tastes great (had one just the other day!). No nasty caramel taste or other nasties.

21 March 92  
Krudge

1 can M&F stout  
1 lb each amber & dark dme  
200 g each black patent, chocolate malt, roast barley  
600 g crystal malt  
16 g gypsum  
2 oz chinook (boil)  
1 oz centennial (boil)  
1 oz cascade (finish)

Crush grains; steep at around 60-70 C; sparge with lotsa cold H2O. Add extracts, gypsum, boiling hops. Add finish 5 min before end; total time in copper around 45 m. Chill brewpot on ice; bring to about 3.5 - 4 gal.

Racked at 5 days; minimal activity at this point  
Bottled at 11 days; no activity at all at this point  
primed with 100g sugar/400ml H2O  
got 20 pints and 5 big pints  
SG= ???  
FG= ???

Taste: (initial) nice, bitter, sweet  
(after 2 months) similar to Canal Sludge Stout

Good luck!

>digest, and seeing it in a store, I bought a bottle. I'm glad  
>that's all I bought. Perhaps I got a bad bottle, but it tasted  
>infected. Mind you, I've never had a Belgian beer before, so I  
>don't know if they are supposed to taste this way. But, when my  
>beer has tasted like this, I poured it out.

This subject comes up from time to time. After all, for  
beginning brewers, the simplest advice is "if you like to drink  
it, it's OK".

<soapbox mode on>

However, there comes a time when you really want to try other  
styles or analyze what can be improved with your regular brew or  
what went wrong with a bad batch. IMHO, bringing such beer to a  
homebrew club meeting is about the best method there is.  
Essentially, you want other people to give you  
feedback--hopefully experienced beer tasters. This could be the  
folks at the homebrew supply store, the homebrew club meeting, or  
even a homebrew competition, for example.

Only when you learn to taste beer analytically can you hope to be  
able to answer such questions as "Is this commercial beer  
infected or oxidized or otherwise damaged, or should it taste  
like this?" or "Is my beer infected, or just not brewed as well  
as it could be?".

Now we have seen in the past here that not everyone \*wants\* to be  
able to analyze his/her beer, which is fine. But for those who  
want to keep learning and improving, it is essential.

From: Mark Rich <MPR8A@acadvm1.uottawa.ca>  
Subject: Fruity stuff

Well, here it is; my first (beginner alert!!! bweep!bweep!bweep!) posting.

So please, oh seasoned brewing veteran gods, curse me not! Ok; enough with the disclaimer/warning; on to the question... My wife-to-be is NOT a big fan of beer; but she does like those DURANGO fruit/malt/cooler-type beverages. In particular, she loves the orange and citrus flavour stuff. I don't mind the stuff either, (forgive me, oh brew gods) so I was wondering if anybody out there in the land had experimented with recipes for this sort of thing. I am not very experienced... (a couple of kit beers) so please be detailed in your modus operandi. I have read Papazian's new book; and checked out the Cat's-Meow, with no luck. Any bits of wisdom would be greatly appreciated. I can be e-mailed directly at MPR8A@ACADVM1.UOTTAWA.CA

I have been subscribed for about two months now, and I'd like to put in my \$0.02 worth... There is a lot of great info to be had, but all this nastiness seems rather uncalled for. From personal experience, I can tell you that it does make us rookies a tad nervous about asking questions; lest we be smitten by a bolt of lightning. My advice to people with nasty comments: LIGHTEN-UP !! !! or maybe form a new interest-group; like SnideRemarks@malcontent.get.a.life. and keep that ##it off an otherwise friendly and enjoyable forum. Hypothetical question: You're at the garage, waiting to talk to the mechanic about the noise your car is making and what the problem might be. The guy just before you describes the same noise to the mechanic as you listen in; The mechanic rolls his eyes, and tells the guy he is LAME for not knowing what the problem is. Do you. ...  
a) agree that the guy should not ask such stupid questions?  
b) leave quietly and take your business elsewhere?  
c) ask the mechanic the same question and brace yourself?

We can't all be mechanical or brewing wiz'... Think about it

From: HOGLE RICHARD A <HOGLE@CRDGW2.crd.ge.com>  
Subject: A few cents worth of stuff

Hi all,

I've been a regular read for some time now (#320 something was the first issue I received), and have been brewing for about 5 years with 70 batches complete. Just thought I'd add my two cents:

On Labels:

I use a Mac to make labels which I stick onto the bottle caps with a glue stick. Dimensions are 1." x .5", then reduced by 25-30% before printing (use a copier machine to reduce if your software can't). This takes about 5 minutes to make and print 40 or so labels. Takes another 5 minutes to cut the labels out. I can fit the batch #, name, date, and major ingredients onto each label. I don't really care if the labels are bigger than the cap- it's great to be able to see what went into the beer your about to drink.

Starting a Siphon:

I fill the siphon tube part way up with water, then drain into a cup, stopping it just after some beer flows out the end of the tube.

On Brewing:

I still brew with extracts (over 5 years now) and am pretty happy with the results. In fact, the brews keep getting better and better, partly from some tips I've gotten from HBD and partly from moving up the learning curve.

- The two biggest improvements in my beer came when I went to liquid yeast and started using an immersion-style chiller.

Using the chiller:

The wort cools from boiling down to about 90F in about 15 minutes. Then I siphon the cooled wort into my carboy that has about 1.5 gal of cold tap water. (leaving behind whatever break material and hop particles might be in the pot)

Then

I top off the carboy with tap water, and pitch the yeast. I don't use a starter (I'm too lazy) and generally see visible fermentation within 8-24 hours.

Brewing takes me about 2.5 hours, from the time I pull the pot out, until

I put it away clean.

I brew 12 to 15 batches per year. Wyeast costs me about \$4. per pack.

That's about \$2.50 more than dry yeast per batch, or about \$38 spread out over a year. To me, it's worth it, but not so expensive as to force me to try culturing.

When the kids are older and when I have more free time, I'll try some

all-grains, 'til then, I'll stick with extracts.

#### On Fermentation:

I use single-stage fermentation in a glass carboy (5-gal) with 3/8" blow-off (never had a clogging problem, as I used to strain the hot wort as I poured it into the carboy- probably oxidizing the wort. Now I siphon as above)

I rarely rack to a secondary, mostly because it seems like extra work.

The times that I did, I did not notice any improvement in the final product (though that was prior to liquid yeast days, so maybe I try again to see if there's a difference).

Fermentation is usually complete in 2-3 weeks. Sometimes I don't get around to bottling for a month or 2. I have notice that if the beer sits in the primary for more than 6 or so weeks, off flavors start to appear, so recently I've been trying to bottle before then. I haven't taken an SG reading since about batch 15.

#### Bottling:

I fill my priming tank (a plastic tub with a spigot at the bottom, from Williams) with cold tap water and 1/2 cup clorox. Then I attach a plastic hose to the spigot and rinse out my bottles with this sanitizing solution.

This way I sanitize the tank, the hose, and the bottles in one operation.

I also put anything else that will touch the beer into the tank while I'm rinsing the bottles.

When I'm done, I rinse everything with tap water, but after reading some of the comments in HBD, I may hold off on rinsing for one batch to see how it turns out.

I use two glass tubes during bottling, one about 20" which goes into the carboy, the other about 12", which I use for bottling. Glass is nice since it's easy to clean and sanitize.

To bottle, make a sugar syrup of 3/4 cup corn sugar, about 1.5 cups tap water in a sanitized Pyrex measuring cup. I heat this to a boil in the microwave (~4min). The syrup goes into the priming tank.

Using the plastic tube with the two glass canes, I siphon the beer on top of the syrup. I move the priming tank up to the table, transfer the hose-end at the carboy to the spigot, I open the tap and start bottling. The smaller glass tube goes all the way to the bottom of the bottle. I just crimp the end of the plastic tube when the bottle is full, grab another bottle, and fill.

I use the old two-handle bottle capper and have never had a problem with this over the 5 years of brewing (70 5-gal batches).

Bottling takes about 3 hours, from when I start collecting bottles,  
until  
I put the clean carboy in the basement.

oops...

I have had my share of boil-overs, under/over carbonated bottles,  
etc..

but not so often anymore. Of all the batches I've brewed, only one  
was undrinkable and got pitched. With that batch, I had tried letting  
the break settle overnight, racking to another carboy, then pitching  
the yeast. It was mid-June and there were just too many beasties  
around.

I learned my lesson.

Finally,

A long time ago, I brewed several batches of beer in succession,  
thereby giving me a stockpile of 5-8 cases which now remains more or  
less

constant. When I bottle a batch, the bulk of it ages for a month or  
two

or three before it reaches the front of the stack. The beers come out  
crystal clear and nicely carbonated, and of course, I always have a  
variety

of beers on hand (each with an ingredient label as above).

With this scheme, sometimes a few bottles from a batch might be  
around for a year or more. I've noticed that the beer improves for 6  
months or so, and then stabilizes. I've not noticed any detrimental  
effects of having beer in the bottle for more than a year. The beer  
is stored in the corner of my basement (in a small room I built- some  
2x4's, dry wall, and insulation) at 60-75F.

Relax, Don't worry, Have a Homebrew.

From: jim busch <busch@daacdev1.stx.com>  
Subject: Re:DMS from Briess

There has been much talk in the digest recently about DMS problems that are attributable to Briess malt. Certainly the DMS precursors can come from the malt. I just have a problem with homebrewers claiming such problems since so many micros, pub breweries and mega breweries use the same malt without DMS problems. Here's my experiance:

Most of my beers are made using 2 row lager malt from Froedtert Malt Corp. I make mostly ales, but a Maibock was made from this malt with great success. In May, my malt supplier installed an auger and i was without a malt source and switched to precrushed Briess brewers grist. I always do a 122F protein rest followed by a 152-154F Saccrification, and a 170-175 mash off. I recirc the runoff 30 minutes (horrors!), and sparge 60-90 minutes total. I also stir my mash as the heat is added to do the upward step mash. Boil in the kettle is at least 90 minutes and a whirlpool technique collects the hop cone. Counterflow chilling (4 1/2inch refridge copper lines inside 4 3/4 inch garden hose)

Then ferment with 1 lb/BBL healthy, viable Narragansett yeast.

The results: Nobody could tell the malt change. The resulting beers won blue ribbons. Even a decoction mashed Wheat beer did well. Maybe the body is a little thiner than with lager malt, maybe not.

The local brewery, Old Dominion Brewing CO, uses the same malt...never, never have they had a DMS problem. They make lagers and ales/hybrids. Numerous other respected breweries employ this malt with great results. Are all these DMS problems with lager beer only?? Has technique been adequately ruled out? Is the yeast truely healthy, and in adequate supply and is enough Oxygen introduced??

I have to believe this is another MOMILY since i respect the brewers and beer produced with this malt and while i expected the quality of my beers to go down with this malt, it did not.

Just another data point...

From: Alan\_D.\_Thomson.LAX1B@xerox.com  
Subject: Oxidation

Just my tow cents.

I'm an extract brewer (for the last year and a half). About a year back, I started to boil my brewing water (I live in LA). I noticed a big difference in the quality of the brew. I also figured that during the boil, O<sub>2</sub> would be lost. With that in mind and knowing that it is also possible to cause oxidation to occur in cold wort, I decided to aerate the boiled brewing water. So, what I do now is shack the boiled water in my secondary, fill my primary with cold wort, fill the primary with (aerated and boiled) water to five gallons, and aerate the primary just a little.

If this sounds cracked, please let me know.  
AT

PS.  
I've noticed some inquires about Watney's Cream Stout, but no response. If someone has a recipe, pleas post.

From: gjfix@utam.uta.edu (George J Fix)  
Subject: Malt (George Fix)

I think Tim Norris deserves a medal for making the Belgium malt available to homebrewers. I was told when I was in Germany a few years ago that France and Belgium were the prime areas for growing barley, and that malt made from these grains was the best available. Now that I have actually brewed with them I am a firm believer. In fact, I just recently ordered 200 lbs. from Tim which included the Pils, Pale Ale, Cara-Vienna, and Cara-Munich. From this point on this is the only malt I am going to use. Tim's prices are also very reasonable.

The Cara-Vienna has one serious defect that can be detected by chewing some. Namely, it tastes so good that I have to use all my willpower to keep from having it for breakfast! We have a Vienna currently in the secondary that was made from the Pils malt as well as the Cara-Vienna and Cara-Munich in the same amounts cited in our book. The Cara-Vienna was used to replace both the Irek light crystal and the English caramel. Already it is promising to be the best version we have done.

I am getting slightly higher yields with the Belgium malts than I got from the Irek malts. For example, in the Vienna we were shooting for 12.5 P (1.050), but wound up with 14 P (1.056). We also are getting more color extraction, e.g., 11 deg L instead of our usual 8-9 deg L.

I want to second Micah Millspaw comments about the bad malt that is out there. For example, a malt analysis showed protein levels at a staggering 13.5%. The Belgium malts, on the other hand, range from 9-10 %. Also the SMM levels were 4 to 5 times that of normal malt. (SMM is the major DMS precursor in malt). I agree with Micah that malt like this is not fit for brewing. There are some deserving cows out there which can put it to much better use!

From: Jeff Benjamin <benji@hpfclub.fc.hp.com>  
Subject: Re: Conducting the boil and beer color

Richard.Goldstein@EBay.Sun.COM asks:

> 1) What is the proper way to conduct a boil (for an all-grain brew)?

You're correct in using a full rolling boil for the entire time. Another purpose of the boil, besides coagulating proteins, is to eliminate unwanted volatiles via the steam. Maybe someone knows the exact chemistry, but I've heard that various sulphur compounds and other nasties are boiled away. Try condensing some of the steam from the boil kettle and tasting it -- yuck!

I always seem to lose more liquid than average as well, so my solution is simply to top up the boil with water if it falls below the optimum amount. You can pre-boil the water if you're worried about the drop in temperature, but since it will boil again after a few minutes, you don't need to pre-boil it for sanitary reasons.

My kettle is graduated, which makes it easy to tell what the current volume is. If yours isn't, take your charismatic wooden spoon and notch it at 1/2 gallon intervals. Then you can stick it into the boiling wort and tell how much you have left.

> 2) How do I make a light colored beer?

I asked myself this question for a while too. I think it would be somewhat difficult for a homebrewer to make something as pale as BudMilloors. The big boys use uncured malt that hasn't been roasted at all after being kilned dry, and so is lighter than most malt I've seen at the brew shop. You may want to ask your malt supplier about getting uncured or unroasted malt.

I'd guess that your average big commercial lager also contains more water than your average homebrew. That would make it lighter for sure.

I've never seen a beer style as pale as American lager; I think the reason for the paleness is more due to economics than aesthetics. But who wants to homebrew a Bud? You can achieve a satisfyingly pale beer by using only light malts (pale and maybe a small portion of Vienna) and making sure your wort has a reasonably low starting gravity (say 1.040, give or take).

See the recipe I posted a few issues back (#954) for Kolsch. That beer consistently comes out only a few shades darker than Bud.

From: Richard Childers <rchilder@us.oracle.com>  
Subject: various and sundry

Ed Westmeier says :

"One of our local club members did some extensive experimenting with an electric drill attached to a Corona (after getting the plates adjusted to his liking).

"The result of his research was that anything faster than one crank per second gave unacceptable results (too much flour). A cheap adapter from the local hardware store stabilized his drill at 60 rpm and he is now a very happy camper who makes some pretty terrific beer."

Thanks !!!

Carlo Fusco asks :

"1) I added hops to my last brew for the first time. I did not want the hassel of sparging the leaves so I improvised. I boiled the hops in a small pot of water for 30 minutes. (I used pellets) I then used a coffee filter to add the hop water to my boiling wort. I stirred it in and transferred it to a open primary. Is this an acceptable way to add the bittering qualities of hops to my brew? Or, am I missing something really important by not boiling them in my wort? "

Hops are used in two ways. The first application is for bittering, and relies upon the boiling action to loosen and detach the bittering molecules upon the flower-leaf complex.

The second application is for flavoring, and this application requires nothing like boiling in order to utilize, in fact it is often compared to a 'tea' ... so your method would work for the second purpose of hops, but be less useful for the first application.

"2) My last batch of beer is undercarbonated. I used 1 cup of corn sugar to prime 5 gallons. It has been sitting at room temp. for 2 weeks now and still the problem persists. I think it is because I did not leave a large enough air space in the bottle. If I pour out some of the beer and recap the bottles and leave them for another week, will carbination increase? If I do this will the risk of contamination greatly increase? Will there still be enough sugar

and active yeast in the bottle to further increase carbonation?"

I tend to fill my bottles up to within a half inch or so, and while the carbon-

-ation is not readily visible in a closed bottle, this does not mean that it is non-existent. The only true test is to open a bottle and see.

A note about over-carbonation ... you can tell that it's time to open the bottles if you see the caps are convex, bulging upwards from CO2 pressure

...  
this is useful for avoiding the 'glass grenade' syndrome.

Date: Wed, 9 Sep 92 12:50:03 -0400  
From: trush@mhc.mtholyoke.edu (Thomas P. Rush)  
Subject: Hop Yields (Tom Rush)

If anyone would like to compare notes on hop yeilds(Southern New England vs. The World) I have just finished harvesting for the season. Grading is subjective with "outstanding" interpreted as the upper vines covered with cones, almost enveloping the leaves, and the lateral vines sagging under the weight of the cones.

1st year crop  
Bullion-excellent Fuggles-excellent  
Willamette-poor(healthy vines)  
Nugget-outstandingGalena-excellent  
Perle-good Eroica-good  
Centennial-outstanding++ Goldings-fair(vines fair to good)  
Hersbrucker-none(happy to have vines survive)  
Liberty-none(vines late but healthy)  
Chinook-poor(vines late but vigorous)  
2nd year crop  
Tettnanger-outstanding(triple the yeild of hallertau)  
Hallertau-good  
Cascade-outstanding+++ (several gallon-size freezer bagfuls of tightly packed dried hops)

I don't use insecticides, fungicides, etc. Only problem thus far are japanese beetles who seem to love Perle, Goldings, and Liberty leaves(some cones) they avoid others in decending order to the point of ignoring Bullion.

I find that drying on screens in the garage is not adequate in humid atmosphere of this area. Placing the screens around the furnace (which runs occasionally for hot water)for 2 to 4 days depending on the size of the cones will dry them consistently and also preserve their color and aroma.

Finally, two questions:

1. Does anyone know a vendor who sells "Northern Brewer" rhizomes? I also have not seen "Challenger" for sale. This would be for the 1993 spring planting.
2. Has anyone had anallergic reaction to picking and drying hops? I have no known allergies but for some reason this year I had naseel congestion during part of the picking season. Coincidence? Are the lupulins powerful enough to necessitate a dust mask?

Thanks...Tom Rush

From: "John Cotterill" <johnc@hprpcd.rose.hp.com>  
**Subject: Cajun Cooker=Toasted Porch**  
Full-Name: "John Cotterill"

I have been using my Cajun Cooker for a couple years now. In the past, I have brewed out in the driveway, generally at night. Well I had a day off yesterday, and decided to brew a batch during the day on my front porch (out of the sun). The porch is cement painted red. Well, as my wort was coming to a boil over the rocket engine (Cajun Cooker), I noticed all the paint on the porch was peeling up! Oooops. My solution was to space a piece of aluminum off the porch with a few small pieces of angle iron. Then, I put the cooker over this heatshield. Note that the legs of the cooker must rest on the porch, not the heatshield, to support 15 gals of H2O.

Sure am glad I didn't try it on the redwood deck!

>From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
>Subject: "Sterile enough"

I think the subject says it all. There seems to be a strong emotional need here to name a cause everytime someoneELSE has a problem. As sterility is difficult to prove, it is one of the old standbys.

>It's kind of funny -- I'm running around paranoid about infection and she's much more casual.

On the other hand, when a batch goes bad, it comes out of your pocket and I will bet she is spending taxpayer's money.

> : mcnally@wsl.dec.com

>If you're doing a single-step mash by heating water and adding the grain to the water, the dough-in step is a pain.

"Nothing great is lightly won." B.F.

> I've had success in breaking up flour by using a big wire whisk vigorously for a couple of minutes after dumping the dry grain into the mash water.

That's a good approach but breaking it up is not the same as getting it into solution and the only way to do this is a thorough and careful doughin.

>From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>

>Just take a chunk of dry ice, and put it in the bottom of your bottling bucket, and allow it to "melt" (actually, sublime.) As the CO2 changes from solid to gas, it will displace the air in the container, and, since it is somewhat heavier than air, it will (hopefully) stay there.

That is a good idea. However, I suspect that dry ice is not all that convenient to come by for most people. Those of us who keg beer accomplish the same thing by squirting a bit of CO2 into the keg prior to filling. You could do the same in the priming bucket and be ready for keggung when you are ready to make the full plunge.

>But, now that I think about it, I wonder if the dry ice might be full of contaminants and nasties. Any thoughts on that?

Doubt that much could survive at that temp to be much of a bother.

>From: hartman@varian.varian.com (John Hartman)

>On a different topic, I plan on motorizing my grain mill. I have a 1700 rpm, 1/4 HP motor which I'd like to use. I'll be attaching it to the mill with what I guess you'd call pulley wheels and a radiator belt. I don't know who sells these pulleys though. Does anyone have a vendor for such pulleys, or at least an idea of what type of vendor sells them?

Ace Hardware stocks a whole series of pullies (they are actually called sheaves) and belts that I have used. You need the smallest you can get and

the largest. I used a two inch on the motor and a ten inch on the mill. That gives you a ratio of 5:1 so your mill will be running at 340 RPM.

This

is much faster than has recently been recommended for the Corona. I have

never even seen one so I have no opinion on the speed. You will also have to

match the bore on the pulley with the motor shaft and the mill shaft.

The

smallest I have seen is 1/2" so you will probably have to get a bushing to

get it down to the right size for the mill.

>From: chuck@synchro.com (Chuck Cox)

>Subject: Re: Electric Corona

>I have only tested it with small amounts of grain. I hope to have my new

brewery finished this week, then I'll run about 20 lbs through it.

Please share with us the thruput when you get it working. I would be interested also in knowing how long it takes to mill a single pound and a 12

lb lot.

>From: Richard.Goldstein@EBay.Sun.COM (Richard Goldstein)

>The reason I am wondering is that I seem to be boiling off more than most of the books/recipes assume.

For what it is worth, Baderbrau claims that one of their secrets to the character of their beer is "firebrewing". What this "boils" down to is a

very vigorous boil. Enough to caramelize part of the beer.

What you are boiling off is only water and what you are looking for in the

character of your beer determines what you do about it.

If you want a heavy beer, boiling it off concentrates it. If you are hungup

and recepies and numbers, you can always put some of the water back to get

the numbers you are looking for.

I prefer to use more sparge water and make more wort to allow for the greater loss.

It's your beer and only you can determine what works best for you.

>But what do you folks do to create light colored beers?

If "you folks" includes Bud, I suspect adding lots of water and sugar  
will do  
the trick.

From: BELLAGIO\_DAVID@Tandem.COM  
Subject: RE: Big Bad Wolf and Beginner HOP question

Jack the Wolf,  
I was wondering if you have this effect on everyone you meet?  
Do people that know you quickly turn and run when they see you coming  
down the  
street? I don't know what all the fuss is about, as since I've been  
reading  
this digest nothing you have said, or anyone has said for that matter,  
has  
offended me. I simply read this and all digests relating to brewing beer  
so  
I can become the ultimate beer maker, since I am already the ultimate  
beer  
drinker. Since I have only brewed 5 batches to date, I have a long way  
to go.  
So I need all those more advanced brewers to continue posting their  
advice and experience, good or bad, right or wrong, so I can at least  
have the  
choice to accept it or discard it as I see fit. So, hopefully, no one  
will  
discontinue their participation in this digest simply because they don't  
like  
someone. Although, since this is America, they can do whatever they  
like.

About the beginner Hop question, I use a boiling bag to hold my hops  
while it  
is in the wort. I think this does not give me the same extraction rate  
as if  
I just dumped the hops in. I usually use whole hops and I guess I was  
worried  
that they would clog my siphon after the wort is cooled. Maybe I will  
give  
it a try next time.

Date: Wed, 9 Sep 92 22:00:52 EDT  
From: Pierre Jelenc@cunixf.cc.columbia.edu  
Subject: sterile, anaerobic, and carbonic

In HBD # 965

re: sterile enough

I tend to concur with Spencer Thomas's wife: extreme sterility is overdoing it. At home I do my plating in the kitchen, with no special precautions whatsoever but flaming the loops. I even do not quick cool the loops, I use two instead: while one is in use, the other is cooling, and no, it does not attract all the nasties of creation, these things have such a small cross-section!

While it is true that brewing takes longer than the overnight culture of *E. coli*, a good starter will introduce zillions of yeasts, and one or two lone bacteria won't stand a chance in the time it takes for a few percent of ethanol to build up and stop them in their tracks.

re: aerobic vs anaerobic

The CO<sub>2</sub> blanket over a fermenter is a fairly good insulator when it comes to oxygen, but in addition the yeast will gobble up any stray oxygen, maintaining the concentration to a very low level; also, it is not strictly true that fermentation is an anaerobic process: while under anaerobic conditions, only fermentation can provide energy to the yeast, it is also the case that under high nutrient conditions (i.e. wort with lots of sugars) the lazy yeasts will prefer to ferment rather than going to the trouble of maintaining the complicated machinery required for respiration. They will thus produce alcohol even in the presence of adequate oxygenation. This is not true in the case of poor media (apple juice for instance).

re: dry ice

Chuck Coronella worries about contaminants in dry ice. He's right, it's a bit grungy, but the solution is simple: put the dry ice in a bottle, and fit a piece of plastic tubing in the mouth, with a pierced stopper if necessary. Place the open end of the tubing in the bucket or carboy, and wait for the CO<sub>2</sub> to sublime in the bottle and pass into the bucket via the tubing. For extra safety, put a piece of sterile cotton in the mouth of the bottle before fitting the tubing.

From: Todd Enders - WD0BCI <enders@plains.NoDak.edu>  
Subject: Chimay Yeast & Banana, another data point...

Just another data point for strong banana ester production with Chimay yeast at higher temps. I brewed what started out to be a dubbel, but the FG it ended up at, and the color made it closer to a trippel. Oh well...

Batard de Belgique

6# US 2-row  
3.25# Dexteryne malt  
2# unmalted wheat  
1# light brown sugar  
1C blackstrap molasses  
1.5 oz. 6.1% alpha East Kent Goldings  
2/3C Corn sugar (priming)

Cook 0.5# 2-row malt and the 2# of unmalted wheat in 4-5 qt. of water until gelatinized (about 45 minutes). Mix cooked wheat into main mash water and stir until well mixed.

Mash in: 12 qt. @ 138f  
Protein rest: 30 min. @ 126-131f  
Mash: 2 hrs. @ 148-152f  
Mash out: 5 minutes @ 170f

Sparge 6.5 gal @ 170f

Boil: 2.5 hrs.  
Hops: 1 addition, 60 minutes from end of boil.

OG: 1.070 (5.75 gal)  
FG: 1.011

The long, rather cool mash seemed to break down the dexteryne malt more than I would have liked, and I only had 1.5 oz. of hops around, so the batch is underhopped. I didn't notice a lot of banana ester during the fermentation, and it tasted sweetish and has a somewhat strong molasses note at bottling, with a noticeable, but not too strong, banana component. Underneath was the characteristic woody-spicy accents I associate with Chimay. One week after bottling, the banana seemed to subside, and things \*seemed\* to be going along rather nicely. However, at two weeks after bottling, the banana component came back with a vengeance! I dropped off a 6-pack for one of my brewing comrades, and he called me yesterday to say that it was "rudely banana".

I hope the esters subside with age, as it is overpowering right now. On opening, a bottle almost fills the room with the ripe banana smell. The taste is intensely banana!!! Fermentation was at about 70-75f, for what it's worth.

Only time will tell, I guess...

From: localhost!davevi@uunet.UU.NET (David Van Iderstine)  
Subject: Re: Christmas Brew

Here's my favorite Christmas Ale, reprinted from an old HBD. I came up with the recipe myself. It was a well-received, all-extract brew. Don't believe any bullsh\*t about brewing with extracts; you can make great beer without ever going to grains! I have found the most important ingredient is the yeast, and only use liquid cultures now.

-----  
This is a composite recipe, designed to mimick Harpoon's 1991 Winter Warmer offering. I started with the spice list, as published in the Beer News (or whatever that fine newsprint rag found in various lobbies is called).

Armed with the spice list, I searched all my HBD back-issues for each spice. Whenever I found one of the spices being used, I looked for its relative weight as compared to all other ingredients in that particular recipe. By doing this for all the spices listed below, I arrived at a statistical "average" for the relative concentrations of all of them together.

Thanks to all the spice-brewers on HBD, from whom I drew my data. Maybe this proves that composite recipes work well? Does that mean that, armed with enough recipes, all other recipes possible can be derived from them? That, and a roomful of typing monkeys?

Date: Wed, 9 Sep 92 22:54:05 CDT  
From: Jacob Galley <gal2@midway.uchicago.edu>  
Subject: New Al pot / Barleywine yeast

A question and a recipe.

I'm in the process of taking the plunge into mashing: Today I bought myself an 8 gallon aluminum boiling pot (\$65 at Marlinn Restaurant Supply at 73rd & Cicero, fyi south Chicago readers) -- yay! But I forgot to ask about how to prepare the thing for use. Don't I have to cure it somehow, like most metal cookware?

Also, a while ago someone asked about what yeast to use for barleywine. My best beer so far is my first and only barleywine\*\* made about five months ago, using this technique: After chilling the fresh wort, I racked onto a yeast cake of Wyeast German Ale descent. The yeast chewed on this for a while, and settled down. Since I had a mead waiting to be racked for its secondary fermentation, I racked this and then racked the barleywine\*\* onto the mead's Red Star Champagne yeast cake. This produced a vigorous secondary ferment, and a yummy beer, five months later! The recipe is an adaptation of Rob Bradley's Russian Empirical Stout on page 5-6 of \_Meow II\_.

FINE LINE BARLEYWINE\*\*

5.3 lbs Edme Dark SFX  
6 lbs Briess Amber DMX  
1.5 lbs Briess Crystal 60^L  
1/3 lb Briess Chocolate Malt  
1/3 lb Briess Black Patent Malt

2 oz Cluster Pellets (90+ minute boil)  
1.5 oz Northern Brewer Pellets (90+ min)  
1 t Dried Rosemary (30 min) [imperceptible]  
3 T Roasted Chicory Root (30 min)

0.5 cup Corn Sugar for conditioning

SG 1082 -> ale yeast -> 1059 -> champagne yeast -> 1022

I used the standard "bring specialty malts to a boil" method, and boiled only about 3 gallons of wort in my crappy ceramic coated pot which is about to become a bath chiller. If I could do it all over again, I'd add more rosemary and quaff a few with a venison steak. Rob Bradley had a very good idea when he didn't add finishing hops. The chicory and malt alone give a hell of a nose (but Rob didn't use chicory).

By all means let it age a few months! Though it's wonderful after one month, it becomes heavenly, as I'm finding out tonight!

\*\*Okay, okay, I know the original gravity is a little low for a barleywine (and on the roasty side too); so sue me. No matter what it is, this is the first brew I'm confident enough to enter in a competition, if there's enough bottles left by Xmas.

Cheers, etc.  
Jake.

From: polstra!larryba@uunet.UU.NET (Larry Barello)  
Subject: Re: Follow-up on SG vs Temp.

With regard to adjusting the SG for temperature. Why not play it safe and always read at the calibration temperature? I use a tall drinking glass filled with ice and water (enough water to make it easy to fit my hydrometer tube in). Then just swirl the hot wort in the test glass until it is to the proper temperature. It usually takes just a couple minutes.

BTW, this is the recommended way to do it since cooling in a pan or chilled pot (my earlier method) can evaporate significant amounts of liquid, thus affecting the reading.

I think that measuring at the calibration temperature (near room temp) is also going to avoid any errors from the expansion of the hydrometer itself. I know that if I measure hot wort, correct for temperature and then remeasure when chilled I can get 2-4 points error. Perhaps something else is going on, but I now keep it simple and stupid and just measure at the calibration temperature.

Cheers!

From: tighe@kc.camb.inmet.com (Michael Tighe)  
Subject: re: Skimmin the Skum

Brian Walter (walter@lamar.ColoState.EDU) asks about why one should skim the skum from mead during the boil.

Brian - from my experience, the "skum" is particulate matter which makes the taste of the mead "muddy" or very thick. I've been brewing mead for a while and I once tried a batch without any skimming. The result was only an OK mead with a tendency to leave a waxy aftertaste or coating on the tongue and a "cloudy" appearance and flavor. Normally, if I pay very close attention to skimming the skum, my mead tastes very light and clean - so that even the lightest spicing and flavor is noticable in the mead.

My guess is that when you use raw honey, you have miscellaneous bits of wax, bee-parts, and pollen still in the honey. These are too small for mere "screen" filtering, but they create a foam when you boil the honey. The "skum" is the white foam (later in the boil it's brown foam) that rises to the top of the boil. Skim it off with a slotted spoon or just a wide spoon (and don't worry about losing some of the must, that's normal).

You'll find that skimming improves the taste of the mead quite a bit, no matter what the recipe!

From: lipkens@ccwf.cc.utexas.edu (Bart Lipkens)  
Subject: Wyeast Belgian (Chimay) and banana ester

Another data point for Wyeast Belgian.  
I brewed a batch of David Line's recipe for Chimay,  
I think it called for pale malt, black patent, honey and brown sugar,  
I forgot the amount of each. I did a regular step mash.  
I fermented at 80 F (yes,80F), because of the summer in Austin and  
a defect AC in the house. Anyway, apparently Belgian brewers don't shy  
away from high fermentation temperatures, so I gave a try.  
There is a notable smell of banana esters but the taste is great and  
hardly (if any at all) taste of banana component. It is been in the  
bottle  
for about three months now and still getting better.  
If I brew this one again I think I might go for the high fermentation  
temp. again.  
Just my \$ 0.02.

>contaminants and nasties. Any thoughts on that?

Sounds like a good idea, and I doubt you have to worry about any  
contaminants in dry ice, as the extremes in temperature and pressure  
in making the dry ice probably would kill anything...

I wouldn't be so confident. I used to make bicarbonate buffers  
titrating with dry ice. The solution that resulted was cloudy and had  
"floaties" in it. (Filtering removed most of the material. I  
eventually switched to a CO2 cylinder for titration which lead to much  
clearer solutions.) My experience leads to the conclusion that no  
special care is taken to make sure dry ice is clean in any way.

As for killing bacteria... A common method for storing bacteria is  
under liquid nitrogen. (OK, there's also 15% glycerol present too.  
[Imagine a long discussion about ice crystals fracturing cell  
membranes and glycerol preventing this.]) I think it has been  
discussed in previous HBD's that cold is not an effective way to  
sterilize.

Date: 10 Sep 1992 10:48:19 -0600 (MDT)  
From: SLK6P@CC.USU.EDU  
Subject: Sterility&Yeast/Honey/References

Ok- a little catch up time. The last HBD I read had a few statements I'd like to respond to (or FLAME AT ARDE HAR DE HAR mateys!)

1) Sterile Enough: E.coli culturing more relaxed than we are w/yeast.

I don't know what kind of lab your wife works in, but ALL the molecular labs I've been in are very careful with the treatment of their cultures. If you are doind DNA work you do not want contaminating organisms in your cultures! Sounds like it is not critical, or they are sloppy.

a. As stated, YES: Yeast growth medium (extract) is richer than most E.coli media. Hence is is more likely to develop contaminants.

b. Many of these media contain selective agents (antibiotics) which encourage growth of the specifically desired organism and inhibit the growthy of "growlees", like our friendly fuzzy fungus.

c. Working in a biological laboratory under normal lab conditions should mean a fairly sterile environment to start with. This is not the case for the average homebrewer. We use kitchens, bathrooms, have kids and dogs and puppies romping around kicking up the dust, and sticking noses/fingers in our goodies.

d. I personally do not use a sterile hood, but use the same type of practices I would in the lab. I clean my hands, and the counter top (my desk) before beginning. I use a flame source to sterilize utensils, and YES I DO FLAME MY TUBES! It is VERY SIMPLE and quick. The goal of flaming a tube is to push air out of the mouth of the tube, so fungal spores and bacterial cells are not falling in. The goal is not to HEAT the glass but just push the air. I generally NEVER heat glass (rods, tubes...etc).

e. Glass should be dipped in ethanol, then burn it off the surface. Metal should be heated till it glows. I just let it cool in the air for a second, then touch unused agar, or in liquid, let it sizzle, you'll still get cells. If you use a proper inoculating loop it is designed to cool quickly.

f. I have a surplus at the lab if anyone wants to trade me a homebrew-

I'll send you one.

2) Honey skimming. The way I understood it, it removes proteins/waxes which remain in the honey, and are not desirable to the ferment. It is not the SAME as skimming of blowing off of beer, since it is a product of HEATING, not the fermentation. It won't hurt. BTW the skum will settle back into the honey upon cooling.

A honey packer on the net suggested NOT BIOLING honey, but Pasteurizing it by heating to 150-160 for an hour or two. He said bad things of boiling honey in terms of chemical modifications of the sugars. But all the recipes I've read describe boiling honey. I've done it and enjoyed my meads (so did Jack). so what the hell.

1 pack of yeast per gallon! Geesh. OVERKILL!!!!!!

- a. You will likely have a yeasty taste.
- b. You are spending too much on yeast. (good work on the part of you homebrew supplier! Sucker. (just kidding- we're supposed to trust them.....BUT DON'T!))
- c. Take one packet, and make a starter.

d. Mead- tastes like.....mead! Champagne- when it's sparkled, wine when its not. You can't put a label on it. It's like asking "What does beer taste like". (nothing if we're talking american or canadian pisswater) It depends on what you put in. I've had bubbly effervescent champagnes, to thick rich brandys. TIME will tell. Make me an offer, and I'll send you a sample.

3) HOPS GETTING IN THE WAY. The easiest way is to wrap them up in cheesecloth or get a hop bag. They'll never get into your carboy if you do that. DON'T boil them separate. You need the volume, and a full hour of boil to get all the goodness out. If you use pellets, mix in some leaf

hops in the back and you won't have pellet goo squeezing out. I like pellets for dry hopping. Leaf+ for boiling.

If the hops are both fresh and packaged properly- Leaf should definitely be fresher. It has not be PROCESSED into pellets, so hey- it's right off the plants.

No one seems to have offered up an answer to checking IBU's of fresh home grown hops. I just picked some of unknown type (thanx toot), but am not going to worry about it. I usually guesstimate amounts anyway, so...

I would think that you could send off a sample to a hop supplier to have it tested. I'll look into it.

4) Here are a couple of references on more of a scientific bent discussing

YEASTS.

- a. YEAST TECHNOLOGY G. Reed, and T.W. Nagodawithana
- b. The BIOTECHNOLOGY OF MALTING AND BREWING J.S. Hough
- c. BREWING SCIENCE J.R.A. Pollack

I got them from our campus library. If anyone want more info (or selected xeroxed for educational purposes) e-mail me and we'll chat.

Subject: Listerman gadget & dry-hopping

To any and all interested and helpful Wizards of Wort:

First question: I am an extract brewer with a little over a dozen batches behind me (well, o.k., they went through me, really). Occasionally I daydream

about going all-grain.

Has anyone tried the "Listerman mash/sparge system" or whatever it's called, available from the Home Brewery? It seems reasonably priced, and since I'm not a tinker-er by nature I'd be willing to spend the money if I

had independent confirmation that it works as well as anything I could tinker up myself.

Second question: I like to dry-hop in the secondary using leaf hops tied up

in a muslin bag. Does anyone think I'd get more hop flavor if I could find

a way to submerge the hops rather than allowing them to float on top? If so, how should I do this? Weight the bag down with something that will

not react with the beer (like what?)?

Are there any dedicated pellet dry-hoppers out there? Seems to me I've read some things about problems with clarity possibly resulting from pellet

dry-hopping (which is why I haven't tried it myself), but if there are folks

out there who can speak to the contrary, I'd like to hear from you.

Subject: Another horror story: let this be an example to you

I had ano interesting experience. I racked to my secondary fermenter, a 5 gallon carboy. I didn't fill it completely, which I don't normally worry about. However, I had this yeast starter that never grew anything just sitting there, so I used it to top off the stuff in the secondary.

Yow! It started foaming and oozing out the top of the carboy through the airlock for about another six hours.

Never give your yeasties more food like that unless you are ready.

>Live Long and Prosper,

The scum that forms on the boiling mead is coagulated albumin. If you don't skim this off, the mead will take forever to clear out. It is not applicable to beer brewing. Also I question whither this mead won Byron that prize, or he won it for some other reason, known only to the AHA.

Subject: "World of Beers" in Raleigh, NC

This message isn't worth reading unless you're in easy driving distance of Raleigh, NC. On Friday, September 18 from 7:00-11:00 at the Raleigh Civic Center will be the "World of Beers" exposition which is a fundraiser for the Raleigh International Festival held in early October. The cost is \$15.00 per person and includes a 14-ounce plastic mug, all the 65 beers you can taste, light food (Italian meatballs, German sausages, finger sandwiches, pretzels, chips), music (the Little Oompah Band and Mickey Mills Steel Drums (reggae/calypso)), and dancing. Most of the 65 beers will be commercial bottles (representing 20 countries) in addition to Raleigh's brewpub entrant, Greenshields. Beer will be served TWO OUNCES at a time. Considering it's a fundraiser, it might be a reasonable value.....

First, I have a comment about Spencer's post. I think that there's a big difference between E. Coli cultures on (what I assume to be) a selective media and our wort which is loved by many, many wort-spoiling bacteria and funky-flavor-producing wild yeasts.

Regarding Fritz's methods, I agree that they may work for you and Florian Bell too, who reported using such techniques also, years ago in HBD. However, my comment on your procedures is the same as the one I posted on Florian's, namely, that it's an invitation for trouble. If you drink the batch in a month or two, I doubt you will ever know that you've got a bacterial infection. Also, if you are pitching a healthy, attenuative yeast, it may be eating up most of the sugars in the wort, and then subsequently in the bottle, before the infections can make a difference. Note that these two statements are related. Our wort is a mixture of many different types of carbohydrates, some of which are fermentable by our pitched yeasts and some that are not. The dextrins (unfermentable, long chains of glucose) and the non-fermentable sugars that remain in the beer, and this is the most important part, ARE FERMENTABLE BY OTHER MICROFLORA. In some cases slowly, in others quite fast. Some brewers who report "I used to have infections, but now I don't" may only have changed their procedures enough to have killed the fast-growing bacteria and wild yeasts, but still may have problems with slow-growing ones. Only if you leave a few bottles around for a few months will you know. I sometimes use the dregs from my own beers as the yeast source for a starter in another batch. I must note that I only do this with beers that are made from first-generation cultures to minimize chances of mutated strains. Doing this can only be possible if you're POSITIVE that you don't have an infection in the bottle.

Finally, and I must stress that I'm \*not\* implying that this may be true in Fritz's case, but some homebrewers (and commercial breweries) have infection problems, but don't even know it. Some wild yeasts and bacteria make very subtle off-flavors which are hard to detect and identify and often are referred to as "house character." Tuesday, I had a old bottle of Red Tail Ale which had a mild "cabbage" aroma. This is most definately caused by bacterial infection (one of the slow ones I mentioned earlier) and I failed to sense this in a younger bottle of the same beer. Also, obviously, a dopplebock or a stout are going to cover up off-flavors a lot more than a cream ale -- I had a stout that I forgot about in the keg and the last gallon was a dry stout but the first four were a sweet stout only 18 months earlier -- no off-flavors or off-aromas, though.

From: bryan@tekgen.bv.tek.com  
Subject: Baderbrau Pilsner

A little over a year ago at the Oregon Brew Festival, I had a pilsner which I believe was made by Baderbrau. It seems like the guy who started it/ brewmaster had worked for a major brewery in the US, but was from Czechoslovakia.

It was excellent! Very Refreshing! I just bought a used freezer for brewing in and have a Hunter Airstat on the way, so my thoughts are turning to brewing something like it.

Can anyone tell me what style of a beer this is? Referring to Zymurgy I see a "Classic Pilsner" and a "German Pilsner". What beer from a major brewery would approximate it? The idea being it is easier to find out information about a more widely known beer. Anyone have any all-grain recipies for a beer like this one?

This is really reaching, but does anyone know what the OG, SG, bittering units and type of hops used for bittering and finishing are?

This is really my day for questions, but are Saaz hops grown in the US? Is there a "Saaz type" hop grown in the US?

Thanks,  
Bryan Olson

Date: Thu, 10 Sep 92 15:27 CDT  
From: korz@iepubj.att.com  
Subject: Breiss DMS

DMS gets produced from its precursors when the wort is above 140F. It's true that different malts have more or less of these precursors, but as Jim suggested, technique can also be a big factor. During a vigorous boil, the DMS gets boiled off, so a non-vigorous boil can increase your DMS levels. When the heat is turned off, is when most of the DMS that remains in your beer gets produced. Cooling quickly with a wort chiller to below 140F is the best way to minimize DMS production during this stage of the process. I'm sure that Micah uses a chiller, guessing this based on the equipment he built and was displaying at the National Conference, so the only factor I can guess, if Micah's boils are vigorous, is tapwater temperature. Perhaps Micah's tapwater is warm and an ice-bath pre-chiller would help cool the wort quickly enough to keep DMS below sensory thresholds?

As a related aside, I recently, reluctantly drank Old Style beer (at a Cubs game) and noted an incredible DMS nose. Jackson writes of Old Style (something like): a weak little beer with corn in the palate. Does G. Heilemann's use Briess?

From: hartman@varian.varian.com (John Hartman)  
Subject: re: DMS and Briess Malt

In digest #966, jim busch <busch@daacdev1.stx.com> makes a very good point:

>I just have a problem with homebrewers claiming such problems since so  
>many micros, pub breweries and mega breweries use the same malt without  
>DMS problems.

I've considered this argument too and must admit that it's a compelling one. Nevertheless, after the first bad batch I was extra careful in every aspect of brewing the following batch. It too suffered problems similar to the first. It has a DMS nose and is quite cloudy. I pitched it with a healthy, adequate starter and gave it plenty of aeration. Fermentation had begun within 12 hours. Both of these beers were ales.

Let me say that I've always used Briess malt. That's probably 30 or 40 batches over the last two years and this is the first time I've had a problem. I've been quite happy with the malt until now.

Mega breweries likely conduct expensive analyses on the grains they use as part of their quality assurance. If anything can be said for the megas, it's that their quality is unquestioned. I.e., they consistently produce their (insipid) products free of defect.

I'm not saying that all Briess malt is bad. I'm saying that the particular lot that I'm currently using likely is. I wish I had the sophistication necessary to prove this. Then I wouldn't feel spooked, as I presently do. Under my circumstances, I found Micah's experiment involving Briess and Great Western malts quite compelling.

Micros who experience a problem such as this will not necessarily make mention of it. Perhaps it's happened and we haven't heard about it. Certainly none would brag. "Say, have you tried our new Campbell's Creamed Corn Ale? Mmmm good. People just can't stop talking about it" :-)

Thanks to all who have recommended ideas about motorizing mills and bay area grain vendors.

Cheers,  
John

Subject: Gelatin etc.

To: Homebrew Digest  
Fm: Jack Schmidling  
>From: jeorg@chs.com (Houck)

>could someone send me a quick description of how to use  
gelatin to clear a batch? (jack, i think you do this)

Did... not "do". The last time I did it was the batch I took to  
Milwaukee  
because I was pressed for time. Judging from the reaction to the beer,  
I am  
not above using THAT as an excuse for its lack of character.

However, it really does work and if you want to try it....

Heat 1/2 teaspoon of gelatine in a cup of water or beer to about 180F to  
Pasturize it. Pour this into a clean carboy and rack your beer onto  
this.  
It will clear within a few days.

For what it is worth, I tried it on my dandelion wine and it had no  
effect  
that I could see. It just does not want to clear. I suspect this is a  
problem with raisins and will never use them again.

The "Fall Wine" is in the primary ready to be racked. It is 5 gals of  
apple  
juice and 11 lbs of mixed fruit... grapes, elderberries and mullberries.  
All from the garden. I added 5 lbs sugar to get the gravity up to 1.  
080 and  
will no doubt have to add more to finish it. At this point, the  
mullberries  
seem to dominate the flavor. I used pure cultured RS champagne yeast  
and  
expect a dry, rose colored table wine.

Subject: Re: Hop Yields

Tom Rush asks about hop yields. Here is my yield for my first year crop in order of yield.

Northern Brewer - about 25 ounces  
Cascade - about 20 ounces  
Willamette - about 9 ounces  
Fuggles - less than one ounce  
Saaz - No cones :-(

All plants very healthy (didn't notice any bugs or eaten leaves) but outgrew my 14' hop poles in July. The Northern Brewer grew to the top and back down and long the garden fence. Next year I'm increasing the poles to 20'.

I got my rhizomes locally at Brew and Grow, (612)780-8191. Don't call before midnight tonight, they stock them in the spring.

I noticed no allergic reactions just sticky fingers :-).

Well, I haven't tried dry hopping (only brewed 7 batches so far) but it  
would seem logical that submerging the hops would help. Why not throw  
a few sanitized glass marbles in the bag with your hops? That should  
weight it down enough, not react with any beer stuff and fit through  
the neck of the carboy.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Wyeast Belgian (where's my bananas?)

While I don't want to be in the position of defending Wyeast's Belgian yeast strain, I'm fascinated by the reports we've been receiving about people smelling giant Chiquita bananas in their fermenters? Here I am, probably one of the few people here who WANTS large quantities of esters, and I get absolutely nothing!

I previously posted a note on my first experience with Wyeast Belgian, and the batch referred to is now carbonating nicely and has a cognac-like flavor and aroma. No bananas.

I can now offer a preliminary report on the second batch using this yeast. This is a 3-gallon partial mash which includes 1/2 pound of Belgian candy sugar as well as some glucose, with an OG of 1.076. I brewed this on Monday (Labor day), and racked it to a secondary on Wednesday. In fact, the stuff was practically done fermenting, and had a gravity of 1.013. Today (Friday) I'll actually be bottling it--four days after brewing.

As I noted before, this yeast is an incredibly fast, effective fermenter, but even this surprised me. While my house is indisputably warm (varies from 74 to 80 or so), I have another batch made with Wyeast European that's been in the secondary for two weeks and is still perking along. These are in the same room, so the difference in fermentation speed is obviously the yeast. Both batches were pitched in a 1-pint starter, by the way.

As for batch #2--no bananas. Either I'm doing something wrong or doing something right. Anybody who wants to see what I'm doing is welcome to come over--these beers have so much alcohol that I'll never be able to drink it all myself. Finally, I can say that on Wednesday Bill Ridgely was over and tasted these beers, so I have a witness.

From: trush@mhc.mtholyoke.edu (Thomas P. Rush)  
Subject: Hop Yields Revisited

I am surprised by the amount of email received on the very informal report of my hop growing efforts. Thanks to all for yours concerns, advice and questions. I will try to address the above with one follow-up article since the volume of mail is so large.

I agree with your suggestions that my sniffles were caused by a head cold or a high mold spore count during this rainy summer. I am an admitted "hophead" who has been getting high on bags of hops for years[as in ether sniffing ha-ha].

As to the question of vigorous growth for 1st year vines, I should tell you the almost total disaster I encounterd during the spring of 1991. I decided in LATE spring (May) to start a hop garden and purchased Mt. Hood, Chinook, and Tettnanger from my local supplier. Mt. Hood and Chinook never came up and Tettnanger struggled up about five feet. In desperation I visited a small winery in Hatfield Ma. who I knew had an established hop yard. He generously gave me growing off shoots of Cascade and Hallertauer which promptly grew to about 10 feet before the season ended.

My conclusion, solution and suggestion(this has worked for me but your on your own) is:

1. Buy and plant your rhizomes in EARLY spring, prepare your soil this fall.
2. If your afraid of hard late frosts, start in large flower pots in sterilized potting medium. Its a pain but its worth it.
3. Follow the directions which come with the hops. I have purchased from Marysville Oast, MCC, and Freshops and they all sent large, healthy, well packed rhizomes.

I believe temporary refrigeration shocks them back into dormancy, small shoots rot and the rhizomes gives up and rot as the cold spring turns hot.

I built a Beach/Marysville Oast-type support system, it needs to be higher than its present 12 feet (100 feet long) but I don't have time to apply for a pilot's license.

By far the most asked question is "How do you know when to pick?". Again, this works for me take it for what its worth. I think if I were a commercial grower I would develop ulcers, because I believe there is a very small "window" when hops peak in their potency. Crushing and smelling, in my opinion, play a very small part in deciding when to pick. When the lupulin glands rupture and the yellow powder is exposed your entering the critical phase, it is ripening and oxidizing at the same time. Coloration cannot be trusted since each variety matures with different shades of green.

I put all my trust in the feel of a mature cone, it should be papery yet tight and springy not cold, damp and hard(immature). If the cones are wide open and turning brown(even slightly) you've overshot the picking. Err on the side of picking early, there is nothing worse than musty,cheesy old hops--at the most there is a five day window. On the other hand good home grown hops will beat commercial hops every time.

Finally, the question of "Liberty" hops. According to Marysville  
coasts it is a triploid, aromatic Hallertau-AA5% developed by  
Al Haunold. Al also developed the virus-free Saazer clone for  
Anheiser-Busch. Its gaining in popularity around here.

From: connell@vax.cord.edu

Subject: Kriek

Has anyone tried to produce a cherry-flavored beer by adding a Danish cherry wine to batch of already fermented beer? The basic idea is similar to the process by which port is made - a high alcohol distillate is added to a fermenting wine must. In the case of a cherry-flavored beer, I'd assume one would allow a low-hopped wort to ferment out and then add some as yet to be determined amount of the cherry wine. The main problem I would anticipate with this would be carbonation since any sizable addition of cherry wine would raise the alcohol level beyond the point at which ordinary yeast shuts down. Perhaps one could get around

this problem by adding champagne yeast at bottling time, or by trying to brew a low alcohol beer into which to add the cherry wine (but this might produce a thin beer) or by mechanically carbonating in a keg. Any suggestions or experiences along these lines would be appreciated.

From: HOGLE RICHARD A <HOGLE@CRDGW2.crd.ge.com>  
Subject: some more stuff

Jim Buchman writes:

Since your system is operates on a first-in first-out basis, I suggest that what you have is a queue, not a stack (which is first-in, last-out ;-)

Well, actually, a queue with random re-prioritization, depending on my mood :-)

On Kettles:

I use a 5-gal Anodized aluminum pot - you know, the ones that are black. They're a bit cheaper than SS, but I got it as a gift so that wasn't a real concern. Works great.

On Aged Beers:

Just last nite I visited a brew partner of some years ago. He pulled out a couple of red bitters and steam beers we had brewed way back (can you believe it!) in January of 1988! The beers were excellent, with no off-flavors or aromas that my admittedly untrained senses could detect. They were also very nicely carbonated. These beers would never have been around my house this long (and I don't understand how they survived at his place either!, I'll have to have a talk with that boy). Just another data point.

Date: Fri, 11 Sep 1992 08:01 PDT  
From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Sam Atoms recipe

Here is a recipe for an amber lager that was recently requested. I call it Sam Atoms. This beer does not really fit any common style categories except maybe American Pilsener. The bottom line is it was an excellent beer and I'll make it again some day.

Batch size 10 gals  
21# - pale malt (adjust to get specified OG)  
2# - crystal malt (40l) added in mashout  
1# - cara pils  
1# - wheat malt  
3oz - Tettanger (AA 4.5)  
1oz - Perle (AA 7.6)  
2oz - Cascade (for dry hop)  
1t - Gypsum (in mash)  
2t - irish moss (last 15 mins of boil)  
Wyeast 2206 lager yeast (repitch from previous batch)

Mash schedule :  
Mash grains at 154 deg f for approx 60 mins  
mashout at 170 for 10 mins

Hop Schedule:  
Boil 2oz Tettanger for 75 min  
Boil 1oz Tettanger for 50 min  
Add 1oz Perle at end of boil and steep for 10 mins

Total boil time 90 mins

OG 1054      FG 1016

Fermentation Schedule:  
2 wks at 55 deg f  
Rack and dry hop with Cascade  
Lager for 2-3 wks at 45 deg f with dry hops

Filtered, kegged and artificial CO2 to approx 2 vols

This beer is a very close clone of Sam Adams. There is some sort of synergy between the cascade hops and kettle hops used here that is hard to explain. The flowery cascade nose is not present as you would expect. The nose is a more complex blend of malt and hops, sort of a spicy quality.

I hope you all make as good a beer as this recipe made for me.

Bob Jones

From: tony@spss.com (Tony Babinec)  
Subject: belgian malts, description and suppliers

George Fix's posting (welcome back, George!) and recent queries on availability lead me to re-post a summer posting on Belgian malts. I've modified it slightly to reflect new information. Also, I post it with the usual disclaimer about no commercial interests...

De Wolf-Cosyns Maltings is one of Belgium's oldest and largest floor malting plants. They supply many of Belgium's lambic brewers along with more conventional breweries in Northern Europe. Only the finest European barley and wheat are used. The barley (all two-row) and wheat berries are larger than domestic malts. The dark grains are flavorful and not in the least harsh or astringent.

Here is a listing of the available malts along with color ratings:

Base Malts

pale ale	3.5	-	4.5L
pilsen	1.5	-	2
wheat	1.4	-	1.8

Color Malts

Munich	7	-	8
Aromatic	23	-	28

Caramel Malts

Caramel-Pils	5	-	10
Caravienne	15	-	30
CaraMunich	70	-	80
Special B	150	-	250

Roasted Malts

Biscuit	23	-	33
Chocolate	450	-	550
Black Malt	700	-	800
Roasted Barley	700	-	800

Here are some comments on the malts. Note that Pierre Rajotte's Belgian Ale book mentions some of these. The color ratings given above differ a bit from those in Rajotte's book, but the ones listed above are from the supplier.

The pilsner malt rivals the finest pilsner malt available. It should be used instead of U.S 2-row or 6-row for such styles as Trippels, wit beers, and various Specials. Note that George and Laurie Fix's Vienna book also argues that Pilsner malt should be the base malt for the Vienna-Marzen-Fest style. You might also use it in your best Pilsner.

The Munich and Aromatic malts provide malt aroma, body, and color. The Aromatic is slightly darker than a dark Munich, and its name says it all so far as aroma and taste are concerned.

The CaraPils (not to be confused with American Cara-Pils!), CaraVienne, and CaraMunich are basically very fine crystal malts comparable to 10L, 20L, and 80L crystal malts you might use. The Special B is a highly colored caramel malt that, in Rajotte's words, "...Gives a rich caramel-malt taste. It is used in Scotch ales and stouts brewed under license in Belgium. Darker Specials

and Abbey beers at times use this type of caramel malt. Its effect is noticeable in beers, giving lots of additional body and coloring. Beers using Special B have more well-rounded malt character than beers colored with only candi sugar." Again, George Fix in his Vienna book argues for using the finest crystal malts to avoid astringency in the beer, especially for that style. Note from George Fix's posting his substitution of Cara-Vienne and Cara-Munich for the German and British crystal malts cited in his recipes. If I read him correctly, use Cara-Vienne in place of "German Light" and "British Crystal," and Cara-Munich in place of "German Dark."

Question/challenge for George and Laurie Fix and anyone else: George and Laurie Fix settled on crystal malt as the coloring malt for Vienna beers in part due to dissatisfaction with available Vienna and Munich malts. Now, with Belgian Munich and Aromatic malts available, Vienna and Bock recipes ought to give these a try in addition to the crystal malts.

At homebrew club meetings, those of us in the Chicago Beer Society have been able to sample these malts, as the local Siebel Institute's retail branch had them. NOTE, however, that Siebel Institute is not a supplier of these malts. Siebel has split into two parts, one of which handles the brewing courses, and the other of which supplies the commercial brewing industry.

Here are a few suppliers:

- Tim Norris, Chicago, IL 312-545-4004--Tim runs a basement homebrew shop. He suggests that homebrew clubs get a collective order together, but is willing to ship small orders. Tim also has a fax number: 312-545-0770.

Address: 3717 N. Kenneth, Chicago, IL.

Recent prices were:

50 pound bag	\$32.50
5 pound bag	\$ 3.75
1 pound bag	\$ 0.95

To these prices, add shipping and packaging, I assume.

- North Brewery Supplies, Franklin, WI 414-761-1018--Brian North runs a basement homebrew shop located between Milwaukee and Kenosha. For those of you thinking of getting into kegging, Brian has all sorts of stuff, and can service and refurbish equipment.

- Chicago Indoor Garden Supply, Streamwood, IL--Don't have their phone number, but their ad is in Zymurgy. Owner Dave ITEL (Ittel?) runs a very complete homebrew and gardening shop. As of this writing, they either have the grains or will be getting them shortly. Rumor has it that Dave will be opening a shop in the 1800 N. Clybourn building, which also houses the Goose Island Brewery. This will be a boon to Chicago-area homebrewers, as that part of town is very accessible and there will be two reasons to visit!

- Great Fermentations of Santa Rosa: I don't have their catalog with me, but I recall seeing some of the Belgian malts mentioned.

Subject: additives

Dear Brewers,

Quite some time ago (maybe a few months) I purchased some ingredients that I never used. Actually, they're additives: Irish moss, yeast energisers and some gypsum. I don't really have a need to use any of these in my next batch (I'm planning to brew up a Weitzen - Papezian's recipe) except for the gypsum, which I plan to add to the distilled water I'll get from the grocery store (...unless I really shouldn't do this. My thought is that I can reduce the lime with distilled water, but maintain the "hardness" of the water with a small amount of gypsum. If I'm off on this point, please someone fill me in, 'cuz I'd hate to ruin a batch unnecessarily...especially when it's my first attempt with liquid yeast.)

And that brings up another question. I've already received alot of very useful help and advise on how to use liquid yeast and make a starter. None of that advise, however, mentioned using a yeast energiser to boost it along. My feeling is that I don't need it. But I've got some (purchased a while back with the rest of the stuff) just sitting around... Should I toss some in, or leave it for when I brew a high-gravity something.

Finally, about the irish moss. I have absolutely no planz to add any of this to my weitzen. I'm just wondering how to store it. Will this stuff get stale if not refridgerated/frozen like old hops? Or can I leave it in the un-opened, as yet unrefridgerated pouch indefinitely? Which brings me to my post-final question ;-) About the hops.... I have about an ounce each of pelletized and leaf hops that are about three months old, but I've kept them both refridgerated - later freezing them - but not in air-tight bags. Should I simply toss 'em out and get some that are fresher? I'm not planning to use them in my plans for the weitzen (I've already got fresher hops of a different variety), but I'm wondering if they're still worth keeping.

Thanx for any and all direction.

Cheers!

John (always the novice, so don't flame me!)

From: tony@spss.com (Tony Babinec)  
Subject: ersatz baderbrau recipe

Many German light lagers are brewed using only pale malts, and using a decoction mash. Most all-grain homebrewers, I assume, use an infusion mash. So, to get color, use some color malts. Baderbrau is certainly a pilsner, but its color is almost too dark for the style. Other than that, it's a fine beer.

Here's a stab at a recipe:

8.5 pounds pilsner malt  
1 pound light Munich malt  
0.5 pounds crystal malt (40L)

2 oz Saaz (alpha 3.1) at 60 minutes until end of boil  
1 oz Saaz at 30 minutes until end of boil  
1 oz Saaz at 10 minutes until end of boil

Wyeast Bavarian Lager yeast

Conduct step infusion mash with starch conversion temperature around 152/3 degrees F.

Comments: the grain bill assumes 70% extraction efficiency, and will produce about a 1.048 starting gravity. You might substitute 0.5 pounds U.S. cara-pils for an equal amount of pilsner malt if you desire a bit more body. The combination of Munich and crystal malt will make the beer gold to light amber in color. The Saaz hops, assuming the alpha acid rating of recent Crosby and Baker compressed foil packets, will produce an IBU rating of about 37. Pilsners, and Baderbrau in particular, are hoppy. Wyeast Bavarian lager yeast is said to be used by a lot of German commercial breweries, and will produce that German lager character. Overall, it is important to use good ingredients, conduct the primary fermentation at around 50 degrees F, and cold-condition the beer in secondary.

From: bgros@sensitivity.berkeley.edu (Bryan Gros)  
Subject: christmas beer

My christmas beer has been sitting in the secondary for six days now. (Since Sept. 6). The OG was about 77, and now it is down to about 18. I tasted it last night and the spices were not very prevalent, it was not too bitter, but it was very alcoholic tasting. Will this mellow out between now and christmas?

I decided to add some Cascade yesterday. How long should I let it sit now before bottling? I see many people let their barleywines sit for months in the secondary. I figure another week. What are the advantages and disadvantages of aging in the secondary versus the bottle?

I saved some sparge runnings (SF = 33) to prime with. Charlie gives the formula in an appendix somewhere. Is this formula right? Any advice for a first-time krausener?

Thanks.  
- Bryan

From: guy@mspe5.b11.ingr.com (Guy D. McConnell)  
Subject: **Attacking Briess malt**

This may be strictly coincidence but it occurred to me anyway. I wonder how much of this recent Briess malt bashing is related to their decision to stop selling directly to homebrewers. I seem to recall several posts of complaints about this decision. Just a thought.

Re: "beatles and hops" from Russ Gelinis:

The secret is out! If you listen (and more importantly, let your beer listen to) Beatles music while brewing, it increases hop utilization, brewing efficiency, and the quality of the end product. O.K., maybe not, but it sure makes \*me\* enjoy brewing even more.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Hop yeild in N.W. Washington

When people are reporting their yeilds, it would be very helpful to know how many plants they were harvesting. My pico-hopyard is two years old. I have only two varieties, Willamettes from Freshops (all two yrs old) and Cascades from a local garden and Freshops (three plantings). I have 21 plants in four rows, The rows are five feet apart and the plants spaced about three feet. This is too close, and if I was going to replant, I would space everything on a six or seven foot grid. I grow on 15-18 foot alder poles. All of the Willamettes could have used taller (20') poles, as they became very topheavy. The Cascades have not done as well, only three of the plants did as looking as good as the Willamettes, and the Cascade cones were uniformly smaller. The Willamettes yeilded 8 7/8 lbs and the Cascades gave 5 1/4 lbs.

When we were picking the Willamettes, everyone got itchy red rashes on our forearms and back of the hands. It felt like the irritation you get from handling fiberglas insulation. It went away the next day, and nobody had a problem with the Cascades. I can't decide if it was from the little spines or some chemical irritant. No insecticides were used other than some soap spray in the late spring.

One reason that homegrown hops may have more zip than commercial hops could come from the picking. The picking machines knock the stuffing out of the hops. They litterally rip the cones and leaves off the vines, and then bounce the cones on a series of sloping cloth belts to separate the cones from the leaf and stem trash. This may shake off a significant amount of the lupulins.

It does come off the ripe hops fairly easily. I took extra precautions to capture the powder that came off of mine during drying and packing, and now have about a half ounce of yellow powder from each of the varieties. Has anyone every used the powder? I think I remember that the powder is 30 - 40% alpha acid, but I can't find the reference.

Subject: Why Should I Buy a Grain Mill?

I picked up twenty pounds of pale malt yesterday, and while I was waiting for them to grind it and bag it, I noticed a Corona mill for sale for \$60. At first I thought, "that's not a whole lot of money", but then I tried to figure out how cost-effective it really is.

I buy grains twenty or forty pounds at a time, for \$0.64 per pound. For an extra \$0.04 per pound, they grind the grain for me. So to get that Corona mill to pay for itself, it would take 1500 pounds of grain; three-quarters of a ton! At about eight pounds per batch, that's about 187 batches of beer, and at roughly thirty batches per year, I'm looking at over six years for a \$60 investment to pay off. That doesn't strike me as very good economics.

(Maybe \$60 is too expensive...I don't know. Let's say for the sake of argument that I found one for \$20. That still comes out to 500 pounds of grain, 62 batches, and two years to pay for itself.)

Now I realize that many people aren't in that situation, and need to be able to grind their own. That's different. My question is: am I getting a good deal as it is, or am I overlooking something that would convince me to buy a grain mill?

Subject: Corsendonk, Gammel Brygd

Hello,

Recently someone posted an article about Corsendonk saying that they thought it should have been poured down the drain. All I can say is that I have had many Corsendonks and have thoroughly enjoyed them; all except one. One time I was in a bar where I had drunk Corsendonk before and found it be disgusting, with little chunks of nastiness in it and a foul taste. I returned it and ordered something else, but I have had Corsendonk since then and it has been delicious. Has anyone else had this problem? Anyway, sometimes you can't judge a beer from just one bottle.

Also, on a totally different subject, my favorite beer in the whole world is a Swedish beer from the Falcon brewery called Gammel Brygd. Unfortunately I don't think it is available in the U.S. If anyone knows anything about this beer, how it is made, recipes, etc. please post.

Thanks,  
Erik

From: "Stephen J. Vogelsang" <sv0k+@andrew.cmu.edu>  
Subject: Hopped malt extract syrup

Howdy,

I am a beginner homebrewer. For my first batch I basically did the following: Used 1 can (3.3 lbs) M&F Hopped amber malt extract + 1.5 lbs of M&F light DME. I boiled the extracts in water for 30 minutes then added 1/2 oz cascade hop pellets and boild another couple of minutes. Then I cooled the wort, added pre-boiled water to make 5 gallons (I think I actually only ended up with 4.25 gallons). I sanitized my fermenter (big plastic bucket w/lid), bottles, and everything else that touched the beer with a bleach soln.

The beer had good carbonation after about 1 week in the bottles. The head is nice and creamy. I honestly don't like the stuff, but it's certainly not "undrinkable." It has a strong bitter taste that was not quite the right type of bitter. The beer was also not very well balanced. As a novice, I couldn't tell whether this bitter flavor was tainted by infection thus making it sour-bitter, or if it was just the type of bitter flavor the cascade hops and the hops used in the M&F extract are supposed to have.

Before I begin my next brew, I have the following concerns:

- 1) What kind of hops are used in the M&F extract syrup?
- 2) I did not strain the hops out of the beer before fermentation, could this have caused the unbalanced bitter flavor?
- 3) Is it likely that i just don't like the taste of cascade hops? And, can someone tell me of a beer that uses cascade hops so that I can see if it has the same flavor as my beer?
- 4) In my next brew, should I add my own hops and use unhopped extract?  
note: unfortunately I already have another can of hopped extract.
- 5) Should I use a different kind of finishing hops, or no finishing hops?

I'm not overly concerned about these issues since I figure that within 2-3 more batches I'll have adjusted the beer to my liking. I currently plan to do the following for my next batch. I'll use 1 can (3.3 lbs) of M&F hopped amber extract syrup (since I already have it), 3 lbs of M&F light DME, 1/2 lb of crystal malt. I also plan to use 1/2 oz of fuggles hops (hop plug) for finishing. I will add the hops after the boil, and remove them before I pitch the yeast. I'm also using whitbread yeast this time (can't remember off hand what yeast I used the last time). I will also try to be more sanitary (it took forever to cool the wort last time. This time I will probably buy a couple of bags of ice, and immerse the brew kettle in ice water to cool the wort.) I also went out and bought a 5 gallon carboy for fermenting. Actually, this leads to another concern. Is a 3/8" blow off tube sufficient? After all of the horror stories about exploding carboys, I'm somewhat concerned.

Well, I just wanted to get some opinions and suggestions about my plans. I'm not terribly concerned. I'm sure all of you went through similar dilemmas when you started and you somehow managed to figure them out. As

we all know, practice makes perfect.

Thanks,  
Steve

From: Carlo Fusco <G1400023@NICHEL.LAURENTIAN.CA>  
Subject: Kegging beer in soda kegs

Hello to all,

This is my second post to the digest. I had such a great response to my previous questions I do not feel scared to post anymore. First some background. I am on my 5th batch of beer. I am an extract brewer who is afraid of grains (I'm sure this will change). I now know how to use hops correctly (boil them in the wort, not seperately), and not to be so impatient when waiting for the bottled beer to carbonate fully. Face it, novices can't wait to taste the first fruits of their labours.

Here is a question probably asked a thousand times. But, I have not been reading the digest long enough to hear the answer. I would like to try kegging my beer in soda kegs. There is a Coke bottling company only a few blocks from my apartment. I found out that I could get soda kegs from them by paying the \$20 deposit. By the way, I am in Canada (specificly Sudbury in Norther Ontario) and I don't know if the soda kegs used here are different than in the US. I am pretty sure that the kegs are 3 gallons and made from aluminium. Here are my questions:

- 1) Do I have to do anything to the keg before using it, other than sanitize it?
- 2) If beer is left in the keg for any lenght of time will it take up a metal taste that you sometimes get from canned commercial beer?
- 3) What else would I need besides a CO2 tank, regulator, hose from regulator to keg, and a hose from keg to tap? Where can I get these things cheap in Canada?
- 4) Is there anything else I should know before trying this? (I seem to remember something about adding pressure to the keg to get a seal?)

Thanks for any advice you can give. Also, thanks for the digest I am learning a great deal about homebrewing.

From: pmiller@mmm.com  
Subject: Maintaining flames (the real kind)

Greetings!

I've been pondering the problem of the Monster Burners getting blown out easily when throttled down to idle. Here's a trick that's used to maintain secondary combustion in some funky hi-tech wood burning stoves:

Wrap some high temperature wire (nichrome?) around your burner in such a way that a portion of the wire is suspended in the flame. Once the flame is lit, the wire glows red hot. If the flame is momentarily blown out, the hot wire will automatically re-ignite the gas.

I've never tried this (and I don't know how well this technique works in wood burning stoves either), but it sounds like it should do the job.

Any comments?

Date: Fri, 11 Sep 92 16:25 CDT  
From: korz@iepubj.att.com  
Subject: Hop yields Midwest (with caveat)

These hop yields that people have been posting lately, are these pre- or post-drying?

My four, 2nd-season plants had these yields after drying:

Nugget -- 2 ounces  
Wilamette -- 1 ounce  
Hallertauer -- perhaps 1/4 ounce  
Hersbrucher -- perhaps 1/8 ounce

These are not a good data point for the Midwest. My growing conditions are a lot less than they could be -- mostly because of #5 below. Here's why I suspect I got low yields for a 2nd season harvest:

1. Last year was a complete wash -- no harvest at all -- because I got an aphid infestation, which I wanted to avoid using pesticides on, so I prayed and prayed till the plants completely dried up, virtually leafless, less than 5 feet tall in late July. This year I blasted em with Sevin till I saw the beginnings of hop buds. From then on, no pesticides.
2. Last year I only gave the plants about a gallon each of water and no fertilizer at all. This year I give each plant 6.5 gallons of water via electronic-timered soaker hose each day and started giving them a blast of fertilizer once a week from June till the end of August.
3. I seem to have a severe Magnesium shortage in my soil. The oldest leaves begin to turn yellow between the veins, which spreads throughout the leaf, after which the leaf turns brown and withers. I started giving each plant a tablespoonful of Magnesium Sulfate (Epsom Salts -- see your neighborhood drug store for some BIG boxes of food-grade variety) weekly, and they stopped yellowing. However, I don't think that I should be needing so much of the stuff. My Argricultural Extension people were of no help -- I'm going to call some AG experts in the Pacific NW for hop info -- the people here in the Chicago area had no data on Humulus Lupulus. If I stop giving them the MgSO4, they begin yellowing again. I must have something in my soil that is blocking uptake of Magnesium. I will get a soil analysis before next year.
4. The Hallertauer and Hersbrucher were at the end of the soaker hose and the Wilamette and Nugget were at the beginning of it. The difference in size in July got me thinking and I rearranged the hose to put more loops around the far end hills and less on the near-end hills. The height of the plants almost evened out by the end of July, but they never quite got even in size of leaves, vines, etc.
5. And this is the big one: not enough light. My plants only get filtered sun from July onwards and it's too cold for them to start in March, so they don't grow as much as they could in July and August. I've got LOTS of 200 year old oaks and some very tall hickorys all over my lot and the hops just don't stand much of a chance. I've even considered grow lights!

Al.

From: klein@physics.Berkeley.EDU (David Klein)  
Subject: Xmas and bay area

Well, since it seems that the topic of xmas brews has been breached, I though I would fan the flames and give my recipe from last year, for ideas of those who want.

BEFORE i give it, I am interested in bay area brewing info, like clubs, for I am new to the area and want info. Could local brewers respond, and tell me the deal?

Recipe:

2 # munich  
.25 # dextrin  
1 # xtal  
1 # 2 row toasted @350 15 min  
3/4 cup R barley  
1/2 cup Bl patent

low T mash (145) 4 hours 2 gal h20 with 2 t gypsum  
I didn't write down the sparge water amount...

brought ~7 gal to boil, once at boil added

6 # aussie amber  
3 bags of spicy duck spices (cinn., anise, fennel, fenubar, clove)  
4 sticks cinn.  
2 t crushed cardamon

after 45 min

(oh yea, I forgot 1 oz chinook at the beginning)  
another 1 oz chinook  
irish moss

after 1 hour, turned off heat, added:

2 # dark honey  
zest of 5 oranges  
2 t cloves  
2 sticks cinn.  
1.5 t allspice  
dash nutmeg  
1.5 oz fresh grated ginger

Use Wyeast Brav. ale

OG 1.1  
FG 1.028

secondary had 2 oz hops (did NOT write down the kind)

3/4 corn sugar to prime

This won 2 awards (small pools though) I would recomend not using Chinook (this was my first time using them, and I discovered I did not like them) less oranges, more spicing. Unless you feel like boiling a long time or like wasting alot of your potential sparge, I would recoment at least

using 3 lb of extract to bump the gravity.

Dave

From: Darren Evans-Young <DARREN@ualvm.ua.edu>  
Subject: Listermann Sparger / Dry Hopping with pellets

On Thu, 10 Sep 92 12:03:03 cdt, "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>

asks about Listerman gadget & dry-hopping:

Listsermann Sparger:

I have a Listermann Sparger and am pleased with it. I'm sure Jack will chime in with his opinions. I tend to agree with what he has said before about it. I like the sparger but feel the sprinkling arm is unnecessary. I keep my water level at least 2" above the grain bed...sometimes as high as 4" if I get distracted. :-)  
It does allow the hot sparge water to enter the grain bucket gently. I take a full hour to sparge 7+ lbs of grain. My extract efficiently went up significantly when I sparged for an hour instead of 20 mins.

The other thing I changed about it was replacing the hose clamps with a plastic inline tubing valve. It was far too difficult to adjust the flow rates with the standard hose clamps. With the inline tubing valves I got from Williams Brewing, I have absolute control over the flow rates.

Dry Hopping with Pellets:

I've heard somewhere that a brewer used marbles (easy to sanitize) to weigh down a muslin bag.

Clarity problems with dry hopping with pellets? Quite the opposite. I dry hopped two German Pilsners with 1 oz Saaz pellets each. The hops break up and float so you have to gently swirl the carboy to get the hops to mix in the beer. The hop bits will float again. I do the carboy swirl at least twice a day for about a week. Eventually, more and more of the hops will sink. After a week of swirling, I let the carboy sit for another week. At the end of the two week period in the secondary, all the hops have sunk. The addition of the hops also helps clear my beer. It's almost crystal clear by this time too. When you siphon for bottling, place a sanitized muslin bag over the end of the racking tube to keep the hop bits out. This is necessary! The hop bits trap some CO2 underneath the sediment and as the weight of the beer is removed, the bubbles escape churning up the hop particles. I've been very happy dry hopping in this manner.

Darren

Subject: Questions before I start...

Hello all,

I've been a beer drinker for around ten years, but have just been introduced to brew-pubs and micro-breweries since I moved to California last August.

After visiting several brew-pubs in California, Oregon and Washington, my interest in attempting to make my own brew is pretty high. I've contemplated this venture for the last three months, and I am ready to take the plunge.

The books available at my local library are late 1970 to early 1980 type books on brewing. Can some of you recommend a couple of good books/authors to start out with?

I have about seven catalogs and price sheets fro various homebrew suppliers. Which suppliers do you recommend I use or not use? Name, number and address appreciated in case I do not have any info on/from them.

What about these starter kits that are offered for sale? Is this an ok way to get started for my first few batche

Looking forward to my first batch, and to asking intelligent questions about home brewing in the future!

>With regard to adjusting the SG for temperature. Why not play it safe and always read at the calibration temperature? I use a tall drinking glass filled with ice and water.....

I can not conceive of dropping a hydrometer in boiling or even hot wort but I guess people do it. It just seems intuitive that it would explode.

Your method certainly is the scientific way to do it but I doubt that anyone can read or trust the cheapo homebrew hydrometer to within 2 points and that is the difference between 60 and 80F. So cooling in tap water is my lazy man's alternative and good enough for practical purposes.

>From: bryan@tekgen.bv.tek.com  
>Subject: Baderbrau Pilsner

>A little over a year ago at the Oregon Brew Festival, I had a pilsner which I believe was made by Baderbrau. It seems like the guy who started it/ brewmaster had worked for a major brewery in the US, but was from Czechoslovakia.

He is just a good salesman. Born in the US and visited there several times.

>Can anyone tell me what style of a beer this is?

I wouldn't begin to tread on such hallowed ground without the proper credentials.

>What beer from a major brewery would approximate it?

ARF Generic Lager, of course.

>Anyone have any all-grain recipies for a beer like this one?

This is my synthesis of their recipe from conversations with the owner during the shooting of my video.

12 lbs pale malt (they use Briess)  
1 lb caramel malt (source unknown)  
3 oz SAAZ hops  
lager yeast

"Firebrew", vigorous rolling boil.

Ferment and age at 45F for 35 days.

>This is really reaching, but does anyone know what the OG, SG,  
bittering  
units and type of hops used for bittering and finishing are?

The only hops used is imported Saaz. Gravity, BU's and ratio of crystal  
to  
pale malt, he would not reveal. Actually, he didn't even know but when  
I  
pressed him to find out, he declined.

The numbers in my recipe are just a guess but the ingredients and  
lagering  
temp/time are correct.

He claims adherence to Reinheitsgbot and that absolutely nothing else  
is  
added.  
.....

The following was posted to usenet and I thought I would share it with  
the  
Digest....

> cscil80b@cl2.cl.uh.edu (Bill Fay) writes:

>1) How much care should I give in sterilizing my bottles while  
bottling?

>I've tried the standard bleach solution but its kind of a pain finding  
a  
>place to soak 50+ bottles at one time.

Let me lay out a procedure that has always worked well for me.

Rig up a short length of plastic hose to your water tap with the usual  
adapter readily available at any hardware store. The length of the hose  
should reach only to about one inch above the bottom of your sink.

Line up some clean bottles on the sink.

Fill the first one with bleach and stick a funnel into the next one and  
pour  
the bleach from the first into this one.

Set the empty one in the bottom of the sink and poke the hose into this  
and  
run the tap.

Pour the bleach from number two into number three and stick the hose  
into  
number two.

Pour the water out of number one and it is ready to fill. Everytime you  
fill  
one, you move the others down the line.

The process is continuous and you only sanitize what you need, as you  
need  
them. The straight bleach requires almost no resting time to do its job  
and  
the sanitized bottles are exposed to the air for the bare minimum.

Try it, you may like it.

Subject: Oops--spoke too soon!

The debate on Wyeast Belgian has been going on for some weeks, and just yesterday I sent in a comment suggesting that all this banana stuff might be a bit exaggerated. This was based on the two brews I've made with it, the second of which was sitting at home while I wrote the message, waiting to be bottled.

Well, unbeknownst to me, at the same time as I was writing the message, someone broke into our house, chloroformed the dog, and (\*gasp!\*) put a banana in my beer.

So far at least the taste and smell are discernable but not overwhelming, and since it was meant to be a Belgian beer in the first place the flavor doesn't seem that weird (I'm sure my Belgian friends wouldn't object). On the other hand, I certainly wouldn't want ALL my Belgian beers to taste that way.

So, I will eat crow and offer apologies to all. In memory of the event, I have even re-named the beer. Anyone want a glass of Bananabrau?

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: Liberty clone

About six months ago, someone asked for a Liberty Ale clone. Rick Larson responded with an all-grain recipe for "Taking Liberty Ale," based on Quentin Smith's Zymurgy winner. I took Rick's recipe and came up with this extract version:

Taken Liberties Ale

1/2 lb. crystal malt, 60L  
1 c English 2-row pale malt  
7 lbs. light Munton and Fison dried malt extract  
1/2 oz. Galena pellets (alpha = 12.0; 60 minutes)  
1/2 oz. Irish Moss (15 minutes)  
1 oz. Cascades pellets (alpha = 5.5; 12 minutes)  
Wyeast American Ale 1056 (dregs of secondary, previous batch)  
1 oz Cascades pellets (alpha = 5.5; dry hop)  
1/2 c. corn sugar for priming (with a keg; more if bottles)

Cracked grains and steeped in 2 (U.S.) quarts 150-155F water for 45 minutes. Collected runoff and sparged with an additional 1 and 1/2 gallons 170F water. Added to brew kettle with enough additional water to make 5 and 1/2 gallons. Dissolved extract and boiled 65 minutes, adding hops and Irish Moss as shown. Chilled with an immersion chiller down to 70F. Racked off break and pitched onto dregs of the secondary of a previous batch, a la Father Barleywine. Active fermentation in under 12 hours. O.G. = 1.056; IBU = approximately 33 (not counting the dry hopping which would have added a point or two). Single-stage blowoff fermentation in the low 70's. Primary was 4 days, after which I attached a fermentation lock and dumped in the dry-hopping hops. After another 19 days of secondary, I racked to a Cornelius keg primed with 1/2 c. of corn sugar. After waiting a week or so, I tapped, keeping 20 psi on the keg at all other times. (Keg stored at room temp, dispensed through a jockey box.)

Comments: Two weeks after priming, I did a side-by-side with a bottle of Liberty Ale. The beers were of a similar clarity and hue, although Liberty Ale is slightly lighter in color. Liberty is also more aggressively carbonated, but the heads are similar. Liberty Ale is slightly more bitter, but, paradoxically, it also has a slightly maltier taste. (Incidentally, my Anchor Steam clone has the same difference in malt taste. I use M&F for it, too.) The cascade aroma of the two beers is similar, but Liberty Ale has a more pronounced Cascade flavor, and definitely a more pronounced Cascade aftertaste. My beer is smoother and has more body. The brews are similar enough that if you served mine to someone who was expecting Liberty Ale, they probably would not be able to tell the difference, although a side-by-side comparison would reveal the imposter. Next time, I'm going to decrease the lovibond of the crystal a little bit (to get a lighter color), and also use a little more Cascades for finishing and dry hopping (say on the order of a quarter ounce).

From: stevel@chs.com (7226 Lacroix)  
Subject: Stout to Porter Alchemy

The other week, I decided to try one of the Cat's Meow recipes. I was trying the Mackeson Clone, with a few changes...therein lay the problem. After a Woody Allenesque episode (no, not that) with a yeast starter the night before, everything went rather smoothly during the boil. I added a pound of rolled oats on the front of the recipe (steeped until the H2O boiled, then removed) and didn't really notice anything odd about the wort until I racked it into the primary. Then, almost right before my very eyes, the oddest protein formations started to form in the carboy! I left about 3/4 inch of trub in the brewkettle so I was somewhat surprised

when this occurred. The wort was about 77F going into the carboy, but wow!

After a couple of hours there were "sludge separations" at various levels in the carboy separated by layers of clear wort. Any way, after fermentation started, and about a gallon of liquid blew out of the tube/bottle

it settled down (all in less than 24 hours). As the vigorous fermentation

stopped, a fair amount of sludge (1 inch) began to settle at the bottom of

the carboy. I racked into a secondary and found the sludge to be sort of a gelatinous (probably the oats) substance and yeast bodies. Almost immediately after the "Stout" (now a mere 3.5 gallons of its former self.

I started with a 5 gallon batch) stopped fermenting and yeasties dropped to the bottom of the secondary. By the time I bottled, leaving another inch

of sludge in the bottom of the secondary, I ended up with about 3 gallons!

Interestingly enough, the "Stout" tasted more like a nice Porter...not so strange but certainly unexpected. So, to answer some questions before posing my own...1) The oats were not boiled, but were "Quick Oats" 2) The

Secondary was VERY clean and sterile (read borderline anal on this point) 3)Wort was cooled with an immersion chiller prior to racking into the primary 4)I underused the black patent by 1# 5)It's still in the bottle, my

sample came during bottling, so I don't have a final final result. Now the

questions...1) Where did all of those "protein" formations come from? (Answers like "From God" will be silently disregarded) 2)Since the fermentation was so vigorous could it complete itself in 24 or so hours? 3) Would fermentation at say 65 degrees limited the blowoff volume (I fermented it at about 70-75F)? 4) When using oats, can I expect to lose so

much in the first racking to the "sludge factor"?

I realize that I've omitted some of the facts, and that this note rambles a little, and I'm not panicky about the whole thing, but damn has this thing piqued my curiosity?? (above reference to cinematic genius..

see "Sleeper"...kitchen scene) Comments????

Subject: Re-using CO2

Gooday!

Re: collecting and re-using CO2

I recently met a fellow homebrewer, Alan, (via a mutual acquaintance) who has been brewing for some time in relative isolation as he lives in a country town.

He's been grain brewing for some time and has become quite accomplished, brewing large batches and dispensing from kegs. One advantage he has is that he is close to a northern Victorian hop farming district and knows some of the growers.

I told him about HBD and discussed the many gems of HBD lore and net-wisdom! Alan has been working on getting his conditioning gas levels right for various styles and has tried to develop a relationship between beer volume, gas pressure and temperature. Recalling discussion on HBD I searched the archive and FTP'd the CO2 tables. I sent them to him along with CM2, 6 weeks of HBD's various collected notes and recipes. Alan was pleased to put it mildly!

I was impressed when Alan told me that he has been experimenting with re-using CO2 given off during fermentation, just like the big brewers! Transport costs force up the price of CO2 refills where he lives, so he started by collecting the gas in another keg attached by blowoff tube. Alan then runs a small 12V diaphragm car tyre pump to raise the pressure into a cylinder. Details are sketchy.

The collected gas has been used to successfully condition beer and to push it around. I asked Alan whether he had equipment to dry (or filter) the gas before compressing it but he said he hadn't addressed that issue as yet.

Alan and I would be interested in any comments netbrewers may have on re-using CO2?

Cheers... David

From: "C. Lyons" <LYONS@adcl.adc.ray.com>  
Subject: Question on yeast ...

I've brewed several batches of beer recently with Whitbread and Vierka yeast (4 batches each). I believe I see a definite difference. All batches with the Whitbread yeast had gentle fermentations with a relatively thin Kraeusen lasting approximately two days. In a 6.5 gallon carboy no blow-off setup is needed, as the kraeusen doesn't rise high enough to warrant it. However, for the Vierka yeast the primary fermentation was much more violent, with a blow-off setup recommended (or, since I didn't bother, plenty of rags to pick up the overflow). The primary fermentation with Vierka lasts 3 days, 1 day longer than with Whitbread. Some additional specifics include: all brews are of the pale ale style, most were extracts (although a partial mash and an all-grain behaved the same), all were fermented at 65F (basement temp.), and all worts were quickly cooled to 60F before pitching yeast. After 8 batches, I'm convinced that the difference is with the yeasts. These two yeasts act considerably different. I am concerned with the final alcohol content of my beers. Would a yeast such as Vierka, which results in high kraeusen give a higher alcohol content, or does the kraeusen have any bearing on the actual fermentation? Is it possible that the Whitbread is doing an equivalent job of fermenting in a shorter period with a thinner kraeusen? What characteristics do people look for in their yeasts (i.e. what is desirable?). I'm very confused and concerned (but not worried YET), and would appreciate any comments on what type of yeast activity is preferable (and why).

I'm still an extract brewer but my grain brewing friends purchase their  
grain from brewpubs ALREADY CRACKED. Most U.S. brewpubs buy their grain  
ALREADY CRACKED! The reason is simple- most brewpubs are relatively  
small and  
if they cracked their own grain in a brewing or food area, flour would  
make a  
MESS of the place! And you can bet that the 100# bags of grain the  
brewpubs  
get are cracked CORRECTLY for the specific type of grain.

From: hamilton@roadrunner.pictel.com (Charlie Hamilton)  
Subject: water chemistry question

Hi gang,

I have a question about water chemistry. I called my town's water department to request info on the mineral & ion content, etc. of my water. They gave me the amounts in milligrams/liter. I want to compare them against the recommended numbers in Dave Miller's book. The only problem is that Miller measures in units of ppm.

Is there an easy way of converting from mg/l to ppm, or do I have to figure out the molecular weight of each ion and compare it to the number of H<sub>2</sub>O molecules in a liter. If I have to do that I won't. I'm not even sure its worth it at all, because my town gets water from 5 different sources, and the guy claims that these numbers are correct for all of them. He can't be right, because I used to live on the other side of town, and the water there is brown, and my water is now clear.

Has Nybody taken their water to a lab to get the mineral/ion content? If so, how much does it cost.

Thanks,

Charlie (hamilton@pictel.com)

From: gjfix@utam.uta.edu (George J Fix)  
Subject: Belgium Malt

I want to thank Tony Babinec for his excellent post in HBD #968. The data he supplied is going to be very useful.

In our book, Laurie and I expressed the wish that "... color malt problem may simply go away ..." with the malts Siebels was about to import from Belgium. It has indeed gone away, and emerged again in a different form; namely, with all the sensational color malts available which ones should we use? We selected the Cara-Vienna and Cara-Munich in our Vienna since this was the closest to our original recipe. We have been hearing some really good things about the Munich, Aromatic, Caramel-Pils, and Special B. We plan to try these for various beer styles in the future as well. Boy, there is a lot of brewing that needs to be done!

The Biscuit malt is the most unusual malt I have ever seen. Has anyone brewed with it? I personally would love to hear about other people's experiences with it. I bet someone could create an entirely new beer style with this malt.

From: jim busch <busch@daacdev1.stx.com>  
Subject: Briess malt for ales

About the recent thread on Briess malt: I think most of us who have used different malts realize that Briess is not the highest quality malt available, it is what it is, cheap. That said, I repeat my claim that good ALES can be made using this malt. I am not as convinced about quality lagers created with this malt, although several breweries do (as noted previously, Old Dominion and Adler Brau). I am convinced that the beer quality from these breweries would get even better if a higher quality malt was used.

I think the consensus here is that for consistent high quality lager beer, Briess is probably the worst choice. I am now switching back to Froedterts malt since my supplier and price have returned. I am also going to try out this Belgium malt, since for homebrewers cost shouldnt be a big issue.

From: card@apollo.hp.com  
Subject: Racking during primary fermentation

In Miller's new book, for certain top fermenting yeasts Wyeasts, such as 1007 he recommends racking off the krausen, just as the head starts to recede. He claims that if the yeast is allowed to fall back into solution, the beer will take months to clear?

If I remember correctly, Miller was always against the blow-off method claiming it to be wasteful, as well as possible source of contamination, caused by back-ups. Sounds like his new, (?) racking at high krausen method, is a lot riskier than blow-off tubes.

Any thoughts?

>> IE. exploding bottles.  
>>  
>> IN ANY CASE, ONCE THE YEAST HAS BEEN ADDED, CARE SHOULD BE TAKEN, AND  
IF THE  
>> LID SWELLS, SIMPLY RELEASE THE PRESSURE WITH A QUARTER TURN OF THE  
COVER AND  
>> RETIGHTEN.

A recent batch of very active wyeast 1028, actually deformed (buckled)  
the canning lid about 12 hrs after I added to my starter. I feel lucky  
it didn't explode.

I liken the deformed lid to a safety valve in electrolytic capacitors  
that prevents the can from exploding. A portion of the pre-formed top  
simply opens releasing the pressure.

From now on I'll use the conventional air-lock method. BTW, Miller  
advocates sterile cotton balls jammed into the air-lock, instead of  
liquid, for yeast starters. This allows one to swirl and oxygenate  
the starter without liquid from the air lock dripping into solution.  
I tried it after the my dented lid incident. Seemed to work great.

From: trush@mhc.mtholyoke.edu (Thomas P. Rush)  
Subject: More on Hop Bines

I also had the same experience as Paul, while picking Centennial I had a prickly, burning sensation on my arms and face. It happened on only one day and didn't reoccur picking Centennial again or any other variety. This was one of the reasons I thought I may have had an allergic reaction to the resins. I now think it may be due to picking on a hot, humid day where the skin moisture may trigger a reaction to the loose resin. Ever notice old photos of hand pickers dressed in long sleeved shirts?

Also, I agree about rough handling of the cones can cause excessive powder loss. When a hop cone is pulled off the bine instead of snipped off with my thumbnail I notice a small shower of fine powder. Incorrect picking could aggravate the deposit of powder on the picker(s).

Regarding follow-up questions on the Japanese Beatle problem-- you're correct Russ, J.B.'s do avoid the Cascades. Generally, they prefer all the "noble" varieties(real class) this includes all the Hallertauers. This is followed by the English aromatics. They are particularly fond of Perle(German of English parentage?), Liberty, and Goldings.

They're out there now a-munching and a-mating...a-munching and a-mating... I can understand why they a so detested. Not only am I giving them a free lunch, they shamelessly flaunt their sexual prowess of dual mind control.

Keep a-brewing and a-pouring,

Tom Rush

**Subject: 1056 and Slow Fermentation**  
Full-Name: "John Cotterill"

I currently have a batch of IPA in the primary. I am using 1056 yeast and the starting gravity of the brew was about 1.060. The fermentation took off like gangbusters to about 1.040. Now it is creeping along at 1 SG per 3 days or so.

It seems that whenever I use 1056 yeast in higher gravity beers, the fermentation really slows down after the first few days of fermentation. Has anyone else ever noticed this?

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: DMS rebutts from Micah Millspaw

Micah rebutts about DMS

>DMS gets produced from its precursors when the wort is above 140F. It's  
>true that different malts have more or less of these precursors,

The sulfur content of the barley malt can be greatly effected during the  
malt process. So I say its the malt.

>as Jim suggested, technique can also be a big factor. During a vigorous  
>boil, the DMS gets boiled off, so a non-vigorous boil can increase your  
>DMS levels.

Not only do utilize a vigorous and long boil (I've a 375,000 btu blaster)  
but I have a forced draft on the kettle as well. If this set up can't  
evaporate normal DMS I don't know what can. So I say its the malt.

> When the heat is turned off, is when most of the DMS that  
>remains in your beer gets produced. Cooling quickly with a wort chiller  
>to below 140F is the best way to minimize DMS production during this  
>stage of the process.

The is more or less true.

>I'm sure that Micah uses a chiller,  
>so the only factor I can guess, if Micah's boils are vigorous, is  
tapwater  
>temperature. Perhaps Micah's tapwater is warm and an ice-bath pre-  
chiller  
>would help cool the wort quickly enough to keep DMS below sensory  
thresholds?

I live in the sierra foothills and my tap water is in the summer 50F max.  
Also this is the same wort chiller that I have been using for the last  
few years and no problems there. I say its the malt.

Also, this happened to others in my club who bought malt from this same  
lot  
we each got several 50# sacks. So I say that its the malt.

Subject: RE: Sinking hops

If you have much fermentation going on, it can take a lot of weight to sink hops. My friend Perry [the notorious Rev. Perry 10X Mills] frequently dry hops in his open fermentor. For a ten gallon batch he will use 2 - 4 oz of hops in a cheesecloth bag. He started out using a rock the size of a large egg. It floated! Now he uses a rock the size of a baking potato[e]. That keeps the herbs down with Davy Jones...

Marbles sound like a good idea, but it will take a lot. I know Perry's rock won't fit through the neck of a carboy. Myself, I use pellets and shake the carboy every once in a while. The pellet duff will sink eventually, but it doesn't stick to the bottom.

Lastly, using a bag may slow down the diffusion into the beer, so loose leaf vs. pellets vs. bagged leaf may all give different results with similar amounts.

Yo ho ho. Make them hops walk the plank, matey! -- Paul

Subject: Steeping rolled Oats

Concerning yesterdays post about rolled oats which went as follows:

>The other week, I decided to try one of the Cat's Meow recipes. I was  
>trying the Mackeson Clone, with a few changes...therein lay the problem.  
> [stuff deleted]  
> I added a pound of rolled oats on the front of the recipe (steeped  
until  
> the H2O boiled, then removed) ..... Then, almost right before my  
> very eyes, the oddest protein formations started to form in the carboy!  
> I left about 3/4 inch of trub in the brewkettle so I was somewhat  
surprised  
> when this occurred. The wort was about 77F going into the carboy, but  
wow!  
> After a couple of hours there were "sludge seperations" at various  
levels  
> in the carboy seperated by layers of clear wort.  
> [stuff deleted]  
> As the vigorous fermentation stopped, a fair amount of sludge (1 inch)  
> began to settle at the bottom of the carboy. I racked into a secondary  
> and found the sludge to be sort of a gelatinous (probably the oats)  
> substance and yeast bodies. Almost immediately after the "Stout" (now  
> a mere 3.5 gallons of its former self.. I started with a 5 gallon  
batch)  
> [more stuff about oats etc...]  
>  
>Now the questions...1) Where did all of those "protein" formations come  
from?  
>

I too had a similar experience when STEEPING rolled oats for use in an  
oatmeal  
stout. I was afraid of getting oatmeal from the oats so I didn't even  
bring the  
water to a boil, only to about 160 f. Nonetheless I too found what I  
think was  
basically oatmeal at the bottom of my primary fermenter. All the Oatmeal  
I've  
ever eaten has a thick clear-to-whitish paste that accompanies the actual  
oats  
and I think this is what you end up with in your primary fermenter. I  
assume  
that this paste is made up mostly of starch and glutens. Unfortunately,  
it also  
has incredible capacity for absorbing water or beer :( . I too lost a  
half  
gallon or so of beer to the oatmeal sitting in the bottom of my  
fermenter. Had  
I been thinking more quickly, I might have saved it for my morning  
breakfast.  
Somebody could probably market oatbeermeal or oatstoutmeal :).

I posted this experience of mine earlier this summer, but I think the  
point  
got lost in the discussion of mashing/steeping of specialty malts and  
adjuncts.  
As my stout was only my third batch, there are clearly more people out  
there

with much more experience, but I myself will NEVER, EVER, steep rolled  
oats  
again. I would advise all other extract brewers like myself to put out  
the  
extra effort to find steel-cut oats. I found some (only after my stout  
was  
history) in a local health-food store. Since these have not been  
gelatinized,  
I don't think they will produce the oatmeal-in-the-primary problem.

Regarding the noticed similarity between the attempted stout and a  
porter.

There was no mention of roasted barley in the posting. Did you use  
roasted  
barley ? It seems to be the ingredient (aside from difference in gravity  
and  
hopping rate) that makes the difference between a porter and a stout.  
Though  
since Mackeson is more of a sweet stout, maybe it shouldn't have the  
roasted  
barley bite.

Cheers,

Brian Cole

Subject: request for listing of brewpubs

Hi out there in tera-biera land,

I live and work in Southern Maine and I brew like a madman up here (long, cold winters).  
I enjoy visiting brewpubs and sampling all fare at these establishments.  
..BUT, I find  
that nearly all of the micro-pubs in the Boston/NH/ME area serve 90%  
traditional English  
type stuff...Oh there is the occasional Weizzen ... but how I long for a  
real DoppleBock  
or an Octoberfest with some real FEST to it! I will be traveling soon,  
actually the last  
week in OCT to San Fran and I've only been to one place there.... Tank 20  
(?!?) right?  
It's been a couple of years but I recall them having a pretty decent  
assortment. Anyhow,  
If any of you know of ANY other places and can give me addresses and a  
quick review of  
the brew (no matter how 'hole-in-the-wall` the place(s) may be), I would  
be forever  
indebted (or atleast reasonably appreciative). I have seen some listings  
before here in  
the digest, but they were more general to the BAY-AREA and I need  
something more San  
Fran specific. I'm sure there has to be more than just ol' Tank 20. So  
please feel  
free to flood me with all possibilities.

As a side note I plan on brewing, what I will call, a Colonial  
Thanksgiving Ale. Although  
I haven't completely formulated my recipe (I love to create and rarely  
follow any recipe  
to the letter) I would be very interested in anything like this that any  
of you may have  
tried before. I know there will be pumpkin and brown sugar and cinnamin  
and crystal malt  
and fresh well water from S. Maine (really quite excellent) and wyeist #?  
??? but thats  
about it for now.... I know I want more so feed me seymore...

thanks in advance ..... true brew for me and you. TSV (Todd@Thoreau)

From: Andrew Patti <patti@ee.rochester.edu>  
Subject: Visit to Rochester NY

To Bob Jones' question about brew pubs in Rochester, I know of two:

- 1) The Rochester Brew Pub, Jefferson Rd. between Rts 15 and 15a
- 2) The Rohrbach Brewing Co., Gregory Rd.

Of the two, the Rochester Brew Pub is much better.

Andy

From: "r. j. harvey" <HARVEYRJ@VTVM1.CC.VT.EDU>  
Subject: honey brews

dear list:

as a relative newcomer to this list, I'll pose a question that perhaps has been addressed in back issues; if so, I'd appreciate any guidance in that direction.

the question is: I've been experimenting with brewing batches using a high percentage (50% and up) of honey substituting for malts, and have been generally pleased with the results, especially if the OG is not too high (e.g., 50-55 or less). however, I have yet to find a choice of hops that seems to work well (I've been using 1-2 oz of Cascade pellets). in particular, my wife claims they are too bitter (I don't agree, but that's largely irrelevant). for malts, I use light extracts primarily (either cans or powdered).

I add 1/2 - 3/4 of the hops at the start of boil, and rest as finishing, and strain out as much of the hop solids when sparging to primary fermenter.

I realize this is pretty low-tech, but any suggestions would be gretly appreciated.

r. j. harvey

From: korz@iepubj.att.com  
Subject: Re: Bananabrau

Over the last few weeks, we have heard from many, who have reported mixed results with Wyeast Belgian yeast. I haven't been keeping track but I know that several have said that they \*did not\* get the banana esters that many (including me) have gotten. So, in the interest of finding the correct fermentation temperature for this strain of yeast, I am announcing a...

CALL FOR TEMPERATURES:

All brewer's who have used the Wyeast Belgian strain, please send me email which includes the temperature at which you fermented and whether or not you got the banana esters. Please send to:

korz@iepubj.att.com

I'll collect responses for a week or so and then post the results. Hopefully, we can thus find the right temperature and finally get that elusive Chimay flavor, sans the bananas.

Al.

P.S. Regarding aromas and flavors -- technically, there exists no such thing as "banana taste" nor "strawberry taste" nor "chocolate taste." Our tongues only discern four tastes: sweet, salty, bitter and sour. Our nose, on the other hand, can discern thousands of smells and it is the combination of smell and the four tastes that we attribute to a flavor. You should breathe as you taste, so if you smell the banana ester, you should be tasting the "banana flavor." The two are inseparable.

From: mm@workgroup.com (Mike Mahler)  
Subject: water quality

A call to my water department yielded some very interesting results:

Ph in our area is about 6.2-6.3 but has been down to 4.0! Sheesh, acid baths in the morning. No wonder our pipes are leeching copper into the fixtures.

We have soft water at 24 ppm of calcium carbonate (what's recommended for amounts of BWS to be added for Pale Ale brewing with this soft water?)

We have a sodium level of about 8ppm.

I also found out that the EPA has enforced our city to build a 3 million dollar water treatment facility which the dep't of health thinks is bullshit considering that water in our area is very good quality. At least they can give us a less aggressive ph when it's finished...

From: korz@iepubj.att.com  
Subject: Re: Wyeast Munich #2308 (was lagering temps)

Suurb asks what is the right temperature to ferment and lager a batch made with Wyeast #2308 Munich Lager yeast.

Well, I can tell you what temperature to \*NOT\* ferment and lager at, lest you want the Chicago Tribune to report you brew home perm solution.

I used this yeast to make a borderline bock/dopplebock (1075 OG) and here were my temperatures (I did not use a starter -- date code Dec 91, incubated package 48 hours before brewing on April 18th -- package swollen to about 1.5 inches):

Pitched at 68F  
32 hours at 62F (till tiny bubbles were just beginning to rise in fermenter)  
24 hours at 50F  
2 weeks at 45F (wonderful yeasty smell in fridge -- no sulfur or perm smells)  
racked to secondary  
4 weeks at 45F  
bottled (perm smell very prominent)  
2 months at 45F

Good, clean beer with faint off smell -- only identifyable as perm solution if the brewer foolishly volunteers the information and draws attention to it! Perhaps a few more months at 40F (which is where it is now) will drop the aroma below perception threshold level.

This was my very first lager, so let me ask the lager experts a question:

When I noticed the off smell at bottling time, should I have left it to lager for several more weeks?

Al.

From: korz@iepubj.att.com  
Subject: Pre-cracked grain

I've checked all the back articles that I've saved and I guess I threw out the one I'm thinking of. It gave some figures about a microbrewery that changes their recipe based on how long it's been since they crushed their grain. Although I wish I had the actual figures (perhaps someone still has this article saved) suffice it to say, that they increased their grain some percentage (it was 10 or 20%) if, for some reason, they could not brew the day they crushed the malt. This was done to get the OG they were shooting for.

I haven't done any experiments to back this up (I use my grain minutes after crushing), but if it indeed is a 10 to 20% yield difference in one day, it certainly is a case for owning your own grain mill. I would suspect that crushed grain, a few months old would be quite a bit worse. I've purchased these black and gray, locking, plastic storage containers that hold about 100 lbs of grain and they really make storing bulk grain easy. I know that they are air- (and mouse-) tight because when I open one, the whole room fills with a wonderful fresh grain aroma. I got mine at Builder's Square, but I've also seen them at True-Value Hardware for about \$25 each. I think they are made by Rubbermaid.

My point is, that with the added savings of buying grain in bulk and the increased yield with freshly-crushed grain, I think the benefits of owning your own mill outweigh the cost. And let's face it, when compared to hobbies/sports like model-aviation or golf, brewing is a bargain and you get to drink your results!

Al.

>

> I'm still an extract brewer but my grain brewing friends purchase their  
>grain from brewpubs ALREADY CRACKED. Most U.S. brewpubs buy their grain  
>ALREADY CRACKED! The reason is simple- most brewpubs are relatively  
small and  
>if they cracked their own grain in a brewing or food area, flour would  
make a  
>MESS of the place! And you can bet that the 100# bags of grain the  
brewpubs  
>get are cracked CORRECTLY for the specific type of grain.

The reason may be even simpler: In any large scale milling operation,  
there  
is a significant explosion hazard. Even if the pub manages to keep the  
milling isolated from the customer area (who wants to sample good beer  
with a nose full of flour?), the risk is great enough that I suspect  
the insurers wouldn't allow it.

My father repaired office machinery for a living - one of his clients  
was a flour mill in the Chicago area. He described some fairly elaborate  
measures they took to avoid explosions. Sealed switches. If a piece of  
equipment is being unplugged, the power to the circuit is cut first to  
avoid a spark. Membrane covers over anything with pushbutton switches.  
Telephones with double-walled housings to avoid exposing the spark when  
the handset is lifted. For a small scale operation, no problem. For  
a large operation, running continuously for long periods, flour dust in  
the air is as explosive as a natural gas leak. I won't insist that  
a small brewpub is milling on that scale, but who's going to risk it.

Of course, for a pub located in an urban area, they may not be willing  
to sacrifice expensive floor space for an operation that can easily be  
done elsewhere...

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: RE: hop rash/irritation

Tom Rush pointed out something that I had ignored about the irritation on my arms when picking hops. He says that it happened to him on a warm day and not on a cool one. It was the same for us. I was sweaty the day that I got the red irritation and itching on my arms and backs of hands.

I tend to think that the irritant is related to the vines and leaves, not the cones. I picked around 4 pounds (dry weight) that day and my fingers were sticky with resin. But the rash was worst on the inside of my forearms.

Later, when I was packing the dried hops in heat-sealed bags, I was getting covered with sticky, yummy, yellow resins. It was particularly thick on the back of my hands (where I had the irritation when picking). I had no reaction to the resins, other than sniffing my hands a lot and being more prone to naps than normal. I'm going to make some hop pillows!

Tom's speculation about pickers wearing long sleeves makes me think that its the little stickery things on the vines and leaves (physical rather than a chemical irritant). In the 1990 Zymurgy Hops and Beer special issue, there are some pictures.

p.29: Hop yard workers, six with rolled up sleeves. One woman with long dark hair is wearing gloves.

p.51: Two women picking hops. The woman in right foreground is wearing a long sleeved sweater. The woman in the center appears to be wearing some sort of forearm protector and a short sleeved dress.

p.56: Indian hop pickers. Only one man (far right) has his sleeves rolled up, but the man holding the pole is wearing gloves.

p.27: Two oast house workers. Both have their sleeves rolled up, no gloves visible, though the man on the right only has a small part of one hand showing.

If the resins were irritating, I would think that the oast house workers would be the most likely to be protecting themselves. My dad grew up near Yakima and remembers hop picking season. He says that some people wore gloves because their hands got sore, but it was looked down on because it slowed down picking.

I'm still not sure. But if the pillows cause any irritation, I'll have some real "hop head hops".

Paul

From: korz@iepubj.att.com

Subject: mg/l vs ppm

It's probably not worth it to take your water to a lab yourself. The Zymurgy special issue on Water and Beer gives adjustments for almost every beer style so you can custom-match your water to the style you're brewing. Some styles, like Burton Ales or Dortmunder cannot be accurately reproduced (not even close) without adjusting your water. Sulfate ions, for example, accentuate hop bitterness and give the Burton ales thier dry finish. Regarding conversion from mg/l to ppm, this question came up a year or two ago and a lot of people were unsure about it, but my favorite answer from that discussion was: multiply by 1 to convert from mg/l to ppm and divide by 1 to convert back (actually, I had to think for a moment to make sure the two are one-in-the-same ratio).

>After 205 ales, I've decided to brew my first lager, and yesterday  
>I bought a packet of Wyeast Munich #2308. I have no idea what  
>temperatures to ferment and lager at. Would those of you who have  
>experience with this yeast please send me some advice? Thanks.

I've made my only (true) lager (after 34 ales) to date with Wyeast  
Munich #2308, in my food fridge, in 3-1gal jugs @ 32-35F. 3 months  
got the SG down to mid-20's from 1.075. I then left it at basement  
temps (60F) for a few more weeks to make sure it fermented out that  
last little bit, so I wouldn't get glass grenades (plus miller says  
when you ferment at extremelty low temps, you should raise the temp  
towards the end - was it for diacetyl reduction?). Anyway, you can  
almost freeze the yeast and it will still ferment.

Date: Tue, 15 Sep 92 14:16:08 EDT  
From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: 1056 and Slow Fermentation; Xmas ale

John Cotterill asks about slow fermentations with 1056 yeast. I have had similar experiences - one brew started at 1.042, fermented vigorously for three days but was only down to 1.036. I racked to secondary, where it took 40 days to ferment down to 1.017, at which point I bottled it. It took a long time (about another 40 days) to carbonate well. My suspicion is that I may not have aerated it well enough, and never really built up a large enough yeast population (?).

Regarding the recent interest in Christmas ales. My third batch of beer (brewed last December 1) was a Christmas ale, and is getting pretty good, if you like ginger (I've found several members of our homebrew club who LIKE ginger, as does my wife). This one takes a long time to mellow out so it is too late for this year....

"Christmas in July" Spiced Holiday Ale

8 lbs. light DME (I used American Eagle)  
3/4 lb crystal malt  
3 oz. roasted barley  
3 lbs wild clover honey  
1 oz. Northern Brewer hops (boil)  
1/2 oz. Northern Brewer hops (finish)  
6 oz fresh ginger, peeled and grated (1/2 boil, 1/2 finish)  
grated peel of 4 tangeloes (1/2 boil, 1/2 finish)  
1 stick cinnamon  
1.5 tsp. nutmeg  
1.5 tsp Irish Moss  
Whitbread Ale Yeast

The crystal and roasted barley were steeped in six gallons of water while it was heating. They were removed at 190 degrees and the DME, honey, boil hops, half of the ginger, half of the tangelo peel, the cinnamon stick and the nutmeg were added. The Irish Moss went in 40 minutes into the boil, and the rest of the ginger, tangelo peel and hops went in at 50 minutes. At 60 minutes, cooled quickly (counter-flow chiller) and let sit for 3 hours. Racked off the copious trub, aerated and pitched with a pint of starter from two packages of Whitbread Dry Ale yeast (my all time favorite dry yeast). OG 1.085

It fermented slowly but steadily with daily rousings for 30 days, at which point it stalled at 1.040. I added 1/2 tsp of amylase enzyme, which started it back up. On January 24, I bottled it with 3/4 cup corn sugar priming. The F.G. was 1.032. After about three months in the bottle it was interesting, but not what I was looking for -- Steve Russel's comment was "Well, it's a very interesting ginger beverage, but I'm not sure I'd call it beer!". Now, it has matured quite nicely, and has a couple of real fans. It is still VERY gingery, so unless you really like ginger I'd cut the ginger back by 1/2 or 2/3.

Date: Tue, 15 Sep 92 15:17:48 EDT  
From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Carboys and Casks for sale

There is a store in Pittsburgh which sells carboys and casks of various sizes:

Pennsylvania Macaroni Co.  
2010-12 Penn Avenue  
Pittsburgh, PA 15222  
phone (412) 471-8330

(for natives, this place is on The Strip)

For glass containers, they have 4,8 and 14 gallon carboys ('demijohns'). The 8g is \$60, the 14g is \$80, both include plastic carry baskets and metal spigots near their bases.

The oak casks are available both wax-lined and charcoal-lined in sizes 5,10,15 and 20 gallons. The prices for the wax-lined barrels are: (5g,\$50) (10g,\$60) (15g,\$74) (20g,\$82). One must 'inquire' about charcoal barrels, but there was a 10g on display for \$87.35. There were also full-size bourbon aging casks available, empty (and stencilled with distillery information) but still smelling sweet; no prices given. I don't know what size they are; 30g? 40g?

THEY MIGHT NOT MAIL-ORDER! I didn't have time nor presence of mind to ask. Perhaps somebody might be able to fill in this data-point -- in the mean time, ask nicely if you're phoning long-distance.

This place is primarily an Italian grocery with bargains on cheese, bread, pasta, oils, etc., and these containers seem to be a sideline. However, they also carry cider and grape presses in various sizes (I didn't check prices on them). I have no affiliation with this store, etc. etc.

>please post.

Being in a virtual beer hell (Sweden), where I have yet to taste a low-cohol (l[tt|l] beer not exhibiting strong amounts of DMS, I couldn't resist this quest. So off I went to the state-run liquor store, Systembolaget, the only place one can buy anything stronger than 3.5% by volume. I was able to procure a bottle of '90 Gammel Brygd - yes it is vintage dated.

Gammel Bryggd is "bryggd" only once a year by Falcon, one of six Swedish breweries, and comes in a special green bottle that has been spray painted matte-black, a la Simpatico. Each bottle comes with its own metal bottle opener, with the "vintage" stamped on it.

The label says: "Bryggs endast en g[ng] per [r]. Sedan den h[r] tappningen bryggdes i november 1990 har [let] lagrats f[r] att n] sin fulla mognad. V[rt]styrka 14.0% Klass 3 4.5% vikt 5.6% volym", which I take to mean "Brewed once a year. Since this here 'vintage' was brewed in november 1990, the beer has been lagered in order to reach its full character. Wort strength 14% Class 3 (at most) 4.5% alc/wt, 5.6% vol." What 14% wort strength means is anybody's guess - maybe Plato? (I have never used Plato - what[s the SG on 14 degrees?)...

While the liquor catalog only lists the beer as being "middle-bodied tasty beer with good hop character and roasted tone," I can tell you it is a slight variation on the VIENNA/M[RZEN/OKTOBERFEST style. (Did you get that MR. GEORGE FIX???)... It has a dark, deep copper color, and a strong, slightly greyish head. The heavy malt aroma is immediately noticeable, even with my "recognized" nose. Hop aroma is rather light, and flowery. Malt flavor is readily apparent, as is a moderate amount of residual malt sugars, which are not balanced by hop bitterness. There is some truth to the roasted tone, but I attribute this to a heavy "toasting", or possible some black malt, rather than any roasted malt.

Overall I'd score the beer in the 40-42 range...

The beer costs Skr15:70, or just over \$3, at today's exchange rates - this is for one bottle, no volume pricing (that would encourage drinking, which is inherently bad)... Mind you that most all available high alcohol beers here cost Skr10-15.

Erik, and others, who may want to make this brew, should buy the Fix couple's pulitzer prize winning Vienna/M[rzen/Oktoberfest, and lighten the hops, but darken the malt...

Subject: To boil or not to boil honey for mead?

Hello,

I am ready to make my first batch of mead and have read numerous recipes from both the Cat's Meow and the NCJOH. Papazian says to boil the honey to coagulate the proteins in order for the mead to clear better. I have heard and read recipes from other people that say to only pasteurize it at 170-180 degrees to help retain the effervescence of honey that boils off. I was wondering if anybody has made a side-by-side comparison of two batches, one with the honey boiled and one without the honey boiled? If not, I guess I will take the action item. Also, I guess I was going to use champagne yeast from the start. What temperature is ideal for a typical champagne yeast? Any other comments or suggestions before I get started will be appreciated.

Super Dave

Subject: Water Analysis

In HBD#969 Charlie Hamilton asked about water analysis at labs. Just wanted everyone to know that Sears (no I'm not affiliated with them) will do a water analysis for you at no charge. They give you a bottle with a self mailer. Fill the bottle with a sample of your tap water and send it off. In 10-14 days, lo and behold, a water analysis shows up at your door. Sears does this so that you may be inclined to purchase one of their wonderful water purifying systems. If you live in the boonies, I understand that this service is also available through their catalog. I did this before I started brewing so I really don't know how good the analysis is but it may be worth a try. It's free!

From: Richard.Goldstein@EBay.Sun.COM (Richard Goldstein)  
Subject: Wyeast #1007 (was Racking during primary fermentation)

Here is a recap of my experience with this yeast, and then some questions.

Mal Card said:

> In Miller's new book, for certain top fermenting yeasts Wyeasts,  
> such as 1007 he recommends racking off the krausen, just as the head  
> starts to recede. He claims that if the yeast is allowed to fall  
back  
> into solution, the beer will take months to clear?

Now you guys tell me?! I'd been wanting to use this particular Wyeast (#1007, German Ale) for a long time, and I finally did over the Labor Day weekend. This stuff produces a wild fermentation. The recipe was a basic Kolsch of 7.5 lbs of Klages, 1.0 lb of Vienna malt, and Saaz hops for bittering and flavoring. The OG was about 1.048.

I pitched a 750 ml starter (after 24 hours) into 5 gals of wort in a 7 gal carboy. 20 hours later I had about 2-3" of krausen. My wife and I went to a movie, and when we came back 2 hours later it looked like the Sta-Puft Marshmallow Man was trying to squeeze his way through my airlock. I quickly switched to a blow-off, and things subsided enough to put the airlock back on after another 24 hours.

This krausen was thick, firm, shiny and creamy looking. It has now been 10 days in the primary, and the krausen is now just a 1/8" film, but still looks almost stiff, and has big bubbles imbedded in it. For the last 2 or 3 days, I have gently shaken the carboy a few times a day, and have observed the chalky looking yeast quickly descending to the growing yeast layer on the bottom of the carboy.

During the active fermentation the whole thing was one huge churning blizzard of wort, trub, and yeast: pretty typical of most of my fermentations. Today it is still bubbling about once every 10 seconds, and the beer itself still looks like an incredible murky turbid mess, like iced tea with a pound of flour stirred up and in suspension.

So should I have really racked under the krausen before now? If racking is to get the beer off of the trub and dead yeast, then until yesterday it didn't seem worth it given the amount of stuff still in suspension. I have always been a little uncertain as to when to rack into the secondary. I can definitely believe that it may take months for this beer to clear.

As an aside, I've wondered for a while whether the size and stability of the krausen is directly related to head POTENTIAL. I know that the amount of sugar/gyle/etc will affect carbonation, but are the krausen's properties an indication of the future head properties of the beer?

As usual, thanks for your thoughts/comments/theories/experiences.

Subject: Cracked Grains Folklore

I heard from my local homebrew store that grains should not be cracked more than 3 days or so before use. They were somewhat vague, but managed to give the impression that doing so would allow the grain to pick up "off" tastes and might affect enzyme content. They recommended storing the grains in the refrigerator after they had been cracked.

Anyone have any hard data?

Yes it's a 1 to 1 ratio because they're the same (at least according to the person I talked to at the Ft. Worth water department.) He said they used to use the term ppm, but it has fallen out of favor and they now use the term mg/litre, but they are equivalent.

Subject: dry beaning

Hey now- I saw someone's posting of a x-mas brew recipe that had some vanilla extract in it. That got me thinking about doing a porter with some form of vanilla in it. I'm assuming that alot of the aromatics of vanilla extract would get scrubbed away either in the boil or primary fermentation so I figured on putting a tablespoon or two into the secondary. A little more pondering led to the thought of tossing a vanilla bean or two (or three) into the secondary as a sort of dry hop process.

So what do you think? I've never really used whole vanilla beans for anything so I'm not too sure about their characteristics. I know you have to slit them open and scrape out the guts, but that's about it. Is 2 or 3 beans too much? Any head-reducing oils involved? Anyone? Anyone?

thanks  
dab

From: SMITH@EPVAX.MSFC.NASA.GOV  
Subject: really low O.G. question

greetings humans.

I've got a troubleshooting question for you folks. Last night I brewed up a Christmas ale-type wort, using the below recipe:

Woolypate Christmas '92

Steep in 1 1/2 gal water at 155 degF for 30 min: 1 lb 10 degL crystal malt, 1/4 lb chocolate malt, 1/4 lb cara-pils, 1/4 lb flaked barley  
Add 6 lb Breiss pale extract, 6.6 AAU Fuggles, 1 cup blackstrap molasses, 6 oz. diced/peeled ginger; boil 45 min.  
During last 10 min. of boil, add: 10 1" cinnamon stix, 15 cracked cardamom pods, 1 tsp nutmeg, 12 cracked allspice, zest of 4 oranges  
Cool, add to carboy to make 5 gal, and pitch Wyeast Irish Ale at 78 degF.  
Future: maybe dryhop with 1/2 oz Saaz if I feel like it.

However. Upon measuring O.G. of this mixture, it read only 1.020! (yes, I remembered the temperature conversion.)

I see several possibilities:

- 1) my hydrometer is seriously ill
- 2) this liquid extract was diluted by the supplier in the store (I bought bulk by mail order). \*\*
- 3) the 5-gal mark on a 5-gal carboy is not where I think it is. I'm using a 7-gal for the first time and marked the 5-gal point by filling up a 5-gal carboy, pouring this into the 7-gal, and marking the level.
- 4) IT'S ALL BREISS' FAULT! (sorry, couldn't resist)
- 5) the ever-popular "other"

\*\* I thought it seemed a little thin. I won't say where I got it unless the other two 6-lb jars turn out to be thin.

2) seems a little outrageous, as does 3) and 4). 1) would require a sudden change in my hydrometer, it used to work fine.

Could anyone suggest a way to find out what happened? And a way to add some oomph to this brew if it's actually as thin as it seems?

From: tony@spss.com (Tony Babinec)  
Subject: wyeast "munich" #2308

Here is the description from Wyeast of their "Munich" #2308 strain:

"Munich Yeast from Wissenschaftliche in Munich #308. One of the first pure yeast available to American homebrewers. Sometimes unstable, but smooth, soft, well-rounded, and full-bodied. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 50 degrees F."

Homebrewers should not be discouraged from using this yeast, as it produces great lagers. It is often described as "unstable," and I think what is meant by that is that it can produce sulphury aromas and flavor notes.

I'm not sure what is meant by "optimum fermentation temperature" in the Wyeast description, but I'll guess that it means this: if you ferment colder, you're needlessly slowing down the primary fermentation; if you ferment much warmer, you'll speed up the fermentation at the expense of true lager flavor (for example, undesired "fruitiness").

What has worked well for me is this: ferment for 3 to 4 weeks at 48/50 degrees F. When you sense that fermentation is dramatically slowing, which is evident both from the drop in krausen and the slowing of the fermentation lock, step the temperature up to 60 F to encourage diacetyl reduction and the completion of fermentation. See Byron Burch's comments on this yeast in his article in the Yeast Special Issue of Zymurgy.

Also, in the latest Zymurgy, George Fix has an interesting article on sulphur flavors in beer. At one point, he talks about experimenting with this yeast and conducting a 3-step fermentation that starts cold (mid-40s) versus a constant temperature fermentation.

Date: Wed, 16 Sep 92 10:37:10 CDT  
From: tony@spss.com (Tony Babinec)  
Subject: wyeast "belgian" ale experiences

I've made a few beers with Belgian yeasts. When I was making the first one, I didn't know at what temperature to ferment the beer. Some brewers advised cold, and others advised warm. Since then, I've read Pierre Rajotte's superb "Belgian Ales," and he has settled the question for me. Rajotte says that Belgian brewers will ferment their beer warm, up to 86 degrees F. If you think about it, in using Belgian yeasts, you are looking for flavor notes from esters, phenols, and the like, imparted by these yeasts, and warm temperatures will encourage exactly this.

The first Belgian-style beer I made was with bottle-cultured Chimay yeast. I bought the freshest Chimay Red I could find, drank it (yum!), and pitched the dregs into some starter wort. I plated out some yeast, and isolated and built some up. The beer made with this yeast was fermented at a winter basement ambient temperature of 60/62 degrees F. The resulting beer had that Chimay character, although it was no rival for the real thing, and it did have some banana-ester and "bubblegum" flavors. I don't know what effect the temperature had, although I believe a warmer ferment would have led to more pronounced flavors. I also don't know how healthy the yeast were, although to all appearances they performed well. The good news is that over time the banana and bubblegum flavors have receded and a phenol flavor, sort of spicy like cinnamon on the tongue, has come forward. All in all, it's an enjoyable Abbey-style beer. So, I'd say give the beer some time in the bottle, especially as these beers tend to be high gravity beers.

I've used Wyeast "Belgian" on a couple occasions. In one instance, I moved the carboy to a relatively warm room, and fermented at about 76 degrees F. The resulting beer was recently bottled, and tasted great at bottling time. I don't know whether Wyeast "Belgian" is Chimay, but they produce similar flavors. The net effect is a big plus to homebrewers. The homebrewer doesn't need to go through the effort of bottle-culturing Chimay, as Wyeast "Belgian" is readily available. This opens up a whole range of styles. See Rajotte's book for many recipe ideas. By all means, obtain bottled beers and try to isolate their yeast, but know that the "Belgian" yeast is available.

The above experiences are anecdotal and don't really prove anything. But, again, my sense is to ferment warm or at ambient temperatures, and make no special effort to ferment cool.

>  
> Also I question whither this mead won Byron that prize,  
> or he won it for some other reason, known only to the AHA.  
> Micah

I probably shouldn't but I take offence to this comment for two reasons. Whatever other complaints one might have about the AHA, how it is run, or how it handles various activities, the judgings are run as fairly as possible. Since I'm a judge myself I have personal experience and am probably inclined to take the comment more personally than intended. Furthermore a friend of mine (and member of our club), Gordon Olsen, judged the meads in the finals. He was once meadmaker of the year and knows his meads. Not only did he come back raving about this mead but he would never take part in any 'fixing' of the competition.

I'm the first to admit that the quality of judging isn't as consistently high as I would like but no one who is thinking about submitting a beer to the competition should be discouraged by any thoughts that they don't have as good a chance of winning as anyone else.

>My four, 2nd-season plants had these yields after drying:

Nugget -- 2 ounces  
Wilamette -- 1 ounce  
Hallertauer -- perhaps 1/4 ounce  
Hersbrucher -- perhaps 1/8 ounce

Just for reference... my four, 1st season plants (all Chinook) produced 1.5 oz after drying. Just enough for a batch to compare with commercial.

All of the hops came from one plant. Two of them were the original plants I bought in mid-Winter and the other two, I propagated from stems off these two.

The original plants are both about 15 feet tall but one is completely barren. The freebees are about 5 feet tall with no flowers either.

>From: gjfix@utamata.uta.edu (George J Fix)  
>Subject: Belgium Malt

Just a note for the health nuts..... I had a chat with Siebel's yesterday to learn more about their malt. I would love to find a local source instead of having to have it shipped from Minnesota.

My first question was, "is it direct or indirect kilned?" He was a bit flustered at first and the upshot was that he really didn't know. He stated emphatically that the nitrosamine level was 4 PPB. I think what he meant to say was that it is less than 4. This is the FDA standard and was arrived at by asking the maltsters how low they could get it without converting to the indirect method. So, when someone says 4, you can pretty well bet it is not indirectly kilned, which results in less than one or undetectable levels.

That point aside, my question is, are we talking PPB or PPM? In conversations with Bries, the limit was stated as 4 PPM. It doesn't make much difference from a practical standpoint but it is hard to sound convincing when one could be off by a factor 1000.

>From: Kinney Baughman <BAUGHMANKR@CONRAD.APPSTATE.EDU>  
>Subject: The cost of a Corona

>Richard Stueven writes:  
>Subject: Why Should I Buy a Grain Mill?

It is most interesting that, with almost 200 MALTMILLS and tens of thousands of Coronas out there, all we have heard so far are reasons NOT to own a grain mill. So to balance the discussion, I will offer my totally unbiased opinion.

Clearly, the reason is not to save money. I built my first mill because the only source for nitrosamine-free malt (that I am aware of) does not crush it. I was left with taking it the local brew shop to be pulverized on his "modified" coffee grinder.

I suspect that everyone who makes the plunge can supply his own reason but I would guess that the major reason is that it just makes brewing that much more fun to have all the right equipment. Once a person decides to have the right equipment, the cost (within reason) is not all that important. This is probably also the reason why many folk opt to spend even more money for a roller mill.

Although they both do an excellent job at what they were designed to do, one was designed to crush malt for homebrewers and the other was designed to grind corn for tortillas.

I make tortillas, BTW and wouldn't mind having a Corona. Grinding corn in a blender is another good example of not having the right equipment but then, I don't take tortillas as seriously as I do beer.

js

p.s. The above was written before reading this mornings Digest and I was glad to see Korz bring up that old article. My recollection is that the pub crushed it to start the brew at night but if something came up that put it off till the morning, they had to increase the grain my 10%. Mighty hard to believe but great for mill promotion.

I have made the last last two batches in a manner that simulates the \$5000 machines with multiple rollers and screens and it made absolutely no difference. I ran the malt through with the spacing set at about .075 and then again at about .030. I still get that boringly consistang yield of 28 pts/lb/gal.

jjs  
Z.

Oops.. looks like I did it again. Dont know how to fix it.

>  
> Any good (and relatively easy) hard cider recipes out there? Any  
> responses will be appreciated!  
>

I picked up a pamphlet this last weekend, after having the opportunity of tasting some hard apple cider at a local bar in San Francisco ...

Picking my way carefully through the maze of options I was cognizant of in the realm of apple cider production, I arrived at the following recipe.

purchase 1 gallon of unfiltered cider  
1 packet of champagne yeast ( or white wine )  
1 size 9-1/2 rubber plug with hole  
1 vapor lock of your favorite variety

heat 1 gallon of cider, in jug, to 160 F, using candy thermometer, water bath ( large pot ) and wooden spoons ( as insulators from the bottom, for jug ), to 'terminate' any infectious agents, with cap loosely attached to top of jug, for @ 30-60 mins.

Tighten cap, allow to cool to room temperature.

Add ( re-hydrated ) yeast to apple juice, attach vapor lock.

This brings us up to the present. The apple juice is fermenting nicely. It took a day or two to start, but now it's quite productive, foaming up and into the vapor lock, which I'm changing about twice a day.

Next time, I'll insert a short plastic piece of pipe into the stopper, and attach a piece of tubing, guided into an overflow container, to avoid this messy business, and attach a real vapor lock later in the sequence, after fermentation has mellowed out a bit.

A few caveats :

- (1) I have no idea where this will end up. (-: I'm making a guess that from here on, it will conform to regular ways of dealing with fermented solutions, including the option of multiple fermentations, and a precipitate on the bottom that will include living yeast cells that can be recycled.
- (2) There seem to be several ways to approach this business of 'pasteurization'. First off, when you buy it, it is most likely already pasteurized, to extend shelf life, even if you buy it from an organic food store, as I did.

Methods include the addition of various chemicals, as well as slow heating over a long period of time, and a quick heating to a precise temperature for no more than fifteen seconds. The tradeoff is between changing the flavor versus entertaining an infective agent which will

ruin the batch. Experimentation is indicated. Keep the temperatures low. ( One interesting approach was to do the pasteurization after the bottling !! )

(3) There seem to be several schools of thought regarding the proper yeasts. As has been noted here by several others, the 'real' cider yeasts exist on the skin of the apple and are a part of the ecology, not easily isolated, best dealt with as a synergy. This school of thought regards the above sequence of pasteurization and the addition of foreign yeast colonies, I suspect, as an abomination. They might be right. But this was once true for every drink brewed on the planet, and is no longer, and we seem to be coping OK. (-:

(4) There is considerable agreement that the type of apple is important, and that blending gives the best results. For this reason, I chose my apple juice with care, selecting one that named the species used. 'Delicious' apples are not inappropriate, but should be modified by the addition of some crab, pippin, or other small apples, for acidity.

Subject: Coors & Civil War era Brewerys

These aren't related !

First Coors takes a real bashing and rightfully so but .....

Don't bash them too hard until you've tried Coors Winterfest.

Only brewed at Christmas time and difficult to get.

This beer has a lot of character and can be ranked right up there with some of the Micro Brews.

Next , while visiting Terre Haute, IN . I got drug into an antique store by my wife only to find that the antique mall was an old Civil war era Brewery at one time and the owner had researched the history and found that

the brewery is underground about 30 ft. for lagering. and they actually brewed

underground.

He hopes to find some old equipment while excavating the underground I'll keep the HBD posted.

From: johnc@das.harvard.edu (John Chervinsky)  
Subject: Papazian's Propensity Pilsner Lager

Hi,

Does anyone have any experience with the Propensity Pilsner Lager recipe in Papazian's book?

The recipe calls for "light" clover honey but I have been unable to find anything labeled as such. Is this just a subjective reference to color?

I would like to lager this beer. What would be a good starting point for primary and secondary fermentation temperatures and conditioning temperatures?

How does this recipe compare to Budvar?

Thanks very much for your help!

From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: Adjunct Clarification (Get it?)

Sorry about the pun in the subject line, but I couldn't resist. It seems that there is still a little confusion about which adjuncts need to be mashed and which don't. Adjuncts high in unconverted starch need to be mashed. This includes any form of unmalted (and unroasted) cereal grain such as oats (any form: steel cut, flakes, powder, extruded pellets), wheat, rice, barley, potato, cat tail roots, you name it. The yeast can't eat starch, and prefers maltose, but will settle for other simple mono, di, and tri saccharides.

The starch can be converted to simple sugars by beta and alpha amylase enzymes which you can get from malted barley, malted wheat (a little), diastatic malt extract, and from Enzyme-in-a-Drum (TM). Most homebrewers use the excess enzymes present in most of today's American 2 or 6 row malted barley to convert the starch in their favorite adjunct by doing a partial mash, usually 50:50 malted barley to adjunct.

Adjuncts that don't need mashing, i.e. can easily be used by the extract brewer, include most of the color malts (most of the starch has been burnt) and crystal/caramel malts (kind of premashed by the maltster). For both of these, a simple steeping will extract all the goodies from the crushed grain. Malted wheat and rye as well as plain old malted barley \*do\* need to be mashed.

Hope this didn't cloud things further;^)

From: Pat Lasswell <patl@microsoft.com>  
Subject: Beer and Food; ppm <--> mg/l

Recently somebody requested references on what foods go well with what beers. Last night my wife gave me a book entitled, REAL BEER AND GOOD EATS; it describes the history of brewing both in Europe and America, the state of beer today, and has chapters for California, the Northwest, the Midwest, the Northeast, the South and for the region from Texas to Montana (which it calls "North of the Border"). Each of the regional chapters contains some history, some beer travelogue, and lots of recipes that both use beer as an ingredient, or are intended to be eaten with beer. The book contains numerous suggestions as to which beer styles go well with what kind of food, but poses no pretense of correctness:

But above all, feel free to experiment. Any writer on beer and food is just giving you his or her educated guess based on individual tasting experiences. You might prefer something entirely different. Have a potluck beer and food party with your friends: Line up a bunch of different beers, set out some delicious foods, and taste away. Experiment, enjoy, and put together your own favorite combinations. As the bishop said to the actress, it's an intrinsically pleasant experience any way you choose to do it.

The details:

REAL BEER AND GOOD EATS, Bruce Aidells and Denis Kelly. Alfred A. Knopf, New York, 1992. ISBN 0-394-58267-5. In Canada, the book is published by Random House of Canada Limited. Hardcover, 355 pages, price unknown.

Usual disclaimers....

1 ppm = 1 mg/l. Parts per million is a ratio of weights of solvent to solute.  
1 liter of water is 1,000,000 mg\*, therefore 1mg of solvent in 1 liter of water gives a concentration of 1 ppm.

\* at 3.98degC to be exact.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: RE:cookers BTU

JLIDDIL wonders about the relative merits of different size propane cookers:

I have two propane cookers, one "American Cooker" [made in USA] rated at 135K Btu and one "American Camper" [made in Taiwan] rated at 35K Btu. The big one is a "blowtorch" type burner and the little one is a ring burner, like on a kitchen stove. Both burners gain efficiency when surrounded by a sheet metal enclosure to hold the heat to the kettle. The larger burner does not heat water 4 times faster than the small one, it is maybe twice as fast.

I speculate that the blowtorch type of burners entrain much more air, and thus have less concentrated heat and lower efficiency. It is easier to scorch the bottom of th kettle with the ring burner.

It should be noted that Btu rating for burners only refers to their gas consumption (i.e. the size of the orifice). Heat transfer to worty fluids is usually not marked on the box. Bigger is faster, but not more economical. Another blow against the myth of economy of scale.

From: "John Cotterill" <johnc@hprpcd.rose.hp.com>  
Subject: Re: 1056 Slow Fermentation  
Full-Name: "John Cotterill"

Thanks to all who have replied on my problems with a slow 1056 yeast fermentation. To recap I have a batch of IPA where the fermentation was vigorous for a few days from a starting gravity of 1.058 to about 1.040. Once the SG hit 1.040, the fermentation has slowed dramatically. I would now estimate the SG is dropping by .001 every 5 days. Some more data: the beer is extract based, I used a 16 oz starter, and aerated the cooled sweet wort for 3 hours using an aquarium pump (with filter). Some suggestions that I have gotten from the HBD readers are:

- 1) Not enough O2 in wort (probably not the cause for this one)
- 2) Not enough nutrients in malt extract for healthy yeast
- 3) The yeast flocculated (sp?) too soon and is sitting on the bottom of my vessel
- 4) Rumor has it that Wyeast has had some problems with mutant 1056 yeast this year (may be related to 3 above)
- 5) Try another starter

So what I have done you ask? The first thing that I did was prepare a sterile batch of yeast nutrient (1/4 tsp of yeast nutrient boiled in 20cc H2O). I added this to the fermenter. Next I agitated the beer by shaking the heck out of the fermenter (a keg - watch out for that liberated CO2!). I hope this gets the yeast back into suspension. I realize that I have done two things here, and won't really know which one helped if the fermentation starts up again. I have also called Wyeast to see if they know of any current problems with 1056. I'll let everyone know what happens.

From: guy@mspe5.b11.ingr.com (Guy D. McConnell)  
Subject: Miller Reserve Draft

As has been mentioned a number of times before, Alabama is not a mecca of good beer. With the opening of the microbrewery in Birmingham, the soon to open brewpub in Mobile, and the number of decent beers beginning to show up on the shelves here in Huntsville, that may be changing. I saw Miller Reserve All Barley Draft in a local Brunos store the other day. While I don't expect it to be the best beer I've ever had, I intend to try it. Anyway, I saw a commercial for in on TV the other night which I found quite amusing.

They start out saying "In 18something Frederick(?) Miller created an all barley draft beer and held it in reserve because he knew it was something special. Now Miller is bringing it back in Miller Reserve All Barley Draft. It's an idea whose time has come around again" or something to that effect. So now they're taking credit for "reviving" beer made the way God intended. I'm sure this move has nothing to do with the continued decline in sales of the mega-brewers over the past few years.

From: "John Cotterill" <johnc@hprpcd.rose.hp.com>  
Subject: Wyeast 1056 Info (Was: 1056 Slow Fermentation)  
Full-Name: "John Cotterill"

I just got off of the phone with Dave at Wyeast. I described my problem to

him and he offered the following help and information:

- 1) Make sure that the wort is WELL aerated. (In my case this is not a problem)
- 2) 1056 is VERY susceptible to mutation. They recommend that the yeast be used within one month of the date on the package. They expect mutations to occur within 30 to 90 days after the date on the package. How does one culture this stuff without mutations? I should have asked. Anyone know?
- 3) My notes are not good on this one, but..... If your starting gravity is 1.048, no problem. If you get 8 points above this, Dave said that the pitching rate should be doubled (I started with 16oz, so that means a 32oz starter with my starting gravity of 1.058). For every 8 points above 1.056 double the rate again.

Bottom line for me. Dave suggested that, since my beer is at 1.040 right now, that I repitch with a 16oz starter, aerate as before, and I should be in good shape. He also said that they would credit the store I bought my original yeast from, so the store can give me a free package to get me going. Pretty good of them I'd say!

By the way, I went home at lunch and it still looks like nothing is happening even after trying the things I mentioned in my previous message, so I will re-pitch and hope for the best.

From: j\_freela@hwking.cca.cr.rockwell.com (Joe Freeland)  
Subject: Extract Brewing - Camping Stoves

Reading about cookers and BTUs I just couldn't help post an idea that's worked real well for me so far. We have a camping stove that I think puts out around 20000 BTUs. It has two burners but only one is used. I put this on a tool cart out in the garage (the floor would work too I'm sure) and do my extract boil there. This beats my electric stove by about 3 times as fast as far as heating goes.

I use an immersion chiller so the hose is convenient for chilling, etc. The best thing is that a boil over causes no real harm, since camping stoves are supposed to get dirty. Of course, I have not had one yet, go figure.

Use of 2308 yeast

>After 205 ales, I've decided to brew my first lager, and yesterday  
>I bought a packet of Wyeast Munich #2308. I have no idea what  
>temperatures to ferment and lager at. Would those of you who have  
>experience with this yeast please send me some advice? Thanks.

I got some tips on using this yeast from Steve Daniels and they have worked well for me. It is necessary to build up a very large starter culture, at least a quart of slurry for five gallon batches. Cool the wort down to 60F or cooler if possible, pitch the yeast, then you will have to refrigerate to carboy of wort to get the temp down to the 48-52F range as soon as possible. At this low temp it will take at least 3 weeks to ferment out. But it is worth it, I've made my cleanest lagers in this manner.

From: John Adams <j\_adams@hpfcjca.sde.hp.com>  
Subject: Papazian's Propensity Pilsner Lager

> Does anyone have any experience with the Propensity Pilsner Lager  
> recipe in Papazian's book?

I brewed this recipe with one exception, without the aid of a refrigerator I was only able to brew it as "stream".

> The recipe calls for "light" clover honey but I have been unable to  
> find anything labeled as such. Is this just a subjective reference  
> to color?

I used a light in color honey since this recipe intends to also be light in color as traditional pilsners.

Most homebrew shops carry many of the higher quality brands as you can find in the supermarket except they charge more.

> How does this recipe compare to Budvar?

Having never tried Budvar I cannot say but I was very pleased with the results. Mine had a great deal of the character of Pilsner Urquell but fruitier and full bodied as I would have expected from a steam.

As soon as I locate a old refrigerator I plan on redoing this recipe as a true lager.

Date: Thu, 17 Sep 92 10:52:44 EDT  
From: jim busch <busch@daacdev1.stx.com>  
Subject: "Right equipment" and yeast

In the last HBD JS writes:

Clearly, the reason is not to save money. I built my first mill because the

...  
I suspect that everyone who makes the plunge can supply his own reason but I would guess that the major reason is that it just makes brewing that much more fun to have all the right equipment. Once a person decides to have the right equipment, the cost (within reason) is not all that important.

If this is the way jack feels, I suggest he invest (well spent money) in a stainless steel perforated sheet false bottom for his lauter tun. These are commercially available in 16 gauge thickness, I forget the hole size. I got mine in Portland for \$50 and had a local shop spot weld legs on it. This screen with a bottom outlet will increase the yield per pound significantly over the double bucket method and I suspect the easy mash through a screen method. Of course, you will have to recirculate the runoff for 10-15 minutes to clarify. If your kettle is the same size as the lauter tun (mine is), you can also use this as a hop back in your kettle. It even supported the entire hop bed when I lifted it off the kettle bottom.

On another note, tony@spss.com (Tony Babinec) writes,

What has worked well for me is this: ferment for 3 to 4 weeks at 48/50 degrees F. When you sense that fermentation is dramatically slowing, which is evident both from the drop in krausen and the slowing of the fermentation lock, step the temperature up to 60 F to encourage diacetyl reduction and the completion of fermentation.

I would suspect that if it take 3-4 weeks to primary ferment a 1.050 lager at 48/50 F, you did not pitch enough yeast and/or oxygenate the wort enough. Primary should be complete in less than 2 weeks at this temp. Also, I would recommend a lower Diacetyl rest temp, I personally dont like to get my lagers this warm. This is certainly a topic for debate but I do a diacetyl rest at 42F prior to rduction to 31F. Three days works for me. I completely agree with the 48F primary temp.

On another note, "John Cotterill" <johnc@hprpcd.rose.hp.com> writes,

My notes are not good on this one, but..... If your starting gravity is 1.048, no problem. If you get 8 points above this, Dave said that the pitching rate should be doubled (I started with 16oz, so that means a 32oz starter with my starting gravity of 1.058). For every 8 points above 1.056 double the rate again.

The rule of thumb is 12 million cells per ml. This is good for a 1.048 (12 degree) wort. For each increase of one degree, add a million cells. Of course, you need to count cells to know this, but the idea is valid. The point is to NOT double pitch per 2 degrees plato although this

doesn't really hurt much, ie: yeast bite. A good rule of thumb is 1lb. of slurry per Bbl of wort. Also, the recommendation to re-aerate is a double edged sword: you have already created Ethanol and by adding O<sub>2</sub>, you will oxidize Ethanol into nasty aldehydes (see Dr. Fix's book). If you get enough healthy cells growing, get them past the aerobic stage, then pitch, you MAY get away with kick starting the batch without adding O<sub>2</sub>. I had a Barley wine go from 26 degrees to 12, then jump started it with 200 grams of Narragansett Ale yeast. Finished at 5 degrees, with no additional O<sub>2</sub>!

Someone asked about yeast culturing, email me and I can refer you to a supplier.

From: mgx@solid.ssd.ornl.gov (Galloway M D)  
Subject: mashing (&more)

I have been toying with the idea of going all grain but after reading Miller's chapter on water in TCHOHB I am beginning to worry. My water is quite similar to the example of 'London Water' that Miller uses near the end of the chapter: the alkalinity of my water will "doom" a pale mash due to the high bicarbonate level and the low calcium level (hence the inability to decarbonate by boiling). My problem is that I am a little uncertain on the proper use of acids to acidify (acidulate?) the mash. I have access to 88% lactic acid via my local homebrew shop. What I think I should be doing is to use a dilute solution of lactic acid (Miller suggests 2 teaspoons of 88% lactic in 3 cups H2O) to adjust the pH mash to an appropriate value (say 5.3). What quantity of this dilute solution should I start with? Is all this really necessary or am I just being a worry wort (sorry for the pun).

As an aside, has any of you closet wine makers out there had any experience with wine grape juice supplied in 'aseptic, nitrogen purged bags'. What is the shelf life of one of these creatures. Also, never having actually made wine, is there enough head space in a 6.5gal carboy to conduct primary fermentation of 5-6 gal of grape juice?

Thanks in advance!

Micheal

From: ALTENBACH@CHERRY.llnl.gov  
Subject: Micah's Mead

In HBD 970 Micah made a comment concerning his mead and the AHA National Competition, which was further discussed in HBD 971 by Geoff Reeves.

Micah

did not state the facts behind his comment, so Geoff got the feeling a contest "fix" was being insinuated. Here are the facts. Immediately after the

best of show (3rd round) mead judging in Milwaukee, I had a conversation with one of the judges, Brian North, who told me that there had been a "problem" with the mead judging from the second round. We didn't get into the

details of what the problem was. However, the 3rd round judges took the top

3 meads from each class and REJUDGED them all, instead of just picking between the 1st place winners to decide best of show. Brian told me that this

resulted in a switch of the 1st and 3rd place meads in one of the classes.

Examination of the returned scoresheets shows that Micah's mead was judged

1st in his class by the second round panel, and his scores were higher than

those given to Byron's mead. These two were the ones switched between 1st and 3rd places by the 3rd round panel. Note, no further written comments or scores were given in the 3rd round. So Micah has a 1st place score and a third place ribbon, and no explanation as to why this happened. It would

be nice to hear first hand from the judges involved and the competition director, to understand their reasons for these actions. BTW, I'm a Certified Judge, and judged at the 1st round in SF and the 2nd round in Milwaukee (in beer classes) and have never come across any inappropriate judging procedures in national or large regional competitions.

**Subject: fast fermentation**

question:

I brewed my first batch of ale last saturday, I got it into the fermenter about 1 pm and it was bubbling away by 6pm. By the next morning it had a good foam head approximately 2 inches high and was just looking good. By the early evening it slowed way down and by monday morning the foam was

gone and the bubbling had ceased. It has been settling since then. I pitched the yeast at 80 deg f and kept it at about 70 deg f throughout the

fermenting process. Now to my question, everything I have read says that the fermenting takes 5-7 days, mine took two, maximum. I am kind of nervous

to open it up until settling finishes, say saturday to measure the gravity.

Should I be concerned with the "fast" fermentation?

Subject: Re: Is a Grain Mill Necessary?

In HBD #969:

> I'm still an extract brewer but my grain brewing friends purchase their  
> grain from brewpubs ALREADY CRACKED. Most U.S. brewpubs buy their grain  
> ALREADY CRACKED!

I'm assuming you have the facts and figures to back up this statement. IMO, the additional space and equipment necessary to crack the grains is inconsequential compared to the benefits of having a fresher product. I would suspect that once the grain is cracked, the malt begins to lose its freshness at an accelerated rate. Who knows how long that cracked grain has sat around? They don't nitrogen flush the bags once they crack the grain, do they? It is true that the effects due to the cracked grain "spoilage" (oxidizing) will probably be masked by other flaws in the brewing process - such as the rampant infection problem that many of the brewpubs seem to have.

Guess I need to take some tours of more brewpubs to find out what their grain-cracking process is. Purely in the interest of science, of course! :-). The one brewpub I have toured was in Munich (yes, I'm working on my notes and will post when done!) and the cracking and de-flouring was done in the same room in the basement in which the bags of malt were stored. No big deal.

> The reason is simple- most brewpubs are relatively small and  
> if they cracked their own grain in a brewing or food area, flour would  
make a  
> MESS of the place! And you can bet that the 100# bags of grain the  
brewpubs  
> get are cracked CORRECTLY for the specific type of grain.

I'd expect they are 50# bags of grain. They might be 50 KILO (110#) bags in Europe - that's what the Belgian Malts (which have had so much press) come in. [BTW- anyone in the South Bay (San Jose, CA) want to split a bag or two of the Belgian Malt? e-mail me.-dougd]

Date: Thu, 17 Sep 92 10:49:48 PDT  
From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: Addition to adjunct post

In my post yesterday about which adjuncts need mashing, I neglected to mention additional important info (thanks Jim). There are a few different forms of common grains which can be divided into two groups: those that need precooking, and those that have been cooked already. Remember-both groups need to be mashed!

The important factor here is whether the starch is easy for the enzymes to get to. Any grain that has been precooked e.g. flakes, puffs, what have you, has its starch already gelatinized and can be added to the mash as you get it from the store. Raw grains like corn, rice, whole or crushed oats, need to be cooked in order to gelatinize their starches. The minimum cooking temp varies with the grain used; I think Papazian has a chart on this. The cooked grain is then added to the mash.

Malted adjuncts don't need precooking and are added directly to the mash.

Hope that's all,

Glenn

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: 1007 head

Wyeast 1007 (German Ale) makes for a great brew. It makes a terrific thick krausen in the primary. Unfortunately, this didn't translate into a terrific thick head on the final beer, at least not in the last 2 batches I made with it. Both batches were racked to secondary after the primary krausen was well gone, both were (mostly) clear going into the keg, and both would not hold a head for more than 1 minute after conditioning in the keg. But, both brews were very clean and tasty, and they didn't last much more than 1 minute in the glass anyway.(!)

Obviously, lack of head could be caused by any number of other reasons, but here's 2 data points that say that the thick 1007 krausen does not necessarily lead to a thick head. FWIW, I've had no head stability problems with previous similar batches fermented with other yeasts such as 1056 or Whitbread dry.

Subject: Free Beer

Geez, I hate using such lame and deceitful tactics to get your attention.

I got absolutely no response to my question about kraeusen characteristics and head retention. So, I am going to state this in an inflammatory manner and hope for the best :).

OBVIOUSLY the larger and thicker and richer and creamier the kraeusen during primary fermentation, the larger and thicker and richer and creamier and longer lasting will be the head on your beer after priming. This relationship MUST be true. I DARE someone to give me examples/experiences to the contrary (or, uh, to support it).

And I still want to hear anyone's experiences with Wyeast #1007 (German Ale); someone out there must have tried it.

>Future: maybe dryhop with 1/2 oz Saaz if I feel like it.

>

>However. Upon measuring O.G. of this mixture, it read only 1.020! (yes,  
>I remembered the temperature conversion.)

First of all, that's a lot of ginger! I used 2 ounces fresh, peeled,  
grated

in last year's X-mas brew and it was just about right. The 10 minute  
boil

of all the spices is probably boiling-off a lot of their goodness -- I  
suggest just plunking them into the wort after turning off the heat and  
leaving them there until you cool and are ready to go to the fermenter.

Now, back to your question. Either you do have a very sick hydrometer,  
or

(more likely) as John D. recently posted in the Brewer's Forum, you did  
not mix your hot wort well enough with your cool water. If the wort at  
the top of the carboy feels cooler (or warmer) than the wort at the  
bottom,

then you haven't mixed it enough. The heavy wort will just sit there in  
the bottom and any samples you take from the top can be off by a lot!

Notice that also, as you say, some malt extracts are quite thin. Although  
I haven't used it in a batch \*by itself\*, but although Alexander's Sun  
Country

Extract is very light, it doesn't add a lot of points to your wort -- I  
believe only about 28 or 29 points/lb/gal (i.e. 1 lb of extract in 1  
gallon

will give you 1.028 or 1.029 wort).

Al.

Subject: uh...oops

fellow brewers:

It has been brought to my attention that my last post was pretty insulting to the supplier who sold me my Breiss extract (who reads the HBD). I'd like to apologize to them for any aspersion on their character; I was just listing all the possibilities I could think of for low o.g. without regard to how silly they were. So I'll come out and say that the supplier does not stand accused of fooling with their stock; I'm quite satisfied with my order from them. Good prices, too. So that's a recommendation for those of you who figured out who the supplier is. :)

Things I've learned from responses:

- 1) Extract viscosity is not a good indicator of its extract potential; Breiss is indeed thinner than many extracts, but according to the supplier it consistently gives about 1.036 for 1 lb/1 gal. Apparently, viscosity is partly a function of vacuum-chamber temperature when the extract is being concentrated; lower temperatures (which are better) give lower viscosity.
- 2) My problem was probably failure to stir up the mixture in the carboy sufficiently before drawing off a sample (from the top). O.g. for this batch is probably 1.040-1.050.

As always, feel free to email me shoehorns with which to extract my feet from my mouth....

Subject: Wyeast #2308

Have I been asleep \*that\* long?

I normally ferment this yeast at 55 F in the primary, usually about 4-5 days. Then I rack it off into the secondary and let it come back to life--about 2 days. Then I start lowering the temperature about 2 degrees every other day. Upon reaching 45 or so, I let it completely bubble out. I then keg it and gradually lower the temperature to 35. It stays at 35 for 4-6 months. I get super clean, clear, brew with this one.

From: mccamljv@ldpfi.dnet.dupont.com  
Subject: George Washington Porter

Brew Brothers and Sisters,

What a crazy summer, I have a three (3) month backlog of HBD's to catch up on. Anyway, I find that I now have a little time on my hands and would like to pose a few questions to the digest.

- 1) Has anyone out there in net land ever had the priviledge of trying the George Washinton Porter brewed by the Samuel Adams Brewhouse in Philadelphia ??? This stuff is incredible. I think it is probably a little too sweet for the style, but I can't get enough of it. With that in mind, does anybody have an approximate recipe. I suppose I could force myself to go there, drink a few pints, and try to pry it out of the brew master (I think I'll do that anyway) but if he is a true brew guru he probably wouldn't divulge the entire recipe to little old me.
- 2) I have a dunkelweizen that has been sitting in the primary for about six months (looong story). Any hope of recovery?? I am planning on bottling some of it and using the rest as an organic fertilizer. I'll keep you posted.
- 3) I would like to use a touch of licorice in my next pale ale. I plan to use 1 1/2" in the last 15 minutes of the boil. I would wait for advice and pointers from the net, but I'm brewing tonight. The info would do me and I'm sure others good though. Any pointers, hints, tips etc...???

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: RE: milling grain/preground malt

Crushed malt that has absorbed moisture from the air is called "slack" malt, or is said to have "become slack". This is mentioned in two of my old references from the 1800's. The odd part is that there appears to have been a controversy [some things never change] about whether slack malt was preferred or not. Some said yes, some said no. If allowed to become slack, the strike heat for mashing in can be very difficult to predict. The more slack [slacker?] the malt is, the higher a strike heat [initial water temperature] is needed to hit the chosen mash-in temp. There is a brief discussion of this in Brewing and Malting Science, but I didn't understand it...

I wonder if the brewpub mentioned previously was trying to adjust the mash temp? What was the digest #?

As a sidelight to brewpubs crushing their own malt, it needn't take much space and safety/insurance/codes needn't be a problem. Twenty years ago, I helped install a flour mill in the local organic food co-op. Building and codes gave us merry hell over explosion proof motors, switches, lights, conduit connections, etc... They had never approved a new mill and were positive that a bunch of long-hairs would screw things up. It took a lot of hassle, but it was allowed by the zoning, so we got to do it.

We did a crackerjack job, including building a room within a room with air-lock, and dust filters on the air. The whole area was only 8x8 feet, so space and safe construction is no big deal. That co-op mill, BTW, is now the largest organic grain mill in the Pacific NW. It is bigger than 8x8 feet, though...

Flour dust is MORE explosive than natural gas. Natural gas isn't very explosive, you have to get the fuel/air mix just right. Propane, now that's REAL explosive, it has a very wide explosive range.

The plus of having your own mill is that it's just one more variable you get to control/goof up. How much is that worth? -- Paul

> They start out saying "In 18something Frederick(?) Miller created an  
all  
>barley draft beer and held it in reserve because he knew it was  
something  
>special. Now Miller is bringing it back in Miller Reserve All Barley  
Draft.  
>It's an idea whose time has come around again" or something to that  
effect.  
>So now they're taking credit for "reviving" beer made the way God  
intended.  
>I'm sure this move has nothing to do with the continued decline in sales  
of  
>the mega-brewers over the past few years.

But it still tastes like pisswater. Which leads to 2 (or more)  
possibilities:

- 1) Miller is trying to get to the segment of the beer-drinking population  
which has never tried beer. They drink Miller Reserve, and say  
"It's good, but it's not that much different", and promptly go back  
to drinking their regular beer. When someone offers them what we  
consider a "real" beer, they turn up their noses and say "I've had  
an all-barley beer before and it's no big deal."
- 2) They started out with good intent, but the marketing analysts made  
them  
dilute the product to make it taste more like american ultra-light.

Anyway, they remembered to leave out the corn, but they forgot to  
replace it with extra barley...

From: jxs58@po.CWRU.Edu (John Stepp)  
Subject: Re: WYEAST 1056

t'sup?

I used 1056 for the first time in my last batch, an extract pale ale. The fermentation went fine: firm yet steady for ~5 days then slowed. I dry hopped it at 7 days with 1 oz of Saaz plugs and let it go for another week, then bottled. After 2 weeks in the bottle the carbonation is great, but the flavor was quite "watery". After 3 weeks in the bottle, it has gotten better but it's still not what I aimed for. I normally brew heavier beers, and have only recently switched to liquid yeast cultures. My question is: Is it "normal" to let this type of brew bottle-age longer than other, heavier brews? There's plenty of malt in the recipe (at home unfort.) so that's not the problem. Thanks in advance for comments.

Subject: Questions part II

Homebrewers,

Thanks to all of you who replied to my first set of questions.

Here are a few more while I anxiously await for my books to arrive and backissues of Zymurgy:

- I'm having trouble finding true long-necks. Should I absolutely not use twist off bottles? I've asked almost every eating establishment in town, but they will not give up their returnables.
- What is the purpose of a secondary fermentation tank. My first batch uses this method, but doesn't require me to add anything, and doesn't give a reason for doing this.
- I am writing from MCI Mail, and tried to use the PUCC MailServer. They have recently changed to allowing BITNET users only. Is there another Server that I can use to access the HBD site through Mail FTP. I do not have access to Telnet or FTP at this time.
- I live in Suisun, CA. North of the San Francisco Bay Area, near Fairfield, Vacaville, Vallejo. Do any of you homebrewers live nearby? Any homebrew clubs near me?
- When my fermentation is nearing completion, does the yeast go into a dormant state or just die?
- When the priming sugar is added at bottling time, does this "revive" the yeast, or just cause some sort of chemical reaction to cause carbonation?

Thanks again for helping a new guy out!

>eating establishment in town, but they will not give up their  
>returnables.

Some people use twist-off bottles without problem. Still, I wouldn't unless I got desperate. Do you know anyone who drinks beer of the type that doesn't come in twist-offs? Like Sam Adams or Bud Dry? You could also consider using plastic soda bottles or American champagne bottles--you can usually get the latter from champagne brunches at restaurants. Not to mention the ever-favorite IBC root beer bottles.

>- What is the purpose of a secondary fermentation tank. My  
>first batch uses this method, but doesn't require me to add  
>anything, and doesn't give a reason for doing this.

Here are my favorite reasons:

- 1) Gets the fermenting beer off of the trub. I get a fair amount of dead yeast and other things at the bottom of my primary and I don't use blow-off. Thus, I want the beer off that quickly.
- 2) Gives the beer an extra settling or clearing, leading to much less sediment in the bottle than if you went directly from the primary to the bottling bucket (at least in my case).
- 3) Allows more flexibility in scheduling the bottling session. With small children and travel for work/vacation, I have often left beer in the secondary for months at a time before finding time to bottle. Since it isn't sitting on all that trub in the primary, it doesn't get hurt by this.

>- I am writing from MCI Mail, and tried to use the PUCG

>- When the priming sugar is added at bottling time, does this  
>"revive" the yeast, or just cause some sort of chemical reaction  
>to cause carbonation?

I don't know the technical terms for what the little yeasties in your beer are doing when they aren't fermenting, but not all of them die, that's for sure. So when you add more fermentables,

for example at bottling time, all the live yeasties start fermenting again happily. Of course they start giving off all that CO2 during this process, which will carbonate your beer under the right conditions.

From: berthels@rnisd0.DNET.roche.com  
Subject: Reducing Sugars

For those interested in the technical discription of the antiquated term "reducing sugar" read the textbook extract below, simply speaking it refers to a monosaccharide (glucose for example) rather than a di or polysaccharide

>From "Principles of Biochemistry" by A.L. Lehninger  
Monosaccharides readily reduce such oxidizing agents as ferricyanide, Hydrogen peroxide, or cupric ion ( $\text{Cu}^{2+}$ ). In such reactions the sugar is oxidized at the carbonyl group, and the oxidizing agent becomes reduced. (Remember that reducing agents are electron donors and oxidizing agents are electron acceptors.) Glucose and other sugars capable of reducing oxidizing agents are called reducing sugars. This property is useful in the analysis of sugars. By measuring the amount of an oxidizing agent that is reduced by a solution of a sugar, it is possible to estimate the concentration of the sugar.

I hope this is helpful-S.J.Berthel

I've never found a place that would just give me their bottles, but (at  
least in the states I've lived in) most places will sell you a case of  
longnecks for the deposit money (\$1.10/case in AL).

> - When my fermentation is nearing completion, does the yeast go into a  
dormant  
> state or just die?

They go dormant. If you wait too long before priming you won't get  
carbonation, because once the yeast go dormant, they need things that  
finished beer lacks in order to wake back up. Carbonation is done by  
the yeasties that haven't gone dormant yet at bottling time; there are  
still a bunch of them in suspension even when the beer looks clear.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: nice timing, liquid yeast

Hmmm, interesting placement of articles about Wyeast #1007 in the last digest, dontcha think?

Someone mentioned that their brew fermented with Wyeast 1056 tasted thin. I've noticed that any brew fermented with Wyeast \*seems\* thinner than those done with other (ie. dry) yeast. First, the Wyeast is usually going to be more attenuative, leaving a dryer beer, which can seem thinner than what you're used to. But I think more importantly, the Wyeast will ferment \*cleaner\*, meaning there are a lot less Funky Flavors(tm) and a much smoother feel and taste, so the beer might seem watery (that's the word) again compared to what you're used to. Drink a few liquid yeast fermented brews, then go back to a dry yeast brew, and compare. What was once "watery" will now be "smooth".

Subject: Bud ads

Dear Brewers,

Has anyone seen the latest series of (Oh, no! they're going to be made into "Info-Soaps"... to-be-continued types) advertizements from Bud? They almost seem to be taking their cues from Miller light (admirable product that it is...NOT!) It starts with a "tastes great / less filling" type of psudo-debate, only they're arguing over whether "its the rice! / It's the hops!"

When I saw this, I gaffawed! RICE?! And they're advertizing it?! I've always thought that rice was added to beer to stretch it - "cut" it, if you will. I think I remember Papezian addressing this as well in reference to the history of Beer in America, especially in post-WWII modernity. (Sit tight, critical theorists, this is the HBD, not the PSN :-)

Just an observation...

John

From: mcnally@wsl.dec.com  
Subject: re: keeping lauter buckets warm

Here are two techniques I use to keep my grain warm in the lauter bucket:

- \* I bought some nifty "insulation" stuff at a local hardware store (Minton's for those in the South Bay or Mt. View). It's composed of two layers of plastic bubble wrap---the stuff you use to pack fragile things for shipping if you can resist popping all the bubbles---coated on both sides with reflective mylar film. It's very light and reasonably cleanable. A layer of that stuff wrapped around my lauter bucket works great.
- \* I have one of those little Rival electric burner elements. I keep it on "high" and rest the collection pan for recirculation on top of it. Thus, the wort does not drop in temperature during the recirculation phase. These burner elements cost about \$15 and are available at any "drug store" (Walgreen's, Long's, Pay Less, etc.).

With these two additions to the normal setup, I can easily keep the grain bed at about 165 degrees. Neither the insulation nor the burner were (what I consider) expensive.

Subject: Reducing Sugars

In HBD 972 <Spencer.W.Thomas@med.umich.edu> asks:

>I started reading Belgian Ale last night, and came across a term in  
>the "profiles" that is not explained (as far as I can see) anywhere in  
>the book (yes, I looked in the glossary, but I can't remember if I  
>consulted the index, so be gentle if it's in there). The term is  
>"Reducing sugar" (or sugars?), as in  
> Reducing sugar (as maltose): 1-2.5%  
>What the heck is he talking about?

Chemically speaking, reducing sugars are carbohydrates that reduce Fehling's reagent (alkaline cupric ion solution complexed with tartrate ion) or Tollens' reagent (a solution of silver ammonia ion).

The important thing here is that all monosaccharides are reducing sugars and most disaccharides (including maltose) are reducing sugars. Sucrose (table sugar) is a notable exception. It is a non-reducing sugar.

Looking at Rajotte's "Belgian Ale" book, it is not clear to me whether the line

Reducing sugar (as maltose): 1-2.5%

means that 1-2.5% of the reducing sugars left are maltose or whether the final composition of the beer contains 1-2.5% reducing sugars. I suspect the latter.

Just another example of where a little better editing could help this book.

Isn't it too bad that Pierre isn't connected to HBD like George Fix is? :

From: Bob Konigsberg <bobk@NSD.3Com.COM>  
Subject: Wine Questions

I'm posting because all mail to mgx@soild(or solid).ssd.ornl.gov is bouncing. If you'd like to "talk" more, email me @ bobk@nsd.3Com.com.

No experience with aseptic grape juice in bags, since we make ours starting with grapes.

As for fermentation, we do the wine fermentation in covered plastic barrels,

but not airtight. I'm not sure what analogy to draw, since ours has grape skins (red wine) and seeds in there. My neighbors do Chardonnay in carboys, but they're in an ice water bath to slow the fermentation down. My guess is that at ambient temperatures in the 70's a 6.5 gallon carboy would safely hold 5 gallons, but much more and you're pushing your luck. It would be better to buy and sterilize a covered plastic garbage pail of about 10 gallons capacity. Prior to using it, wash it very thoroughly with chlorinated TSP for both sanitation, and to remove any oils left from the manufacturing process.

Wine yeasts are more robust than their beer cousins, and will do just fine.

You would also need to do at least a 1 quart starter prior to pitching or breaking the seal on your bag of grape juice. A 1 day start is ok, 2 days is better. Use concord grape juice for red wine, apple juice for white wine. The frozen concentrates in the grocery store are fine. By the way, some stores carry a RED concord, so you get a better color match in that respect.

Peter Nesbitt asks questions regarding:

1) Longneck Bottles => Don't use twist-offs; The thin lip is fragile, and can break during capping. In addition, if you don't have the right capper, you may not get as good a seal on the bottles. As far as obtaining them, around here, some liquor stores will "sell" you cases of longnecks.

2) Secondary Tanks => the purpose of a secondary is to allow the initial fermentation to finish gracefully while not on the trub from the fermentation. Allowing the beer to sit on the trub can allow autolysis (east digesting its spent cousins), and does terrible things to the flavor of the beer. It is really not a "second" fermentation per se, since there has been no added sugar at this point. The bottle priming is a true second fermentation.

3) Fermentation Completion => The yeast go dormant, but there are enough of them in suspension to do the second fermentation for bottle conditioning.

Subject: draft pilsner urquell arrives in chicago!

Yes, it's true. A number of us were sampling the beer lineup at Berghoff's Festival, and we were discussing rumors we had heard. We headed to O'Callahan's, in the River North area, and sure enough it was on tap. Needless to say, we drank a few rounds. My need to catch a train saved me from a long night :-)! Of course, I'll be back.

From: korz@iepubj.att.com

Subject: Milling on-site

I don't know what percentage of brewpubs buy their grain pre-milled, but of the four in the Chicago area that I know do all-grain, the two Winekeller's buy their grain pre-milled, Berghoff's has a mill (Seiben's used to mill their own, but I don't know for sure if Berghoff's, who bought Seiben's, still does) and I don't know if Goose Island mills their own (Tony? Steve?).

I'd like to point out that simple square footage is not the issue in whether a brewpub has a mill or not. Milling should be done in a room set aside for milling, which is isolated from the rest of the brewery (for sanitation reasons -- grain dust is a great source for lactobacillus -- this is true for us homebrewer's too!) and equipped as an explosive environment.

The iodophor you bought should list the percent "available" iodine" .  
Typically it is 1 %. This is 1 gram/ 100 milliliters. 10000mg/L or  
10000  
ppm

You want to use a solution of 12.5 ppm. This is a dilution of 1:800.  
This  
is

1.25 ml/L. A gallon is equal to 3.785 liters. So you add 4.73 ml/  
gallon or  
23.7 ml/5 gallons. A tbs is equal to half an ounce. An ounce is  
typically  
about 30 ml so maybe your solution is more than 1% available iodine.

You should not rinse the level of 12.5 ppm is the recommended  
concentration  
for  
bars and restaurants to use to rinse dishes and glasses with no rinsing.  
I  
use  
this amount or even 25 ppm to be safe and notice no taste problems. The  
FDA  
allows up to 25 ppm in food. After things drain you have even less  
present.

It is safe for all your brewing equipment though your plastic may take  
on a  
brown tinge with time. If you find it aesthetically displeasing soak your  
stuff  
in bleach and the color will be gone.

I only make a gallon at a time. I did a test and found a 15.5 ppm solution to be stable for only 30-40 hrs. I make it fresh each time I use it. You can get

iodine test paper through a pharmacy sometimes or Williams Brewing in California (510)895-2739 carries it. Also the hardness of your water affects stability. If you have more questions e-mail me.

Subject: Mill control

Paul writes:

>The plus of having your own mill is that it's just one more variable you  
>get to control/goof up. How much is that worth?

It can also be one less variable that your suppliers can goof up. Of the  
seven or so homebrew supply shops that I've bought from, one owner is  
more experienced than I am (it's Tim Norris, btw), one has been a  
homebrewer

longer than I have, but he brews all extract and he always asks me for my  
advise on how to improve his beers, and all the rest had little or no  
brewing experience. I wouldn't trust them to mill grain for my bread let  
alone my beer. Quality control is worth a lot.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Why crush your own grain?

There's been a good bit of discussion regarding the necessity of having one's own grain mill, and as a (lame) beginner in the mash department I've noticed one factor that hasn't been mentioned yet.

I've done two partial mashes so far. For the second one I ordered my grain pre-crushed at a very reasonable price from a leading East-Coast homebrew supply house. The problem was that even a beginner like me could tell that the crush was much, much too coarse. Having read that it's better to go too coarse than to turn the stuff to flour in a blender, I decided to brew anyway. Well, the yield was about 30%, and if I hadn't had lots of DME and candi sugar it would have been a total loss. Fortunately a friend with a Corona mill helped me grind the remaining malt to the proper consistency.

While it's obviously going to take a long time to pay for a mill at \$0.10 per pound, and on the other hand it's nice to have the equipment, the fact is that one reason to have the mill is to have the control you need. Have I bought one yet? No--I'm trying one more supplier, and if this doesn't work out, I'll take the plunge.

By the way, I don't mention the name of the poorly-crushed grain supplier because I've yet to call them to complain; this may have been an aberration, and I hate for anybody to get a bad rep if they don't deserve it.

Anyway, my new motto is: LAME, AND PROUD OF IT!

> but they will not give up their returnables.

Twist tops work for me, in emergencies. Others ( Jack Scmidling ) have  
used  
plastic bottles. Experimentation is indicated, your mileage may vary,  
etc.

> - What is the purpose of a secondary fermentation tank. My first  
batch  
> uses this method, but doesn't require me to add anything, and doesn't  
> give a reason for doing this.

The transfer of liquids leaves a lot of sediment ( trub ) behind, making  
for  
a clearer, cleaner beer. Also, beer in a secondary fermenter can be left  
there  
and will be fairly stable, for lack of these aforementioned sediments.

> - When my fermentation is nearing completion, does the yeast go into a dor-  
dor-  
> -mant state or just die?

Both. There will always be living yeast cells in your solution, unless  
you  
boil it or filter it. These cells can be recovered and recycled into your  
next batch, incidentally.

> - When the priming sugar is added at bottling time, does this "revive"  
the  
> yeast, or just cause some sort of chemical reaction to cause  
carbonation?

It revives the yeast. They eat it, excrete CO2 and ethanol, and multiply.

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: preground vs pre-preground

There's alot of discussion about preground malt versus whole malt. Obviously there are advantages and disadvantages to both, some trivial, some not so trivial. I think your decision should be based on which type of malt fits into your brewing procedure best. Some people prefer preground while others prefer to grind their own. What ever flips up your skirt. I have had great beers from both.

I feel the more pressing issue is not which form of malt to purchase but how to store the malt. Long term shelf life will adversely affect malt regardless of form yet preground suffers sooner.

An air-tight container, in conjunction with some form of desiccant, is probably the best way to go. For small amounts, I have found that old plastic containers are great for the 1 - 5 lb range. Clorox bottles, milk and water jugs all work great. A recent addition has been the new type of cat litter containers. They hold about 5 lbs and have wide mouths.

For larger amounts of malt some homebrewers prefer containers large enough to hold 100 lbs. Myself and other indolent ectomorphs prefer smaller containers. I have found that the 5 gallon plastic buckets with snap-on lids answer the call with gusto. They are designed to be stacked and 100 lbs of malt can be split up into 4 or 5 buckets so that while using one bucket of malt, the other portions of malt stay sealed. These buckets are usually free for the asking and can be obtained through numerous sources.

Extract breweries are a good place to start as their buckets are the most prized. Their extract comes in buckets with notoriously tenacious snap-on lids that have built-in o-ring seals. They hold 25 lbs of grain and have no residual odors.

The local bakery. Most wet ingredients a bakery uses are shipped in buckets. My local bakery, small by comparison, generate about a dozen buckets a week. Slightly smaller, these buckets hold 20 lbs of grain and sometimes have rather pleasant residual odors. Of the buckets I have received, one smelled of chocolate as it held chocolate filling, another smelled of raspberries as it held red raspberry preserves and another smelled of marzipan (yum!). These smells didn't scrub out, bleach out or dissipate in sunlight so I reserved the stronger smelling buckets for dark malts. It's kind of a game to try to marry malts with buckets that have complimenting smells. Chocolate malt and the chocolate filling bucket. You get the picture.

Lastly, restaurants are a good source but at times supply can be spotty. They are similar to the malt extract buckets. And talk about residual smells. I've received a bucket that smelled of kosher pickles, another of sauerkraut and another of squid (blech!). As these odors didn't come out with conventional chemical weapons and I obviously had no malts of a complimenting aroma, these buckets now hold tomato(e) plants.

Gee honey, I haven't a clue why that cats hang around that one tomato plant.

Date: Fri, 18 Sep 92 16:51:15 CDT  
From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Yield

Yield as it is normally defined is the percent of a grains weight that is converted into wort sugars (both fermentable and nonfermentable)

Most barley malt familiar to me typically has a carbohydrate concentration which ranges from 80 to 85% of its weight, with the lower end being more common. This means that using a malt rate of 1 lb. per gallon would result in at most .8 to .85 lbs. of wort sugars per gallon of wort. Converting to metric, this is equal to 9.6 to 10.2 grams extract per 100 ml. of wort.  
>From the Balling Tables we see that this is equivalent to 9.3 to 9.8 grams extract per 100 grams of wort (i.e., percent by weight or degrees Plato if you like). The Balling Tables also show that this is equivalent to a specific gravity of 1.037 to 1.039. Thus, it would appear that a malt rate of 1 lb. per gallon could give at most 37 to 39 gravity points, and that this is equivalent to a 80 to 85% yield.

In my system I get nowhere near the maximum rate. In a step infusion mash I typically get around a 65% yield, or what is the same, 30 gravity points per unit malt rate . I am getting a bit more with the Belgium malts. By the way, this drops to a 60% yield (or 28 points) in a single stage mash. I believe the difference lies in the action of alpha-amylase enzymes in their role as liquifying enzymes, which is to be distinguished from their role as starch converters. In particular, they seem to do better in the former role at temperatures below 60C (140F), and this leads to better yields. Having said this I have seen no other differences between the these two mashing techniques vis-a-vis beer quality, assuming of course that everything else is equal.

I have often been asked about the yields reported in Dave Miller's books. I consider him a good friend (we have each dedicated books to one another), but I must say that Dave's mashing procedures are unorthodox. In particular, as a homebrewer he did a massive amount of mash recycling (to use Micah's term), and that with a step infusion mash will give the high yields he quotes. He is now a commercial brewer using a BRD system, a company for which I consult. He uses a single step mash in his St. Louis brew pub, but retains his preference for high extraction rates through extensive recycling. In fact, in a company site visit last April, he wowed one and all with a full 2 hrs. of recycling.

I do not happen to brew this way, and my ideas about these matters are much closer to Micah's. However, this is Dave's style, this is the way he likes to brew beer, and I feel that each of us get to call our own shoots about such matters. The brew pub (St. Louis Brewing) is doing very well by the way.

From: whg@tellabs.com  
Subject: Wyeast #1007

My limited experience with 1007 was definatley similar, thinkkk kraeusen that floated on top forever. I racked off this after a week o a little less. Both beers I made with this yeast cleared quickly after racking. The beers were clean but frankly boring. This is the "cleanest" fermenting yeast I've every used. So clean that it IMHO beats all the character right out of the wort. I've been told the same thing by other very reputable sources (tony@ssps.com (can't say I personally know of any more reputable source)). FWIW the #1338 European is my yeast of choose for Kolsch and Alt's.

Subject: Questions about hop vines

Greets Brew-brethen,

I've been reading quite a bit about all of you hop vine growers and your experiences in the past 10 or so HBD's. It wouldn't happen to have anything to do with harvest season, now would it? But it got me to thinking...

There's a spot at my house on the way to the front door, where the previous owner, for some unknown reason, erected a sort of awning frame, which extends over the walkway. It occurred to me that if I could find some sort of vine (see the connection?) to grow up from the planter next to the house, up the wall, and across the framework, it would make sort of a vegetation tunnel.

The questions are:

- 1) Do hop vines make for attractive plants? Are different species more or less attractive than other?
- 2) My planter is just a 1' wide strip of dirt next to a concrete walkway. Its about 15' long. Is this enough ground to support enough hop vines to form a nice wall o' cones?
- 3) How will hop vines react to being corralled horizontally once they reach the framework, which is about 10' high?
- 4) Do the fresh cones give off such an aroma that guest walking into my house will demand at gunpoint that I serve them homebrews until they drop?

Thanks in advance for any answers. Hoppy harvest to all of you farmers.

Mark

From: Todd Enders - WD0BCI <enders@plains.NoDak.edu>  
Subject: Chimay & banana update...

Well, the latest sampling of the banana trippel is most promising! The banana flavour and aroma is subsiding nicely, and the spice and some bubblegum are coming through after 4 weeks in the bottle. Another month or two, and it'll be so good I'll hardly be able to stand it! :-) I suspect that one has to have Benedictine patience to wait for something brewed with Chimay yeast to come around. :-)

One thing, though... I think the banana ester production is highly dependant on the SG of the brew. I didn't notice any high levels of esters in my starter (about 1.025 OG). A dubbel at about 1.060-1.065 will come together faster than a trippel starting at 1.070+ I don't know just how long they condition Chimay in the bottle before they ship it, but I suspect it's longer than 4 weeks.

So my personal advice is not to worry alot about the banana ester level at bottling or shortly (1-2 weeks) thereafter. It just takes time for a strong brew to come together. Brew it and stash it away for a couple months or so, and prepare to be rewarded! :-) IMHO, Chimay yeast, obtained from whatever source, does a fine job, and the taste is worth waiting for! :-)

Now, if I can isolate the proper strain from the 5 strain melange that is Orval...

From: joseph@joebloe.maple-shade.nj.us (Joseph Nathan Hall)  
Subject: That Yummy Malt Flavor

This is a thread I've been pushing on r.c.b for a while now. I thought that some of you Digest readers, in particular George Fix, might have some more authoritative answers for me, considering the thread on Belgian malts etc. that has gone on here for a while.

I'm looking for the right combination of ingredients needed to produce the BIG, round, caramely, yummy malt flavor found in (for example) MacAndrews Scotch Ale, Ayinger Celebrator, Ayinger Oktober-Fest, even Pilsner-Urquell. I believe that the missing ingredient is British or Continental 2-row pale and/or crystal malt.

I've gotten replies from brewers in the UK and Europe who have said, "What's the big deal?" and have given me recipes that use 10-15% crystal .. just like my recipes. Sorry, but the malt I've used (with at least 1/2 dozen different ale yeasts, and several lager yeasts) just doesn't work the same! This includes British 2-row, some British crystal, lots of Klages, American crystal, etc.

I tried a friend of a friend's brew that used 30-40% crystal (!). It was indeed round and caramely, but had some other troubles.

I don't believe that the yeast is directly responsible for this character. Certainly the choice of yeast can affect body, dryness, fruitiness, etc., but I don't think that yeast makes or removes much of the deep caramely flavor that I am looking for. Those of you with some sophisticated knowledge of sensory perception are welcome to agree with or correct me.

If someone out there has made, say, a MacAndrews clone that tastes truly similar to the real thing, I'd appreciate a recipe, along with the name of the maltster, mashing details, yeast used, etc.

My next step will be to get my hands on some more British crystal (which Fred Eckhardt claims affects the flavor of beer much more than American crystal), and some German Pilsner malt, and try brewing with that. Unless, of course, some of you have better ideas. (Please?)

> expected by standard recipes).

Absolutely. The part I don't get is on p. 259 in *Malting and Brewing science*, where "slaking heat" (gram-cals/degree) is used to figure strike heats. I don't get it, so here's the formula and table:

Paraphased from *\_Malting and Brewing Science\_* by Hough, Briggs and Stevens

-----  
==

$$\text{Initial heat} = \frac{St + RT + 1/2H}{S + R \quad S + R}$$

S - Specific heat of malt  
t - temperature of malt  
R - ratio of liquor to grist by weight  
T - temperature of the liquor (strike heat)  
H - slaking heat of the malt in gram-cals/degree temperature

The expression is applicable to both centigrade and fahrenheit providing terms are expressed in the appropriate units.

Table 10.1:

Specific heat and slaking heat of a malt at various moisture contents

% moisture	slaking heat (gram-cals) at specific heat mashing temp of 150F
0	0.3833.5
1	0.3829.0
2	0.3925.0
4	0.4018.8
6	0.4114.5
8	0.4212.4

[from the accompanying examples, it appears that these figures are appropriate for degrees F.]

-----  
=

-end of plagiaristic paraphrase

I still don't get what going on, nor do I see why slack malt should have a huge effect on yeilds. There is no mention of reduced yeilds for slack

malt, either here or the other places I've looked. I frequently grind the day before, or sometimes earlier, so this enquiring mind would like to know.

From: homebrew@tso.uc.EDU (Ed Westemeier)  
Subject: Novice hop farmer's report

Hop Farming for Fun

Let me start off by explaining that I'm nowhere even close to thinking of myself as an expert. In fact, I really don't know beans about hops, except that I like 'em in my beer -- lots of 'em!

Anyway, on the Saturday pub crawl through Boston after the 1991 AHA conference, my group got the grand tour of the Boston Brewing Co. from none other than Jim Koch himself (Mr. Sam Adams). Jim also likes hops, and he talked a lot about the benefits of fresh hops as well as (much to my surprise) the benefits of aged hops (that's another story). So I started taking a more serious interest in them.

I had called Freshops in Oregon early last spring and ordered four rhizomes: Cascade, Hallertauer, Northern Brewer and Saaz. The rhizomes came through in fine shape, well packed and marked: four slightly damp scraggly roots, each about five inches long and the thickness of a pencil.

I planted them according to directions, and waited.

Last year they all grew pretty well, and I just let them go pretty much where they wanted. I actually harvested about 1/3 of an ounce (dried weight) from the Cascade, about a dozen cones from the Hallertauer, and nothing from the others.

This year, I did it somewhat closer to right. First, I trimmed off all but two shoots from each variety (the trimmings were delicious, but that's another story). I planted poles and let the vines climb up some twine. I got over four ounces (dried) from the Cascade, a little over an ounce from the Hallertauer, about a dozen cones from the Northern Brewer, and nothing from the Saaz. Th Cascade and Hallertauer grew to almost 20 feet, the Northern Brewer 12 feet, and the Saaz less than 10 feet.

OK, some varieties do better than others. I can handle that. But nothing from the Saaz two years in a row? I asked a couple of people at the AHA conference in Milwaukee this year about them, and one person told me that I shouldn't expect anything from the Saaz before the third year. Well, maybe so, but I decided that I knew better. Since the Saaz vine gets a bit less sun than the others, I decided that was the problem so I resolved to dig it up and transplant it to another location. After digging down a little, I got a real surprise. The Saaz main taproot is now as thick as my wrist! Obviously, it's putting all its energy into growth below ground level, and I have high hopes for it next year.

By the way, I should mention that I haven't fertilized any of them, just dumped a little compost around the roots from time to time. The conventional wisdom is that hops don't grow very well below 40 degrees of latitude (I'm at 39) but some of them seem to like this area just fine. I don't know what the alpha acid percentage is in my homegrown hops, but then I don't really need to know. I can buy hops for bittering and the supplier will tell me down to a tenth of a percent. I can use my own for dry hopping where the percentage doesn't matter much, and I'll know that

I'm using the freshest hops around.

From: mdcsc!gdh@uunet.UU.NET (Garrett Hildebrand)  
Subject: Re: Apple Cider

Hard apple cider is not particularly hard to make. I have been using the following simple method with great success. Beer making veterans may be aghast at the lack of controls, but it does work just fine.

1 Gallon bottle of pure apple cider, no sugar added.

1 small can of apple cider or apple juice concentrate, frozen

1 packet of champagne or ale yeast.

- square of saran wrap
- rubber band

Open the apple cider and pour out enough to leave headroom down to where the bottle is no longer curved in. Drink what you pour out or save it for something else.

Add in 1/2 of the frozen concentrate. If you have lost the headroom, you did not pour enough out, so pour out some more.

Shake it up real good, then add in the yeast and shake it up some more.

Put the saran wrap over the bottle mouth, wet, so it slips around a bit and is not making an air-tight seal. Place a rubber band around the neck near the top. The idea is to keep things from getting into the bottle, but act like an air-lock thus letting blow-off out. Don't make a big deal out of this step.

Put the bottle in the sink or on a place on the countertop and let it sit out for two to three days, then put it in the refridgerator.

\*\*\* At no time should you cap the bottle or it will explode \*\*\*

Beginning with the third day you can start drinking the stuff. It will change in character from day to day. The longer you let it sit the less sweet and the more alchoholic it gets. If you leave it long enough it will clarify.

Mine never lasts that long.

You can play around with sterilization and pasturization and air-locks and what-not, but it never made mine taste any better. Stay loose.

Porch)  
Subject: Barley Wine

A group of intermediate brewers is getting ready to make a batch of  
barley wine. In the recipe in Dave Miller's book calls for the addition of  
1 pound of brown sugar to bring the sugar content up. We would like to  
know from you out there who brew barley wine if this is the best thing to  
add  
or would something else be better.  
The recipe calls for :  
7 lbs pale ale malt  
8 oz. British crystal malt and  
1 lb light brown sugar

This makes 2 gallons.

Subject: Malt Beverage

Have you seen those non-alcoholic beers? Well I tried each one with open mind and mouth. ...and to my surprise they were all about as good as Coor's Light, maybe better!

I have found a non-alcoholic beer (malt beverage) that is worth a try:  
MALTA INDIA  
"Brewed from water & the choicest barley malt. corn sugar. corn & hops."  
" 'Non-alcoholic-contains less than 0.5% alcohol by volume.' "  
produced for Cerveceria India, Inc. of Puerto Rico by The Lion Inc.

Malta India is very malt and almost too sweet.  
If you can find it, try it.

From: "Jeff McCartney (919) 541-7340" <FP\$JEFF@RCC.RTI.ORG>  
Subject: I Need the Opinion of Certified Homebrew Judges

HELP! I need some advice from certified homebrew judges!!!

I'm entering a beer of mine into a local homebrew competition. My recipe approximates Old Peculier. A similar batch I brewed in 1987 but entered in last years's competition took first place in the stouts as a sweet stout. Thus, I feel compelled to enter this one (which in my opinion is better than the one I entered last year). I recently told a friend I had a sweet stout for him to try and he tasted it and said "it tastes just like Old Peculier to me!" I then decided to examine my books and back issues of Zymurgy.

Papazian, in The New Joy of Home Brewing (p.142) classifies Old Peculier as a Brown Ale. The Special 1991 (Vol. 14. No.4) issue of Zymurgy classifies it as an English Old Ale or English Strong Ale. Michael Jackson's Pocket Guide to Beer (first printing 1982) classifies it as a strong ale. Here is my problem: if I enter it according to the National Homebrew Regulations as a class 7a (English Old Ale/Strong Ale), the definition says "light amber to deep amber/copper". Old Peculier is dark brown! Will the judges take off points and say "color not appropriate for style"? Our competition is such that each category will have at least one certified judge per category working with other non-certified judges. I know from experience that when in doubt, the judges consult the guidelines and if they don't know from experience that Old Peculier is a dark brown English Old Ale/Strong Ale, they will read the blurb and say "color not appropriate for style". Because this is a local competition which helps my brewclub, I'm not writing this to get a leg up for a prize. I'm more interested in how this might be dealt with in a national competition by all certified judges. Any comments?

Similarly, because I'm an extract brewer, my light lagers don't turn out as light as the style suggests. For example, I've brewed several quality pilsners but because they are amber in color, I've had to enter them as Vienna! Now if I were a commercial brewer and I produced an amber pilsner, the critics would say I had an amber pilsner. This would then be documented as an "acceptable" (although not preferred) exception to the color code for a pilsner. Then, if a

homebrewer entered his beer as an amber pilsner the judges could say  
"well,  
yes, because Brewery ABC brews a pilsner similar in color to this guy's  
pilsner, I won't take off points".

This message has taken up plenty of space. I'd advise writing me with  
comments  
directly at INTERNET::"FP\$JEFF@ZEUS.RTI.ORG" or FP\$JEFF@RTI for BITNET.

Subject: old bay

Hey now- Just wanted to turn you all on to some upcoming happenings at The Old Bay restaurant in New Brunswick, NJ.

October 3rd- Octoberfest Celebration, Noon - 4 PM  
\$3 Admission, Free German buffet

October 7th- Stoudt's Night with special brewery guests

October 17th- Red Bank Homebrewing talk and mashing demo  
Noon - 4 PM, announcement of holiday brew competition

Please note that I have no financial interest in Old Bay (I wish I did), it's just a cool place to hang. Now that Rutgers is back in session it gets a little crowded with bud-swilling students (hey, we were all young once) but there are usually some homebrewers hanging around as well as the guys from Red Bank Brewing Supply. I understand they're getting Stoudt's Octoberfest, Anchor 1992 Holiday Ale and Old Foghorn, and Sierra Nevada Celebration Ale on tap towards the end of the year.

see you there

Subject: 1007,crystal

For those asking about a 1007 timeframe: brewed on 8/28, kegged on 9/6, gone on 9/18. The brew (a brown porter) was clear on about 9/11. So it cleared in about 2 weeks. I agree with Walt(?) that 1338 would be better for Alt/Kolsch; 1007 left the beer just a little too dry. \*Very\* clean though.

I've run across a source of M&F crystal (British) and won't go back to US crystal. The difference is like Bass vs. Pabst, well maybe not, but the M&F has much more character.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Brewing in Belgium/Bananabrau

On October 1 I'll be taking off on a trip that will include a week in Belgium. This will be my sixth trip there, but all the previous tours took place in a former life (i.e., before I started brewing). On the itinerary are tours of several breweries (probably Brasserie de Bocq and La Bincheoise), and in addition to this my Belgian friends are setting up a brewing session with a friend of theirs who is establishing a brewpub.

As you might imagine, I plan to gather as much information as possible without actually stealing trade secrets. I'm therefore making up a list of things to ask about, and would be happy for any help from the HBD community. The question list so far:

- Use of candy sugars (particularly relating to quantity)
- Availability of yeasts
- Use and handling of unmalted grains
- Fermentation temperatures
- Mashing procedures
- Bottle-conditioning procedures
- Use of fruits

These are quite general, of course. I therefore welcome questions from anybody who's interested, which I will compile and take with me, and I will be happy to post anything I learn as a result of this. I should offer the disclaimer that I haven't sampled the brew pub wares yet, and have no idea whether the people I'll be seeing will be able to answer everything. I should also add that any info gathered will be limited by my own ignorance. Still, I'm hopeful.

I do speak French, and will probably be focusing on breweries in Wallonie. However, my French-language brewing vocabulary is limited at the moment to basic brewing ingredients. If there's anybody out there who can help me out I'd be most appreciative (Pierre Jelenc, vous etes la?).

Lastly, I read Todd Enders report on Wyeast/Banana with some interest. I've just sampled my (very young) Bananabrau, and found that the banana flavors were quite pleasant and not out of line at all. The yeast provides several different tastes, and the banana is just one of them. Overall I'd say the predominant yeast flavor is more caramel/cognac, similar in a way to Chimay Bleu (Grande Reserve). I don't think I have any qualms about using it again.

From: mm@workgroup.com (Mike Mahler)  
Subject: Wyeast #1056

I used this used in about 5 batches, starting with a steam and I concur that it starts off smoothly and ferments over the course of a week in the primary and also it seems to leave very little behind. The beers are usually drier than most and crisp and SEEM less filling, but it could be the recipes I've used it in since they've all bent towards lighter beers. I've also used Wyest Bohemian in another batch and it had the same characterstics.

My fav yeast with regards to little lag time and nice finish is WHitberead Ale yeast. I've heard a rumor that they are not going to make it anymore, does anyone know if it's true? It works great on some stout recipes I've made.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Mill control

I had a chance yesterday to directly compare grain milled with a MaltMill(tm) to grain "professionally" milled. We were giving a brewing demonstration at the Renaissance Festival in Holly, MI (still going for one more weekend). Pale malt was supplied by the sponsor, Frankenmuth Brewing Co. I am not sure whether they mill their own, or have their supplier (Briess) do it for them. We brought some crystal malt that one of us had crushed using a MaltMill(tm) at the shop. The grain from Frankenmuth had a very nice crush, with basically unmangled husks (as desired). So did that from the MaltMill(tm). However, the particles in the MaltMill(tm) crush were about twice as large (in "width", so 8 times the volume). Whether this makes a real difference, I am not competent to say. As far as results go, we used 16# pale malt and 1.25# crystal, with a total extract efficiency of about 32pts/lb/gal (in 10 gal).

From: FWALTER%RULUPI@ccmail.sunysb.edu  
Subject: the world's greatest beer

I've been ruminating about some of the editorial comments that have passed through this digest over the past few months. I fear that some beginners may be getting the wrong message. There is no single best way to make beer, and even with relatively simple techniques one can brew a good, nay, great beer.

Does it really matter whether you go all-grain, extract, or kit?  
Does it really matter whether you use liquid or dry yeast?  
Does it really matter whether you bottle or keg?  
Does it really matter whether your beer is enough of a clone of a defined style to win a prestigious competition?  
Clearly to some it does matter, but to me and my more relaxed bretheren, what matters is:

- 1.) Do you enjoy making the beer?
- 2.) Do you and your friends enjoy drinking the beer?

If you can answer yes to both, then why worry?

Every homebrewer can honestly say "I BREW THE WORLD'S GREATEST BEER".

Fred

-----  
-----  
The author has been an extract/specialty grain brewer for 9 years, with about 60 batches to his credit. All have tasted great and been more filling. The author uses dried yeast (ale in the summer, lager in the winter), relies on the thermal mass of a concrete basement for temperature control, bleach for sanitation, a rolling pin for cracking grains, and elbow grease to remove old bottel labels.

From: korz@iepubj.att.com

Subject: Wyeast vs. Dry

I've found just the opposite of what Russ posted -- In general, I've found that the dry yeasts that I've used (Muntona, Bierkeller, Geordie, Old Danish, and Doric Lager) are more attenuative than most Wyeast strains. Secondly, I've found that the liquid yeasts are very predictable and bacteria-free, whereas the brews made with dry yeasts have invariably eventually become gushers. Mind you, these were not pure-cultured versions of the dry yeasts, rather simply rehydrated straight from the package and then pitched. Although I've never used it, I've read that Edme Ale yeast is one of the most attenuative yeasts you can buy. Whereas with Wyeast #1028, London Ale yeast, I've been able to brew beers with a relatively high residual sweetness, without adding any non-fermentable sugars (like lactose).

use  
> twist off bottles? I've asked almost every eating establishment in  
town,  
> but they will not give up their returnables.

Just go to your friendly neighborhood beer distributor (look 'em up in  
the yellow pages) and ask for X cases of returnable bottles. They'll  
probably charge you a ten cent deposit. It's not a good idea to use  
twist-offs because a) you can't cap them with a hand capper and b) the  
walls are thinner than on returnables and thus more likely to explode  
under the pressure of over-carbonation if you screw something up in your  
beer. By the way, I've found Coors light and Stroh's labels to be the  
easiest to get off (It's your beer, remember?) and Miller Lite all but  
impossible. High Life and Genuine draft come in clear bottles, which  
you don't want, either.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: PPM, God, Right

To: Homebrew Digest  
Fm: Jack Schmidling

>From: korz@iepubj.att.com  
>Subject: mg/l vs ppm

>Regarding conversion from mg/l to ppm, this question came up a year or two ago and a lot of people were unsure about it, but my favorite answer from that discussion was: multiply by 1 to convert from mg/l to ppm and divide by 1 to convert back (actually, I had to think for a moment to make sure the two are one-in-the-same ratio).

This is getting a bit overworked but another way of looking at it is: one in a million is the same as a thousandth (mili) of a thousand (liter=1000 ml).  
Hmm, this always made sense till I tried to spell it out. Oh, well... I think we have enough opinions on this erudite subject already.

>From: guy@mspe5.bll.ingr.com (Guy D. McConnell)  
>Subject: Miller Reserve Draft

>I saw Miller Reserve All Barley Draft in a local Brunos store the other day. While I don't expect it to be the best beer I've ever had, I intend to try it.

You can save yourself the trouble. It is not only NOT the best beer you have ever had but it is just about indistinguishable from all the other rubbish they call beer.

>Now Miller is bringing it back in Miller Reserve All Barley Draft. It's an idea whose time has come around again" or something to that effect.

So now they're taking credit for "reviving" beer made the way God intended.

Not sure how your god makes beer but mine would send them straight to hell after washing their mouth out with soap for lieing.

The only way one could make all barley beer that tasteless is to dilute it about 10:1 with water and fortify it with alcohol.

>From: jim busch <busch@daacdev1.stx.com>  
>Subject: "Right equipment" and yeast

>If this is the way jack feels, I suggest he invest (well spent money) in a

stainless steel perforated sheet false bottom for his lauter tun. These are commercially available in 16 gauge thickness, I forget the hole size. I got mine in Portland for \$50 and had a local shop spot weld legs on it. This screen with a bottom outlet will increase the yield per pound significantly over the double bucket method and I suspect the easy mash through a screen method. Of course, you will have to recirculate the runoff for 10-15 minutes to clarify.

Not sure how to respond to this without being accused of commercialization again. I guess if I leave out the upper case letters, that will have to do.

My very first batch of all grain was made (attempted) with exactly such a device. A 16 inch SS plate with a zillion holes punched in it and copper feet screwed into it. Not sure what 16 gauge is but I could stand on mine.

To make doubly sure there could be no problems, I built the screen gizzmo (described elsewhere) to keep anything, that got through, out of the spigot.

It created no end of problems on the very first batch. Mash got under it and scorching was just about impossible to control. So in disgust, I pulled it out, continued the mash and assumed a disaster was at hand.

Much to my incredulous delight, when I opened the spigot, the wort ran clear after about 3 oz of turbid runoff. I have since made about 30 batches using only the screen gizzmo and get very consistent and respectable extract yields.

What I ended up with is a complete system in a single kettle. I mash and sparge in the same kettle with no need to transfer anything, anywhere and have total control over the temp during the entire process.

One can boil and later ferment in the same kettle without having to hassle with hops and grain getting stuck in the spigot or siphon. I now have a 16 gallon kettle for boiling so I don't have to store wort while cleaning out kettles.

So, the bottom line is, the "right" equipment is not always obvious and is the reason we all read these fora to get new ideas. If anyone wants more info on this process, email to me. Yes, there is a teeny commercial at the end but the process is detailed and a parts list is furnished so you can get

the stuff at a hardware store.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: pre-ground malt

Another thing to watch out for:

If you buy your malt pre-ground in large quantities, the husks can sift to the top while the cracked grain/endosperm settle to the bottom. You then take enough from the top for the first batch, and you get no problems with runoff because of the large amount of intact husk material, but your efficiency seems low since much of the goddies settled to the bottom of the bag. toward the bottom, there will be a higher percentage of finely-cracked grain, with few husks intact. Your sparge will be much slower, but your efficiency seems better (assumming that you get the sparge to work at all.)

From: CW06GST <CW06GST%SJUMUSIC.bitnet@CUNYVM.CUNY.EDU>  
Subject: Swedish beers

Recently, I asked about a Swedish beer called Gammel Brygd made by the Falcocon Brewery. Thanks to those of you who answered some of my questions. What I would like to do now is try to formulate a recipe that might approximate Falcon Gammel Brygd. The last time I had it I remeber it being dark and sweet and very malty without much hoppiness (Kurt?). Here's my idea for making Falcon Gammel Brygd:

#### Fakin' Gammel Brygd

6-7 lbs German? dark malt extract syrup (Bierkeller maybe?)  
1 lbcrystal malt  
1/2 lb chocolate malt  
0-2 cupsbrown sugar (just guessing)  
1 oz Hallertaur hops (boiling)  
1/2 oz Goldings hops (finishing)  
lager yeast (any suggestions)

I do not have much experience with lager yeast, so any help in this area would be greatly appreciated, i.e. brand, type, fermenting temperature, lagering time.

For a dark beer I would figure on a fairly long boil, say at least 45 minutes.

Also, there has been a lot of talk lately about Christmas beers (I guess it's time to get busy). I have an idea for a Christmas ale that I would like to run by everyone.

#### Gl:gg Beer

5lbs light American malt extract syrup (brand?)  
up to 1lb crystal malt  
up to 1lb light honey  
1 oz mild hops - fairlylow bittering (suggestions please)  
some type of ale yeast

Right about now you should be saying: "what is this guy thinking? Why is this a Christmas beer?" This is where I need some help.

My bright idea is to add glogg essence. In Sweden, at Christmas time, they make a soiced wine that is served warm with almonds and raisins and is given to guests when they come in from the cold. Glogg can be bought at the liquor store or you can buy the essence and add it to red wine with sugar and vodka (vodka is optional). I have in my possession several bottles of glogg essence and would like to spice my beer with it.

When you open a bottle of this stuff and take a whiff you can just about hear Bing Crosby sing "White Christmas". It contains cardamom, cinnamon and several other spices that don't translate well, in a 65% alcohol base. When I use it to make glogg I use about 25ml for 1 gallon of red wine. It comes out very heavily spiced, a little to spiced for beer. What I was going to try was to add 45ml (3 bottles) to a 5 gallon batch of beer at the end of the boil. I figures if I boiled it too long I would lose a lot of the aromatics and flavor. I thought about adding

it after the boil but I'm worried about contamination and figured I would boil it for a couple of minutes for sanitary reasons, plus I dont know if the alcohol present in the essence will have a detrimental effect on the yeast.

Please, everyone, feel free to comment, suggest, agree, vary, modify or trash. Nothing is written in stone, and it will be at least a week before I brew again.

Yours in brew,  
Erik

From: Paul AndersEn <ECZ5PGA@MVS.OAC.UCLA.EDU>  
Subject: All about Beer, Hoegarten wheat

Hi Yawl, Do any of you subscribe to the publication "All about Beer" or "Suds 'n Stuff"? If you do, is it worth the twenty bucks to subscribe or would you discourage it? For those of you who do not know what they are, they are publications from Oceanside California on the subject of beer from

all over the world. A friend gave mine gave me an old edition and it was pretty interesting to read, and I got a few more catalogue for homebrew merchandise distributors sent to me from numbers I got out of it.

Eventhough

the 16 page magazine comes from california, it does not only talk about beer in california. It gave all the results from the the Great American Beer Fest, and a bunch of short paragraphs ranging in topics. The one downfall to the 16 page paper mag is that it costs 15 bucks to subscribe for a year (there are 6 mags a year). I don't think I will join, but the "All about Beer" publication is supposed to be a bigger mag with more information. Again, if anyone has seen it or subscribes, I would be interested

to hear what it is like.

If anyone out there is interested in these publications:

Beer Drinker's Int'l  
P.O. Box 586402  
Oceanside, CA.  
92058

By the way, I am in no way affiliated with this magazine, so please do not take this as an advertisement.

Side note: If you haven't tried a beer called Hoegarten from Belgium I highly recommend it. If you live in the Los Angeles area, the only place where you can get it is at The Wine House on Cotner st. just north of Pico in West L.A.

Prost!

Subject: Boston Visit

So there I was at the Wind River Systems booth at BusCon '92, in my official capacity as Wind River's Technical Support Manager (insert appropriate fanfare here), when I saw a marginally familiar name on this attendee's name tag: "Charles Cox".

"Hmmm," says I, "that's certainly a marginally familiar name...where have I heard it before." The wheels spin.

Further down on the name tag is his company name: "Synchrosystems".

"Holy cow," says I! "You're Chuck Cox, the World's Fastest Homebrewer!"

"The same," says he.

It's amazing who you can run into three thousand miles from home.

Our schedules didn't permit me to buy him a beer, but Chuck gave me pointers to all of the Boston brewpubs, and I drank some amazing beers that night. Watch for my upcoming article, "The T Tour", which will probably be finished before my "Beer Odyssey from Hell" article, unfortunately.

Thanks, Chuck! If our paths cross again, it's my treat!

Subject: Kegs

Greetings fellow homebrewers,

Although this is my first post and I have numerous questions, I'll keep it short and only ask one today.

I was cleaning out a couple of old kegs (cornellius and firestone) and wanted to replace the gaskets on top of the springs in the stems but cannot seem to disassemble the stems to get at the spring mechanisms. How does one go about getting to these gaskets.

Thanks in advance,

RJP

Subject: Carboys and plastic water jugs

Thanks again to all who have been helping me along.

I just finished calling up all the local water distribution companies in my area. I was trying to find a less expensive way of purchasing the glass carboys. Not a single company here uses glass any more. They did assure me that the plastic used is a \*\*\* non-porous plastic \*\*\*\*.

What is the HBD net wisdom on this? Could I safely use plastic water jugs as my carboy? At \$6.00 a pop, this would sure beat paying \$18 for a glass one when the need arises!

From: jdg@grex.ann-arbor.mi.us (Josh Grosse)  
Subject: Incredibly good extraction rate

Spencer Thomas and I brewed a Vienna Lager this Sunday at the Renaissance Festival (Holly, MI) as he described in an earlier post. He calculates that we got 1.032/lb/gallon, but I think we did a little better than that, as we used slightly less malt than he noted. Also, we did not add our crystal malts until mashout.

The two of us were able to obtain extractions at 1.032 - 1.033 /lb/gallon through the use of a mash tun with a recirculating pump. This pump pulled wort from below the false bottom, and had an outlet at the top of the tun. During the mash, we watched the wort at the outlet become absolutely clear. The mash itself created an impressive and recirculated filter bed, and we recirculated throughout the entire mash, to be sure of even heat and an extremely effective filter bed.

We used a 15 gallon pilot brewery designed and built by Dave West and Mike O'Brien, a system which Spencer described in the HBD about a year ago. The key to its effectiveness is the pump, which we used three times. The first time was during the mash, as described. The second time was during wort cooling, when we attached the pump to the boiling kettle to improve the effectiveness of an immersion chiller. The third time was to rack the cooled wort into carboys to take home.

We now have a data point that corroborates Dr. Fix and Mr. Miller on the effect of recirculation on mash efficiency.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Sugar in barleywine

Phillip Porch asked about Dave Miller's instructions for putting sugar into barleywine.

In Belgian Ale Pierre Rajotte opines that using additional malt after obtaining a gravity of 1.075 or so is unnecessary and wasteful. While I wouldn't go that far myself I have just finished the third of three high-gravity beers using sugar and have no intention of going back. What you get is all the intoxicating aspects (speaking both physiologically and gastronomically) but with a "lighter" body. I.e. if you want crankcase oil, go all malt. If you want a refreshing, strong beverage, use sugar. (Not that I'm prejudiced or anything. . .).

While you should DEFINITELY make your own decision, my own advice would be to add ANOTHER half pound of sugar, and cut back on the corresponding quantity of malt.

Yes, I know, now everybody's going to be horrified. . .

Subject: corrected, dry vs. smooth

Ok, I stand corrected. Most dry yeast will be \*more\* attenuative than Wyeast. I guess I was thinking back to days of underaerated extract batches, fermented with dry yeast, that finished very sweet. Somehow I forgot about the super-dry gushers.

The real topic is why Wyeast fermented beer might seem "watery" to someone used to dry yeast ferments. I feel the reason is that the dry yeast produces many of the components usually considered "harsh" - higher alcohols, etc. The Wyeast-ferments produce less, leaving a cleaner, smoother brew (less harsh). This smoothness can be perceived as "watery" when one is used to the "bite" of the harsh components.

Obviously, this doesn't hold true for all dry yeast and there are other factors which can affect harsh/watery/smooth etc.....

From: "Robert Haddad" <RHADDAD@bss1.umd.edu>  
Subject: Help with first partial mash...

This past weekend, I decided to take the plunge towards mash brewing with a partial mash recipe from Papazian. "Sayandra Wheat Beer". It calls for a 3.3 lb can of DME extract and 1 lb of malted wheat.

I followed directions for the mash closely, did several iodine tests (which showed starch-sugar conversion was taking place). Yet when I placed the wort in the carboy for primary fermentation, O.G. was a pityful 1.015 !!! I had to scavenge around to find some corn sugar, boil down a concentrated solution and top off the carboy.

Papazian writes that Sayandra is a low alcohol wheat, but his is 1.030.

P.S. my wheat was milled at the store, and seemed fine enough.

Any thoughts about what went wrong?

Thanks,

Robert Haddad

From: Robert Schultz <SCHULTZ@admin1.usask.ca>  
Subject: Adjuncts - steep or mash

Some extract recipes call for one to steep the specialty malts (e.g crystal malt, toasted malt, choc. malt etc.from a cold water start) whereas other seem to imply that one should mash the specialty malts prior to adding the extract & boiling. In all grain I assume that all the grains go through the mashing process.

My question relates to extract brew and the addition of specialty malts. Does one get more goodness from the specialty malts if they follow the mashing process or do you get enough (for the specific recipe) if you simply steep the specialty malts to boiling point?

Relaxed and wondering ????

Robert Schultz.

From: "Roger Deschner 6-9433" <U52983@UICVM.UIC.EDU>  
Subject: Old Peculier without a category

Jeff McCartney wrote concerning his difficulty in getting his Old Peculier immitation judged correctly. After analyzing his dilemma with the references I had at hand, I can only conclude the same as he has - that there is a deficiency in the AHA Contest Style descriptions. This is not the first time this has happened, but this is one of the best defined cases of a problem.

Jeff noted that the Zymurgy Special 1991 (Vol 14 No 4) issue listed Old Peculier as a English Old/Strong Ale - a classification which makes sense. However, that same article states that color will be 10-16 SRM, and Old Peculier does not fit that range. Fred Eckhardt, in "Essentials of Beer Style" states "Color ... 8-13 SRM (but up to 45 in Old ales)." SRM 45 is the low end of the black range. The AHA Contest descriptions are said to have been extracted from this issue of Zymurgy, and picked up this incomplete color range indication.

I hope that future AHA Contest descriptions will note this exception for Old Ales, something like: "Typically light amber to deep amber/copper, but Old Ale can range to black."

You could go through a whole rigamarole of negotiating with the contest coordinator, etc., but why not just try entering it as 8b) Scotch Strong Ale? It ain't one of those, according to more detailed references, but the AHA style description for 8b, if that's what the judges are following, could fit your beer.

(Fit the category to the beer? No. I didn't say that. Wash my mouth out with Bud Light.)

Date: Tue, 22 Sep 92 10:49:42 EDT  
From: tmc!david@uunet.UU.NET  
Subject: Christmas brews

Jay marshall and rein@stat.berkeley.edu asked for Christmas recipes recently. I'd like to add one more recipe that appeared last year in the HBD, but which I haven't seen in the Cat's Meow (It may have made to a recent edition: I have an older copy.. .) My hard copy of this post is dated 08/02/91. I am attempting to copy last year's post verbatim, since there is some confusion.

\*\*\*\* Old post \*\*\*

Following is Phil Fleming's recipe for Christmas Ale that I posted last fall in these electronic pages. The recipe is in the latest special issue of Zymurgy. I judged this beer in Oakland at the AHA competition. All I can say is that after the first sip I was singing "Jingle Bells"! It finished runner up in Best Of Show.

Ingredients for 5 gallons

3 1/2 pounds Munton and Fison Stout Kit  
3 1/2 Pounds Munton and Fison amber dry malt extract  
3pounds M & F amber dry malt extract ] ?? Typo??  
1/2 ounce Hallertauer hops (60 minutes)  
1/2 ounce Hallertauer hops (5 minutes)  
3/4 pound honey  
5 3-inch cinnamon sticks  
2 teaspoons allspice  
1 teaspoon cloves  
6 ounces ginger root  
6 rinds from medium size oranges (scrape the white insides of the rind away)  
Wyeast 1007 German ale yeast  
7 ounces corn sugar for priming

\* OG: 1.069

\* TG: 1.030

Primary fermentation: 14 days @ 61 degrees FG.  
age when judged: six months.

Brewer's specifics:

Simmer spices and honey (45 minutes) Boil malt and hops (50 minutes)  
Add finishing  
hops and boil (5 minutes) Cool, strain and pitch yeast.

MY COMMENTS:

The second call for 3 pounds of M & F Amber dry is probably a type in the magazine. 7

pounds of extract + 3/4 lb. of honey should give you around 1.069 OG.

....

This was THE best Xmas ale I've ever tasted.

....

\*\* END of old post \*\*

I did not save the author of this post when I printed it out, so I don't know to whom the "I" refers.

I brewed this recipe in late August last year, and had to exercise tremendous self discipline for it to last until Christmas. It was DELICIOUS. I compared it to several of the microbreweries' offerings, and it was just as good. This was my 7th batch.

I made a variation of the same yesterday, so that I'll have a reasonable amount left for new years partying. It's a little late to brew it this year, but if anyone is planning to brew this coming weekend, I highly recommend this recipe.

Actually, I've seen no observable / tasteable difference between clear  
and  
dark bottles...In fact clear bottles are easier to fill. I think if  
there  
not in the sunlight, it doesn't matter what color the bottles are.

What are the alternatives to using bottles? I've heard that you can  
bottle  
in Coke (or Pepsi) syrup containers... Is anyone doing that, and how much  
would it cost to get the equipment? (a container, and a co2 system for  
it.)

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Yield2

Rich Goldstein asked via private e-mail (thanks Rich!) what volume I used to determine yields, something I neglected to mention in my recent post. The one I was referring to was the volume of the chilled wort delivered to the fermenter. This is somewhat common since it takes into account the loss of extract that occurs throughout the wort production process.

When debugging new systems, or trying out new malt, it is sometimes useful to estimate the total amount of extract present at any particular point, and hence get a handle on the "yield" that is achieved at various points. The following is data obtained from a recent brew using the Belgium pale ale malt in a single step infusion mash.

MASH:

Vol. of Mash= 32 l. (8.5 gals.)  
Wt. of Grains = 10 kg. (22 lbs.)  
% Extract at End = 19.5 g/100g (measured)  
SG= 1.081 (tables)  
% Extract-vol. =  $19.5 \times 1.081 = 21.08$  kg/hl  
Extract at End =  $21.08 \times 32 / 100 = 6.75$  kg (14.8 lbs)  
Effective Yield =  $(6.75 / 10) \times 100 = 67.5\%$   
(31.2/lb/gal)

START of BOIL:

Vol. Collected from Sparge = 56 l. (14.8 gals.)  
% Extract = 11.3 g/100g (measured)  
SG= 1.046 (tables)  
% Extract-vol =  $1.046 \times 11.3 = 11.82$  kg/hl  
Extract=  $11.82 \times 56 / 100 = 6.62$  kg (14.6 lbs.)  
Extract loss in Sparge=  $6.75 - 6.62 = .13$  kg (~2%)  
Effective Yield = 66.2 %  
(30.9/lb/gal)

WORT in FERMENTER:

Vol. = 50 l (13.3gals)  
% Extract = 12.5 g/100g (measured)  
SG= 1.051 (tables)  
% Extract-vol =  $12.5 \times 1.051 = 13.13$  kg/hl  
Extract=  $13.13 \times 50 / 100 = 6.57$  kg (14.45 lbs.)  
Extract loss in Boil =  $6.62 - 6.57 = .05$  kg (<1%)  
and Cooling  
Final Yield = 65.7%  
(30.8/lb/gal)

This, by the way, is higher than the usual 60-62% yield I get with a single step infusion. Is anyone else noticing higher yields with the Belgium malts?

Following a tip from Rodney Morris I obtained a used refractometer for extract readings. Only a drop of solution is needed to get a reading, and temperature corrections are not necessary. The model I got was from Cole-Palmer (1-02940-20; see page 937 of their catalog). They cost \$175 new, and 1/3rd that used. The Brix scale used is exactly the same as degrees Plato (i.e., % extract by weight). Rodney has one that reads the equivalent SG. He got new it on sale for about the same price I paid for the used one.

P.S. Kurt Swanson> Did you get my e-mail? Our mailer sends messages meant to go the the UK to Mars. I hope those for Sweden stay on this planet.

From: G.A.Cooper@qmw.ac.uk  
Subject: Barlet Wine, Styrian hops

Phillip Porch asks about barley wine:

> ... the recipe ...calls for the addition of 1 pound of brown sugar to  
> bring the sugar content up. We would like to know from you out there  
> who brew barley wine if this is the best thing to add or would  
something  
> else be better.

Experience of making, drinking and judging (both local and UK national) and of discussions with numerous UK beermakers over many years, the best all-grain (mashed) barley wines are those that use only grain - no sugar. (OK, I know a lot of you will have counter-examples. Perhaps we might get some discussion on that point!) So, omit the sugar and increase the pale malt. To get the high OG, say 1.100, you will have to take only the 'first runnings' from the sparge (2+x gals where x is the amount of boil-off in your system). You will also find you need a fairly stiff mash (rather than runny) and no excess water under or over the grain bed unless you are prepared to boil for a long time to reduce the volume. Stopping the sparge early means not all fermentables will find their way into the barley wine, so your estimate of how much grain you need must be correspondingly higher. (If you normally expect 30 per lb then guess at 25 or even a bit less). Of course, you don't waste the fermentables left in the grain, continue the sparge as normal and use these 'second runnings' as the basis of an extract brew. Party gyle re-visited. I frequently make two beers this way.

These suggestions obviously increase your work so if you want a simpler answer then: if I find I need to increase the OG of a barley wine I do so by adding extract (EDME DMS usually) into the boil.

All this was IMHO of course. (BTW what does MOMILY mean?)

Also, on barley wines, someone (can't remember who) made comments on the way they used multiple yeasts. I add two strains at the beginning an ale yeast (usually Truman's dried) and a high alcohol tolerance wine (usually a S. Bayanus, 'champagne' yeast) both at the same time. The wine yeast seems quite capable of 'taking over' and, empirically, I find that I have no difficulties in getting complete fermentation. But I am aware that the yeast will probably be all pooped out so I often add a fresh culture at, or shortly before bottling. I was surprised, though, to find that his final gravity was 1.004. I think (IMHO of course :-)) that this is a bit low for a barley wine. I find that plenty of body and high residual dextrins are needed to balance (that word again!) the high alcohol. That in turn needing a firm hop. I would target a final gravity below 1.020 but not much below.

From: Stefan Karlsson, Styrian hops - how are they?

Styrian, aka Styrian Goldings, are an attractive low alpha (the highest I

have had was 4.8% but they are usually nearer 4% and often less) aroma hop.  
Not normally used in large quantities in the copper (kettle tee hee) but as a late addition (last few minutes) or dry hop. I have used them for aroma in a few lager styles and liked them. I have also used them to good effect in pale ales. They might be a little different but well worth trying.

>From Bart Lipkens

> I was going through David Line's recipe book, and noticed that a lot  
> of the recipes call for invert sugar.  
> What is it?

Invert sugar is sucrose that has been broken down into glucose and fructose.  
You can do this yourself by heating sucrose in solution with an acid such as citric, but don't bother. Ale yeasts are quite capable of 'inverting' sucrose by producing the enzyme invertase. So just use some form of sucrose, you could try some variety by choosing brown instead of white - have a bit of fun experimenting. The original idea was that invert sugar would be easier for the yeast to work on and less likely to cause fermentation problems (as in stuck ferments). This is different from 'brewing sugars' that add flavour, colour and some higher sugars.

From: STROUD <STROUD%GAIA@leia.polaroid.com>

> Looking at Rajotte's "Belgian Ale" book, it is not clear to me whether  
> the line

>Reducing sugar (as maltose): 1-2.5%

> means that 1-2.5% of the reducing sugars left are maltose or whether  
the  
> final composition of the beer contains 1-2.5% reducing sugars.

This does have a clear meaning. If a beer is said to have 2% reducing sugar as maltose, it means that it contains (unspecified) reducing sugars that have the same effect as if 2% maltose were present. Note there need not be any maltose present. Put another way, the amount of reducing of the cupric ions that has just occurred in my test is the same as if I had done it on a 2% solution of maltose.

A similar statement occurs in home winemaking where we talk of the amount of acid present 'as tartaric'. If a wine has 6ppt acid (as tartaric) it might not have any tartaric acid in it, but whatever acids they are (citric or malic for example) they have the same effect as if it contained only 6 ppt of tartaric and no others. This value is approx the same as 4 ppt 'as sulphuric' which is the measure some people (still) use. This is because the amount of NaOH needed to neutralise sulphuric acid is about 1.53 times greater than needed for tartaric. That is 1 part sulphuric is equivalent to 1.53 parts tartaric.

I hope that is clear rather than confusing. BTW I liked the descriptions  
of  
what a reducing sugar was.

Sorry for the long posting

Geoff

From: korz@iepubj.att.com  
Subject: Re: the world's greatest beer

First of all, I don't mean to sound argumentative, so I hope this post doesn't turn out that way. I just want to express my opinion on the subjects that Fred brought up.

Fred writes:

>Does it really matter whether you go all-grain, extract, or kit?

You can brew great beer both ways, but some styles need all-grain to have all the appropriate characteristics (specifically malt nose and flavor). To brew an excellent Munich Helles, I (personally) feel you need to go all-grain.

>Does it really matter whether you use liquid or dry yeast?

I really think so -- for my beers I would not use dry again. You should try liquid yeast and see if you like it. I did and never went back.

>Does it really matter whether you bottle or keg?

No.

>Does it really matter whether your beer is enough of a clone of a defined

>style to win a prestigious competition?

No, but I enter competitions for two reasons: 1) to get feedback on my beers so I can make them better and 2) awards make me feel good -- I consider them an honor and a reward for the work I put in to my beers. Note that you don't need to win 1st, 2nd or 3rd at the Nationals to win something -- if you brew a beer that doesn't have an infection, you will probably get at least a Bronze Certificate no matter what category you enter your beer in - -- call it a pat-on-the-back.

>Clearly to some it does matter, but to me and my more relaxed bretheren, >what matters is:

> 1.) Do you enjoy making the beer?

Yes.

> 2.) Do you and your friends enjoy drinking the beer?

Yes.

>If you can answer yes to both, then why worry?

Agreed.

>

>Every homebrewer can honestly say "I BREW THE WORLD'S GREATEST BEER".

Yes, but I want to continue to improve my beers and I know that I'm not objective about my own beers -- I tend to be too critical and miss areas of improvement -- one needs to push oneself for excellence and listen to experts' advice for a reality check.

>

>Fred

All in all Fred brings up some good points, but perhaps the most important one is that homebrewing is different things to different people. To me, it is: 1) a source for great beer, 2) fun, 3) pride in workmanship, 4) 75% of my waking hours ;^), 5) a topic for hours of conversation at homebrew club meetings, and 6) safer than skydiving.

Finally, judging at this years' Nationals, I confirmed my theory that the best beers in the world are found at homebrew competitions -- no doubt! We all have the added benefit of seeing the recipes for the National Homebrew Competition winners for the price of a Zymurgy subscription. I'm not positive, but I'll bet that you can get the recipes for the winning beers in this years' Dixie Cup with a subscription to the appropriate club's newsletter...

...and the IBU competitions and CBS and Maltose Falcons and Foam Rangers and Wort Processors and BOSS and Beerocrats and Hop, Barley and the Alers...

From: chuck@synchro.com (Chuck Cox)  
Subject: Best of Show

Howdy-

Over on JudgeNet we are having a lively discussion about the validity of Best of Show competitions.

To paraphrase the arguments:

Con:

Best of Show tries to compare apples to oranges, so the results are meaningless.

Pro:

The competitors know Best of Show is highly subjective, but they like it anyway.

I'd like to hear from the competitors. Should homebrew competitions include a Best of Show judging? I am particularly interested in the opinions of homebrewers who have entered at least one competition and are not beer judges.

I recommend sending your opinions directly to me instead of cluttering the digest.

From: Darryl Richman <darrylri@microsoft.com>  
Subject: Carboys and plastic water jugs

The plastic 5 gallon water jugs now in use are made from polycarbonate, are impervious to ethanol, reasonably unbreakable, and of course, are very light. You can sanitize them with boiling water if you like, eliminating wor^H^H^Hconcerns about rinsing, as well as being far more effective at getting bugs that may be hiding in scratches. They are slightly permeable to air, so they may not make the best lagering vessels.

> place where you can get it is at The Wine House on Cotner st. just  
north  
> of Pico in West L.A.

There is a close facsimile of this available from Austin Texas, called  
"Celis White". The brewmaster at the Celis brewery is Peter Celis,  
who revived the "Wit" style in Hoegarten a few years back. He (had  
to) sell his brewery to a conglomerate, so he moved to Texas and  
started over. It's a real nice beer; a little watered down "for  
American tastes", but definitely not to be mistaken for BudMilLob.

Subject: mead forum (?)

After my recent request for the addresses of the mead and cider forum I've been SWAMPED with requests for the address of the mead forum. BTW, special thanks to Mike Hall. Ironically there is no address for the mead forum as there is no mead forum (as far as I can tell).

Due to the overwhelming number of people looking for a mead forum, maybe its time to start one. Afterall, there is a forum for lambics. Lambics?

What this calls for is a mead-making, honey-lovin', sticky-fingered, beehive-robbin' take-it-upon-yourself type of Unix geek. I'm all of the above except for the Unix part. Well, and maybe the take-it-upon-yourself part as well.

Anyone up to answering the call to start a mead forum?

Second Annual Brewmaster Oktoberfest

Homebrew Competition - HWBTA Sanctioned

Entry Deadline: Saturday, October 10, 1992 (NLT 5pm)

Entry Fee: \$5.00 (payable to Brewmaster)

Entry Requirements: 3 bottles; 12-14oz brown or green with caps  
blacked out with a marker. No labels. Attach to each bottle  
(with a rubber band) the following information: name,  
address, phone number, and category. One entry per category.

Categories: Ales - Pale Ale, Brown Ale, Porter, Stout, Barleywine  
Lagers - Pilsner, Amber/Oktoberfest, Bock  
Mixed - Wheat Beer, Fruit Beer, Mead

Refer to AHA/HWBTA Guidelines for Category Descriptions

Closed session judging takes place on October 18, 1992.

Prizes for 1st Place winners and best of show.

Send or deliver entries to: Brewmaster  
2315 Verna Court  
San Leandro CA 94577

From: adiron!scott@uunet.UU.NET (Scott Barrett)  
Subject: Another hop harvest data point

First year Freshops rhizomes, planted in April in central New York.

Variety	Dried weight (oz)	Comments
Cascade3	1/2	Strong plant, nicely coned.
Mt. Hood	6	Abondanza!
Tettnanger	3/8	Good plant, sparsely coned.
Willamette	2 1/4	Strong plant, sparsely coned.
Chinook2	3/4	Single vine, nicely coned.

The Mt. Hood grew to about 17 feet, the others grew to 13 or 14 feet. All of the vines were healthy, though the Chinook was late to appear. All were grown up 20 foot cut saplings with all but 4 inches of each branch removed.

Each sapling was tied to a 5' metal fence post that was driven 1 1/2 feet into the ground. There were a couple of ladder harvests for most varieties, followed ultimately by a lower-the-pole harvest. Some of the cones (Chinook particularly) were larger than my thumb -- it blew me away! There's nothing like pulling out a fresh bractiole and rubbing it against the roof of your mouth with your tongue. Wonderful aroma as you breath through your nose, followed by mouth-watering bitterness that washes down your throat. I'm hooked!

I had some aphid problems on the Willamette, but no Japanese beetles. Some invisible beast was making the lower Cascade leaves look like Swiss cheese, though frequent inspections turned up no suspects. The only real annoyance was a thin, 1/2" long green worm that liked to bore through the cones of all varieties (avoiding the lupulin) and weave filmy weblike material.

I was also able to find people in the area who grow (for mostly historical reasons) an unidentified variety of hops. I was able to harvest 19 ounces and some root stock. The hops are pretty bitter, but not very aromatic. My first guess at the variety is Clusters, since I've seen references to it being the predominant variety grown in the area (Madison County, NY) back when it was a flourishing hop farming region. There is also a resemblance to the photos shown in the Zymurgy hop issue and it seems to fit the highly analytical roof-of-the-mouth characteristic profile.

If anyone would like to trade root stock or potted growing tips in the spring, please let me know by email. Any identification of my favorite pest is also welcomed.

Two pounds of fresh hops in the freezer and looking forward to some IPAs (and other lupulomania),  
Scott Barrett

 From: strasser@raj3.tn.cornell.edu (Tom Strasser)  
 Subject: Clear/Green Bottles and Lightstruck Beer

Before the discussion about clear or green bottles vs. brown gets off the ground I wanted to point everyone back to the discussion about 1 year ago here about these issues. For the most part the discussion centered around whether the lightstruck flaw in beer was caused by 520 nm light only or sub 500nm light (there are references claiming both of these to be the case, I believe the 520 nm reference was from the AHA conference transcripts in 88 or 89, and the <500nm reference was an article published by a Louisville(?) University publication entitled "The Photochemistry of Beer" which was written by some Belgians (if I rememeber right)). While perhaps this was left up to individual people to decide, one thing which was discussed was that for *\*either\** case, brown bottles protected the beer much better than green or clear bottles. I direct people back to last November's HBD's to follow the discussion, but the result I contributed was a measurement of the relative transmission of various bottles as a function of wavelength. I will include the ascii graph again here (as it is likely the thing I spent the most time on ;-). The transmission looks like:

The above are three individual bottle measurements, however I measured 2 or 3 different bottles from different breweries, both import and domestic, and found *\*very\** similar behaviour to the above for bottles of the same color.

You can see from the above transmission plot that the brown bottles transmit significantly less UV light than the clear or green ones (regardless of which region causes the lightstruck flaw). This would be the difference between brown and clear (or green) bottles. Another thing worth mentioning here is that in the wavelength regime of interest there is little difference between the green and clear bottles.

Perhaps Dr. Fix might want to comment on the most important regimes on the above chart ;-).

Auf ein neues,

From: gdt@garlic.LCS.MIT.EDU (Greg Troxel)  
Subject: Re: Help with first partial mash... and OG samples

I just did my second partial mash. While it isn't bottled yet, I feel that it was successful.

I did a partial mash with 2 lbs pale ale malt, 2 lbs mild ale malt and 1 lb crystal, and got 20 pts/lb/gal extraction as a rough estimate (I didn't measure the volume very carefully). I think that my crush wasn't fine enough, and I think sparged way too fast. But I think I got significant character/body from this, as I mashed at 158 (intending to get a dextrinous wort). I was intending to make something that falls somewhere in between the styles between pale ale, Scotch Ale, and ESB (depending on my extraction and how dextrinous the wort was, which I knew I couldn't yet control precisely). This isn't bottled yet, but the bit I tasted when racking to secondary seemed good, as did the OG sample (more on this at the end).

What I did:

5 gallon batch:  
6.5 lbs light liquid extract  
2 lbs pale ale malt  
2 lbs mild ale malt  
1 lb crystal  
a small amount of gypsum calculated to raise the Ca content of the  
3 gal mash water to 60 ppm (from the 0 ppm it was from the tap).  
~60 ibus bittering (~1.5 oz eroica 9.1% for 45 minutes at boil gravity of  
1065)  
2 oz cascade leaf at boil end  
1.5 oz cascade leaf in secondary  
Wyeast 1056 American Ale yeast (750 ml starter)

I mashed the grains for 45 minutes at 158, and did starch tests. I got an OG of about 1065. 20 pts/lb/gal is 66% of what homebrewers can get (more or less - I'm not trying to pick a fight about theoretical maximums) when they basically do everything right (30 pts/lb/gal). I estimated that I would be between 33% of that (10) and 100% (30), and adjusted bittering for the middle, hoping I would get something reasonably balanced (according to my hophead tastes) either way.

As far as your experience, I have a few comments:

1) if you used 3.3 lb (liquid??) DME and 1 lb malted wheat, and were supposed to get 1030, shouldn't you have had  
 $3.3 \text{ lb} * 35 \text{ pts/lb DME} = 115 \text{ pts}$   
 $1 \text{ lb wheat} * 25 \text{ pts/lb} = 25 \text{ pts}$   
140 pts  
in 4 gallons = 1035 (you didn't give your batch size).  
in 5 gallons = 1028 (but I'll assume 5 gallons)

I just guessed on the 25 pts/lb for wheat, but the point I am trying to make is that final gravity isn't overly sensitive to the wheat extraction efficiency. If the wheat gave you 0, then  $115/4$  is 1029 and  $115/5$  is 1023. So I think something else is wrong besides your mash if the gravity was 1015. Perhaps the wort was not uniform and you took a gravity reading from the top.

2) Another thing you should check is the mineral content and pH of your water. My water is extremely soft, and I added a small amount of

gypsum (about 1 tsp/gallon, I think). My mash pH was 4.9, which is below the range usually quoted. Next time I won't add gypsum until taking a pH reading. If your water has bicarbonate hardness, though, your mash pH may have been too high.

3) I would recommend that you try another partial mash and plan it so that it will come out reasonably if your extraction rate is anywhere between 0 pts/lb/gal and 30 pts/lb/gal. A generic ale recipe with 6 lbs of extract, 1 lb of crystal, and trying to mash 2 lbs of pale malt, with the hopping rate adjusted for 15 pts/lb/gal extraction will give you something that will be good no matter what your extraction rate is, and you can then not worry while mashing. My first partial mash was like this and it is one of the best beers I've made (until the next one, of course :-).

When I take a sample to measure the OG, I try to do so after agitating and aerating the cooled wort. I then place the sample in a clean small glass, and either dribble a small amount of the yeast starter into it, or have already added yeast before aeration/agitation. I then cover the glass with plastic wrap, and taste it after 4 or 5 days. I am quite careless with sanitation of the sample, and view it as an 'early-warning' system --- if that sample tastes infected after a few days, I'll try harder on other things, with any luck before I lose a batch.

Date: Wed, 23 Sep 92 10:44 CDT  
From: korz@iepubj.att.com  
Subject: Dry vs Wyeast

I think Russ makes a good point:

> The real topic is why Wyeast fermented beer might seem "watery" to  
> someone used to dry yeast ferments. I feel the reason is that the dry  
yeast  
> produces many of the components usually considered "harsh" - higher  
alcohols,  
> etc. The Wyeast-ferments produce less, leaving a cleaner, smoother brew  
(less  
> harsh). This smoothness can be perceived as "watery" when one is used  
to the  
> "bite" of the harsh components.

I think this may be a very valid difference between dry and liquid  
yeasts.

Perhaps the small numbers of wild yeasts present in dry yeast packets,  
produce some added complexity -- the bacterial problems I've encountered  
with dry yeasts keep me from going back, though. Flavor preferences \*  
are\*  
very dependent on what one is used to and this is why it's important to  
keep an open mind and keep tasting -- especially other brewer's homebrews  
-- they tend to be farther "off the beaten path."

By the way, I recently tried a batch made by a friend from a Cooper's  
Real Ale Kit with the dry yeast included. Excellent beer! I wonder if  
they sell the yeast that comes with the Cooper's kits separately --  
it seems to be a good one, at least in terms of flavor cleanliness. I've  
got no data on bacterial counts for it, however.

Al.

From: korz@iepubj.att.com  
Subject: London Ale Yeast

Mark asks about the attenuation of Wyeast London Ale yeast (#1028):  
>6.6#'s dark extract, 2 #'s brown sugar, and 1/2 #  
>crystal. I had an OG of 1.058, which seemed pretty  
>good. But I had an FG of 1.008 which seemed way too  
>low.

I agree it's too low. What you got is  $1 - (0.008/0.058) = 0.86 = 86\%$  attenuation. That's too much attenuation compared to what I've been getting with #1028, namely 65% to 67%. The brown sugar is roughly 95% fermentable, so it's bringing down your FG, but IMHO, not all the way to 1.008. Perhaps it's an infection problem. I've found that dry yeast starts about twice as fast as Wyeast and thus the sanitation techniques that worked for dry yeast may be not good enough for Wyeast. Re-evaluate your techniques and spruce-up the weak links. Using a starter will shorten lag time and thus may give the yeast enough of an advantage on the bacteria to make them insignificant.

From: Alan\_D.\_Thomson.LAX1B@xerox.com  
Subject: Hydrometers

Maltose-mates,

After about two years of brewing, I've decided to go all grain. The problem is that I have a vision problem making it VERY hard to read my (yet unused) hydrometer. While brewing extracts, this has not been much of a problem (in fact no problem at all), but what I've read about all grain brewin', it's necessary to read the big H (with very small lettering) to determine when the runoffs SG has dropped to a cretin point. Now to my point: How can I get an SG reading without "reading" a hydrometer?

Now, I can't be the only HBDer in the dark?  
AT

PS: Just to shed some light on the subject, I do have some vision (enough to get myself in trouble with C). But, not enough to read small print (phone books, newspapers, boring manuals, etc...)

Date: Wed, 23 Sep 1992 13:21 EDT  
From: HULTINP@QUCDN.QueensU.CA  
Subject: Invert Sugar and other stuff

Hi there, this is my first posting to HBD. I am an all-mash homebrewer with about 7 years experience. My stuff comes out under the aegis of the "Brown Mouse Brewery" (strictly in fun!).

Anyhow, in HBD #974, Bart Lipkens asks about INVERT SUGAR. Invert sugar is simply a mixture of glucose and fructose resulting from the hydrolysis of sucrose aka cane sugar aka table sugar. It is sometimes known as "high fructose corn sugar". A cheap and available substitute therefore is simply the ordinary corn sugar sold in homebrew stores, although invert sugar is somewhat sweeter. Invert sugar is NOT the same as table sugar, as a result of the hydrolysis step.

Also in HBD #974, Peter Nesbitt asks about plastic carboys. I used plastic for several years with success, but discovered a big problem which has caused me to abandon this material. Plastic can be easily scratched during cleaning, and once scratched, can be next to impossible to sterilize due to bacteria getting hidden in deep grooves. I spent quite a while trying to locate the source of off flavours in a year-long series of brews, until I ditched the carboys and got glass ones. Stick to glass, the higher cost initially is worth the saved anguish of spoiled brew!

Finally, Josh Grosse told about using a pump to recirculate during mashing. What sort of pump was this, and how did you protect it from clogging, and how was it cleaned for use?

All the best to all out there. Phil Hultin.

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Solder

I have recently checked this out in some detail so I will offer some advice.

Use a plumbing grade solder that has some silver in it (often called silver bearing). All modern plumbing solder is lead free, the make up for silver bearing solder is:

- 90% Tin
- 5% Silver
- 5% Antimony

This type of solder is approved of use in drinking water systems both hot and cold and should safe in any brew use. In order to solder with this you have to make sure everything is very clean and you must use an approved flux. The flux but me designed for use with water pipe so it will wash away with water. You can get all this stuff for a plumbing supply store.

If the make up of the solder is not printed on the package ask for a material safety sheet. These are required for most industrial materials.

Hope this helps,

Tom Feller

Subject: Seattle Info, 6 Month Primary

Brew Brothers and Sisters,

I'll be travelling to the Seattle area for a wedding at the end of Oct. I used to live there (Olympia), but that was 6 years ago and I'm sure things have changed.

Could someone post here or e-mail to me directly a listing with all of the must see/go to Brewpubs/Micros in the Sea-Tac/Olympia area. I would greatly appreciate it. Thanks in advance.

Wheat Beer with six(6) month Primary update:

This is a follow up to a post I had a couple of issues ago where I told yawl about a wheat beer I brewed that had been in the primary for 6 months. Well I bottled a case worth (~2.25 gals.) and used the rest for fertilizer (as promised).

Believe it or not, it is not too bad...The FG was 1.004 (OG 1.048) which is way too low, but overall it tasted like a wheat beer. I only siphoned out the top half of the carboy, maybe that had something to do with it ??? I was really expecting some pretty nasty stuff. Anyone out there with a similar experience???

Date: Wed, 23 Sep 92 15:30:44 pdt  
From: Brian Davis <brian%mbf.uucp@ics.uci.edu>  
Subject: Thanks for the importing info

I'd like to thank all of you who replied to my request for info on bringing beer home from Belgium. I didn't have nearly as much time in Belgium as I thought I would, so I didn't have a chance to tour any breweries or try any bars.

But I did manage to bring back 13 liters of wonderful fluids. I had hoped for more. But I was traveling by train instead of car, so I couldn't buy more than I could carry. The customs guy at LAX raised his eyebrows when I told him how much beer I had, but he waved me through.

When I started buying this stuff I got carried away and started picking up any bottle within reach. ( It was a wonderful feeling! ) I'm going to need some help figuring out what some of this stuff is.

What I've got is:

Chimay blue label, '91 and '92 ( couldn't buy only lambics! )  
F. Boon Kriek Marriage Parfait  
F. Boon Lambic Marriage Parfait  
Cantillion Kriek  
Cantillion Gueze  
Cantillion Rose de Gambrinus  
Cantillion Gueze Vigneronne ( OK, I figured out what this was, lambic with raisins. But I've never seen a sensory profile for this stuff. What should I expect? )  
\*\*\* Cantillion Bruocsella 1900 ( label says "old lambic", cork says 1992 )  
\*\*\* Cantillion Brabantiae

So, what are these last two?  
How long are these beers aged before they leave the brewery?

To my questions, C.R. Saikley said:  
>The best place I found to purchase beer for carry-out is in Brussels.  
>It's called Biers Artisinals, and has a huge selection of beers and glassware. I don't have the address handy, but can email it if desired.  
>If you go there, talk to the proprietor, Nasser Ektaferi. Nasser is full of info about the Belgian beer scene, and enjoys meeting beer freaks from other parts of the world. His recommendations were excellent, and as I was leaving his store, he gave me a couple more bottles of his favorites. Try doing that in the states!

This was indeed the Mecca of the Belgian beer scene. I talked to a man who seemed to be the proprietor. I didn't get his name, but the sig on the receipt doesn't look at all like Nasser. Whoever it was had some very good news. He

said that he was going to be in Los Angeles next week in order to work on opening a branch of Biers Artisinals there!! He was shaking a stack of federal paper work at me, and questioning me about why Americans are so stupid that they have to have warning labels on beer telling you that it will get you drunk. Just wait until he sees the paper work he'll have to do for California.

He did give me a free bottle of some stuff named Delerium Tremens. Nasty kick in that bottle -- very alcoholic. They have cute t-shirts and glasses with their pink elephant logo.

And later CR said:

>A couple of folks have requested the address of Biers Artisanales in  
>Brussels, so here it is.  
>  
> Waverse Steenweg 174  
> 1050 Brussels  
> Tel 02/512.17.88  
>  
>The nearest subway stop is St. Gilles

Of course being a bilingual country everything in Belgium has two names. The name of the street as it appears on their letterhead, the street signs and the Michelin map is Chaussee de Wavre.

If your travel companion doesn't want to go to Belgium just to drink beer, don't despair. When in Paris look up the Taverne de la Biere at 15 rue de Dunkerque. They are conveniently located across the street from Gare d'Nord. They have 109 beers from Belgium alone! ( 103 bottled, 6 on tap ) If you're really homesick, they even have Michelob for 38 Fr per bottle. I spent four evenings in this place, having about four beers per night. Not only was the beer always served in the proper glass style, the glass almost always had the brewer's logo on it. Their glassware storage room must be HUGE!

Subject: Competition Level

In HBD # 975, Al K. makes some good points about the merits of entering competitions. There was one point, however, that went off like a landmine in my mind when I read it.

>Note that you  
>don't need to win 1st, 2nd or 3rd at the Nationals to win something --  
if  
>you brew a beer that doesn't have an infection, you will probably get at  
>least a Bronze Certificate no matter what category you enter your beer  
in  
>- -- call it a pat-on-the-back.

This will vary considerably depending on your location, size of competition, ability of other brewers in your area, etc. If you live in CA, this is definitely not true. Larger competitions generally have preliminaries, and infected brews don't make the cut. As a judge, it's not uncommon to be faced with 12 Pale Ales that are all free of infection. I've tasted many a good brew that finished 4th, 5th, 6th....

The overall quality of homebrewed beers has improved drastically over the last few years, which is a truly wonderful trend. Having a tougher time winning awards seems like a small price to pay.

Subject: archive questions

Hello,

I have just been looking through the archive for the homebrew digest. I found some files titled homebrewstax.sit.hqx. Are these files for the Macintosh? If yes, are they for HyperCard? What do they contain? How do I download them?(I tried downloading them using FTP binary to get them to the VAX and used Zmodem to get them to my Mac, then used Stuffit Classic to de'binhex them and unstuff them, but it did not work, the machine got caught in a loop)I guess all I want to know is: What are these files and how do I get them? Is there a list of abstracts for the entries in the archive?

How do I use the archive?

Thanks to all those who reply.

>From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>

>However, the particles in the MaltMill(tm) crush were about twice as large (in "width", so 8 times the volume).

First of all, feedback from such comparisons is not only useful but hard to come by. The only other input was from George Fix who said he saw no such difference BUT he had an adjustable mill and this might have made a difference.

Having said that, I am not surprised that there is a difference in the largest particle size for the following reason:

Proper commercial mills use multiple sets of rollers with progressively closer spacing and screens to sort out anything that has not gone through the last set of rollers. The result is that largest particles will not exceed the narrowest spacing. They also cost many thousands of dollars.

On a mill with a single set of rollers, a compromise is necessary. If too close, the grain will not be grabbed and the starting torque is excessive.

If too far apart, the grain is not properly crushed. With the optimum spacing, a reasonable approximation of what comes out of an expensive commercial mill can be achieved. This will also vary slightly with different types of grain.

> Whether this makes a real difference, I am not competent to say.

I guess that is the real question and to find out, I simulated multiple rollers on my last batch. I ran the grain through at a wide spacing and again at the narrowest spacing used on a commercial mill. The extract yield was no different from previous batches run through with the standard spacing.

.....

BTW, just for the record, the review in Zymurgy incorrectly states that the MALTMILL rollers are stainless steel. They are cold rolled steel as the cost of ss rollers would exceed the selling price of the mill.

From: gjfix@utam.uta.edu (George J Fix)  
Subject: Stout from Pilsner Malt???  
Subject: Yummy Malt Flavor

I somehow missed Joseph Hall's original post concerning beers with a very high malt profile. The following was sent to him via private e-mail, but it bounced.

Clearly the malt types used is a matter of the utmost practical import. However, I have found that to get a very high malt flavor the sparge must be omitted as well. This is an expensive way to brew since the amount of grains needed must be increased by a factor  $\sim 4/3$ . Nevertheless, some of the world's great ales and lagers have been brewed this way, and I have found it works in homebrewing as well for special beers. Clearly this is not the way to brew our standard beers.

The following is offered as an illustration. You clearly may want to modify things to suit your environment. The control batch is more or less my standard procedure, and the experimental batch is the no sparge version. A three step infusion (135F, 152F, and 162F) was used for both along with a 1 1/2 hr. boil. Hopping is according to your preferences, but I have found for these beers more is better than less.

#### CONTROL BATCH

Brew Size = 50 liters (13.3 gals.)  
Grain Bill = 11.5 kg. pale malt (25.3 lbs.), 1 kg. crystal (1 kg.)  
Mash Water = 32 liters (8.5 gals.)  
Sparge Water = 32 liters (8.5 gals.)  
Vol. at the Start of Boil = 56 liters (14.8 gals.)  
Starting Gravity = 1.060 (15 deg. Plato)

#### EXPERIMENTAL BATCH

Brew Size = 50 liters (13.3 gals.)  
Grain Bill = 16.5 kg. pale malt (33.75 lbs.), 1.25 kg. crystal (3 lbs.)  
Mash Water = 44 liters (11.5 gals.)  
Water Directly Added to Kettle = 20 liters (5 gals.)  
Vol. at the Start of Boil = 56 liters (14.8 gals.)  
Starting Gravity = 1.060 (15 deg. Plato)

Note that the mash thickness is just about the same in both batches. In the experimental batch the extra water not used in the mash is directly added to the kettle.

Note: If you have the extra vessels, sparge, boil, and then pasteurize the dilute wort that normally be left in the grains in the experimental batch. I have found it useful for yeast storage and yeast propagation.

Subject: Hops as preservatives

I love spicy food, and wish to do more experimentation with using herbs OTHER than hops for flavor and aroma. I have had some excellent experiments with coriander, cardamon, fennel, and licorice. My question is, how much hops would be recommended as preservative?

Do hops need a long boil for the preservative, or do the later additions help as well?

BTW: A wide variety of herbs will provide bittering if boiled for an hour. There is such potential for a homebrewer to explore here! I'd just like some guidelines for preserving my stability.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: RE: headaches

There are several causes for headaches, none of which are specific to homebrews, though some homebrews can have these causes. I have suffered most of my life from severe migraine headaches. Many people are vulnerable to "triggers" for headaches which may be associated with food or drink: 1) low level allergic reactions; 2) specific allergic or toxic reactions.

Low level allergic reactions are very common and also very hard to pin down. They are typified by a (2-12 hour) delay between the allergen and the headaches.

The specific reactions (these are the ones that I suffer from) are almost instantaneous. I have reactions to many higher alcohols and aldehydes, (paints, solvents, diesel oil and exhaust, cheap perfumes) and have had this reaction from some beers (both commercial and homebrew). For this reason, I use blowoff for my own beers, and have never had a reaction to them. The homebrews that have given me headaches were all fermented in open primaries.

Many of the mega-brew otter-water brands will give me a headache, so I feel safer with micros and homebrews. This makes me wonder if the use of raw (non-malted) grains may produce more higher alcohols. I know that many grain distillers intentionally produce fusel oils as a commercial byproduct of rapid fermentation.

From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)  
Subject: BOS Mead Judging at the Nationals

There has recently been a discussion in the HBD about the BOS Mead Judging at the Nationals. Let me summarize with some excerpts:

Micah Millspaw wrote:

> Also I question whether this mead won Byron that prize,  
> or he won it for some other reason, known only to the AHA.

Geoff Reeves responded:

> Whatever other complaints one might have about the AHA, how it is run,  
> or how it handles various activities, the judgments are run as fairly  
> as possible. [...]  
> Furthermore a friend of mine (and member of our club), Gordon Olson,  
> judged the meads in the finals. He was once meadmaker of the year  
> and knows his meads. Not only did he come back raving about this mead  
> but he would never take part in any 'fixing' of the competition.

Then, Tom Altenbach said:

> Here are the facts. Immediately after the best of show (3rd round) mead  
> judging in Milwaukee, I had a conversation with one of the judges,  
> Brian North, who told me that there had been a "problem" with the mead  
> judging from the second round. We didn't get into the details of what  
> the problem was. However, the 3rd round judges took the top 3 meads  
> from each class and REJUDGED them all, instead of just picking between  
> the 1st place winners to decide best of show. Brian told me that this  
> resulted in a switch of the 1st and 3rd place meads in one of the  
> classes. Examination of the returned scoresheets shows that Micah's  
> mead was judged 1st in his class by the second round panel, and his  
> scores were higher than those given to Byron's mead. [...]  
>  
> It would be nice to hear first hand from the judges involved and the  
> competition director, to understand their reasons for these actions.

Well, I thought that things should be clarified a bit, so I sent complete copies of all the postings to Gordon Olson, one of the BOS judges and a member of our local homebrew club (Yea HillHoppers!). He wasn't able to post directly to the HBD, so I'm including his posting for him.

Mike Hall  
hall@lanl.gov

---

Gordon Olson responds:

This is my first posting to the HBD, so I hope it gets there OK.

In response to HBD 970 and 971, I was one of the mead judges at the AHA National Competition held in Milwaukee. My opening remark is to remind everyone that until the winners were announced, none of the judges knew who brewed which mead. We judged each mead solely on its own merit.

In the second round I judged traditional meads. We had many excellent brews, with four of them getting more than 40 points for an average score. One mead was made from wild honey and became

controversial. I thought it was too stongly flavored and too wild tasting, almost medicinal. Another judge thought that it was wonderfully complex and flowery. The one mead we all agreed on was a simple mead that was clean and well balanced. It was assigned first place. The wild honey mead was given second place as a compromise. Third was given to a sparkling champagne-style mead that was deemed to be perhaps too appley in its nose.

Dave Welker, the competition organizer, had been called in to give his advice on the discussion of the wild honey mead. He carefully did not express his opinion, but encouraged us to reach a compromise. Later Dave asked two of us who judged the traditional meads and two from the non-traditional table to get together the next day to judge best of show.

Probably due to the controversy about the wild honey mead, Dave brought the top three finishers from each category to the BOS judging. This surprised all of us, but we said: Why not, let's taste six good meads instead of two. We quickly found that the melomels and metheglins this year were not as good as the traditional entries. To my surprise, the mead we had placed first the day before, now tasted more mediocre than I had remembered and the other judges quickly set it aside as good but not great. The other judge from the traditional category did not recognize it as the same mead. It appears that there was significant bottle-to-bottle variation! Which bottle should be judged? The decision as to what to do was not lightly made. We decided that the four assembled judges were the best qualified, unbiased (we had no entries of our own, of course) judges available and we had to judge the merits of the mead in the bottles in front of us.

Then the discussion quickly narrowed down to the merits of the wild honey versus the sparkling champagne-style mead. We split two against two on which was best. After much discussion, the sparkling mead was given a very narrow victory.

With that done, the question arose as to what to do about the previous day's judging and results. It was decided to make the second round consistent with the BOS judging. I modified my previous day's scores by one point on one sheet and by two points on another sheet. The scores were so close that that was all that was required to give numerical victory to the sparkling mead.

So the "problem" that Brian North was referring to was what to do when there is significant variation between the bottles that are judged. Another "problem" was what to do when an unusual mead with wild honey shows up in the competition.

I have judged best-of-show at our state fair competitions. None of them were as tough as the AHA mead BOS this year. Be assured that the judges do not take their jobs lightly and the judging is truly a "blind" tasting.

I hope that this message clarifies what happened.

Two years ago my sack mead was first place in the traditional category, but I did not make it as Mead Maker of the Year. Next year, I want to be winning BOS rather than judging it.

Gordon Olson

>Re-evaluate your techniques and spruce-up the weak links. Using a  
>starter will shorten lag time and thus may give the yeast enough of an  
>advantage on the bacteria to make them insignificant.  
>  
>Al.

Interesting, I just finished a batch of beer where I used Wyeast #1028  
and also  
came up with about the same results. I have been using Wyeast for  
sometime now  
and am very cautious about bacterial infection. I use a starter of about  
500ml  
and have activity within the first eight hours(probably less time, but  
after  
all the homebrew that was consumed during brewtime it takes me about  
eighth  
hours to get going ;-). Anyway, the last batch was a maple ale (turned  
out real  
good, I will post the recipe later). The main ingredients where:

5lbs. Amber Malt Syrup  
0.5lbs. Scottish Crystal Malt  
0.5lbs. Wheat Malt  
1 Qt. Dark Maple Syrup(the pure, expensive stuff)

OG of 1.054  
FG of 1.008

By the figures given above I get  $1 - (0.008/0.054) = .851 = 85\%$ . Well I  
wonder if  
anyone else is getting an attenuation with #1028 that is equally as low?  
Anyway  
my Maple Ale came good, but a little dry, could have had a little more  
sweetness to it.

From: Dave Coombs <coombs@cme.nist.gov>  
Subject: Re: garden pests (was: Another hop harvest data point)

Scott Barrett has pests in his hops.

I'm not sure what the green worm is, but when I find that sort of thing in my garden, I just pick it off the plants and destroy it.

The mystery pest that munches the lower leaves may be slugs. I never had big slug problems in Rochester NY, but since I moved to the Washington DC area, I've become much better acquainted with them. If you don't see the varmint in daylight, try looking a couple hours after sunset. If there are slugs, I'd expect to see them crawling on the leaves and the ground nearby. If you've had a hard frost (and you just did, right?) I don't know if you'll be able to see any more this year.

There are several common methods for controlling slugs (ie, capturing and indisposing them). I have always used the passive method of laying out a shallow pan of beer into which the creatures crawl. They subsequently fail to crawl out. ("Help! I've fallen into a vat of beer, and I can't get out!") However, I discovered one evening that 90% of my slugs were ignoring the beer (maybe I shouldn't have bought the cheapest beer I could find for them...) and were munching away on my green bean plants. So I went out early one overcast morning, rolled up my sleeves, and picked them off the plants and soil. I pitched them in the handy beer receptacles to drown. (Good luck washing the slime off your fingers!) Another common method is to lay a shingle on the ground near the crop. Slugs are said to crawl under them to hide. Simply check these traps in the morning and destroy the pests. I haven't tried this yet.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Yeast culturing question

I streaked out the dregs from a batch that I bottled over a year ago.

One of the `plates' had a thin grey `fog' on it and five colonies of yeast alone in the corner (it smelled marvelous).

[The other `plates' had only grey-green or black beasts on them, my kitchen isn't as clean as I'd like].

I picked the three colonies furthest from the grey stuff and put them in ~2oz of sterile unhopped wort (pressure cooked, last spring), put a trap on it and stuck it in the corner of the heated waterbed (~83F).

Bubble, bubble, bubble.

A day or so later I added enough sterile unhopped wort to double the volume.

Bubble, bubble, bubble.

A day or so after that, the wort began to clear, so I moved the whole meghilla (sp?) to a sanitized bottle and doubled the volume again with sterile unhopped wort. I tasted the remains in the first bottle, no `off' flavors but very estery. (big surprise! esters at 83F! :)

Bubble, bubble, bubble.

I now have ~10oz of yeasty wort that I'd like to use as a starter for a three gallon batch, my first since January (Oy! such busyness!).

\*\*\*\*\*

THE QUESTION:

How safe am I in assuming that there's nothing living in there but yeast?

\*\*\*\*\*

This yeast was originally cultured from a bottle of Sierra Nevada Pale Ale. The resulting beer was bottled early last August. This last spring I discovered that a few bottles had been left in a cooler in the (separate and unheated) garage over the (New England) winter. I brought the bottles in the house where they sat in a dark cupboard through the summer (some got put in the fridge). The beer's still good. I figure that the yeast that I've got now is some tough stuff.

It might even make good beer.

Carl West

When I stop learning, bury me.

From: trush@mhc.mtholyoke.edu (Thomas P. Rush)  
Subject: Collecting Bottles

I hope the following is helpful to anyone in choosing bottles,  
I have taught myself thru trial and error.

1. Avoid using twist-off cap or one filling bottles they're not as sturdy as a true "bar bottle" which is returned, washed, and reused. I've had the one-shot returnables chip while washing and capping.
2. In my state (Massachusetts) all bottles are returned for deposit. A true bar bottle is heavier than a one time bottle, its packed in a heavy cardboard 24b. case and comes in 12 or 16oz.-I prefer the 16oz., you pour once off the yeast sediment, there is less air space ounce for ounce in the neck--it just seems to have a better quality coming out of a pint bottle.
3. They're difficult to get UNLESS you are willing to do the following. A. Find a large package store, they should have stacks of FILLED cases of bar bottles. B. Ask permission of the manager to pick thru a certain brand of bottled bar bottles (never had a problem). C. Pick the newest, cleanest case, some can be very crummy. D. Pick over the best bottles from several cases, there is something about an old reused bar bottle with white rings and scratches that really turns me off and probably my guests. There are about 10% to 20% new bottles mixed into a case due to loss, breakage, etc. E. Return home and enjoy the commercial brew, some of the stuff isn't that bad-I think the fact that they are 16ozers and in glass makes a difference.

The fact its such a pain to gather good bottles is one reason I don't like to give away my beer. It breaks up full cases and nonbrewers treat them as throwaways as in, "Gosh, that was great beer--whadya mean where are the bottles?"

Good hunting,

Tom Rush

From: "JOSEPH V. GERMANI" <GERMANI%NSLVAX@Venus.YCC.Yale.Edu>  
Subject: Seattle beer--ah, heaven!

Greetings,

In response to Joel McCamley's request for info on Seattle drinking, let me refer you to HBD #894 in which Don Scheidt gave a great summary of places to visit. I was in Seattle last week and found that his advice was excellent. By the way, thanks Don, even though I wasn't the person who asked for the info originally.

Now let me add my own two cents. My two favorite places that Don mentioned are the Trolleyman Pub at the Red Hook Brewery, and the Big Time Brewpub. I had a chance to sample Red Hook's original ale (they had a \$1/pint special for their 10th anniversary) which seems to be infrequently brewed. It was a very interesting beer with lots of esters. I was a little confused until I found out that they use a Belgian yeast for it. And then there is Red Hook ESB, one of the best beers in the world, IMHO. Big Time has a rye beer they call a Hefe-ryezen that is wonderful. Both places have what I consider to be great atmospheres for drinking great beer. Pikes Place, a real micro micro, near the market of the same name, makes a very nice ale that you can sample just down the street at Liberty Malt (a fun brew supply store to visit) as well as at many local bars. Also of note are two porters that I had a chance to try: Night watch (not too sure of the name) was pleasantly nutty, and Blackhook (by Red Hook) was like a great cup of coffee. I also recommend anything by Grants, in Yakima, especially if you like hops. This is just a small sampling of the great beer in Seattle. I liked it so much that I'm on the verge of forgetting my PhD in physics and moving to Seattle to try to get a job at Red Hook or Big Time.

Enjoy,  
Joe

**Subject: Bronze Awards**

Oops! I guess I wasn't clear about the Bronze Certificates. What I was referring to was the AHA National Competition, in which, besides the 1st, 2nd and 3rd place, there are also Certificates given out for quality beers whether they placed or not. A score of 25-29 earns you a Bronze Certificate (they may be called "Awards" I don't recall), a score of 30-39 earns you a Silver and a score of 40-50, earns you a Gold. To restate my comment: if you brewed a infection-free weizen and entered it in the stout category, you probably would still get 25 points, a Bronze Certificate and a few comments like: "too bad you didn't enter this in the wheat beer category..."

Al.

Invert sugar can be simply described, I have been told, as the mirror  
image  
of a conventional cane sugar molecule, IE, laevo ( left-handed ) versus  
dextro ( right-handed ) structure.

All of the taste, allegedly, but none of the consequences, as the  
molecule  
does not 'fit' into reserved niches where normal sugars will, and passes  
out  
of the body without influencing tooth decay, obesity, or any other  
concerns.

It was first refined in the late 1940s, I believe, but - for obscure  
reasons  
associated with a supposed bad taste that was later found to be  
unduplicated  
by scientists reproducing the solution, decades later - it never made it  
to  
the market, until recently. ( My guess is that the sugar industry paid  
big  
bucks to suppress it. )

I'm wondering if the purpose of its addition to beer brewing is to  
sweeten the  
beer without providing sustenance for those little yeastie beasties ... I  
kind  
of prefer honey, myself, but I may give invert sugar a try, now.

> \*\*\* Cantillion Bruocsella 1900 ( label says "old lambic", cork says  
1992 )  
> \*\*\* Cantillion Brabantiae

>So, what are these last two?  
>How long are these beers aged before they leave the brewery?

The blue is my favorite from the Chimay family, nice choice. As much as I  
love Chimay, I've always felt that its flavors were somewhat in conflict.  
The  
carbonation is overdone, which detracts from the malty sweetness, which  
doesn't meld with the crazy yeasty by-products. If these flavors could be  
brought more into balance, what an exceptional beer would result!

My favorite Trappiste ale is Rochefort 10, which is somewhat rare, even  
in  
Belgium. Its carbonation is lighter and its flavors are generally more

harmonious. It still has flavor peaks which tug and pull at each other, but less so than Chimay. It's a shame that Rochefort will probably never be available in the US, and I'll probably never become a monk at Rochefort : -)  
Anybody out there know this beer??

>From the Cantillon clan, the Vigneronne is my favorite. As I've mentioned before, I've come around to believing that Cantillon brews lack balance and could be improved. They use more fruit than most (300g of cherries/liter of Kriek, FBoon uses 200g/l, Timmerman's 100g/l), yet the fruit is overwhelmed by the lambik hardness. In the Vigneronne, the fruit actually makes a sizable dent in the other flavors. JP Van Roy, the brewmaster there, told me that Vigneronne was made with white grapes. He mentioned nothing about raisins, but his English wasn't as developed as his beers, so it's possible that I misunderstood him.

The Bruocsella is a straight Lambik, not a Gueuze. Gueuze is a blend of Lambiks of different ages, which is refermented in the bottle ala Champagne. Bruocsella, whose name is Latin for Brussels, is an unblended, three year old Lambik. As such, it is often entirely lacking carbonation. Since it spent three years in a barrel, it's pretty well fermented out by bottling time. I did run across a sample with a slight sparkle, but this had been bottled in 1990. The 1992 on yours is the year it was bottled.

I'm less certain about the Brabantiae, but I believe that it's an unblended Lambik as well. Don't know what distinguishes Brabantiae from Bruocsella.

>This was indeed the Mecca of the Belgian beer scene. I talked to a man who >seemed to be the proprietor. I didn't get his name, but the sig on the receipt >doesn't look at all like Nasser. Whoever it was had some very good news. He >said that he was going to be in Los Angeles next week in order to work on >opening a branch of Biers Artisinals there!! He was shaking a stack of >federal paper work at me, and questioning me about why Americans are so stupid >that they have to have warning labels on beer telling you that it will get you >drunk. Just wait until he sees the paper work he'll have to do for California.

I'm sure that Nasser isn't the only one who runs the shop, especially since there are two shops. Their opening a branch in LA is great news. Any idea where in LA??

I have a friend here at work who clamis homebrew/microbrew always gives him headaches. He asked me about it and I have no clue. He didn't remember having headaches with authentic German beers so it can't be a problem with malt. I suspected he may have had trouble with one or two brewpubs and developed the idea that all good-tasting beer gave him headaches ;- ) I dismissed the whole thing until your post. Now I'm not so sure. Personally though, I've never had any problems with homebrew that I didn't have with the same consumption of commercial beer.

From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Yards of ale availability

Dave Gilbert <solomon!dave@yoda.eecs.wsu.edu> asks about the availability of yard ale glasses.

Mine was given to me as a gift, and was purchased near Albany at a Corning Glass factory outlet. They have other outlets, so if you have one near you it may be worth a visit. The package for mine has a \$30 price tag on it, but as my friend mentioned that it was a display model, i don't know if this was the store's regular price or its display model discount.

Nightwing Enterprises sells "Coachman's glasses" in three sizes; foot, half-yard, and yard. Each includes a stand (as does the corning glass) and "competition sets" are available (a double stand with two glasses). Each competition set is roughly half again the price of a single set. The price for a yard is \$69.95 plus s&h. I haven't tried nor seen these glasses, but they advertise in All About Beer and Zymurgy. Their phone number is 607-723-5886. Nightwing also sells a brush for cleaning the glass and a wooden cap to keep dust out. I'm contemplating getting the brush, which is \$5.

Incidentally, we measured my yard glass at three pints even. Nightwing claims its glass is forty ounces, which probably means they measure by filling to the lip (we allowed some room for a head/spillage prevention when we measured ours).

From: jdg@grex.ann-arbor.mi.us (Josh Grosse)  
Subject: Recirculating pump details

Earlier this week, I posted an article entitled "Incredible extraction rate" in which I described a pump that recirculates the mash from below the screen back up to the top of the mash. It was also used to recirculate the boiled wort to facilitate immersion chilling.

I received a number of requests for information about that pump. It's a Teel (sp?) brand pump, rated to 230 F, available from W.W. Grainger's catalog. It was not self-priming, but that didn't matter, as the pump was attached to the bottom of the tun or kettle, so it's gravity primed. We were able to detach it and move it to the kettle, as there were valves and standard union joints to facilitate this.

]dextro ( right-handed ) structure.
]
```

I feel that as a chemist I have to stop this one before it grows into another myth.

The first poster got it right. Invert sugar is the product of breaking apart sucrose into its two constituent parts, glucose and fructose, via a process called hydrolysis. Another issue is raised here, that of handedness or what is called chirality in chemistry. Sucrose does indeed have a handedness to it. Molecules that have this property also have the property of rotating plane polarised light (Polaroid lenses will polarise light into one plane by only letting that one through and this is why you get no transmission if you hold two such lenses in front of each other at the right rotation with respect to each other). The direction of rotation is not related in a simple way to the handedness of the molecule. Sucrose is dextrorotatory -it rotates light in a right handed screw direction. Dextrose is also dextrorotatory and fructose, also called levulose, is levorotatory - it rotates light in a left handed direction. Fructose rotates light to the left slightly more than dextrose does to the right, and the invert sugar mix is therefore slightly levorotatory as a result.

```
]All of the taste, allegedly, but none of the consequences, as the
molecule
```

]does not 'fit' into reserved niches where normal sugars will, and passes out  
]of the body without influencing tooth decay, obesity, or any other concerns.

I am sorry to have to say this, but this is utter nonsense. Sucrose is processed by your digestive system into glucose and fructose. Glucose is the fuel for all energy processes in the body, the only thing you brain actually uses as 'food' is glucose.

]It was first refined in the late 1940s, I believe, but - for obscure reasons  
]associated with a supposed bad taste that was later found to be unduplicated  
]by scientists reproducing the solution, decades later - it never made it to  
]the market, until recently. ( My guess is that the sugar industry paid big  
]bucks to suppress it. )

Here again, invert sugar has been know for a long time. It is actually slightly sweeter than cane sugar. It is used commercially in confections and brewing and processes that require retaining moisture.

]I'm wondering if the purpose of its addition to beer brewing is to sweeten the  
]beer without providing sustenance for those little yeastie beasties ...  
I kind  
]of prefer honey, myself, but I may give invert sugar a try, now.

<sig. del.>

If there are any questions as a result of this I will try to answer them.

From: BELLAGIO\_DAVID@Tandem.COM  
Subject: Cheaper Yards of Ale

Hold on! I too was yearning for those Yard glasses after seeing them in Denver for the first time. I noticed them in Zymurgy and other brew type catalogs for about \$49.00 for a half yard and more for yards. Then I went to the outlet mall in Gilroy California and ventured into the glass outlet store ( which is now being merged with the Corning outlet store ) and lo behold they had yards, half yards, and foots of Ale! The great thing is that the prices were \$29.00 for a yard, \$19.00 for a half yard, and \$11.00 for a foot! These are the exact same as the ones I've seen in the catalogs. I got a half yard which holds 32 oz to the brim. This is great for a big brew of 22 oz or 25 oz. I was told the yards hold 60 oz. If anyone wants the phone number to this store I have it at home. I don't think they mail order but maybe they can do something.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: help with glassware

Yep, you can use #800 wetordry, use it wet, (the dust would be bad to breath). This will leave you with a `ground glass' finish. Actually, depending on how much glass you wish to remove, you might want to start with some #400 or #600, then go to #800, then maybe even #1200 or #1600. If you have access to jewelry polishing equipment, you might be able to get it down to a smooth, shiny surface again. Watch out for heat buildup if you're using machines, it'll crack the glass. Lots o' work.

Good luck.

From: gummitch@techbook.com (Jeff Frane)  
Subject: Cooper's Extract & Yeast

Al Korzonas mentions good results from Cooper's kit yeast. I have to had my agreement. If I was absolutely unable to find a clean liquid yeast and had to use dry yeast, Cooper's is the only strain I'd risk. I made a couple of batches with it a few years ago (with two cans of Cooper's extract, no sugar, and some finishing hops) and made an amazingly good ale. I also had WYeast clean up the yeast and brewed with it as a pure culture and it was a bang-up strain. I think the primary brewing yeast is very vigorous and this makes up for the slight contamination (yes there was some).

From: oconnor@ccwf.cc.utexas.edu (donald oconnor)  
Subject: AHA mead competition

This is a commentary on the BOS judging at the AHA nationals in Milwaukee. I base my comments entirely on facts outlined in Friday's HBD by Gordon Olson (thru Michael Hall). Based on those facts and the Rules and Regulations governing the AHA competition, it is clear that the first and third place awards in the Traditional Mead category and the BOS award, Mead Maker of the Year, and perhaps top club award should all be changed.

First let me say that I know none of the principals involved personally. Neither Byron Burch, Micah Millspaw, Gordon Olson, David Welker, ... Nor do I question in any way the integrity or sincerity of any of the people involved. In fact, it is transparent by Gordon's post that he is conscientious, sincere, honest and well-intentioned. He should be respected and commended both for the integrity he brought to the competition as well as the candidness of his post.

However, the Rules and Regulations of the competition were not followed on the last day of judging and this directly affected the outcome in both the traditional mead class as well as BOS. The rules clearly state that the BOS judging will involve the 1st place winners from each class. A mistake was made, apparently by David Welker, in bringing the 1st, 2nd, 3rd place to the BOS judging. The judges then erred in judging the 6 meads although this is quite understandable considering the organizer presented them for judging. Finally, score sheets from the previous round were altered in order that the BOS judging appeared to be within the rules and regulations. In other words, the judges were aware of the fact that they could not award the BOS award to the 3rd place mead in a class.

These series of mistakes, however honest and well-meaning they were, have seriously diminished the integrity of the competition. Fortunately, I believe all of the data is available to correct these errors and restore the credibility of the competition. The rules and regulations were followed through the finals of each class judging. It is a simple matter to award the proper award to Micah Milspaw and Byron Burch based on those results. The BOS award should properly be awarded to either Micah's mead or the 1st place mead from the other category based on the scoresheets of the final day of judging as the rules clearly suggest. That is easily done if the AHA retains copies of the scoresheets. If the AHA does not retain the scoresheets, it is not which of those 2, and only those 2, should get BOS. I would suggest it be awarded jointly in that case. (i meant to say it is not CLEAR which of those, and only those 2 should get BOS). Finally, it is my understanding that the club competition was very close this year and i suspect that a proper amendment of the results inthe mead competition might well affect that as well.

I am not a judge nor a member of a club (except D.U.M.B., donalds united making beer) nor have i entered a competition for several years. But I do think competitions have a good deal of value for homebrewing, but that value is greatly diminished if the integrity of the competition is compromised as in this case. Hopefully, this will be rectified by the AHA in the near future.

Finally, I wish to emphasize once again that I do not believe for a second that Gordon Olson nor anyone else involved did anything other than make an HONEST mistake.

From: "Stephen Hansen" <hansen@gloworm.Stanford.EDU>  
Subject: Accessing the Homebrew Archives.

I apologize for the length of this but I think it's necessary given the number of people having problems accessing the archives. Besides, the length of the digests seems to have dropped a bit since the MALTMILL lottery debacle.

The Homebrew Archive at Sierra.Stanford.EDU has been very active of late. At the same time there have been a lot of errors reported when people try of access files incorrectly. To help those of you who have been having problems and to help keep my mailbox clean I thought I'd post a short tutorial. Following are instructions for accessing the archives either via ftp or via mail using the listserver. Appologies to those of you to whom this is old news, but we were all young once :-)

#### FTP Access:

This is the preferred method. Use your local ftp program to connect to Sierra.Stanford.EDU, do not use the telnet or rlogin programs. If your system can't resolve the name you can try using the IP address, 36.2.0.98, instead. Once connected to Sierra you log in as "anonymous" or "ftp", either will do. No password is required but tradition and courtesy says that you should type in your user id and hostname in place of the password (i.e. name@host).

Once logged in you connect to the homebrew directory.

```
cd pub/homebrew
```

The commands "dir" or "ls" will show you the files and directories there. Unless you know exactly what you want I recommend that you first retrieve the index of available files.

```
get index
```

Many of the files are compressed (these have a .Z suffix) and a few are PC or Macintosh binary executables. You will need to set the transfer mode to type binary BEFORE you get these files. You do this by typing "binary" to the ftp prompt.

```
binary
```

Since a binary transfer mode will work on text files as well, I generally make it a habit to set to binary mode first thing.

When retrieving files in a subdirectory you can either connect to the directory and then get the file or you can stay where you are and get the file by specifying the relative path name. The following are equivalent:

```
cd 1992    get 1992/9206.shar.Z  
get 9206.shar.Z
```

For those of you unfamiliar with Unix (tm) conventions, the parent directory is referred to at "..", so to move up to the parent directory you would type

```
cd ..
```

To make use of compressed (\*.Z files) or uuencoded (\*.uu or \*.uue) files you will need to have the uncompress or uudecode utilities on your system. C language versions of these utilities are available at Sierra in the pub/source directory.

#### Listserver Access:

A listserver is available for those of you without ftp access. The listserver looks for certain commands in the body of a mail message and mails help information or requested files back to the originator. The listserver software on Sierra is VERY picky about the format of its commands so you have to be careful.

The standard for internet text messages (rfc822 if you care) says that a mail message consists of several header lines (To:, From:, Subject:, etc.) separated from the message body by a blank line. The only line in the header that the listserver cares about is the From: or Reply-To: line, so the Subject: and other header lines are ignored.

The listserver expects that the body of the message contains only listserver requests. If it sees anything that it doesn't recognize it will generate an error message and stop processing the message at that point. Several people have mail utilities that generate special memo format lines at the top of the message body. These confuse the listserver and cause it to reject the message. Other people put one or more signature lines at the end of the message. Since these lines are at the end of the message they don't stop the listserver from successfully processing the requests but they will cause it to generate an error message (both to you and to me). To avoid this you should follow the convention that says that signature lines are preceded by a line beginning with two dashes (--).

Mail to the listserver should be sent to listserv@sierra.Stanford.EDU. If you haven't used the listserver before I recommend that you first ask for the help file. Send a message to the listserver consisting of the word help on a line by itself. To get a listing of the files available from the homebrew archive put the following on a line by itself.

```
index homebrew
```

The "get" command is used to get to have the listserver send you a copy of an archived file. The general format of the get command is

```
get <archive> <file>
```

The archive of the digests from November 1991 are stored in the file 9111.shar in the 1991 directory. To get this file send:

```
get homebrew 1991/9111.shar
```

The listserver will in some cases break files into pieces if they're larger than 100K. The index indicates when a file will be sent in more than one part.

The current month's digests are stored as individual files. They are stored under the homebrew-new archive so in order to get one of this month's digest before they're archived send:

```
get homebrew-new NNN
```

to get issue number NNN.

Here's an example of a request for the homebrew index file and a copy of the shar file containing the Digests from November 1991.

To: listserv@sierra.Stanford.EDU  
Subject: (not required)

index homebrew

get homebrew 1991/9111.shar

Subject: <topic>

I guess that there is a lot of interest in Maple Ale as I have had many messages asking for a post on the recipe. Anyway I just used a basic pale ale recipe and added the maple syrup. I decided to use Scottish crystal malt (I bought it from the Home Winemaking and Brewing shop in woodland hills, Ca.(home of the Maltose Falcons ;-)) because it had such a rich, thick, malty aroma. I think that this would make a good base for a christmas ale by adding some cara-pils(I think that a good christmas ale should be a little heavy in the mouth feel), and an assortment of various spices and orange peel. The recipe called for 5 lbs. of malt extract syrup. The reason for 5 lbs. not 6 was that I had used the other pound for priming of another batch and also in making starters for my yeast. Anyway here is the recipe:

#### Pale Maple Ale

6 gal. brewing water  
5 lbs. Malt Extract Syrup(Amber)  
0.5 lbs. Scottish Crystal Malt 80L  
0.5 lbs. Wheat Malt(dry extract)  
1 qt. Maple Syrup(Dark, Grade A)  
1 oz. English Goldings hops (5.2%) 60 min. boil  
0.5 oz." " " (5.2%) 30 min. boil  
0.5 oz." " " (5.2%) 10 min. boil/steep  
2 tsps. Irish Moss  
2 tsps. Gypsum  
1 pkg. Wyeast #1028 London Ale yeast

#### Procedure:

1. Prepared yeast per instructions on package. When yeast pkg. was swollen I added it to 500ml sterile starter.
2. I steeped the crack crystal malt in 2 qts. 150 F water for 30 min.(I put the pot in the 150 F preheated oven) Sparged the grain into the boiling pot with another 2 qts. of 170 degree water. Added enough water to bring volume in boiling pot to 5 gallons. Brought this to a boil.
3. Added Malt Extract syrup, Wheat malt, gypsum, and 1 oz. hops. Boiled for 30 min.
4. After 30 min. of boil, I added 1 qt. Maple syrup and 0.5 oz. hops. boiled for an additional 20 min.
5. At 50 min. mark of boil I added 2 tsps. Irish Moss and the last 0.5 oz. of hops. I let this boil for additional 10 min. then covered, turned of flame, and allow it to steep for 5 min.
6. Chilled, strained, and racked into primary fermenter. Pitch yeast.

SG 1.054  
OG 1.008

Notes:

The ale was in the primary fermenter for about 5 days(it had a head on it that was about 4 in. tall). Transferred to secondary and allowed to finish ferment (another 7 days). I used 1.5 cups Malt extract to prime.

I tried the ale after 5 days in the bottle and was extremely pleased with the brew. The only thing is that it is a little dry(lost some of it's sweetness(maybe another 0.5 lb. of crystal)). I will do this one again, but I think that I will use another yeast type (maybe Wyeast european ale #?).

(I hope this will be of some assistance. Sorry if I rambled on, but I think I broke my little toe this morning and the medication is taking its toll)

Subject: Imperial Stouts

>From time to time I go off on a tangent and brew nothing but one particular style of beer. I do this in the hopes of getting the style down cold through repetition and experimentation.

My latest style of study has been Imperial Stouts. I have been brewing this style all summer, ten batches all together. Talk about a beer out of season. Ahhh, drinking a full-bodied, high gravity beer in the heat of July (rawlp!).

Due to it's neutral qualities, I used Wyeast Chico ale yeast (#1056) for all batches. Onc interesting discovery is that reusing the yeast cake after a high gravity beer made the second beer exceptionally dry. In fact the beers using repitched yeast were so dry they were unpleasant and subsequently dumped.

Many interesting Imperial Stouts were produced. The one I liked the most had all the trappings of an Imperial Stout but without that expected alcoholic flavor. A Big Beer without the Burn. The alcoholic strength was present but the corresponding alcoholic flavor was masked by the "brick house" body. The beer was so thick it looked like 10-40w motor oil. Really.

#### Imperial Stout

5.5 lb Belgian Pale malt  
3.0 lb Dextrine malt  
3.0 lb Belgian Carapils  
2.0 lb Belgian Special-B  
1.0 lb Wheat malt  
1.0 lb Crystal malt (60L)  
1.0 lb Belgian Biscuit  
.75 lb Chocolate malt  
.75 lb Black Patent  
.50 lb Roasted Barley

2.0 lb Dark Brown Sugar  
2 Licorice sticks

1 oz 60 min Bullion (10.0%)  
1 oz 45 min Cascade (5.9%)  
1 oz 30 min BC Kent Goldings (4.9%)  
1 oz 15 min Fuggle (3.1%)  
1 oz 0 min Mount Hood (3.5%)

Mashed 1 hour at 160 F  
Collected 7.0 gallons, boiled down to 5.5 gallons.  
OG 1.092 FG 1.032  
Wyeast Chico ale yeast, 1 quart starter

Date: Mon, 28 Sep 92 08:50:43 CDT  
From: gjfix@utam.uta.edu (George J Fix)  
Subject: Yield3

I have got quite a bit of e-mail asking about the relationship between the yield formula in Dave Miller's book, and the calculations I used. The answer is that they are the same, and Balling should get credit for both.

Specific gravity (SG) is the ratio of the weight of a solution to the weight of an equal volume of water. Balling apparently wanted brewers to start measuring this, which of course can be done with a scale and graduated flasks. He understood he would run into resistance from practical brewers because the weight of wort comes not only from sugars, but other wort solids as well. He therefore launched into a lengthy empirical study, which led to the conclusion that the sugar fraction of wort (i.e., extract) can to a very high degree of accuracy be regarded as an equivalent amount of sucrose. This permitted him to construct his tables, and build his hydrometer relating % extract by weight (PE) to SG. Balling's measurements had minor errors due to his failure to tightly control temperature. Plato corrected these, and it is his values that modern extract tables and hydrometers are based.

Most hydrometers give both PE and SG. The term "Brix" is used on some, but this is the same as PE. My refractometer gives only PE, so I need the numerical tables to get SG. It should be noted that SG, unlike PE, varies with temperature. Thus, the SG-PE equivalence is valid only at the calibration cited on the hydrometer or table. Different tables and instruments use different calibration temperatures, and this will lead to slightly different numerical values.

The units involved tell the entire story about yield calculations. PE has the units of kg extract per 100 kg of wort (which of course is the same as lbs. of extract per 100 lbs. of wort). SG, on the other hand, is dimensionless. However, since 1 liter of water weighs 1 kilogram at the std. temp. (this is why metric units are so useful in brewing), the product

(1)  $PE * SG * 1.0$

gives the percent extract on the basis of volume; i.e., kgs. of extract per 100 liters (kg/hl). Thus, multiplying (1) by the volume in hectoliters

gives the no. of kg. of extract. That divided by the kgs. of grains used times 100 gives the yield. So you see, Balling did all the hard work!

I have also had some e-mail from brewers expressing concern about the low yields they are getting from their systems. I do not feel this is necessarily

a problem for I am aware of brewers consistently producing quality brews with yields well below 30/lb/gal. For example, Anchor uses a no sparge procedure with Old Foghorn, and get extremely poor yields. Conversely, I tasted beers from ill conceived high yield systems that had a very unpleasant grainy/husky astringency. On the other hand, whenever my yields drop much below normal levels, I usually have gotten some bad malt. In the final analysis, it seems that the malt character of the beers we make is the best guide to

determining if our yields are appropriate, be they low, medium, or high.

Date: Mon, 28 Sep 1992 10:13:50 -0400 (EDT)  
From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: 1056 re-use

Chris C. notice that batches made with Wyeast 1056 slurry got progressively drier, to the point of being too dry. I've noticed the same thing. 2 re-uses (3 batches total) is my limit; the 3rd batch comes out quite dry. It must be a good adapter to one's brewing conditions.

I have heard that it can be unstable (but it's a great yeast nonetheless)

.  
Is there a Wyeast strain that does not exhibit this behavior, or at least is not so quick about it?

And, wrt. aeration/oxygenation/oxidation of wort/beer: Aeration is the introduction of air into the wort/beer. This puts oxygen into the solution.

This can be a good thing or a bad thing, depending on when it happens. Aeration at post-boil/pre-ferment time is good ("oxygenation"), and aeration after ferment is bad (causes "oxidation").

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: RE: headaches (clarification)

In my earlier post, when I mentioned ketones, I was saying that ketones are ONE of the substances that gives me a headache from very light exposure (specifically lacquer and some paint fumes.) I don't know what it is in some beers, both commercial and homebrew, that gives me a headache. By analogy, higher alcohols (aka fusel oils) are similar and may be at the root of the problem. The beers that give me headaches sometimes have a sharper/harsher edge to the flavor. I think the mechanism is an allergy, rather than toxicity. Anybody in the medical community care to comment?

Paul ---- "But I'm feeling \*MUCH\* better now." :-)

From: "Jim N. Deakin" <J.Deakin@sheffield-city-poly.ac.uk>  
Subject: Invert sugar

According to the books I've seen, the 'inverting' of sucrose normally has to be done by an enzyme in the yeast (invertase or -ase, not sure which), so by pre-inverting the sugar you get the yeast off to a good start. It gives less lag time, and presumably the invert sugar would be used first, leaving those with more effect on flavour till later.  
Cheers!

From: djt2@po.CWRU.Edu (Dennis J. Templeton)  
Subject: HB headaches

I've been following the line on headaches recently, and here's my 2 pennies.

I think the line on "ketones" is off track... there are probably some ketones in beer, but at least the simpler ketones should be metabolized pretty well. Diabetics who have a crisis have lots of ketones in their system and I don't recall headaches as being a common complaint. On the other hand there are sometimes higher (more complex) organic compounds (e.g. fusel alcohols) that may have biological complications that vary depending on the individual.

On the third hand, there is a very well established phenomenon of headaches due to a compound called Tyramine. This is very often found in wine (particularly red) and affects only some individuals. It seems to be related to the process involved in migraine headaches. If your HB gives you a headache you might ask yourself.. does red wine too?

Actually, I can't recall if tyramine is commonly in beer. Anyone out there know?

By the way, I really believe that whatever may be in HB is likely to be in commercial full-bodied beers too. People are quick to suspect home-made stuff, but I'm equally suspicious of what's made in a factory. (How many roach parts are allowed per spoonful of Welch's grape jelly?) The obvious exception is an infected HB. If it tastes bad, don't drink it.

Disclaimer... while I am a physician, this is not my area of expertise.. I'm dredging memories from med school.

To: Homebrew Digest  
From: RIDGELY@CBER.CBER.FDA.GOV (Bill Ridgely)  
Subj: McAndrew's Scotch Ale

This is in response to Joseph Nathan Hall's request for a recipe for McAndrew's Scotch Ale. Actually, I had hoped someone else would respond to it. McAndrew's is an aberration among Scotch Wee Heavy Ales, and I'd be interested in a recipe as well. There don't appear to be too many people among the readership with expertise in the style, however, so I thought I'd help out as best I could.

BTW, McAndrew's is reviewed in the "Bottle 17, 1991" issue of World Beer Review and receives one of the highest ratings ever (5-stars). I'll condense & paraphrase some of that review here.

First, some brief background - McAndrew's (called Caledonian Strong Ale in Scotland) is brewed at the old Lorimer & Clark Brewery in Edinburgh using direct-fired, open coppers. The brewery is actually an operating museum. One of the coppers has been in continuous use since 1869, when the brewery first opened. Caledonian (as it has been called since 1987) is now one of the few independents operated in Scotland. It also brews a 70/- Heavy, a 80/- Export, an XXX Bitter, and a 1.042 OG Porter.

McAndrew's is brewed from highland pale malt (a strain called Golden Promise), crystal, amber, and small amounts of chocolate, black, and wheat malts. The hops are whole, compressed Fuggles and Kent Goldings. I have no details on the yeast used, and the beer is filtered & pasteurized so there's no chance of culturing it.

A brief profile is: OG 1.078 (7.6% alcohol vol); color bronze (much lighter than the typical 90/- Wee Heavy); aroma of fresh hops (also untypical of the style) but balanced by malt sweetness & some roastiness; body very full; palate sweet at the start but developing into a very rich balance of malt sweetness, roastiness, and intense, spicy (from the Goldings) hopiness. Finish is long and bitter.

If I were to attempt to brew this beer using a partial mash (my normal style of brewing), I would use about 2 lbs of English pale ale malt, about 1/2 lb of fairly light crystal malt (maybe 20 Lov) plus 1/2 lb of Victory malt or Belgian Biscuit malt (the closest things available to English Amber malt), 1/2 lb of wheat malt (for body & head retention. Carapils would accomplish the same result), and a small amount of Chocolate malt (maybe 1/4 lb or less) for the roastiness. I wouldn't use any black malt or roasted barley because of the darker color it would impart.

The remainder of the OG would be provided by about 6 lbs of pale dry extract (DME) and 1 lb of light brown sugar (for that treacle-like sweetness typical of Scotch Ales).

I would use about 1 1/2 to 2 ounces (depending on the alpha acid content) of a fairly high-alpha hop for bitterness (Northern Brewer is one of my favorites), then dry hop with about 1 1/2 ounces of Kent Goldings.

I'd use the Wyeast #1028 London Ale yeast on this one. For Scotch Ales, the Wyeast #1098 (Whitbread) is slightly less attenuative, but this beer is a bit drier than others typical of the style.

Remember, the above is purely conjectural. I haven't actually tried brewing this. If anyone attempts it, please post the results.

Slainte!

Subject: Altbier availability?

Our club runs an annual "Brewola" -- "everybody" brews a beer from the same recipe, then we taste and rate all of them. This year we chose Papazian's Osmosis Amoeba Alt as the recipe. Of course, club members are now wondering what an Alt "should" taste like. I am unable to find any commercial examples in the Ann Arbor (MI) area. There is a possibility I could get a friend to bring some from Chicago, if he knew where to get it. Or, I would be willing to reimburse expenses for someone to mail me a few bottles, for "analytical purposes" (check with me by e-mail before doing this, of course!) It is also possible that I could make a run to Toledo (Ohio) or Windsor (Canada).

According to Eckhart (sp?), Pinkus, Weihenstephan, and Widmer make Altbiers.

Subject: Sparging Questions

In #977 George Fix writes:

> Clearly the malt types used is a matter of the utmost practical import.  
> However, I have found that to get a very high malt flavor the sparge  
> must be omitted as well. This is an expensive way to brew since the  
amount  
> of grains needed must be increased by a factor  $\sim 4/3$ . Nevertheless, some  
of  
> the world's great ales and lagers have been brewed this way, and I have  
> found it works in homebrewing as well for special beers. Clearly this  
is  
> not the way to brew our standard beers.

As I am about to venture into all-grain brewing, I have been wondering  
about  
the absolute necessity of sparging. Since the purpose of sparging is to  
rinse the sweet wort from the grains why couldn't you just increase the  
amount of grains to get the same extraction rate without the sparge. Even  
assuming \$1.00/lb. of grain for a five gallon batch you would only spend  
2 to 3 dollars more to save an hour or two of time. For me, I would  
rather  
spend the extra money and eliminate the biggest pain-in-the-butt of going  
all-grain.

With George's comments above, I now must question whether sparging is  
just  
an economic issue. If eliminating the sparge creates a maltier brew, what  
is it about sparging that reduces maltiness? He states: "Clearly this is  
not the way to brew our standard beers." Why not? Does sparging  
inherently  
cast certain properties on the beer that unsparged beers won't have?

Subject: SECONDARY & AIRLOCK

I'm making my first attempt at a true lager brew, and racked to the secondary after two weeks of primary fermentation at 40 degrees F (a little long, I agree). After transferring to the secondary, I put the carboy in the fridge, and noticed that the fermentation lock was working in reverse for a short time, due to the temporary fact that the air trapped in the fermenter was warmer than the air in the fridge, and was contracting as it cooled. Is there a way to prevent the water from dribbling back in, other than temporarily using a blow-off tube for a few hours while the air cools?

Subject: Homebrew Headaches

Here is a story for which I have no explanation:

I brewed at a friend's house (casual friend) and fermented and bottled there.  
We each kept a case and I more-or-less forgot about it. I hadn't seen him for awhile when he came over and said he was moving out of the area and wanted to return a sixpack he never drank. It was covered with dust and who knows how it had been stored.

I was a little leery, but washend one off and put it in the fridge, then tasted it about a week later. It gave me a blinding headache. I went down and tasted one from my case stored in my basement and it tasted great--no unusual side effects. I tried another bottle, just half, from his six pack and had another bad headache.

Considering they were all brewed and bottled together, I have no idea why they ended up so different, or what would be wrong with these other bottles to taste about the same but give a very painful headache.

From: Peter Maxwell <peterm@hpdtlpm.ctgsc.hp.com>  
Subject: invert sugar

I came across the term while researching "golden syrup", a common item in England, New Zealand and Australia. Here is part of the text, which might help to work out what invert sugar is ....

I've seen reference to it (golden syrup) in an American book as "golden invert syrup", as one form of liquid sugar. At any rate, the sugars make up 74.4% by weight of the stuff. If this was in the form of sucrose alone, it would crystallize out, likewise if it were reducing sugars, glucose would crystallize. The proportion (1.75 reducing sugars to 1 of sucrose) produces a stable liquid. In the refining process, none of the syrups in process have a high enough reducing sugar content, so special batches of "invert syrup" are made (sucrose solution heated in acid environment -> equal quantities of glucose + fructose). This is added to other syrups to obtain the right proportions.

>From this invert sugar might be a fancy name for glucose.

Peter

**Subject: invert sugar**  
Subject: AHA mead competition  
Reply-To: glo@r.lanl.gov (Gordon L. Olson)

Unfortunately, it is now impossible to "correct" the results of the mead BOS as suggested by Donald Oconnor (oconnor@ccwf.cc.utexas.edu).

I have not read the "fine print" in the judging rules. What I do know is that best-of-show is not awarded to the highest scoring mead or beer. When comparing across styles, the point scales are quite useless. You must compare the meads or beers head-to-head. Which one is the best of its particular style? That does not resolve itself in points. The final round, BOS, judges do not fill out score sheets.

If an error was made, and I am not sure that an error was made, we can not now reconstruct the judging and compare mead A of one style to mead B of another style.

Gordon L. Olson

Subject: Beer news

The following article (slightly abridged) appeared in the Des Moines Register,  
Thursday, Sept. 24, 1992:

>>>Belly up to the bar, folks. Central Iowa has a brewery. After a few months of perfecting its brew, the Dallas County Brewing Co. in Adel started shipping "Old Depot" beer to local stores and restaurants last weekend. Kevin Rice, the brewery's president, says Old Depot is the first beer brewed in central Iowa since Des Moines' last brewery closed in 1917. The name comes from the nearby old Milwaulkee Railroad Depot, which will soon open as the Old Depot Restaurant and Pub. The brewery, once a glove factory, is located just south of the restaurant...on highway 6. ....Overseeing the yeasty operation is brew master Al Bush, who was previously with Buffalo Brewing Co. in Buffalo, N.Y. ....Rice, formerly a senior vice president at Heritage Communications, Inc., decided to open the brew pub and restaurant simply because "I like beer." It was while he was travelling in California for Heritage Cablevision that Rice discovered the microbrewery trend.... Iowa's first microbrewery, Millstream Brewing Co. of Amana, opened seven years ago. Since then a few other breweries or brew pubs...have opened. One brew pub, Fitzpatrick's Brewing Co., opened in September, 1990, in Iowa City. The other part of the Old Depot endeavor, the restaurant, is expected to open Oct. 5. Rice plans an ambitious menu that includes bison, venison, pheasant, rabbit, steaks, lamb flown in from New Zealand and an array of pasta and vegetarian dishes. ....Old Depot wil be available in four styles. [lager, ale, porter, and light.] <<<

An accompanying article highlights some information on Iowa breweries from a book called "The Breweries of Iowa," written by Randy Carlson (no publisher or ISBN given).

I've lived in Iowa for three years and have always thought it was a rather civilized place. Now with micros popping up hither and yon, I'm sure of it!

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>  
Subject: sugary question

I've been following the discussion on invert sugar with interest although a lot of the chemistry is lost on me. I ask the following in hopes of getting a less complicated answer: Anybody know anything about, or better yet used "demarara" (sp?) sugar? Is it really different from your garden variety "brown" sugar? Where does one get it? In what sorts of recipes does one use it? Thanks in advance for your wisdom.

Thanks in arrears, by the way, to all those who responded to my queries a couple of weeks ago. Lots of people suggested using marbles (easy to sanitize) as the means to sink a bag of hops for dry-hopping in the secondary, but lots of people also think pellet hops are as good or better, since they can actually provide a sort of fining action. The Listerman mash/sparge system gets mixed reviews.

Why not fill the fermentation lock with cheap, high proof voodka? It will not freeze in your fridge, and if some of it gets sucked back into the secondary, no big deal.

From: HULTINP@QUCDN.QueensU.CA  
Subject: Organic chemistry of Beer

A lot of talk lately about ketones etc etc. What are ketones? I am not sure that the chemical structure would be much use, but recall that the fermentation process produces a range of alcohols (hopefully mostly ethanol but some having longer carbon chains as well). In addition to this process, yeast contain various other enzymic systems, several of which can oxidize alcohols to compounds known as ketones and aldehydes. These are more or less toxic, and can result (just as can the higher alcohols) in headaches and hangovers etc etc. What to do about this? Use clean yeasts, keep fermentations cool (not cold, I just mean, not at summertime high temps either), and IMHO use a blow-by system in your primary fermenter to remove the crud. Most of this unwanted junk is less dense than water, and much of it is only somewhat soluble, so it tends to rise to the top amidst the froth, and can be blown over and out of your beer. BTW, even if you are carefully sealed up, and are sure that your beer is not "oxidized", you will still get some amount of oxidation processes going on. But this is minimal, and should not be harmful. Relax....

Finally, Thanks to Richard Childers in HBD #978. That makes two of us as publicly confessed chemists.

From: HULTINP@QUCDN.QueensU.CA  
Subject: Advice on a Tasting Method

Ok, first off, so I can't read email addresses before my first coffee.  
Thanks go to Dominic Ryan the chemist.:-)

In early November, I will be giving a class on "beer appreciation", in which I will be trying to highlight both what it is that makes a beer taste the way it does, and also , how our modern taste differs from those of the past.  
To do this, I am modifying a class I attended in Madison WI about 4 years ago, in which we took a totally beige commercial beer, and added to it hop teas, malt teas, salt, sugar etc etc, to see what happened to the taste as various flavours were added or augmented.  
I will be using as my base a version of a 16th century unhopped ale, brewed from Sir Kenelme Digby's "Closet...". The question for you all to opine on is: What is the best way to prepare extracts of various malts and grains so that addition of a small amount of the extract to a beer will more or less accurately reflect the flavour of that grain in an actual brew?

Reply by email or by posting as you wish. Thanks. Phil Hultin.

Date: Tue, 29 Sep 1992 06:46:44 PDT  
From: John\_D.\_Sullivan.wbst311@xerox.com  
Subject: all-grain

All Grain Brewing

I am a 2 year extract and adjunct brewer. I decided to try an all grain brew last Saturday because I can't seem to get the real malty flavor and nose with liquid or dry extract that Sam Adam's and many good beers have. Maybe I'm on the wrong track and need some kind of dry malting?

Anyway, I've got a couple of questions as I've never seen all-grain done (I relied on HBD and Charlie P.). My goal was to make a 3 gallon batch of Amazeing Pale Ale with 4 lb.pre-crushed 2-row Pale, .5 lb. crystal, .5 lb. cornstarch, gypsum and Irish moss.

I built the 2 bucket lauter tun and in the section on using one Charlie says to start out with water in it and add the mash, and while sparging always leave the water level above grain bed(unless I misunderstood something). But in the recipe that water isn't figured into the formula. So I skipped the extra water in the bucket. Also when I keep hearing about recirculating the sparge, I assume you mean to take the runoff out of the bottom bucket and run it back over the grain bed. I tried this 3 times but it was about the consistency of runny oatmeal and I kept getting a stuck sparge. I had to stir it gently to allow runoff but that was making the runoff very cloudy. I ended up running it thru over and over while cleaning up the bucket each time till it was clear. I did end up with a very good extraction rate.

After the boil I ran the wort thru my chiller, (hot wort running thru copper coils that are immersed in ice water, syphoned directly into carboy), I racked off cold break, and pitched Telford's dry yeast (sorry, liquiders, my taste buds and I have drawn our own conclusions) . 2 hours later I went down to check on it and it had 2 inches of krausen and bubbling madly! By last night(Monday)it had slowed to a crawl and hydrometer read 1.008. Tasted excellent. 650F fermentation temp, BTW.

Now to my questions(sorry about the long-windedness):

1) did I sparge right?or do you just let it sit there while it sloowly drips thru? or maybe the grain was crushed too finely?The top of the bag had lots of

chunks of husk, the bottom pretty floury.

2) does all-grain normally start and finish so quickly? It tasted very clean.

maybe the cornstarch kicked it into high gear?

3) is \$1.69/lb or \$6.95/ 5 lb way too much for grains? the whole and pre-crushed grains were the same price. I don't have a mill yet (maybe soon

Jack). I didn't seem to save any money.

4) do I ask too many questions? I'm hoping the tolerance level has gone up some lately.

Thanks alot for your patience and any replies.

John

From: tony@spss.com (Tony Babinec)  
Subject: alts--commercial comparisons and recipe ideas

My beer and brewing friends who have visited Dusseldorf came back raving about the alt beers. Unfortunately, it is difficult to suggest an appropriate commercial comparison, and in my humble opinion, this is one of the less well-understood styles in the homebrewing and beer-judging community.

In its loose form, an "alt" is a German beer brewed in the "old" style, namely, top-fermented. Alt beers can be found in different parts of Germany, but it is the Dusseldorfer alts that are most distinguished. To the best of my knowledge, none are available in the U.S.

Pinkus Alt is a good and interesting beer in its own right, but it does not typify the Dusseldorf alt style. Pinkus Alt uses a grain bill of 60% barley malt and 40% wheat malt, and also employs a lactic fermentation to give the beer a tart edge. Interestingly, Pinkus Weizen uses the reverse proportion of grains, namely 60% wheat malt and 40% barley malt, and is a good Bavarian Weizen style beer. By all means, taste them both side-by-side.

The Chicago Beer Society holds two blind beer tasting/dinners a year, and American alts have won them a number of times. Old Detroit, from the Detroit Brewing Company (?), is contract-brewed by Frankenmuth Brewing Company. I believe they won twice. Alaskan Amber, from Alaskan Brewing (?) and perhaps accessible to West Coasters, also won. Fred Eckhardt is a big fan of Widmer Alt, which I haven't tasted, but appears to be an excellent beer, if perhaps too hoppy for the style. Indianapolis Brewing has had a lot of success with its Dusseldorfer Ale, which I'm not sure is really a Dusseldorf Alt. The Free State Brewery in Lawrence, Kansas, brews an Amber Alt.

The Zymurgy style guidelines on Alts are:

SG 1.044 - 1.048  
IBUs 25 - 35  
Color 11 - 19

You should adhere to the suggested starting gravities--this is a 1040s beer. A slightly stronger alt, termed a "Sticke," is occasionally tapped and served to clientele lucky enough to be around when it is tapped. While the IBU range appears to allow some leeway, it has been my experience that beers hopped to the high end will be judged too hoppy. The same pattern seems to hold with color. Keeping in mind that a Bass Ale is a 10 and Michelob Dark a 17 in color, aim toward the lighter end of the color spectrum.

Grains and hops used should be German. Wyeast has two excellent yeasts from which to choose, namely #1007 "German ale" and #1338 "European ale." Of the two, as oft stated in HBD, #1338 produces a maltier, more complex-tasting beer. If at all possible, chill your fermenter at the end of primary fermentation to about 40 degrees F, then rack the beer to secondary and cold-condition the beer for a couple weeks. This is what the Germans do, and this practice is also recommended by Steve Daniel, who has won the Nationals numbers of times. The rationale for cold-conditioning is

to drop the yeast out, for the fruity-yeasty flavors found in English beers are not desired in Alts. Both of the above Wyeasts drop out well and you get a very bright, clear beer.

A good starting point for a recipe is George and Laurie Fix's "Vienna Mild," substituting an alt yeast for a lager yeast. Such a recipe for a 5-gallon batch might go something like this:

8 pounds pilsner malt (or 6 pounds light, unhopped dme)  
4 oz 10L crystal malt  
4 oz 60L crystal malt  
4 oz 120L crystal malt  
(assumes 75% extraction efficiency)

6 - 7 AAUs German hops (Hallertauer, Tettnang)

Wyeast 1338 or 1007

cold-conditioning in secondary

Alt grain bills can employ some wheat malt, so you might substitute a pound of wheat malt for a pound of pilsner malt.

If your club members are setting out to brew, by all means vary the hops, hop schedule, color malts, and yeast, and let us know how it turns out.

From: Gerald Andrew Winters <gerald@engin.umich.edu>  
Subject: Dormant yeast?

In HBD # 973 James W. Smith responds to the following question...

>> - When my fermentation is nearing completion, does the yeast go into a  
>> dormant state or just die?

>They go dormant. If you wait too long before priming you won't get  
>carbonation, because once the yeast go dormant, they need things that  
>finished beer lacks in order to wake back up. Carbonation is done by  
>the yeasties that haven't gone dormant yet at bottling time; there are  
>still a bunch of them in suspension even when the beer looks clear.

I'm wondering if the solution to my long standing problem lies in James's  
response. The problem I have is that it takes an exceptionally long time  
for my beers to reach a proper carbonation level. No way do my beers  
become properly carbonated after a month or so. I would say my beers  
need  
about four months or so. Sure, I use 3/4 cup corn sugar as many do. And,  
yes, I have tried different sources for the sugar in case of a bad batch  
or  
something. But my results have been uniform, regardless. What strikes  
me  
in contrast is something I recall reading in Papazian's TCJoHB. I  
believe  
he says that because of his busy schedule, many times he does not bottle  
until after 4-6 weeks settling time in the secondary. Indeed, I usually  
wait about this long. At this point fermentation has nearly ceased (1  
bubble  
> 3 min.). It seems to me that much of the yeast going dormant is a  
possible  
explanation for my problem. I should also mention that I use Wyeast  
liquid  
cultures and brew both lagers and ales.

So my question is, can someone provide a good rule of thumb as to when  
bottling should occur? And is my presumption correct that letting the  
beer sit too long in the secondary may cause sluggish carbonation later  
on.

From: Don.Veino@East.Sun.COM (Don Veino - Sun USOPS WSU New Products  
Introduction)  
**Subject: Moron Labels**

Hi All,

Just a little more on the labels subject...

A few folks asked about an easier way to get removeable labels  
for the body of a bottle... so, I took a walk down the hall to  
our supplies closet and came up with two suggestions:

- \* Post-it notes (pick your size - large for body, small for neck labels)
- \* Removeable address labels (Avery Mfg, Cat # S-6432, 3-up 4x2 in. was  
in stock here) or file folder labels

I personally use plain white paper (more environmentally friendly!)  
labels photocopied from a 3-up master. I made the labels go the full  
width (8.5 in) of the paper, so when cut and adhered to the bottle  
(white glue), they wrap \*\* all the way around \*\* and then stick to  
themselves. Never had a problem with them coming off until wanted, but  
easily done then. Recycles easily too!

>and do they do anything positive?

BDA is the political arm of the industrial brewers. They lobby for laws that promote the interests of large brewing companies, often at the expense of the smaller breweries. They also oppose all relegalization efforts for drugs other than alcohol, because they argue that it's not possible to use the currently-illegal drugs in a responsible manner. (Please let's not argue that last point on HBD. There are more appropriate places.) A more likely explanation is that they want to avoid any possible added competition for their markets.

Their one positive copntribution might be the "Party Smart" program, but that always seemed to me to be a marketing scam to sell more Bud Light.

I joined last year and learned all this from their own newsletters, and I have since let my membership expire.

hope this helps

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Yeast washing questions

I've heard tell of `washing' yeast with acid to kill off bacteria.

My questions for the microbiologists are:

What pH should this acid bath be?  
Is it important what acid is used?  
What is the procedure?

and my questions for the chemists are:

Using distilled water and, say, standard distilled white vinegar  
(what does 5% acidity mean anyway?), how would I mix up a bath of  
a particular pH? I have neither a pH meter nor pH papers to check it.

Carl

> aeration  
> after ferment is bad (causes "oxidation").

Also, aeration of hot wort (generally above 80F) results in oxidation which  
is also bad, even though it is post-boil/pre-ferment. Cool your wort  
before aeration.

David asks:

> My first lager batch has been merilly fermenting away now for  
> three weeks now and I'm getting anxious to get it away from the  
> sediments that have settled to the bottom. However, it has not  
> stopped fermenting and I'm a little concerned with that. Is it  
> alright to rack to secondary before primary fermentation has  
> completed?

Yes, it's alright. In fact, siphoning before active fermentation has  
ended has the added benefit that most of the oxygen that might get  
introduced during siphoning would then get scrubbed-out by the actively  
escaping CO2. The only snag might be that the siphon may have a  
tendency to break, but you can reduce the chances of this happening  
by (increasing the flow rate) making the height difference as big as  
possible and making sure that the hose does not have too large an inside  
diameter.

Thanks to Bill for taking a stab at a McAndrew's Scotch Ale recipe.  
It happens to be one of my favorites. I would just like to add that  
McAndrew's Scotch Ale has a very intense Goldings flavor. I would  
suggest adding 1/2 to 3/4 ounce of Goldings (East Kent, B.C., U.S.,  
maybe even Styrian would work) during the last 15 minutes of the boil.  
See Jackie Rager's article in the Hops Special Issue of Zymurgy for  
how much bitterness the 15 minute boil will add to the final beer.  
Another beer that has an intense Goldings flavor is Young's Special  
London Ale -- another of my favorites.

Bill also writes:

I'd use the Wyeast #1028 London Ale yeast on this one. For Scotch  
Ales, the Wyeast #1098 (Whitbread) is slightly less attenuative,

I thought just the opposite -- that Whitbread was more attenuative than  
London Ale. Comments?

John writes regarding All About Beer Magazine:

> IMHO, it has some interesting articles, but seems to be primarily write-  
> ups  
> about places with lots of beers, written by the owners/managers of those  
> establishments. Not enough of my cup of tea to subscribe.

I'd like to add that every issue that I've read of AAB, has had lots of  
technical errors. For example, Duvel given as a Trappiste Ale and no

mention of Orval, Westmalle, St. Sixtus (the secularly-brewed version of Westvleteren), Roquefort or Shaapskooi (pardon my spelling -- I don't have my books here at work).

John asks:

>contracting as it cooled. Is there a way to prevent the water from  
>dribbling back in, other than temporarily using a blow-off tube for a  
>few hours while the air cools?

I use all three-piece airlocks and make sure to not overfill them. If when you fill one you have the level of the water above the bottom of the "thimble" then it will work in both directions without sucking water. Although I don't own one, I believe the "triple-ripple" airlocks work in both directions also, without any special precautions.

Al.

Chris was also making strong ales from the yeast, which tends to  
select for the more alcohol-tolerant mutants. This happens to all  
yeasts, to one degree or another. If the batches are low-alcohol,  
it wont happen to near the extent.

Save some for a gran cru!

I don't know, but Bass ale seems to give me that headache that is right  
smack dab in the middle of your head, and it's pretty hoppy, and tastes  
like it was fermented at a high temp (=> fusel alcohols). Double diamond  
is almost a Bass clone, but tastes cleaner, like it was fermented at a  
lower  
temp, and I have no such problem with it.

What is it about mead that makes for such mean hangovers?

>and a small amount of Chocolate malt (maybe 1/4 lb or less) for the  
>roastiness. I wouldn't use any black malt or roasted barley because  
>of the darker color it would impart.

Since it is my favorite (affordable, < \$2 / bottle) beer, I tried to brew  
up a McAndrews clone last week, and came quite close on the color and  
taste.

I used the Belgians malts, also: 4 lbs aromatic, 4 lbs caravienne, 10 lbs  
Pale malt, mashed @ 156F. made 4.25 gallons SG 1.086 wort with my bad  
sparge efficiency. 1/2 oz ~7% Northern Brewer, 1 oz 4.5% fuggles, 1 oz  
5.6% Goldings for 70 min, and another 1.5 oz goldings and 1 oz fuggles  
spread throughout the boil. I used distilled water for the mash, and no  
water treatment whatsoever for the sparge (except to acidify it); I  
didn't

want hard water accentuating the bitterness. I pitched whitbread Ale  
yeast for the diacetyl notes, and now the primary fermentation has  
subsided after 5 days, with a SG of 1.040.

I always considered McAndrews to be quite hoppy, but side-by-side my  
clone  
had the appropriate bitterness, but too much flavoring hop (time should  
fade it somewhat, and we'll see how it turns out). My brew was the same  
dark-orange color, but a shade lighter. It also definitely needs a  
little  
roasted barley or other dark malt in it. The McAndrews was a bit  
maltier;  
the fresh hop flavor in mine is probably masking the malt somewhat.

Next time I'll try: 8 lbs aromatic malt for even more maltiness, 9 lbs  
pale ale malt, 2-3 oz roasted barley or maybe 5-6 oz of the special B  
malt

instead (black patent may be more authentic - forget the chocolate... it  
needs that slight burnt note), the same hot-mash > 155F, the same long  
boil to get some caramelization. The same bittering hops, and cut the  
flavoring hops in half, with none in the boil for less than 30 min.  
Avoid, no matter how you're tempted: hard water, brown sugar, and dry-  
hopping.

Your mileage may (and definitely will) vary, and I'd be happy to trade  
bottles if you attempt it (for comparison purposes only, of course :-)

- - - - -

Use an S-shaped airlock instead of an econo-lock. blow-off tubes  
will also suck liquid back into the brew if they are not long enough.

bb

**Subject: Federal Regulations**

An earlier posting on R.C.B concerning the home production of whiskey led me, on a lark, to call the local office of the bureau of Alcohol, Tobacco, and Firearms for a citation of the law (for reference it is Title 26 USC 5171 that outlaws production of distilled spirits by other than a bonded distillery)

Along the way an interesting tidbit came up: according to the IRS Federal regulation 27CFR25.207 it has ALWAYS been legal for the proprietor of a brewery to remove up to 200 gallons per year from the premises, for personal use, without paying taxes on it. This even before homebrewing became legal.

Some guys have all the luck!

In a book I read on making hard apple cider, they suggested pasteurization after bottling, and I wonder if this might be used to kill remaining yeast cells in the solution, after bottling, but before drinking ?

I don't suffer from these headaches - at least, not now - so it's up to another person to test this theory.

According to the book, pasteurization was accomplished by submerging the bottles containing the product in 160 F water for about an hour.

Note : this should be done after the beer has carbonated in the bottle.

From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Sneezing in my beer

Tangential to the issue of headaches from homebrew is a problem  
i develop from some beers: sneezing fits.

Some unfiltered, unpasteurized beers cause it, some don't. I've never  
had a problem with filtered and/or pasteurized beers, so i would assume  
the problem would be the yeast. Since not all beers with live yeast  
cause it, i would assume that my sensitivity would be to certain  
strains.

The reaction doesn't last long, and i don't get too congested.  
My only other allergies are to some pollens and to the antibiotic  
arythromycin (sp?), so i am certain that the grains or hops are not  
the problem.

Has anybody else had this problem?

Date: 29 Sep 92 18:04:17 EDT  
From: James Spence <70740.1107@compuserve.com>  
Subject: Nat'l Comp. Mead Judging

The AHA's position on the Mead best-of-show.

We became aware that there were some concerns in the way the best-of-show meads were judged this year via a letter we received from Micah in July. After receiving Micah's letter, I looked into the situation to find out what happened. I discovered that there were some inconsistencies in the way the best of show meads were judged compared to previous years. I also discovered that all 4 judges and the judge director unanimously agreed on the final decisions. The AHA stands by their final decision as a fair representation of best of show.

I wish we had run a perfect competition, but unfortunately, we did not. We are always striving to improve the competition and Micah's letter informed me of a situation I was previously unaware of. I assure you all that steps have and will continue to be taken to avoid any future misunderstandings and inconsistencies.

Anyone who wants to participate on the National Homebrew Competition Committee may contact me through CompuServe (70740,1107) or at PO Box 1679, Boulder CO 80306 (303) 447-0816. For those currently on the committee, a new package is in the works for everyone and I hope to have it the mail shortly after the GABF. It will include a working list of those people who have agreed to participate as well as first round judging topics.

Sincerely,

Karen Barela  
AHA Vice President

Date: Wed, 30 Sep 92 09:09:23 EDT  
From: Steve Anthony <steveo@Think.COM>  
Subject: How to make non-alcoholic brew?

My wife has needs to take a perscription medicine, and that medicine precludes any alcoholic beverages. This includes her favorite, my own porter. So instead of us sitting around, me with an IPA and her with a Porter, I'm sitting there with the IPA and a case of guilt, and she's got a glass of water and a case of frustration! So I began to wonder what might be involved in making a no alcohol brew.

My thought was that I'd have to make the beer as usual, and then take all 5gal of the fermented product and remove the alcohol, by heating to maybe 165F to boil to alcohol off, yet not boil the beer. This, I surmize would get rid of the alcohol, but also kill off the yeast that one would use for carbonation. So, then some form of artificial carbonation would be required. Maybe something like they do for soda. Which implies that some kegging system would be needed. This seems expensive.

Thus, my question. Is there any other way? Has anyone experimented with any kind of process to remove alcohol from the beer yet still render it drinkable?

Any and all thoughts will be appreciated!

Steveo

From: jim busch <busch@daacdev1.stx.com>  
Subject: Re: Micah got the shaft

I have followed the AHA judging of the mead BOS thread with interest. It just shows how bad the AHA judging can be at times. From the circumstances clearly stated in this forum, Micah got screwed out of a first place position in the second round. The rejudging indicates a lack of credibility in the AHA process. If they dont have confidence in the judges of the earlier rounds, they have no buisness doing the judging. What ever happened to "the decision of the judges is final"?

This lack of credibility became apparent to me after a 3 week swing through California, Oregon, Washington and Colorado immeadiately prior to last years GABF. I maintain a log book of all my beer travels, and carefully rate all beers based on style on a 5.0 max scale. Very few beers get a 5.0, and 4.0+ is a great beer in my system. When I heard the announcements of winners at the second day of last years GABF, I checked my notes to compare with my memory of some beers. Beers that were rated quite poorly at the brewery suddenly emerge as silver and gold winners. Either some breweries are pulling a fast one and brewing "special" beers for the fest (so they too can be the best beer in america) or the AHA has serious judging problems. I suspect both are contributing factors.

That said, I just took the BJCP exam, so maybe I can be part of problem soon :-). Anyway, Micah got shafted, and at least this forum has heard the news that I am sure will not be disclosed in print in Zymurgy.

>>> - When my fermentation is nearing completion, does the yeast go into  
a  
>>> dormant state or just die?

>>They go dormant. If you wait too long before priming you won't get  
>>carbonation, because once the yeast go dormant, they need things that  
>>finished beer lacks in order to wake back up. Carbonation is done by  
>>the yeasties that haven't gone dormant yet at bottling time; there are  
>>still a bunch of them in suspension even when the beer looks clear.

>I'm wondering if the solution to my long standing problem lies in  
James's  
>response. The problem I have is that it takes an exceptionally long  
time  
>for my beers to reach a proper carbonation level. No way do my beers  
>become properly carbonated after a month or so. I would say my beers  
need  
>about four months or so. Sure, I use 3/4 cup corn sugar as many do.  
And,  
>yes, I have tried different sources for the sugar in case of a bad batch  
or  
>something. But my results have been uniform, regardless. What strikes  
me  
>in contrast is something I recall reading in Papazian's TCJoHB. I  
believe  
>he says that because of his busy schedule, many times he does not bottle  
>until after 4-6 weeks settling time in the secondary. Indeed, I usually  
>wait about this long. At this point fermentation has nearly ceased (1  
bubble  
>> 3 min.). It seems to me that much of the yeast going dormant is a  
possible  
>explanation for my problem. I should also mention that I use Wyeast  
liquid  
>cultures and brew both lagers and ales.  
> So my question is, can someone provide a good rule of thumb as to when  
>bottling should occur? And is my presumption correct that letting the  
>beer sit too long in the secondary may cause sluggish carbonation later  
on.

I have also noticed that long secondary times result in long  
bottle aging to achieve carbonation. Perhaps one answer would be  
to add yeast at bottling. I suspect lager yeast would be best  
for this, but I'm not sure. I'm also not sure how much yeast  
would be needed for a 5 gallon batch primed with 3/4 cup corn  
sugar. On my last batch I tried 1 teaspoon (twice the amount I  
use for rootbeer) of dry yeast. That seemed to cure the problem.  
Any others adding yeast at bottling? If so, what kind and how much?

... Christopher Lyons

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Flatulence

OK, since we're all airing (pun intended) our personal problems here on headaches and sneezing, how bout we vent are opinions on homebrew generated flatulence. I have noticed some people (not me of course) have a big problem (read nuclear farts) after homebrew club meetings. I always tell these people that this is caused by infected brews. Is it really? Could it be the yeast metabolizing some other sugars hanging around in their stomach?

Any ideas out there or is this just a local problem. Feel free to AIR your ideas here on the digest, NOT in my office.

From: rfozard@sword.eng.pyramid.com (Bob Fozard)  
Subject: Red Hook ESB

I picked up a recipe profile sheet from Brian at Fermentation Frenzy yesterday that lists all of Red Hook's and Sam Adams' brews. The one I'm particularly interested in is Red Hook ESB. This beer has the tastiest hop character I know of. The sheet lists ESB as using Willamette and Tettnang. Not having my senses properly and fully calibrated for hop-guessing yet, I cannot confirm this. Can any of you?

p.s. Brian wasn't sure either, he didn't prepare this sheet.

Subject: labels

This may be old news, but..

I have been using rubber cement for my homebrew labels. I usually go through 2 "regular" sized bottles of the stuff for about 40 bottles of homebrew, but they stay on until you want them off. When you finally pull them off, they are easily removed without leaving anything behind. The labels are plain white paper used in xerox machines.

Subject: RE: Steam beer

Jake Zaagman asks:

- > 1 - Is there a normal ferment temp for steam beer?
- > 2 - Or is there something that just covers up the off flavors?

I have brewed many batches of steam beer, mostly because I don't have refrigeration although I do enjoy the style. My most successful batches have been fermented at 15C (umm... 58F?). During the summer, I was fermenting at 20C (70F?) and I did indeed get off flavors. Perfume. Quite obnoxious, although aging seems to be curing the problem somewhat. I have noticed that brewing with even a little crystal helps mask the problem (I don't know why, I just seems to work for me). The worst batch was brewed with Wyeast #20?? (Danish) but I haven't really done enough experimentation to blame the yeast yet.

From: eurquhar@sfu.ca

Subject: demerara sugar-different?

In a word, yes. Demerara sugar is a special form of sugar which is very dark brown and almost sticky. It has a strong, caramelly almost fruity smell and flavour to match. Roger's Sugar here in Vancouver, B. C.

makes this grade and it is the basically cleaned raw sugar which has been re-crystallized. They use the same process as Tate and Lyle in Britain use to make Demerara.

Nothing is removed except plant fibres, dust, etc. and the natural plant acids which would invert or cause the sucrose to breakdown into it's

component parts glucose and fructose. No molasses is extracted but instead

is returned to the sugar before crystallization.

The raw sugar often called 'turbinado or raw sugar"

produced/available in the States is a very pale imitation of the real thing.

However, REAL ENGLISH DEMERARA IS AVAILABLE IN THE USA from the Cellar in Seattle. Never tasted this one but likely its good. The Cellar, P.O. Box 33525, 14411 Greenwood Ave. N., Seattle, Washington 98133 telephone #206-365-7660.

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Beer and Health

Beer is a natural organic food, which consumed in moderation is health positive. There have been numerous independent studies that have clearly shown that everything else being equal, beer drinkers enjoy better health than nondrinkers. In fact, many of these studies have shown that regular beer drinkers tend to be in better health than wine drinkers or those who consume spirits. The key of course is moderation. Studies have shown that health benefits increase with beer consumption, but only up to a point. After that it decreases and rapidly goes negative.

The major ketone in beer is diacetyl. It has a flavor threshold of .10-.15 mg/l. In normal beer it will be present at 1/2 to 1/3 this level. Margarine, for example, contains 40-50 times as much. I personally have a reaction when I taste beer whose diacetyl level is above threshold. There is absolutely no doubt in my mind, however, that this reaction is emotional/psychological and not physiological. Everytime I pick it up in my beer, I know I have screwed up!

The major aldehyde in beer is acetaldehyde. There are other aldehydes present. They are at such low levels in normal beers that they can be ignored for health purposes. (Beer flavors are a different issue.) Acetaldehyde is theoretically toxic, however for this to be a practical issue we are talking about consumption levels approaching 25-30 liters per day for decades. Interestingly, the US beer with the highest acetaldehyde level is Bud. It is typically present at 10 mg/l, which is close to its flavor threshold. This has been the case throughout this century, and results from AB's "chip fermentation". It is also responsible for the subtle apple-like tones found in Bud. This is not IMHO the ideal brew in so far as beer flavors are concerned. Yet, think about the number of gallons of this beer that have been brewed and consumed over the years. Compare health statistics of regular Bud drinkers with those who engage in a known health hazard, i.e., cigarette smoking. I think the proper conclusion is that we can forget about the aldehyde content of beer as being a health risk.

The major health issue centers around the alcohol content of beer. Because beer, unlike wine or spirits, is made with a relatively low gravity fermentation, it generally should have much lower levels of fusel alcohols than other libations. These long chained "higher alcohols" are indeed toxic and quite intoxicating. They make "moonshine" the health hazard it actually is, and to a much lesser extent, the same can be said for brandy. Much has been said on HBD about the negative effects of the fusel oils, and there has been some really good advise about how to keep their levels low. I agree with all of this and its relevance to beer flavors. However, from the point of view of health related issues, it is important to keep in mind that even with defective beers the fusel alcohol level will typically be a good factor of 50 below that found for example in brandy.

The issue associated with ethanol is more complicated. I think the data out there shows that it is health positive at low levels, however there is absolutely no doubt that it will have deleterious effects with high

levels of consumption. As an enthusiastic brewer I do not warm up to moderation easily. However, the more one looks at the data the more attractive this posture becomes.

From: chuck@synchro.com (Chuck Cox)  
Subject: Re: Best of Show

Thanks for all the messages about the validity of BOS judging. Here is a summary of the responses. Not all responses were clearly pro or con, but I did my best to try to understand the various viewpoints. I should add a disclaimer that I am very strongly in favor of BOS.

I realize this sample set is too small to be statistically valid, but the results seem reasonable to me.

Total responses: 16 (7 judges, 9 competitors)

For BOS: 9 (3 judges, 6 competitors)  
Against: 4 (3 judges, 1 competitor)  
Don't Care: 3 (1 judge, 2 competitors)

My interpretation:

Judges are divided about BOS, but competitors want it.

All competitors stated that they were aware of the subjective nature of the judging. Several mentioned the analogy of dog show BOS.

An interesting point: one competitor said he didn't like sending an extra bottle for BOS judging. I sympathize with this. I don't enter many competitions anymore because I don't want to waste 3 bottles of excellent beer just to find out if someone else thinks it's good too. I would like to suggest a compromise: make the BOS bottle optional. If the first-place beer in a category didn't include a BOS bottle, that category won't be in BOS. I think most brewers are fairly realistic about their chances of a win, so let them decide whether they want to sacrifice an extra bottle on the chance that they take first. I don't think this would be too much of a burden on organizers. Opinions?

My opinions:

- If the competitors want BOS, they should get it.
- The BOS bottle should be optional.
- If certain judges are uncomfortable judging BOS, they should let judges who are comfortable with BOS do it.
- Master judges should be competent, informative, and entertaining BOS judges.

I really enjoy judging BOS. I think one of the great benefits of being a Master judge is that I get asked to judge BOS quite often. I would be very disappointed if BOS started disappearing from competitions.

The latest edition of Zymurgy has a good article by Ray Daniels on targeting gravity. What rivitted my attention was an elegantly simple little equation that I used on my very next batch. As the majority of hombrewers probably do not subscribe to the magazine, I thought I would pass it on to this forum along with my thanks to Ray for what, like all good ideas, now seems so obvious.

The problem is to determine the gravity of a wort after boiling or dillution, based on its present gravity.

The trick is to determine the "total gravity" which can then be divided by any volume to predict the final gravity. This is done simply by multiplying the present gravity by the present volume then dividing the product by the anticipated volume.

For example:

10 gals of sweet wort have a gravity of 1.030 (30) prior to boiling and we want to boil this to a volume of 7 gals.

$30 \times 10 = 300$  total gravity

$300 / 7 = 48$  (1.048) gravity after boiling

It works the same way for adding water.

Maybe I just read the wrong books and Ray just plagarized this but it made wading through the magazine worth the effort. Thanks Ray.

The problem is especially common in high alcohol beers, and has  
an easy solution: just add more yeast at bottling time. Make sure  
you use the same type of yeast that you used for the fermentation.  
If you use a more attenuative strain, the beer can become overcarbonated.

From: abirenbo@rigel.cel.scg.hac.com (Aaron Birenboim)  
Subject: Advanced Tapping and fluid dynamics

I have been having a problem with getting foam and flat beer from my kegging system. I have heard about restaurants keeping their beverages under pressure (15-20 lbs) and using restricted and/or long lines to drop this pressure to 1/2 pound at the nozzle.

I never took any fluid dynamics.... so where might I get information as to how to dispense my beer properly at 5000 ft. elevation. I hear the general solution is a restrictor on the beverage line, and increased dispensing pressure. I do not want to be doing a lot of modifications to my built-in refrigerator system. I want this right the first time. Remember that the rule of thumb I was told to follow is that the pressure at the tip of the nozzle should have dropped to a differential of 0.5 psi. I guess that this pressure drop would be due to an aspiration effect in flowing beer.

..  
so might this not even work unless I can get a nozzle with smaller tubing??? ya know.... as the fluid is in a narrow cross-section the pressure changes (drops?), but if the cross section gets larger... will the pressure not rise again as flow velocity decreases?

anyhooooo..... I'd really like to get my fridge going happily. I have invested too much in it for foamy beer.

I received no confirmation of this posting and have not seen it in the Digest so I am resending it with additions at the end.

.....

The latest edition of Zymurgy has a good article by Ray Daniels on targeting gravity. What rivitted my attention was an elegantly simple little equation that I used on my very next batch. As the majority of hombrewers probably do not subscribe to the magazine, I thought I would pass it on to this forum along with my thanks to Ray for what, like all good ideas, now seems so obvious.

The problem is to determine the gravity of a wort after boiling or dillution, based on its present gravity.

The trick is to determine the "total gravity" which can then be divided by any volume to predict the final gravity. This is done simply by multiplying the present gravity by the present volume then dividing the product by the anticipated volume.

For example:

10 gals of sweet wort have a gravity of 1.030 (30) prior to boiling and we want to boil this to a volume of 7 gals.

$$30 \times 10 = 300 \text{ total gravity}$$

$$300 / 7 = 48 (1.048) \text{ gravity after boiling}$$

It works the same way for adding water.

Maybe I just read the wrong books and Ray just plagzarized this but it made wading through the magazine worth the effort. Thanks Ray.

.....

Last weekend's batch was the first to use my homegrown hops and the results are less that exciting.

I harvested 1.5 dry oz of Chinook and this just happens to be what I normally use for a 7 gal batch. I was very disappointed not to smell the usual

powerful hops aroma within seconds after dumping it into the boil. The  
aroma  
slowly built up but never approached that which I get from pellets.

The wort seemed to have the proper amount of bitterness but there was  
just  
something totally unnerving in not having the smell permeate the area  
for the  
two hour boil.

The taste at this point (about to move to secondary) is confusing to say  
the  
least. I will reserve final judgement till it is kegged.

.....

My most recent batch of NA was equal parts de-alcoholized beer and  
water. It  
just keeps getting better. The secret of NA is out.

.....

To: George Fix..... I give up on email. Did you get my beer? What  
are  
your comments? Feel free to post them publicly, my ego is bulletproof.

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Belgian Malts

I have question about Belgian malts.

Where is the best place to get them?

I talked with Tim Norris(very nice to talk with) about ordering some his prices and selection are great but the shipping hurts. At \$ 0.95 to \$1.30 per lbs it cost more to ship the grain than buy it. When I work out the number at \$0.95/lbs shipping I get a cost of about \$ 1.65 lbs. Now for high quaity grain I don't really have a problem with this but if I could find a source closer to Portland, Oregon or if I could find a cheaper way of shipping 170 lbs of grain it would be nice.

Does anyone out there have any ideas on this?

Are there any other Portland brewers who want get together on an order?

Thanks to Tony Babinec for his post on Alt beers, interesting stuff. On Widmer Alt, it IS a very good beer. Perhaps my favorite Widmer brew but I have heard they no longer brew this due to low demand (I may be wrong on this but I have not seen it for a long time). I am not sure about it being over hopped it did not seem very hoppy but being a west coast hophead I am not a unbaised judge.

Thanks all,

Tom Feller

Subject: 1992 Dixie Cup

Well, I've finally taken the time to actually read the header info on my copy of the hbd, and I've figured out how to post to this auspicious (sp?) forum. Here's a thing I've had for a couple of weeks, and the time is drawing nigh, so I thought I'd post it for posterity. Hope to see some of you from out there in hbd-land at this shindig. Of course, I've never met any of you, but I'll be around all weekend. I should be easy to spot, 'cause I'll probably have a few copies of the Cat's Meow for sale.

The 9th annual Dixie Cup Galactic Homebrew Competition  
October 16th & 17th, 1992

The Official Dixie Cup Entry Booklet must be obtained from the Foam Ranger/DeFlaco's by writing or calling DeFlaco's at the address or fone numbers given below. That's because we want everyone to use the same entry form so that we don't get confusd.

Entry Requirements:

Each entry shall consist of 3 bottle (12 oz. preferred). All commercial labels must be removed. Please do not use homemade labels on entries.

Entry fee is \$6.00, \$7.00 after October 1, with a \$1 discount to dues paying members of homebrew clubs. Any official entry label must be attached with rubber bands to each bottle, with all info on the label completed.

A complete recipe form should accompany each entry.

If score sheets are desired, a SASE should be included, one per 3 entries is sufficient. Clubs may have their score sheets returned to a central address, a large envelope with 1 oz. of postage per 3 entries will be sufficient.

Entry Deadline is 6 PM Monday, October 12th.

Send entries to:

DeFalco's Home Wine & Beer Supplies  
5611 Morningside  
Houston, TX 77005

Inquiries should be addressed to the above, or call or FAX: (713)523-8154 (voice) (713) 523-5284 (FAX).

It is suggested that the entries be packed with each bottle individually wrapped with newspaper or bubble wrap, placed in box, bagged, and placed in another box. Label the box "Kitchen Supplies" UPS is suggested as the carrier.

Submission of entries as early as possible is suggested!

#### AWARDS

\*\*\* Dixie Cup Trophy \*\*\*

Given to club with most points, awarded as follows:  
1st place in each category - 5 points

2nd place in each category - 3 points  
3rd place in each category - 1 points

Club Quality Awards (Courtesy of Crosby and Baker)

Awarded to the club with the top 5 scores in the preliminary round. Clubs will receive "certificates" redeemable at any homebrew shop that does business with CROSBY & BAKER.

1st Place -\$50  
2nd place -\$30  
3rd place - \$20

-- Best of Show --

Best beer overall - "Super-deluxe engraved pedestal and a swell mug"  
Best all grain - Deluxe Engraved Pedestal  
Best Extract - Deluxe Engraved Pedestal  
Best Mead - "Super-deluxe engraved pedestal and a swell mug"

- Individual Awards -

Awarded to winners of each category  
1st place "A magnificent mug and a swell ribbon"  
2nd place "A nifty ribbon"  
3rd place "A nice ribbon"

--- Label Contest ---

Submit a label of your design with your name, address and phone number on the back. No fee. Please send labels without bottles attached. Nifty ribbon for winners.

#### ACTIVITIES

The DC is more than a competition. The following activities are "on tap" for the weekend:

Potluck dinner.  
Friday night after the first round there will be a potluck dinner put on by the Foamys and anyone else we can con into bringing food. The Kings of Tasteless Music and Flatulence from the Crescent City Brewers Club usually serve up something good.

4th annual Fred Eckhardt Epicurean Extravaganza  
This year's taste treat is "Beer and Bread"  
The gluttony takes place Friday night after the potluck.

8th annual Microbrewery tasting

>From the casual sharing of a few beers among friends ahs grown this Saturday night festival of fine fermented beverages. If you're traveling to the DC, please bring some beer to share. Saturday night after the awards presentation.

5th annual milli-conference

Guest speakers for this Saturday morning hangover chaser will be Brad Kraus of the Santa Fe Brewery (former Foamy and DeFlaco's slave); Mr. Pierre Celis of Hoegaarden of Belgium and Celis Brewery of Austin, TX; Rodney Morris, Yeast guru and RIMS inventor; and other speakers to be imposed upon in the future. Cost is \$10 which includes a breakfast buffet.

Beer Judge Certification Program Test

A BJCP test will be given on Saturday morning if 3 people who feel good enough to take the test and have \$40 can be found. The test will be administered by a BJCP Master Judge.

Purgatory on wheels pub crawl.

For those who don't think that watchin 4 people taste the best beers of the Competition without sharing them is any fun, there's a pub crawl on Saturday afternoon after the second round judging. Only \$10! (includes the possible return of Mr. Creasote's Commerative Barf Bag!)

World's Fastest Homebrewer

If all of the above fun is not enough, challenge Chuck Cox to the title at the Malibu Grand Prix on Sunday Morning.

ACCOMODATIONS

The location of the DC is the Hilton Southwest in Houston. 6780 Southwest Freeway at Hillcroft. Cost of a room is \$49/night. Call (800) 545-0064 and mention that you're coming for the Dixie Cup. Tell them that you have been quoted this special rate in advance. Be firm. If you're going to arrive early or stay late, mention it to them, and they should give you the rate for the length of your stay.

DISCLAIMER

All of the above is my best effort at typing the DC booklet at a keyboard. All of the above info is superceded by the official DC booklet. So there!

Subject: chocolate malt vs chocolate

greetings -

i've been planning on making a mocha stout... I've seen discussions about the use of coffee in beer - but what about chocolate in beer.

My homebrew supplier stated that the use of regular chocolate makes the beer quite cloudy and that chocolate malt should be used instead. True - False

any opinions on this subject maybe sent directly to  
to the list or sent to:

cmsmarc@ugs.bitnet

thanks...

Subject: warning, creative batch

First, since this was recently mentioned: BE VERY CAREFUL WHEN PASTEURIZING CARBONATED BOTTLES!!!!!!! A carbonated bottle heated to 160 deg. or so can explode, violently. It's happened to me. Luckily I wasn't there for the actual explosion, but I did find the cover to my cermaic pot blown 15 feet across the room, and shards of glass everywhere. I'm very glad I wasn't checking the water bath temperature at the time.

Ok, feeling creative, I made a strong ale yesterday, with 2 interesting aspects. One, I made my own smoked crystal. This was done by soaking .5 lb of 2-row, then putting it on a long flat pan in a gas grill. On top of the "lava rocks" of the grill, I put 4 chunks of this quasi-peatmoss that grows around my house. Low heat for about 1.5 hours, until the grains started to stick to the pan. The grains came out sweet, and slightly smokey, 'though not smokey enough. The other interesting thing was that the yeast was Whitbread slurry from the primary of a batch of cider(!), complete with raisins. Ferment started within 2 hours.

(DELETED)

I agree with Tom on all counts, but for me, shipping has \*always\* been an issue. The local HB suppliers around Cleveland have miserable grain selection, and if they special order it for you they add in shipping charges. I've had a hard time getting grain for less than \$1 a pound.

However, I found myself in Chicago, (I flew, but my wife had the car) and I had a chance to visit Tim's smorgastbord of malt. It was like being in a candy store, (munch munch) and I found it an educational experience that I wouldn't have had with a hundred orders from a mail order place. Thanks Tim. So I brought back enough grain to last me a year or more, about 10 varieties.

I'll probably be in Chicago again before it's all gone.

For longer distances... the answer probably lies in volume. Tim said that the shipping costs don't drop until the shipments reach a half ton or more (I think) Group orders seem appropriate here... your club, or your regular supplier shipping a big order. Maybe Tim could arrange a shipment of that size direct from the malters to the west coast?

Another suggestion is to buy from your local brewpub... that hasn't worked for me but it could. Maybe convince them to switch to Belgian malt? (ha)

dennis

p.s. with the blatant endorsement for Tim Norris's malts, I should give the phone number: (312)545-4004.

From: wegeng.henr801c@xerox.com  
Subject: Re: Flatulence

I don't think that flatulence is caused only by infected brews, since the problem also occurs with commercial beers. I saw in a cookbook dedicated to bean recipes the theory that this problem is caused by complex sugars that many of us cannot digest because our digestive systems don't have the proper enzymes.

There's a product you can buy at your local drug store called "Bean-o" (or something like that) which contains the enzymes. My experience is that it seems to help (I'm bringing some to the GABF this weekend). Another possible solution is a Chinese herb medicine called "Po Chai Pills", which I'm told you can sometimes purchase at Chinese markets. I've never tried this, but my source for this information (a well known AHA officer) swears by them.

From: tony@spss.com (Tony Babinec)  
Subject: more ramblings on Alts and Kolschs

Thanks for all the comments online and offline. Here's a followup posting, as I thought these points would be of interest.

Here are the Wyeast descriptions of the two yeasts:

1007 "German" ferments dry and crisp leaving a complex yet mild flavor. Produces an extremely rocky head and ferments well down to 55 degrees F. Flocculation is high and apparent attenuation is 73-77%. Optimum fermentation temperature: 62 deg F.

1338 "European" is a full-bodied complex strain which finishes very malty. Produces a dense rocky head during fermentation. High flocculation, apparent attenuation 67-71%. Optimum fermentation temperature: 70 deg F.

So, European is less attenuative than German, and therefore should leave more residual sweetness. European also produces a maltier beer. Both yeasts drop out of the beer well. When used at conventional temperatures, they don't produce the fruity, estery flavors desired in British ales.

A Kolsch is a bit tricky so far as getting the right body and sweetness. It is not a "big" beer; starting gravity should be 1.042-6. It is also somewhat less bitter, with the hop range being 20-30 IBUs. And, of course, it is light in color. Its flavor should have just a slight edge of sweetness. Commercial comparisons are difficult to suggest. In Chicago, the Goose Island brewpub uses a real Kolsch yeast and makes a Kolsch true to style. It's been years since I've seen Kopper's Kolsch in the States.

By the way, either of these yeasts makes a good American Wheat beer. Use barley malt and wheat malt in the ratio of 2:1 to 1:1 to make a mid-1040s beer, and hop the beer lightly, say 18 IBUs. Cascades, say 0.25 - 0.5 ounce, make a good finishing hop.

If you can't cold-condition your Kolsch or Alt, rack the beer to secondary and let it sit and clear at cellar temperature.

I don't think it's at all "bad" to use Saaz hops in an alt. Their best use is anytime in the last 15 minutes of the boil. Another popular German hop for alts is Spalt (sp-alt!).

Can an alt be dry-hopped? Sure. I understand that this is especially true for the slightly stronger Sticke beer. (Thanks to Jim Busch for reminding me of this.) Also, as I tried to say, 35 IBUs is fairly hoppy. Zum Uerige, a German Dusseldorf alt, is quite hoppy, and is one of only 32 beers to get 4 stars in Michael Jackson's Pocket Guide. I don't mean to legislate morality regarding hoppiness, but it has been my experience that well-hopped alts when entered in competition get knocked for being too hoppy, and it appears here the U.S. beer judge community is wrong and needs educating!

What about Vienna or Munich versus crystal malt in the grain bill? Well, the color contribution of Vienna/Munich is less dramatic, so you can get away with using more of it. A Kolsch is a light-

colored beer, so a grain bill such as the following will work:

6-7 pounds pale lager malt  
1 pound Vienna or light Munich  
0.5 pounds light (10L) crystal malt

In an alt, you can use more of the color grains. These beers can range from amber to dark copper-colored. The "Vienna Mild" recipe produces a beer on the light end of the spectrum, and can be tinkered with to produce a darker beer.

Happy brewing!

From: "Rad Equipment" <rad\_equipment@rad-mac1.ucsf.EDU>  
Subject: RE- Flatulence

Subject: RE: Flatulence Time:7:41 AMDate:10/1/92  
Bob Jones brought up the topic, so here's my story.

About two years ago I outfitted my dispensing fridge with a tap which would allow me to keep a keg of one of Anchor's products on line (Anchor and Bass use a unique tapper except for Steam in CA). As Steam is only distributed in Golden Gate kegs here in California, I decided to go with Liberty. Soon after this I began to suffer from the nuclear gas attacks to which Bob refers as well as some other significant changes in my lower tract behaviour.

I was in the process of building my 1/2 bbl system at the time so I wasn't brewing and so wasn't drinking much homebrew. That seemed to rule out yeast. I was convinced I had some sort of intestinal infection or parasite but tests came up negative. I went off alcohol for two weeks to see if that was the problem without any relief. I resigned myself to living with it.

By the time 3 kegs of Liberty had passed, I had completed my brewery and was back to supplying my own beers. Since I had enough of my own brews I let the last keg of Liberty sit empty for a month or so. Coincident with this, my toilet habits returned to normal and the gas subsided. Not one to accept such a potential finding to go unconfirmed, I bought some bottled Liberty and consumed it exclusively for 2 or 3 evenings. The gas returned.

During the National 1st Round I get to spend a lot of time at Anchor after hours and have access to lots of Liberty, so I did the experiment again. I got the same results. Following that, I had a conversation with a fellow Malt (who also happens to work at Anchor) during which I mentioned that "I liked Liberty but it didn't like me." My friend responded that he too had experienced the same symptoms when Liberty was a steady diet.

My guess is that the hops are the factor. I have not attempted to confirm this with other similarly hopped brews. I do consume a fair amount of SN Pale Ale when I culture yeast from the bottle (I use the dregs from 4 bottles to make my starters) and I have noticed some similar effects but to a minor degree. I guess I should write a grant proposal to study this problem.

Anyhow, that's my story. If you plan to go camping with me, don't bring  
any  
Liberty along (;-).

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Draught system design

In the last HBD Aaron Birenboim asks about draught system dispensing pressures. I feel so guilty about not passing along my most recent discovery, I hang my empty stein in shame. I'll try and redeem myself now.

I too had problems with proper keg dispensing of beer. The brews would either have a great head and no CO2 if I increased the gas pressure or no head and flat beer if I decreased the gas pressure. As per some helpful HDB'ers I increased my liquid line to about 8 feet long with only a small improvement. Well at the AHA conference this year, Dave Miller talked on proper dispensing pressure for beer. One of his handouts detailed the pressure drop for different ID lines. The 1/4 inch ID lines most of us use has a pressure drop of about 1 psi per foot. 3/16 inch ID PVC line has a pressure drop of about 3 psi per foot. BINGO, a 300% increase in pressure drop. I was so excited to try this 3/16 inch line I almost stopped at the hardware store on the way home from the airport. I converted all my liquid lines to 4 feet of 3/16 inch ID PVC. I then artificially carbonate all my beers to about 2.5 volumes of CO2 at 43 deg f. This is about 12 psi. I then dispense the beer at 12 psi. The 4 feet of 3/16 line then gives about a 12 psi pressure drop. I am really happy with my draft system now. I know of several people that keep say 12 psi on their kegs, then release or drop the pressure to a few psi before dispensing. This will work but really is a pain if you have several beers on tap as I have. Besides why do something if you don't have to?

A few words of warning. It isn't easy to get the 3/16 line onto the 1/4 inch barbs. Heat them up in hot water and push fast. Also the inline check valves we all SHOULD have in our gas lines have about a 2 psi drop across them. My system has one at the regulator output and I have one at each output from my gas manifold. Therefore I have 2 x 2 psi drop or 4 psi. Because of this I set my gas regulator to 4 psi above 12 psi or 16 psi.

Get a copy of the gas saturation tables, available in the archives or old AHA conference proceeding. I have had one of these charts for years, I got it

from Zahm and Nagle over 10 years ago. I didn't really start using it  
until  
recently, now I use it everytime I keg beer.

Subject: Shipping malt

Regarding Tom Feller's concerns about high shipping costs, I don't know where Tim Norris is, but UPS will ship 70# coast-to-coast for about \$25. Parcel post is about \$30.

Funny story...I was trying to send a case of my homemade wine to my brother-in-law in Alaska. I went to UPS where I was informed that they wouldn't ship booze. So I took it to the post office where the conversation went something like this:

"Can I ship wine to Alaska via parcel post?"

"Gee, I don't know..let me look"

(some shuffling of books and pages)

"Can't say for sure, but I don't think so"

"How about vinegar?"

"Sure vinegar's no problem"

"Good, today I brought the vinegar, I'll worry about the wine later"

Wine arrived in a week.

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Mead BOS, sneezing & yeast washing from Micah Millspaw

First, I would like to thank everyone who was/is involved in getting some answers to the mead BOS problem. I very much appreciate the info I've recieved. Also I want to make it clear that this is not a personal vendeta and that in the long run this somewhat negative publicity will help assure us of better competitions.

On the topic of beer related sneezing. A friend of mine who really likes beer noticed that certain brands of beer when consumed made his eyes and nose run and caused sneezing fits. He asked me what I thought of this, and so we did some experiments. The easiest was to go through the ingredients that make up beer. he smelled and tasted several types of grain, nothing, then he went to the hops and things got interesting. We found that he had quite a strong and immediate reaction to certain varieties of hops, and was not bothered as much by others. I then went to the books to find out what varieties hops were used in the brands of beer that most bothered him. It all matched up and now he avoids certain brands and certain of my homebrews. Just an interesting item.

Also I noticed a question about growing yeast and the correct ph, some mention was made about not being able to verify the ph and want some volume/weight mix info.

When I do an acid wash on my yeast I've found that they really like a ph of 3.5-4.0, this is done with an acid blend that can be had from most home wine shops. As for mixing it up, it would not be a good idea to rely on a volume/weight type mix since the ingredients (your water and the acid blend) can vary widely. I strongly suggest that a ph test kit be used to verify your solution before subjecting the yeast to it. The stuff to check ph is really cheap and easy to use.

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Beer Judging

I find this discussion about the AHA judging very interesting  
I am sure it will be of use to the members of the HBD which  
do or hope to enter brews in competitions. I am also sure that  
digesters who serve on the AHA judging committee are following this  
discussion with great interest.

The key here appears to be that beer judges are just like us, human.  
I believe that Micah first place finish in his entered category  
should have stood. Judging is a subjective process and the judges  
decide at the time that Micah was the best of the presented meads.  
The problem is not with the Judges themselves, I believe everyone  
acted in a way which they believed was correct. The problem lies  
in a flaw in the judging guidelines, the rules need to be changed  
to address this situation. Of course someday another problem will  
arise which is was not considered when the current rules were written  
but that is part of the process.

I understand Jim Busch's remarks were intended to add insight into  
this question, which they did, but I have a question about his  
"credibility test". Are you saying that there were beers entered in  
a category which you rated a 4+ or 5 that finished out of the running  
while beers you rated a 1 or 2 finished 1st or 2nd? Did any of the  
beers which you rated highly finish 1st or 2nd?

There are number of local brews which I believe are outstanding  
which other knowledgeable friends believe are only fair. This  
only shows the subjectivity of judging. I have just begun my work  
to become a beer judge and I am sure I will learn of much more  
about this credibility question. My hope of this discussion is that  
we will come to understand how difficult it is to judge beer and  
that the errors we see in our 20/20 hindsight will be considered  
when new judging rules are made.

>  
>Mine never lasts that long.  
>  
>You can play around with sterilization and pasturization and air-locks  
>and what-not, but it never made mine taste any better. Stay loose.

Although I'm sure that Garrett's method will produce good cider (this is how my father's been making it for years and years), I'm curious if we might not be able to apply some homebrewing techniques to cider-making.

Can, for instance, cider be bottled? I know that there are examples of bottled cider in England (taste-profiles, anyone?). How would one control carbonation and/or secondary fermentations? Hopped cider?

just some thoughts...

From: matth@bedford.progress.com  
Subject: Digest # 980 and mead headaches

In Digest #980 Brian Bliss asks:

What is it about mead that makes for such mean hangovers?

I believe it has to do with the high sugar content. I know I found out the hard way in college (when I was soooo much more of a refined drinker than I am now!-) that liquors that are very sweet (such as schnapps) can produce some of the worst anvil pounding headaches ever. I would believe that mead has the similar characteristic.

As far as headaches go, I find I get them more from commercial brews than homebrew, but there is a link between the two. I'm a pretty severe allergy sufferer and as such have fairly constant sinus problems. When I get them I usually get wicked sinus headaches from drinking the brew. It's not the temperature of it 'cause I can have a big glass (or more) of any ice cold non-beer beverage and not get the headaches.

The good news is I've finally figured out when I will get one of these and stay away from the beer at such times. (It usually coincides with a weather pressure change or some such activity.)

I guess beer isn't the cure all I thought it was in college...

-Matth

Matthew J. Harper ! Progress Software Corp. ! [disclaimer.i]

From: BOB JONES <BJONES@NOVAX.llnl.gov>  
Subject: Alt beer from Micah Millspaw

On the topic of Alt beer. I happen to live near St. Stans the Alt beer brewery. Their amber alt is usually quite tasty and is more or less in the Dusseldorf style. As for their other versions of alt same are quite good but not really what I would call an Alt. Their yeast however is excellent, myself and other members of SAAZ have brewed much truer to Dusseldorf style using more appropriate ingredients with Stans yeast. It does need to be cold fermented however for the best results. Alt is the mirror image of Steam, fermentation wise. Since St.Stans only filters to 3 microns it should be possible to culture from a bottle. I haven't tried it because I can get my yeast directly from St. Stans. Nor do I know how available this beer is nationally. Have fun.

Subject: Homebrew related ailments

There has been much debate recently about the causality of ailment with relation to consumption of beer, or more specifically homebrew. Many people are proclaiming, with support from statistics, that element X in homebrew doesn't cause symptom Y. This may generally be the case (and thus the statistical support) What I suspect, is that any symptom that seems to be tied to the consumption for a single person, may actually be. This is most likely a mild allergic reaction or a higher sensitivity of one persons body to a specific element of that which is consumed. This is quite common with other things (Chocolate is not bad for you, but many peoples bodies have an intolerance for it). Also, with the continued consumption of an aggravating ingredient over an extended period (maybe even years), your body could become more sensitive to it.

With that said, I think I'll have another beer.  
It's good for ya, ya know.

Subject: Sparging temperature

Hi gang. I have a simple question that can probably be answered via email, though it might border on traditional family brewing values rather than science and hence cause some discussion. Those who can answer probably know:

What bad happens if my sparging water is not ~175°F?

If I read Dr. Fix correctly, than cooler sparge water will simply not break down the starch -> sugar enzyme system. Why is this a big deal? What are these enzymes going to do after they chew up the starches?

This is my crude partial mash procedure, as it has evolved after three batches: I mash in a gallon pot on the stove. Two cups at a time, I scoop the grain out of this pot and into a typical kitchen strainer. I dunk the grain in the water in my boiling pot, which at this point is just tap-hot, in order to rinse it somewhat. I pour a little more hot tap water over the grain to be thorough. I repeat the process until all the grain is "sparged."

I'd also appreciate any suggestions for improving my procedure (but I won't implement them for a while if they involve money or building things!).

Cheers,  
Jake.

Subject: A Different Perspective

The following article appeared in the Daily Herald, October 1, 1992.  
Reprinted without permission.

Brewers Preserve Special Niche for Beer  
By Olivia Wu, Daily Herald Food Editor

Beer is a grain preserve. It is, or used to be, a way to store barley and drink of its goodness throughout the year.

Even though you might not be interested in the feature story on home-brewing, it is very much a food story, a story about conserving the harvest. It's something most of us can relate to. Maybe you made strawberry jam once or froze ronn or stood over caldrons of bottled tomato sauce. Perhaps you are one generation removed. You remember the smell and temperature of the kitchen as your mother - OK, your grandmother - put up food.

Beer, however, doesn't immediately stir sympathetic remembrances. It's alcohol. It's a man's drink. It's the root of evil behaviour. It isn't food, you say.

On the contrary, it is - and in its most basic sense. Originally, to conserve barley after harvest, and more importantly, to extract its nutritional content, the grains were sprouted. The earliest brewers took the most life-giving of foods in its utmost nutritional moment (the sprouted seed) and tried to conserve it through the winter. The process extended a grain's ability to nurture.

This is a food story - and more. It's a story of science, agriculture and human creativity.

Many of our most basic foods were created in this way including bread, cheese, vinegar, wine, soy sauce and miso. A type of fermentation was encouraged to stretch the keeping quality and taste of these foods.

Beer, however, doesn't spring to mind as one of these. On the contrary, I tend to profile beer as an alcoholic, high calorie, filling, tasteless and not very expensive drink which I can do without for my good health.

Then I realize my reaction is a response to numbing overabundance. It is the response of a woman who never goes hungry, fights calories, doesn't lack nutrition and whose taste has been killed by mass-produced beer. She forgets that this drink originally is fruited by the earth.

I usually ignore Oktoberfests. I think of them as culturally foreign. They seem male, European and they flout alcohol. But this year, I realize Oktoberfest is a harvest festival, a celebration of earth, sustenance, human ingenuity and human merriment.

I think how far we've traveled, and not in the good sense of the word. Modern inventions have transformed the making of this food and many of our foods by mechanical shortcuts. The process sucks out the very nutrients it originally preserved. It also robs us of our food's original culture - of time, place and feeling. Not to mention the culture of celebration and of earthy, intense taste.

All around us, however, are small producers and farmers who have

engineered a resurgence of foods that are appropriate to time, place and nourishment. They make wines, cheese and bread in small ways, honest to the season and honest to their abilities. And sprinkled amongst us are folks who in their basements and kitchens measure the temperature of water, mix it with grain and yeast, bottle and wait.

Homebrewers, I like to think, touch real food. Then understand Oktoberfest.

Subject: Draught System: CO2 connection

While we're trading little hints about kegging systems (re:Bob Jones) I have found a method that takes some of the bother out of maintaining a draught system. I have one old fridge that I use for lagering and storing kegs for dispensing. With all the shelves removed, it can hold either four 5 gal kegs or 3 kegs and a 6 gal PC carboy. The twist is, instead of having holes in the side for the CO2 lines or worse yet, storing the CO2 bottle inside, I simply carefully carbonate each keg once at the appropriate time (ie. after conditioning) and then leave them in the fridge without a CO2 connection. This removes the requirement for a multi-port manifold and the associated check valves (both of which I have but have since stopped using). I simply maintain a desired carbonation/delivery pressure by periodically re-connecting the CO2 line to each keg. The key to having this system work, is to know how many volumes of CO2 you are originally putting into each keg AND to make sure it is actually dissolved. The method of dissolving the CO2 has been described before either in HBD or in the newsgroup, but basically consists of methodically inverting the keg SEVERAL times when originally introducing the CO2. I started using this method after I lost my first bottle of CO2 to the atmosphere thanks to a loose connection on the regulator output. Not only did this waste the CO2, but stirred up 5 gal of ale that required an additional couple of days to settle back down. Thus, if you don't leave the CO2 bottle connected 24 hrs a day, you avoid several problems.

I thank Bob for sharing his pressure drop secret with us since I am also experiencing fantastic heads but short-lived carbonation in the glass.

Subject: chocolate malt v. chocolate

marc julian asks about chocolate malt and chocolate ...

the term "chocolate" malt refers not to the malt's flavor, but its rich brown color.

as for using chocolate in beer, go for it! I made a porter with ~4oz bakers chocolate which was fantastic! the chocolate was very apparent in the aftertaste and also in the smell. it got rave reviews from my beer drinking friends.

Some things to watch out for, though:

chocolate does contain oils which are bad for head retention. I had this problem to a small degree - maybe some of the more knowledgeable beer gurus could tell us how to help this!

bakers chocolate is very bitter. I backed off the hop rates a little to compensate for this - unfortunately, i don't have the recipe here at work, so i can't say how much

hope this helps!

From: geoff@csi.on.ca (Geoff Burd)  
Subject: Tyramine in beer

In HBD 979 Dennis J. Templeton writes (concerning headaches and beer):

> On the third hand, there is a very well established phenomenon of  
headaches  
> due to a compound called Tyramine. This is very often found in wine  
> (particularly red) and affects only some individuals. It seems to be  
> related to the process involved in migraine headaches. If your HB  
gives  
> you a headache you might ask yourself.. does red wine too?  
>  
> Actually, I can't recall if tyramine is commonly in beer. Anyone out  
there  
> know?

My wife takes medication which makes her very sensitive to tyramine in  
food  
and drink (the reaction is an extremely severe headache). To quote from a  
list  
of dietary guidelines she was given:

"Tyramine is an amino acid. It is generally found in higher amounts in  
foods  
that have been fermented, aged, pickled, or spoiled. Foods which have  
been  
stored a long time, overripe or not properly stored may have a higher  
tyramine  
content. Foods high in tyramine which should be avoided are: All  
aged/ripened/matured cheeses, dried and fermented sausages, ... IMPORTED  
BEERS  
AND NON-PASURIZED BEERS (use domestic brands of beer in small amounts) .  
..  
meat and fish paste, pate, caviar, sauerkraut, YEAST EXTRACTS, BREWER'S  
YEAST,  
... etc."

So not only is homebrew out, so are most of the foods that go well with  
it!

..Geoff.

Subject: malt question

I've seen some people using Munich/Vienna malt interchangeably with crystal. Crystal malt is already converted to sugar, and so doesn't need to be mashed. I thought that M/V malt was not converted, ie. it is like pale ale or lager malt, and needs to be mashed. In fact, I've seen recipes where the majority of the grain bill is composed of M/V malt. Obviously that's not just to add residual sugar, as is the case with crystal or cara-pils. What's the story, is Munich/Vienna malt like crystal or like pale?

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>  
Subject: Pitching Yeast, Orange Peels

Wishing to avail myself once again of the wisdom of the digest (the recent thread on digestive difficulties notwithstanding), I ask two questions.

1) I made a starter for my next batch. I would say that the starter in the flask is now at "high krausen" which is when the directions on the (Wyeast) package say to pitch. However, I hadn't checked the weather reports and we've got Indian Summer with a vengeance here over the weekend (80's) and I don't want to heat up my non-air-conditioned house by brewing under such conditions, nor do I think I want to be brewing when all the windows are open letting airborne beasties in looking for sweet wort to jump into (I've gotten away with it before but....). So, it seems to me that I should be able to pitch even after a few days without **\*\*worrying\*\*** -- that is, even if the fermentation has slowed, there will be **\*more\*** yeast cells in the starter solution, who will wake up, say "YUM, YUM" and start fornicating when dumped into the beer, right? Has anybody had difficulty starting fermentation after waiting "too long" to pitch your starter solution?

2) I wanted to make a spiced ale involving orange peel. Most people posting on the digest have said to scrap off the white stuff. This seems like the hard way to me. Can one not simply grate the outside of the peel (the "zest") and dump this in?

Thanks in advance and happy imbibing.

Jonathan

(P.S. Of COURSE beer is good for you. It's liquid bread, right?)

From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)  
Subject: Sparge Temp

I tried to send this directly but it bounced so I am sending it along to the HBD.

To: gsl2@midway.uchicago.edu  
Subject: Sparging

I have been working this stuff out for away. With the help of the HBD and a number of texts I think I can offer some insights.

First we need to define the difference between mash-out and sparging.

Mash-out is raising the grain temp to 165-175. This breaks down both the alpha and beta enzymes, although at different rates but this is a longer story. How important the mash-out is varies greatly depending on what and how you brew.

The sparge is rinsing the grain bed with hot water, again 165-175, this rinses the sugars from the grains. The higher temp does a better job of rinsing the sugars from the grains. Now because you do partial mashes and use extract to provide most of your fermentables how efficient your mash/sparge procedure in not of great importance. The goal of a partial mash is to add unfermentable which will bring a greater complexity to your brews.

I used your same method many times for partial mashes with great results. The problem is when you do all grain brews your need a 10-12 in grain bed to filter the run-off. Without the grain bed filtering you will get very cloudy brews with unwanted flavors because of boiling to the grain husks and solids. Again this is generally not a problem with partial mashes because of the relatively small amount of liquid the partial mash add to you total brewing volume. In my case I use 1.3 qts per lbs of grain and then sparge with enough water to bring my total brewing volume to 7 gal. It often takes 20 mins of recirculation to get the run-off clear.

I hope this make some sense,

Tom Feller

P.S. I know that is post is way over simplified but I believe the general idea is correct. Please feel free to correct any gross errors I made.

From: Robert E Nielsen <Robert\_E\_Nielsen@ccm.hf.intel.com>  
Subject: maple syrup stout

Maple Syrup Stout

6 lbs. Dark Extract (syrup)  
1.5 oz. Bullion boiling hops  
12 oz. MacDonalds Pure Maple Syrup (No, not ronald mcdonald syrup! ;  
-) )  
4 oz. Chocolate Malt  
8 oz. Crystal Malt  
1 pkg Whitbread Ale Yeast  
3/4 cup corn sugar (priming)

Place the grains in 150deg water, steep for 1/2 hour

Remove grains

Add extract syrup

Bring to boil, and add hops

I boiled for a full hour, adding the Maple syrup during the last five minutes of the boil, like a finishing hop. I didn't want to boil off the maple aroma.

Ferment took place at about 65 degrees. this stuff fermented fast! I racked to the secondary in 48 hours, and then bottled five days later.

Tasted good at bottling, although the maple flavor was masked by the "greenness" of the beer. It took a few weeks to age, but then the sweetness and light flavor of the maple syrup was perfect.

From: jim busch <busch@daacdev1.stx.com>  
Subject: re:BOS & caustic comments

In the last digest, Thomas D. Feller remarked about my somewhat caustic post about Micah's unfortunate judging experience. Let me say that I really do think an error was made when Micah had his mead rejudged, this should never occur.

Now, I did say some rather nasty comments about GABF judging as well. I am not claiming to be the worlds greatest judge, but I have traveled extensively and tried to be very fair and meticulous about rating beers based on accepted standards of origin to style and noticable faults in the finished product. Tom asks:  
>Are you saying that there were beers entered in a cagegy which your rated a 4+ or 5 that finished out of the running while beers you rated a 1 or 2 finished 1st or 2nd? Did any of the beers which you rated highly finish 1st or 2nd?

Beers that were found to be excellent usually did place well in the GABF competition. On the other hand, a certain Weizen Bock that even Mr. Papazian thought was excellent did not even place third. I believe there is a combination of problems in judging and in the process. I'm not sure the process can be changed without going the route of the Oregon Brewers Festival, no judging. OF course, it is many of the brewers who want this judging to occur, mostly for well intentioned advertising. So, it would seem that in the AHA and in the GABF competition, the skills of the judges must be unquestionable. Hopefully, this is a reflection on the newness of our craft beer industry. As we brewers become more educated and experienced, this type of error should be reduced to a non-issue. I certainly hope so.

Subject: STOPPING SECONDARY FERMENTATION

This is my first time responding to anyone out there in home brewing. If I sent it right I'll crack open a cold one.

Anyway, I have been making wines for eleven years now. There was a question regarding bottling cider and the possible disastrous consequences of a secondary fermentation. Once upon a time I made a Zinfandel wine which had a secondary fermentation and blew most of my corks across the room. The surviving bottles were similar to Cold Duck. Anyway, I now religiously us 1/2 teaspoon of Potassium sorbate per gallon of hooch at bottling time. This prevents yeast from budding, i.e. it will inhibit renewed fermentation. IT WILL NOT STOP ACTIVE FERMENTATION.

The only way I know to HALT fermentation is by pasteurization.

Potassium sorbate is commonly found in wine making supply shops and is usually called "stabilizer". They try not to make it too hard for those of us who savor the flavor of our brew.

Now I have a question for the network;  
I have a rhubarb wine which is ready to be bottled. The recipe I used has left me with a liquid which is in desperate need of sweetening. Anybody have any successful sweeteners besides granulated sugar? Thankx,  
Michael Blair (Univ. Colo.-Denver)

From: imagesys!shannon@uu.psi.com (Shannon Posniewski)  
Subject: Re: Chocolate Malt vs. Chocolate

Personally, I never really thought chocolate malt as very "chocolatey" tasting. I think its name is a tribute to its color. It's lighter than black patent and is somewhat sweet. When brewed with, it makes the beer taste sort of nutty.

I've made one batch with chocolate. We used a modified Elbro Nerkte Brown Ale (from Papazian) and added 8 oz of unsweetened baker's chocolate (in addition to other adjuncts such as dark brown sugar). (I'll post/send you the recipe if you'd like.)

We added the chocolate with the finishing hops.

Upon opening the fermenter for racking, we found large white cakes/flakes of what smelled like chocolate floating on top. Cocoa butter? They were VERY bitter, but this may have been due to the fact that they were sitting in a hops bath for a couple weeks.

The beer smelled really chocolately, but didn't taste like it.

That's my single data point for using chocolate in beer.

Date: Fri, 2 Oct 1992 19:45 EDT  
From: HULTINP@QUCDN.QueensU.CA  
Subject: Herbs other than Hops

There was a recent posting asking about other flavouring herbs for beer. As you may have gathered from my other postings, I am interested in historical brewing methods. Here are some herbal suggestions from the past.

>From the Paston Letters (Davis, Norman (ed.) "Paston Letters and Papers of the 15th Century, Part II", Oxford: Clarendon Press; 1976, p 14  
"Pur faire holsom drynk of ale, Recipe sauge, auence, rose maryn, tyme, chopped right smal, and put this and a newe leyd hennes ey in a bage and hange it in the barell. Item, clowys, maces, and spikenard grounden and put in a bagge, and hangen in the barell. And nota that the ey of the henne shal kepe the ale fro sourynge."

That is, sage, [I don't know this one: avence?], rosemary, thyme, added to ale [unhopped in this case] when laid down in barrel, with a fresh egg [complete with shell]. A second approach is cloves, mace, and spikenard [I don't know the modern name for this offhand - it is still available though] added in the same way.

>From William Harrison's "Description of Britain" (1575) (Harrison, W. "Elizabethan England", Furnivall, F.J. (ed.) London: Walter Scott Publ., 1876, pp98-103. This is an excellent description of the complete process of brewing at this time, in a domestic setting, from the purchase of malt to the final accounting of cost and yield. The text is too long to reproduce, but it mentions addition of 1.2 oz. of "arras" [again, offhand not translated] and 1/8 oz. of bayberries powdered, to a total grain loading of 8 bushels malt and 1/2 bushel of wheat meal, and 1/2 bushel of oats, into 80 gallons of mash water. He also mentions use of "long pepper", but does not like it so much.

In William Ellis' "The London and Country Brewer", London: Thomas Astley, 1744 (5th edition) [Available in the rare book library of U of Toronto] He mentions as substitutes for hops, but explicitly does not recommend use of seeds of wormwood, wild carrot seed [says it gives a "peach" flavour] or horehound [which he says is at least "wholesome"]. Later, he suggests that if fermentation is slow, one should add ginger [deemed a "hot" substance, and so able to increase rate of ferment. according to the theory of the day]. Again, later in the text he mentions that some brewers add *Coculus India Berry* [??] which he says is "a violent poison", and also the use of coriander seeds, to enhance the mouth feel of the brew [I have tried this, it is quite satisfactory, perhaps 1-3 tbsp finely powdered into the boil of a strong beer.]

This is all I can find easily on the subject. Of interest is that while in the mid 16 th cent., hops are a detested innovation, by 1575 Harrison takes them as essential, and by 1744 other herbs are decried as contaminating the brew. The other interesting note is that while at the end of the 16 th cent. it is explicit that ALL malt should be as pale as possible [to maximize nutritive quality], by 1744 Amber, and Brown malts are considered a key ingredient in the finest English beers.

I hope you all find this stuff useful and interesting. I am sorry that I cannot provide equivalent data on continental practices. By the way,

unhopped ale is quite palatable, if perhaps a bit dull, and keeps for at least a couple of months under modern storage conditions.

Phil Hultin.

Subject: Re: Dusseldorf Altbier

Ah, all this talk of the wonderful Altbiers of Dusseldorf is truly making me thirsty. But alas, this is a thirst which cannot be quenched in the United States. I might have to cash in on one of those bargain transatlantic air fares being offered this autumn. Or better yet, just make it at home.

The best reference for this style is Michael Jackson's Pocket Guide to Beer. I commend the Dusseldorf section to everyone, ESPECIALLY to those who might be revising the AHA contest guidelines, or judging this category in a contest. JACKSON is very specific - gravity 12 plato (1.048), Spalt hops, bitterness from the lower 30s to the 50s, (\*NOT\* the 25-35 which the AHA lists!) colour around 35 EBC. Tony Babinec went on at some length about the yeast. Wyeast #1338 "European Ale" is the genuine Dusseldorf strain. This yeast is the key to achieving the big malty character with only a moderate gravity beer. This yeast is also one of the major elements which makes Alt different from the superficially similar Brittish pale ales. (This yeast is, by the way, a real pleasure to work with.) Also key to this style is the technique of warm fermentation followed by cold lagering. The malt bill can contain about 10-15% wheat malt. I prefer using a portion of Vienna malt rather than crystal, with a touch of chocolate malt for coloring, to offset the lightening quality of the wheat. I've made very good Alt with partial extract methods, using Laaglander dry light unhopped extract. My most common mistake in making Alt is to let the gravity get too high; relax don't worry etc., and just call it "sticke".

What most people, including beer judges, don't understand about Alt is that it is supposed to have a big, malty flavor profile, with lots and lots of hop bitterness. This misconception, no doubt, stems from the lack of good commercial examples available here - it takes a trip to Dusseldorf to taste it. This is a BIG beer.

Of the Zum Uerige brewpub's altbier, Jackson sums it up: "\*\*\*\*\*". He goes on: "Zum Uerige ... produces the classic Dusseldorfer Altbier, an aromatic, tawny brew, deep in colour and flavour, with a slowly unrolling hop bitterness in its big and sustained finish. Zum Uerige \*\*\*\* beer is the most assertive, complex, and characterful of the Alts. It is also the most bitter."

There are several American pretenders, but none of them measure up. WIDMER ALT was originally attempting to duplicate Zum Uerige, and was doing a pretty good job of it, but recent samples have been rather disappointing. ALASKAN AMBER and OLD DETROIT are both creditable. (There's something about Alaskan Amber which makes it particularly delicious with smoked salmon - probably not an accident.) DUSSELDORFER DARK ALE from Indianapolis Brewing Co. tries hard. It is a tasty, very smooth beer (when fresh), but it is nowhere close to hoppy enough. The two ST. STAN'S alts are just not in the Dusseldorf style.

I will always remember my evening at Zum Uerige, drinking perhaps the best beer I have ever had, and watching the staff roll the wooden barrels out to be dispensed by gravity. (I wonder if the wooden barrels have something to do with the magical flavor. There has been some research on this topic.) It made Dusseldorf - an otherwise unspectacular city - the high point of a 3-week European vacation. Discussing it makes me so thirsty that I'll have to make that Wyeast #1338 starter and get brewing, because I can't afford airfare to Dusseldorf. Like they say, if you want

it done right, do it yourself.

From: Jim Grady <jimg@hpwalq.wal.hp.com>  
Subject: Spiced Apple Wine

Some of the discussions about cider on the digest lately gave me an idea. What about a spiced apple wine? I was thinking of using spices that one frequently uses for mulled cider & maybe taking a look at some of the Christmas brew recipes, e.g. cinnamon, cloves, nutmeg. I have not decided

whether I should make it still or sparkling. I was thinking of making the must from:

- Fresh Apple Cider
- white wine grape concentrate (how much?)
- honey/sugar to bring S.G. up to 1.100
- white wine yeast
- spices

Anybody have any thoughts as to when I should add the spices? I was thinking of adding them when I pitch the yeast and removing them when I rack to the secondary. Has anybody else tried this? What spices did you use?

Thanks in advance.

From: psealover@hns.com (Paul Sealover)  
Subject: Dried cherries in beer

I've got a question about using dried cherries in beer.

My wife brought me two pounds of dried cherries from her recent trip to Michigan. I just pitched a German Ale and am going to add the cherries to the primary after the krausen falls.

The question is ... do I still need to add campden tablets to avoid possible infection. Seems like dried fruit would be safer than fresh but thought it wise to consult the powers that be since I have a few days.

Also, I've never used the campden tablets before .... do they affect the flavor of the brew ????

Thanx,  
Paul.

From: Dave Coombs <coombs@cme.nist.gov>  
Subject: Re: Orange Peels

I recently brewed a spiced beer with orange and lemon peels. I had planned to simply grate the fruits, but the grater didn't seem to do a very good job. Maybe it was too dull, but the grater didn't seem to dig in well. I cut the peels into strips, as you would for marmalade, but I was too tired to slice off the white part. There are a lot of spices in it, though. I can't tell you how it will turn out, but it smells like I'd expect "mulled" beer to smell. After a few days of fermenting at 70F with London ale yeast, the gravity had dropped by half, but it was far too sweet to be judged.

If you know how to zest citrus, I'd like to hear it. Maybe I just gave up too soon. Curiously, I couldn't find a reference to citrus zest in Fanny Farmer, my old standby.

So, what's the motivation for removing the white fleshy part of the rind?

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: First Lager

To: Homebrew Digest  
Fm: Jack Schmidling

This weekend was my first attempt at a lager. Unfortunately, a mini-heatwave began the day I started the yeast. I have been able to keep it under 60F but that is the best I can do without help from Mother Nature.

The yeast I used is Pilsner Urequel that I received from a customer who claims it came directly from the brewery this year. I have since noted that someone mentioned Wyeast has a PU yeast and would like to hear from anyone who knows what their source is and when and how they got it.

This yeast seemed to be far more vigorous during starting than the Edme I am used to. Twice it squirted out of the ferm lock in the flasks and in volumes I normally use.

I was agog when I opened the fermenter this morning to find a head that was snow white and looked more like angle food cake than the usual foam I see. It was also about twice as high as the Edme head would have been.

A sample tonite from the spigot tastes great and seems clearer than usual. I would have expected a bottom fermenting yeast to be more turbid from the spigot. It also seems to have a higher level of carbonation than an ale. At this point, a little more than 24 hrs into fermentation it is a perfectly drinkable beer.

My daughter's wedding party is at the end of the month so it WILL be ready then. Hopefully, the next one will be a real lager.

Subject: Belgian malts from Micah Millspaw

These new belgian malts has any one used them yet? I bought some carraviene and some special B malt. I am going to use the carraviene in a barleywine this weekend, it seems appropriate. The special B is a tuffer choice, the stuff looks like 120 caramel malt but tasted like lightly roasted barley. I'm thinking that it would be a excellant taste for a scotch wee heavy (my favorite style) rather than the roast barley that I now use (in tiny amounts). Does anyone out there in HBD land know of these malts original uses, if so I'd like to know. Also any other styles that might be enhanced by these malt would be welcome.

>

If it smells like vinegar then it is lost.

As to why it went like vinegar, I can't help but wonder what the bottle  
had been exposed to before you used it to make the cider. The recipe  
does not state explicitly that a new bottle should be used, but assumes  
it; otherwise, I'd pasturize the cider to kill of bad stuff and clean  
the bottle like you would any fermenting vessel, then add the yeast.

Subject: haze

i just tried two brews that had the same problem. i brewed both with malted barley that i roasted and crushed with a rolling pin. both beers had excessive haze. the haze settled quite a bit after a week and a half in the fridge (after 2.5 weeks aging). i put the adjuncts in the cold water and left them in until boil (possibly slightly longer in the beer that had the worst haze). is the amount of haze directly proportional to the amount of time the adjuncts spent at temp's in excess of 170F? Is there something else i was supposed to do with the adjuncts. what are the other reasons for removing the adjuncts before boil? what is the real cut off temp for them? both were extract brews but otherwise had nothing in common and were brewed in my usual manners. Thanks.

From: Pierre Jelenc@cunixf.cc.columbia.edu  
Subject: Wyeast question

I have had a curious experience with Wyeast Champagne yeast. I received a package that looked like it had burst in shipment, and was not ready to use it, so I tried to plate the yeast for future use. I slit the pouch, and discovered that the inner bag had not burst, but instead was swollen tight. I fished it out with sterile tweezers, opened it, and plated 10 microliters of the inside and the outside liquids, expecting to see a difference, perhaps a contamination somewhere, or yeast in the inner but not the outer compartment.

What I got instead was identical growth from both, same rate of colony growth, same number of colonies (I used a calibrated loop for the inoculation), and in both cases no bacterial contaminants, but about 30% of minuscule colonies that I take to be petite mutants.

What does it all mean. Why is there yeast in both the inner and outer bag? Is it the same strain (it's supposed to be a single strain)? Where is the yeast supposed to be?

Any help and suggestions welcome.

Subject: Stuff left in clorox solution...

I had left some clear siphon tubing, bottling spigot, and glassware in a plastic (fermenting) bucket filled with a clorox-water solution (I didn't have a good place to hang the tube, and, sure, I was lazy). The clear tube has become cloudy.

The best advice I have heard is : "Tubing is cheap, replace it."

-Is this the general concensus?

-Can I safely use it?

-Will it impart yuccy (a technical term) flavors? If so, this would mean that

I may have ruined the fermenter as well...

-Anyone know what the reaction is?

-What's the preferred way to store tubing (and other plactic stuff)?

-Should I dilute the clorox with ammonia? (Kids, don't try this at home)

:-)

From: Pierre Jelenc@cunixf.cc.columbia.edu  
Subject: Re: Wyeast question

The colonies growing from the Champagne yeast package described in my previous post have now been examined by several knowledgeable people in the micro department. The large colonies appear to be healthy *Saccharomyces*, but the small ones are in fact bacteria!! They appear to be some sort of bacillus, thin rods which aggregate easily, clearly not *E. coli* or salmonella.

The consensus is that it should not be too surprizing that bacilli grow poorly on YPD plates, especially since many if not most are anaerobes and these plates were aerobic.

There are now two problems, therefore: where does the contamination come from, and why were there yeast both in the inner and outer compartments.

From: polstra!norm@uunet.UU.NET (Norm Hardy)  
Subject: Alt Beers

The recent comments about the Duesseldorf beers and some USA versions prompted me to post this.

[1] Widmer Alt was originally a Uerige Alt clone, or as close as Kurt Widmer could do (he did, and maybe still does, use the same yeast). Problem was, it just wasn't selling. When asked by a Seattle beer columnist why Widmer changed the beer to be less bitter, Kurt replied: "because I have to sell the stuff!". Even the Portland area doesn't fully appreciate the stuff.

[2] The alt beers of Duesseldorf are varied, from light amber to very dark amber. The tastes run from semi-malty and sweet (Schlosser, Diebels) to VERY bitter (Uerige and Schumacher and some others I can't remember now). My last time there, in 1990, I found the alts to have a grapefruit kind of bitterness that I found off-putting. Perhaps this coming summer will prove to be more enlightening.

[3] Some German locals have said that some alt beers could be blind tasted and could be confused for pilsners (again, BLIND tasted). Interesting conjecture....

>E. coli or salmonella.

First, if the pack was swelling before puncture, it was probably a defective sample. The other interesting point is the contamination level. We examined a pack of Wyeast Ale (I dont recall which one) in the spring and were astonished to see the quantity of peddiococcus (spelling??). Just another data point.

I have noted this same phenomonon. It seems particularly noticable in highly hopped american pale ales, typically when Cascade or Centennial hops are used. I also noted the same thing when I was drinking the Alts in the Altstadt area of Duesseldorf. I suspect some correlation between very high hopping levels and citrus notes. I'm sure there is a good chemical explanation to this.

Date: Tue, 6 Oct 92 08:49:22 CDT  
From: Doug Behm <DBEHM@UA1VM.UA.EDU>  
Subject: Spiced Wine

>From 'Penguin Book of Homebrewing and Wine-Making'  
Basic apple wine  
Mixed apples 8 to 16 lbs  
sugar as standard syrup 2 to 3 lb  
pectinaze  
rohament P  
acid blend if necessary  
yeast  
A.P or white wine as starter  
vitaminzed nutrient as starter

Summarized: wash apples, rinse and crush apples and put in sulphited water before they go brown.( 1 campden tablet per gallon). Cover fruit with not more than 6 pints of water in which pectinaze and rohament P has been dissolved and leave for 24 hrs, after which the apples should be pureed. Add hot water to bring to desired gallonage at fermentation temp and stir in sugar, nutrient and yeast starter. After a week strain off pulp, put under fermentation lock and proceed as 'usual'. Drinkable at 3 months, better at 6. For cyser, substitute 1/2 pint white grape concentrate for 1/2 lb sugar. For mead cyser  
honey 2lb  
apple juice 1/2 gal  
acid blend 2 teaspoons(check pH, about 3)  
tannin 1/4 teaspoon  
vitaminized wine yeast nutrient  
mead, white wine or A.P. yeast starter  
pectinaze 1 tablespoon

Ferment apple juice. nutrient and half the acid should be added. Diluted honey, rest of acid and tannin are mixed together and added immediately after first fermentation slackens.

Dissolve honey in warm water and sulphited at 100 ppm (2 tablet per gallon), dissolve other ingredients and make up to desired volume. leave closely covered for 24 hrs before yeasting. Acid mix - 4 parts each of malic and tartaric and 2 parts of citric. juice of 2 lemons will do in a pinch.

Never tried any of this.

Subject: Re: Orange zest

Dave Coombs asks about peeling oranges:

I use a lot of orange zest: for brewing, for an occasional cocktail, but mostly for putting in my morning cup of black coffee (try it, you'll like it). Here's how I do it:

Take a whole unpeeled orange and with a standard potato/carrot peeler slowly slice a spiral of zest from the "north pole" of the orange to the "south pole". With a little practice you can even get it all off in one continuous strip. I keep the excess in a small glass jar in the fridge. If you like, leave the peel out on the kitchen counter for a few days. It will dry and curl up. This will keep in a jar in the cupboard. You can grind the dried peel into a powder to be used in your spice beer or you can use it fresh. I find the veggie peeler makes it easy to remove the zest and not the white part (the pith) which is very bitter.

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>  
Subject: Re: Orange Peels

Dave Coombs <coombs@cme.nist.gov> asks about zesting oranges. The easiest way to do this is, of course, to use an orange zester. Such a tool can be had for \$5 or so (US) at your favorite kitchen supply store.

Just so you know what you're looking for, it will have a handle, then a small curved head with sharp holes in it running parallel to the handle. Sort of hard to describe, so I'll try a silly ASCII picture. This is looking at it from the front, down the length of the handle:

```
-----  
  /  /  
0-0-0-0-0
```

You simply scrape it along the peel, and the holes gouge out thin strips of the outer peel with no white pith. The reason you want to avoid the pith is that it's very bitter; all the essential oils you want are contained in the orange zest.

Since everyone is gearing up to make Xmas brews (including me), here's an easy recipe that turns out extremely good. I'm normally an all-grain brewer, but it's easier to make large quantities of extract brews for parties and things, and the spices tend to cover up some of the extract qualities. Of course, you could use the same spicing technique for an all-grain batch, too.

Remember to go easy on the spices. The flaw with a lot of commercial Xmas brews is that the spices overwhelm the flavor of the beer rather than complement it.

#### Quick & Easy Spiced Brown Ale

MountMellick Brown Ale Kit  
3-4 whole cloves  
3 whole cinnamon sticks  
1/4 tsp nutmeg  
4 oranges  
1/8 cup fresh Hallertau hops (leaf)

Simmer spices, hops, and zest of 1 orange in 1 qt water for 30-45 minutes. Make brown ale according to 3.6 gallon recipe. Add spice mixture (do not strain) and zest of other three oranges to wort. Ferment, strain, and bottle according to kit instructions. The flavors balance very nicely after only a short aging time, but it gets better after a couple of months. An excellent holiday beer.

Subject: Various topics

Dear Brewers

I have a couple of things to post:

First, I'll be moving to a new e-address, so any personal responses should go to xlpsjgn@luccpua.it.luc.edu (John Norton). I'll still be at this present address until the end of the month (I think?). I'll be re-subscribing at my new address soon.

Secondly, my apologies to the HBD net for a short personal, but I need to contact ERIK (of Glo:gg fame) re: Glo:gg here in the Swedish Village in Chicago. I couldn't find the Glo:gg essence - with the high alcohol content - but did find a glo:gg "mixer" of sorts. It comes in a 16oz(?) bottle and might be usable in the later stages of the boil?? Please advise. And/or, if anyone else on the HBD can advise us as to using something like this, please let us know. It's not in a concentrated form, but is, well, like a mixer like you'd get at a grocery store: just add the booze.

Finally, I just wanted to say that I bottled the Weiss I'd been brewing and snuck a peek at it after only 2 days in the bottle. With the exception of an expectedly low carbonation (it should get better as the brew matures) I thought it was quite good, but still not the Weiss-like brew that I'm used to; it didn't have the characteristic Weiss bite, but more of a Samule Adams taste (like I said, I'm not complaining Papezain's recipe (this was what I used) says that it should be ready in a few more days - 10 max - but is this really enough time for an all extract, 50/50 wheat weiss to mature? Thanks in advance for any reactions.

Cheerz,

John

Subject: Wyeast steam beer?

In a recent (981?) HBD, Russ Gelinas asked about a upcoming Wyeast version of steam beer yeast.

I was at Kedco on Long Island on Saturday (10/3). They had JUST recieved a Wyeast shipment (dated 9/30!!). One of the offerings was "California"; I'm almost certain the number was 1214. The fellow at the store said it was to be used at ale tempretures, but could be "lagered" in the secondary (I hope I'm quoting correctly). This is probably your answer, Russ. I bought a packet, but haven't tried it yet.

If anyone has/does soon, please consider sending me a short post about what primary/secondary temperatures you used.

Dave, I use a citrus peeler made by Sunkist. It has a "zest peeler" on one end of it. You can get them at most any grocery store in the produce dept. They are only a \$1 or so. The motivation for removing the white fleshy part of the rind is that it leaves a bitter flavor.

From: Dave Coombs <coombs@cme.nist.gov>  
Subject: [hinkens@mac.wisc.edu: Citrus Zester]

To summarize the responses I received, the motivation for using citrus zests is to get the great oils that lie near the surface of the rinds without the bitterness from the "white stuff" underneath. Potato peelers have been suggested. I'm not sure it would work much better on the slippery rind than the grater did, but it might. Another suggestion is a nutmeg grater. Here's one response verbatim. Thanks to all who responded.

I saw a device that is designed for zesting fruit. I'll try my hand at ASCII drawing:

Side View:    Front View:  
-----  
\*^    [\_]    <---- Sharp "Box" to \_\_\_\_\_  
      Handle cut the zest.

The device has a smooth metal plate much like a spatula that rides on the fruit's rind and a sharp 1/8 inch square "box" that cuts the zest.

My mother showed me the unit though I'm not sure where she got it. I would try the larger department stores or mail order houses like The Chefs Catalog.

Good Luck!

Subject: Yeast Starters

I recently bought Dave Miller new book, Brewing the World's Great Beers (I think that is right) and was reading his section on making yeast starters. He says to put some noble hops in the starter, in the past I have never done this. I believe the reasoning is the hops offer some preservative action. I use a pressure cooker to can by wort and believe that 10 min at 240 degF should kill any unwanted living things. I am sure that the pressure cooker does a far better job than adding hops.

I do have a couple of question about making starters,

Do I really need to boil my DME before canning? When I remove my wort for the canner it is boiling away so in effect I am boiling it twice.

Should I transfer the trub from my canned wort into my starter jar? It has been stated that the yeast will use the trub as it starts to ferment so I have always transfered this to help the yeast start.

Happy Brewing

Subject: cider

Garrett Hildebrand, Andy Kurtz and Charles Spiteri (+ others?) have been pursuing a cider thread lately. My \$0.015:

You can make a great beverage, simply and quickly, from "soft cider" and ale yeast. However, I strongly recommend yeast nutrient. I have some stuff that seems pretty standard. From "Wine Inc." A 2 oz. bag cost <\$2 and has enough for many gallons (1 tsp/gal).

The following is embarassingly easy for any brewer, and produces good results. Start with a 0.5 gal. or 1 gal. bottle of juice. All that seems to matter is that it's sugar- and preservative-free. I've used juice reconstituted from concentrate as well as stuff that has never been concentrated. Filtered as well as unfiltered. "Ye olde all-natural family farm" brand as well as major US food conglomerates.

Remove the top. Pour off two cups. Drink one, mix the other with yeast nutrient and dried ale yeast (I've used Edme). Return to the bottle and affix an air-lock.

Q: Does anybody use Wyeast with cider? Which variety(ies)?

A starting gravity in the 1045-1050 range seems typical. Final gravity will be near 1000, so it's quite dry and apt to be - ahem - cidery. It also has a fair kick to it, being 6% or more alcohol by volume. Siphon it off the dregs and drink immediately or bottle. You can pour more juice (with nutrient) on top of the dregs for your next batch. I get good results in 10 days, but I suspect it would be acceptable in a week. Before I started using yeast nutrient, it took longer. In any case, bottle aging gives a mellower drink.

I've never had `vinegar' problems, but the nose does recoil a bit at the first whiff upon removing the airlock: lots of alcohol and acid seem to get trapped in the head-space.

For either sweet cider or strong cider, add a pound of brown sugar per gallon. With ale yeast, the alcohol whould eventually kill the yeast leaving residual sugar. Alternately, use champagne yeast to get something the strength of table wine. The latter needs months of aging to mellow out.

I have 3.5 gallons of regular and one gallon of sweet fermenting now. I'm thinking about experimenting with added fruits later this season. In fact, I added half a pound of raisins to the sweet cider, following a recommendation in the HBD two years ago. Has anybody tried other fruits?

Cheers,

Rob

> Im off to Indianapolis for a weekend in November...and might have some  
>time to sample the local brews..if there Are any!

> Where does one go, in and around Indianapolis, for good beer?

There are two breweries in Indianapolis. The first to open was the Indianapolis Brewing Company. They are a micro, not a brewpub, so you can't drink there (unless of course you know someone :-). Their Dusseldorf Alt is quite good, although it wouldn't please a true Alt-head. At one point they landed an account at the Hoosierdome, selling their Pils to basketball fans during Pacer games. This was something of a coup, giving them some much needed public exposure. They've had their ups and downs, but are hanging in there. If you call them (317-898-1235), they'll be happy to tell you where their accounts are, which would be a good starting point in seeking specialty beer houses.

The best place I've found to imbibe in Indy is the Broad Ripple Brewing Company. As the name suggests, this pub/brewery is located in the Broad Ripple district, very near 65th and Cornell. They make some good beers (their ESB won a gold at the '91 GABF), and carry an interesting variety of midwestern micros. Proprietor John Hill drives all over the midwest to keep his establishment well stocked.

Indiana's archaic laws have forced John to jump through some hoops, including making the pub and brewery two separate businesses with separate addresses. They are in a single building, but there can be no doorway directly between them. To go from pub to brewery, one must go outside and down a sidewalk and then into the brewery. This can be fun in January. Initially John was told that there could be no beer lines running between the two businesses, and that he would have to keg the beer in the brewery and wheel it down the sidewalk. He managed to get around that bit of stupidity, but must still maintain separate records of each business, and "sell" his beer from the brewery to its only customer, the pub. Last I heard business was doing well.

Enjoy,  
CR

From: James S Durham <js\_durham@pnl.gov>  
Subject: Wyeast Problem?

I recently brewed two batches of different beers on two consecutive days. For the first, I used two packages of dubious yeast: A (yikes!) Red Star Ale and the yeast supplied with a M&F Old Ale kit. I brewed an India Dark Ale (at least, that's what I call it). I made up a starter by taking out two tablespoons of boiling wort and adding water to cool it to 100 degrees F. The second batch was a stout, and I used Wyeast Irish Yeast. The package was completely inflated with CO-2 when I cut it.

Here's the interesting part. The IDA began visible fermentation within two hours. It took the Wyeast 2 days to begin actively fermenting. Is this normal? Both are fermenting side by side in the same closet, and both brews were essentially identical with respect to sanitation practices. What gives?

Incidentally, what do you call a beer that uses an India Pale Ale recipe (including oak chips) with 3 of the seven lbs of light DME replaced with dark DME? Is there another name for India Dark Ale?

From: whg@tellabs.com  
Subject: Extract gravity

While formulated in a recipe today I realized how empirical most of my OG estimates are when doing an extract/partial mash recipe. For mashed grains I know that I get 28-30 pts/lb/gal. However, I don't even really have a rule of thumb measure for extracts. Obviously each brand will vary and I wonder if anyone out there has a chart that says for lists pts/lb/gal for different brands of syrup and DME. I'd guess that DME gives about 38 pts/lb/gal and most liquid extract give around 34 pts/lb/gal. However, again rather intuitively, I think I get the about the same O.G. using say 2 4lb. cans of Alexanders or 2 3.3lb cans of M&F.

Anybody out there got any info,  
Walter

From: whg@tellabs.com  
Subject: Trappist Ale (?)

This coming weekend I'm planning a brew that I hope will be a something close to a trappist ale. Being the first beer of the new brewing season, I'm doing a "quick and dirty" partial mash. I'm using the Belgian malts for the first time. The grains will be:

1.0 lb Biscuit malt  
0.5 lb Belgian Crystal (what is this 50L)  
0.5 lb Special B (120L ?)  
0.5 lb Roasted Chocolate

I'll mash the above for 45 minutes or so and then sparge. And boil with 6 lb of Northwestern Amber Extract and 1 lb of pure dried wheat extract. The expected OG will thus be in the 1.055 to 1.065 range. Hopping rate will be 35 IBUs worth (? this may be wrong but I'll look it up) of Tettinger pellets and Kent golding plugs, at least three additions with a Tettinger steep and a Golding dry hop. I popped my belgian ale Wyeast and will make up at least a 16 oz starter around thursday (brewing saturday night). This will be a full boil with an emmersion chill.

So what does the collective consciousness think? Will this be at all in right general style? (this is an off the top of the head recipe) Will the biscuit malt have enough enzymes for a happy mash? does it matter? should I use some pale malt? I don't know if Golding dry hops are appropriate but they're spicy finish seems like it should be OK. Besides they're sooo good  
I can't resist. I'm I just hopelessly lame? ;-]

Thanks in advance for any comments/advice,  
Walt

When I was in Munich, I noted that the Hofbrau Haus did the same thing and it would depend on your opinion of that beer. I suspect it is not considered to have any magical flavor :)

>From: garti@mrg.xyplex.com (Mark Garti mrgarti@xyplex.com)  
>anyone ever put hops in their liquid yeast starters?

All the time.

>if so why?

Because my starter is a pint drawn from the previous batch after chilling. It is my last hydrometer sample and instead of risking contaminating by pouring it back, I use it to start the next batch (after sterilizing of course). Aside from that, it gives the yeast a foretaste of what it will be doing soon in a big way. Seems like a reasonable thing to do. There are those who would dilute it down to about 1.020 but I quit doing it when it didn't seem to make any difference.

>From: Pierre Jelenc@cunif.cc.columbia.edu

>The colonies growing from the Champagne yeast package described in my previous post have now been examined by several knowledgeable people in the micro department. The large colonies appear to be healthy Saccharomyces, but the small ones are in fact bacteria!!

You are violating net protocol. Wyeast is NEVER contaminated.

> They appear to be some sort of bacillus, thin rods which aggregate easily, clearly not E. coli or salmonella.

Just for the record, E coli is a bacillus.

>The consensus is that it should not be too surprizing that bacilli grow poorly on YPD plates, especially since many if not most are anaerobes and these plates were aerobic.

E. coli is aerobic and facultative anerobe.

>There are now two problems, therefore: where does the contamination  
come from, and why were there yeast both in the inner and outer  
compartments.

It's a conspiracy :)

>between very high hopping levels and citrous notes. I'm sure there is  
>a good chemical explanation to this.  
>  
I think the answer \*might\* be dry hopping. I and a couple of brewing  
comrades noticed this effect during an IPA brewing stint. Namely, the  
harder you dry hop, the more of a citrus peel finish you get. Higher  
alpha  
hops seem somewhat worse in this regard. We went as high as an ounce of  
hops  
per gallon in the secondary. The results were reminiscent of chewing on  
a  
piece of grapefruit peel, pith and all! :-)

We didn't experiment with different methods of dry hopping, so I can't  
say what effect differences in technique would have. But IMHO, Jim is  
correct in suspecting the correlation between the grapefruit notes and  
high  
(dry) hopping levels.

As to a chemical explanation, I can't say, other than to speculate that  
there are similar flavour components in the hops and citrus which get  
leached  
out in extended dry hopping. Most likely volatile oils of some sort,  
since  
when we quit dry hopping, the grapefruit finish went away, even though we  
used more hops in the kettle.

From: "Ken Schriner" <KENS@saturn.uark.edu>  
Subject: BAA and beer judging

As a slightly isolated homebrewer in northwest Arkansas (fayetteville is where I work), I was ecstatic to learn of Beer Across America (i am in no way affiliated, just a happy customer.)

One of their first shipments (several months ago) was from Boulevard Brewery in KC. As a former Kansas boy, I am particularly fond of their beer. Anyway...as I was drinking some of their fine beer, it occurred to me that several of the members of this list were probaby enjoying this fine beer for the first time. And mentally noting how good it was, how it compared to others of the same style, how it compared to their home brew. In short...judging it.

I have always wanted to learn more about judging beer. But...isolated in the Ozarks as I am (and loving it) it was difficult to compare my notes with others' on the subject of judging beer.

But...if many folks were drinking the same beer, folks interested in beer, folks interested in judging, folks connected to each other by an electronic network...well it seemed a natural. A National Electronic Beer Judging Club. Those that are getting the beers from BAA could judge those two beers each month. Those that don't belong to BAA, could participate by obtaining the same beer from their local outlets. Once a month we would all be judging the same two beers. And comparing our notes, etc.

Is there any interest in this from any other HBD'ers? I think a natural point to start from would be getting one of the certified judges to post some info about how a beer is judged (I don't know how.) and maybe someone else could also post how to join BAA (I don't know how, mine was a gift from a great wife.)

Any interest?

From: ZLPAJGN%LUCCPUA.bitnet@UICVM.UIC.EDU  
Subject: Samule?? Quayl??

Dear Brewers,

I just caught an error in my last posting to the HBD (various topics). I was referring to \*Samuel\* Adams (not 'Samule'). Geez! Perhaps I could have been a contender for the V.P.'s slot!! (NOT!!)

OK, onto more serious matters: brewing! I think I'm going to try the Quick-n-Easy Spiced Brown Ale recipe for Christmas that was posted in the last HBD. I'm not sure whether I'll try to incorporate the Glo:gg 'mixer' I spoke about; perhaps this Ale recipe might provide a good base for it? But along those lines, I'm curious about a few things:

1) What type of yeast to use... I'm assuming it'll be an ale yeast, but is there a specific brand/type that I should use? Further, after using my first liquid yeast, I DON'T want to go back to a dry yeast, and I'm assuming this recipe calls for a liquid yeast?

2) I'm inclined to think that this recipe might benefit from a single-staged method, allowing for a maximum attenuation (?) of the spices. If this is the case, then wouldn't pelletized hops be better than leaf?

3) Finally, while I was looking the Glo:gg essence I also found the pre-measured ingrediants for brewing your own home-made Glo:gg, or at least the brew into which you add the wine and/or vodka. The pouch of ingrediants contained a variety of dried spices, almonds, rasins, and I think even orange rinds, but I can't remember. So my question is, can I substitute and/or add these ingrediants to the recipe? How should the almonds be treated?

This recipe, especially with the addition of the Glo:gg stuffs sounds both promising and tasty, the perfect Yule-tide spirit for the Home-coming. But, as I'm always the novice at this craft, I'd really appreciate any input, guidance, words of experience and advice from others who can impart their brewing wisdom ;-)

As always, Cheers

John

From: pjd@craycos.com (Phil Duclos)  
Subject: GABF '92

Some of you have asked, so I thought I would fill you in on my experience at the GABF this year.

This was my first time at the GABF. I decided to go up early on Saturday for the AHA members only tasting at 2pm and then return at 6:30pm for the regular session. The 2pm session was wonderful. ~700 beers and about as many people. There were serving people there although the adverts claimed "just you and the beer." Oh well.

I tried the chili beer from Crazy Ed's in Cave Creek, AZ first. This was probably a mistake as it was really hot! I had to ask and yes, they do put a chili in each bottle. My palate was ruined. I had a couple other non-descript tastes on that aisle and then hit what was to become my favorite of the evening, Celis White from the Celis Brewery in Austin TX. It was wonderful. I really like spicy tasting beers (not chili!) and the Celis White is flavored with coriander and orange. The other 2 Celis brews were good too, but the White won Gold a little later in the day.

There were plenty of other great beers, some flavored, some not. It quickly became difficult to choose which to try. We only had 3 hours and even though they only poured about 1 ounce, it quickly adds up. Pacing is important. This makes the decision quite difficult. I avoided most of the ones I can get locally or have tried before, except, of course, my favorites. I did taste a few bad beers. A couple had that "cooked corn" taste and a few had too much phenolic. Only one was truly bad and had to be poured out. I thought to myself, strolling past the empty Coors booth, that its quite easy to get spoiled with access to this much good beer.

I bought a commorative T-shirt (\$21!!!!!! AHA isn't losing money on this affair). There was quite an assortment. All quite pricey.

They kicked us out at 5pm, said something about Dobermans. I left.

I came back about 6:45pm with my wife and mother in law for the evening session. Wow! What a line! Too many people. Having seen the size of the hall already I was curious about where all these people standing in line outside thought they were going. We got inside and found out. What was earlier a large airy hall had become a snarled sea of people. We quickly grabbed our glasses and headed for the "Z" section which was furthest from the door. Most of the mass was slamming drinks in the "A-C" section so it wasn't too crowded at the other end. We had a couple nice beers on that aisle but I noticed a disturbing trend. Some of the better beers had run out!

It quickly became a race against the masses to reach all the beers which had won medals. We missed a bunch and were disappointed.

I was also disappointed by the crowd's attitude. At the earlier session, it was most common to see people tasting their beers with a careful attitude.

At the evening session it became apparent that many were there merely to slam back a few beers. Quite a few times I had to wait while a couple of guys slammed down each of the brewery's different beers in quick succession.

I was reminded of chugging contests in college. Now I'm not trying to tell others how to drink beer, but it seemed a waste of both good beer and a rare opportunity for the drinker when the goal became quantity, not quality. It was humorously suggested that the mega-breweries have booths which provide full 12 ounce glasses for those who are intent on slamming. This, of course, is a bad idea, but the joke seemed appropriate at the time. We left early.

In conclusion, I had a wonderful time in the afternoon, but the evening session was a zoo. The volunteers were working hard, but I will probably volunteer next year. Friday night might be better just because all of the beers were available. Of course on Friday night you don't know who the winners are (just have to judge for yourself). Saturday afternoon is not to be missed. There were too many really good beers to remember them all. Its easy to become disoriented and confused about which beers you tried and liked because there are so many. A lot of brewmasters were on hand in the afternoon and the discussions sometimes got technical.

Everyone (except the Dobermans) was quite friendly and many seemed to be having a truly good time. I'll be back next year.

Subject: Re: Orange Zest

While all these techniques for removing an orange's zest (the orange part, excluding the inside white part) are fine, there is a kitchen implement call, strangely enough, a "zester". It is a somewhat spoon-shaped device, with a row of sharp-edged holes in the end of it. It very effectively removes little strings of orange stuff into a waiting vessel. Mine cost around \$3, at better and worse kitchen stores near you.

Subject: Yeast starters from Micah Millspaw

>Subject: liquid yeast starters

>anyone ever put hops in their liquid yeast starters?  
>if so why? anyone not do it?

I feel that this question opens a whole can of worms as far as yeast propagation goes. While it might not hurt anything to put hops in the yeast starter it can serve little but to increase the cost of the process ( oh, it is possible that the hops can lower the ph enough to help, but its not a viable method of ph justment). The approaches that homebrewers seem to take to yeast propagation is often the result of misinformation, marketeering and just plain wrong thinking about the metabolic process of yeast.

The common way the hbers increase their pitching volumes is buy using dry malt extract (and sometimes hops) and water, boiling it, cooling it and adding yeast. So what have you got? A little batch of beer. The little batch of beer will help you get a somewhat faster start at fermentation but it realy not what you need and plus DME is very expensive and messy.

Here is where understanding comes in. It is known that yeast have two major life cycles (metabolically speaking) aerobic and anaerobic.

This is the idea behind aerating the cooled wort. You see the yeast need to have oxygen (and other trace gases) to respire, in the respiratory

mode they reproduce much, much more effectively than at any other time. If they reproduce, you get more yeast, which is what you want rather than a little batch of beer.

So the trick is to set up conditions in your yeast starter that encourage the yeast to respire and hence increase bio mass. The most practical way for homebrewers is to use proper yeast nutrients ( which have been dicussed on earlier HBDs) and prehaps more importantly proper carbohydrate sources. It is known that yeast can respire more effectively when exposed to some carbohydrate sources than others. Brewers yeast does the worst (as far as reproduction goes) on maltose and other mash derived complex sugars. It follows that the use of dry malt extract is not the best choice. Interestingly, brewers yeast respire best with sucrose, glucose and galactose, these occur in common sugar ( like from the grocery store). Also this type of sugar is not very pure and contains all sorts of excellent trace nutrients that the yeast like. This stuff is readily available in powdered form ( which mixes up more easily) and is very cheap.

With any luck this will help HBers off to faster starts and better brews. Just remember, you want to grow yeast not make little batches of beer.

Subject: McAndrew's Addendum

As I was sipping my McAndrew's Scotch Ale this afternoon (I'm vacationing this week), I remembered my post on duplicating this fine brew. Suddenly, I realized that neither I, nor Bill mentioned the smokiness of McAndrew's.

Historically, Scotch Malts were kilned in peat-fired kilns, so the malts got a smoky flavor which was subsequently passed on to the beverages they were used to make. To add that smoky flavor, I would suggest smoking a quarter pound of pale malt (if you're mashing) or crystal malt (if you're brewing from extract + specialty grains) and then adding that to your brew.

And now, back to my honeymoon, already in progress...

Subject: Plastic Bottles

Please forgive me if this subject has come up before; I am new here and have seen something which has me concerned. I have seen some discussion of plastic soda bottles used for brewing. I have always been told that this is a bad thing to do for several reasons. First, that the plastic is slightly porous, and so the brew will slightly oxidize. Second, and more important, I have been told that the alcohol will tend to dissolve the polymers, introducing a small bit of poisonous plastic into the brew.

Any chemists who can confirm/refute this?

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Belgian Malt

To: Homebrew Digest  
Fm: Jack Schmidling

I just received an info kit from Siebel describing the De Wolf-Cosyns Maltings Company in Belgium and their yeast and brewer's supplies. The yeast is a bit high priced for home brewers (\$100 for two slants) but I notice they also supply dry yeast. Apparently, enough brewers use dry yeast to make it worth their while to sell it.

Much to my delight, when thumbing through the color brochure on the malting operation in Belgium, I came across the statement, "steam heated indirect kilning". There is also a pictorial diagram of the kilning system with another reference to indirect steam heating.

Contrary to the misinformation (or lack of) I got on the phone, it seems that I now have found a local source of indirectly kilned malt, and the highly touted Belgian malt to boot. It costs a bit more than the stuff I was buying from Minnesota but I can pick it up and save the shipping charges and come out even.

I was going to try this stuff anyway on my next batch of ale but now I can do it without feeling that I am compromising my anti-nitrosamine crusade.

I am going to use the Pale Ale malt and exactly the same recipe as my most recent batch of ale and see if I can taste any difference. Needless to say, I will report back with the results.

js

p.s. I would like to get a Corona for making tortillas. (honest) I have an early vintage MM that I would be willing to trade, preferably someone near Chicago.

From: eurquhar@sfu.ca  
Subject: Yet another use for Wyeast Belgian... Mead

Well, my first batch of fruit mead (melomel?) was brewed up last Sunday. Several contributing factors inspired me to try a mead. First, honeybee researchers at SFU sell exceptional raw honey every year at a reasonable price. Second, the very good bartlett pears were available at as decent price and ginger goes very well with them. Lastly, all this talk of the banana/fruit/caramel flavours created by Wyeast belgian and its ability to ferment to high alcohol therefore providing aging potential. The thought of these flavours coming together was more than I could stand. The basic composition followed the proportions published in the excellent article in the latest zymurgy issue.

Pear/ginger mead/melomel/metheglin (take your choice)

5 lbs pears, seeds and flower end removed and frozen so they would breakup easier  
5 lbs raw new honey (wildflower/raspberry/blackberry blend)  
3 oz. finely ground fresh young ginger (more lemony than mature ginger)  
1 primed package Wyeast belgian #1214  
1/2 tsp. pure ascorbic acid (to keep the pears from going brown and because it tastes like lemons)  
1/2 tsp. Difco yeast nitrogen base (yeast nutrient)  
16 cups water

Everything but the yeast nitrogen base was put into a big pot and brought up slowly to 200 F and kept there for 20 minutes to pasteurize and extract the ginger flavour and allowed to cool down naturally (about 2 - 3 hours)

Next time, I'll extract the ginger with boiling water a few times to get more ginger flavour out and add as part of the water used (the ginger flavour is only sparingly soluble in water). The final specific gravity was 1.100. Any comments/questions/suggestions would be gratefully appreciated.

YIELD: about 2 gallons in the primary

...p.s. It was bubbling like crazy 24 hours later and the banana was evident when I opened the yeast envelope. This weekend ginger beer!

- > from the Great American Beer Festival?

Sure! Wrote these down with my own hot little hands Saturday afternoon, and posted then on the CompuServe Beer Forum. It's unofficial, but it should be 99.44% accurate. (I also compared my notes with the AHA's list.)

#### GREAT AMERICAN BEER FESTIVAL WINNERS, OCT. 3, 1992

##### CLASSIC PALE ALE

Gold: Sierra Nevada Pale Ale, Sierra Nevada Brewing Co., Chico, Calif.

##### INDIA PALE ALE

Gold: Solstice Ale, Hubcap Brewery & Kitchen, Vail, Colo.

Silver: Banty Rooster India Pale Ale, Starbright Brewery, Santa Cruz, Calif.

Bronze: Commodore Perry India Pale, Great Lakes Brewing Co., Cleveland.

##### AMERICAN PALE/AMBER ALE

Gold: McTarnahau's Ale, Portland Brewing Co., Portland, Ore.

Silver: Ruedrich's Red Seal Ale, North Coast Brewing, Fort Bragg, Calif.

Bronze: Abemarle Ale, Dilworth Brewing Co., Charlotte, N.C.

##### TRADITIONAL BITTER

Gold: Moon Dog Ale, Great Lakes Brewing Co., Cleveland.

Silver: Atlas Amber, Big Time Brewing Co., Seattle.

##### SCOTTISH ALES

Gold: Sonoma Irish Ale, Sonoma Brewing Co., Petaluma, Calif.

Silver: Kidder's Scottish Ale, Kidders Brewpub, Fort Myers, Fla.

##### BLONDE ALE

Gold: Prime Time, Big Time Brewing Co., Seattle.

Silver: Alpine Pearl Pale, Tied House Cafe & Brewery, Alameda, Calif.

Bronze: Bicentennial Ale, The Mountain Brewers, Bridgewater, Vt.

##### PORTER

Gold: Boulder Porter, Boiulder Beer, Boulder, Colo.

Silver: Pleasure Point Porter, Seabright Brewery, Santa Cruz, Calif.

Bronze: Parleys Porter, Squatters Pub Brewery, Salt Lake City.

##### DRY STOUT

Gold: Stout, Butterfield Brewing Co., Fresno, Calif.

Silver: Rainbow Trout Stout, Hubcap Brewery, Vail, Colo.

Bronze: Old No. 38 Stout, North Coast Brewing Co., Fort Bragg, Calif.

##### SWEET STOUT

Gold: Seabright Oatmeal Stout, Seabright Brewery, Santa Cruz, Calif.

Silver: Zoser Stout, Oasis Brewery, Boulder, Colo.

Bronze: Oatmeal Stout, Goose Island Brewing Co., Chicago.

#### STRONG ALE

Silver: Imperial Stout, Pacific Coast Brewing Co., Oakland, Calif.

Bronze: Eye of the Hawk Select Ale, Mendocino Brewing Co., Hopland, Calif.

#### BARLEY WINE

Gold: Sierra Nevada Bigfoot, Sierra Nevada Brewing Co., Chico, Calif.

Silver: Old Crustacean, Rogue Ales, Newport, Ore.

Bronze: Old Bawdy Barleywine, Pike Place Brewery, Seattle.

#### FRUIT, VEGETABLE

Gold: Passion Pale, Tied House Cafe, Alameda, Calif.

Silver: Woodruff Ale, San Andreas Brewing, Hollister, Calif.

Bronze: Sangre de Frambuesa, Santa Fe Brewing, Santa Fe, N.M.

#### HERB, SPICE

Gold: Celis White, Celis Brewery, Austin, Texas.

Silver: Our Special Ale, Anchor Brewing Co., San Francisco.

Bronze: Sigda's Green Chili Beer, CooperSmith's Pub, Ft. Collins, Colo.

#### SPECIALTY

Gold: Trippel Threat, Cambridge Brewing Co., Cambridge, Mass.

Silver: Greyhound Honey Ale, Flying Dog BrewPub, Aspen, Colo.

Bronze: HefeRyzen, Big Time Brewing Co., Seattle.

#### SMOKE FLAVORED

Gold: Alaskan Smoked Porter, Alaskan Brewing & Bottling Co., Douglas, Alaska.

Silver: Welcommen, Rogue Ales, Newport, Ore.

Bronze: Vermont Smoked Porter, Vermont Pub & Brewery, Burlington, Vt.

#### BOCK

Gold: Frankenmuth German Style Bock, Frankenmuth Brewery, Frankenmuth, Wis.

Silver: Mai Bock, Stoudt Brewing Co., Adamstown, Pa.

Bronze: Blue River Bock, Breckinridge Brewery & Pub, Breckenridge, Colo.

#### DARK LAGER

Gold: Schwarz Hacker, Rock Bottom Brewery, Denver.

Silver: Lowenbrau Dark, Miller Brands, Denver.

Bronze: Neuweiler Black & Tan, Neuweiler Brewing Co., Allentown, Pa.

#### MUNCHNER HELLES & DORTMUNDER EXPORT

Gold: Export Gold, Stoudt Brewing Co., Adamstown, Pa.

Silver: Golden Lager, Stoudt Brewing Co., Adamstown, Pa.

Bronze: Hard Times Select, Old Dominion Brewing Co., Ashburn, Va.

#### EUROPEAN PILSNER

Gold: Legacy Lager, Chicago Brewing Co., Chicago.

Silver: Garten Brau Special, Capital Brewery Co., Middleton, Wis.

#### AMERICAN LAGER

Gold: Schlitz, The Stroh Brewery Co., Detroit.

Silver: Hamm's, Pabst Brewing Co., Milwaukee.

Bronze: Stoney's Beer, Jones Brewing Co., Smithton, Pa.

#### AMERICAN LIGHT LAGER

Gold: Michelob Light, Anheuser-Busch, Denver.

Silver: Busch Light, Anheuser-Busch, Denver.

Bronze: Bud Light, Anheuser-Busch, Denver.

AMERICAN PREMIUM LAGER

Gold: Lowenbrau Regular, Miller Brands, Denver.  
Silver: Genuine Draft Regular, Miller Brands, Denver.  
Bronze: Signature, Stroh Brewery Co., Detroit.

AMERICAN DRY LAGER

Gold: Keystone Dry, Coors Brewing Co., Golden, Colo.  
Silver: Olympia Dry, Pabst Brewing, Milwaukee.  
Bronze: Coors Dry, Coors Brewing Co., Golden, Colo.

AMERICAN MALT LIQUOR

Gold: Olde English 800 Malt Liquor, Pabst Brewing, Milwaukee.  
Silver: Silver Thunder Malt Liquor, Stroh Brewery Co., Detroit.  
Bronze: Colt 45 Malt Liquor, G. Heileman Brewing Co., La Crosse, Wis.

DUSSELDORF ALTBIER

Gold: Samuel Adams Boston Stock Ale, Boston Beer Co., Boston.

AMERICAN LAGER/ALE CREAM ALE

Gold: Scrimshaw Beer, North Coast Brewing Co., Fort Bragg, Calif.  
Silver: Dock Street Cream Ale, Dock Street Brewing Co., Philadelphia.  
Bronze: Little King's Cream Ale, Hudepohl-Schoenling, Cincinnati.

GERMAN WHEAT

Gold: Hops! Hefe-Weizen, HOPS! Bistro & Brewery, Scottsdale, Ariz.  
Silver: Samuel Adams Dunkelweizen, Boston Beer Co., Boston.  
Bronze: Heartland Weiss, Chicago Brewing Co., Chicago.

AMERICAN WHEAT

Gold: Marin Hefe Weiss, Marin Brewing Co., Larkspur, Calif.

MAERZEN/OKTOBERFEST

Gold: Fest, Stoudt Brewing Co., Adamstown, Pa.  
Silver: Landmark Octoberfest, Minnesota Brewing Co., St. Paul.

VIENNA

Gold: Brooklyn Lager, The Brooklyn Brewery, Brooklyn, N.Y.  
Silver: Golden Rail, Cherryland Brewery, Sturgeon Bay, Wis.  
Bronze: Anchor Steam Beer, Anchor Brewing Co., San Francisco.

ENGLISH BROWN ALE

Gold: PMD Mild Ale, Goose Island Brewing Co., Chicago.  
Silver: Steelhead Nut Brown Ale, Pizza Deli & Brewery, Cate Junction, Ore.  
Bronze: Bond Street Brown Ale, Deschutes Brewery, Bend, Ore.

AMERICAN BROWN ALE

Gold: Pete's Wicked Ale, Pete's Brewing Co., Palo Alto, Calif.  
Silver: Oktoberfest Ale, North Coast Brewing Co., Fort Bragg, Calif.  
Bronze: Brooklyn Brown, The Brooklyn Brewery, Brooklyn, N.Y.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: Wyeast California and Belgian

I posted in HBD 985 about Wyeast 1214 & Wyeast California.  
In HBD 986, Phil Hultin suggested that they are not one in the same.  
Phil is right.

California is 1212

Belgian is 1214

Both are newer Wyeast strains, so there is no corresponding check-off box for either on the package. The number is written on the package in pen without a name for cross-reference. So, when I visited Kedco on Saturday, I was given the wrong package by mistake. An honest mistake by the folks at Kedco which I had know way of knowing about. Many thanks to Phil for pointing out the problem; I would have been mighty surprised (and confused) if I'd made steam beer with Belgian yeast!

Ken at Kedco says that California, despite having a 1000-series number, is a bottom-fermenting yeast. It works well at temperatures up to 68 Fahrenheit. Sounds like Steam Beer to me.

Cheers,

Rob (bradley@adx.adelphi.edu)

Date: 8 Oct 92 17:12:40 GMT  
From: "Jim N. Deakin" <J.Deakin@sheffield-city-poly.ac.uk>  
Subject: wort coolers.

I've been ploughing through back numbers of the HBD, thinking about making a cooler from 3/8 tubing as most notes seem to recommend, and I noted

how many people were concerned about saving water, or whose tap water came

too warm to use. Here's an idea, (it might have been suggested before though)

Make TWO coolers, and connect them in series. Put the first in a bucket of ice-water. Fill the complete system with water from the tap, then connect the inlet and outlet to each side of a drill-powered pump (Pump outlet to the ice-

bucket). Bingo! a cooler, with minimal water usage. It even keeps the wort on

the outside where the tubing can be cleaned! and if the drill is a variable

speed job, you can optimise the flow rate!

Any comments? any criticisms?

Happy brewing

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>  
Subject: Re: Quick-n-Easy Spiced Brown Ale

In answer to the questions about my post of Quick-n-Easy Spiced Brown Ale (in digest #985, in case you missed it).

> 1) What type of yeast to use... I'm assuming it'll be an ale yeast,  
> but is there a specific brand/type that I should use?

Just use your favorite ale yeast. I used dry before, but will probably use liquid this time around. The spices will help mask any mild infections, if you get one. I suppose you could make this beer as a lager as well, but the fruitiness and esters in an ale seem to go well with the spices.

> 2) I'm inclined to think that this recipe might benefit from a  
> single-staged method, allowing for a maximum attenuation (?) of  
> the spices. If this is the case, then wouldn't pelletized hops  
> be better than leaf?

As it was supposed to be Quick-n-Easy, I did do a single stage ferment. I don't think, though, that racking after 5 days or a week would hurt the spice characteristic. Remember, the recipe calls for simmering the spices beforehand to "extract" the flavors. The hop addition to the simmer was just an afterthought, and the beer turned out well enough that I didn't want to mess with the recipe. The small amount used wasn't enough to cause any clogging problems, either in the airlock or at bottling time.

> The pouch of ingrediants contained a variety of dried  
> spices, almonds, rasins, and I think even orange rinds, but I can't  
> remember. So my question is, can I substitute and/or add these  
> ingrediants to the recipe?

Of course! My recipe certainly isn't the only one out there. I just happened onto a combination of beer and spices that balanced very nicely. Other good spices might include corriander, allspice, cardamom, ginger.... Just go easy on them so you don't overpower the beer. You can also vary the base beer to get different effects (use a different kit, hop your own, or brew all-grain. Of course, it gets less Quick-n-Easy the more involved you get).

From: Chris McDermott <mcdermott@draper.com>  
Subject: Boston Stock Altbier?/Seabr

Boston Stock Altbier?/Seabright Brewery  
Hidy ho neighbors,

I was on vaction last week (honeymoon actually) so its taken me a while to catch up on my digest reading, and consequently I am a little late catching on to the Altbier thread.

When I returned, I found the results of the '92 GABF in my mailbox and saw that Samuel Adams Boston Stock Ale had won a gold in the Dusseldorf Altbier catagory. No silver or bronze was awarded.

Now my question is: Is Boston Stock Ale really representative of the Dusseldorf Alt style? Or did the The Boston Beer Company enter it in a catagory with no other entries so that they could win the gold medal necessary for their tried and true marketing campaign? "Samuel Adams has won a gold medal at the Great American Brew Festival N years in a row."

On an other note. While I was on my honeymoon, I happened upon the Seabright Brewery in Santa Cruz CA. One of their special brews was call Century Red and my wife, not being much of a hop-head, loved it's dark, sweet maltiness. Has anyone out in HbD land tried this and if so could you help me make a guess at an all-grain recipe for it? I tried to talk to the brewer, but he was at the GABF picking up his three, count 'em, (1 gold, 2 silver) medals. While I only tried the Red, it sounds like they brew a good deal of quality ale there.

>the alcohol will tend to dissolve the polymers, introducing a small bit  
>of poisonous plastic into the brew.

I'm not a chemist, and can't directly answer your question, but here's a data point and more speculation.

Plastic soda bottles are usually made of PETE, polyethylene terephthalate.

When hard liquor (e.g. 100-proof vodka) is packaged in "plastic" bottles, the material used is almost always clear polycarbonate ("Lexan"). Since I'm pretty sure PETE is cheaper, there must be another reason they don't use it.

From: Bruce Mueller <mueller@sdd.hp.com>  
Subject: Phosgene from Clorox + Ammonia--NOT!

The former message about mixing bleach and ammonia was incorrect. Phosgene contains carbon, bleach does not. There is no way to form phosgene from this mixture. However, (mono)chloramine IS formed and is nasty. Incidentally, this is now commonly used as the sanitizer in municipal water supplies, since it is longer acting than chlorine gas (and unable to form chlorinated organic compounds at the use level).

Just had to clear up the chemistry a bit.

Subject: Pellet Hops vs. Whole Flowers

In HBD #986, ZLPAJGN asked:

> If this is the case, then wouldn't pelletized hops be better than leaf?

Offhand, I can't think of ANY situation in which pelletized hops would be better than whole flower (NB: it is the flower, not the leaf, that we use!). This is, of course IMHO.

Perhaps some of you out there can suggest advantages for pellets I am unaware of?

BTW, The best hops I currently know of are packaged in 1/2 oz "bungs", which consist of, you guessed it, 1/2 oz of fresh whole flowers compressed (not minced and packed) into a plug. On addition to the boil, the bung expands and releases the whole flowers into the brew. I have got mine via my brother in Vancouver, but they come from Morris Hanbury International Hop Merchants (USA) Inc., in Washington State.

To: Homebrew Digest  
Fm: Jack Schmidling

>From: whg@tellabs.com

>Sorry Jack but I just couldn't resist. It seems to me that back when you were trying to get people to define the difference between an ale and a lager (sort of like trying to describe the difference between apples and oranges BTW) you just wouldn't buy it when people describe a lager as cleaner. You wanted to know what that meant.

Don't you see the difference between wanting to know "what it meant" and not buying it? I am making a lager now to experience it myself. I don't know if I will ever know, other than by definition, but I am giving it a try.

> Well, what to my wondering eyes did appear in yesterday's digest? Jack S. describing the taste of his first lager as "cleaner" than any of his previous beers. Don't knock a description till you've tried it I always say. ;-)

I suppose even the World's Greatest Brewer could make a typo but the word was supposed to be CLEARER as would be explained by the following sentence, wherein I stated that, I would have expected a bottom fermenting beer to be more turbid near the bottom. The opposite of turbid is clear, not clean. I was referring to the optical transparency which I can appreciate and not the taste which I have trouble appreciating.

.....

Just picked up 11 lbs of the Belgian Pale Ale malt and ran a quick extract test on it and got exactly the same number I get with my regular malt. This is a 400 ml batch size, using 60 grs of malt, that I use for various and sundry tests. When converted to pts/lb/gal, the result is 29.

What blows my mind is that after the usual test, I sparged out another 400 ml of wort and boiled it all down to 400 ml. I left it settle out after chilling in a tall graduated cylinder and poured off the clear stuff on top to test the gravity again and it went from 1.036 to 1.030. I poured it back with the trub and measured it again and it read, 1.038, about what I expected

but I did not expect to need the trub.

What's going on here?

js

p.s. I received a lot of mail asking for the source of the malt.

**Subject: clarification regarding Wyeast California and Belgian**

In yesterdays (October 8, 1992) digest Phil Hultin requested confirmation regarding Wyeast California and Belgian yeasts. Here is the information from  
Wyeast "fact sheet".

2112 - California Lager Yeast - Warm fermenting bottom cropping strain, ferments well to 62 F while keeping lager characteristics. Malty profile,  
highly flocculant, clears brilliantly. Apparent attenuation 72-76%.

1214 - Belgian Ale Yeast - Abbey style top fermenting yeast suitable for high gravity beers, doubles, triples, and barley wines. Medium flocculant strain which clears well. Apparent attenuation 71-75%.

hope this helps you,  
Happy Brewin!

From: Hal Laurent <laurent@tamdno.ENABLE.com>  
Subject: Brewpubs in Baltimore

Someone asked about Baltimore/Washington area brewpubs. I can help with the Baltimore part.

The two brewpubs in Baltimore of which I am aware are:

Baltimore Brewing Company (on Albemare St. just north of Little Italy)

Sissons (on Cross St. in Federal Hill)

Personally, I think BBC's beer is better, but Sissons isn't bad and they have \*wonderful\* Cajun food.

There are also a number of bars that, while not brewpubs, carry a good selection of beers, including local ones. A couple that I'm personally familiar with (both in the Fells Point area) are Bertha's (on Broadway) and the Wharf Rat (on Ann St. -- don't confuse it with the Wharf Rat at the Inner Harbor). Bertha's carries Oxford (made somewhere on the outskirts of Baltimore), Wild Goose (made in Cambridge, Maryland), and lately have been carrying some BBC stuff (the brand name is DeGroen, I think). The last time I was there they had a wheat beer from DeGroen. The Wharf Rat also has a good selection. I don't remember it in detail (I'm more likely to go to Bertha's 'cause I like the bar better), I do know that they tend to carry the DeGroen Marzen(which is very good).

I guess I should also mention the Cat's Eye (Thames St. in Fells Point). They carry a number of British Ales and also Olde Heurich lager from Washington D.C. The Cat's Eye also has a rather eclectic selection of musical entertainment in the evenings and on weekend afternoons. You might see anything from Jazz to Blues to Country to Bluegrass to Irish to Rock.

Oh yeah, one more thing... Sissons (see above) also has monthly homebrewing meetings, as well as occasional homebrewing classes.

From: Peter Bartscherer <BARTSCHP@DUVM.OCS.DREXEL.EDU>  
Subject: Cider on Yeast & Guinness

This weekend I plan to brew a Belgian style ale, and although I've never tried it, I'm intrigued with the idea of racking the beer off the yeast and adding fresh wort for a second batch using the same yeasties. I've seen a number of posting regarding this, and have been following the cider thread with interest. Now here's my question: has anyone tried pouring a few gallons of cider onto the yeast instead of new wort? If I do, should I add anything else (yeast nutrient, tannin, ...). And speaking of tannin, a friend suggested I could make a very strong tea (just plain old teabag type tea), let it cool and add it as my source of tannin. Suggestions? Reactions?

Secondly, any of you in the Great Guinness Test Markets know the success of the nitrogen capsule Guinness? Does anyone know if I can expect it anytime soon in a store near me?

In the last digest, Chris McDermott <mcdermott@draper.com> inquires about Sam Adams Stock Ale/Altbier. Here's what I was going to post to usenet when my server gets unjammed, but I'll just do it here instead.

OK, so I read the GABF results for the last few years and while the results raise numerous questions about the categories, one in particular jumps out.

How does Sam Adams Boston Stock Ale win so many medals in the \*ALT\* category??? Dont get me wrong, I enjoy this beer (as well as the lager), but what the hell makes it an \*ALT\* beer? This beer is dry hopped with fuggles and goldings, right? It is especially strange to find a classic english-hopped beer repeatedly winning medals in a German ALt category! Whats next, a dry hopped hallertaur and saaz beer winning in English traditional bitter? How about Sierra Nevada Stout as an Irish Stout?? Anchor Wheat as a Bavarian HefeWeizen.....I guess the "Professional Tasting Panel" knows something us stupid brewers dont :-)  
Sheesh....

Subject: Cane sugar starters

OK, before you all either jump on Micah (afterall he is already down) for his cane sugar starter suggestion, or you lay off of him because you feel

sorry for him, I would like to add my 2 cents. When Micah and I first meet

and he told me he was using cane sugar for starters I told him YOU CAN'T DO

THAT! He said he gets bigger yeast yields and it's cheaper and more convenient. But I said, does it make better beer? Well after challenging him and knowing that most great discoveries are accidents, we got some text

books on yeast and discovered that this is close to how the yeast manufacturers build large quantities of yeast, They use beet sugar. Well, I'll leave all the details to Micah to explain, afterall he started this thread. My results with using powdered cane sugar for starters have been good. I have not seen any difference in the lag times, attenuation or flavor profile of yeast grown up this way. Ok now that you all have at least one more data point, I'll ask Micah to give more data on this matter.

His responses are usually a little later, due to his non access to the net

(we can't trust him).

From: hamilton@roadrunner.pictel.com (Charlie Hamilton)  
Subject: John Harvard brewpub

I went to the John Harvard brewpub in Harvard Square last night, and tried all of their available beers. They have the following beers all the time:

Cristal Pilsner  
Bock  
Light Ale  
Pale Ale - draft  
Pale Ale - cask conditioned  
Irish Export Stout

The special that they had was a Nut Brown Ale.

For some reason their lagers were not available, so we tried all the ales. My overall impression of the beer was not very good. The Light Ale didn't taste fresh. The cask conditioned Pale Ale was the best (IMO), but was a little sweet with not much hop flavor or aroma. The stout and nut brown ale both had a slight burnt taste, and were OK, but again, there was not a lot of character to them.

I didn't get a chance to talk to anyone who knew how they made their beer, so I don't know how long they age their beer, whether it's filtered, or what ingredients they use, etc.

The atmosphere was nice and the food was OK, but the service was lousy, however, it was Thursday night, and very crowded.

In general, the beer was OK, but it seemed that they put more effort into making the place look nice than making the beers taste good, but hey, this America, the home of Form-Over-Substance(TM).

I think I'll stick with the Cambridge Brewing Co. as my brewpub of choice. What do the rest of you think?

From: abirenbo@rigel.cel.scg.hac.com (Aaron Birenboim)  
Subject: Re: Great American Beer Fest

I'd like to share some of my GABF experience in response to Michael Howe:

The "Pumpkin spice" was (i think) Adler Brewery, Appletown Wisc. (corrections anyone?) I tried about 5 of his beers, and each and every one of them was absolutely world class. I feel that he deserves some mention since he was probobally the best brewer across the spectrum from hefe-weizen, to bock, to porter, to lager, a damn impressive pilsner, and of course the pumpkin spice.

Celis White (from the brewmeister of Hoegarten Wit) totally knocked me out. I went right out and bought "belgian ale" from the classic beer series.

What suprized me most was that I had 3 infected pale ales from far away micros or brewpubs. I will not mention names (even if i remembered them ;-)) but i was shocked that somebody would try to pass off these severely incevted beers to the mostly sophisticated drinkers at the GABF. All three were lactic acid bacillus infected.

What were some of the classics that i missed?

>Perhaps some of you out there can suggest advantages for pellets I am  
>unaware of?

I use pellets exclusively. There is only one objective criterion  
where pellets out perform whole hops, and that is alpha acid  
% utilization. It's up around 30% for pellets (the best you can  
hope for) and somewhere in the mid 20's for whole hops.

The reason I use pellets is convenience: you don't need to filter  
them out when you chill your wort (they cone up nicely at the  
bottom of the pot if you whirlpool the wort), and they're much  
easier to use for dry-hopping than whole.

I view all of these reasons as preference only, and would never argue  
pellets are better than whole.

BATTLE BREWING IN BOSTON

by Matthew Brelis--Globe staff

Concerned that beer lovers searching for their product will be left with a bitter taste in their mouths, Boston Beer Co., maker of Samuel Adams lager, has filed suit in US District Court against Commonwealth Brewing Co. complaining of trademark infringement.

In the multimillion-dollar world of Boston beers the suit is more than frivolous froth according to Norman Soloway, the lawyer who represents Boston Beer.

"If someone goes and buys a bottle of beer from Commonwealth Brewing with Boston on it, thinking it is ours and they don't like it, we have no control over that," Soloway said. "You never even know that you lost a customer, you don't know if you are being injured."

According to the suit, Boston Beer has had more than \$2 million in sales in the Boston area in each of the last two years and more than \$15 million nationally each year.

But Joe Quattrocchi, co-owner of Commonwealth Brewing, a restaurant and microbrewery on Portland Street in Boston said that while a label on the neck of its bottled beers says "Boston" his labels would not be confused with the labels of the Boston Beer Co.

"We've been bottling some beers since 1986 and you can't trademark a geographic location," Quattrocchi said. "Boston is a very common name in these parts" [good line!] said Commonwealth Brewing manager Jim Lee.

Trademark lawyer Kenneth Plevan said geographic names are more difficult to protect as a trademark, but they can be protected.

Soloway said Boston Beer has a registered trademark for "Boston Ale" and has applied for a trademark for "Boston Beer."

Quattrocchi said Boston Beer was a giant picking on small

business with its suit against Commonwealth and an earlier action against Boston Beer Works, another microbrewery in Kenmore Square.

"We recently found out that Commonwealth Brewing was offering a couple of beers with the Boston family trademark on them, and if we failed to police it we could lose our trademark, Soloway said. "We asked them to stop and they said no."

The case has been assigned to US District Judge Douglas P. Woodlock.

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Yeast Cycles (George Fix)

There has been a lot of interesting discussion concerning yeast cycles on HBD, and I can not resist inserting my two cents worth.

I have really enjoyed the insights Pierre Jelenc has shared with us. He is absolutely correct in asserting that the classic division between aerobic respiration and anaerobic fermentation greatly oversimplifies what is actually going on in individual yeast cells. Nevertheless, the aggregate behavior, where the total collection of cells is viewed as an enzyme system, does display regular behavior. In fact, the differential equations of enzyme kinetics are derived from such models much in the same way thermodynamics is derived from particle models via ensemble averaging. It is important to stress that the equations of enzyme kinetics are valid only as a description of the system as a whole. They do not predict the behavior of individual yeast cells, since the eccentricities of the latter have been averaged out.

The kinetic models give the following picture of the fermentation. In the early stages there is a net consumption of dissolved O<sub>2</sub> as well as a reduction of wort lipids such as oleic and linoleic acids. There is a net increase of metabolic energy, which can be characterized as an equivalent amount of ATP (adenosine triphosphate). This is accompanied by a net increase in the cell density  $N(t)$  with time  $t$ . The biochemistry is involved, but the associated mathematical description is simple, since the kinetic equations are linear in this regime. Solution of these equations shows an exponential growth in  $N(t)$  with time  $t$ , which is usually written in terms of logarithms as follows:

$$\log(N(t)) = C*t,$$

where  $C$  is the growth constant. I feel it is valid to call this regime the aerobic respiratory growth phase, even through individual cells may deviate from the aggregate behavior.

As the cell density increases and the dissolved O<sub>2</sub> level decreases, the nonlinear regime is approached. Things get really interesting here from a mathematical point of view. Ironically, the biochemistry is straightforward.

What happens in the aggregate is carbon splitting of elementary sugars such as glucose (G) and fructose (F) followed by formation of pyruvic acid and then acetaldehyde. The final step is the reduction of acetaldehyde to ethanol by yeast enzymes. Since O<sub>2</sub> is not involved and since alcohol is formed, I feel it is valid to call this phase anaerobic fermentation. It is important to note that there is a net expenditure of metabolic energy during this phase.

This is why the ATP buildup in the aerobic phase is so crucial to obtaining a complete fermentation. Also the curve for  $N(t)$  vs. time flattens out.

There are a number of mechanisms that have been identified for inducing the

transition to the nonlinear regime (i.e., from respiration to fermentation). One of the most important as far as practical brewing is concerned is the Crabtree effect. It has been shown that a sufficiently high cell concentration of G and F sugars will strongly induce anaerobic fermentation. Brewing yeast take G's and F's directly into the cell. Sucrose (G-F) is broken up outside the cell, and then the G and F fractions are then transported inside. In contrast, maltose (G-G) and maltotriose (G-G-G) are taken intact into the cell, only later to be broken down into G units. In an all grain wort, maltose is the major fermentable sugar followed by maltotriose, the others being under 10% of the total. This has important practical implications for respiration, for the maltose concentrations will not induce the Crabtree effect (at least in the levels that exist in normal beer wort) until the maltose is broken into G units. At this point a proper respiratory cycle will have occurred, assuming of course that a sufficient amount of O<sub>2</sub> is dissolved at the start of the fermentation.

Because of this, I am in complete agreement with the general principles put forward in Micah Millspaw's post on yeast propagation. I am less inspired by the use of dextrose (which is the same as glucose) and sucrose as a substrate for propagating yeast. The reason centers on the Crabtree effect. I am not suggesting his methods will not work. Micah has a wall full of ribbons to prove the contrary. I am suggesting, however, there may be a better way to go.

Over 85% of commercial propagation and those done in research labs involved with brewing strains use dilute wort (SG ~ 1.020). Paul Farnsworth has an excellent description of this procedure in his article that appeared in the yeast issue of Zymurgy. I belong to the minority that propagates with full strength hopped wort. The reasons for this and a description of the procedure can be found in my article that appeared in Vol. 6 of BREWERY OPERATIONS published by Brewers Publications. I also use an O<sub>2</sub> feed during propagation to induce the Pasteur effect, which is the exact opposite of the Crabtree effect. Here fermentation is repressed in favor of respiratory cell growth.

I was working only with half a voice during the AHA conference in June, and likely many points I was trying to make did not get across. I hope this is not the case with the point about the practical value of testing yeast that have been aerobically propagated. Minor technical errors can lead to major problems, not only with aerobic bacteria but with mutation as well. Both should be

checked. Interestingly, the Wyeast strain 1056, which is the same as Siebel's BRY-96, does particularly well with aerobic propagation. In fact, I have found the much discussed tendency of this strain to mutate (something that has happened with samples from both Wyeast and Siebel) is closely related to the lack of a proper respiratory cycle. Thus, brewing procedure is the culprit, not screw ups in Chicago or Portland.

In the multimillion-dollar world of Boston beers the suit is more than frivolous froth according to Norman Soloway, the lawyer who represents Boston Beer.

"If someone goes and buys a bottle of beer from Commonwealth Brewing with Boston on it, thinking it is ours and they don't like it, we have no control over that," Soloway said. "You never even know that you lost a customer, you don't know if you are being injured."

According to the suit, Boston Beer has had more than \$2 million in sales in the Boston area in each of the last two years and more than \$15 million nationally each year.

But Joe Quattrocchi, co-owner of Commonwealth Brewing, a restaurant and microbrewery on Portland Street in Boston said that while a label on the neck of its bottled beers says "Boston" his labels would not be confused with the labels of the Boston Beer Co. [This is true]

"We've been bottling some beers since 1986 and you can't trademark a geographic location," Quattrocchi said. "Boston is a very common name in these parts" said Commonwealth Brewing manager Jim Lee. [Good line!]

Trademark lawyer Kenneth Plevan said geographic names are more difficult to protect as a trademark, but they can be protected.

Soloway said Boston Beer has a registered trademark for "Boston Ale" and has applied for a trademark for "Boston Beer." Quattrocchi said Boston Beer was a giant picking on small business with its suit against Commonwealth and an earlier action against Boston Beer Works, another microbrewery in Kenmore Square.

"We recently found out that Commonwealth Brewing was offering a couple of beers with the Boston family trademark on them, and if we failed to police it we could lose our trademark, Soloway said. "We asked them to stop and they

said no."

The case has been assigned to US District Judge Douglas P. Woodlock.

===

Well, you all get the idea. Jim Koch is once again trying to trademark the words "Boston" and "Beer". Can Jim say the word "Boycott"?

Thanks to Eric Haas for typing it in.

From: polstra!norm@uunet.UU.NET (Norm Hardy)  
Subject: Hop Pellets vs. Cones

Simply stated, hops are more practical when pelletized due to storage concerns and long term stability. Heck, I've got some 3 year old Saaz double sealed in the deep freeze that are still making a great aroma used with Urquell yeast and decent malt.

Hop cones are aesthetically better. I remember the Redhook people here in Seattle saying that they used cones when they started, partially for the good P.R. I believe they use mostly pellets nowadays.

I note that Lowenbrau Dark took several medals and my first reaction is to conclude that the GABF must be a farce. I fell in love with the stuff in Munich and spent years trying to duplicate it. When Miller bought out the rights to make it here, one glass told all. It was rubbish and not even an attempt to duplicate. It tasted like Miller with caramel color.

I have not tasted it since that first one. Didsomething change or is the GABF a farce for serious beer drinkers?

>From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

> Jack S.: You're concerned about nitrosamines which are found in malt which has come from gas-fired kilning. Do you have any numbers wrt. the amount of these chemicals in such malt, as opposed to the amount found in say, a grilled hamburger, or toast?

Good question, the answer to which is yes/no. However, I do not eat grilled hamburger and if I make toast, I don't let it get very dark for exactly those reasons.

I suspect backyard barbecues kill far more people than beer but I don't do that either.

I also roast my own barley and stop when it is friable and crunchy, not when it gets black.

The bottom line is, I avoid carcinogens to the extent that I have control or am willing to sacrifice. If I can get a malt with none, I exercise that control with little sacrifice..

>From: thomasf@deschutes.ico.tek.com (Thomas D. Feller)

>So your you describe in more detail how you make and use yeast starters.

I find it hard to understand why people have to "make" yeast starters. Why not just save a bit from the current batch for the next?

From: G.A.Cooper@gmw.ac.uk  
Subject: Sorbate, geranium, Sweetening, H2S

These threads don't seem to have been picked up so ...

> Michael Blair (Univ. Colo.-Denver)

> Anyway, I now religously us 1/2  
> teaspoon of Potassium sorbate per gallon of hooch at bottling  
> time. This prevents yeast from budding, i.e. it will inhibit  
> renewed fermentation. IT WILL NOT STOP ACTIVE FERMENTATION.

> Potassium sorbate is commonly found in wine making supply shops  
> and is usually called "stabilizer".

As Michael says 'Sorbate' is an inhibitor - it doesn't kill anything especially not bacteria. So a word of caution. Some strain(s) of lactic acid bacteria can attack sorbate and, it is said, produce geraniol (or is that 2-ethoxyhexa-3,5-diene? I had to look that one up) which imparts a strong smell of geraniums (and a corresponding off-flavour). If sorbate is used then you must sulfite at the same time to kill off the bacteria. The problem can also occur later if the 'hooch' gets contaminated later. So, because of the hazards, only stabilize if you need to. There is no need (IMHO) to stabilize a dry wine - If you get a secondary ferment then it wasn't dry was it? (Digression: unless of course it is a malo-lactic ferment, which in itself implies the presence of lactic acid bacteria, which could, just as easily, be the strain that attacks sorbate, OK?)

Also Michael he asks:

> Anybody have any successful sweeteners besides granulated sugar?

Probably a number of people have replied suggesting lactose, which is not fermentable, and artificial sweeteners including sorbitol. Has anyone suggested xylitol? (the first syllable is pronounced like the start of xylophone). Although slightly expensive, it has the same perceived sweetness as sucrose (lactose only has about 1/4 the sweetness) and doesn't suffer from the bitterness of some artificial sweeteners. It occurs naturally, in small amounts, in raspberries, strawberries and yellow plums. It is my preferred sweetner if I have it to hand.

Prior to that, Neil (kruse\_neil@tandem.com) posted:

> A few days ago I made a gallon of hard cider. However, when I  
> smelled in the bottle is smelled like rotten eggs. What would  
> cause this to happen?

Hydrogen sulfide, H2S, is a natural by-product of yeast fermentation. Different strains produce it in different quantities and, being gaseous is normally scrubbed out by the CO2 being produced. So if you get it in a fermentation, don't panic it usually goes away. Only if it persists do you have a problem. Some of the causes: if the must is heavily sulfited some yeasts will reduce the excess SO2 and produce H2S; its production is more likely if the wine/cider is allowed to stand on the 'lees' too long; and also if the 'must' is deficient in some nutrient components (especially pantothenic acid I am told). If caught early enough in a finished wine try

racking and sulfiting

$$\text{H}_2\text{S} + \text{SO}_2 \rightarrow \text{H}_2\text{O} + 2\text{S} \quad (\text{if you are lucky})$$

then filter to remove the elemental sulfur.

In bad cases you can get related, offensive, compounds such as thiols and mercaptans, which won't react to sulfite, so you could resort to using copper. You can expose the wine/cider to some newly cleaned strips of copper foil or wire. (The very brave, which excludes me, will add a pinch of copper sulfate (poison :-()) to a gallon of wine!). The copper reacts with the sulfur compound to form insoluble copper sulfide. Then fine with bentonite to take out any residual traces of copper.

Another technical posting from a non-chemist. Will you chemists out there read the above and correct me if there are any errors. Ta.

Subject: Re: GABF

> I note that Lowenbrau Dark took several medals and my first reaction is  
to  
>conclude that the GABF must be a farce.

Lowenbrau Dark took exactly one medal: a Silver in the Dark Lager  
catagory. I  
assume that what you`re really trying to point out is that several  
catagories  
seemed to be dominated by the megabreweries. This is no accident - the  
characteristics of these catagories were designed to allow the  
megabreweries to  
win some medals. Why? Because the GABF needs their support. A glance  
at the  
program from this years event will show that the megabreweries provide  
much of  
the funding for the GABF.

Some people may cry `foul` for this, but I don`t have a problem with it.  
After  
all, these beers are significantly different from the beer brewed by most  
microbreweries, and a \*lot\* of people like to drink the megabrewery  
stuff, so  
why not consider these styles to be different?

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: yeast nutrient

I posted last week (HBD985) in the matter of cider.

In autumn 1990 I made both cider and mead. I used yeast nutrient in the mead and it turned out well (with aging; I still have 4 bottles from that season). I made cider without nutrient. It turned out well, but the fermentation was slow and extended. It also needed long aging.

After 23 months of brewing nothing but beer, I made cider again this year. I used yeast nutrient and was impressed: fermentation got off to a flying start with a real krausen head and did most of its work in about 4 days. I drank the first 1/2 gallon batch on day 10 and was duly impressed. With that success and a fifth straight batch off to a flying start, I posted on my experience and recommended using nutrient to all cider makers.

Among the e-mail I received was one letter claiming good results without nutrient and another telling of off flavors coming from nutrient in cider he'd made.

The nutrient I used in the 1990 mead and the first two batches of 1992 cider was from Lil' Olde Winemaking Shoppe in Illinois. It came in a plain zip-lock bag and was simply labelled 'yeast nutrient'. I bought some Wine Inc. nutrient more recently and yesterday racked a batch made with that. The hydrometer sample had a metallic flavor.

Could be a random problem. Could be caused by the new type of nutrient. Could even be that the nutrients were the same and, having the suggestion planted in my head by Thomas M., I found something that I missed the first time. Or imagined something that was there in neither batch.

The Wine Inc. nutrient lists its ingredients as 'food grade urea and ammonium phosphate'. Visually, the old batch seemed different: coarser, more translucent crystals.

My questions:

- \* Anybody willing to share, by e-mail, experiences of cider successes/failures with/without nutrient?
- \* Does apple juice/cider have natural nutrients? (On a related note, it seems that raisins do: B vitamins, some protein, minerals.)
- \* What's the big deal with ammonium phosphate, or the aluminum salts Thomas told me about? There isn't anything like that in the naturally occurring yeast nutrient components of wort, is there?
- \* Urea? Goodness, it's the major component of urine!!! Seriously, it's CO(N<sub>2</sub>)<sub>2</sub> so undoubtedly provides a good source of much-needed nitrogen. Nevertheless, it's a poison that mammals need to get rid of. Maybe it's not poisonous to yeast, but should I be drinking it, even in trace amounts?
- \* Anybody got any suggestion on natural yeast nutrient (perhaps something like the de-activated brewer's yeast sold in health

food stores)?

For the record, I NEVER use nutrient in beer.

Cheers,

Rob (bradley@adx.adelphi.edu)

Rob> While I'm posting, does anyone know why the GABF has decided to give  
Rob> exposure to malt liquor? This "Olde English" stuff is making teens  
Rob> and others all over the country dead and brain-dead in 40 oz.  
increments,  
Rob> and they give it a category and a gold medal!?

I get the feeling that the GABF provides a category for almost every style of beer that is brewed in the US. And while I find many of these categories less than interesting (including dry, light, dry-light, dry-light-draft, and the other dozen or so aliases for North American Light Lager), I suppose they do have their place. But if the GABF people expect us to believe that they really do have appreciation of good beer and socially responsible use of beer as an alcoholic beverage as goals, then they're going to have to do away with the Malt Liquor category, a "style" whose marketing tactics have nothing to do with responsibility. Giving gold medals to A-B, Miller, et. al. may be a nice gesture, a way of repaying them for the dollars they pump into fighting the temperance movement, but I think that recognizing Olde English 800 and the others in that category is going beyond the call of duty, as well as contradicting the goals of the Festival.

If you agree, tell it to the Association of Brewers:

Subject: near-flat beer

Hello.

I am having a problem with near-flat beer. That last four batches that I have brewed have been under-carbonated. For the first two, I thought that it might have been over sanitizing my bottles and leaving enough residual chlorine to kill my yeast. So for the last two, I used the dishwasher. No chemicals or detergent at all. I primed with 3/4 cup corn sugar, waited two weeks (bottles were kept in a cabinet at a temperature of about 83 degrees), and tried one. There was some carbonation, but very little. Waited longer but did not improve. 3 weeks ago, I popped open 4 bottles and added 1/4 teaspoon of corn sugar to each. The first one foamed all over the kitchen, but I capped the other three before the reaction got started. Tried one last night, and the carbonation level seems EXACTLY what it was before. What gives? I'm using wyeast american ale, if it matters.

Thanks,  
Tom

From: "BOB JONES" <bjones@novax.llnl.gov>  
Subject: Yeast starters from Micah Millspaw

I seem to have stirred the hornets nest, good.

Per the many requests to further expand on my yeast growing practices, here goes. And nobody accuse me of JSing.

I have been using powdered sugar in my yeast starters for the last 4 years with great success. When I started brewing there was very little info available on homebrewing in my area. I'd been brewing for a while when the liquid yeasts came out, so I switched to using them, worked fine. Later on when I built the big brewery (1/2 barrel) I needed more yeast to pitch. I called up my hb retailer and his advice was to buy several of the yeast packets, this was unacceptable. And so being on my own I started reading and trying ideas. A lot of good info came from a course in cellular and molecular biology at CSUS. So I got some nutrients and sugar and started growing yeast and making great beer. Never gave what I was doing another thought until I met Bob Jones. One day this topic came up and when I mentioned what I was doing he wanted to know why it worked and if it did, why did no one else do this. Things got really involved after that. It was found in a yeast textbook that of effect of different sugars on the ability of brewers yeasts to respire (and reproduce) supported my techniques. Conversations with Clayton Cone of Laalmande and Mary Miranda of UC Davis

indicated that I was not doing anything terrible and in fact was in a inefficient manner doing what the commercial growers do. The object is to get the yeast to reproduce, not to ferment, so you need not worry about getting a selective breeding program by accident. This whole mess lead to further work with yeast and total aerobic growths followed by totaly anaerobic fermentions but that is outside the scope of this digest.

So heres what I do to just build up a starter.  
I boil water and powdered sugar together with some yeast nutirent for about ten minutes, cool it and add the yeast, and shake well.  
The solution has approx 1020 gravity. Once a day i will "feed" the yeast some more sugar solution of successively greater concentrations to allow for dilution of additional liquid. From a yeast packet i can grow up to my pitch volume of 700mls dense slurry in three days with out a lot of excess liquid involved to dilute to wort. The yeast is grow at 80 F. I normaly see 2 hour lag times with 15 gallon batches. Sanitation is important so be carefull.

Micah Millspaw

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Spelunking at Chimay

This one is somewhat embarrassing, but makes for a good story.

CR

=====  
=====

In the southernmost part of Belgium, as the countryside becomes more and more French, there lies an Abbey named Notre Dame de Scourmont. Beer aficionados know it simply as Chimay.

My unlikely adventure at the abbey began when I met Frere Jacque in the visitors center. Frere Jacque had lived in a monastery off of the coast of Wales for 33 years, and his command of English was a welcome blessing. I inquired about visiting the brew house, only to be told that it was "Not for the public". Not wanting to miss anything, I expressed my sincerest devotion to the craft (after all, I had traveled over 5000 miles on my thirsty quest). Upon hearing my story, Frere Jacque did his utmost to arrange a tour. It turned out that the brewmaster was occupied, so Frere Jacque was given permission to escort me through the brewery. Since his work was in the abbey's gardens, my guide knew little about the brewery. So we struck a deal, he'd show me around the brewery, and I would explain it to him.

We passed through the inner courtyard, and much to my surprise he led me into one of the most modern breweries I've seen anywhere. Gone were the romantic images of traditionally clad monks stirring big vats of wort. Instead I saw an enormous 372 hecto liter (316 barrels) computer controlled stainless steel system. When it comes to brewing, these monks are definitely not stuck in tradition.

We moved on to the primary fermenters, rectangular stainless vessels about 12' X 14' X 14'. Peering into an empty one, I decided to take a photo. As I attempted to compose my picture in the dark, an ominous sound was heard. . . . . a slight "click" followed by "tink tink tink". Much to my chagrin, the battery cover on my flash decided to detach itself, and drop into the fermenter! Half

in a state of shock, I explained the predicament to Frere Jacque while his earlier words rang in my head, "Not for the public.....Not for the public...  
...Not....."

Since he was the gardener and I the brewer, Frere Jacque immediately asked me the obvious question, "What shall we do?" Wishing to assure him that everything was under control, I proceeded to instill confidence by stammering and stuttering indecipherably. There was a brief moment of lucidness, and we began searching the brewery for a ladder and a flashlight. We eventually found a ladder on the top floor, and then started our harrowing descent back down the spiral staircase. As we gingerly maneuvered the ladder down the stairs, I couldn't help noting the beautiful stained glass windows. Given the recent chain of events, it seemed inevitable that things were only going to get worse, but fortunately the windows survived. We arrived at primary fermenter #8, and down I went in search of my wayward battery cap.

By the time I reached the floor of the tank, I was having flashbacks to conversations I'd had with other Belgian brewers, "You'll never get in to Chimay.....Not for the public.....You'll never get into Chimay....."

Groping about on hands and knees in the pitch black delirium, I eventually found what I was looking for, and could then focus my attention on the ascent. I turned to the small window, emanating a single shaft of light from above. Frere Jacques's angelic face was complete with halo and perfectly framed. The roar of a thousand Hallelujah's reverberated in my head as I rose up into the light and in to Frere Jacques's embrace. As I made my way out of the tank, Frere Jacques's voice cut through the din, "You must feel very, um, embarrassed." I could only nod in agreement. He responded by saying, "It is OK. I can wear your shoes."

The brothers of Chimay encourage visitors to tour the bottling plant nearby, but the brewery is definitely "Not for the public."

CR

=====  
=====

### Belgian Impressions

For the true beer devotee, there can be nothing quite like a trip to Belgium. No other place on earth can boast beers of such variety and depth of character.

Belgium is a small country bordering France, Germany, and the Netherlands, whose 10 million inhabitants are culturally and linguistically divided. In the southern part of the country, known as Wallonia, the people speak French. In the north and west, the language is Flemish, which is similar to Dutch. Only in the capital city of Brussels do the two coexist.

This tiny country is a haven of many gastronomical delights. The Belgians have taken both food and drink to an extreme state of refinement, and some of the finest cuisine I've ever experienced has been there. Meals are taken at a very leisurely pace, and typically served with beer. To borrow an idea from Jackson, Belgian food matches that of the French in its sophistication, while the portions would satisfy the appetite of a German.

As in most brewing countries, public houses are very popular. The Belgian embodiment of the public house is the cafe, or estaminet in French. The cafe is a center for socializing and conversation, and of course refreshment. As such, it is the ideal environment to experience the world of Belgian beers, and even the most modest establishment will usually offer 12-15 selections. A cafe specializing in beer may have a bewildering 100-200 choices, and some can be found with over 1000.

Although great beer is commonplace in Belgium, it is by no means taken for granted. Unlike most of the world, the Belgians regard beer as the noble beverage that it is, and treat it accordingly. When serving, each beer is presented in the appropriate glass, often with its own coaster. When consumed, the experience is slowly savored. Such ceremony is not reserved for special occasions, for beer is generally considered an essential part of

everyday life.

Unfortunately, all is not well in paradise.

Like people everywhere, many Belgians consider their government inept, and a recent anti-alcohol campaign would seem to confirm this. The state has started spending large amounts of tax dollars on a massive advertising campaign which glorifies abstinence and sobriety. As a result, some members of the brewing community feel that beer drinkers are being cast in an unfavorable or even immoral light. The immoral overtones are especially ludicrous when one considers that some of the finest brews come from the monasteries of Chimay or Orval.

Even more unfortunate, the oft repeated theme of the big guys swallowing up the little guys is at epidemic proportions in Belgium today. This past year has seen the closure or takeover of 15 small breweries, including two of Lambik in Pajottenland. A quick comparison of the original and updated versions of Jackson's World Guide to Beer makes this trend painfully obvious. Not only are smaller breweries disappearing, but entire styles are endangered.

The two major brewers of industrial Pils, Jupiler and Stella, have merged to form a large brewing consortium called Interbrew. Maes, another large brewer is part of a larger French company. Furthermore, Heineken appears to be flexing its muscles. Most beer devotees in Belgium detest the formidable brewing giants, while each year, more and more of the small traditional breweries are forced out of business by the consortia.

All is not doom and gloom however. There are several signs of a growing resistance. One of these is a very active consumer group named the Objective Beer Tasters. Similar to Britain's CAMRA, their goal is to promote craft brewing through public awareness, and their ranks are growing. Furthermore, certain beer styles, notably Wit and Faro, are enjoying a resurgence in popularity. Until a few short years ago, both were practically nonexistent. Finally, there is a small trickle of new artisanal breweries striking their kettles and celebrating the uniqueness of Belgian beers.

This may not seem like much, but in the US in 1980, there were far fewer indications of the pending microbrewery explosion. Will there be a similar revolution in Belgium? Most Belgians seem doubtful, but having lived through one renaissance, I can see more than a glimmer of hope.

Subject: Glo:gg and essences

Dear Brewers,

For the past two weeks or so, Erik (sorry, I still don't have your last name..), Geoff Sherwood, I and others have been e-mailing eachother in search of Glo:gg essence - either in its extract (or "tinctute") form, or perhaps the raw ingrediants along with the recipe to make our own. I've looked all around the "Swedish Village" here in Chicago, but have little more than the raw ingrediants, which I have today purchased - no "tincture."

So, I think I'll have to make my own "extract." Geoff e-mailed me with some ideas about how to extract the essencial oils and stuff from the spices, but I'm unclear about the particulars of this procedure. So, here's the question:

The bag of ingredients I have measures about 2 c., made up mostly of rasins. there are also almonds (whole), whole cloves, whole cardamom seeds, 3 sticks of cinnamon, and dried orange peels (not orange zest - the grist is still on). Geoff suggested steeping the ingredients in vodka (preferrably a high-proof vodka) for a few hours, then adding the extract (filtered through a coffee filter?) to the priming vessel just before botteling. But, I'm always new at this, and I need more directions, like how much vodka to use? Can I use grain alcohol? Should I steep at a certain temperature? Will I need to press the ingrediants after steeping to get the most I can through the filter? And how much should I add at botteling?

I sincerely appreciate any and all information I can get on this process of making extract. I will post a summary later if there is enough response.

Cheers!

John

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: low and high gravity propagation

I received a lot of e-mail asking about the relative merits of low gravity vs. high gravity wort for yeast propagation.

Several years ago the EBC did an exhaustive study comparing media for yeast propagation. If the media contained carbohydrates it was probably included in the study, literally everything from exotic sugar solutions to tomato juice. They concluded that dilute all malt wort was the best overall choice. In addition to the Crabtree effect, they also found that elementary wort proteins (amino acids) played a favorable role. This was something that I forgot to mention in my last post. Dilute wort was favored over full strength wort because this avoided the "sugar shock" at the start of the propagation.

Five years ago Dr. Hsu of Siebels recommended that I try full strength hopped wort. He felt that sugar shock was overrated, and that the best results were obtained by minimizing the change of environment in going from propagators to fermenters. In particular, he wanted there to be a minimum change in the osmotic pressure on yeast cell walls. If you purchase slants from Siebels you will also get an instruction sheet which has a detailed description of his procedure. This is a change for them, because they use to recommend dilute wort.

To make a long story short, I tried Dr. Hsu's procedure and found that for 95% of the strains tested (including 100% of those available from Siebel) he was right. I have since modified his procedure with respect to volume increases, but invariably everyone locks on to a detailed procedure that works best for them.

My article on yeast propagation appeared in Vol.7 not Vol.6 of Brewery Operations. The one in Vol.6 is on an entirely different subject ( Thanks Bill!).

>sweetening. Anybody have any successful sweeteners besides  
>granulated sugar? Thankx,

When you say granulated sugar, I assume that you mean table sugar, or sucrose. Sucrose is fermentable and unless you pasteurize the wine or beer, the sweetness you require will ferment away (and perhaps create glass grenades too). I have just recently, successfully brewed a sweet raspberry-cherry ale. I used 8 ounces (net weight) of Lactose (Milk Sugar) in a 15 gallon batch, along with a pound of light-colored crystal malt (which also adds unfermentable sugars and thus sweetness). Note that LACTOSE IS FERMENTABLE BY LACTOBACILLUS (and perhaps *Pediococcus* also), so you better be pretty sure that you don't have a bacterial infection!

Subject: Re: haze

Mark writes (again, sorry for the delay):  
>i just tried two brews that had the same problem.  
>i brewed both with malted barley that i roasted  
>and crushed with a rolling pin. both beers had  
>excessive haze. the haze settled quite a bit after  
>a week and a half in the fridge (after 2.5 weeks  
>aging). i put the adjuncts in the cold water and  
>left them in until boil (possibly slightly longer  
>in the beer that had the worst haze).

What you've got is partly chill haze, and partly starch haze. Whenever you use malted barley in your beers you need to mash them -- otherwise the starches that you extracted from the malt will not get converted to sugars. When you boiled the grains, you extracted a bunch of tannins which later reacted with proteins in your beer to create chill haze. Crystal malts are in effect "mashed in the husk" so you don't have to mash them and I personally don't mash Black Patent Malt, Roasted Barley or Chocolate Malt in my extract+specialty\_grains batches .

>is the amount  
>of haze directly proportional to the amount of time  
>the adjuncts spent at temp's in excess of 170F?

Yes. The more you boil the grains, the more tannins you will extract and the more starch you will extract from the grains.

>Is  
>there something else i was supposed to do with the  
>adjuncts.

You should have mashed them. An option to a complete mash is to use Diastatic Malt Syrup (Edme makes one and so does Munton & Fison) which still has active enzymes. You definitely needed to get some enzymes from somewhere (some unroasted 2-row or 6-row or from Diastatic Malt Syrup) because the roasting killed the enzymes in your malt.

>what are the other reasons for removing  
>the adjuncts before boil?

See above.

>what is the real cut off  
>temp for them?

I stop at 168F, because my pot is stainless steel which is not a good conductor of heat -- therefore there can be hot-spots in the pot. When my floating thermometer says 168F, I suspect there are 175F spots at the bottom.

>both were extract brews but otherwise  
>had nothing in common and were brewed in my usual

Subject: Bottling session from hell (a little long)

- ----- REPLY ATTACHMENT -----  
SENT 10-12-92 FROM SHERRILL\_PAUL @CTS

Paul's bottling session from hell  
(aka. How not to use raspberries when brewing)

Here is my near disaster from brewing. After successfully brewing on great raspberry batch by using the berries in the primary (see recipe in Cat's Meow) I decided to made a psuedo Framboise follwoing Cher Feinstein's recipe in the Cat's Meow.

The recipe calls for wheat extract then after primary introduce the berries into the secondary as a puree. After a rather quick primary I racked to secondary and a few days later planned on adding 6 lbs of berries. I used frozen berries and used my food processor to mush them up. This worked OK. After carrying out the first pitcher full of berry puree I realized that there was not enough head space left in my carboy for all the berries. No problem, I racked the beer back into one of my plastic primaries add added the berries to this. Note that the bucket has a spigot at the bottom to perform bottling. I'm thinking no problem a couple more days in secondary and then bottle straight out of the bucket. There was some residual fermentation (probably do to the oxygen introduced from racking and the sugar in the fruit).

I let it stand for about 5 days to make sure any fermentation will have ceased. Then came bottling day. Pulled the bucket out of the fermentation fridge. Popped off the top and see a decent raspberry head. Reasonably strong but pleasant alcohol raspberry nose. Pour in priming sugar. Attach bottle filler to spigot via 10 inch plastic hose. Commence bottling.

Problem 1: Slow bottling and the stuff in the hose looks like something out of a raspberry slurpee machine. Alright, the combination of yeast fall out and raspberry particles at the bottom of the bucket are two thick to get through my bottling wand (the old orange tip type). Close spigot and try the racking tube. Problem 2: same as problem 1, the liquid is too thick. Clean an extra bucket and rack to this bucket while straining the beer. Sanitize sparging bag place in empty bucket and rack. Now to strain just pull the straining bag up. Problem 3: after pulling the bag up through about 3 gallons it is completely clogged. Hold bag up with one hand (muscle building) while trying to stir in the bag with a small hard plastic tube. After about 5 minutes I realize that this would take at least an hour. So I go for the squeeze of the bag to leech out the liquid. This is working

nicely as the liquid is forced out over the clogged portion. About a gallon left to strain, squeeze a little harder and POP. The seam at the bottom of the bag pops about a one inch hole. Beer and clogging material spew into the bucket and all over the garage floor. I stop the flow and decide no more straining is nessacary.

Onto bottling via racking tube and bottling wand. Problem 4: the bottling is going too slow and the wand won't shut off when lifted. Culprit is raspberry seeds stuck in the bottling wand. Screw it. Pull off wand and use the pinching of the tube method to finish bottling (Of course adding to the now raspberry scented garage floor). Bottling finished. The first bottle that was filled has about half particulate, half liquid. The perfect bottle for those non-homebrew initited types. Only took about 3 hours to finish bottling this batch.

Last night (after being in the bottle for a week) I pop open a bottle and beer sprays out all over the kitchen. The dog likes this, my daughters homework does not like this, wife dosen't care cuz I'll be the one cleaning it.

Pour what is left on the bottle into my glass and this is a good beer although rather cloudy. Many of the bottles have a visible seperation between the beer and where the particles are settling out. Looks like I'll have a good half inch of crud on the bottom of each bottle. My wife in here wisdom says no problem just buy a small strainer for pouring thru when dispensing.

My only question: Is the over carbonation due to the fact that the fruit is fermenting in the bottle? I added the normal amount of priming sugar (about 1/2 cup). The beer does not gush (as has happened when infected) it sprays out uniformly upon opening. Do I have a bunch of glass grenades? And should I pop them open and let them re-ferment then re-bottle?

Lesson learned: Just use the raspberries whole, less mess and the beer still leaches out all the raspberry flavor.

>"tinctute") form, or perhaps the raw ingrediants along with the  
>recipe to make our own. I've looked all around the "Swedish Village"  
>here in Chicago, but have little more than the raw ingrediants, which  
>I have today purchased - no "tincture."

In Andersonville, in Chicago, you can buy this essence from Ericsson's  
Deli, around 5500 N. Clark. It's is a few doors north across the  
street from the Swedish American Museum. Also, Wikstr|m's Deli,  
across the street sells it. At Ericsson's, it lies on a shoulder high  
shelf on the far right side of the northern wall of the store, near  
the front door, next to some various syrups.

The stuff is ok, but if you want to make gl|gg, use the ingredients  
instead. I don't like the bottle mix - (Den [r ganska d]lig...)...  
The "essence" is water-based, same as the essence here in Sweden.

Of course, if you're going to waste it in some beer attempt, buy the  
bottle. (I can post my family's recipe if there is interest.)  
Incidentally, you can buy gl|gg at Ann Sather's restaurants in  
Chicago, one of which is right next door to the Swedish American  
Museum...

Say "hi" to the old lady at Ericsson's if you go...

Subject: American Wheat Ale

Can anyone in the know out there post a description of American Wheat Ale.

I've sampled "AWA's" that have been so close to Weizens that I don't know why the brewer differentiated. On the other side of the spectrum, many micro's (Dave Miller's being an example) brew a wheat ale that is so pedestrian that you'd never know there was wheat in it (The main reason for

the beer seems to be to have an exotic name yet still appeal to the timid masses). So what's the "official" line on American Wheat Ale?

Enquiring minds want to know,

Walter Gude     ||     whg@tellabs.com

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: Our Man Tim

Tim Norris asked that the following be posted:

Siebel is restructuring themselves and in the process are shedding some of their distribution responsibilities, of which the Belgian malts is one. Schrier will be picking up the Belgian malt distribution and expect an increase of maybe a penny per pound. While Schrier will concentrate only on supplying micros and brewpubs, they have no plans to allow any one single distributor to handle the retail side. If an malt gets dropped by Schrier, it will be replaced with a higher quality malt to replace it.

So the bottom line to the nervous nellies (myself included) is that the Belgian malt supply to the US is not expected to be interrupted, the price will rise ever so slightly, and no one single retailer will be allowed exclusive distribution rights.

The question now is: how trustworthy is Schrier? Will they keep their word?

Subject: Re: yarrow

In HBD #990, Jack Thompson asks:

> I would like to brew some pre-hops beer, and wonder whether or not any  
one  
> has information of the use of yarrow to bitter the brew?

Although I cannot answer the question directly, I can say that there was  
a  
book (I don't know if it still in print) called "Recipes for Prizewinning  
Wines" by Bryan Acton (or it may have been Peter Duncan). It had a  
recipe  
for Yarrow Wine in its herb wine section and that may serve as a starting  
point for you. The author said that this wine was used primarily for  
medicinal purposes. It tasted awful (but then again, there was probably  
no sweetness to balance the bitterness) but was supposed to be a great  
help with colds and catarrh.

I cannot find my copy; I bought it in 1973 or so and lost it during a  
hiatus  
in brewing. I have not seen it in stores since then. It was published  
by  
"Amateur Winemaker" - the same folks who publish Acton & Duncan's  
"Progressive  
Winemaking".

If you cannot find that book, you also might want to check C.J.J. Berry's  
book "First Steps in Winemaking." He has a bazillion recipes including  
an "Onion Wine" so he may have tried yarrow by now as well.

Good luck!

From: dab@blitzen.cc.bellcore.com (dave ballard)  
Subject: a fungus amungus

Hey now- It was bound to happen, right? I brew the best batch of my short brewing career- a liberty ale-ish thang that is perfectly clear, perfectly balanced, basically just perfect. I dry-hopped in the secondary with hops grown in a friend's garden (thanks bonehead!) and let it sit for about 2 weeks. I racked to a tertiary on Sunday to let some residual hop junk settle out and planned to bottle on Monday or Tuesday.

So I head down to the basement yesterday after work to start gathering bottles and from a distance the beer in the carboy looks like it has started to ferment again 'cause there's some sort of head on it. I move in for a closer look. My draw drops, my eyes roll back in my head, a blood-curdling cry echoes throughout the house. The surface of the beer is covered with a thin white scum. It's kind of lacy looking with little fuzzy nodules here and there with vein-like things extending into the film. It looks like the stuff the people had on them when they crawled out of the pods in "Invasion Of The Body Snatchers."

I made a valid attemp at bottling anyway, although I'm sure the bottles will develop the same thing since it looked like there were little pieces of stuff floating throughout the bucket when i primed. It still tasted and smelled okay, so I don't know.

Any thoughts on what it is? I didn't do anything to the hops before I added them to the secondary, but I think if it was caused by them it would have appeared sooner. I sanitized the carboy in my usual manner (bleach soak) and basically did nothing different from my usual routine? I'm pretty bummed, so any info would be greatly appreciated. If the scum forms in the bottle I would be more than happy to send some to anyone who wants to take a look first hand.

From: CW06GST <CW06GST%SJUMUSIC.bitnet@CUNYVM.CUNY.EDU>  
Subject: re: glo:gg

Several people have commented on glo:gg essence and I just thought I'd put in my .02. John was saying that he wanted to make his own extract from the glo:gg spices that he had purchased but it was mostly raisins. It is true that glo:gg is served with raisins in it, but I don't think that is what it is spiced with. The raisins are added in addition to the spices. So if you are going to steep the spices to try and make your own tincture I would lose the raisins. But, why not just add the spices at the end of the boil like finishing hops? instead of trying to make a tincture.

Kurt (and others) have mentioned that the essence is available in the Chicago area. He says that the extract is water based just like that found in Sweden. If this is the case then to make your own extract all you have to do is steep the ingredients in water to get the goodness out of them. I have glo:gg essence that I bought in Valbo, (right outside of Ga:vle) Sweden from the pharmacy (apoteket). It is not a water based mixture but is alcohol based, and is what I will be using to make a Christmas ale. As I have mentioned before, it comes in 25 ml bottles and is 63% alcohol. If you would want to make a tincture like this I suggest making up a solution of grain alcohol, the spices and water. Make the volume of alcohol 65% and water 35%. Heat this covered until it comes to a boil. Let cool and strain off the spices. I have never tried this so you might want to heat it a little longer. Experiment|

Kurt also mentioned he had a family recipe for glo:gg. I have spent Christmas in Sweden, and I have tried many different family's glo:gg but noone ever gave me a real recipe. If you post it I would greatly appreciate it.

Good Luck,  
Erik Zenhausern

Subject: Insulating my boiling pot?

Last night, I was watching my 5+ gallons of wort barely boiling, with the 11000 BTU burner on full blast under it, and was trying to figure out what I could do, short of buying a "Cajun Cooker" (and propane, or extending my gas piping outside), to get it to boil faster (or at all!)

I dimly recalled a posting in this forum several years ago wherein the brewer wrapped his pot in some sort of insulation (newspapers?) to get better performance. Since I've got a black pot (ceramic on steel) I imagine that there could be significant heat loss from the sides of the pot. I tried wrapping newspaper around the pot, but it started to char (sitting on a gas burner, after all).

Then I cannibalized an old water heater insulation blanket that I had never used. Figured the fiberglass wouldn't burn (but see below). I did pull off the plastic backing. This worked, and I was actually able to sustain a vigorous rolling boil with the lid partly covering the pot. But I'm not happy about having that "naked" fiberglass so near to my food.

\*\*\* So, here's the question: Has anyone figured out a good solution to the  
\*\*\* problem of insulating the sides of a large pot?

Along the way, I tried to put the pot over two burners, but the configuration of my cooktop makes this essentially impossible (the control knobs end up underneath the pot -- not a good situation). I did manage to melt/burn a little of the fiberglass in the process. (It smelled sort of "plastic-like", so maybe it's not really fiberglass.) Those gas flames are hot!

From: tony@spss.com (Tony Babinec)  
Subject: what is am malt liquor? / beer vs ale etc.

An American Malt Liquor is a blond lager with an alcohol strength stronger than an American Premium. I am not a commercial brewer, and am not certain of the law here, but I believe the cutoff is something like 5% alcohol or something like a 1.050 starting gravity. The analogy might be to the German Pilsner and German Export styles, with the latter being higher in gravity. Of course, the American beers are nowhere near so hoppy as the German! In my humble opinion, most American Malt Liquors are rather sweet and undistinguished in taste, or at least that's what I recall.

U.S. law imposes certain labeling requirements on the commercial brewer. A "beer" falls below the above cutoff, while an "ale" or "malt liquor" fall above. Again, I invite someone with more knowledge of commercial brewing and the law to add to this. But, you'll notice, for example, that Old Foghorn labels have described it as "a barley wine-style ale." I'm guessing that they must call it an ale by law, and by describing it as a barley wine style, they are clueing us in as to its strength and style.

In a related vein, you will notice that some of the German import Oktoberfests are "beers," while others will have a label such as "Oktoberfestbier." Examples of the former tend to be lighter in color, less flavorful, and, it seems, under 1.050 or so in SG. Examples of the latter include Spaten and Paulaner, which in my opinion are tasty and exemplary of style. In "Vienna," George and Laurie Fix point out that many of the German Fest beers are in the 1.051 - 1.055 SG range, which would make them "bier" and not "beer." Or, so I am surmising.

From: tony@spss.com (Tony Babinec)  
Subject: pale ale vs ipa/what is bass ale?

Historically, India Pale Ale was a high-gravity, highly hopped, pale (as opposed to brown) beer brewed to withstand the sea voyage to British colonial outposts, where you can imagine that it, along with gin, was a drink of choice. Today, such a beer would be called a barley wine.

While there are shadings of style rather than a sharp demarcation, AHA style guidelines at least indicate:

```
pale ale india pale ale
SG 1.044 - 1.056 1.050 - 1.060
BU 20 - 40 40 - 60
color 4 - 118 - 14
```

Terry Foster's Pale Ale book suggests higher gravities, higher hoppiness, and less crystal malt in the grain bill for IPAs. Also, as already pointed out in HBD, NO OAK CHIPS! In actual commercial usage, the above guidelines haven't been strictly followed. Bass Ale's label has changed repeatedly through the years, but as noted, carries an IPA designation, while in fact it is a pale ale by the above style descriptions. A glance at CAMRA publications shows that "IPA" has been used by certain breweries to refer to what are actually bitters which are well below 1.050 in SG.

To emulate Bass Ale, follow the pale ale guidelines and use British ingredients (malts or extracts, hops) and an appropriate ale yeast. Anyone have a recipe that is a bass ale knockoff?

>Subject: Cranberry Ale?

>I just racked my first Christmas ale into a secondary and tasted it.  
>Wonderfull stuff. Now I don't want to make a plain ale next time I brew.  
>Since it was Thanksgiving this past weekend in Canada I had the idea of  
>adding cranberrys to my next batch of beer.

>Q1..How much cranberry should I use? Do I crush them?

I made a cranberry beer using a little under 3 lbs of Ocean Spray cranberries. They were frozen in the fridge and I pureed them right before adding them to the wort. They were added right after I turned the heat off and their semi-frozen state brought the boil straight down.

Then after letting them steep for ten or so minutes, I threw in an immersion wort chiller and took the temp down to 80F.

>Q2..Should I add a sweet berry to offset the sourness of the cranberries?

My cranberry ale came out to be light and tart. It has a nice flavor profile on its own. Add it only if you want to change the flavor of the end product to something sweeter, but try not to overpower the cranberry flavor too much.

>Q3..Anyone with a recipe for an extract cranberry ale?

My notes are at home, but I took this as a variant of something I saw in the Cats Meow II.

5 lbs Light Malt Extract  
1 lb. sugar  
1 1/4 oz Fuggles (Boiling 30 min)  
3/4 oz Fuggles (Finishing 10 min)  
Irish Moss  
Gypsum  
Munton & Fison Dry Ale yeast

3 lbs pureed frozen Cranberries

I got two cases out of it. If you want the exact recipie, ask me on email and I'll go drag out the notes. BTW - I primed with brown sugar.

>Q4..Fruit are added at the end of the boil, steeped and transfered into the primary. When I rack the beer to the secondary do I also transfer the fruit?

I had a strainer over the funnel hole and would let the wort drip through it. Then I would press it a bit with the ladling spoon and scoop it out

into a bowl. This took a little while, and some of the wort was left behind in the saturated cranberries (I used hop bags and grain sacks so that there wasn't a lot of other stuff). But I topped it off with some tap water (gasp!) and got a nice two cases out of it.

Some of it was bound to get through though, and sometimes I find a cranberry seed in the bottom of my beer. I recommend you start NOW so that the beer may age properly - this is something that gets better with age.

Subject: Starters revisited

As I've mentioned before, I've been away, so forgive this semi-late post. I'm all caught up now, so I should be back in-sync.

Micah writes:

> I feel that this question opens a whole can of worms as far as  
> yeast propagation goes. While it might not hurt anything to put hops  
> in the yeast starter it can serve little but to increase the cost of the  
> process ( oh, it is possible that the hops can lower the ph enough to  
> help, but its not a viable method of ph justment).

As I believe someone else mentioned, the hops are for antibacterial purposes. However, I don't use them.

> DME is very expensive and messy.

I'm reconsidering my technique (I'm thinking about using higher-gravity starters, based upon what George and others have written), but I've been using 1 ounce (weight) of light DME in 16 ounces of water, boiled 10 minutes, then cooled for my 1.020 starters. At \$9 for 3 pounds, that's 19 cents per 16 ounces of starter -- hardly expensive. Perhaps it's more humid by you -- that's the only reason I can think of it being messy, but during my normal (Oct to June) brewing season, it's not humid enough to make my DME cake-up if I keep in in a sealed plastic container.

> importantly proper carbohydrate sources. It is known that yeast can

> more easily) and is very cheap.

Perhaps, but this conflicts directly with Noonan's claim that if yeast is given a high-glucose environment, they shut down their maltose (di- and tri- saccharide, I mean) metabolism pathways in lieu of (as you said) the "easy sugars." Noonan suggests that yeast raised in a high-glucose environment will take some time to re-start their di- and tri-saccharide pathways, resulting in longer lag times.

However, Bob Jones has reported \*no increase in lag times\* from switching to sucrose starters and Micah gets 2 hour lag times (see below), so perhaps this is an error in Noonan's book?

Then, in a followup post, Micah says:

> So heres what I do to just build up a starter.  
> I boil water and powdered sugar together with some yeast nutrient for

Ahhh... I wondered about this after your first post. On the other hand, as we know from Rob Bradley's post, not all yeast nutrients

are alike. What kind of yeast nutrient do you use, Micah?

> about ten minutes, cool it and add the yeast, and shake well.  
> The solution has approx 1020 gravity. Once a day i will "feed" the  
> yeast some more sugar solution of successively greater concentrations  
> to allow for dilution of additional liquid. From a yeast packet i can  
> grow up to my pitch volume of 700mls dense slurry in three days with  
> out a lot of excess liquid involved to dilute to wort. The yeast is  
> grow at 80 F. I normally see 2 hour lag times with 15 gallon batches.  
> Sanitation is important so be careful.

Given the fact that you use yeast nutrient, I willing to concede that perhaps sucrose+nutrient is a viable alternative to malt extract for starters. In addition, you note that you add additional sugar with successively higher concentrations, which is acclimating the yeast for their plunge into higher gravity wort -- seeings how this increase in gravity (and osmotic pressure) is gradual -- this may be the best argument for this use.

As I see it, all that needs to be determined is if Noonan is right or wrong (biologically, I mean, as there are already Micah's and Bob Jones' empirical data points that Noonan has, at least, overstated it's importance)  
about the increased lag time from yeast raised on glucose. Perhaps Noonan was not using nutrient and thus was creating weak yeast? George's post on the EBC's results seems to support the malt starter argument, but perhaps they did not use nutrients with the non-malt starters either? Mead-makers have repeatedly reported problems with amino-acid-deficient ferments.

Personally, I think I will continue to use malt extract, but will try incorporating Micah's "successively higher-gravity" procedure.

Subject: Pressure cooker & Labels

I'm almost as excited about this, my first posting, as I am about tonight's decisive NLCS playoff game. What a great reason to have a homebrew! First a question: My neighbor just got hold of a 5-gallon pressure cooker. We wanted to use it for brewing (extracts and specialty grains). Has anyone out there in network land ever brewed this way? Do you reduce boiling time due to higher temperatures? What about adding hops, etc. Will the higher temps damage the "enzymes" in the malt or produce nasty by-products? Any help would be appreciated. Also - I've been following the labeling debate & thought I'd mention my variation. I use small round "file markers" from the office supply store to label each bottlecap. They come in many colors, but I just use one until the package is gone. I simply number each batch in my "brewlog" and post a chart on my refrigerator. Each bottlecap has a number on it corresponding to the batch. A look at the bottlecap and a look at the chart tells me what kind of beer I've just grabbed, and reminds me to close the fridge door.

> Bronze: Colt 45 Malt Liquor, G. Heileman Brewing Co., La Crosse, Wis.  
>  
>What is this this stuff? What makes a beer a malt liquor?

Malt Liquor is largely just a legal term. Some states in the US require any beer over 6% alcohol by volume to be called Malt Liquor. Therefore you get some good imported beers, like barley wines, dopple bocks, etc. getting labeled "Malt Liquor" just to satisfy varying state laws. You also get a class of boring American light lager which gets called the same thing on purpose. The above beers have little more character than your typical Budweiser/Coors/Miller type beers. They just have more corn syrup added to the fermenter to give them more alcohol.

As has been pointed out, the only reason GABF gives awards for this swill is so they can stroke the big brewers who sponsor the event.

Subject: Hop substitutes?

Hello,

I have recently been informed that way back in the old days, 1700's or so, that the plant species Myrica gale was used to bitter beer instead of hops. Has anyone tried this and how much do I use. It grows around any lake here in Northern Ontario. Also, are there any other common plants that anyone uses to bitter their beer instead of hops? I've made tea with the Myrica gale and I'm wondering if I should make a tea and then add it to the wort or if I should just boil the dried leaves in the wort.

On the topic of hops. Where do I get rhizoids for growing my own hops? What type should I use a 43 degrees N latitude?

>Lowenbrau Dark took exactly one medal: a Silver in the Dark Lager catagory.

I assume that what you're really trying to point out is that several catagories seemed to be dominated by the megabreweries.

Not at all. What I am pointing out is that, unless Miller changed the recipe

since first introducing Lowerbrau Dark, the only way they could win a medal

in the Dark Lager catagory is if it was the only dark lager entered. It is

pitiful at best. It is nothing but caramel colored Miller.

> This is no accident - the characteristics of these catagories were designed to allow the megabreweries to win some medals.

Dark Lager? You gotta be kidding. That is about as general as it can get.

>Some people may cry `foul` for this.....

Not me, I say farce.

Subject: malt liquor, cream ale

A few comments on the GABF thread:

#### MALT LIQUOR

As I'm sure most of you know, the megabreweries practice something called 'high extract brewing'. The original gravity is significantly higher than you would expect, and the beer is DILUTED ON THE BOTTLING LINE to bring it to the correct strength!!!! [Thus all the bull in the TV ads about shipping 'concentrated beer' by train.]

According to Viv Jones, one-time brewmaster at Upper Canada in Toronto, the final product in a typical North American brewery is 6.5% or more alcohol by volume. [As has been noted before alcohol by volume and by weight are different...the figure of 6% by volume quoted in HBD991 is roughly in line with the figure of 5% quoted earlier in the same issue, assuming that the later is by weight.] The advantages of this style of brewing are obvious: the throughput from a given brew-house is vastly increased. Original gravity is essentially as high as it can possibly be without affecting yeast performance.

Apparently many brewers use the same beer to make light and regular: just add more water for light beer! Is it possible that 'malt liquor' is produced by the big guys by diluting less? Let's look at some GABF results:

#### >AMERICAN LAGER

- > Gold: Schlitz, The Stroh Brewery Co., Detroit.
- > Silver: Hamm's, Pabst Brewing Co., Milwaukee.
- > Bronze: Stoney's Beer, Jones Brewing Co., Smithton, Pa.
- > .....

#### >AMERICAN MALT LIQUOR

- > Gold: Olde English 800 Malt Liquor, Pabst Brewing, Milwaukee.
- > Silver: Silver Thunder Malt Liquor, Stroh Brewery Co., Detroit.
- > Bronze: Colt 45 Malt Liquor, G. Heileman Brewing Co., La Crosse, Wis.

I wonder if anybody out there can verify what, if any, connection there is between Schlitz and Silver Thunder? Hamm's and Olde English?

#### CREAM ALE

Now here's an interesting case where, perhaps, GABF is doing some good. Apparently, the style is called "American Sparkling Lager Ale" and is a 19th century hybrid of Bohemian and North American techniques. Primary at ale temperatures, secondary at lager temperatures. Ale or lager yeast can be used. I grew up on it (-: Labatt's 50.

The night before the GABF results appeared, I was at the local Rite-Aid pharmacy here on Long Island. I noticed, for \$2.39, 6-packs of Genesee Cream Ale, with a sticker saying: winner at the GABF. I knew it must mean 1991 or earlier, since the GABF had just taken place.

Well I'm a Canadian, eh, so I'm not steeped in the local fraternity culture. Nevertheless, I have had regular Genesee and I do know better than to expect great beer out of a can (or for \$0.4 per can). So I wasn't too disappointed. I have since learned that its main claim to fame is its price. To its credit, the stuff has more body than

Bud and a tad more bitterness. No particular hop or malt character.  
It is most decidedly an industrial grade beer.

Well, let's look at the 1992 results:

>AMERICAN LAGER/ALE CREAM ALE

- > Gold: Scrimshaw Beer, North Coast Brewing Co., Fort Bragg, Calif.
- > Silver: Dock Street Cream Ale, Dock Street Brewing Co., Philadelphia.
- > Bronze: Little King's Cream Ale, Hudepohl-Schoenling, Cincinnati.

Hmmmmmmmm. Genesee's been kicked off the list and Little King's  
is just hanging in there. The gold and silver look like micros  
(can anybody confirm?) Seems there's a renaissance going on here!

[Thanks to Tony Babinec who e-mailed me on the subject of Cream  
Ale/"American Sparkling Lager Ale" in March.]

Cheers,

Rob (bradley@adx.adelphi.edu)

From: iknott@biocell.fundp.ac.be

Subject: Postcard from Belgium

Dear HBDers:

Have so far spent ten days beer hunting in the UK, including visits to three breweries and countless pubs. I arrived yesterday here in Belgium, and today had a lesson in yeast handling from some biologist friends in Namur. Notes are being taken on everything that moves, and if it turns out that theres anything useful in the mess I will prepare a report. In any case, having a wonderful time, wish you were here!

Phil Seitz

P.S. A note to any British readers; Tolly Cobbold is now offering a special anniversary ale, which is available for only two weeks; if you find it, dont hesitate!

Subject: American Wheat Ale

>Can anyone in the know out there post a description of American Wheat Ale.  
>I've sampled "AWA's" that have been so close to Weizens that I don't know  
>why the brewer differentiated. On the other side of the spectrum, many  
>micro's (Dave Miller's being an example) brew a wheat ale that is so  
>pedestrian that you'd never know there was wheat in it (The main reason for  
>the beer seems to be to have an exotic name yet still appeal to the timid  
>masses). So what's the "official" line on American Wheat Ale?

The pedestrian version you and I both dislike is, in fact, American Wheat Ale. If it's close to a Weizen in taste then it is a Weizen. American Wheats have similiar grain bills and hopping rates to Weizens- i.e., 50-75% wheat malt, very low bittering, little or no finishing hops. The primary difference between them is the yeast used to ferment them. A Bavarian style Weizen uses *Saccharomyces delbruekeii*; this yeast produces all the wonderful spicy/fruity esters associated with the style. American wheats, exemplified by the insipid Anchor Wheat and Red Hook Brewery's Wheat Hook, use standard ale yeast. The result is an underhopped, virtually flavorless beverage reminiscent of Miller Lite.

I would guess that they were originally trying to duplicate the Bavarian style but didn't have access to the proper yeast. But then they discovered that their customers were buying more of their tasteless wheat beers than any of their good beers, so they continue to make the crap. Such is life in our market driven society. No problem, still plenty of good Bavarian imports, and *S. delbruekeii* is available to us homebrewers from Wyeast (#3056).

From: G.A.Cooper@qmw.ac.uk

Subject: Myrica Gale and Yarrow

There have been a number of questions about pre-hop beers, in particular the use of Myrica Gale and Yarrow. The first two recipes in John Harrison's book 'Old British Beers ...' suggests an OG 50 beer might have 1 gram each

Myrica Gale (Sweet Gale)

Ledum Palustre (Marsh Rosemary) and

Achillea Millefolium (Millfoil or Yarrow)

in one imperial gallon (=1.2 US gallon). The herb mixture should be boiled

with the wort for 20 minutes. The OG 80 beer requires 1.5 gram each of the

herbs. No hops.

Disclaimer:

Yes I do have an interest in the book; I am a member of Durden Park Club.

From: Nick Zentena <zen%hophead@canrem.com>  
Subject: Insulating pots

Hi,

One thing to try is the sort of insulation sold for use on hot water pipes. The kind I got for my old lautertun had glue on one side and foil on the outside.

Whatever you use the best idea on a stove would be not to go all the way down the pot. Even insulating 2/3 of the pot should make life much easier.

If having fiberglass nearby bothers you then think about using wood. Wooden slats tied somehow around the pot should also help.

Hope this helps  
Nick

Subject: Re: Maple Syrup Beer Recipes

> I have a cousin that brews mostly extract beers. He is looking for a  
> recipe that has Maple syrup in it. I look in the latest edition of  
\_Cat's  
> Meow\_ but I only found a porter. He prefers lighter beers.

Well, as a matter of fact my last brew was done with 16oz of Pure Maple Syrup from Quebec Canada. I also do most of my brews using mostly extracts, and this one was made with John Bull hopped light extract, some LME, crystal malt, and the syrup. I was rather disappointed with the brew as the Maple Syrup was not as prominent as I had hoped. I added the syrup to the boil after about 20 minutes. The syrup boiled for about 20 minutes, and steeped for about 15 minutes. I am thinking about adding the syrup at the very end (15 mins of steeping), and/or adding it to the primary after the boil is done, allowing it to do it's thing in the primary. I figure that may give me more of a maple flavor to the beer.

Any comments on this?

Also, in preparation for my christmas beer, I just made an experimentation batch from a 2.2lb Can of Premeir (first time using it....it was cheap and I got it from the local grocery store even...I just wanted to see if there was a major difference between that and what I can get at my homebrew shop), some orange peel, nutmeg, and cloves. I made an xmas beer last year, it wasn't bad, but it also wasn't what I wanted.. (and you know how picky those homebrewers get when it doesn't taste the way they wanted it to...;-) Anyone have any favorite tricks of the trade for xmas brews?!

>> We wanted to use it for brewing (extracts and specialty grains). Has  
anyone  
>> out there in network land ever brewed this way? Do you reduce boiling  
time  
>> due to higher temperatures? What about adding hops, etc. Will the  
higher

I wouldn't do it. Pressure cookers come with instructions that tell  
you never to cook stuff that will foam up a lot. The foam can block  
the pressure valve and cause a big boom if things get overheated. As  
we all know, the initial stage of boiling wort is about the foamiest  
thing known to mankind. If you think stories of exploding carboys are  
bad, just wait until that aluminum grenade goes off on your stove.

However, pressure cookers are ideal for preparing sterile wort for  
yeast propagation. Boil the wort as normal in a different pot, then  
pour into canning jars. Screw on the lids loosely, then put them  
in a few inches of water in the pressure cooker. Pressure cook for  
a while (I do 10 min.), then let the pot cool with the lid on. When  
you open the pot, screw down the lids on the jars, and you've got  
sterile wort.

Chris McDermott writes:

> On another note. While I was on my honeymoon, I happened upon the Seabright Brewery in Santa Cruz CA. One of their special brews was called Century Red and my wife, not being much of a hop-head, loved it's dark, sweet maltiness. Has anyone out in HbD land tried this and if so could you help me make a guess at an all-grain recipe for it? I tried to talk to the brewer, but he was at the GABF picking up his three, count 'em, (1 gold, 2 silver) medals. While I only tried the Red, it sounds like they brew a good deal of quality ale there.<

While at the GABF, I had the good fortune to run into Steve Parkes, an old friend and now brewmaster at the Humboldt Brewery in Arcata, CA. Along with other distinctive products, Humboldt brews a delightful beer called Red Nectar, very similar to the Century Red noted above. Steve is actively campaigning to have the style, which he calls "California Red", recognized as a distinct new beer category. Afficionados may note that many California breweries produce a similar beer, usually with the word "red" somewhere in the name.

While the flavor profile of "California Red" is fairly complex, I find it quite simply to be a Maerzen-style beer brewed as an ale rather than a lager. I believe a fair proportion of Vienna malt is used in the grist, and a high mashing temperature brings out the residual sweetness. Ale yeast gives the beer its fruity characteristics. Original gravity is about 1.050.

To make this beer, I recommend using a good basic Maerzen/Okttoberfest recipe and then substituting the traditional lager yeast with a somewhat low-attenuating ale yeast (such as Wyeast's German Ale).

BTW, attendees at the GABF may remember me as the one with the "BURP" t-shirt pulling beers at the Humboldt booth on Saturday night. Sorry the Red Nectar ran out so quickly.

On the subject of the GABF blind tasting, I would note that the beers are not judged using the 50-point AHA/HWBTA scale, simply because there is not enough time (and not enough judges - and, I suspect, not enough expertise) to provide this level of analysis for 700+ beers. Therefore, emphasis is on adherence to style and drinkability. Unfortunately, brewers are given no feedback as to how their beers are judged, and I personally feel that after selecting 18 medalists (count 'em!) in the American Lager, Light Lager, Premium Lager, Dry Lager, and Malt Liquor categories, these judges can easily be brain-damaged enough to let Jim Koch's Boston Stock Ale slip through as a classic example of Dusseldorf Alt!

IMHO, the gold medal in Scottish Ales should have gone to Old Maclunk from the Boulder Creek Brewing Co. - a classic example of

the 80-shilling export style.

From: rstya@map.mda.ca (Roy Styan)  
Subject: I think I killed my yeast.

I am currently brewing a batch of cream ale. It went through an 8 day primary fermentation at 15C. I racked to secondary and let it sit for a couple of days to let the yeast build up before lagering. It seems it still had a lot of fermenting to do, as it built up a strong (for a secondary) ferment. Despite all warnings from just about every source imaginable, I just chucked the carboy into the fridge and let it cool down to about 1 deg. C. The yeast were not happy. I think I killed them. There were no signs of life in there. I raised the temp. to 4 deg. C. Still no sign of life. That was over a week ago.

What do you guys think? Should I repitch? Raise the temp. back up to 15C and try again? Ignore the problem?

Roy.

What the folks at Anchor told me was that most states require  
anything labeled "beer" over a certain alcohol strength to also  
be labeled "malt liquor".

So they get around these laws by not using the word "beer" on the  
stronger brews. Luckily they can use real beer terms, like "ale"  
or "lager" or "barley wine" or "porter" and accurately describe  
the product, while still getting around the "beer" laws.

From: rone@alpine.pen.tek.com (Ron Ezetta)  
Subject: What is Bass Ale?

>To emulate Bass Ale, follow the pale ale guidelines and use British  
>ingredients (malts or extracts, hops) and an appropriate ale yeast.  
>Anyone have a recipe that is a bass ale knockoff?

I've been experimenting with a recipe from the Cat's Meow - here's  
the latest.

7 lbs 2-row (Infusion)  
1 lb Dark Brown sugar  
1 lb Crystal - 40L  
1 oz Perle (60 minute boil) 7.6 HBU  
1 oz Fuggles (30 minute boil) 5.3 alpha  
1 oz Fuggles (15 minute boil) 5.3 alpha  
1/2 oz Willamette (seep)  
1/2 oz Willamette (dry hop)  
Wyeast #1028 British #2

This recipe has taken on a "Northwest" style - that is, more  
hop flavor and aroma than the bottled, mishandled, product  
that we drink over here. Folks from the UK have pointed out that  
I \*really\* don't know the true flavor of Bass. I agree and look  
forward to hop (no pun) the Atlantic and try a couple of properly  
pulled pints.

With that in mind - a closer approximation of Bass would replace  
the Willamette hops with the seeping of 1 oz Fuggles.

Of all the experimenting, the biggest change came with the use  
of Wyeast #1028 which seems to give a more reasonable reproduction  
of Bass than my former stand-by, Whitbread dry. The two yeasts,  
yield two very different beers. The Wyeast #1028, produces a beer  
with more caramel and malt flavors. While Whitbread dry, lets the  
hops come through with a vengeance. Next time I plan to ferment  
using #1028 at ~65F degrees rather than the 72F of my last effort.

I've made this beer using all-grain, and extract (Stienbart's  
American Light - which is suppose to be 100% 2-row), and have  
detected very little difference.

This recipe, and its variations, have help enlighten me in the ways  
of hop schedules, fermentation temperatures, and yeasts. I have  
more fun with this beer than any other.

Subject: BAA

Yesterday I heard a third-hand report of some difficulties they're having at Beer Across America. (For those of you who are not familiar with BAA, it is a mail-order service you can "subscribe" to, in which every so often (once a month?) they send you a six-pack of a beer from some microbrewery (a different one each time) and a bill for something like \$12.95 including shipping. While this may seem a bit expensive for a six-pack of beer, it's worth it to many subscribers if most of the beers are not available in their areas.)

The problem they're having is, you might say, one of being too successful for their own good. They've had so many respondents subscribe to the service that the amount of beer they have to ship out each round has gotten quite huge. So huge that many smaller brewers, the ones they had most hoped to give visibility to through the service, are unable to produce a full shipment of beer for the BAA. So the BAA sends out mostly beers from the relatively larger microbreweries.

Although I am not currently a BAA subscriber, I like the idea and would like to see it succeed. Perhaps they could develop a system where they don't send the same beer to every subscriber every month.

Offline, Spencer pointed out that I goofed. I guess I was rushing and  
got  
cocky and sloppy. Sucrose is, in fact, a di-saccharide (it is a glucose  
and a fructose bonded together). What I should have simply said was:

>Noonan's claim that if yeast is given a high-glucose environment, they  
>shut down their maltose metabolism pathways in lieu of (as Micah said)  
>the "easy sugars," glucose and fructose.

As I mentioned before, Bob Jones and Micah have, empirically, proven that  
this may not be a big a deal as Noonan suggests.

Sorry for the goofup.  
Al.

From: hinkens@macc.wisc.edu

Subject: Re: Insulating my boiling pot?

My brew-friends and I brew 15 gallon batches of beer in an old stainless steel half-barrel with the top cut off. We have a Cajun Cooker, but as you have probably read in the digest, it can consume a lot of propane during a 90 minute boil!

We discovered that if we simply wrap a sheet of heavy duty aluminum foil around the brewpot, we capture a lot more heat from the flame. We do not wrap it tightly. We use a piece of foil long enough to make it all the way around the pot with about a foot extra. We crunch the ends together (to make a seam from top to bottom) and make it just tight enough to stay put. We place it low enough to extend below the bottom of the pot.

I think this works so well because it creates a "chimney-effect" which draws the hot air up the side of the vessel (between the foil and the keg).

It works very well, we can really turn down the heat and maintain a very rapid boil.

A method such as this could be adapted for stove top boils as well...

-Jay

Date: 15 Oct 1992 20:34:02 -0400 (EDT)  
From: KLIGERMAN@herlvx.rtpnc.epa.gov  
Subject: calcium chloride

In regard to the posting on the use of calcium chloride, I fail to see its value in brewing since it would add twice as much chloride for each ion of calcium added. Since it is used as a dehydrating and dehumidifying agent, it would be hard to get an accurate weight unless it was completely dry. If I remember my basic chemistry correctly, if the molecular weight of  $\text{CaCl}_2$  is 111, then for every 111 mg/liter of  $\text{CaCl}_2$  added to 1 liter of water (assuming complete solubility), you would obtain 40 ppm  $\text{Ca}^{++}$  and 71 ppm  $\text{Cl}^-$ . It seems like adding  $\text{CaCO}_3$  would be a better choice. From Zymurgy vol.14 #5 p.30; one gram/gallon of  $\text{CaCO}_3$  would give you 107 ppm  $\text{Ca}^{++}$  and 159 ppm  $\text{CO}_3^{--}$  if completely dissolved. If I am wrong in my assumptions, please correct me.

>Jack, I couldn't resist this one. I, and most other homebrewers,  
while appreciating the appearance of our beers, even more appreciate  
the taste, with which (i hope) we have no trouble.

Normally, I wouldn't bother responding to a rhetorical joke but this one  
is  
as devoid of humor as it is devoid of facts so I will use it as an  
opportunity to give a little sermon.

It is the ribbon mongers and identity insecure that are hung up on  
appearance. When did I ever write word one about the color of my beer?  
In  
fact, it was all the certified experts that refused to accept my Generic  
Ale  
as a style and it drives them wild to this day.

People whine incessantly here about the clarity or lack of in their beer  
but  
if I suggest that my first lager seems clearer than my past ales, I get  
a  
lecture relating to some previous discussion about "clean" beer.

Now, you tell me that I am hung up on appearance.

>Perhaps if you brewed something other than the WGB or ARF the taste  
would  
be more to your liking and you wouldn't have to rely on appearances,  
after  
all they can be deceiving.

How can you possibly suggest that I would make beer that I do not like?

Finally, appreciating the subtle taste differences in beers is hardly  
in the  
same category as recognizing optical transparency. That fact that I am  
not  
capable of detecting many of the flavors or have a poor taste memory, is  
not  
to say that I therefore brew for clarity. I would drink water if that  
were  
the case.

On the other hand, I suspect the reason so much is made of the color of  
different styles is precisely because it is so much easier to learn to  
judge

and most of the instant experts created by the judging program probably  
are  
capable of not much more. I suspect it takes years if not decades to  
train  
the taster and most of the people who claim to be experts are just  
insecure  
windbags.

From: cook@uars.DNET.NASA.GOV (Chris Cook, NMOS Quality Engineer - (301) 386-7807)  
Subject: Small Batches

I've got a problem with my beer brewing, and I think it's a problem many of you will have seen, too.

I've been brewing extract batches for years. You're all familiar with the standard, 5-gallon a batch brewing schedule I've been following. I've recently taken up all-grain; that's been fun too, and after 5 batches, I'm even more interested in the possibilities.

Here's the rub. Recently we've all heard about the Belgian malts, with names like Caravienne, Special B, Biscuit and such. Sound interesting to you? It does to me. I want them, and I want them badly. I want to try a batch with 5# pilsner and 4# Caravienne, just to see, or add significant amounts of Aromatic malt to a batch and breath deeply over it, or try the wheat malt with a little Munich, or maybe I should start with the Pale as the base instead of the Pilsner. Or, or, or.

Lots of possibilities. Way too many. My problem's simple economics: I can't afford to become an alcoholic. Sorry, but it's just not in my budget.

These 5-gallon batches are fine for beers that I know I like, but they're way too much for simple experimentation. I already brew too much beer that's technically good but uninteresting to me personally. To cut the risks of too much bad beer I've depended on lots of recipes. I have to thank people for the loan of their expertise, but I want to find some of this stuff out for myself. I want to try a batch with a little of that neat stuff, a little more and finally with lots, but I don't want to take 3 years to get rid of the stuff if I was wrong.

How have other people had this problem? Seems like everyone would. I know that after years I've found recipes I like, but I don't want to spend several more years just scratching the surface of these new malts. Patience, I seem to keep saying, is not my long suit.

My first thought was to share like crazy. Too expensive, although very popular. Then I thought about charging my costs (pretty low) but the thought of that much brewing gives me hives.

The option that appeals to me more is to start brewing a lot of experimental, 1-gallon batches. Has anyone else worked this way? I'm running blind here, and if anyone's worked out some of the pitfalls, I'd love to hear them. Do you just scale all the ingredients by 5? Doesn't seem like it'd be that easy, but maybe. Yeast pitching rates? I figure to divide a Wyeast package (using my standard starter) into 5 or more; any complications or precautions are welcome. Any obvious changes in technique? That seems relative unchanged, but who knows. As an aside, does anyone know a source for gallon glass bottles? (Near Washington, DC)

Mashing gets simpler, I guess, but all my stuff assumes at least 5 pounds of grain. I expect the 44 quart cooler/lauter tun will

get cumbersome quickly, for example. Jack, you're Easymash may be the best bet.

The big question is simple. Am I trading away quality by working in such small batches? Opinions are always welcome, and experience even more so. Dive on in.

As an aside, does anyone have a source for the Belgian malts on the right coast? Near DC, preferably, but the eastern seaboard is close enough. I'm trying to save shipping, and since they to come in this way anyway, there should be someone east of Chicago with the stuff.

I've gone on too long. Talk at you later.

\*\*\*\*\*

-----

Date: Fri, 16 Oct 1992 08:34 EDT  
From: HULTINP@QUCDN.QueensU.CA  
Subject: Yarrow

In HBD #990 (which I missed) and again in #991 there is talk of the use of yarrow (or milfoil) as a bittering agent in "pre-hops" brews.

In H.S. Corran "A History of Brewing", David & Charles Inc., North Pomfret Vt., 1975 (ISBN 0 7153 6735 8) we find:

" Before hopped beer became customary in Germany, a mixture of herbs including bog myrtle, rosemary, and yarrow, among others, was employed; this mixture was known as gruit... There is no doubt that similar herbs were used in England, France and the Low Countries also."

There is no data supplied on how much gruit was used or how much yarrow etc was in the gruit.

As for the question of "pre-hops" this term can mean quite a long time ago in some parts of the world. England got hops relatively late, and there is a lot of data on 16th century recipes for unhopped ale. However, the continent was mostly switched on to hops by the beginning of the 16th century, and if you want "authentic" products, finding the recipes for continental styles will be tough.

BTW unhopped ale brewed according to an English recipe from the late 16th century without any bittering agent actually is pretty good, in a different sort of way!

In today's digest, #992, Jack S. Says:

> How can you possibly suggest that I would make beer that I do not  
like?

I wish I could attain that type of consistent perfection! I know I've had batches that either not what I had intended for the final product or for some reason I just wasn't wild about. I have a hard time believing that every brew someone makes the brewer loves \*unless\* the brewer is not trying new styles or only uses recipes that he/she has tasted from other brewers.

Yes, \$12.95 does sound high for a six-pack of most beer. The good  
news is  
that BAA sends \*two\* six-packs, one each from two different breweries  
each  
month for \$13.50, plus shipping, I believe. Their number, for those  
interested,  
is: 1-800-854-BEER.

RE: HBD #992

Rob Bradley says about Genesee Cream Ale:

> I have since learned that it's main claim to fame is its price.

Back in college, before I developed better taste, we had a saying that  
wnd like  
this:

"When your wallet says NO, Genesee says GO."

Some thoughts about maple flavoring in beer:

A few people have commented on using maple syrup in their recipies and  
have  
felt that the resulting brews did not have much maple character. Dan  
Vachon  
(dvac@druwa.att.com@hplb.hpl.hp.com) says that next time he will try to  
add the  
syrup at the end of the boil. I don't think this will work any better  
because  
I don't beleive the maple character is lost in the boil. This is because  
maple  
syrup itself is made by boiling down maple tree sap. This leads me to  
beleive  
that the maple flavor is either lost as its constituents are used up in  
the  
ferment, or is scrubbed out by the ferment's co2 production. So my  
suggestion  
is to add maple syrup at bottling time instead of the normal priming  
sugar.  
Comments?

> virtually flavorless beverage reminiscent of Miller Lite.

I have to disagree with Jon's invective against the American Wheat style. While not as radically different from a pale as as as stout, or even a Bavarian Wheat, American Wheat beers can be different from Miller and even be extremely tasty.

A well-made American Wheat should have a low hopping rate (as does the Bavarian style), but that does not preclude having any hop character at all. Even we hop-heads have to come down every once and a while. The main characteristic of an American Wheat should be a sharp fruitiness from the wheat malt that doesn't exist in an all-barley pale ale.

I do agree, though, that Anchor and Red Hook do not exemplify the style very well. Try a Schell Wheat beer, or if you're in Ft. Collins, Colorado look for O'Dell's Heartland Wheat (seasonal), or come by my place and try a blue-ribbon winning Fat Wanda's American Wheat.

From: brians <brians\_a\_neripo\_lbrians+r%NERI@mcimail.com>  
Subject: Homebrew Digest #992 (October 16, 1992)

MHS: Source date is: 16-Oct-92 11:42 EDT

I'm putting together my Xmas beer. NOrmally, I make 5gal and use a full mash + extract to get gravity up. Since I have 50# of malt sitting around, I'd just as soon not buy extract if I don't have to. My thought is to scale down to 3 gal and use ~9# grain in the mash, using only first runnings. I'd like to get a 1.060-1.070 gravity if possible. My calculations show this is possible; anybody else have a prediction for using just first runnings? If the 1st runnings seem low, could I just sparge a couple gallons and boil for 2-3 hours to get the volume & gravity where I want it? Are there risks to a long boil apart from caramelization?

=====

In HBD 992, Chris Cook wonders:

>The option that appeals to me more is to start brewing a lot of experimental, >1-gallon batches. Has anyone else worked this way? I'm running blind here, >and if anyone's worked out some of the pitfalls, I'd love to hear them. Do >you just scale all the ingredients by 5?

My experience has been that scaling is fine with extract+steep grains, but if you are doing all grain, you'll have more trouble. I tried once to step down a Weizen recipe from 5 to 3 gal, and got horrifying yield; the grain bed behaves very differently for me when the amount of grain is <4# or so (I use the popular yet oft-vilified Zapap(c) bucket in a bucket system). My entirely unscientific explanation for this is the "one for the pot" theory: when you make tea you are supposed to put in a certain amount of tea for each cup, and "one for the pot". I find if you don't do this, a 5 cup pot of tea might be fine with only 5 measures, but a 2 cup pot is too weak without that third. A similar effect may be at work with my mash. Lameness may also be at work.

>I figure to divide a Wyeast package (using >my standard starter) into 5 or more;

You're welcome to, but that sounds perilous to me; maybe making up a good 2 pints of starter would make this possible, though making sure each batch gets a

decent dose of yeast might require 5 small starters.

My one comment is that you might be better off doing 2.5 - 3 gal batches.

It

isn't as cost effective but the difference in scale isn't quite so dramatic.

Remember, when you make a 1 gal batch you'll leave plenty behind with the yeast

slurry, etc., bottling maybe only .75 gal. Do you trust an

"experimental"

batch that yields so little? Finding 3 gal carboys shouldn't be too tough.

Good luck!

From: Darryl Richman <darrylri@microsoft.com>  
Subject: Revisionist history: AWA

Today's (yesterday) post by Jon Binkley speculates on the history of American Wheat Ales. Jon's point, if I may be so bold to summarize, is that these are the bland variety of wheat beers that have little to distinguish them from industrial beer.

In fact, I disagree with this estimation; run a tasting with AWAs and industrial beer side by side and you will see, true to their micro heritage, that AWAs have substantially more body than Miller Lite, or Miller Genuine Draft for that matter, and more flavor and character as well.

As to their origin, I believe that Anchor Wheat is the originator of the style. Fritz Maytag has been quoted several times as saying that the design of the beer was purposeful. Maytag was well aware of the German Weizens, their unique character, and how it is brought about, and had access to the yeast strains required. But he wanted to produce a quality product for his market, which at the time was California, and which is very hot and dry in the summer (SF excluded, of course ;-). This required, he has indicated, a beer that was more in the vein of a lawnmower beer.

AWAs are definitely the training wheels beers for many micros' line ups, along with other bland styles like Cream Ale and sometimes the pale lagers. Jon is absolutely correct to point out that there is plenty of other micro beer available to enjoy, and even the occasional micro that does attain the interesting character of a Weizen.

But to denigrate a brewery for attempting find competitive niches is counterproductive. After all, it's not as if Anchor or Red Hook stopped producing some of their other, more distinctive products in order to make room for these. Such an attitude can also smack of snobbishness, which can turn off a lot people who might otherwise be interested enough to try "different" styles of beer.

From: iepubj!korz@ihlpa.att.com  
Subject: Re: dryhop VS end-of-boil/dead yeast?/Small batches

Chris McDermott asks:

>What will give a beer more hop aromatics, hopping at the end of the  
boil, or  
>dry-hopping with an equal amount? Say hopping at the end of the boil  
means  
>steeping the hops for a few minutes after turning off the gas.

Without a doubt dryhopping. I suggest dryhopping after all the  
fermentation  
is over (so the escaping CO2 does not scrub out the aromatics) for 7 to  
10  
days. Once the fermentation is complete, there is generally little sugar  
left for nasties and the acidity and alcohol will kill most that would  
dare to live on the hops. I like whole hops over pellets because they  
float and then you rack (siphon) out from under them. Pellets float for  
a while and then sink, making racking a problem.

Roy Styan writes:

>Subject: I think I killed my yeast.  
>  
>I am currently brewing a batch of cream ale. It went through an 8 day  
>primary fermentation at 15C. I racked to secondary and let it sit for  
>a couple of days to let the yeast build up before lagering. I seems it  
>still had a lot of fermenting to do, as it built up a strong (for a  
secondary)  
>ferment. Dispite all warnings from just about every source imaginable,  
>I just chucked the carboy into the fridge and let it cool down to about  
>1 deg. C. The yeast were not happy. I think I killed them. There were  
>no signs of life in there. I raised the temp. to 4 deg. C. Still no  
sign of  
>life. That was over a week ago.  
>  
>What do you guys think? Should I repitch? Raise the temp. back up to  
15C and  
>try again? Ignore the probLem?

What's the gravity? If it is 25 to 35% of the original gravity (you can  
estimate the OG if you didn't measure it -- send me private email if you  
don't know how), then I'd say don't worry. If there is more gravity  
left,  
I'd say you did kill the yeast. In this case, I suggest bringing it back  
up to 15C and pitching more yeast. Note that if you did not aerate your  
wort well, you may end up with a high final gravity anyway, but 8 days  
at 15C sounds reasonable. Whatever you do, don't re-aerate. I suspect  
that it should be all fermented out.

Chris Cook asks about how to try a lot of recipes without becoming an  
alcoholic:

[stuff deleted]

>My first thought was to share like crazy. Too expensive,  
>although very popular.

There. You've answered your own question, but you don't know it yet.  
Join a club, or start one if there's none around. Keep good records

and urge your fellow club members to do so also. Between 20 brewer's you can try 80 different recipes per month and you only need to bring eight bottles of your beer to a meeting. Look at the recipes in the back of Zymurgy or in books. They don't really vary that much, do they. Keep your experiments within the general boundaries of normal recipes and you won't make undrinkable beer (i.e. don't try adding 5 pounds of roasted barley or 7 ounces of Nugget to a 5 gallon batch).

>

>The option that appeals to me more is to start brewing a lot of >experimental, 1-gallon batches. Has anyone else worked this way? >I'm running blind here, and if anyone's worked out some of the >pitfalls, I'd love to hear them. Do you just scale all the >ingredients by 5?

Yes and no. I have not tried this, but Jay Hersh has written in this forum that hops don't scale linearly. Jay-- if you could shed some light on this, please do.

>Doesn't seem like it'd be that easy, but >maybe. Yeast pitching rates? I figure to divide a Wyeast >package (using my standard starter) into 5 or more; any >complications or precautions are welcome.

Splitting your starter sounds like a good plan.

>Any obvious changes in >technique? That seems relative unchanged, but who knows.

I suggest changing only one thing at a time. Keep the hops and yeast the same and change the malt, etc.

>As an >aside, does anyone know a source for gallon glass bottles? (Near >Washington, DC)

Check with glass recycling centers. I got my gallon jugs with Ocean Spray Cranberry Juice in them at the grocery store. Perhaps you could ask your neighbors to help you out buying juice by the gallon? Perhaps a restaurant nearby buys juices by the gallon?

>Mashing gets simpler, I guess, but all my stuff assumes at least >5 pounds of grain. I expect the 44 quart cooler/lauter tun will >get cumbersome quickly, for example. Jack, you're Easymash may >be the best bet.

I disagree. With very little grain in the bottom of the pot, your grain bed would still be very shallow. This would also accentuate the poor extract efficiency of the Easymash system -- its biggest design flaw is that the runoff is drawn from a very limited area of the grain bed. I suggest, the "Al Korzonas LITTLE MASH System(tm)" -- a coffee can with a bunch of holes in the bottom and a grain bag in it. No muss, no fuss, no shipping, no handling, no sales tax, no stamps please. (Actually, it's not my idea -- either Papazian or Miller say this is what one of the industrial brewer's did to measure extraction efficiency through a deep grain bed -- they used a lot more than one coffee can -- wasn't it 7?!)

Al.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: apparent attenuation

So what's the big deal with apparent attenuation, and how can Wyeast be so sure in predicting it?

Let OG = original gravity (without decimal, e.g. 1046 instead of 1.046)

FG = final gravity

Then AE = apparent attenuation  
is computed by means of the equation

$$AE = \frac{OG - FG}{OG - 1000} \times 100 \%$$

My latest, Stewart Namor Pale Ale, (conscious typo: SNPA, see?) yields

$$AE = \frac{1048 - 1012}{1048 - 1000} \times 100\% = 75\%$$

I used Wyeast 1056 (apparently not Sierra Nevada yeast after all)-: which, according to Wyeast literature, has "apparent attenuation 73-77%".  
Right on the money, Wyeast!

So how can they be so sure? Don't I have a lot of control over my final gravity through mash time and temperature? Is the Wyeast figure based on the assumption of either extract or a fairly standard mash, or is the figure 73-77% largely independent of mash schedule?

Last season I brewed 6 ales with OGs in the 1045-1057 range, all mashed in a relatively hot, short infusion mash, all fermented with either Edme or Munton & Fison dried yeasts. For all batches, AE was in the range 60-65% with an average of 63%. Have other dried yeast users gotten similar numbers?

Using Wyeast 1056 in my SNPA (a recipe similar to last season's ales) has knocked about 6 points off the final gravity. I kind of miss the extra body, and the unexpected FG has thrown my hop/malt balance off.

A final question: A fact sheet I have describing 1007, 1028, 1056, 1098 [German, London, American and British] all list AE range as 73-75 or 73-77. Then we have 1084 [Irish] at 71-75% and 1338 [European] at 67-71%. Is there some particular polysaccharide which the first four can eat but the last two cannot? And a further one which European can't eat but the others can? Or is it more complicated than all this?

I know I'm stealing somebody else's line here, but inquiring minds want to know.

A resident of Stewart Manor, NY,

Rob (bradley@adx.adelphi.edu)

Date: Sat, 17 Oct 1992 15:45 EDT  
From: HULTINP@QUCDN.QueensU.CA  
Subject: Glo:gg Recipe

There was a request for a recipe for Glo:gg from scratch. This is the recipe my family has used every Christmas for the last 20 years or so. It comes from Brown, D. "Foods of the World: The Cooking of Scandinavia", Time-Life Books, New York, 1968.

"PROFESSOR'S GLO:GG"  
20-25 Servings

Mix in 6-8 quart enamel pot: 2 qts dry red wine  
2 qts muscatel  
1 pt sweet vermouth  
2 Tbsp Angostura Bitters  
2 cups raisins  
1 orange peel (without white part)  
12 whole cardamoms, bruised in mortar/pestle  
10 whole cloves  
1 piece, ca 2" fresh ginger  
1 stick cinnamon

Let this stand, tightly covered, at room temperature at least 12 hours.

Shortly before serving, add 12 oz aquavit  
1.5 cups sugar

Mix well, heat rapidly to full boil on high heat. Remove from heat as soon

as it boils. Add 2 c whole blanched peeled almonds

Serve it immediately, hot, in small cups.

The drink is quite chunky, and we usually put a small spoon in each cup to eat the raisins and almonds with. It goes to your head very sneakily and tastes really good so people tend to drink a lot of it! The aquavit is important, the caraway flavour is noticeable in the glo:gg so don't substitute vodka or any such stuff.

Have fun with it. Phil Hultin.

Subject: Malt Liquor

Howdy all,

With the talk of malt liquor, and a definition of style, I believe it most appropriate to turn to Micheal Jackson for the answer. In perusing my copy of The New World Guide To Beer which I picked up at the GABF, Malt Liquor is defined as follows:

Malt Liquor - American term for a strong lager. American versions are usually cheaply made, sometimes with a high proportion of sugar. Not very malty, and not liquor. Often consumed for a quick "high". Serve at 7C (45 F).

Well, I believe that about says it all, although I disagree with Mr. Jackson on the serving temperature. If I remember my early college days I always found malt liquor best served as close to freezing as possible ;^)

Subject: efficient wort chilling

For rapid and efficient wort chilling: I use an immersion-type wort chiller and I live in drought-stricken Santa Cruz (no water, but 3 brew pubs! 8-). To ease the water usage of wort chilling, I have developed the following method (excuse me if this is obvious!). I siphon water from an intake bucket with ice in it, thru the wort chiller, into an outflow bucket. The ice water chills the wort rapidly, I use much less water than if using straight tap water, and I can easily control the flow rate by changing the height of the uptake bucket.

The details: I can chill 2.5-3 gallons of wort (I'm still doing extracts!) in 10-15 minutes! I usually dump the first gallon of outflow water down the drain and replace the water in the intake bucket with cool tap water. However, being quite water conscious, I recycle the rest of the water from the outflow bucket by dumping it into the intake bucket. The ice in the intake bucket chills it once it's dumped in. To be even more water-efficient, I start the intake with the water I've used for sanitizing. The ice comes from my freezer.

This method may seem like a bit more work (I need to refill the intake 1-3 times during chilling and I empty the outflow a couple of times), but it sure does save water. It also chills the wort VERY rapidly. The water running through the chiller is 32F and it doesn't require as much equipment as the 'double-chiller' method I've seen described. Also, the temp of your tap water is no longer an issue. Just prepare ahead and freeze some ice!

By the way, you can start the siphon by holding the intake end over a faucet, sealing it with your hand and using the water pressure to fill the system. Don't try sucking! If you can suck through 30-40 feet of tubing, then you've got some lungs! I got a sprained diaphragm when I tried :-)

Subject: Pilot batch, unhopped

Just before the Yarrow thread began, I got a notion I'd like to brew some unhopped ale. I made a half-gallon pilot batch yesterday while brewing up a regular (5 gallon) batch of porter. My experience may illuminate Chris Cook's question in HBD992 about brewing 5 x 1 gal batches and the responses by Brian Schuth and Al Korz.

With 8-10 lb. of grist, UK malt and a hanging bag sparger I get a pretty consistent 30-33 pt/lb. I mashed 1 lb. Munton & Fison pale ale malt and sparged in a large strainer (arranging the grains to follow the shape of the strainer -- a flattened hemisphere -- with uniform thickness) with the usual amounts of mash and sparge water scaled down to 1 pound. The result was 1/2 gallon at 1048, a miserable 24 pt/lb :-)

In a few weeks I'll let the list know how this unhopped ale tastes. Is the lack of hops likely to affect the fermentation in any way?

Cheers,

Rob (bradley@adx.adelphi.edu)

Subject: Reynolds Tapper - info?

hey folks.

This past weekend I acquired a 2 1/2 gallon mini-keg called a "Reynolds Tapper." It has a built-in tap (labeled "Falstaff" which I assume is some cheap Yankee beer :) and is barrel-shaped, meant to lie on its side, cask-style. It is filled from one end, and the sealing cap has some funky valves and a gas cylinder in it. It looks like the idea is, you fill this with beer, stopper it, and charge the cylinder with enough CO2 to dispense the brew. Neato.

So, the question: does anyone know where to get specs, info, replacement parts etc. for this thing? Are they still in use north of Mason-Dixon somewhere? Can anyone tell me what sort of tools/fittings are necessary to open and close the stopper, and fill the cylinder? The valves are truly weird looking and the HUGE snapping holding on the stopper is a real pain.

This little keg would be great to keep in the fridge with half-a-batch of HB, or to take to parties sans CO2 setup, if I could just get it refurbished.

Subject: 8-to-10 gallon boiling kettle ...

I have now made three all-grain batches and it has become clear to me that a larger kettle would be helpful. I currently have a 5 gallon kettle and find myself having to evaporate the wort down to add more of the runoff. Does anyone have any recommendations on a place which sells 8 to 10 gallon kettles at a reasonable price. I do have one restriction ... my stove has a flat heating element and the bottom of the kettle needs to be flat to contact the heating element. I was able to find a 33 quart kettle, but it had a concave bottom and would not contact my heating element. I would like to get past this problem and try out several recipes in mind. Any suggestions would be greatly appreciated.

Thank you!

Subject: Priming with molasses

Hi-

I'd like to prime with molasses. Papazian suggests 1 cup/5 gallon batch. Unfortunately, he doesn't specify the type of molasses. As many of you have guessed, the beer is Yorkshire's Old Peculiar and the list of fermentables includes 2#s dark brown sugar.

I have 12oz. of Brer Rabbit dark 'full flavor' molasses I'd like to use. The question is, how much?

Douglas Behm asks:

> What happened in the fight for control of this company ? When I read  
the post  
> that control had changed so did the taste of the beer. I must be highly  
> susceptible to suggestion or did the beer change ?

I tried all last week to contact Lee Nicholson, co-founder and original Brewmaster at Birmingham Brewing, but was unable to reach him. I called the brewery and talked to John Zanteson, who is the current brewmaster. Lee had hired John, who came from Mendocino in Hopland, when he was still with the brewery. Anyway, John said that Lee had been in arbitration hearings all last week over his status with the brewery and his lawyer partner. No decision has been returned by the arbitrator yet. Lee may be reinstated in the end but I think that John is more than capable of brewing a quality beer, as long as the lawyer will let him.

As for the taste changing, I'm not sure. The Red Mountain Red Ale was first brewed for the City Stages festival in Birmingham. Lee said that they tweaked the recipe for that brew after the first run but I don't think it has been changed since. The Gold Ale and Golden Lager were both shipped on the first brewing run, one of Lee's major complaints against his partner. Lee felt that they should brew a test batch of each before putting it into the mass market in order to fine-tune them and get them right. The lawyer won out and the gold lager we got briefly here in Huntsville (on draught) was cloudy. They may have been fine-tuning these brews in the field so to speak. We just got the Red Mountain Red in bottles here last week and it tastes quite good. It is still better on tap at Dugan's in Birmingham but I'm glad to have the bottled version in town. I don't think they've shipped the Gold Ale or Golden Lager up here in bottles yet. They also brewed a wheat beer but they only brewed a single run and it is almost gone according to John. They have not yet decided whether to brew it again. I also asked about the possibility of them brewing a Christmas beer but John said that the packaging costs for a special brew were prohibitive at this time. He said they plan to "do some

specialty brews" starting in the spring. I'll post more after I talk to Lee.

Carl J. Appellof replied

>I wouldn't do it. Pressure cookers come with instructions that tell  
>you never to cook stuff that will foam up a lot. The foam can block  
>the pressure valve and cause a big boom if things get overheated. As  
>we all know, the initial stage of boiling wort is about the foamiest  
>thing known to mankind. If you think stories of exploding carboys are  
>bad, just wait until that aluminum grenade goes off on your stove.

In practice, however, it doesn't happen. I know a few people who use  
pressure cookers all the time without any problems. The biggest hazard  
is getting a hop seed stuck in the valve (they fit quite nicely) which  
results in the safety valve blowing (and the ceiling of your brewery gets  
re-decorated). Construct a gauze filter around the pressure valve inside  
the lid to prevent that happening (Another use for that window screen  
stuff  
you have over there?).

With pressure cooking, boiling time can be reduced (15 mins at 10lb might  
be enough for some beers).  
However, you don't get as much reduction in volume so you cannot sparge  
as long and then rely on the boil to get the volume back down. Sparge  
efficiency is therefore more important, but that might not be a bad thing.  
Also you don't get as much DMS boiled off, so it might be best if you  
stick to normal kettles for beers where DMS is a problem. Otherwise, try  
it and let us know how you get on. Meanwhile I shall relax ...

Geoff

From: Michael Howe <howe@gp\_sparc45.gwl.com>  
Subject: Oops! -Lager yeast goof..

Hello,

My roommate and I have a concern and thought this might be a legitimate forum to ask about it. We are relatively new to all grain brewing. Yesterday, we were happily brewing up our Christmas/Holiday offering. We were brewing a brownish ale with all of the obligatory holiday spicings (including nutmeg, cloves, cinnamon, etc). Everything was going fine until it was time to add the yeast. As I was about to pour it in, I noticed that it was lager yeast instead of ale yeast. Being the wild and crazy guys that we are (not to mention, the stores were closed and we couldn't get more yeast), we decided to go ahead and put it in anyway. Now the problem, as I see it, is that we should allow fermentation to take place in a cooler environment for the yeast to be able to do its thing (is this correct?). We do not have an environment to do so. Are we wasting our time allowing it to ferment at room temperature (about 68 F.) or not. Does anyone see any problems that are going to arise from this situation. If so, is there anything we can/should do at this point to save our beloved holiday beer.

Thank you very much in advance,

From: Jon Binkley <binkley@beagle.Colorado.EDU>  
Subject: Snobbery, Pretension, and American Wheats

Darryl Richman sez:

>But to denigrate a brewery for attempting find competitive niches is  
>counterproductive. After all, it's not as if Anchor or Red Hook  
>stopped producing some of their other, more distinctive products in  
>order to make room for these. Such an attitude can also smack of  
>snobbishness, which can turn off a lot people who might otherwise be  
>interested enough to try "different" styles of beer.

Well, I've never attempted to defend myself against charges of being  
a beer snob, and I'm not going to start now ;-)!

But what bothers me more than either snobbery or bland taste is  
unwarranted pretension. I consider Sam Smith's Oatmeal Stout  
a snob's beer. It's WAY overpriced, and I refuse to buy it  
for that reason, but it is definitely great beer and the snobbery  
is justified. At the other end of the spectrum is the bland  
mega-brewery products we all love to bash. Sure they're tasteless,  
but they're also cheap and rarely pretend to be anything they aren't;  
I tend to avoid them, but their existance doesn't bother me.

In between are the pretentious beers- little better in quality  
than the tasteless stuff, but priced like a snob beer- and this stuff  
bugs me. Into this category I lump Carona, most mass market  
Euro imports, most mass market Canadian beers, and, getting back  
to the subject, American Wheat Ale (of course there are a few  
exceptions to the rule, like Grant's and Schell's; the stereotype  
I'm bashing is exemplified by Anchor Wheat or Wheat Hook).  
Hey, if Anchor and Red Hook charged \$3.50 a six pack for their  
wheat beers I'd have no complaint, and would even buy some for  
lawn mowing purposes. Lowering their prices they'd also sell  
more to the masses, supporting the production of their good beers  
and introducing more people to their well made beers. Charging  
the same price as they do for Liberty Ale or Ballard Bitter is  
down right offensive, and reeks of UNWARRENTED snobbery to this  
accused and confessed beer snob.

From: GREG PYLE <S1400067@NICHEL.LAURENTIAN.CA>  
Subject: Stuck fermentation?

I have acquired 2 15 gallon carboys for brewing beer. I have used them for three batches now and I have had problems with each one. Each time I have brewed in them, I simply took a 5 gal recipe and multiplied all of the ingredients by 3. After the secondary fermentation, the specific gravity would be about 1.020. This would normally mean stuck fermentation. I can usually get the fermentation going again if I stir up the bottom vigorously.

I have been told that if you multiply a recipe by more than two, stuck fermentation is unavoidable because the centre of the carboy has a much higher temperature than the sides of the carboy thereby damaging active yeast.

Is there anyone who knows how to avoid these problems for brewing batches over 5 gallons?

Subject: Extract Astringency

I'm halfway through the starch conversion on a batch a Kolsch and have some time to kill so I flip open Miller's TCHoHB into the "MASH" section. Reading the steps for the 400th time I note that he mentions that mash out in a picknick cooler requires removing a portion of the mash and boiling it, then return to the mashtun to raise to mashout temps. This seems to me to be a sort of pseudo decoction mash, and got me wondering about the whole thing.

I use the stove pot - insulated box method for mashing and I've never done a decoction mash, always infusions. I assume that sparging above 168F is not good because of tannins creating astringency and other negative effects will result. My question for the decocters in the crowd is; why does boiling a portion of the grist not extract tannins during a decoction?

From: fingerle@NADC.NADC.NAVY.MIL (J. Fingerle)  
Subject: Beginner questions

Hello everyone, I hope you don't mind some questions from a beginner. Two weeks ago, I bought my equipment kit and brewed my first batch. I followed the instructions on the can of malt but almost everything I've been reading since I brewed tells me that I should not have followed them. The specifics:

I used the Munton and Fison Stout Kit (3#5ozs). It calls for 6 cups (2#3ozs) of spraymalt, which the clerk at the store said was unnecessary and recommended using 6 cups of the corn sugar supplied with my kit instead. I did this. First, what is "spraymalt?" Secondly, everything from Papizon to the NBS catalog recommends against the use of that much corn sugar. Is this correct and why?

Also, the instructions on the label said add the softened malt, the spraymalt, and 1 gallon of boiling water to the primary and stir. Again the same sources I've been reading almost universally recommend adding the malt to boiling water and then continuing the boiling on the stove for some amount of time. What's the difference? Is this necessary?

In any event, the beer seems OK so far. Bubbling through the lock began at about 48 hours, reached its peak activity at about 80 hours and stopped by the fifth day. After checking with the hydrometer, I bottled on the seventh day. I opened one last night (its been a week) and it was pretty good. I will, of course, continue to let this batch age.

Any suggestions anyone might have would be welcome. I'd like to stay with this one type of malt for several batches while "tweaking" the ingrediants and procedures. Thanks for your help.

So how do you get Wheat Hook to mow your lawn? Tres' cool!

Sluggish sales is not exactly the problem I saw at Red Hook when I visited in September. In fact, I got the distinct impression that they were selling all they could produce and could sell TWICE what they produce. The main reason that they steadfastly refuse to ship beer to the east coast is that they can't produce enough to satisfy the pacific northwest. Therefore, I have to settle for coming home from the occasional trip with *\*very heavy\** carry-on luggage 8-Q

So-ooo... Don't looking for big price reductions any time soon. Personally, I wish I lived in Seattle, so I could be ripped off with alarming regularity. I worry more about businesses like this lowering their quality than lowering their prices. There are plenty of \$3.50 six packs to be had out there, but not enough good beer.

My expert (sic) analysis of Wheat Hook?

A decent beer,... but a GREAT poster!

Rob ("Wheat Hook: It's where you find it") Winters

From: "Rick (R.) Cavasin" <cav@bnr.ca>  
Subject: re:decoction mashing

Glenn Anderson asks about astringency problems with decoction mashing. I mash in my lauter tun which is insulated (I use the two bucket approach with closed cell foam glued to the outer bucket), so that I can draw off some of the mash water which I then boil and return to the tun to increase the temperature. The amount of husks in the runoff is probably negligible, but one could recirculate the decoctions. After doing decoctions for a while, you get a feeling for how much of a temperature increase you can expect from a decoction of a particular size. (as a percentage of the total mash - I suppose coming up with a formula wouldn't be too difficult)

If you are doing a fairly straightforward infusion type mash, the number of decoctions needed is small. If you want to do an acid rest, protein rest, etc. etc., the number of decoctions needed can make the process a little tedious, especially if you are worrying about establishing a grain bed for each decoction (you break up the grain bed each time you stir in the boiled decoction). I've been told that you should confine each decoction to no more than 1/3 of the total mash water used to avoid depleting too much of the enzymes. If you are decocting for the mash out however, I don't think you need to worry about this.

Cheers, Rick C.

Subject: boil ALL the water?

I've been an extract brewer for a few yaers, and I have been reading all the homebrew books with an eye toward trying all-grain soon.

But, looking at the "beginners" section of Dave Miller's 'Brewing the World's Great Beers', I see that he recommends boiling all of the water that ends up in the fermenter. I have always added the extra few gallons of water straight from the tap to the fermenter.

The reason he gives for boiling is the presence of chlorine in tap water. Does this make sense? Would boiling the tap water increase the chlorine concentration, or does it really help?

Thanks in advance, Tom Dube

Lager yeast will ferment just fine at low or high temperatures. By  
fermenting  
at higher temperatures, you will get more esters and fusel alcohols,  
however.  
Every yeast behaves differently and some will go distintively banana on  
you  
at higher temperatures, others will get very phenolic, others will not be  
affected as much. I haven't used Wyeast #2112, so I don't know what it  
will  
do a room temperature, but you'll recall that the California Common style  
of beer is a beer brewed with lager yeast at ale temperatures... not  
quite  
up to 77F -- mid 60's would be much more to style.

Michael didn't mention which brand/strain of yeast they are using, but  
don't  
worry -- brew away -- since it's a X-mas brew and has a lot of spices, I  
doubt that the yeast will contribute a large percentage of the final  
flavor.  
This seems like a good point to repeat my "the yeast you use is the  
biggest  
factor in the final flavor of your beer" diatribe. Within reason, of  
course,

but changing from Fuggles to Goldings or adding 20% more chocolate malt will affect the flavor of your beer a lot less than changing from Wyeast #1028 to Wyeast #1056, let alone changing from dry to liquid yeast.

It's WAY overpriced, and I refuse to buy it >for that reason, but it is definitely great beer and the snobbery >is justified. At the other end of the spectrum is the bland

Around here, SS Oatmeal Stout is \$10.99/six. With tax, let's say \$2/bottle. Back in July, I paid \$3/12oz (I think) for keg Old Style at Wrigley field. Keg Budweiser was the same price. In downtown Chicago you can find places that sell Beck's for \$4/bottle.

Besides the lousy exchange rate with Britain and the cost of shipping, Samuel Smith's Tadcaster Brewery is a small operation, by comparison, and thus will have quite a bit more overhead than say Bass or Courage or Scottish and Newcastle etc. etc. Finally, I'll bet there's more malt in a single bottle of SS Oatmeal Stout than in a case of Bud.

Personally, I'll keep buying SS and Duvel and Young's and Timmerman's. (Heck, I rejoiced at seeing Timmerman's Gueuze for \$3.29/bottle and bought every bottle in the store!)

\*\*\*

GREG PYLE believes that he has a stuck ferment because his 15 gallon batch has stopped at 1.020:

[stuff deleted]

>I have been told that if you multiply a recipe by more than two, stuck >fermentation is unavoidable because the centre of the carboy has a much >higher >temperature than the sides of the carboy thereby damaging active yeast. >Is >there anyone who knows how to avoid these problems for brewing batches >over 5 >gallons?

I would need more information to tell if 1.020 really is stuck. For example, I brewed a Young's Special London Ale clone that started at 1.063 and finished at 1.022. Ok, so it was a bit high for YSLA, but the flavor was there - - I used Wyeast #1028. Thanks to John the HopDevil, I expect to soon be able to use \*REAL\* Young's yeast -- direct from the brewery in London!

Glenn Anderson asks:

>astringency and other negative effects will result. My question for >the decoctors in the crowd is; why does boiling a portion of the >grist not extract tannins during a decoction?

Darryl Richman finally cleared this up for me too. He recently posted that it's the pH! I interpret this as meaning that as long as the pH is

down in the vicinity of 5.2, extraction of tannins is much lower than if it's up high.

Hello-

While thumbing through the recent superior products sale catalog I noticed yards w/ stands for \$40.?? and w/o stands for ~120 for a case of six. They also have 1/2 yards and foots (feet?). It seemed like a pretty good deal to me.

Sorry I don't have the catalog here at work so I can't post the number. I gave the catalog to my fiancee and mentioned that a yard would make a really cool christmas present :-). I am pretty sure that someone on HBD must know the number, because this is where I got it from.

Subject: Re: molasses, lager yeast goof

David\_O'Neill.Wbst129@xerox.com asks about priming with molasses. First off, I don't think I'd do it at all. Most molasses has a pretty strong flavor, and it seems that with the amount needed for priming, the flavor would be overpowering.

That said, the type you use depends on how strong a molasses flavor you want. I'd go with the lightest unsulphured molasses I could find. You should probably avoid blackstrap :-).

that  
> it was lager yeast instead of ale yeast.

As the saying goes, "relax, don't worry...." Using lager yeast at room temps produces a "steam beer", as in Anchor Steam. You'll get a quite different flavor profile from the lager yeast due to different ester production, but it ought to work fine. In fact, I just bottled a batch of steam beer (a hoppier-than-usual amber ale fermented with WYeast Pilsen lager yeast). It tastes great. Also, the spices will help mask any off flavors or aromas, should any develop.

I did notice, however, that my steam beer was still cloudy and extremely hazy after two weeks of secondary fermentation. It was still dropping in gravity, but very slowly. I went ahead and bottled at 1.016, hoping I wasn't setting myself up for gushers.

Does lager yeast take longer to finish than ale yeast even at room temperatures? Barring infection (which I don't think happened), that's the only thing I can think of to explain the activity after so long.

```

I'm not that good at massaging data, maybe some of the rest of you are,  
but

I don't see a correlation with temperature. However, high-gravity and  
high-glucose seem to have some effect. There was a suggestion that there  
was a bad batch of yeast, but alas, no data on the date codes. I've been  
recording my Wyeast date codes, but don't have anyone else's.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: Wyeast Belgian

well, I made another batch using Wyeast Belgian ale yeast 2 weeks ago. pretty similar to the one I made this spring, but not quite as strong. Both were fermented 65-70F (varying with the weather), except that I let this latest batch get pretty hot during the first few days of fermentation, as I wrapped the carboy in a towel, which helps keep the heat of fermentation in.

Unlike the first batch, this latest batch does not have the obnoxious banana esters. One other difference between the two batches was that the latest batch had 2 lb raw cane sugar in it. Could the (relative lack of) simple sugars lead to the production of banana esters by the yeast? Were all those banana estery batches people experienced also all-malt brews? Did anybody use an appreciable amount of sugar in a batch fermented with yeast belgian, and notice excessive banana esters? If so, what kind of sugar was it?

looking for a few data points on this not-yet-examined variable,

"Yesterday, we were happily brewing up our Christmas/Holiday offering. We were brewing a brownish ale with all of the obligatory holiday spicings (including nutmeg, cloves, cinnamon, etc). Everything was going fine until it was time to add the yeast. As I was about to pour it in, I noticed that it was lager yeast instead of ale yeast. ... Now the problem, as I see it, is that we should allow fermentation to take place in a cooler environment for the yeast to be able to do its thing (is this correct?). We do not have an environment to do so. Are we wasting our time allowing it to ferment at room temperature (about 68 F.) or not."

Try it and see ... lager yeasts are known to ferment at higher temps than conventions dictate. It's the only thing you can do, now.

You can lower the temperature by putting it in a tub of ice, or placing it in a basement or cool place in the house, away from the sun, resting on the foundation of the house, perhaps even submerged in your bathtub, with ice added periodically.

Subject: Re: Wyeast #2112 California Lager Yeast

/-/ello:

A while back I used Wyeast #2112 on a batch of ale, because I didn't even realize it was a lager yeast at the time (obviously, I'm fairly new to this craft). The batch fermented at 65 F to 75 F and came out just fine. The batch, named "2112 Red Star" (no relation to Red Star yeast =^), had a complex character and received many compliments, though it was, unfortunately, underhopped. I may even try this again, though with more hops.

Just goes to show you: Necessity may be the mother of invention, but Ignorance sometimes makes a good father.

Cheers,

Subject: Revisionist history revisited

In HBD#993 Darryl Richman suggests that Anchor was the first US micro to produce a wheat beer.

I believe that the late, but not forgotten, Hibernia Brewing Co. (from Eau Clair ???, Wisconsin) was selling their Dunkel Weizen quite a while before Anchor's product ever hit the market. I recall it as being the first American brewed wheat beer that I ever saw.

As far as wheat beer and snobbery go, I land somewhere in the area of Jon Binkley. Most American wheat ales aren't worth the effort, \*especially\* given the price and the availability of German weizens.

There are a few exceptions, most notably Celis White from Austin. A group of Boston-area homebrewers just got back from the Dixie Cup; while there, we visited the Celis brewery and were given a most gracious welcome. Their White beer is a world-class witbier in every way, \*and\* it is priced well (local beer stores sold it at ~\$21/case or ~\$6/sixpack). It is a delicious, flavorful, quenching beverage, well-suited to the Texas climate. If you live in San Francisco or Boston, you will see it soon in your local market.

And if you'd like something to look forward to, Celis just produced a batch of Celis Grand Cru. (SG ~ 18.1 plato). It is happily fermenting in the primary even as I type. I look forward to trying a bottle or two when it is available (we were told that it should hit the shelves and taps around Dec. 1)

**Subject: Boiler Crud Removal? Thanks...**  
Full-Name: "John Cotterill"

I was looking at my SS boiling kettle yesterday and I noticed the inside bottom is coated with some hard white crud. I assume this is some form of calcium precipitated from boiling hard water. The other thing that I noticed are rings of dis-colored stainless steel running away from the bottom of the boiler up the sides of the boiler. I think this indicates something about the metal temperature during boiling. It occurred to me that maybe the white crud acts as an insulator and is changing the boiling characteristics of by boiler. Even if its not a real problem, I want to remove it. Does anyone know what works best for getting rid of the white stuff???

And thanks to all who responded on places to visit in Vancouver WA. I can't wait to get up there.

From: fjdobner@ihlpb.att.com  
Subject: Another Brewpub Beachhead

I have just seen an article that my father sent me from the South Bend Tribune.

Subject is Indiana now has its fourth brewery. It supposedly opened yesterday

and serves the Mishawaka, Indiana area. An interesting difference struck me from other openings of microbreweries of brewpubs: this one is in a rather small town (~20,000 people). Capacity of 1,500 barrels per year crafting four styles of beer: Founder's Classic Dry Stout, Mishawaka Gold Lager, South Shore Amber Ale, and Lake Effect Pale Ale. The menu features American favorites as well as typical English fare (shepherd's pie, fish and chips, Scotch eggs, and ham and leek pie).

Supposedly, one can even join the Anacreontic Society (named after a 1800's English men's health club). Anacreon was an ancient Greek writer of love poems and drinking songs. Meetings are held at the brewpub. The meetings begin by singing the song (Anacreon in Heaven) sung to melody we know in the US as The Star Spangled Banner." I may attend....

Although towns like Hopland (population of 700) have been able to support brewpubs on the left coast, the midwest has been a bit slower in coming around. BTW the brewpub is called Mishawaka Brewing Company.

Frank Dobner

PS: Anybody know anything more about it, please post it!

In #995 Tom Dube asks about Dave Miller's recommendation to boil all the water that gets into the fermentor and writes:

> The reason he gives for boiling is the presence of chlorine in tap water.  
> Does this make sense? Would boiling the tap water increase the chlorine concentration, or does it really help?

The purpose here is to get rid of the chlorine. In his previous book, "The Complete Handbook of Homebrewing," he recommends pre-boiling all water for 15 to 30 minutes to drive off the chlorine. IMHO, it is a function of your water supply. When I lived in Lexington, MA, the water was quite good and I could add it directly to the fermenter and the beers were fine for my untrained palate. When I moved to North Andover, MA, I could smell the chlorine in the water & the water dept. said the chlorine level was 0.7 ppm - swimming pools range from 1 - 2 ppm. I started boiling the water then; I did not try a batch without boiling the water.

I would call your water department. If you have Miller's previous book, he lists all the minerals & gunk to ask about. I found our water department very helpful.

> I have always added  
>the extra few gallons of water straight from the tap to the  
>fermenter.  
>  
>The reason [Dave] gives for boiling is the presence of chlorine in tap  
water.  
>Does this make sense? Would boiling the tap water increase the  
>chlorine concentration, or does it really help?

Boiling tap water will drive off dissolved chlorine gas, which is what  
most  
water utilities use to disinfect. It will increase chlorIDE  
concentration,  
which is generally not relevant to brewing because neither the original  
nor  
the final concentration is very large.

I suspect that this problem is what is making my beers unpleasant. All  
my  
brews have had the same underlying nasty taste, despite my changing of  
many  
variables (including going from dry to Wyeast). At a brewclub meeting,  
this taste was described as "medicine-y", and according to Dave's book,  
chlorine residue can cause this problem. One variable I have never  
changed  
is that I add my 2-gallon boil to 3 gallons of cold tap water. I intend  
to boil all my water for the next batch to see if that fixes the problem.

Interestingly, none of my meads have had this taste. This I do not  
understand. I would give a lot to make just ONE good batch of beer,  
to prove to my friends that homebrew is not intrinsically bad...though  
I like even my medicine brew better than Bud....

> recommends against the use of that much corn sugar. Is this correct  
> and why?

"spraymalt" is dried malt extract. It is sometimes more convenient than the canned stuff, especially since you can measure out arbitrary amounts.

Sugar is disrecommended because (1) it adds no body or flavor to the beer, just alcohol, and (2) it can contribute to the development of a "cidery" flavor. In any case, 6 cups of sugar will contribute significantly more alcohol than 6 cups of malt extract.

> Also, the instructions on the label said add the softened malt, the  
> spraymalt, and 1 gallon of boiling water to the primary and stir.  
> Again the same sources I've been reading almost universally recommend  
> adding the malt to boiling water and then continuing the boiling  
> on the stove for some amount of time. What's the difference? Is this  
> necessary?

You don't want the heat turned on while you are adding the extract to the water. If it is, you run a big risk of burning some of the extract, as it immediately falls to the bottom of the pot, and needs vigorous stirring to mix it into the water. If you are using a pre-hopped kit (as it seems you were), you really only need to get the ingredients hot enough to kill nasty micro-organisms. The sugar certainly needs no more boiling.

Boiling accomplishes two purposes: (1) it coagulates some proteins in the malt extract, and (2) it extracts bitterness from the hops. Purpose 2 has already been done in the manufacture of your kit, and to some extent so has purpose 1. You will get more crud (technically called "trub", pronounced "troob") if you boil it for a while. This is stuff that could otherwise end up making your beer a little cloudy, and could perhaps contribute some off-flavor notes in the long run.

On the other hand, if you are going to boil it, I would add more than 1 gallon of water. Otherwise you run a significant risk of caramelizing some of the sugars, darkening the wort and coarsening the flavor.

> bottled on the seventh day. I opened one last night (its been a week)  
> and it was pretty good. I will, of course, continue to let this batch  
> age.

This is the bottom line, of course. If you're happy with the end product, then you did fine. If, you want to continue to make better and better beer, then some of the points covered above may help you to do that.

We just recently made a Belgian Dubbel using this yeast, and 1lb. of  
Demarara Sugar from the Cellar, with absolutely no banana taste or smell.  
So maybe the sugar idea has some merit.  
Lots of phenolics though, true to style. Hard to distiguish it from a  
Chimay red. Get the Dubbel recipe from Rajotte Belgian Ale book!

From: joseph@joebloe.maple-shade.nj.us (Joseph Nathan Hall)  
Subject: Crystal vs. Caramel, divers

I'm still looking for an answer to my "Crystal vs. Caramel" question of a week or so ago. Again, George Fix implies that there is a difference between "crystal malt" and "caramel malt" in his Vienna book, but he doesn't tell us what that difference is. Since I have not seen this distinction made in any other book on brewing I've read, I'd like to know exactly what the difference he recognizes is.

\*\*

) From: dube@GROUCHO.CS.NYU.EDU (Tom Dube)  
) But, looking at the "beginners" section of Dave Miller's 'Brewing the World's Great Beers', I see that he recommends boiling all of the water that ends up in the fermenter. I have always added the extra few gallons of water straight from the tap to the fermenter.  
)  
) The reason he gives for boiling is the presence of chlorine in tap water.  
) Does this make sense? Would boiling the tap water increase the chlorine concentration, or does it really help?

Boiling tap water removes chlorine very quickly. Boiling is not necessary. Aeration will remove it. In fact, letting tap water stand in an open pot for a couple of days or so will do it. (I wouldn't recommend this, though!) Chlorine diffuses out of water fairly quickly at room temperature. (It's not a matter of how soluble chlorine is, it's the fact that there isn't any chlorine in the air.)

In general, chlorine in tap water will rarely be a problem. Some city water systems, however, have high chlorine levels and/or use chloramines (chlorine + ammonia) to protect water. The type of beer, water hardness, etc., all taken together determine whether you will have a chlorophenol problem in your beer.

My suggestion is that if your beer tastes like Listerine, try boiling your tap water. I don't think that chlorophenol problems tend to be subtle.

Sodium thiosulfate can be used to remove chlorine (and other halogens) from your tapwater, although I haven't heard this recommended for homebrewing. A carbon filter is also 100% effective, and may remove other impurities as well.

\*\*

) From: Robert Pulliam <pulliam@monty.rand.org>  
) [...] Also (and I know that this has probably been beaten to death) could someone let me know why no one uses Aluminum pots to brew with.

Many folks do. In fact I have heard many more people say that they brew successfully using aluminum than I have heard complain about

it. Maybe the people who had problems with aluminum are silent about it, I dunno. (Maybe they can't remember. :-)

The heavy restaurant-grade pots are at least OK for the production of beer. Wine (with a lower starting pH) I don't haven't tried and don't know about. Don't bother trying a cheap aluminum pot. Most "aluminum" is alloyed with one metal or another, and this apparently greatly affects its acid resistance. I would avoid "shiny" aluminum and go for either anodized (black-gray) or the dull silver finish found on other restaurant-grade aluminum pots.

The problem you may have with aluminum is a marked metallic taste, resulting from aluminum dissolved by the acid in your wort. Apparently different people have different sensory thresholds for this, so if you brew in aluminum and are unsure about your pot, take some of your brew to several other folks for tasting.

In many respects, aluminum is far superior to stainless steel for cooking. In particular, your wort will never stick (under normal conditions) to the bottom of a heavy aluminum pot, since aluminum is an excellent conductor of heat. You will also find that the hop resins, caramelized wort, etc., at the surface of the liquid (the "boiling ring") are much easier to scrub off, usually only requiring a plastic scrubber with a little water and detergent, since they are not burned on.

From: bszymcz%ulysses@relay.nswc.navy.mil (Bill Szymczak)  
Subject: Re: Aluminum Pots, White Spots on SS.

In HBD995 Robert Pulliam asks

> but extract will do just fine). Also (and I know that this has  
> probably been beaten to death) could someone let me know why no one  
> uses Aluminum pots to brew with.

My wife (who, being Italian, cooks a lot of tomato sauce, and also has a minor in chemical engineering) told me that boiling something acidic like tomatoes or wort can cause chemical reactions with the aluminum to occur. That is, the acid can eat into the aluminum, initially causing pitting, and if boiled long enough can actually compromise the structural integrity of the pot. Even worse, aluminum (carbonate?) or something like that can get into your wort->beer->stomach->bloodstream.

Also, in HBD995 John Cotterill asks:

>I was looking at my SS boiling kettle yesterday and I noticed the inside  
>bottom is coated with some hard white crud. ....  
>Even if its not a real problem, I want to remove it. Does anyone know  
what  
>works best for getting rid of the white stuff???

I had the same problem a few days ago. After trying to scrub them off with a bleach solution, B-Brite, and finally with a steel wool soap pad without any luck, I again consulted my wife. She told me to try boiling some white vinegar in the pot, and like magic it worked. It even removed the small specks of rust which I had on the bottom of my SS pot.

A few days ago in HBD993 Rob Bradley comments:

>Using Wyeast 1056 in my SNPA (a recipe similar to last season's ales)  
>has knocked about 6 points off the final gravity. I kind of miss the  
>extra body, and the unexpected FG has thrown my hop/malt balance off.

I had a similar, but perhaps more drastic experience with a batch of stout I bottled last Friday. I was using Papazian's Dark Sleep Stout recipe which calls for

6.6 lbs John Bull dark malt extract syrup (unhopped)  
1 lb dark DME  
1/2 lbs roasted barley  
1/2 lb black grain malt  
1/2 lb crystal malt  
2 oz bullion hops (boiling)

When I brewed this batch last year I used one package of dry Edme ale yeast and obtained

OG = 1.057  
FG = 1.028

This batch was very full bodied, relatively well balanced, and had a pleasant licorice flavor. For my new batch I used the same recipe but used yeast A1 from Dr. Schiller's Yeast Culture Kit, which I believe is the same as WYEAST 1056. For this batch the starting and final gravities were

OG = 1.053

FG = 1.014 !!!

Considering the amount of unfermentables in the recipe this final gravity must be near some theoretical limit.

The difference in starting gravities is due to the fact that this time I was fermenting a little more than 5 gallons (about 5 1/4 gal.)

While bottling, I tasted some of the new batch, which needless to say was quite a bit dryer (similar in dryness to Guinness), but was very clean tasting (not clear like Jack's lager). Other factors which may have influenced these results were:

1. The yeast for the new batch was pitched from a 1 liter starter, while the dry yeast used in last year's batch was simply sprinkled on top.
2. The new batch was fermented in glass carboys with primary fermentation lasting 3 days, and secondary another 8 days. The previous batch used single stage fermentation for 13 days in plastic.

**Subject: Boiler Precipitate Removal**  
Full-Name: "John Cotterill"

Thanks to all who responded to my questions about removing the white precipitate on the bottom of my boiler. The consensus is that the stuff is calcium carbonate. The following suggestions were given as a means of removal:

- 1) Vinegar
- 2) Lime-a-way plus detergent wash
- 3) Caustic Soda
- 4) Brillo pad plus elbow grease

Thanks again gang. I'll start with the vinegar.

Subject: Re: Beginner Questions

Jimmy writes:

>Hello everyone, I hope you don't mind some questions from  
>a beginner.

Not at all. We all started as beginners.

>Two weeks ago, I bought my equipment kit and brewed  
>my first batch. I followed the instructions on the can of malt  
>but almost everything I've been reading since I brewed tells me  
>that I should not have followed them. The specifics:  
>  
>I used the Munton and Fison Stout Kit (3#5ozs). It calls for  
>6 cups (2#3ozs) of spraymalt, which the clerk at the store  
>said was unnecessary and recommended using 6 cups of the corn sugar  
>supplied with my kit instead. I did this. First, what is  
>"spraymalt?" Secondly, everything from Papizon to the NBS catalog  
>recommends against the use of that much corn sugar. Is this correct  
>and why?

I offer that the clerk at your store gave you misinformation. This is unfortunate. One of the great advantages of buying from a store rather than mailorder is, that you've got a person who can advise, taste your beer, advise again, etc. It's too bad that the clerk at the store was not as well informed as they should have been.

Onward. Spraymalt is another name for Dried Malt Extract. It is basically the same as Extract Syrup except that \*all\* the water has been removed. About 20% of the weight of Malt Extract Syrup is water, so it only has 80% of the "strength" of dried malt extract, pound for pound.

You're right about the corn sugar. Virtually everyone (except the industrial brewers) agree that all-malt is best and that corn sugar should be left out of your beer recipes. Some, such as some Belgian beers and some English beers, call for non-malt sugars like Candi sugar and Demerara sugar, but generally, they are a small percentage of the fermentables. Why? Because corn sugar ferments out to a cidery (like apple cider, or even lemonade) flavor. I tasted a homebrewed "beer" in Canada last year that tasted like watered-down apple cider -- you guessed it -- more than 50% of the fermentables were from corn and table sugar!

>Also, the instructions on the label said add the softened malt, the  
>spraymalt, and 1 gallon of boiling water to the primary and stir.  
>Again the same sources I've been reading almost universally recommend  
>adding the malt to boiling water and then continuing the boiling  
>on the stove for some amount of time. What's the difference? Is this  
>necessary?

Munton & Fison (I have been told and have reason to believe based upon my use of M&F) malt extracts require a shorter boil than most malt extracts. Perhaps this is because M&F boils their wort longer before concentrating it into a syrup, but I've gotten very little hot (and cold) break from my M&F Syrup batches. If you are adding boiling hops, you still need a 60 minute boil if you want to get ~30% utilization of your hops.

The purposes of the boiling are:

1. to sanitize the wort (the water-extract-hop soup),
2. to isomerize (i.e. make soluble) hop oils from any hops you added to the boil,
3. to coagulate large proteins so they don't cause haze in your finished beer (this is called hot break), and
4. in the case of all-grain beers (beers primarily made from grains rather than from extract), to boil off excess water (i.e. after extracting all the goodies from the grains, you've got 7 gallons of wort, but you want to make a 5 gallon batch).

>In any event, the beer seems OK so far. Bubbling through the lock  
>began at about 48 hours, reached its peak activity at about 80 hours  
>and stopped by the fifth day. After checking with the hydrometer, I  
>bottled on the seventh day. I opened one last night (its been a week)  
>and it was pretty good. I will, of course, continue to let this batch  
>age.

You did not mention any priming sugar. Some recipes, and I don't know if M&F recommends this, suggest that you bottle when the gravity drops to a particular level and then relies on the remaining sugars to carbonate the beer. This is not the most reliable method of carbonation. I suggest that you let the beer ferment out completely (I wait till the airlock bubbles less than 1 bubble per 2 minutes, but that's probably excessive) , siphon the beer into a sanitized food-grade bucket, add priming sugar (boil 1/2 to 3/4 CUP of sugar in two cups of water), stir gently to mix and then bottle.

From: iepubj!korz@ihlpa.att.com  
Subject: Carmelization/clorine/DMS

Mark asks:  
>what is carmelization?

Chemically, I can't tell you, but empirically, it is the darkening (toasting) of sugars.

>how does it happen?

The heat you add to the mash kettle, decoction kettle or boil kettle causes it.

>what do you do not to get it?

Don't add too much heat and stir, stir, stir!

>do you ever want it? if so why?

Some styles of beer (Lambics, for example) rely on some caramelization for flavor -- it tastes like..., well..., caramel! An HBD poster a few years ago suggested using gravy browning to add caramel flavor and color. You can also get it from using darker Crystal malts (also called Caramel malts!). You can use it to your advantage (not in Pilsners :^) but it's a bit tricky. I suggest using Crystal malts -- they are much more repeatable.

and then later:  
>what is DMS? how is related to brewing?

DMS is dimethylsulfide. It smells like cooked sweet corn or (some say) cooked cabbage. In most styles of beer, it is undesirable even in small quantities and undesirable in all in larger quantities. It comes primarily from the malt itself and can come from bacterial infection. One reason for boiling that I forgot to mention in my earlier post is that boiling drives off DMS. DMS is created from it's precursor, which is inherently in the malt (some malts have more than others of this pre-cursor, S-methyl methionine) during kilning, mashing, boiling and cooling. However, most of it is boiled off during the boil or scrubbed out by CO2 during the ferment. From the time you turn off the heat in the boil, till you cool below 140F, more DMS is being created. The two things you can do to minimize the creation of DMS in your final product, is to maintain good sanitation and cool the wort from 212F down to below 140F as quickly as possible (with a wort chiller of some kind).

Also, Tom asks, why boil your tapwater:  
>The reason he [Miller] gives for boiling is the presence of chlorine in tap water. Does this make sense? Would boiling the tap water increase the chlorine concentration, or does it really help?

Chlorine is quite volatile and will boil off, so boiling decreases the concentration of Cl. Another reason to boil all your water is to kill any bacteria that may be in it. Another reason for doing a full boil is because a lower gravity boil will increase your hop utilization --

something you must compensate for when trying to duplicate a full-boil recipe while using a partial boil. I suggest everyone should have a copy of the Hops Special Issue of Zymurgy -- turned to Jackie Rager's article on hop utilization every time they formulate a recipe. I do.

>>I have been told that if you multiply a recipe by more than two, stuck  
>>fermentation is unavoidable because the centre of the carboy has a much  
higher  
>>temperature than the sides of the carboy thereby damaging active yeast.  
Is  
>>there anyone who knows how to avoid these problems for brewing batches  
over 5  
>>gallons?

I forgot to address what I wanted to address! I don't believe "the  
centre  
of the carboy has a much higher temperature than the sides of the carboy  
thereby damaging active yeast." A few degrees higher won't harm yeast,  
but  
I don't think there's even a several degree difference. Consider that  
the  
warmer wort would rise and draw cooler wort in from the bottom -- if  
indeed  
the centre is warmer than the sides, that's GOOD, I would say. In such a  
case, the center would indeed rise and draw cool wort from the bottom and  
thus sides, and therefore create convection currents -- this would rouse  
a flocculent yeast. However, I don't think the temp differences are big  
enough to do this.

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: Yeast nutrients,mini-kegs,molasses,stuck fermentations from Micah

Sorry, I haven't been responding much lately, I did see that post with the nutrient questions but later forgot all about it. Also there have been several E messages about this to me I 'll post an answer.

Most definitely do not use that yeast nutrient with the urea base. These are really cheap nutrients and they are based in the idea that yeast can directly metabolize ammonia in the presence of nitrogen, hence urea! Unfortunately it doesn't smell or taste good IMHO. (some may be accustomed

to this taste) In the past this has been a huge problem for mead makers resulting in several year aging times for the urine smell to go away.

This is not viable for beer with its lesser shelf life. I have actually met mead makers and hbers who thought that the ammonia smell was supposed

to be in the flavour profile of their meads and even liked it.

I use Difco's nitrogen base nutrient for yeast. I've noticed that others on the HBD use this as well, perhaps a posting would help find a source in your own local.

>This past weekend I acquired a 2 1/2 gallon mini-keg called a "Reynolds >Tapper." It has a built-in tap (labeled "Falstaff" which I assume is some

>cheap Yankee beer :) and is barrel-shaped, meant to lie on its side, cask-style. It is filled from one end, and the sealing cap has some funky >valves and a gas cylinder in it. It looks like the idea is, you fill this

>with beer, stopper it, and charge the cylinder with enough CO2 to dispense >the brew. Neato.

A few years ago one of the guys from the club got one of these little kegs and brought it to me to figure out. What I ended up doing was altering the CO2 cylinder in it to be refilled by the owners CO2 set up on his draft system. This was done by removing the existing "bicycle" type valve and drilling it out to accept an 1/8 NPT (pipe thread) this was then adapted to a pin lock fitting purchased from FOXX Equipment. The resultant little keg proved quite useful for outdoor activities.

>I'd like to prime with molasses. Papazian suggests 1 cup/5 gallon batch.

>Unfortunately, he doesn't specify the type of molasses. As many of you have

>includes 2#s dark brown sugar.

>I have 12oz. of Brer Rabbit dark 'full flavor' molasses I'd like to use. The

>question is, how much?

If your making an Old peculiar copy I suggest that you use Lyles black treacle instead. It will give the proper flavour profile. Use no more

than 6 ounces, 3 should be enough as it is very strong flavoured by not especially fermentable. Lyles treacle syrup is a common item in British import shops.

>Subject: Stuck fermentation?

>I have been told that if you multiply a recipe by more than two, stuck >fermentation is unavoidable because the centre of the carboy has a much higher

>temperature than the sides of the carboy thereby damaging active yeast. Is

>there anyone who knows how to avoid these problems for brewing batches over 5

>gallons?

I have been brewing 15 gallon batches for several years and find them easier

than fives. I am guessing that the problem is that you didn't at least triple the amount of yeast that you pitched when you tripled the other ingredients. This story about the vessel size is a crock of #@#%, if it were true AB in Fairfield would be in trouble, their fermenters are 1600 barrel each (1600\*31=gallons). So I say use lots of yeast. Ten percent

pitching rate works great for me.

From: Victor Reijs <Victor.Reijs@SURFnet.nl>  
Subject: lager yeats at higher temp. and stuck fregmentation

Hello all of you,

I think that it will not be a problem to use lager yeast at room temperature. All the wine/beer yeast belong to the same family and these work between 5 to 30 degree Centigrade. Yeast will go dead above 40 degrees Celsius. The lager yeats is only a yeast which will also fregment at low temperatures, while normal yeast will not do it (like wine yeast).

What yeast needs at the beginning of its live is oxigen. With out that it can not multiply. So if you are making a lot of beer, be aware that the water you are using has enough oxigen in it (water which has been cooked will have a low oxigen content, so stir this water heavily!). Another reason why a fregmentation can stop is that there is no sugar any more. There are beer which will stop at 1020 (depending on the type of ingredients and type of producing the malt.

I do not expect that yeast will go dead in the middle of a barrel, because of the temperature. THE water will always circulate (due to the temperature and due to the formation of CO2). But if you think it is the temperature, measure it;-)

All the best,

Victor

From: Victor Reijs <Victor.Reijs@SURFnet.nl>  
Subject: Re: sake

Hello Will,

This is not a recipe but it is perhaps addition information! If possible you can buy at Japanese or Indian shops stuff which is called 'koji' or 'ragie' (these are the words we are using in Holland). This is a kind of yeast which is able to ferment the starch of the rice. After boiling the rice for an hour and cooling it down one can put the 'koji' in the rice+water. After some 4 days it will taste sweet and then the fermentation will start.

If you get good results, please let us know.

All the best,

Victor

From: fjdobner@ihlpb.att.com  
Subject: William Mares "Making Beer"

A book entitled "Making Beer" by Willian Mares was issued this year. A very nice easy reading book. As opposed to the many "how to" books that enable us to improve/learn in homebrewing, Mr. Mares takes it one step further and adds some great personal stories of the hows and whys he got into homebrewing. His stories begin though when the market for basic homebrewing implements was very thin and so were the offerings.

I especially liked his replacement line for Mr Papazians "Relax. Don't Worry. Have a Homebrew" nostrum. Mr. Mares line is "Pay Attention. Worry Intelligently. And Have a Homebrew When You're Done." Words I can at least partially relate, except for that last bit.

I will probably have more to say about the book after I have finished.

Date: Wed, 21 Oct 92 17:30:31 -0400  
From: cook@uars.DNET.NASA.GOV (Chris Cook, NMOS Quality Engineer - (301) 386-7807)  
Subject: Small Batches

When I wrote about trying 1-gallon, experimental beer batches, I didn't think I would get the number of responses that I did. I know you're heard it before, but I still have to thank all the people who have emailed me with suggestions and support. I really didn't expect the personal attention.

One question that many people asked was why I wasn't simply joining or forming a larger group of homebrewers and trading recipes. Five of us could brew 5 batches and trade. This would be much less work than five individual experimenters making 25 little batches.

Unfortunately, that's not my answer. Too much pride, I think. Who among us, if they were going to share their beer with, say, four other skilled and knowledgeable beermakers, would brew a simple, possibly bad, experiment? Even shared, a batch is too much work to waste on questionable, experimental stuff.

I know, I know, I (and my four friends) should have the emotional fortitude to be able to avoid this 'Blockbuster' mentality. I can't speak for my friends, but I don't. I simply wouldn't experiment as monotonously as I need to.

Could you and 4 friends make 5 simple ales (five gallons each) with 1/2#, 1#, 2#, and 4# of Caravienne, along with a control batch, just to see how the malt affects the taste? How about batches mashed at 149, 152, 155, and 158? I don't mean you any harm, but if you and your friends have that kind of stamina, I think you should consider hanging around with a different crowd.

Besides, everyone does this differently, and the noise from these little differences could easily overshadow the experiment. I know that my methods aren't perfect, or even right, but at least they're consistent. Even if the five of us started with the same ingredients and directions, I'm pretty sure the differences would embarrass us all.

Some of the small-batch suggestions are very interesting. One person gave directions for doing the mash in the microwave. Fantastic! Who could pass up trying that? There were several variations on the 'coffee-can(s) taped together' lauter tun, although (given the small thermal mass) I'm going to try to modify a 1 or 2 gallon thermos.

The one question still hanging in my mind is about Hop utilization rates. I've gotten contradictory suggestions about hop bitterness. Obviously there's been some research on scaling up from the common 5-gallon batches to pilot brewery scale; I seem to remember that huge breweries don't have to use anywhere near the hops rates we use. Anyone got some quick hints?

I'm still waiting for the Belgian malts to arrive, so I haven't started yet. Once I get moving, I'll be able to tell you more detail on the mechanics.

Subject: Al's Special London Ale

Due to numerous requests, I am posting my best yet recipe for a clone of Young's Special London Ale. Here it is:

Al's Special London Ale

6.6 lb M&F Unhopped Light Malt Extract  
1 lb 10 oz Laaglander Light Dried Malt Extract  
1 lb Crushed 2-row british Crystal Malt ~40L  
1/2 tsp Burton Water Salts  
5.5 gal Chicago Tapwater  
2.1 oz Northern Brewer Pellets (6.2%AA) (60 min boil)  
1/4 tsp Irish Moss (15 min)  
0.5 oz East Kent Goldings (whole) (5 min boil)  
0.5 gal Boiled Chicago Tapwater (added after boil to adjust OG)  
8 oz Starter from Wyeast #1028

1 oz East Kent Goldings (whole) (dryhop last 7 days before bottling)

1/2 cup Corn sugar for priming

Procedure particulars:

Steeped crushed crystal malt in a grain bag while the liquor + Burton Water Salts went from tapwater temperature up to 165F. Removed grain bag and let "wort" drain out of it. After boiling down to 5 gal, OG was 1071, so I added the additional 1/2 gallon of boiled water (not a big deal, but hop utilization would have been different with a 6 gallon boil). By the way, Chicago water is quite soft -- I suspect distilled would be close enough.

Fermentation in glass, with blowoff, at 68F.

Dryhops simply stuffed into the primary after fermentation ended, seven days before bottling.

OG=1064

FG=1022 (yes a bit heavy, but yummy)

Comments:

Closest attempt yet to Young's Special London Ale. Could use a bit more diacetyl. At the 1992 AHA National Conference, Charlie said: "Great London Ale!"

>From: matth@bedford.progress.com  
>Subject: Digest 992 and Jack's perfect brews

In today's digest, #992, Jack S. Says:

> How can you possibly suggest that I would make beer that I do not like?

>> I wish I could attain that type of consistent perfection!

You have taken the statement out of context and ignored the whole point of the discussion. It was suggested that I don't care what my beer tastes like as long as it is clear and I was responding to that absurd notion.

.....

I counted to 10 (waited for two more Digests to see if anyone else would speak out) before responding to this, so you all can save your heat. I thought it out clearly and mean exactly what I am about to say.

>From: iepubj!korz@ihlpa.att.com

>Chris Cook asks about how to try a lot of recipes without becoming an alcoholic:

>>Mashing gets simpler, I guess, but all my stuff assumes at least >5 pounds of grain. I expect the 44 quart cooler/lauder tun will >get cumbersome quickly, for example. Jack, you're Easymash may >be the best bet.

>I disagree. With very little grain in the bottom of the pot, your grain bed would still be very shallow.

So far so good but he could use a tall/skinny pot.

> This would also accentuate the poor extract efficiency of the Easymash system -- its biggest design flaw is that the runoff is drawn from a very limited area of the grain bed.

I find this totally unfounded statement, not only factually wrong but just about the lowest this group has slithered to bring personal animosities into the discussion on home brewing. to maintain any semblance of keeping commercialism out of the discussions. When a product of mine is publicly trashed, I reserve the right to publicly defend it.

The range of extract efficiency over about thirty batches made with an EM has been between 26 and 31. Most of the variation was caused by improper measurement technique and basic measurement error. The most recent 5 batches have been 29 exactly, all five of them. There are those who claim to get higher efficiencies and no doubt do, on occasion. However, the EASYMASHER was designed to make it easy for the extract brewer to transition to all-grain with the minimum additional equipment and a fool-proof process that is guaranteed to produce a good beer, the first time, with no hangups. I suspect that most beginners and many old timers would be delighted with an extract efficiency of 29.

The alleged "design flaw" is only seen as one, by someone who has never used an EM and hasn't the foggiest idea of what he is talking about, but interested only in stroking his own ego.

As a result of the extremely efficient screening device, the mash runs clear after only an ounce or two are run through, instead of the more usual recycling of quarts or gallons of turbid runoff.

Not only does this get things under way with minimum effort but it allows one to stir the entire mash, all the way down to the bottom as often as one feels like it during the sparging process. This keeps re-suspending the grain so that the sugar is in a solution that is continually being diluted by the sparge water so that by the time sparging is complete, the remaining liquid, throughout the entire grain bed, is so dilute as to make the location of the out-flow totally irrelevant.

The only "flaws" in the system seem to be that it is too simple, it works too well and it was developed by the "World's Greatest Brewer".

>From: "CBER::MRGATE::/"A1::RIDGELY/"@CBER.CBER.FDA.GOV

>This past weekend I acquired a 2 1/2 gallon mini-keg called a "Reynolds Tapper." It has a built-in tap (labeled "Falstaff" which I assume is some cheap Yankee beer :) and is barrel-shaped, meant to lie on its side, cask-style. It is filled from one end, and the sealing cap has some funky valves and a gas cylinder in it. It looks like the idea is, you fill this with beer, stopper it, and charge the cylinder with enough CO2 to dispense the brew. Neato.

Not quite. The CO2 cylinder is a throwaway and not meant to be refilled by the user. These things went out of circulation about ten years ago as far as I know. Fallstaff was a Midwestern beer, I can't recall who made it but

there was one other brewer who used the Tapper also. I have several of them,  
all modified in various ways to make them re-usable. They are great for small batches but I never found a source for that wierd CO2 cylinder and their cost would probably make them impracticable. I just put a small aircock on the keg and charged them from the regular tank.

In my rebirth as a hombrewer, I no longer wish to drink beer out of aluminum  
so they are collecting dust in a corner. They were originally coated on the  
inside but the coating has long since worn off and I probably drank it.

Probably explains why I am such a nice guy.

From: mgx@solid.ssd.ornl.gov (Michael Galloway)  
Subject: terms, koji, and #1000

In issue #996 Victor Reijs asks:

>Because I am coming from Euroep, I have sometimes some problems with  
>your wordinngs;-). Could somebody help me with the following:  
>grist  
>quart  
>2#s dark brown sugar  
>DMS  
>wyeat 2112

Victor,  
Grist is an amount of grain for grinding/crushing or the product obtained from the grinding/crushing process. For our purposes, grist is crushed malted barley and other adjuncts (roasted barley, etc).  
A quart is a 'quarter' of a gallon. A gallon is 128 ounces (fluid).  
2#s refers to pounds. The sharp, #, is the English symbol for the pound. One pound is 16 ounces.  
DMS is dimethylsulfide, well defined in issue #996.  
WYeast #2112 is WYeast's 'high' temperature lager yeast. Usefull for making steam beers. Are WYeast products available to you in the Netherlands?

In the same issue Victor also refers to koji as a type of yeast:  
>If possible you can by at Japanes or Indian shops stuff which is called  
>'koji' or 'ragie' (these are the words we are using in Holland). This  
>is a kind of yeast which is able to fregment the strach of the rice.

Victor, koji is an enzyme, similar to alpha-amalase (sp ?) which is one of the enzymes which converts the starchs in malted barley to sugars. Koji converts the starchs in rice to fermentable sugars.

To Danny near Pierre SD: Although East Tennessee is somewhat more densely populated than SD, I am afraid that I too will be drinking alone next Tuesday (or Wednesday ?) when issue #1000 comes out.

Hey, have any of you netmongers out there tried to use IRC as a means of discussing homebrewing issues? Just a thought.

Subject: Chimay

Greetings...

I live in Ottawa, Canada. Last weekend I was visiting my local liquor store, when I looked up on a shelf and noticed a 750 ml bottle of "Chimay" trappist ale. I hear all kinds of great things about this stuff on the web so I figured: Hey, sign me up. So I tenderly cradle the bottle all the way home so as not to disturb the sediment, and put it on the balcony to chill lightly (it's a little cold up here!!!) and wait with anticipation. The moment of truth finally comes, I light some candles on the mantle, place the bottle between them and give praise... then... POP! I gently pour a glassful into a wide-wine glass; raise it to the light and observe the rich redness; wow! Then a noseful, fruity and somewhat (newly coined smell term)-citrusy. Finally a sip... BLECH!!! Is this stuff supposed to taste like that? Please tell me it ain't so... very sour, extremely bitter, and an awful aftertaste. I hope this was bad sample.

Subject: Malt Storage (How Long is To Long?)

I was cleaning my garage out last weekend and found several cans of malt that have been sitting in varying degrees of heat and cold for 2 to 3 years. They are Muton and Fison pale and have been through Texas summers as well as Northeast PA winters in the garage. My question .... would this malt still be brewable or should I toss it out? My brewing equipment has also been in storage and is really dusty. What would be the best way to clean this stuff? It is food grade plastic. Is there a lifetime to food grade plastic, when do you know you need new containers?

Thanks in advance for any help.

Subject: Beer Engines

A question on hand pumps or beer engines:

Can anyone explain how beer engines work? What is used to displace the volume taken up by the expelled beer? Can you get a beer engine for home use? I

understand that in England, beer is "conditioned" and contains still active

yeasts and is allowed to attain the perfect level of carbonation before serving. Once tapped however, the beer must be served quickly. Is this due to

the fact that the beer engine causes the beer to age or go stale more quickly?

I've been seeing beer engines in use more lately. The Commonwealth Brewery in

Boston has quite a few of them and the new John Harvard Brewpub in Cambridge

has one. I've also seen a few on the west coast, the Lyon's Brewery in Dublin

CA to name one.

Subject: used terms

Hi Victor --

You asked for a few definitions:

Grist: Your "grist" is the mixture of various malts or other grains that will be ground for brewing. The mixture after grinding is also called "grist".

Quart: A unit of volume, very slightly smaller than a liter (litre?) It is
is quart because it is 1/4 (one quarter) of a gallon.

The sharp or hash-mark (#) is a symbol used to stand for "pound".

Pound: A measure of weight, about 1/2 kilogram.

Brown Cane sugar, less refined than the normal, white granulated stuff
Sugar: people use for baking, and in tea. It has molasses flavor. As most flavors, you need to try it to really know. The less refining, the darker in color it will be.

2# Dark Brown Sugar is, therefore 1 kilo of less-refined cane sugar.

DMS Dimethylsulfide. Smells like cooked cabbage. There's a good explanation in today's (22-Oct) homebrew digest from Al Korz(?)
iepubj!korz@ihlpa.att.com

yeast A brand and strain designation of brewer's yeast. The yeast 2112 will have to explain further...

Reply to: Wheat Beer Validity
(Apologies if this shows up twice. I never got a confirmation from the Digest when it went out the first time so I'm sending again. Gave me a chance to add comments regarding Steve's in today's Digest. RW...)

Jon Binkley comments:

>Hey, if Anchor and Red Hook charged \$3.50 a six pack for their >wheat beers I'd have no complaint, and would even buy some for >lawn mowing purposes.

You seem to infer that these beers are produced with a lower standard. That they are made with cheaper materials. I cannot speak for Redhook, however I do know my way around Anchor and can speak to their methods. There is no less effort or expense in the production of Anchor Wheat. Actually there is more labor involved due to the slow sparge that occurs from the use of the wheat. As far as I know there was never any intent to compete with the budmilcoors of the world, rather to offer a product which is lighter in taste and body (without resorting to the use of rice or corn) which might appeal to those who are not into the rest of Anchor's line. The use of the term "lawnmower beer" here refers to the refreshing quality of the lighter brew, not to it's price.

There are many folks around who really like wheat beers, Anchor's included. If you are not one of them Jon, don't buy it! Save your pennies for that bottle of Oatmeal Stout. And don't attach any socio-political significance to it either. It's just another style of beer, and some people like it.

And I believe Fritz is credited with creating the style, not brewing the first Wheat in the US in modern times.

From: palladin@muscle.trincoll.edu
Subject: Medicine-y taste

James Smith describes an underlying medicine-y taste in his beers that he suspects may be from chlorine in the tap water. I have also had a similar taste in my extract+adjunct beers and was wondering the following:

- 1) What is a "phenolic" taste? Plastic-y? I know this is like asking " what does pineapple taste like?", i.e. difficult to describe without tasting it.
- 2) I noticed that this unpleasant taste is more pronounced if I ferment at higher temps (ales). This led me to believe that it is the dreaded "phenol" and that I could probably fix it by switching to liquid yeast and fermenting at lower temps. Is this idea all wet?
- 3) Do digest readers think it *is* due to chlorine in the water? My water dept says that they add almost no chlorine to the water.

Note that this funny taste is medicine-y, not plastic-y.
I agree with Tom that my beers are much better than bud-miller but they still have this "homebrew" taste.

One more data point - the one time I brewed a lager it had very little of this problem. It was fermented at about 50 deg F and also used dry yeast.

One final clue - no matter how much malt I seem to use, this taste masks any malty residual sweetness, i.e. even with 7lbs of extract and 1 lb of crystal there is no appreciable maltiness. The taste that lingers on the tongue is bitter and alcoholic.

Any Suggestions?

Subject: "Making Beer", by William Mares

Frank Dobnar writes about William Mares's book, "Making Beer" in the HBD 996.

I've read this book too and although it's amusing, I wouldn't recommend it to anybody who wants to learn more about making howebrew if they already own TNCJOHB. The information in Mares is basically a subset of what Charlie writes. Buy Dave Miller's book for more (technical) information if that's what you want.

Mares's book is chock full of amusing anecdotes though as Frank mentions. His first exposure to good homebrew comes as a result of getting his bagpipes tuned. (Honest!) The last 1/3 or so of the book tells about Mares's decision to start a microbrewery and this is what I found interesting. Mares was amazingly level-headed and got lots of good advice before taking the plunge. In fact, he was so level-headed, he decided not to open a microbrewery. (I know that I wouldn't have the strength to say no.)

So, as Frank says, "Making Beer" is easy reading and amusing, but don't buy it to learn to be a better brewer.

From: James P. Buchman <buchman@marval.ENABLE.com>
Subject: Acid wash

Hi,

I have a strain of German Ale yeast which I cultured from a single cell colony and which has produced two great batches of Extra Special Bitter. The second batch was pitched with yeast cultured from the dregs of the last bottle of the first batch. Since I have heard that three repitchings is about the limit before petite mutants start to affect the performance of the yeast, I would like to try to give the yeast from this batch an acid wash before storing it.

My questions:

- 1) What are the benefits of an acid wash?
- 2) Would a white vinegar/water solution be satisfactory? If so, what PH should I shoot for, and how much vinegar would lower a liter of water to that PH?
- 3) How long should the yeast stay in the acid solution before washing with plain water?

I guess what I could use is an acid wash procedure. I have seen yeast washing procedures posted for plain water, but not for an acid wash.

Thanks,
Jim Buchman

>The difference in starting gravities is due to the fact that this time
>I was fermenting a little more than 5 gallons (about 5 1/4 gal.)
>While bottling, I tasted some of the new batch, which needless to
>say was quite a bit dryer (similar in dryness to Guinness)

I cant pass up an opprotunity to comment on Dr. Schiller's yeast!
First, strain A1 is from the same (or so we think) original strain
as Wyeast 1056, ie: Narragansett, but from a different source than
1056. I use this strain in most of my ales, and it has excellent
attenuation characteristics. My American Pale ales use 10%
caramel 40 and the ferments go from 1.053 (13P) down to 1.008 (
2P) in 4 days! I also brewed a strong ale with this yeast and it
went from 1.060 to 1.008 in 5 days. For another data point, I
brewed a barley wine and pitched cultured Thomas Hardies yeast
into a 26P (1.104) OG. It got "stuck" at 1.050 (typical for
hardies yeast). At this point I pitched a ton of A1 slurry
without oxygenating the batch, and it took off, finishing at
1.024-6, for a whopping 10% by volume! So, the strain is quite
alcohol tolerant and very attenuative. It makes sense, since the
SNPA pallet is quite dry and not very sweet. In Bills, case,
the EDME performed very badly, finishing at 1.028, way high even
for most barley wines, much less a stout. The second batch,
ending at 1.014 is typical when the specialty malt content goes
up. In fact, 1.012-1.015 is a great range for FG with a stout.

>Other factors which may have influenced these results were:
> 1. The yeast for the new batch was pitched from a 1 liter starter,
>while the dry yeast used in last year's batch was simply
>sprinkled on top.
>2. The new batch was fermented in glass carboys with
>primary fermentation lasting 3 days, and secondary another 8 days.
>The previous batch used single stage fermentation for 13 days
>in plastic.

Factor 1: yes! very important to pitch an active 1L starter.
Factor 2: irrelevant, except that the secondary helps clarity &
yeast removal from the bottling stage.

Bill, if you brew this again, it would be interesting to compare
the results of using strain A6 (similar to Wyeast Irish) or

strain A15 (aka Ringwood ale yeast). Both should result in a higher ester quality to the stout which might be quite desirable.

If anyone would like to email me with data points from using any of the Dr. Schiller strains, I would be most interested in comments & experiances. Also, any improvements or suggestions are welcome since it is WE the collective brewing community that this effort is for, and if the process can be improved I am sure an effort will be made to do so.

From: Tom Bower <bower@fubar.rose.hp.com>
Subject: Beer Evaluation

I recently made the jump to all-grain for the first time, and produced what I think is a really tasty stout. I'm anxious to have someone with plenty of beer tasting & judging experience give me some feedback.

What is the best way for me to get expert feedback on my beer?

- 1.) Join a brew club.
- 2.) Send some to a homebrew contest/judging somewhere.
- 3.) Study for and become a beer expert judge wizard guru myself.
- 4.) Find a kindly, thirsty beer judge who is willing to taste & report back if I send beer.

Assume for the moment that #'s 1-3 are not available right now...any takers for #4? Now, before I'm deluged with e-mail from people who just want a couple bottles of my stout: this is an experiment, and for the time being let's treat it as a purely hypothetical question. If there's anyone who lives reasonably close to Roseville or Auburn, CA, and might be willing to volunteer to try my homebrew, drop me an e-mail message!

In the larger sense, I'd be interested in the net's opinions on how a home-brewer would best go about getting knowledgeable feedback on his/her beer.

Tom Bower.

Subject: Re: terms

Victor asks about the meanings of:

>grist

The grist is the crushed grains.

>quart

A quart is a US measure of liquid volume. It is equivalent to 0.946 liters.

>2#s dark brown sugar

The "#" symbol is often used in the US to mean pounds (which is equivalent to 0.4536 kilograms). Therefore "2#s" or "2#" means 2 pounds == 0.9072 kg.

>DMS

Dimethylsulfide. See my post in yesterday's HBD.

>wyeat 2112

Just a typographical error. What was meant was: "Wyeast #2112 California Lager Yeast." It is also called Brewer's Choice Yeast and is made by Wyeast Laboratories.

Al.

From: Phillip Seitz <0004531571@mcimail.com>
Subject: HBD Field Report #1: Information Sources

Came home yesterday from 21 days in England and Belgium with a horrible cold and three suitcases filled with goodies. The take: 7 kilos of candi sugar, 8.85 of Belgian chocolate, 5 beer glasses and just over 12 liters of British and Belgian beers in 33 bottles. Brian D. still holds the overall beer smuggling record, but but I brought back more overall calories!

I passed customs at Baltimore/Washington International Airport, and all the beer was carefully packed in my suitcases except for a rather conspicuous magnum of Villers St. Ghislain (Brasserie de Silly) that wouldn't fit. There was no customs red line (i.e. for those who wish to declare), so I went through the green. When the guy asked if I had any alcohol I indicated the magnum, but by then he'd already rattled off the next six questions and sent me on my way. (Note: these days I am lamentably clean cut and respectable-looking, and I did notice that the guy ahead of me--with long hair, a small bag, and a history of traveling to bohemian haunts such as Amsterdam and Prague--was instantly snagged for more detailed examination.)

My travels included visits to three English and two Belgian breweries, as well as several brewpubs, homebrew stores, and related haunts. I'm planning to sift through my notes and collected materials as my brain slowly recovers from the jet-lag, cold, and excesses of the past three weeks, and hope to post several messages based on these as time (and space) allows. Since I spent a good deal of time looking for published information I thought this might be a good place to start.

INFORMATION ON BEER IN THE UK

I did not purchase a copy of the current GOOD BEER GUIDE published annually by CAMRA, as I had last year's model. The guide was readily available in any decent bookstore, and can be ordered from CAMRA at 34 Alma Road, St. Albans, Hertfordshire, England, AL1 38W. I regret that I don't have the price of the current edition at hand; my suggestion to interested parties is that you write to request the ISBN number, and use this to order through your local full-service bookstore.

CAMRA also sponsors several other publications. These include:

Graham Wheeler, HOMEBREWING: THE CAMRA GUIDE (Alma Books: St. Albans, Hertsfordshire, 1990), 181 pp., illustrated (ISBN 1-85249-107-8). Cost: 4.99 pounds sterling. This is an excellent and handy guide, though probably less accessible for beginners than Papazian's JOY. All-grain beers are the focus, and there's lots of good information on water treatment and other special topics, as well as a chapter on recipe formulation. Also welcome was info for brewing in

metric measures, for those (like me) who are getting tired of mixing cups, pounds, gallons and grams. Note: the Alma press is owned by CAMRA.

Roger Protz, THE REAL ALE DRINKER'S ALMANAC (Moffat, Scotland: Lochar Publishing, 1991), 288 pp., illustrated (ISBN: 0-948403-89-6). Cost: 7.99 pounds sterling. A fantastic guide to beers from all over the UK, and an excellent companion to the above. This book provides tasting notes for the vast majority of real ales available, as well as recipe guidelines (i.e. IBUs, malts and hops used, special techniques). While having this information is still a far cry from being able to duplicate your favorite beer, it's definitely a leg up. Impressive in its scope. Another book, THE EUROPEAN BEER ALMANAC, by the same author and publisher (same price, ISBN 0-948403-28-4) covers continental brews, but was far less comprehensive and tries to cover too much ground, IMHO.

Tony Morris, ed., SUFFOLK REAL ALE GUIDE (CAMRA: no place, 1992), 192 pp. with maps (ISBN: 1-85249-066-7). Cost: 3.00 pounds sterling, and worth three times that. Most of our travels were in East Anglia--the counties of Suffolk, Norfolk, and (depending on your philosophy) Cambridgeshire and Essex. This guide is similar to the GOOD BEER GUIDE except that it lists ALL of the pubs in the county of Suffolk. It's an astonishing piece of work for a county organization, and, once we found it, replaced all our other guidebooks. Includes historical profiles of each town, with maps showing the locations of pubs as well as information on all the beers available in the area. If CAMRA can produce this kind of effort in every county travelers will be very well off indeed! (I gather this is a very new publication: the only place we saw it was in the Ipswich tourist information office.)

INFORMATION ON BEER IN BELGIUM

My search for beer guides in Belgium was quite energetic, and almost equally fruitless. With a wealth of beers and brewing history at least as rich as England's it's astonishing how little information is available. However, you can still look for:

Tim Webb, GOOD BEER GUIDE TO BELGIUM AND HOLLAND (St. Albans, Hertfordshire: Alma Books, 1992). ISBN 1-85249-110-8. Cost: 8.99 pounds sterling. This obvious started as a CAMRA guide, and is published by their press, but does not bear their seal. It is a Lowlands equivalent of the UK GOOD BEER GUIDE, and does a very creditable job. The descriptions of the beers are less detailed, but I would say that this is probably probably essential reading for anyone going to Belgium who doesn't already know where they're going to do their drinking, and is very desirable even if you do.

MENU FROM LE VAUDREE, Liege. Le Vaudree has two restaurant/cafes in the province of Liege, and offers 42 beers on tap and 980 in the bottle. Their menu is 48 pages long and is a veritable dictionary of Belgian brewing. Beers are arranged by category, including one for "Bieres Disparues", or beers from breweries that no

longer exist (try a 15-year old gueuze?). While this is hardly in the same category as the publications listed above it is still a very valuable reference source, and procuring it is likely to be more fun than a visit to your local bookstore. These two cafes are open 24 hours (probably the only thing in Belgium that's open at 3:00 am aside from the bordellos, which probably only serve Stella Artois), and are located at:

Rue val Benoit, 109 Rue Saint-Gilles, 149
4031 Angleur 4000 Liege
Tel: 041/67-10-61 Tel: 041/23-18-80

As soon as my brain is working better I will post information gathered from the brewery visits as well as some other general observations. In the meantime, could someone send me the address of the MEAD LOVERS interest group? A Belgian friend asked for this, and I must admit I didn't save it. Thanks and a bientot!

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: yeast nutrient for mead

Jim Larsen (jal@techbook.com) informed me via e-mail that bee pollen is a (the?) traditional yeast nutrient for mead. Thanks again, Jim. Does anybody have any idea how much to use per gallon?

Acton and Duncan recommend a combination of ammonium phosphate and vitamin B1 for nutrient. I don't feel a whole lot better about ammonium phosphate than I do about urea (although at least my mead won't literally be p*ss-water :-).

I mentioned in an earlier HBD that I was wondering about using health-food-store brewer's yeast as a nutrient for cider. What about for mead? It's not live yeast. It has B1, as well as other B vitamins. I suppose it also has other nitrogenous goodies which the wine yeasts can scavenge from the corpses of the dead brewer's yeast. Does this speculation seem to make any sense? Does anybody have any ideas how much I might use per gallon?

Is there a mead digest?

Cheers,

Rob (bradley@adx.adelphi.edu)

Subject: Malting your own grain from Micah Millspaw

At the October SAAZ club meeting one of the members brought in many five pound bags of barley. This was dry, unmalted barley. He said, evrybody take some. After that a lot of the meeting was about what to do with the barley, most opted to try malting the stuff. Over the past week that is what I did, made malt. This is a fasinating process and very easy to do (quality aside) whither the malt is top notch or otherwise, malting and kilning your own grain and then brewing with it should be a must for any grain brewer (one time). I found this to be an enlightening project as did other members of SAAZ who tried this as well. I'm looking forward to the next few meetings when we'll sample the really homemade beers. As I hickory smoked my malt after kilning, I'll be brewing RAUCH STOUT this weekend.

I thought that the might be interesting to the HBD.

Subject: chlorine/stuck ferment cures

>The purpose here is to get rid of the chlorine. In his previous book, "The Complete Handbook of Homebrewing," he recommends pre-boiling all water for 15 to 30 minutes to drive off the chlorine. IMHO, it is a function of your water supply. When I lived in Lexington, MA, the water was quite good and I could add it directly to the fermenter and the beers were fine for my untrained palate. When I moved to North Andover, MA, I could smell the chlorine in the water & the water dept. said the chlorine level was 0.7 ppm - swimming pools range from 1 - 2 ppm. I started boiling the water then; I did not try a batch without boiling the water.

It's not just the chlorine taste that you want to drive off; the chlorine will act as a buffer and keep your mash ph from getting below 5.8 or so (that figure is from experience), no matter how much gypsum you add (within reasonable limits). A high ph will adversely affect your extract efficiency (but you can still get a fine beer with a mash ph of 5.8, albeit a lighter one unless you compensate with more malt.

- - - - -

For curing a stuck fermentation, try oak chips. I use the kind that look like, and are, sawdust. usually I don't want them to impart too much flavor to the beer (and if I do get an oakey flavor, I want it to be a charred oak flavor), so I toast the heck out of them at 450F for 10-15 min, then boil them, and then strain the water to remove much of the flavor which has been extracted in the water, maybe boil & strain again, and then add the goop to the fermenter.

It works like a charm, but don't ask me why. I don't buy the excuse they give on the A-B tours: "the oak chips effectively increase the surface areas of the fermenter, giving live yeast more area to settle out, and not be suffocated by a yeast cake". The sawdust-type chips could not have this advantage, as they settle out fairly quickly, and form a cake on the bottom, but still work. It must be a chemical phenomenon.

other methods I've tried are:

- 1) rousing the yeast. It doesn't seem to make too much of a difference. For it to make a difference, you have to continually rouse the yeast. If you don't have a method of doing this automatically in the fermenter, you are just exposing the beer, to unwarranted risk of infection and aeration, and achieving marginal results.
- 2) yeast energizer. I've tried two kinds: diammonium phosphate, white crystals, and ammonium phosphate (from wines, inc) which was yellow and smelled like piss. I've had good luck with the former (and not the latter), but there were

too many batch-to-batch variances to blame any taste defects or absence of defects on the yeast nutrient itself, especially when I don't know what off-flavor it's supposed to impart. (I've only used them with meads, and like it was mentioned yesterday in the hbd, maybe I'm accustomed to the flavor)

- 3) adding more yeast. If you do this, make sure you krausen with liberal amounts of actively fermenting yeast, i.e. a starter at high krausen. whatever caused the original yeast to "stick" will probably cause the extra yeast to stick, also - try a more attenuative fermenter.
- 4) add cane sugar to the recipe. What I mean is: all those batches I've added cane sugar to seem to go on forever, whereas all-malt batches can be done in under a week. I don't mean replace part of your malt with sugar - just add a little in addition to all the malt. This keeps the yeast in suspension and happy fermenting the cane sugar, and at the same time they get the last little bit of fermentables from the malt. At least this works pretty well for heavier beers, unless the extra cane sugar gets the alcohol so high it kills off the yeast. I've never added any to a batch that's already stuck, though.
- 5) you can always try changing the temperature.

Subject: Sierra Nevada Pale Ale

Being Canadian and on business to the States a few months ago I was fortunate enough to be able to purchase and bring home some bottles of Sierra Nevada Pale Ale. Fine stuff, it is, and I would like to make it my next project. My question: is the yeast slurry on the bottom viable and is it the same yeast that SN uses for their primary. I've heard some bottle conditioned beers are actually kraeusened with wort inoculated with a strain specifically generated for priming. These bottle loading strains don't make good ales, just fizz to lock the cap on. If anyone has the "goods" on the stuff in the SNPA bottle please let me know. I'm plating it out in a petri dish tonight, we'll see what grows.

While we're on topic, can someone email me their best SNPA emulator?

Thanks in advance.....Glenn Anderson

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: 1056 and clarification

My first batch using Wyeast 1056 is 20 days old and coming into its own. I am most pleased with the results, despite the lower FG noted previously. One great feature is that the yeast sediment in the bottles clings extremely well to the bottom, just like SNPA. You can pour out virtually all the beer.

The beer is not very clear, and doesn't seem to have clarified any in the last few days. Has anybody else experienced this problem? I did not use Irish moss or finings; I found they were unnecessary with the dried ale yeasts I used to use (Edme and Munton & Fison).

I hope that someone more qualified than I can answer Glen Anderson's question about SNPA. I believe I've read in the HBD that the yeast used for bottling is indeed the same one used for fermentation.

From: berthels@rnisd0.DNET.roche.com
Subject: more on sugar

I'd like to dispel a few misconceptions about sugar. As we all know, white sugar is a refined product. Recently the word "refined" has become synonymous with artificial, not so, it simply means purified. If the impurities that were removed are beneficial (i.e. rice bran) then one might argue that a less "refined" product might be better for you. Unfortunately, a great deal of so called brown sugar is nothing more than white sugar that has had molasses added to it, so be careful. In addition, the term "raw" sugar has been used to describe less purified products. It is interesting to note that molasses is the residue from evaporating the "mother liquor" (chemical term referring to the liquid from which crystals form). So in some cases it might be possible for a large sugar company to remove the molasses in it's processing, only to add it back later! If you are using sugar as nothing more than yeast food, white is no different than brown. However, if as I expect, the sugar adds flavor to your brew, use the one that tastes best, just don't use it because you think it's more "natural"-SJB

Subject: Decoction and Tannin Extraction

In HBD#995, Al quotes and responds with:

Glenn Anderson asks:

>astringency and other negative effects will result. My question for
>the decoctors in the crowd is; why does boiling a portion of the
>grist not extract tannins during a decoction?

(Al responds...)

>Darryl Richman finally cleared this up for me too. He recently
posted that it's the pH! I interpret this as meaning that as long as
the pH is down in the vicinity of 5.2, extraction of tannins is much
lower than if it's up high. Al.

I'll have to admit being confused at this point. From what I can
gather from Al's and Darryl's conversation, lower pH will reduce the
extract of tannins. I can accept this, but using this theory I would
feel comfortable acidifying my sparge water to 5.2 then sparging with
boiling water rather than fiddling to get it around 168F. I have
received other mail offline that indicates various process for
decocting (thanks everyone), which ran from boiling only the runoff
to boiling small amounts of grist with the runoff to "why don't you
read Noonan....". I don't want to use up bandwidth talking about a
documented mashing process, but perhaps Darryl or Al could clarify
this Mash pH/temperature/tannin extraction relationship.

Thanks....Glenn Anderson

Subject: hard cider

This is my first posting on the HBD. I am a graduate student at purdue University. Anyhow, I am making hard cider. I am using a recipe from the first volume of cats_meow. The recipe is as follows:

5 gallons of sweet fresh apple cider
3 # of brown sugar
3 # of honey (2/3 clover and 1/3 wildflower)
yeast

I heated 1 gallon of the cider to 160 F in order to dissolve the sugar and

honey. I kept this mixture at 160 F for 15 minutes in order to insure steril.

Next I poured all the apple cider into the fermenter and added the yeast (pastura wine yeast). Fermentation has been strong for about a week. I am

hoping to be able to taste it by Holloween. A few hours after I pitched the

yeast fermentation began(probably more like 8 hours). The next day fermentatio

had all but stopped. I decide to add yeast nutrients and ran to the store.

Immediatly after I added the nutrients fermentation restarted. By the next

day Their was foam comming out the airlock. Luckily my girlfriend is knowlegab

about brewing and attached a blowoff tube. I believe apple cider is lacking in

the correct nutrients for yeast to thrive. If anyone in HBD land has further

information concerning this please respond.

Brewing is more than a hobbie it is my life ;-).

Subject: Re: Medicine-y taste

Joe Palladino asks:

>1) What is a "phenolic" taste? Plastic-y?

Tastes due to the presense of phenolics can vary. Mediciney is a term that is often attributed to phenolics (think wet Band-Aids (TM)). I guess wet Band-Aids are plastic, so "plastic-y" might also be appropriate. Clove-like characteristics are also attributed to phenolics - though this may be appropriate in the right context (e.g. in some wheat beers.)

>2) I noticed that this unpleasant taste is more pronounced if I ferment at higher temps (ales).

Higher fermentation temperatures can and DO induce some strains of yeast to produce more phenolics. Going to a pure, known culture and lower temps sound like a good idea to me.

>3) Do digest readers think it *is* due to chlorine in the water?

Though I've heard from multiple sources that chlorine in your municipal water supply is a candidate for these characteristics, I'm venturing a guess that your problems are directly attributable to your yeast and fermentation temps.

Some of my early brews used dry Munton & Fison (aka Muntona) yeast. ALL of these beers had a distinct wet Band-Aid aroma, and a clovelike flavor profile much like some German wheat beers I've had. I'm quite sure that sanitation wasn't a problem as other beers which were brewed with different yeasts (Edme, Whitbread) around this time period did NOT have this characteristic. I've since learned that there has been problems associated with M&F yeasts producing excessive phenolics. I don't want to say that M&F yeast has ALWAYS had this problem, but at least some production runs appear to have been affected. From those batches, I feel I've been "sensitized" to this flavor characteristic, and I don't care for it at all. I used to enjoy German wheat beers much more, but now they only trigger a bad association. The clove-y-ness of these beers, however, seems to be stronger the less fresh they are.

>One final clue - no matter how much malt I seem to use, this taste >masks any malty residual sweetness, i.e. even with 7lbs of extract and >1 lb of crystal there is no appreciable maltiness.

Unfortunately, I've resigned myself to the fact that to get real, honest-to-goodness maltiness, mashing (at least partial-mashing) is required. Extract brewing is so much more convenient, but just can't produce the maltiness that is sometimes required (e.g. a Pilsner Urqell -type brew.) For other styles of brew, extract brews produce quality as high as all-grain (let's not start the flame-wars, however.)

Subject: ragi and koji

Greetings experimental brewers ...
In issue #996 Victor Reijs spoke about ragi as a southeast asian yeast used for fermentation. I too was intrigued when I found this in a local asian store and it was marked yeast. Well a little investigation provided a better explanation. Ragi is a symbiotic combination of yeasts and fungi (Endomycopsis yeast and Amylomyces fungi are most prominent in Indonesian ragi). The fungi produces strong amylolytic enzymes to digest the starch which the yeast can then ferment into alcohol. The fungi can also produce alcohol with both organisms producing volatile acids. Cooked glutinous or sweet rice is inoculated and liquid accumulates in the bottom after 2 days.

The rice becomes quite sweet with a distinct tangy smell like yogurt with alcohol thrown in develops. If allowed to ferment longer as much as 6-8 % alcohol can supposedly develop. The whole thing is eaten as a dessert which is quite tasty and well loved by Indonesian students here at SFU.

Koji is a japanese/mainland southeast asia product created by the action of Aspergillus and/or Rhizopus spp. fungi on cooked rice. Only the starch is converted with no alcohol production. This is accomplished by other organisms added/which appear later on in the fermentation resulting in sake/soy sauce etc. This is apparently a common process throughout southeast aofrpd.

>about ammonium phosphate than I do about urea (although at
>least my mead won't literally be p*ss-water :-).

...
>Rob (bradley@adx.adelphi.edu)

I have made only two batches of mead, so I am hardly an expert, but I
won't
let that stop me from putting in my two cents!

The first batch was made with processed honey, "Fermax" yeast nutrient,
acid
blend, and Red Star Champagne yeast. It fermented down to about 1.010
over
three months at temperatures around 95-105F (I lived in an attic
apartment).
It had a vile flavor that took another year to age out, but when it
finally
did it had a pretty good flavor.

The second batch was made with raw wildflower honey, a couple of pounds
of
frozen raspberries, and Red Star Prise de Mousse yeast. It fermented
down to
around 0.998 in three months at 75-100F. Its flavor was always good,
though
yeasty, and it was quite drinkable immediately after bottling. I'm going
to
give it a few more months of aging, just to see what it will do, but I'm
very
happy with the flavor as it is.

I think the moral of this story is that you can make good mead without
adding
yeast nutrient. Presumably a major difference between processed and raw
honey
is the presence of lots of bee pollen, so you may be on the right track
there.

Raw honey also has lots of wax and bee parts in it that may add helpful
nutrients that plain bee pollen wouldn't. You can also get raw honey
pretty
cheaply and in more interesting varieties than processed honey. It is
also
possible that the raspberries provided something crucial for the second
batch.

I plan on brewing (is that the right word?) up a batch of lemon grass/
ginger
mead soon, so I'll let you know if raw honey will ferment well on its
own.

Subject: brown sugar

trl@photos.wustl.edu says

> Brown Cane sugar, less refined than the normal, white granulated
stuff

Sugar: people use for baking, and in tea. It has molasses flavor. As
most flavors, you need to try it to really know. The less refining,
the darker in color it will be.

This is not true in the U.S., where food-safety laws require that all
sugar
be fully refined. "Brown" sugar is a mixture of sugar and molasses. I
think there are some other non-white sugars available that are
incompletely
refined but am not sure whether these are produced here or are imports.

From: Carl.Hensler@West.Sun.COM (Carl Hensler)
Subject: SoCal Bier de Garde alert

For those of you in Southern California, the Trader Joe's chain has "Jenlain", a French Biere de Garde, for \$1.99 a 750 ml bottle with champagne-style cork and wire closure. Good stuff!

In Michael Jackson's "Pocket Guide to Beer," he says:

"Just south of Valenciennes, Duyck produces Jenlain *** -> ****, a classic Biere de Garde, with a deep, amber color, fruity nose, and hints of licorice in its long finish. In the tradition of this style, it is a top-fermenting brew, all-malt, 16 Plato (1064; 5.2; 6.5), not pasturized, although it is filtered (ideally it should not be - the original idea of a Biere de Garde was that it could be laid down)."

[In Jackson's rating system, *** is "worth seeking out" and **** is "world classic."]

The label on the bottle says:

"At the turn of the century, over 2000 farms in the North of France brewed their own beer. They produced for themselves and their neighbors distinctive ales that were cool-aged for a month or longer. Called "bieres de garde" these deep amber ales were famous for their full flavor and exceptionally refreshing taste. Today only 30 or so farmhouse breweries remain to continue the tradition. The best known is brasserie Duyck, and their Jenlain is France's favorite country ale."

"Jenlain contains only pure artesian well water, barley malt from the Champagne region and hops from Alsace."

Yes, Darryl, I'll save you some.

Hi all,

In a never ending attempt to brew that 'perfect' beer, I have a few questions. forgive me if these have been asked and answered a hundreds times or more, (which I'm sure they have) but I have to delete these posts frequently.

1. I saw a 5 gal Igloo cooler in a store the other day. I am still experimenting with partial mashes and thought, this is the one I've been looking for! How do you go about replacing the push button valve with one that allows a lot more control in sparging?
2. What is a good extract/grain ratio for partial mashes. 1 3# can to 3#s grain, etc. I guess I should say what is standard.
3. I've heard a lot of talk about efficiency, 90%, so many points, etc. What's it all about.
4. And finally, does yeast really play that big of a role in taste? Excuse my ignorance, but I've always used the little dry yeast packet that comes with the cans (I did buy some liquid once) and my beers taste fine to me. Will they improve that much?

Thanks again,
Chuck

From: oxcommmed@vax.ox.ac.uk
Subject: cider, etc.

I think this bounced the first try. Apologies if it appears in the digest twice!

I arrived back from holiday (that's vacation to you) to find a thread about cider in the hbd. I thought a UK perspective might be of interest. In what follows, "cider" means what you call "hard cider"; in the UK we don't use "cider" to describe unfermented, nonalcoholic apple juice.

Firstly, a correspondent (Andy Kurtz, hbd982) asks whether cider can be bottled. In fact, apart from in pubs and bars (almost all of which will have some cider on draught) most of the cider sold in the UK is in bottles, both glass and PET (see later). This cider is generally highly carbonated (like bottled beer) but this is in every case artificially obtained. Traditional cider is still (uncarbonated), because unlike beer could only be made at one time of year and had to last in the cask until the next year's brew. The high tannin content of old cider apple varieties helped its keeping properties. Commercial bottled cider is generally much sweeter than the traditional stuff, and is filtered and pasteurised. Cider was formerly always made with pure apple juice (i.e. no water was added) and thus had a much greater strength than present beer or cider, perhaps as much as 12 percent.

Another contributor has a batch of cider which has become "vinegary". I can confirm that for a traditional-style cider this is totally authentic! Not to everyone's taste, however. Some remedy can be made by adding sugar (one of the most common problems is when all the sugar ferments out making the residual acidity seem more unpleasant. If the brew is totally vinegary, however, why not put different labels on the bottles and call it cider vinegar? Here this sells as a culinary ingredient at a premium over malt or spirit vinegar, and is used in the same way as wine vinegar. If you suspect that the vinegariness is due to a bacterial infection, however, this is probably not to be recommended..

Ellis, in "The Compleat Cyderman" (London, 1754), recommends adding a pint of wheat to each hogshead of cider to "sweeten and feed" it. I'm not sure whether this is a US or UK hogshead...

On a different subject, people seem to want to add citrus peel to brews. I seem to remember reading somewhere that citrus oils can inhibit yeast growth and/or fermentation.

Yet another subject: Don Levey (hbd986) asked about using plastic bottles. As I mentioned above, in the UK probably half the supermarket sales of cider and beer come in 2 or 3 litre PET bottles. Because of the way that these are

moulded they can withstand high carbonation pressures, are usually brown or green tinted, and appear ideal for beer re-use. The only possible problem might come with sterilising them as some of the more aggressive sterilising agents can weaken plastics.

Subject: do lazy bottles gush?

Is there some reason why beer bottles shouldn't be put on their sides in the fridge? I'm not talking about homebrew, which I always stand up because of the sediment. Nor do I recall ever having a problem with industrial beer.

In the last month or so, all four store-bought beers I've had in the fridge have gushed at least once. All were Reinheitsgebot: Beck's, New Amsterdam Amber, New York Harbor Amber and Brooklyn Brown. They'd all been resting for a day or more and none had been shaken after being removed from the fridge.

Tangentially, I noticed Brooklyn Lager bottles in Spike Lee's "Do The Righth Thing" the other night. I thought it was a new brewery, but the movie was shot in 1989 (or earlier?). Do you suppose the brewery paid a fee the way Coke does to get exposure in major Hollywood movies?

Cheers,

Rob (bradley@adx.adelphi.edu)

Subject: RE: water problems

Suggestion:

For those of you, like me, who live in a water district where you can see more of the water than you want to, and are wondering what is in there that you can't see, do what I do,

Buy 5 gallons of "Mountain Spring" water at the supermarket.

You still should boil all of it for reasons mentioned by others, but this way you are somewhat guaranteed that the water won't be the reason that your homebrew tastes less than pleasing.

Chris

Subject: More about Altbier

Pardon me for being so far behind the times, but I was catching up on some reading and felt compelled to try to add to the discussion. The topic earlier this month was Dusseldorf style altbiers. This is a beer that I've gone to some lengths to research, so some of my observations (and I'm under no illusion about these being subjective observations) may be of interest to some.

A recent trip to Europe brought my new wife and I through parts of western Germany. What a honeymoon, eh? This was by design, of course, we've been interested in the style of altbiers for a coupla years. The characteristic of Dusseldorf's unique product that struck us both was the overwhelming bitterness of the alts at the brewpubs. I qualify the observation that way because we later discovered that the bottled version was less bitter. We visited Zum Uerige, Zum Schlüssel, Schumacher, and Im Fuchschen. Sherri and I had a hard time agreeing on which brewery had the most bitter example. I said it was Zum Uerige, she said it was Im Fuchschen. Both were "Aggressively" bitter and there was a noticable astringency associated with each. I think some of our argument about the relative bitterness of these two was due to the astringency factor. It is often difficult for me to distinguish the two in highly hopped beers. The other two brewpubs had beers similar in overall make-up, but less bitter. I thought that Zum Schlüssel even had a touch of ale fruitiness, differentiating it from the other three. I disagree with those people who contend that this is a big, malty beer.

Roger Deschner writes:

>The best reference for this style is Michael Jackson's Pocket Guide to
>Beer. I commend the Dusseldorf section to everyone, ESPECIALLY to those
>who might be revising the AHA contest guidelines, or judging this
>category in a contest. Jackson is very specific - gravity 12 plato
>(1.048), Spalt hops, bitterness from the lower 30s to the 50s, (*NOT*
the
>25-35 which the AHA lists!) colour around 35 EBC.

Roger is right on the money here, with a gravity of 1048 it can hardly be a big beer, and in fact I suspect the gravity of those at the Dusseldorfer brewpubs was a little less. Note the bitterness, 30 isn't so high, but 50!

Roger describes #1338 yeast and the malty aroma associated its beers. Adding:

> This yeast is also one of
>the major elements which makes Alt different from the superficially

>similar British pale ales.

It does allow the malt to predominate in the nose, as Roger suggests, but this is also because there is *VERY* little hop aroma in these beers. The malt comes through in the aroma, but that is more than offset by altbier's strong bitterness. I'd like to point out that another major difference between alts and pale ales is the amount of esters. Pale ales are required to be estery and fruity. Even the most fruity alt can't hold a candle to a pale ale. I think its important to remember that hop bitterness is not the same as hop aroma. Bitterness is the product of the brewer having successfully gotten the slightly soluble alpha acids into solution by utilizing a big rolling boil. This vigorous boil also volatilizes the aromatic hop compounds which make up the aroma. Without later hop additions there is only bitterness in the beer and no hop aroma. This is what I suspect the alt brewers are doing.

>What most people, including beer judges, don't understand about Alt is >that it is supposed to have a big, malty flavor profile, with lots and >lots of hop bitterness. This misconception, no doubt, stems from the >lack of good commercial examples available here - it takes a trip to >Dusseldorf to taste it.

I agree with Roger that the beer has loads of bitterness, but I don't understand how you can have a big malty flavor profile with it. Then there is that astringency I spoke of.....While at Im Fuchschen I was behaving like a typical beer geek and sticking my nose into the beer glass, holding it up to the light, etc.. A young man sitting across the table from me pointed to my Otter Creek Brewery t-shirt and asked if I was a brewer. I told him I'm a homebrewer and that I'm interested in duplicating (dussellicating?) this style of beer. He said that he was a brewer for a large commercial brewery in Berlin, and although he brews lagers, he knows how they brew the alts as well. Then he took a coaster from the table and diagrammed out the mash sequence for an altbier! It was like this:
Mash in at 52 degrees C for 20 minutes; step up to 62 degrees C for 40 to 50 minutes; then to 72 degrees C for 15 minutes; mash out at 100 degrees C for 20 minutes. He recommended sparging with 78 C water

It seems to me that the mashout at 100 C is as good as boiling the grist. Not quite, because presence of dissolved sugars elevates the boiling point. The real point :-)) is that the astringency that Sherri and I thought we tasted could very well have been there because of that kind of mashing out

temperature. I asked the brewer about grains and he swept the question aside by saying "just use German, and maybe some English, 2-row malted barley" He also recommended a 90 minute boil. I didn't ask about hops, but it was pretty clear that you needed to just boil the hell out of some German hops and get a bitterness in the range of 30 to 50 IBU as Roger noted above. When I got home I made an alt beer based on some of the information I got. It is as close to the real thing as I've ever gotten before. Its 'wicked' bitter with just a hint of astringency (I didn't quite bring the grist to 100C.) It may have a bit too much body for the style, but I like what I've made. Sherri says its too bitter, but she said that in Dusseldorf, too, so that can't be all bad. I'm afraid that I'm now going to enter my best alt beer into competition and I'll get trashed by judges that say its too bitter, or too astringent. Oh well. I like it.

Norm Hardy adds:

>[1] Widmer Alt was originally a Uerige Alt clone, or as close as Kurt Widmer > could do (he did, and maybe still does, use the same yeast). Problem was, > it just wasn't selling.

I think that is easy to understand based on what an authentic altbier is supposed to be like.

>[2] The alt beers of Duesseldorf are varied, from light amber to very dark > amber. The tastes run from semi-malty and sweet (Schlosser, Diebels) to > VERY bitter (Uerige and Schumacher and some others I can't remember now). > My last time there, in 1990, I found the alts to have a grapefruit kind > of bitterness that I found off-putting. Perhaps this coming summer will > prove to be more enlightening.

Norm could be right on the money here because the two he describes as sweeter versions are bottled, the two described as very bitter are from two of the small altbier brewpubs. Personally, I regard the brewpubs as the keepers of the tradition. The larger breweries are more interested in marketing and mass-appeal, surprising?:-) I'd like to hypothesize that the "grapefruit bitterness" that Norm found disagreeable is more like a rind or pith bitterness, rather than what we normally think of as citrusy-bitterness. It may be a product of the astringency, or perhaps the phenols which can be formed when phenolic compounds are extracted from the husks.

>[3] Some German locals have said that some alt beers could be blind tasted > and could be confused for pilsners (again, BLIND tasted). Interesting > conjecture....

Interesting, and not entirely preposterous. There is a lack of the fruitiness associated with ales. Mostly 2-row malt is used, and it hopped to high heaven. If the alt is a little less hopped than the average it could be considered close to a hoppy pils. Then again, I may be totally mad.

Sorry that this was so long winded, but feel a lot better. Thanks for your indulgence.

Subject: Mini Batches. Approach/Bottles

This is in response to a post by:

Chris Cook
cook@uars.dnet.nasa.gov\$

on brewing small batches. (I'm way behind so this has probably been answered ten times already! SOrry...)

What I've chosen to do for the sake of experiment- is to brew a base beer

I feel comfortable with (and pretty certain of- ya know, no frills, just lots of hops!) and then pull some aside for 1 gallon batch, and modify the hell out of it. I recently made a Pumkin Beer (way scaled down from the Pumkin mash in the Meow...) Fruiting a third of a fifteen gallon batch works well.

Just pull some wort aside at the end of a boi- and steep it w/fruit.

What it sounds like you're after is mini-mashes. I haven't done that. When I put in the time (most every sunday) to do a mash, I prefer not to waste time with only one gallon. So I've scaled up. BUT- it is quite do-able, and some author type had a system for mini mashes geared at an introduction to mashing. You may need to modify equipment to handle a smaller

volume, yet still establish an adequate grain bed.

As for gallon jugs... Go but some cider or cransberry juice. Drink it, or ferment it! and you've got a jug! You'll just have to find the right stopper. I have a few, some from the lab, some from juice. Right now I have two working on a cranberry mead (that was one bottle!)

Happy hopping. Go for it! J.Wyllie SLK6P@cc.usu.edu

Subject: more on vinegary cider

Following my earlier posting(s) on vinegary cider, here is another thought, which follows a discussion with a Herefordshire cidermaker last weekend.

Cider naturally has a high acidity, but this is, initially at least, due to malic acid. I'm not sure that my palate would distinguish between malate and acetate very well, given a general appley background. So it may be that what seems at first to be vinegary cider is actually acid with malate. Apparently during the maturing process the malate is converted into citrate which makes the flavour less "rough" but this can take several months.

I realise that I implied in my first post that naturally-conditioned beer has a short shelflife. I was thinking about cask-conditioned ales here (I bottle very little of my beer) - of course bottle-conditioned beer keeps almost for ever (given the chance). Interestingly, cask cider does not rely on a pressurised CO2 blanket for preservation, but on the thick layer of aerobic fungus, dead animals, etc. which forms on the surface of the liquid. So they say, anyway.

P.

Subject: pellet hops

I have used pellet hops rather than leaf hops for my last two batches, and both of them have been seriously overhopped.

It could be that the scale I use at home to weigh the leaves is calibrated differently than the scale at the home brew shop where I weighed the pellets. However, Dave Miller hints that extraction rates for pellets may be higher than for leaves.

Does anyone have a formula (formal or informal) to compensate for this effect, or experience to suggest that the effect is minimal and doesn't need to be compensated for?

That is, if you would use 2 ounces of 6% alpha leaves, would you use 1.7 or 1.5 ounces of 6% alpha pellets?

Thanks,
Laura

Just to clear up what appears to be a common confusion: yeast ARE FUNGI. I asked a local mycologist about where yeast appear in the fungus taxonomy (I was taking a class in mushroom identification from him at the time). He said that modern classification systems place "yeast" in several classes, depending on their characteristics. For example many budding yeast, of which Saccharomyces are our favorite example, are in the Ascomycetes, while fission yeast (which split into two "identical" cells, rather than budding) are in a different class (I don't remember which).

I think the reclassification has been based on similarities and differences in the DNA sequences of the various yeasts & fungi.

Anyway, the upshot is that the above sentence should read "Ragi is a symbiotic combination of yeasts and other fungi..."

Subject: Wyeast European Ale Yeast

hi all,

any one used Wyeast European Ale Yeast?? any comments on it??

it has been said (by i assume Wyeast) that this is a slow fermenter.
it also said the is left a brew with a malty flavor (unattenuative).

my story:

brewed a starter of great proportion (6 gallons). let it ferment till
the
head fell. brewed a 1.049 batch of 40 Gallons, cooled and pitched the
entire
6 gallon stater. it was slow to bubble and never got going (like others
have done). even the starter was slow (head took long time (many days)
to
fall). the gravity after a week has only gotten down to 1.030 or so. it
still bubble occasionally. temp of the beer has been in the lower 60's F
thru-out the week.

side note here: i usually do a "fast ferment", and i did on this one
also.

the fast ferment is down to 1.010, this after a week - which is good,
maybe
a little lower than i would like it but it did ferment out. so i know
the
problem is not the yeast/wort. my guess is the yeast like it warm.

to give it the possible warmth it may need i have turned on the heater in
the
room where the ferment is taking place. overnite it did not seem to make
much differnece. Rousing does not appear to make much of difference
either.

any daya point from the net???

joe

Subject: RE: bottling from keg

Hi All,

In HBD#998, Jay Marshall asks:

>A question to those of you who keg...

>If you want to put some of your wonderful keged brew into a bottle for
>consumption elsewhere, what methods do you use? I am just starting to
>keg and would still like to be able to take some along occasionally.

I bottle from my kegs frequently using a procedure I learned from Bill Slack.

A day or so in advance, put 40psi on the keg, and get it cold, about 40F or so. This will get the beer fairly well carbonated. Sanitize some bottles, and put them in the freezer an hour or so before bottling. Get a piece of poly tubing long enough to fit all the way to the bottom of the bottles, and slip it over the end of the picnic tap. Place a catch basin on the floor in front of the fridge, this process can get a little messy. Attach the CO2 tank, bleed all the pressure from the keg. Put just enough gas on to dispense the beer (5-7 psi or so) in order to avoid excess foaming. Insert the tube all the way to the bottom of the bottle. Fill slowly with beer, raising the tube as the bottle fills, keeping the end of the tube just below the surface of the beer. Adjust flow to minimize foaming. You'll figure it out by the second bottle. Fill all the way to the top, leave no headspace. Don't worry if it overflows a little. Cap *immediately*, the CO2 will come out of solution quickly. I use Fischer swingtops so I can cap the bottle with one hand, and don't have to screw around with another piece of equipment, a bottle capper. If you use crown caps, keep a cap in the capper if it has a magnetic insert. The sooner you can get the cap on, the better. Voila, a sediment free bottle of homebrew, ready for a road trip.

Cheers,
Jim

From: djt2@po.CWRU.Edu (Dennis J. Templeton)
Subject: Does dry hopping slow the terminal fermentation?

In all the posts on dry hopping, I don't recall a discussion of the effect I've seen in my last two batches of PA.

Both batches were all grain, with 90% pale malt and 10% dark crystal, and SG's of around 1040. For the first I used the yeast described here recently from Young's brewery, and the second time I used Wyeast 1056. The major differences were when I added the dry hops (cascade pellets).

The first time I made a major blunder. I added 1 oz of cascade pellets to a 7 gal batch too soon, in retrospect. This was on day three of an active ferment, when I would normally switch from a blowoff tube to an air lock. Well, with the hops debris and the tendency of the Young's yeast to float anyway, I got a slow ooze of junk up through the lock of what looked like baby poop. A major mess. The real problem, though, after all that was cleaned up, was that the ferment continued at a slow pace for 4 full weeks.

Sheesh, I wanted to bottle but it just kept going and going. I figured that it was a quirk of the new Young's yeast.

For the second batch, with 1056 I wised up and waited until fermentation was very slow. Maybe I should have waited another couple of days, but I was leaving town and wanted to bottle when I got back. The hops this time stayed in the carboy, but when I got back the ferment was still trickling along. Now it's three weeks and there is still active CO2 production, and suspended yeast and sediment.

I've never had ferments take so long to complete; I frequently bottle at day 10 (without dry hopping). It seems that either 1) The hops have slowed the pace of the ferment by half or more, so it drags on and on, or 2) The hops have somehow increased the amount of available fermentables in the batch, maybe by increasing the fermentability of the higher sugars.

Do you guys have experience with similar phenomena? One thing for sure is that I will wait next time until the carboy is dead still before adding the dry hops....

Subject: Water Quality

For those of you with municipal water problems, I'd like to recommend a water filter that I've been using for 3 years. It's made by Amtek and is also available at Sears for about \$170 (however, a local place sells the original Amtek version for \$100 on sale). It's an under kitchen sink model and filters chlorine and chloramine out of the water EXTREMELY well. It uses two charcoal canisters in series and has a nice water fountain style faucet you can attach to your sink. The typical plastic hoses used for brewing fit over the end perfectly which makes filling the brew pot simple while it's heating on the stove. You can also use other cartridges for different level of sediment, even down to 5 microns.

The replacement cartridges are \$8.00 for the carbon, 20 micron, (\$5.00 on sale usually and they last about 1000 gallons, less with our water which has ALOT of chlorine). They have another cartridge that claims to filter out heavy metals, including lead and it's \$22.40 for one, so I'm not sure you need to use two since they package them as singles while the others are two in a package. I use the carbon ones and a whole house filter downstairs with a 20 micron sediment filter, which helps extend the life of the carbon filters upstairs at the sink (they die from clogging usually, not from dead charcoal).

Anyway, considering beer is most affected by the water you use, it's a wise investment, not to mention that you'll have clean drinking and cooking water.

Michael

From: Darryl Richman <darrylri@microsoft.com>
Subject: re: Decoction and Tannin Extraction

The question of extraction of tannins is complex, and I do not have an answer. I have got an opinion, however, which I will express in this note.

Although it would seem that the common advice to not boil grains (that will be used as flavoring adjuncts in an extract brew) conflicts with the whole notion of decoction mashing (where the thickest part of the mash--a concentration of the grist with little water--is boiled vigorously), that is not necessarily so. The two processes are used for different reasons and in different environments.

Decocting is used to obtain the best extract with less than fully modified malt. Such malt, which we have often characterized here as continental malt, not only has a lower diastatic power (fewer enzymes), but has more of its starch locked up in a tight, hard protein matrix, which protects the starchy food source from attack by molds until the seed breaks the matrix down to make use of it. As modification proceeds, more of the matrix is dissolved. If the malt is not well enough modified, some amount of starch will be unavailable to attack and degradation by enzymes. Boiling the malt in a decoct, through heat and mechanical action, breaks open the remaining matrix.

(BTW, my experience with the imported continental malts available now is that there is little additional extract to be gained from decoction.)

When using malts as an adjunct to extract brewing, we are interested in obtaining the aroma and flavor from the grain. It would be nice if any starches available were converted to sugars, but it is my perception that this is not usually a focus of the brewer. In this process, a small quantity of malt is added to a relatively large amount of water; its enzymes are highly diluted, and the phytic acid formed is much weaker than in a full mash, making it much less likely that any alkaline buffering in the mash liquor can be overcome.

Glen Anderson is, in my opinion, definitely on the right trail in surmising that acidifying sparge water may reduce tannin yield.

It is this same pH concern that occurs at the end of the sparge, when many brewers will terminate the collection from the lauter tun while there is still some measurable extract being obtained (often at 1.010 or even higher)--because the pH has risen above, say, 6. As the acid wort is drawn off during sparging, the water replacing it has a stronger and stronger effect on the pH in the mash bed. This leads us to the same situation as occurs in the extract brewing above. In these situations of higher alkalinity, higher temperatures will increase tannin extraction. I do not know what the exact relationship is between temperature, pH, and tannin extraction.

Subject: 1992 Dixie Cup results

Ok, Brew Fans! Here they are! The results of the 9th annual Dixie Cup Galactic Homebrew Competition and extravaganza!

There were 589 entries in this year's DC!

First, the only stuff that really matters, the club points!

The Dixie Cup stays in Houston this year, with the Foam Rangers taking 83 points! Club scores were:

- 83 Foam Rangers
- 39 No. Texas Homebrewers Alliance
- 31 Cowtown Cappers
- 18 Boston Wort Processors
- 13 Bluff City Brewers
- 11 Oregon Brew Crew
- 10 Bradenton Brewskis
- 9 Crescent City Home Brewers
- 9 San Joaquin Worthogs
- 6 Malt Hoppers
- 5 Black Hole Brewers
- 5 Unfermentables
- 3 Bock'n'Ale-ians
- 3 Carolina Brewmasters
- 3 Chicago Beer Society
- 3 Washoe Zephyr Zymurgists
- 1 Bay Area Mashtronauts
- 1 Borderline Brewers`
- 1 Homebrewers of Philadelphia and Suburbs
- 1 Sonoma Beerocrats
- 38 Points awarded to non-affiliated brewers

Best of Show Results

Meadmaker of the Year
Buck Wycoff - Foam Rangers
Unnamed - Still Mead

BOS - Extract
Jim Fitzgerald - Boston Wort Proc.
Unnamed - Imperial Stout

BOS - All Grain & BOS Overall
David Wright - Bradenton Brewskis
Hyperbrau - Strong Scotch Ale

High Point Brewer
John Manczuk - Cowtown Cappers
2 2nd Places and 2 1st Places

American Lights 12 entries

1st Bernard Greener
2nd Steve Golas/Darden Bourn
3rd Charlie Gottenkieny NTHBA

Pilseners 18 entries
1st Dougl's Lindley Crescent City
2nd Eric McClary Washoe Zyphyr Zym.
3rd David Guillebeau Oregon Brew Crew
Hon. Mention - Tim Case Foam Rangers

Munich Helles Lager 15 entries
1st Joe Mellon/Tom Henderson NTHBA
2nd Dave Diehl Foam Rangers
3rd Douglas Lindley Crescent City

Dortmund Export Lagers 9 entries
1st LeRoy Gibbins/Chris Todd Foam Rangers
2nd Bill Murphy Boston Wort Procs.
3rd John Jacy Foam Rangers

Oktoberfest/Maerzen/Vienna 27 entries
1st Mike Fertsch Boston Wort Procs.
2nd Jim Lopez San Joaquin Worthogs
3rd Jim Lopez San Joaquin Worthogs

Steam Beer 8 entries
2nd Scott Icenhower / John Don
(only 2nd place awarded here! Judged
by Tim Herring of Anchor B.C. and
Fred Eckhardt!)

Continental Darks 5 entries
1st Philip Schlect Bradenton Brewskis
2nd John Jacy Foam Rangers

Traditional Dark Bocks 9 entries
1st Greg Greener
2nd Steve Roberts Foam Rangers
3rd Ken Haycock NTHBA

Light (Helles) Bocks 8 entries
1st John Manczuk Cowtown Cappers
2nd LeRoy Gibbins Foam Rangers
3rd Joe Mellon/Tom Henderson NTHBA

Strong Lagers 8 entries
1st Charles Sule/Bryan Hardy Foam Rangers
2nd Joe Mellon/Tom Henderson NTHBA
2nd Bill Murphy Boston Wort Proc.

Altbier/Kolschbiers 18 entries
1st Richard & Susan Nelson Malt Hoppers
2nd John Donaldson
3rd Don Cooper Foam Rangers

Light Ales 12 entries
1st Dan Duke/Robin Geiger Black Hole Brwrs
2nd Tim Thompson/Irv/Mike Foam Rangers
3rd Jim Harper Foam Rangers

Classic Pale Ales 35 entries
1st John Manczuk Cowtown Cappers
2nd Phil Rahn Bluff City Brwrs
3rd John Kipp Borderline Brwrs

India Pale Ales 18 entries
1st David Guillebeau Oregon Brew Crew
2nd Dean Doba Foam Rangers
3rd Albert C. Hymer Bock'n'Ale-ians

American Pale Ales 30 entries
1st Phil Rahn Bluff City Brwrs
2nd Douglas Lindley Crecent City
3rd Albert C. Hymer Bock'n'Ale-ians
Hon. Mention - A. L. Kinchen NTHBA
Hon. Mention - Mark Shelton NTHBA

Brown Ales and Milds 17 entries
1st Phil Rahn Bluff City Brwrs
2nd Chales Sule/Bryan Hardy Foam Rangers
3rd John A Fries Sonoma Beerocrats

California/Texas Brown Ales 22 entries
1st Ed Cutrell Foam Rangers
2nd Vance Neal NTHBA
3rd David Lupin Foam Rangers

Traditional Porters 36 entries
1st Jim Lopez San Joaquin Worthogs
2nd Dennis Urban
3rd David Lupin/Ben Dacres Foam Rangers

East Coast Porters 10 entries
1st Jim Woll NTHBA
2nd Ray Daniels Chicago Beer Soc.
3rd Paul Mellander NTHBA

Sweet Stouts 12 entries
1st Rob Stenson Cowtown Cappers
2nd Norm Malone Foam Rangers
3rd John Gordeuk Bay Area Mashttrnts

Dry Stouts 28 entries
1st Thomas Nelson NTHBA
2nd Roman Davis Carolina Brewmstrs
3rd Charlie Gottenkieny NTHBA

Old Ales 16 entries
1st James Creech NTHBA
2nd Lou Carannante/Ron Kline Foam Rangers
3rd Timothy Walters NTHBA

Barley Wines 19 entries
1st David Guillebeau Oregon Brew Crew
2nd J. P. Rappenecker Foam Rangers
3rd Robert Grossman HOPS

Imperial Stouts 16 entries
1st Jim Fitzgerald Boston Wort Procs.
2nd Dave Hammaker
3rd Harold Doty Foam Rangers
Hon. Mention - Tim/Irv/Mike Foam Rangers

Trappist Ales 16 entries
1st Jeff Humphreys Foam Rangers
2nd John Manczuk Cowtown Cappers
3rd Bob Hauptert NTHBA

Strong Scotch Ales 11 entries
1st David Wright Bradenton Brewskis
2nd Lou Carannante/Ron Kline Foam Rangers
3rd Jeff Humphreys Foam Rangers

Light Wheat Beer 27 entries
1st Dave Diehl Foam Rangers
2nd J. P. Rappenecker Foam Rangers
3rd Bob Gorman Boston Wort Procs.

Amber & Dark Wheat Beer 10 entries
1st Ed Kesicki
2nd Lou Carannante/Ron Kline Foam Rangers
3rd Howard Moreland Boston Wort Procs.
Hon. Mention- Stephen Clark Crescent City

Novelty Beer 30 entries
1st Brian Kelly Unfermentables
2nd John Manczuk Cowtown Cappers
3rd J. Andrew Patrick Foam Rangers

Fruit Beer 28 entries
1st Tom Crawford
2nd Richard Coggins
3rd John Melton Malt Hoppers

Specialty Beer 15 entries
1st Ted Smith Cowtown Cappers
2nd Paul Mellander NTHBA
3rd Allen L. Ford Bock'n'Ale-ians

Still Meads 30 entries
1st Buck Wycoff Foam Rangers
2nd LeRoy Gibbins Foam Rangers
3rd Jim Hill Foam Rangers
3rd Steve Sturgen/Ed Parker Foam Rangers

Sparkling Mead 14 entries
1st Carlos Kelley Cowtown Cappers
2nd Mark Koiner NTHBA
3rd Robert Perry Foam Rangers

This year's milli-conference on Sat. morning include a slide show by Mr. Brad Kraus of the Santa Fe B.C. showing the gritty realities of small-scale brewing, a lecture by Mr. Rodney Morris on oxidizing reactions in wort, and a slid show by Mr. Fred Ekhardt of breweries he's known and loved.

All in all it was a wonderful weekend, and we hope that all of you out there in net.land consider attending and/or entering next year.

Subject: pediococcus / BAA

So I'm finally catching up with the 10-5 to 10/13 backlog of hbds that arrived while I was away...

>So I head down to the basement yesterday after work to start gathering
>bottles and from a distance the beer in the carboy looks like it has
>started to ferment again 'cause there's some sort of head on it. I move
>in for a closer look. My draw drops, my eyes roll back in my head,
>a blood-curdling cry echoes throughout the house. The surface of the
>beer is covered with a thin white scum. It's kind of lacy looking with
>little fuzzy nodules here and there with vein-like things extending
>into the film. It looks like the stuff the people had on them when they
>crawled out of the pods in "Invasion Of The Body Snatchers."

A pediococcus infection has a ropy, lacy appearance. Note that Pediococcus is used in lambic fermentations, requiring extended amounts of time to do its stuff. Too bad you hopped the heck out of the batch, or you might have a shot at converting it to a pseudo-lambic.

- - - - -

>Yesterday I heard a third-hand report of some difficulties they're having
>at Beer Across America. (For those of you who are not familiar with BAA,
>it is a mail-order service you can "subscribe" to, in which every so
>often (once a month?) they send you a six-pack of a beer from some
>microbrewery (a different one each time) and a bill for something like
>\$12.95 including shipping. While this may seem a bit expensive for a
>six-pack of beer, it's worth it to many subscribers if most of the beers
>are not available in their areas.)
>
>The problem they're having is, you might say, one of being too successful
>for their own good. They've had so many respondents subscribe to the
>service that the amount of beer they have to ship out each round has
>gotten quite huge. So huge that many smaller brewers, the ones they had
>most hoped to give visibility to through the service, are unable to
>produce a full shipment of beer for the BAA. So the BAA sends out mostly
>beers from the relatively larger microbreweries.
>
>Although I am not currently a BAA subscriber, I like the idea and would
>like to see it succeed. Perhaps they could develop a system where they
>don't send the same beer to every subscriber every month.

I suscribe to them, and personally, I wish they would create specialized mailinglists. I would definitely rather be on a dark ale mailinglist - I'm sick of receiving pilsners!

I was really happy in May when they sent out Dock Street Amber (IMHO, the best brew they've carried), and another red ale to boot. This month's selection was 2 pilsners, which has kind of got me p.o'ed. They have yet to send out a porter or a stout, and seem to be going with "mainstream" beers, afraid to deviate from the norm and piss anybody off.

Case in point: last month they sent out Ed's Cave Creek pilsner. Now they advertized Ed's Cave Creek Chili beer, but you had to special order it, probably thinking it was too exotic to be the selection of the month. I subscribe to BAA so I can expand my beer horizons, and wish they'd open up a little, sending out some off-the-wall stuff, even if there's a person or two who may not like a particular selection.

I should also get off my butt and on the phone and talk to a person in charge, instead of bitching about it on the hbd...

 Subject: Lauter tuns

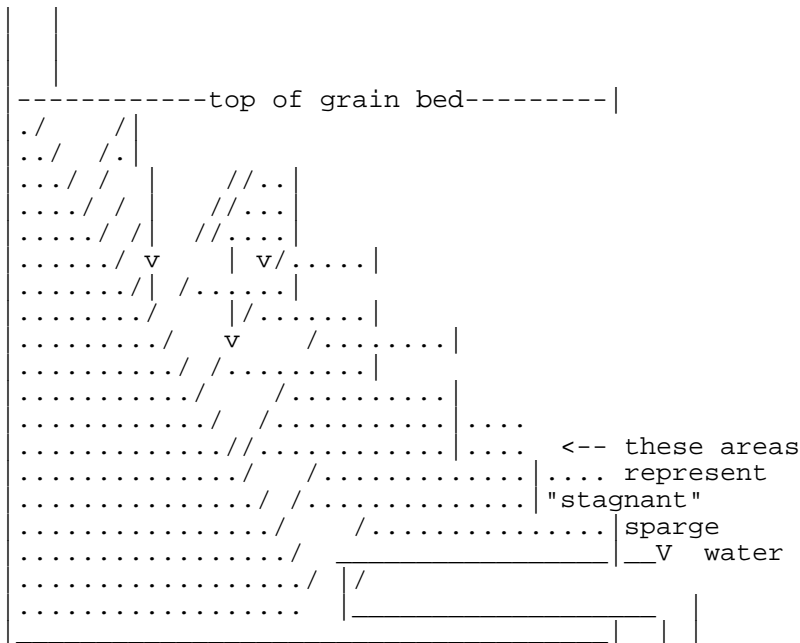

I thought that I had covered this before, but since there still seems to be some confusion as to the theory behind the statements, I have, through the magic of ascii graphics, illustrated the theoretical basis for my contention that runoff from a single point is less efficient (in terms of extract) than runoff from multiple points. I have also taken this opportunity to illustrate a third system, used by some, which I also feel is inferior to the lautering system described as SYSTEM #2. All these diagrams are gross exaggerations of the paths of the sparge water and, at the least, the "first runnings" will make their way to the outlet, wherever it may be. Note that the law of physics upon which all three of these theories are based, is:

"The sparge water will tend to take the path of least resistance."

[Actually, it is a phenomenon called "channelling"].

SYSTEM #1

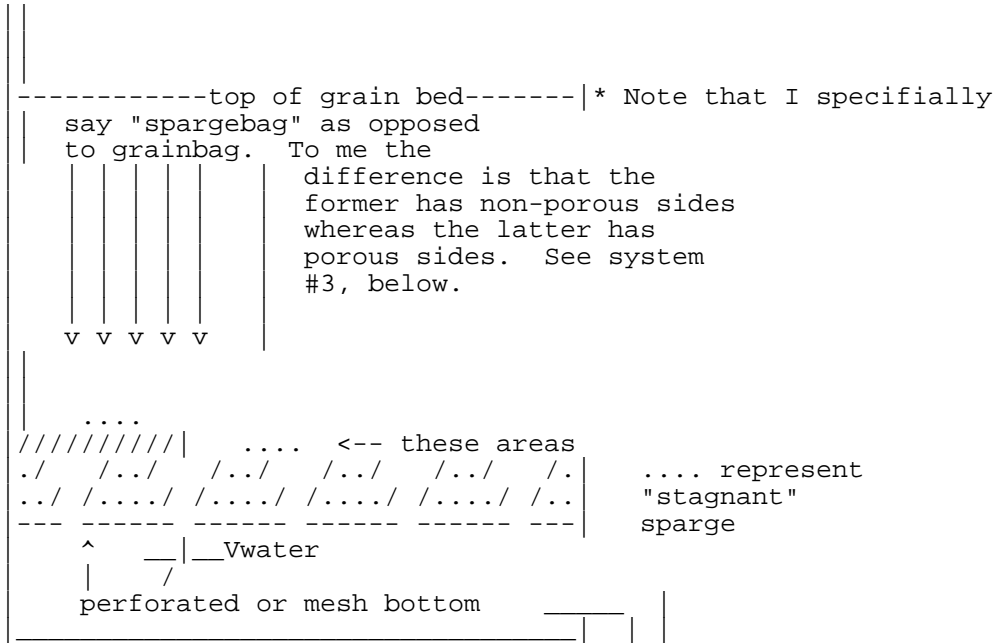

Lautering system which draws runoff from a single point:

Once "the sparge water (indicated by arrows) finds the path to the outlet," it will continue to take the shortest path to the outlet, leaving much of the grain barely touched by the sparge water. In addition to the direct path, some channelling would occur along the walls and bottom of the container.

SYSTEM #2

Lautering system in which the runoff is drawn from multiple points from the bottom, such as the "Zapap Lauter Tun" described by Charile Papazian, the "spargebag*-in-a-bucket system" described by Dave Miller, or the "slotted-copper-tube-manifold-in-a-picnic-cooler" (sorry, don't know who introduced this system):

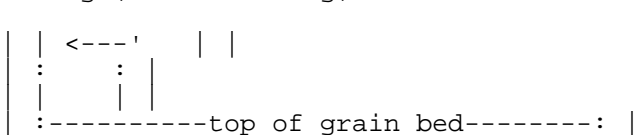

Since the path of resistance to any of the holes at the bottom is equivalent, the runoff should exit through each of them in approximately equal amounts, thereby roughly equally distributing the sparge water throughout the entire grain bed. Actually, if you've got several hundred holes, the stagnant areas would be so small, that they would be inconsequential to the efficiency. As in system #1, channelling would also occur along the walls of the container.

SYSTEM #3

Lautering system in which the runoff is taken from multiple points on the *sides* and bottom, like the "grainbag-in-a-bucket" system:

grainbag (100% mesh bag)

In this case, the path of least resistance is the "holes" in the mesh bag in the sides, near the top of the bag. In ascii graphics, this was very hard to illustrate, but my intention was to show that more sparge water would tend to exit the bag near the top, less would exit partway down the side of the bag, less and less as we look at points further down the side of the mesh bag.

In summary, it is my contention that system #2 is the most efficient of these three systems and virtually all lauterling systems can be approximated by one of these three systems.

Subject: Roller Mill from Junk

A good while back there appeared in the digest a series of posts re. the possible use of conveyor belt rollers in fabricating a roller mill. While I don't exactly recall what all was said, I seem to remember the thread ending with someone actually pricing new rollers and finding the cost way to prohibitive.

Well, the idea always stuck in my head. So one afternoon I decided to call around to a few scrap/salvage/junk yards to see what I could find. Sure enough, they all had scrapped/junked conveyor belts.

So with a little scrounging, I've found my roller mill, basically complete and ready to go. As it turns out, it's not conveyor belt rollers that you are after - the piece you are really after is called a 'tail-end'. It's the unit at the end of the conveyor which the belt wraps around, and optionally, which provides the driving force for the belt.

The unit I found consisted of two rollers, 18" long by 6" dia. that are ball-bearing mounted onto two side plates. Each side plate has adjustment bolts to position one of the rollers in relation to the other. The other roller is the driving roller and had a 6" chain sprocket mounted on the end of the shaft. A simple crank arm can easily be bolted right to the sprocket for hand operation or the sprocket removed and replaced by pulley for a motorized operation.

As I said, basically complete & ready to go and, all for only 25 bucks. Of course it was pretty badly rusted but a trip to a friendly sandblaster made short work of that.

After getting it cleaned up, I mounted the side plates to a wooden base, adjusted the roller gap to .050", fabricated a hopper to hold the grain and mounted a crank arm to the chain sprocket - a functional roller mill. With hand operation, the unit will crush a pound of grain in less than a minute. The crush is of roller mill quality ie. well crushed kernal with husks intact.

That's about it from the mill front ...

Subject: Weeping Radish brewpub

Visited "The Weeping Radish", a brewpub on Roanoke Island in Albermarle sound near Nag's Head in North Carolina. It's part of a German restaurant whose proprietor is originally from Bavaria, near Munich. They brew three beers, a helles and an amber, which are "always" on hand, and an Oktoberfest which isn't. There is a brewery tour available which turns out to be just standing around looking through a large window while the tour guide talks. It's interesting enough though, and I wouldn't let a bunch (25) of tourists get any closer to my wort either.

We heard about some of the difficulties they encountered in getting started:

At the urging of his brother, the owner imported a "brewery" from Germany, which turned out to be a container full of pipes, tanks and pumps with no hint at all regarding assembly or operation. (The brothers no longer speak to each other.) There were also no provisions at the time to allow brewpubs in North Carolina, a situation which the owner was instrumental (through his state Assemblyman) in getting corrected. The Feds insisted on a separate bonded warehouse to store finished (i.e. taxed) goods. He solved this problem using a technique employed by the local tobacco industry; a line painted on the floor dividing the bonded section from the unbonded. Another rule required that the beer be dispensed from a "portable" container. He had planned to serve the brew directly from the lagering tun (about 300 gallons) via pipes to the bars. That one was avoided by attaching wheels to the tuns (they never move).

They get their malt from Briess already cracked. Some was passed around. I was impressed by the uniformity. Every grain was perfectly cracked (none were crushed) and there was no flour at all. For the helles they use a mix of 2-row and 6-row pale barley (unspecified ratio) mashed at 160F for one hour and sparged at 170F for about one hour. The sparging effluent was visible and was absolutely clear. Hops are Hallertauer and Saaz with a one hour boil using superheated steam piped through a coil in the brewpot, which is stainless steel. The guide didn't know the detailed hop schedule nor the gravities but said the beer is "about 5%" alcohol. A very substantial counterflow heat exchanger chills the wort to about 50F in fifteen minutes.

Fermentation is with "Bavarian" yeast for one week at 50F in open vats. Fresh yeast is shipped regularly from Germany and is not reused. We were told of batches which were discarded because of the yeast being delayed in customs. They lager at 45F for six weeks "except sometimes in the summer when we run short".

Amber beer is achieved by the addition of what appeared to be chocolate malt.

Four people seemed to comprise the brewing staff. While we were there, three

of them were standing around (on break?) and one was filling bottles.
Once
a year a brewmaster from Bavaria spends six weeks correcting any bad
habits
picked up since his last visit.

The product is sold only at the pub either in glasses, one liter Grolsch-
type bottles or one gallon mini-barrels (tin cans). Prices are \$1.75 for
8 oz, \$3.00 a half liter, \$5.00 a liter, \$6.00 for the Grolsch-type
bottle
(\$4.00 for a refill) and \$11.00 for a mini-barrel.

Total production is 26,000 gallons per year.

The helles is good but a bit variable. I tasted two batches. Both were
true to type but one tasted cleaner than the other. I liked the amber
better. All the beers were better than the food.

The name derives from a snack food customarily served in the owner's
home district to accompany beer. A large, mild radish is sliced into
a spiral; salt is sprinkled into the cut and the radish is reassembled.
The salt draws moisture out of the flesh. The resultant solution dribbles
down the sides of the radish, giving the appearance of tears.

From: Victor Reijs <Victor.Reijs@SURFnet.nl>
Subject: efficiency/crystal caramel malt/EBC

Hello all of you,

Two subjects:

- crystal malt and caramel malt

There is a big difference between these two!

crystal malt: the grain is soaked in water and kept at 65 Centigrade (for one hour), so that the starch in the grain is converted to sugar. After that the grain is heated to 110 - 120 centigrade. The water evaporates and the sugar gets a crystal like structure. (depending on the length of the heating the crystal malts gets darker)
caramel malt: after the sprouting of the grains, they are heated to 160 centigrade. The grain gets the color of chocolate or caramel.

- efficiency

I define efficiency as being:

```
eff1='total amount of extracted sugar' * 100 /  
'total amount of fermentable sugar in malt'
```

Sometimes people define efficiency (in my opinion wrongly) as being:

```
eff2='total amount of fermentable sugar in malt' *  
100/'total weight of malt'
```

I would say: eff1 is the efficiency, which is dependant on the method of brewing/experience of brewer. Eff2 is more a natural parameter, by nature some malts have more fermentable sugar then others. It is dependant on the natural process of growing and dependent on producing the malts.

Now I have a question related to the color of the malt. I understand that there is defined in US the SRM or Lovibond (by definition both are different). In Europe we have EBC (its definition is: the number of ml of jodide in 100 ml water which give the same color as the beer). My question to you is: What is the definition of SRM and Lovibond?

All the best,

Victor
